x	float
y	float
geometric_objects	collection
x_width	int
y_width	int
utilization	float
cell_list	string or collection
voltage_area_shape	string or collection

ARGUMENTS

-voltage_area *voltage_area_object*

Specifies the voltage_area in which to create this shape.

-region { {*llx lly*} {*urx ury*} } | {{*x y*} {*x y*} {*x y*} {*x y*}...} | *geometric_objects*

Specifies the boundary of the voltage area shape. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}). A polygon is specified by its points as {*x y*} {*x y*} {*x y*} {*x y*} and so on.

A polygon can also be specified as the combined area of a mixed collection of objects with physical geometry, such as

poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

-guard_band {*x_width y_width*}

Specifies the width of the guard band in the horizontal and vertical direction. The guard band width is the spacing along the boundary of the voltage area where cells cannot be placed. The guard band extends outward from the region. The values specified for this option must be positive integers. When no guard_band is specified, the default values are {0 0}

-target_utilization

Specifies the utilization requested for this voltage area shape during shaping. The value specified must be between 0.1 and 1.0. If this option is not specified, the target_utilization for the design at the time of the voltage area shape creation, whether that value is valid or not, will be used. If the target utilization on the design is changed later on, the value on the voltage area shapes will not be automatically updated.

-cells *cell_list*

Specifies a list of cells to be included in this specific voltage area shape. All cells must be at the same physical hierarchy as the current design. Cells can be physical (leaf) or hierarchical. When specifying hierarchical cells, the cells will be expanded into a set of physical cells that reside under them. If cells are later added or removed from this hierarchical cell, the cell membership of the voltage area shape is not automatically updated. Note that one hierarchical cell can expand into multiple physical cells. In (the unlikely) case that the hierarchical cell is purely logical (when it corresponds to a local module that has no physical representation), the cell will map to an empty set of physical cells, and a warning message will be printed. The specified cells cannot already be explicitly or implicitly associated with another voltage area or voltage area shape.

-exclusive

Sets the voltage area shape to be exclusive with respect to other cells of this voltage area. This option can only be used with the **-cells** option. A voltage area shape should always be treated as an exclusive move bound with respect to cells that do not belong to its voltage area. But to cells associated with its voltage area but not explicitly with this shape, it should be treated as an inclusive move bound. With this option set, the voltage area shape should be treated as exclusive even to cells that belong to its voltage area, so that only cells explicitly associated with this particular shape can be placed within the boundary of the shape, and no other cells, including cells associated with the voltage area, can be placed within this shape.

-merge_regions

Merge into this new shape all shapes within this voltage area that abut or overlap with the input shape. Note that if a shape has explicit cell assignment, that shape will remain discrete and it will not be merged with other shapes in the same voltage area, even if they touches or overlaps. For the same reason, this option cannot be used with the **-cells** option.

-top

Place the voltage area shape to the top of the voltage area shape stack.

-bottom

Place the voltage area shape to the bottom of the voltage area shape stack, right above the first shape of the default voltage area.

-above *voltage_area_shape*

Place the voltage area shape above the given voltage area shape.

-below *voltage_area_shape*

Place the voltage area shape below the given voltage area shape.

DESCRIPTION

The **create_voltage_area_shape** command creates a new shape on an existing voltage area. A voltage area shape can be any rectilinear shape. An optional guard band on the horizontal and vertical direction can also be specified, otherwise the guard band is zero.

The command returns a collection containing the newly created voltage area shape if the command succeeded. Otherwise, the command returns "" if it failed, or TCL_ERROR if there was a command syntax error.

By default, the new voltage area shape is created at the top of the shape position stack (**-top**). With the **-bottom** option, the new voltage area shape will be created at the bottom of the stack, directly above the default voltage area shape. With the **-below** or **-above** option, the voltage area shape will be placed one position below or above an existing voltage area shape.

The **-top**, **-bottom**, **-above**, and **-below** options are mutually exclusive. It is a syntax error to specify more than one of these options at a time. It is an error to place a shape above or below a shape from a different design.

EXAMPLES

The following example constrains the instance INST_1 to lie within the voltage area whose coordinates are lower-left corner (100 100) and upper-right corner (200 200):

```
prompt> create_voltage_area_shape -voltage_area VA1 \
  -region {{100 100} {200 200}} -guard_band {1 2}
{VOLTAGE_AREA_SHAPE_1}
```

The following example creates a voltage area shape above an existing shape

```
prompt> create_voltage_area_shape -voltage_area VA1 \
  -region {{100 100} {200 200}} -above VOLTAGE_AREA_SHAPE_1
{VOLTAGE_AREA_SHAPE_2}
```

This example creates a voltage area shape at the bottom of the position stack, above the default voltage area shape.

```
prompt> create_voltage_area_shape -voltage_area VA1 \
  -region {{300 300} {400 400}} -bottom
{VOLTAGE_AREA_SHAPE_3}
```

create_vtcell_fillers

Inserts filler cells based on the threshold voltage types of the cells on the left and right of the gap to be filled.

SYNTAX

status **create_vtcell_fillers**
[-prefix *cell_prefix*]
[-separator *cell_separator*]
[-voltage_area *voltage_areas*]
[-region *region_list*]
[-boundary *region_list*]
[-clear_vt_information]

Data Types

cell_prefix string
cell_separator string
voltage_areas collection
region_list list

ARGUMENTS

-prefix *cell_prefix*

Specifies the prefix for the inserted filler cells.

By default, no prefix is added.

-separator *cell_separator*

Specifies the separator character that is used in the instance name of the inserted filler cells.

The filler cell instance name consists of a prefix, the library reference cell name, and a unique integer. This naming convention allows you to use pattern matching to select the filler cells.

The default separator is "!".

-voltage_area *voltage_areas*

Specifies the voltage areas in which to insert filler cells.

By default, the command inserts filler cells in all voltage areas.

-region *region_list*

Specifies the regions in which to insert filler cells. You can specify one or more rectangles or rectilinear polygons.

Each rectangle is specified by the coordinates of its lower-left and upper-right corners:

{{*llx lly*} {*urx ury*}}

Each polygon is specified by its points:

{{*x1 y1*} {*x2 y2*} ... {*xn yn*}}

-boundary *region_list*

Specifies the regions in which to insert filler cells. You can specify one or more rectangles or rectilinear polygons.

Each rectangle is specified by the coordinates of its lower-left and upper-right corners:

{{*llx lly*} {*urx ury*}}

Each polygon is specified by its points:

{{*x1 y1*} {*x2 y2*} ... {*xn yn*}}

-clear_vt_information

Clears all stored threshold voltage information, including the table with the standard cell threshold voltage types. When you use this option, the command does not perform filler cell insertion.

DESCRIPTION

The **create_vtcell_fillers** command fills the gaps in the block by inserting filler cells based on the threshold voltage type of the cells on the left and right of the gap.

EXAMPLES

The following example fills the block with the correct threshold voltage filler cells.

prompt> **create_vtcell_fillers -prefix "my_fill"**

SEE ALSO

create_stdcell_fillers(2)
set_vt_filler_rule(2)
set_cell_vt_type(2)

create_wire_matching

Creates an analog constraint group with matched_wire intent in the current design.

SYNTAX

collection **create_wire_matching**
[*constraint_group_name*]
-for *objects*
-tolerance *float*
[-match_type length | length_per_layer]
[-relative]
[-exclude *objects*]
[-driver *objects*]
[-force]

Data Types

constraint_group_name string
objects collection
float float

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group.

If you do not specify this argument, the command assigns a system-generated name.

-for *objects*

Specifies the objects that constitute the analog constraint group. The objects can be nets, pins, ports, bundles, or topology_edges, and can be specified as strings (object names) or collections.

This option is required.

-tolerance *float*

Specifies the tolerance within which the constituent objects of the constraint group should match for the specified property.

By default, the command interprets the specified value as an absolute value. To specify the value as a percentage, use the **-relative** option.

This option is required.

-match_type length | length_per_layer

Specifies the characteristic that needs to be matched for all the constituent objects of the constraint group.

The default is **length**.

-relative

Interprets the tolerance value specified by the **-tolerance** option as a percentage.

If you do not specify this option, the tolerance value is interpreted as an absolute number.

-exclude *objects*

Specifies the objects that need to be excluded from the analog constraint group. The objects can be pins or ports, and can be specified as strings (object names) or collections. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in **-for** option but want to exclude a few pins / ports connecting to that net.

-driver *objects*

Specifies the object to be treated as the driver for the analog constraint group. The object can be a pin or port, and can be specified as a string (object name) or collection. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in **-for** option but want to match each driver to receiver connection.

-force

Deletes an existing constraint group with the same name and creates a new constraint group.

If you do not specify this option, the command fails if a constraint group exists with the specified name.

DESCRIPTION

The **create_wire_matching** command creates a constraint group for nets, pins, ports, bundles, and topology_edges with matched_wire intent. Constraint applicable on pin/port check the net which is connecting pin/port to driver pin/port. The constraint is used by the Custom Router tool.

By default, the total length (**-match_type length**) of the objects is compared. You can also match the length per layer (**-match_type length_per_layer**). The selected criteria must match within the tolerance specified by the **-tolerance** option.

EXAMPLES

The following example creates a constraint group named abc for nets and bundles that match the pattern pr* with an absolute tolerance of 10 to match length of each constituent objects. The pr* nets are routed with the Custom Router tool.

```
prompt> create_wire_matching abc -for pr* -tolerance 10
{abc}
```

The following example creates a constraint group named def for nets and bundles that match the pattern pr* with a tolerance of 10 percent to match the length of each constituent objects. The pr* nets are routed with the Custom Router tool.

```
prompt> create_wire_matching def -for pr* -tolerance 10 -relative
{def}
```

cross_probing_filter

Filters a collection based on file name and line number criteria.

SYNTAX

collection **cross_probing_filter**
-source *source_patterns*
objects

Data Types

source_patterns string
objects collection

ARGUMENTS

-source *source_patterns*

This string is the matching criteria used for filtering. Filter a collection by specifying a source file and line number in the "file_pattern[:line_pattern]" format. You can specify multiple patterns by delimiting them with a space character, such as "file_pattern1[:line_pattern1] file_pattern2[:line_pattern2] ...". Objects that match any of the specified file/line patterns are returned in the resulting collection.

The asterisk (*) and question mark (?) wildcard patterns are allowed in the pattern.

objects

Specifies the base collection to be filtered. The base collection may contain cell or port or module or block objects.

DESCRIPTION

Allows you to filter a collection by specifying a source file and line number. This command functions similar to **filter_collection** except the filtering criteria is specific to cross-probing.

You must have a design that was analyzed and elaborated or synthesized using this tool. The tool provides information about where the cell or port or module or block was created, specifying which file and line number the object came from. These objects can be filtered based on file name and/or line number.

Some objects in the design might have been merged, resulting in an object that can potentially have multiple source locations. In this case, the object is returned in the result collection if any of its source positions match any of the specified source patterns specified by *source_patterns*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the result from the **cross_probing_filter** command, returning cells that originated from a source file ending in m.v, and on line 21:

```
prompt> cross_probing_filter [get_cells -hierarchical] -source "*m.v:21"
{mid1/bot1/c1 mid1/bot2/c1}
```

The following example shows the result from the **cross_probing_filter** command, returning modules that originated from a source file ending in top.v, and on line 32:

```
prompt> cross_probing_filter [get_modules] -source "*top.v:32"
{low}
```

The following example shows the result from the **cross_probing_filter** command, returning blocks that originated from a source file ending in top.v, and on line 1:

```
prompt> cross_probing_filter [get_blocks] -source "*top.v:1"
{top}
```

SEE ALSO

report_cross_probing(2)
get_cross_probing_info(2)

current_block

Sets or gets the current block by block name.

SYNTAX

collection **current_block**
[-quiet]
collection Collection containing the block or "".
block Block name in [libName:]designName[/labelName][.viewName] format or a collection of one block.

string *lib_name*
string *block_name*
string *label_name*
string *view_name*

ARGUMENTS

-quiet

Suppresses all messages.

block

Block object or name.

lib_name

The library name prefix, followed by a colon.

block_name

The name of the block to make the current block.

label_name

The label name, preceded by a slash.

view_name

The view name suffix, preceded by a dot.

DESCRIPTION

Sets or gets the current working block for many commands. Without arguments, **current_block** returns a collection containing the current working block. The combination of the current block and current instance defines the context for many commands.

The block name can be a simple name, like "TOP". Or a block of a specific label, like "TOP/routed". Or a block with a view suffix, like "TOP.design", or "TOP.abstract". Or a block with a library prefix like "lib1:TOP". Or a block with both a library, label, and view name like "workLib:TOP/routed.outline". The library can contain a path to the library, like "/libs/refLib:TOP.design". If the lib name is not given, the current library is used. If the view name is not given, the design view is used.

A block must be opened and read into memory before it can be set to be the current block.

If more than one block matches the given name, an error is issued.

To get a collection of blocks currently available in the tool, use **get_blocks**.

The **current_block** command is different that the **current_design** command in that the **current_design** command looks for a block with a given top module name, whereas the **current_block** command looks for a block with the given block name.

EXAMPLES

The following example uses **current_block** to show the current context and to change the context from one block to another.

```
prompt> current_block
{lib1:TOP.design}

prompt> current_block ADDER.abstract
{lib1:ADDER.abstract}

prompt> current_block
{lib1:ADDER.abstract}

prompt> current_block lib1:TOP/myLabel.design
{lib1:TOP/mylabel.design}
```

The **current_block** command can be used as a parameter to other commands. In the following example, **remove_blocks** is used to delete the working block from memory.

```
prompt> current_block
{lib1:TOP.design}
prompt> remove_blocks [current_block]
Removing block 'lib1:TOP.design'...
1
prompt> current_block
Error: Current block is not defined. (DES-001)
prompt>
```

current_corner

Sets a corner in the current session to be current. Operating condition and parasitics configuration commands apply to the current corner.

SYNTAX

int **current_corner**
[*corner_name*]

Data Types

corner_name string

ARGUMENTS

corner_name

Name of a defined corner in the current design.

DESCRIPTION

This command sets one corner in the current session to be current. Operating condition and parasitics configuration commands apply to the current corner.

Corners are used together with modes, which are used for different operating modes and power schemes. Timing analysis is actually done for various mode/corner combinations, as configured by the **set_scenario_status** command.

Multicorner-Multimode Support

This command works on the current corner.

EXAMPLES

In the following example, two non-default corners are created, then the current_corner is set to "LowPower1".

```
prompt> create_corner LowPower1
1
prompt> create_corner HighTemperature1
```

```
1
prompt> current_corner LowPower1
{"LowPower1"}
prompt> source LowPower1_opconds.tcl
1
```

SEE ALSO

remove_corners(2)
set_scenario_status(2)
source(2)

current_design

Gets the current block or sets the current block to the block containing a specified top-level logic module.

SYNTAX

collection **current_design**
[-quiet]
[*design_name*]

Data Types

design_name string

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

design_name

The name of a design, the top-level logic module of an open block. The command sets the current block to the block containing the specified design. If you do not specify a design name, the command returns a collection containing the current design.

DESCRIPTION

This command sets the current block to the block containing a specified top-level logic module, and returns that block as a collection.

When used without any argument, the command works exactly the same as the **current_block** command; it returns a collection containing the current block. When used with an argument, the argument must be design (a top-level module of an open block). To get a list of designs that you can use as an argument, use the **get_designs** command. The **current_design** command then sets the block containing the specified design as the current block, and returns a collection containing that block.

The **current_block** takes a block as an argument, whereas the **current_design** command takes a top-level module of an open block as an argument. However, both commands return a collection containing the current block. The combination of the current block and the current instance (set by the **current_instance** command) defines the context for many commands.

EXAMPLES

The following examples demonstrate usage of the **current_design** command.

```
prompt> current_block
{libLmp:LEON3mp/fp.design}

prompt> current_design
{libLmp:LEON3mp/fp.design}

prompt> get_blocks
{libLmp:LEON3mp/fp.design}

prompt> get_designs
{LEON3mp mul32 leon3s leon3s_2 leon3s_3}

; Set current block to the block containing top module leon3s_2
prompt> current_design leon3s_2
{libLEON3s:leon3s_2/fp.design}

prompt> current_block
{libLEON3s:leon3s_2/fp.design}

prompt> current_design
{libLEON3s:leon3s_2/fp.design}
```

SEE ALSO

current_block(2)
current_instance(2)
get_designs(2)

current_dft_partition

Sets or gets the design partition for the current specification.

SYNTAX

status **current_dft_partition**
[*design_partition_label*]

Data Types

design_partition_label string

ARGUMENTS

design_partition_label

Specifies the working design partition for many commands. If the *design_partition_label* is not specified, the tool uses the last design partition specified. If the *design_partition_label* specifies a partition name that has not been specified previously using the **define_dft_partition** command, an error is issued and the working design partition remains unchanged.

DESCRIPTION

The **current_dft_partition** command sets the design partition for many specification commands, such as **set_dft_signal**, **set_scan_configuration**, **set_scan_compression_configuration**, and **set_scan_path**. When no arguments are specified, **current_dft_partition** returns the name of the current DFT partition.

To display the names of all of the design partitions in the test model for the current design, use the **report_dft -partitions** command.

EXAMPLES

The following example sets the required number of scan chains to 3 and 2 to the partitions *part1* and *part2*, respectively:

```
prompt> define_dft_partition part1 -include {U1 U2}

prompt> define_dft_partition part2 -include {U3 U4}

prompt> current_dft_partition part1
```

```
prompt> set_scan_configuration -chain_count 3

prompt> current_dft_partition part2

prompt> set_scan_configuration -chain_count 2

prompt> preview_dft
1
```

SEE ALSO

define_dft_partition(2)
preview_dft(2)
report_dft(2)
set_dft_signal(2)
set_scan_compression_configuration(2)
set_scan_configuration(2)
set_scan_path(2)

current_instance

Sets the working instance object and enables other commands to be used relative to a specific instance in the design hierarchy.

SYNTAX

string **current_instance**
[*instance*]

Data Types

instance string

ARGUMENTS

instance

Specifies the working instance (cell). If *instance* is not specified, the focus returns to the top level of the hierarchy in the current design. If *instance* is ".", the current instance remains unchanged. If *instance* is "..", the context is moved up one level in the instance hierarchy. If *instance* begins with "/", the tool sets both the current design and the current instance. More complex examples of *instance* arguments are described in EXAMPLES.

DESCRIPTION

The **current_instance** command sets the working instance. An instance is a cell in the hierarchy of a design. This command differs from **current_design**, which changes the working design, then sets the current instance to the top level of the new current design. The combination of the current design and current instance defines the context for many commands.

current_instance traverses the design hierarchy similar to the way the UNIX **"cd"** command traverses the file hierarchy. **current_instance** operates with a variety of *instance* arguments:

- If no *instance* argument is specified, the focus of the tool is returned to the top level of the hierarchy.
- If *instance* is ".", the current instance is returned and no change is made.
- If *instance* is "..", the current instance is moved up one level in the design hierarchy.
- If *instance* is a valid cell (or cell name) at the current level of hierarchy, the current instance is moved down to that level of the design hierarchy.
- Multiple levels of hierarchy can be traversed in a single call to **current_instance** by separating multiple cell names with slashes. For example, **current_instance U1/U2** sets the current instance down two levels of hierarchy.

- The ".." directive can also be nested in complex *instance* arguments. For example the command **current_instance "../../MY_INST"** attempts to move the context up two levels of hierarchy, then down one level to the **"MY_INST"** cell.

EXAMPLES

The following example uses **current_instance** to move up and down the design hierarchy.

```
prompt> current_design TOP
{"TOP"}

prompt> current_instance U1
U1

prompt> current_instance "."
U1

prompt> query_objects [all_instances ADDER]
{"U1", "U2", "U3", "U4"}

prompt> current_instance U3
U1/U3

prompt> current_instance "../U4"
U1/U4

prompt> current_instance
Current instance is the top-level of block 'Alib:TOP.design'.
```

In the following example, changing the **current_design** resets the **current_instance** to the top level of the new design hierarchy.

```
prompt> current_design
{"TOP"}

prompt> current_instance "U2/U1"
U2/U1

prompt> current_design ADDER
{"ADDER"}

prompt> current_instance .
Current instance is the top-level of block 'Alib:ADDER.design'.
```

The following example uses **current_instance** to go to an instance of another design. The current_design is set by the new design whose name is the name after the first slash of the given instance name.

```
prompt> current_design
{"TOP"}

prompt> current_instance U1
U1

prompt> current_instance "/TOP/U2"
U2
```

```
prompt> current_instance "/ALARM_BLOCK/U6"
U6

prompt> current_design
{"ALARM_BLOCK"}
```

SEE ALSO

current_design(2)

query_objects(2)

current_lib

Sets or returns the current library.

SYNTAX

collection **current_lib**
[-quiet]
[*library_name*]

Data Types

library_name string

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

library

Specifies the working or focal library for many commands. If the *library_name* is not specified, the **current_lib** command returns a collection containing the current library. If *library_name* refers to a library that cannot be found, an error is issued and the working library remains unchanged.

DESCRIPTION

The **current_lib** command gets or sets the current library.

Many library-related commands use the current library by default. The current library is automatically set when the **create_lib** command creates a new library or the **open_lib** command opens a library.

This command returns the current library if successful, or 0 if not. If an illegal name is given, a Tcl error is issued.

EXAMPLES

The following example returns the current library in the current session:

```
prompt> current_lib
{"design"}
```

The following example sets the current library in the current session:

```
prompt> current_lib top_design
{"top_design"}
```

search_path(3)

current_mode

Sets a mode in the current session to be current. Constraint creation and modification commands apply to the current mode.

SYNTAX

integer **current_mode**
[*mode_name*]

Data Types

mode_name string

ARGUMENTS

mode_name

Name of a defined mode in the current design.

DESCRIPTION

This command sets one mode in the current session to be current. Constraint creation and modification commands apply to the current mode.

Modes are used together with corners, which contain operating condition and parasitics parameters. Timing analysis is actually done for various mode/corner combinations, as configured by the **set_scenario_status** command.

Multicorner-Multimode Support

This command works on the current mode.

EXAMPLES

In the following example, two non-default modes are created, then the current_mode is set to "Mission1".

```
1
prompt> create_mode Mission1
1
prompt> create_mode Test1
```

```
1
prompt> current_mode Mission1
{"Mission1"}
prompt> source Mission1_constraints.tcl
1
```

SEE ALSO

create_corner(2)
create_mode(2)
remove_modes(2)
set_scenario_status(2)
source(2)

current_scenario

Sets the specified scenario as the current scenario or returns a collection that contains the current scenario.

SYNTAX

collection **current_scenario**
[*scenario_name*]

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the scenario to set as the current scenario. The named scenario must already be defined in the current design.

If you do not specify this argument, the command returns a collection that contains the current scenario.

DESCRIPTION

The behavior of the **current_scenario** command depends on whether you specify an argument.

- If you specify a scenario, the command sets this scenario as the current scenario.

  The scenario's mode becomes the current mode, and its corner becomes the current corner. By default, constraint creation and modification commands apply to the current scenario, mode, or corner.

- If you do not specify a scenario, the command returns a collection that contains the current scenario.

If you change the current mode or corner with the **current_mode** or **current_corner** commands, the tool sets the current scenario to whatever scenario has that mode and corner. If there is no such scenario, the current scenario becomes unset.

Multicorner-Multimode Support

This command works on the current scenario.

EXAMPLES

The following command returns the current scenario.

```
prompt> current_scenario
{m1@c1}
```

The following command sets the current scenario to m2@c2.

```
prompt> current_scenario m2@c2
{m2@c2}
```

current_test_mode

Sets or gets the current working test mode for the current design.

SYNTAX

status **current_test_mode**
[*test_mode_label*]

Data Types

test_mode_label string

ARGUMENTS

test_mode_label

Specifies the working test mode for many commands.

If the *test_mode_label* is not specified, the tool prints the current test mode.

DESCRIPTION

The **current_test_mode** command sets the current working mode. This is the default test mode used for many DFT commands, such as **set_dft_signal** and **dft_drc**.

To display the names of all the modes in the test model data for the current design, use the **list_test_models** command.

To display the names of all the test modes of the current design defined with the **define_test_mode** command, use the **list_test_modes** command.

EXAMPLES

The following example sets the test mode to "Internal_scan" for the current design:

```
prompt> current_test_mode Internal_scan
1
```

The following example gets the test mode for the current design:

```
prompt> current_test_mode
Current test mode is 'Internal_scan'.
1
```

current_design(2)
dft_drc(2)
list_test_modes(2)
list_test_models(2)

current_topology_plan

Reports or sets the current topology plan.

SYNTAX

int **current_topology_plan**
[*topology_plan*]

Data Types

topology_plan list

ARGUMENTS

topology_plan

Specifies the topology_plan to set as the current topology_plan.

RETURN VALUE

The current topology_plan.

DESCRIPTION

This command reports the topology_plan that is set as the "current" topology plan in the current block. When a topology_plan is the "current" plan, then topology node and edge creation commands will create the new topology objects in that plan unless otherwise specified. Also, the querying of topology objects will operate under the context of the current topology plan in terms of name lookups.

If the *topology_plan* argument is specified, then the current topology_plan will be changed to the specified plan. Also, the current topology_plan is automatically changed to newly created topology_plans. If the current topology_plan is removed, then there will be no current topology_plan until another plan is set or created.

Changing the current block will clear the current topology plan, as the block context has changed.

EXAMPLES

The following example gets the current topology_plan.

```
prompt> current_topology_plan
{plan0}
```

SEE ALSO

create_topology_plan(2)
get_topology_plans(2)
remove_topology_plans(2)
report_topology_plans(2)

cut_rows

Splits site rows from the current design.

SYNTAX

status **cut_rows**
  -all
  -within *coordinates*

Data Types

coordinates list

ARGUMENTS

-all

Removes all site rows in the current design. This option and the *-within* option are mutually exclusive.

-within *coordinates*

Removes all rows in the specified region. For a rectangular region, specify the coordinates for the lower-left and upper-right corners as {{ll_x ll_y} {ur_x ur_y}}. For a rectilinear region, specify a list of rectilinear coordinates in either clockwise or counterclockwise order. This option and the *-all* option are mutually exclusive.

DESCRIPTION

This command removes rows from the current design. If you specify the **-all** option, the command removes all rows from the design which are not a part of site arrays.

If you specify the **-within** option, the command removes rows within the specified region which are not a part of site arrays. So if a row partially comes under the specified region, then portion of the row falls under that specified region will be removed and remaining portion(s) will form new site rows depending on the number of parts a row gets cut into.

The unbound site rows (site rows whose site def is removed) can be deleted but not modified. Modification of a site row requires parameters of its site definition which is missing in case of an unbound site row.

EXAMPLES

The following example uses the **-all** option to remove all rows from the current design.

```
prompt> cut_rows -all
1
```

The following example uses the **-within** option to cut rows in the specified rectangular region:

```
prompt> cut_rows -within {{3 0} {6 9}}
1
```

The following example uses the **-within** options to cut rows in the specified rectilinear region:

```
prompt> cut_rows -within {{3 12} {3 16} {9 16} {9 20} {12 20} {12 15} {6 15} {6 12}}
```

SEE ALSO

remove_site_rows(2)

date

Returns a string containing the current date and time.

SYNTAX

string **date**

DESCRIPTION

The **date** command generates a string containing the current date and time, and returns that string as the result of the command. The format is fixed as follows:

ddd mmm nn hh:mm:ss yyyy

Where:

ddd is an abbreviation for the day
mmm is an abbreviation for the month
nn is the day number
hh is the hour number (24 hour system)
mm is the minute number
ss is the second number
yyyy is the year

The **date** command is useful because it is native. It does not fork a process. On some operating systems, when the process becomes large, no further processes can be forked from it. With it, there is no need to call the operating system with **exec** to ask for the date and time.

EXAMPLES

The following command prints the date.

```
prompt> echo "Date and time: [date]"
Date and time: Thu Dec  9 17:29:51 1999
```

SEE ALSO

exec(2)

debug_script

Debug a script using the TclDevKit Tcl debugger.

SYNTAX

string **debug_script** script [*port*] [*hostname*]

ARGUMENTS

script

This specifies the Tcl script(s) to be debugged. This script will be sourced and instrumented for debugging.

port

Specifies the port number that the debugger is listening on for a remote debugging application. By default the debugger will be launched on an available port.

hostname

Specifies the host where Prodebug is already running. This is used to connect to an existing remote Prodebug session.

::env(SNPS_TCLPRO_HOME)

This Tcl variable is used to specify the root of the TclPro installation. It is initialized from the environment variable SNPS_TCLPRO_HOME in the user's environment.

USING THE PACKAGE

The **debug_script** command is in the snpsTclPro Tcl package, and all of the commands in this package are defined in the namespace snpsTclPro. The way to use this command is to load the package, which will import the commands it exports into the global namespace. This is shown below.

```
shell> package require snpsTclPro
1.0
```

These commands can be added to the .synopsys setup file for the system, user, or current directory, or the commands can be typed when the pacakge is needed.

DESCRIPTION

The **debug_script** command simplifies the use of the TclDevKit Tcl debugger available from ActiveState (http://www.activestate.com). First it ensures a connection to the Prodebug debugger either by connecting to a running debug session (given a *hostname* and *port*), or by launching the debugger on *localhost* using an available port, and then connecting to it. If there is already an active connection to the debugger then that debugger will simply be used.

Once the connection to the debugger is set up, the specified script will be sourced and debugged. The default behavior for the debugger is to stop at the first line of the source'd script.

The debugger must be run using a "remote" debugging project if you want to connect the Synopsys tools to a running prodebug session. The port number in use by the debugger can be viewed via the Application tab of the "File->Project" Settings dialog.

EXAMPLES

```
# Launch the debugger and then debug the script myscript.tcl.
shell> debug_script myscript.tcl
Selected port 2576 on host localhost
launching prodebug

# now debug another script using the same session
shell> debug_script anotherScript.tcl

# debug myscript.tcl, connecting to the specified debugger session or
# creating one if the connection fails.
shell> debug_script myscript.tcl 2576 localhost
```

CAVEATS

The debugger currently kills the process that started the debugger when you exit, despite the preferences being set differently in the debugger.

When the Synopsys tool has spawned a debugger, that debugger must be exited before the Synopsys tool can exit. If this is not the case then the Synopsys tool will hang on exit, until the debugger is exited.

The **debug_script** command waits for the debug process to start up, before it tries to connect to the debugger. If **debug_script** times out before the debugger is started due to machine or network loading, simply close the debugger that was launched, and then increase the timeout setting with the command **set_debugger_start_timeout**, and then re-run the debugger. The **set_debugger_start_timeout** command takes a single argument which is the value of the timeout in miliseconds, and the default value for the timeout is 10000.

namespace(2)

decompose_shape_patterns

Decompose non optimal shape patterns to optimal shape patterns in the current design.

SYNTAX

collection **decompose_shape_patterns**
[-verbose]
[-force]
shape_pattern_list

Data Types

shape_pattern_list collection

ARGUMENTS

-verbose

Display additional debugging information.

-force

Ignores the locked status of objects. If this option is not provided and any of the affected objects has locked status, command will generate a Tcl error and exit.

shape_pattern_list

Specifies a list of non optimal shape patterns to convert and replace with another set of optimal and spatially nearby shape patterns. The list can contain via collections specified with the **get_shape_patterns** command.

DESCRIPTION

This command creates a new shape patterns to replace the specified non optimal shape patterns and returns a collection containing the new shape patterns.

EXAMPLES

The following example converts all shape patterns to more optimal shape patterns.

```
prompt> decompose_shape_patterns [get_shape_patterns]
{RECT_PATTERN_0 RECT_PATTERN_1}
```

SEE ALSO

get_shape_patterns(2)

decompose_via_matrixes

Decompose non optimal via matrixes to optimal via matrixes in the current design.

SYNTAX

collection **decompose_via_matrixes**
[-verbose]
via_matrix_list

Data Types

via_matrix_list collection

ARGUMENTS

-verbose

Display additional debugging information.

via_matrix_list

Specifies a list of non optimal via matrixes to convert and replace with another set of optimal and spatially nearby via matrixes with no holes. The list can contain via collections specified with the **get_via_matrixes** command.

DESCRIPTION

This command creates a new via matrix to replace the specified non optimal via matrixes and returns a collection containing the new via matrix.

EXAMPLES

The following example converts all via_matrixes to more optimal via matrixes.

```
prompt> decompose_via_matrixes [get_via_matrixes]
{VIA_MATRIX_0 VIA_MATRIX_1}
```

SEE ALSO

create_via_matrix(2)
get_via_matrixes(2)
remove_via_matrixes(2)

define_antenna_accumulation_mode

Defines an antenna accumulation mode route rule.

SYNTAX

status **define_antenna_accumulation_mode**
[*library*]
[-cut_to_metal]
[-metal_to_cut]
[-cut_to_metal_for_accumulation_area]
[-metal_to_cut_for_accumulation_area]

Data Types

library list

ARGUMENTS

library

Specifies the library to be updated. The value of *library* can be a library name or a one-element collection of a library. The *library* option is not required. The default is to use the current library.

-cut_to_metal

When you specify the **-cut_to_metal** option, cut ratios are accumulated to metal ratios. Support such behavior for antenna mode 2 and mode 5. Default is off.

-metal_to_cut

When you specify the -cut_to_metal option, metal ratios are accumulated to cut ratios. Support such behavior for antenna mode 2 and mode 5. Default is off.

-cut_to_metal_for_accumulation_area

When you specify the **-cut_to_metal_for_accumulation_area** option, cut ratios are accumulated to metal ratios for accumulation area. Support such behavior for antenna mode 3 and mode 6, Default is off.

-metal_to_cut_for_accumulation_area

When you specify the **-metal_to_cut_for_accumulation_area** option, metal ratios are accumulated to cut ratios for accumulation area. Support such behavior for antenna mode 3 and mode 6, Default is off.

DESCRIPTION

This command defines an antenna accumulation mode route rule and stores it in the library. The command returns a status indicating success or failure.

Note: If the options are not specified with the command, it means the options value are FALSE, and the setting(FALSE) will be stored in the library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command defines antenna accumulation mode route rules.

To accumulate metal and cut ratio for antenna mode 2 and mode 5
```
prompt> define_antenna_accumulation_mode \
        -cut_to_metal -metal_to_cut
1
```

To accumulate metal and cut ratio for antenna mode 3 and mode 6
```
prompt> define_antenna_accumulation_mode \
        -cut_to_metal_for_accumulation_area \
        -metal_to_cut_for_accumulation_area
1
```

To accumulate metal and cut ratio for antenna mode 2, mode 5,
mode 3 and mode 6
```
prompt> define_antenna_accumulation_mode \
        -cut_to_metal -metal_to_cut \
        -cut_to_metal_for_accumulation_area \
        -metal_to_cut_for_accumulation_area
1
```

SEE ALSO

define_antenna_area_rule(2)

define_antenna_area_rule

Defines an antenna area rule for the specified mode and stores it in the library. The rule considers metal area and max antenna ratio to identify large metal areas where electric charge might pool and damage the gate.

SYNTAX

status **define_antenna_area_rule**
-mode *mode*
-max_area *area*
[-diode_distance *distance*]
[*library*]

Data Types

mode string
area float
distance float
library collection

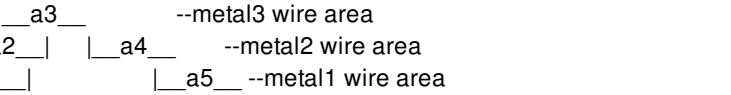
ARGUMENTS

-mode *mode*

Defines the way metal(routing) areas are computed. Valid values are:

- **ignore_lower_layers**: Calculate metal area, ignoring all lower-layer segments.
- **include_lower_layers**: Calculate metal area, including lower-layer segments to the input pins.
- **include_all_lower_layers**: Calculate metal area, including all lower-layer segments.

For example, in the following figure, a1, a2, a3, a4, a5 represent wire areas that connect to the gate. Via connection wire area is omitted in this case.



For different modes, when calculating total routing area for metal3 layer:

- **ignore_lower_layers** : total_routing_area = a3;
- **include_lower_layers** : total_routing_area = a1+a2+a3;
- **include_all_lower_layers** : total_routing_area = a1+a2+a3+a4+a5;

Note that only one rule can be defined for every mode. If two commands contain the same mode number, the second command will overwrite the first one.

-max_area ***area***

This is maximum allowable metal area for a gate, by square distance unit of current library. The metal area (connected to the gate) calculated base on mode can't exceed this constraint.

If this value is zero, the antenna area rule will be ignored.

Valid value: any non-negative number.

-diode_distance ***distance***

This is maximum allowable point to point distance from inserted diode to gate, by distance unit of current library. It is used to prevent diode cell from being inserted far from the gate, so as to guarantee the efficiency of antenna fixing by diode insertion.

If this value is zero, the antenna fixing uses wire rerouting instead of diode insertion.

Valid values are any non-negative number.

library

Specifies the library to define antenna area rule. This can either be a name or a collection of a single library. If not given, the **current_lib** is used.

DESCRIPTION

This command defines an antenna area rule for the specified mode and stores it in the library. The command returns a status indicating success or failure.

EXAMPLES

```
prompt> define_antenna_area_rule -mode ignore_lower_layers \
  -max_area 500 -diode_distance 50.5
```

define_antenna_layer_ratio_scale

Creates an antenna layer ratio route rule.

SYNTAX

status **define_antenna_layer_ratio_scale**
[*library*]
-layer *layer_name*
-layer_scale *layer_scale*
-accumulate_scale *accumulate_scale*

Data Types

library	list
layer_name	string
layer_scale	float
accumulate_scale	float

ARGUMENTS

library

Specifies the Milkyway library to be updated. The value of *library* can be a library name or a one-element collection of a library. The *library* option is optional. The default is to use the current Milkyway library.

-layer *layer_name*

Specifies the name of the layer.

-layer_scale *layer_scale*

Specifies the layer scale factor.

-accumulate_scale *accumulate_scale*

Specifies the accumulation scale factor.

DESCRIPTION

This command creates an antenna layer ratio route rule. The command returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines an antenna layer ratio on the metal1 layer

```
prompt> define_antenna_layer_ratio_scale -layer metal1 \
        -layer_scale 1000.00 -accumulate_scale 2.00
```

SEE ALSO

define_antenna_layer_rule(2)
define_antenna_rule(2)
remove_antenna_rules(2)
report_antenna_rules(2)

define_antenna_layer_rule

Defines an advanced antenna rule for the specified layer.

SYNTAX

status **define_antenna_layer_rule**
[*library*]
-mode *mode*
-layer *layer*
[-name *rule_name*]
[-ratio *ratio*]
[-pratio *pratio*]
[-nratio *nratio*]
-diode_ratio *diode_ratio*
[-scale_factor *scale_factor*]

Data Types

library	collection
mode	int
layer	collection
rule_name	string
ratio	float
pratio	float
nratio	float
diode_ratio	list
scale_factor	list

ARGUMENTS

library

Specifies the library for which to define the antenna layer rule. You can specify either the library name or a collection of a single library.

By default, the command uses the current library.

-mode *mode*

Defines the way antenna areas are computed. The valid values and their descriptions are as follows:

1: Uses the polygon area, ignoring all lower-layer segments.

2: Uses the polygon area, including all lower-layer segments to the input pins.

3: Uses the polygon area, including all lower-layer segments.

4: Uses the side-wall area, ignoring all lower-layer segments.

5: Uses the side-wall area, including all lower-layer segments to the input pins.

6: Uses the side-wall area, including all lower-layer segments.

You can define only one rule for each mode. If two commands contain the same mode number, the second command overwrites the first one.

-layer ***layer***

Specifies the metal or cut layer for which to define the antenna layer rule. You must specify a single layer using either the layer name from the technology file or a collection of a single layer.

-name ***rule_name***

Specifies the name of the created rule.

If you do not specify this option, the command creates or modifies the global antenna layer rule.

-ratio ***ratio***

Specifies the maximum allowable ratio of the antenna area to the gate area if the antenna is not protected by any diode. You specify this value as a floating point number.

-pratio ***pratio***

Specifies the maximum allowable ratio of the antenna area to the p-gate area. You specify this value as a floating point number.

-nratio ***nratio***

Specifies the maximum allowable ratio of the antenna area to the n-gate area. You specify this value as a floating point number.

-diode_ratio ***diode_ratio***

Specifies the allowable ratio of the antenna area to the gate area if the antenna is protected by a diode. You specify this value as a diode ratio vector, which has the following format:

{v0 v1 v2 v3 [v4]}

Each value in the vector is a floating point number. The actual usage of the diode ratio vector depends on the diode mode specified with the **-mode** option. For details, see "Defining Metal Layer Antenna Rules" in the *Fusion Compiler Implementation User Guide*.

-scale_factor ***scale_factor***

Specifies the scale factor of the metal area to the gate area. This option is valid only for diode modes 11 and 12.

DESCRIPTION

This command defines an advanced antenna rule for the specified layer.

The persistency of the rule depends on several factors:

- If you run the command in the library manager, the rule is saved in the cell library and is persistent.
- If you run the command in an implementation tool, the rule is saved in the design library only if all technology data is stored in

the design library and not in a reference library.

However, in most cases, the design library references the technology data in a technology library or a cell library that contains technology data. In these cases, the rule is not saved in the design library and is not persistent.

This command cannot be used with an antenna rule that is defined with diode mode 20 because the diode mode 20 antenna rule is layer independent.

EXAMPLES

The following example defines an advanced antenna rule for the metal1 layer that uses side-wall area and ignores all lower-layer segments.

```
prompt> define_antenna_layer_rule -layer metal1 -mode 4 \
  -ratio 400 -diode_ratio {0.336 -0.5 400 2400}
```

SEE ALSO

define_antenna_rule(2)

define_antenna_rule

Defines an advanced antenna rule for the specified mode and stores it in the library.

SYNTAX

status **define_antenna_rule**
-mode *mode*
-diode_mode *diode_mode*
[-name *rule_name*]
[-metal_ratio *metal_ratio*]
[-cut_ratio *cut_ratio*]
[-metal_pratio *metal_pratio*]
[-metal_nratio *metal_nratio*]
[-cut_pratio *cut_pratio*]
[-cut_nratio *cut_nratio*]
[-protected_metal_scale *metal_scale*]
[-protected_cut_scale *cut_scale*]
[-area_threshold *area*]
[-layer_area_threshold *{min_layer max_layer area}*]
[*library*]

Data Types

mode integer
diode_mode integer
rule_name string
metal_ratio float
cut_ratio float
metal_pratio float
metal_nratio float
cut_pratio float
cut_nratio float
metal_scale float
cut_scale float
area float
layer_area_threshold list
library collection

ARGUMENTS

-mode *mode*

Defines the way antenna areas are computed. The valid values and their descriptions are as follows:

- **1** - Uses a polygon area, ignoring all lower-layer segments.
- **2** - Uses a polygon area, including all lower-layer segments to the input pins.
- **3** - Uses a polygon area, including all lower-layer segments.
- **4** - Uses a side-wall area, ignoring all lower-layer segments.
- **5** - Uses a side-wall area, including all lower-layer segments to the input pins.
- **6** - Uses a side-wall area, including all lower-layer segments.

Note that only one rule can be defined for every mode for a given rule name. If two commands contain the same mode number and same rule name, the second command overwrites the first one.

-diode_mode ***diode_mode***

Defines the protection capability of the diode. By default, all output pins are considered to be a diode. The valid values and their descriptions are as follows:

- **0** - The diodes do not provide any protection.
- **1** - The diodes provide unlimited protection.

  In this mode, the highest metal layer is not checked for antenna violations because the input-to-output connection is completed when the highest metal layer is formed.
- **2** - Diode protection is limited; if more than one diode is connected, the largest value of the maximum antenna ratio for all diodes is used.
- **3** - Diode protection is limited; if more than one diode is connected, the sum of the maximum antenna ratios for all diodes is used.
- **4** - Diode protection is limited; if more than one diode is connected, the sum of the diode-protection values for all diodes is used to compute the maximum antenna ratio.
- **5** - Diode protection is limited; the maximum diode-protection value for all diodes is used to calculate the equivalent gate area.
- **6** - Diode protection is limited; the sum of the diode-protection values for all diodes is used to calculate the equivalent gate area.
- **7** - Diode protection is limited; the maximum diode-protection value for all diodes is used to calculate the equivalent metal area.
- **8** - Diode protection is limited; the sum of the diode-protection values for all diodes is used to calculate the equivalent metal area.
- **9** - Diode protection is limited; scaling is based on maximum diode protection.
- **10** - Diode protection is limited; scaling is based on total diode protection.
- **11** - Diode protection is limited; scaling is based on maximum diode protection.
- **12** - Diode protection is limited; scaling is based on total diode protection.
- **19** - Has well type dependent data in addition to well independent data.
- **20** - Has accumulated area threshold for floating metal or vias.
- **21** - Diode protection is limited; this is a nwell antenna rule which will safe guard by maintaining metal to nwell area ratio.
- **22** - Diode protection is limited; this is a TSV(Through Silicon Via) antenna rule which will safe guard by the ratio of TSV

area to the gate area that are electrically connected.

-name *rule_name*

Specifies the name of the rule to be created. This is an optional option. When not specified, the global-antenna rule is created/modified.

-metal_ratio *metal_ratio*

Specifies the maximum allowable ratio for metal area to gate size if the metal layer is not defined by using the **define_antenna_layer_rule** command. It's required when metal_pratio and metal_nratio are not specified. If this value is zero, the ratio is ignored. The valid value is any non-negative number. This can't be specified for **-diode_mode 20**.

-cut_ratio *cut_ratio*

Specifies the maximum allowable ratio for cut area to gate size if the cut layer is not defined by using the **define_antenna_layer_rule** command. It's required when cut_pratio and cut_nratio are not specified. If this value is zero, the ratio is ignored. The valid value is any non-negative number. This can't be specified for **-diode_mode 20**.

-metal_pratio *metal_pratio*

Specifies the maximum allowable ratio for antenna area (metal) to p-gate area. Use together with metal_nratio, required when metal_ratio is not specified. This can't be specified for **-diode_mode 20**.

-metal_nratio *metal_nratio*

Specifies the maximum allowable ratio for antenna area (metal) to n-gate area. Use together with metal_pratio, required when metal_ratio is not specified. This can't be specified for **-diode_mode 20**.

-cut_pratio *cut_pratio*

Specifies the maximum allowable ratio for antenna area (cut) to p-gate area. Use together with cut_nratio, required when cut_ratio is not specified. This can't be specified for **-diode_mode 20**.

-cut_nratio *cut_nratio*

Specifies the maximum allowable ratio for antenna area (cut) to n-gate area. Use together with cut_pratio, required when cut_ratio is not specified. This can't be specified for **-diode_mode 20**.

-protected_metal_scale *metal_scale*

Specifies the value used to scale the area of the metal layer that is protected by the diode. The option is used only when the mode is 2 or 5. If this value is zero, the scale is ignored. The valid value is any non-negative number. By default, the value is set to 1.0.

-protected_cut_scale *cut_scale*

Specifies the value used to scale the area of the cut layer that is protected by a diode. The option is used when mode is 2 or 5 only. If this value is zero, the scale is ignored. The valid value is any non-negative number. By default, the value is set to 1.0.

-area_threshold *area*

Specifies the threshold for accumulated area of floating metal or via. This can be specified only with **-diode_mode 20**.

-layer_area_threshold *{min_layer max_layer area}*

Specifies the threshold for the layers specified by the range {min_layer max_layer} for accumulated area of floating metal or via. This can be specified only with **-area_threshold**. Max_layer's layer_number should not be lesser than min_layer's layer_number.

DESCRIPTION

This command defines an advanced antenna rule for the specified mode and stores it in the library.

With the use of the **-name** option, the antenna rule definitions should be unique with respect to the values specified with the parameters. If an antenna rule with configurations similar to the one being created, already exists, then the command reports the same and stops processing. Multiple invocations of the command with different configurations and same rule-name will overwrite the previous configuration associated with the given rule-name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of the command specifying a polygon area (ignoring all lower-layer segments), limited diode protection, maximum allowable ratio for metal area to gate size of 1000, and a maximum allowable ratio for cut area to gate size of 0.

```
prompt> define_antenna_rule -mode 1 -diode_mode 2 \
  -metal_ratio 1000 -cut_ratio 0
```

The following example shows the use of the command specifying a polygon area (ignoring all lower-layer segments), limited diode protection, maximum allowable ratio for metal area to p-gate size of 1000, maximum allowable ratio for metal area to n-gate size of 500, maximum allowable ratio for cut area to p-gate size of 0 and a maximum allowable ratio for cut area to n-gate size of 0.8. The example also shows the usage of '-name' option:

```
prompt> define_antenna_rule -name m1_dm2_rule1 -mode 1 -diode_mode 2 \
  -metal_pratio 1000 -cut_pratio 0 -metal_nratio 500 -cut_nratio 0.8
```

remove_antenna_rules(2)

define_dft_design

Characterizes a design as a DFT design to be used for DFT insertion.

SYNTAX

status **define_dft_design**
-design_name *design_name*
[-type *design_type*]
[-interface *access_list*]
[-params *param_list*]

Data Types

design_name string
design_type string
access_list list
model_path_name string
param_list list

ARGUMENTS

-design_name *design_name*

Identifies the design to be instantiated during DFT insertion.

This option is required.

-type *design_type*

Specifies the type of the DFT design to which the design corresponds. Valid design types are:

DECODE CONTROL_FORCE Z_CONTROL_FORCE OBSERV_DGEN
SHIFT_REG BC_1 BC_2 BC_3
BC_4 BC_5 BC_7 BC_8
BC_9 BC_10 WC_D1 WC_D1_S
WC_S1 WC_S1_S INSTRREG TAP
TAP_UC LBIST_CONTROLLER LBIST_CODEC LBIST_XCONTROLLER
LBIST_XCODEC CLK_MUX CLK_CHAIN MBIST_CONTROLLER
MBIST_WRAPPER PAD AC_1 AC_2
AC_7 AC_SELU AC_SELX

There is no default for this option. When the option is not specified, the tool creates a new DFT design type from the specified design name and the specified interface access list.

-interface *access_list*

Specifies the list of signal mapping triplets relating a signal type to a pin of the design specified with **-design_name** *design_name*. The valid format of a signal mapping triplet is as follows:

signal_type_name pin_name pin_polarity

The *signal_type_name* specifies the signal type name of the latest of DesignWare version of the DFT design pin name. The *pin_name* specifies the pin name of the design specified with **-design_name** *design_name*. The *pin_polarity* specifies the polarity of the specified design pin with respect to the *signal_type_name*.

Valid values for *pin_polarity* are **h** for normal polarity and **l** for negative polarity.

There is no default for this option. When the option is not specified, it is assumed that the design does not have interface access pins for use with DFT insertion.

-params *param_list*

Specifies the list of parameter triplets for the specified DFT design. The valid format of a parameter triplet is as follows:

param_name param_type param_value

The *param_name* specifies the name of the parameter, *param_type* specifies the type of the parameter, and *param_value* specifies the value of the parameter. Valid values for *param_type* are **integer**, **float**, **boolean**, and **string**.

These parameters are stored on the specified DFT design for use with DFT insertion.

There is no default for this option.

DESCRIPTION

The **define_dft_design** command characterizes a design as a DFT design of a certain type for use with DFT insertion. Ensure that the specified design functionality matches the standard design of the specified type. The specified design is used to instantiate an IP instead of a DesignWare IP during DFT insertion.

EXAMPLES

The following example instructs the tool to use the *my_des* design as a WC_D1 for wrapper insertion:

```
prompt> define_dft_design -design_name my_des -type WC_D1 \
      -interface {shift_clk capture_clk h capture_en capture_en \
      h shift_en shift_dr h cti si h cto so h cfi data_in \
      h cfo data_out h}
1
```

preview_dft(2)

define_dft_partition

Defines a design DFT partition to be created during DFT synthesis.

SYNTAX

status **define_dft_partition**
design_partition_label
[-include *list_of_design_objects*]
\" [-wrapper disable | enable]

Data Types

list_of_design_objects list

ARGUMENTS

design_partition_label

Specifies a user-defined text string containing only alphanumeric characters (a-z, A-Z, 0-9) and the underscore (_).

-include *list_of_design_objects*

Specifies the list of leaf or hierarchical cells, design references, or core scan segments that belong to the defined partition.

You can mix object types in the list. Wildcards and collections are supported.

\" .IP "-wrapper disable | enable" \" Specifies whether the DFT partition should be core-wrapped. \" \" When this feature is enabled, the **-include** object list must contain \" only a single hierarchical cell. The hierarchical boundary of that cell then \" becomes wrappable when the DFT core-wrapping client is enabled. \" \" The default is **false**. \"

DESCRIPTION

The **define_dft_partition** command allows you to define a specific design partition during DFT synthesis. The partition is referenced to the top level in a top-down flow.

The partition information is then used during the DFT architect and insertion process. Each design partition will be DFT-inserted based on its DFT constraints.

You can include clock-gating cells in DFT partition definitions. Although clock-gating cells are not stitched into scan chains, they will use partition-specific scan-enable signals for their test pins (if defined). Clock-gating cells can be included by leaf cell, enclosing hierarchical cell, or clock. When referencing a Power Compiler clock-gating cell by leaf cell, reference the mapped clock-gating cell inside the hierarchical clock-gating cell wrapper.

EXAMPLES

The following example defines 2 design partitions for use in a DFT insertion. The design contains at the top level 4 hierarchical cells named *U1*, *U2*, *U3* and *U4*, respectively.

```
prompt> define_dft_partition part_1\
        -include {U1 U2}

prompt> define_dft_partition part_2\
        -include {U3 U4}
```

report_dft(2)

define_hdl_library

Maps an HDL library name to a template library location.

SYNTAX

status **define_hdl_library**
hdl_library_name
[-path *path*]

Data Types

hdl_library_name string
path string

ARGUMENTS

hdl_library_name

Specifies the hdl_library_name to be mapped. When specified as "default", the hdl_library_name is taken from **hdlin.hdl_library.default_name**.

-path *path*

Specifies the location of the template library. If the path option is not used, the path is the file join of **hdlin.hdl_library.default_dirname** and the uppercase versions of hdl_library_name.

DESCRIPTION

This command maps an HDL library to a template library location. The template library is not required to exist yet when the command is called. The command does not create template libraries or cause any changes on disk.

EXAMPLES

The following two commands has the same effect:

prompt> **define_hdl_library** my_lib

and

prompt> **define_hdl_library** my_lib **-path** [file join [get_app_option_value -name hdlin.hdl_library.default_dirname] [string toupper

define_libcell_subset

Defines a subset of library cells to restrict the optimization of sequential and instantiated combinational cells.

SYNTAX

status **define_libcell_subset**
[-libcell_list *lib_cells*]
[-family_name *name*]

Data Types

lib_cells list
name string

ARGUMENTS

-libcell_list *lib_cells*

Specifies a list of library cells to be a family. These library cells must abide by the following rules: First, the library cells cannot belong to another family. Second, they must have the same functional identification.

-family_name *name*

Specifies a name for the subset of library cells.

DESCRIPTION

The **define_libcell_subset** command defines a subset of library cells to be protected. After the library cells are grouped into a family, they are not available for use during optimization. However, unmapped sequential cells that are specified by the **set_library_subset** command can be mapped to a library cell in the same family. A mapped sequential/combinational cell can also be optimized to another library cell in the same family as its original library cell. A library cell can only belong to one family. Therefore, if you need to change the family of a library cell, the family should be removed first using the **remove_libcell_subset** command.

To remove a family, use the **remove_libcell_subset -family_name** command.

EXAMPLES

In the following example, **define_libcell_subset** groups logic library cells SDFLOP1 and SDFLOP2 into a family called special_flops. Next, **set_libcell_subset** sets the family for unmapped cells u1 and u2 to the defined special cell family, special_flops, which consists of the library cells SDFLOP1 and SDFLOP2. As a result, u1 and u2 can only be mapped to either SDFLOP1 or SDFLOP2.

```
prompt> define_libcell_subset -libcell_list "SDFLOP1 SDFLOP2" -family_name special_flops
prompt> set_libcell_subset -object_list [get_cells u1 u2] -family_name special_flops
```

define_name_rules

Defines a set of naming rules for ports, cells, and nets in the design.

SYNTAX

status **define_name_rules**
rule_name
[-type *object_type*]
[-special *output_format*]
[-equal_ports_nets]
[-inout_ports_equal_nets]
[-collapse_name_space]
[-map *map_string*]
[-check_bus_indexing]
[-check_internal_net_name]
[-remove_irregular_net_bus]
[-remove_irregular_port_bus]
[-allowed *chars_list*]
[-restricted *chars_list*]
[-first_restricted *chars_list*]
[-last_restricted *chars_list*]
[-remove_chars *chars_list*]
[-replacement_char *rep_char*]
[-reserved_words *list_of_words*]
[-case_insensitive]
[-max_length *length*]
[-prefix *string*]
[-add_dummy_nets]
[-dummy_net_prefix *string*]
[-remove_internal_net_bus]
[-remove_port_bus]
[-flatten_port_bus]
[-flatten_multi_dimension_buses]
[-dont_change_bus_members]
[-dont_change_ports]
[-remove_synonym_nets]
[-reset]
[-target_bus_naming_style *bus_naming_style*]

Data Types

rule_name string
object_type string
output_format string
map_string string
chars_list string
rep_char string

list_of_words list
length integer
string string
bus_naming_style string

ARGUMENTS

rule_name

Specifies the name of the rule set being defined. If this is a new rule set name, the command creates a new set of rules. If this is an existing rule set name, the command adds the specified rules to the existing rule set.

-type *object_type*

Specifies that the rules being defined apply only to the given type of objects. Allowed values for object type are **port**, **cell**, **net** or **all**. By default, the defined rules apply to all object types.

-special *output_format*

Specifies a predefined set of rules for a particular output format. The only output format currently supported is **verilog**.

-equal_ports_nets

Specifies that each net connected to an input port or output port must have the same name as the connected port. If a net is connected to more than one port and none of the ports has the same name as the net, the net's name will be changed to one of the port's name. For a feedthrough net, the net name must be the same as the input port name. By default, net names need not match the names of the connected ports. Note that the rename could fail due to collision of names.

-inout_ports_equal_nets

Specifies that each net connected to an inout (bidirectional) port must have the same name as the connected port. This requirement does not apply to a net connected to multiple ports.

-collapse_name_space

Specifies that ports, cells, and nets share the same name space, which means that each name can be used by only one object. For example, a net and a port cannot share the same name, even if they are connected. By default, ports, cells, and nets each have their own name space, so a net and a port can share the same name, even if they are not connected. Applying a collapsed name space causes the **change_names** command to "uniquify" the port, cell, and net names (in that order).

-map *map_string*

Changes specific names or patterns to new names or patterns. You specify the old patterns and the replacement strings in the *map_string* argument. For details, see "Mapping Rules" in the DESCRIPTION section.

-check_bus_indexing

Sorts the index values of port buses in increasing order and bit-blasts the incomplete buses.

-check_internal_net_name

Prohibits internal nets (those not connected to any port) from having the same name as port.

-remove_irregular_net_bus

Bit-blasts any net bus that contains irregular members. Only if all members are of the same name that is different than the bus name then bus name is renamed to its member's name provided there is no existing net or bus net of the same name.

-remove_irregular_port_bus

Bit-blasts any port bus that contains irregular members.

-remove_synonym_nets

Removes all the synonym nets.

-flatten_port_bus

Ensure that all pins of a bused port have names of the form "*bus_name*[*i*]". This will typically rename buses whose HDL type involved VHDL records, SystemVerilog structs, or multidimensional arrays. Although pin names are changed, the bus's HDL type in memory is not. Regular pin names permit write_verilog to netlist the bus as a one-dimensional bus port.

-flatten_multi_dimension_buses

Flattens multi-dimension ports, net buses, and arrays so writing out is easier. Although pin names are changed, the bus's HDL type in memory is not. If **-flatten_port_bus** and **-flatten_multi_dimension_buses** are turned on, the former overrides the latter. If only **-flatten_multi_dimension_buses** is turned on, then, **-remove_irregular_port_bus** would be enabled as well, to allow write_verilog to successfully write out single dimension buses with non-numeric indices.

-allowed *chars_list*

Allows only the listed characters to be used in object names. The list must contain at least ten characters. You can specify the allowed characters individually or as alphanumeric ranges. Disallowed characters are replaced by an underscore character or other character specified with the **-replacement_char** option, or they are removed if you use the **-remove_chars** option. For details, see "Character Restriction Rules" in the DESCRIPTION section. By default, all printable characters are allowed in names.

-restricted *chars_list*

Prevents the listed characters from being used in object names.

-first_restricted *chars_list*

Prevents the listed characters from being used as the first character of each object name.

-last_restricted *chars_list*

Prevents the listed characters from being used as the last character of each object name.

-remove_chars

Causes characters disallowed by the **-allowed** or **-restricted** option to be removed rather than replaced. By default, disallowed characters are replaced by an underscore character or other character specified with the **-replacement_char** option.

-replacement_char *rep_char*

Specifies the character used to replace characters disallowed by the **-allowed** or **-restricted** option. The default replacement character is the underscore (_).

-reserved_words *list_of_words*

Specifies a list of words that cannot be used as object names, such as words considered reserved in your target system. By default, there are no reserved words.

-case_insensitive

Causes the character case (uppercase or lowercase) to be ignored when names are compared. For example, when you use this option, the names "ABC" and "abc" are considered to be equivalent and therefore conflicting within a name space. By default, the name comparison is case-sensitive; lowercase and uppercase characters are considered to be different characters, so there is no conflict between "ABC" and "abc".

-max_length *length*

Specifies the maximum allowed number of characters in each name. The specified maximum length must be at least 8. By default, names of any length are allowed. Setting the *length* argument to 0 resets the rule to the default behavior (any length allowed).

-prefix *string*

Specifies the prefix used for generating new object names. A prefix is required only for renaming excessively long names when truncation and indexing fail to generate a unique name. By default, the prefix is "P" for ports, "U" for cells, and "N" for nets.

-add_dummy_nets

Adds a new dummy net for each unconnected pin and connects it to the pin.

-dummy_net_prefix *string*

Sets the prefix for generating the names of new dummy nets created by the **-add_dummy_nets** option. The default prefix is SYNOPSYS_UNCONNECTED_.

-remove_internal_net_bus

Bit-blasts all internal net buses that do not have any port connection.

-remove_port_bus

Bit-blasts all port buses. Net buses that connect to ports are also bit-blasted.

-dont_change_bus_members

Specifies not to change the elements that are part of a bus. This option has higher priority than all other options that change bus and bus port names.

-dont_change_ports

Specifies not to change ports.

-reset

Resets all rules to their default behavior, which removes all restrictions on object names.

-target_bus_naming_style *bus_naming_style*

Specifies the rule for bus delimiters to be used in port, pin, and net names to denote bus subscripts while write_gds, write_oasis and write_def or while querying through get_ports/pins/nets. Valid values are "[]", "{}", "()", and "<>".

DESCRIPTION

The tool follows certain naming conventions for ports, cells, and nets. When you export a design to an external format, you might need to have the object names follow different naming conventions. To change the names of objects, use the **define_name_rules** command to define the desired naming rules and the **change_names** command to change the names according to these rules.

The rules defined by the **define_name_rules** command can:

- Force the name of any net connected to a port to match the port name
- Force all port, cell, and net names to be unique across all objects

- Change all occurrences of a given string in object names to a new string
- Allow only a given list of characters to be used as the first character, the last character, or all characters of object names
- Prohibit a specified list of characters in object names
- Prohibit a specified list of words as object names
- Restrict the number of characters in each name to a specified maximum

The **change_rules** command enforces these rules by performing one or more of the following actions:

- Deleting characters
- Changing the case of characters
- Replacing characters with an underscore or other specified characters
- Appending a numeric index to the name
- Assigning an entirely new name consisting of a prefix and a numeric index

The **define_name_rules** command defines a set of rules for naming design objects. You assign a name for a set of rules in the command. Each type of rule is supported by a command option. You can use multiple **define_name_rules** command to specify multiple rules for a given rule set.

After you define all the rules for a rule set, you can use the **report_name_rules** command to report the rules, or the **change_names** command to actually change the names in the design according to the rules. To preview the changes to the design without actually performing those changes, use the **report_names** command.

Port and Net Rules

To force the names of nets connected to ports match the names of the connected ports, use the **-equal_ports_nets** option for input and output ports or the **-inout_ports_equal_nets** option for bidirectional ports. If renaming a net would cause a conflict, or if a net is connected to multiple ports, the name is not changed and a warning message is issued.

Name Space Rules

By default, the name spaces of ports, cells, and nets are separate. Names of ports and cells must be unique within a design. A port, a cell, and a net within a design can all share the same name.

To collapse the separate name spaces into a single name space, use the **-collapse_name_space** option. In that case, ports, cells, and nets within a design must be unique across all objects. Conflicting names are modified by appending digits.

If you use both the **-collapse_name_space** and **-equal_ports_nets** options, the **-equal_ports_nets** rule has priority, so when a net is connected to a port, port and net names still match.

Type-Specific Rules

Name rules can be tailored for ports, cells, and nets object types with the **-type** option. The options to **define_name_rules** that can be specified by object type are as follows:

-max_length
-allowed
-restricted
-first_restricted
-last_restricted
-replacement_char
-remove_chars
-prefix

To specify the maximum length restriction on ports different than the maximum length for cells, make multiple calls to **define_name_rules**.

In the following example, the maximum length of ports is set to 12. The maximum length of cells is set to 8. The maximum length of nets is unrestricted.

prompt> **define_name_rules EXAMPLE -max_length 12 -type port**

prompt> **define_name_rules EXAMPLE -max_length 8 -type cell**

Special Rules

The **-special** option invokes a predefined set of rules for a specific output format. Currently, **verilog** is the only supported output format. Using **-special verilog** is equivalent to specifying the following options:

-collapse_name_space
-equal_ports_nets
-inout_ports_equal_nets
-remove_irregular_port_bus
-remove_irregular_net_bus

You can optionally specify other rules, in addition to the ones implicitly invoked by the **-special verilog** option.

Note: The **change_names** command lets you specify **-rules verilog** as the rule name, which is somewhat different from using the **-special verilog** option in the **define_name_rules** command. For details, see the man page for the **change_names** command.

Mapping Rules

The **-map** option changes specific names or patterns to new names or patterns. You specify the old patterns and the replacement strings in the *map_string* argument using the following format:

{{"*pattern*","*replacement*"} [,{"*pattern*","*replacement*"}] ...}

The elements of the mapping string are grouped into pairs. The first element of a pair is a character pattern to be replaced, and the second element is the replacement string. For example,

prompt> **define_name_rules my_map_rule -map {{"a","A"}}**

This mapping rule replaces each instance of a lowercase "a" with an uppercase "A".

There can be any number of pairs in the mapping string. Each pair is enclosed by curly braces and separated from other pairs by a comma. The **change_names** command performs search-and-replace operations in the order specified in the **map_string**, from left to right.

The pattern string also provides limited regular expression capability. The following 4 special characters are supported to make the mapping strings more specific:

- The **$** (dollar sign) indicates the end of string.
- The **^** (caret) indicates the beginning of string.
- The ***** (asterisk) indicates a wildcard matching 0 or more characters.
- The **?** (question mark) indicates a wildcard matching 1 character.

The following example defines a rule that any name ending with **_reg** is replaced by **in** at the end of the string:

prompt> **define_name_rules my_rule0 -map {{"_reg$", "in"}}**

The following example defines a rule that any name beginning with **_reg** is replaced by **in** at the beginning of the string:

prompt> **define_name_rules my_rule1 -map {{"^_reg", "in"}}**

The following example defines a rule that any substring of a name that begins with **_r** and ends with **g** is replaced by the **in** string:

prompt> **define_name_rules my_rule2 -map {{"_r*g", "in"}}**

The following example defines a rule that any substring of a name that begins with **_r** followed any one character, then ending with **g** is replaced by **in**:

prompt> **define_name_rules my_rule3 -map {{"_r?g", "in"}}**

Once a mapping rule is defined, you can only use **-reset** to reset the mapping rule. You cannot redefine the same matching pattern within the same rule. For example, assume you define the following rule:

prompt> **define_name_rules my_rule4 -map {{"A", "X"}}**

If you then decide to replace all occurrences of **A** with **Z**, you must first execute a reset and then redefine the name rules as follows:

prompt> **define_name_rules my_rule4 -reset**

prompt> **define_name_rules my_rule4 -map {{"A", "Z"}}**

For escaping a wild card pattern single backslash \ can be used.

The following example defines a rule that any substring of a name **_r*g** will be matched and replace with **in**, it considers * as a character instead wildcard pattern.

prompt> **define_name_rules my_rule2 -map {{"_r*g", "in"}}**

Order of Applying Name Rules

The **change_names** command performs changes in the following order:

1. Map rules -- Rules that directly change object names, as specified by the **-map** option.
2. Meta rules -- Rules that extend beyond mapping, as specified by the **-collapse_name_space** option.
3. Design rules -- Rules that apply to object names in terms of whole design naming methodology: **-flatten_port_bus**, **-flatten_multi_dimension_buses**, **-equal_ports_nets**, **-inout_ports_equal_nets**, **-check_internal_net_name**, **-remove_irregular_port_bus**, and **-check_bus_indexing**, in that order.

The **change_names** command changes the port names first, then the cell names, and finally the net names. When there is a conflict between a port name and a cell or net name, the port name has higher priority and is not changed. Instead, the cell or net name is changed.

In some cases, later changes can overwrite earlier ones, possibly resulting in unexpected changes. To control the order in which naming rules are applied, you can create a separate rule set for each rule using a separate **define_name_rules** command, and assigning a different rule set name to each rule. Then you can apply each rule separately using its own **change_names** command in the desired order. Perform the least important changes first and the most important changes last.

Character Restriction Rules

You can restrict the usage of characters in object names by using the **-allowed**, **-restricted**, **-first_restricted**, and **-last_restricted** options.

To specify the characters allowed or disallowed, use the **-allowed** or **-restricted** option. Either of these options overrides any previous settings made with the **-allowed**, **-restricted**, **-first_restricted**, and **-last_restricted** options.

In conjunction with the **-allowed** or **-restricted** options, you can optionally use the **-first_restricted** and **-last_restricted** options to further restrict the characters for the first and last character of each name.

The argument of these options is a string that specifies the characters that can or cannot be used in object names. The hyphen character indicates a range of ASCII characters, for example, the string "a-k m 1-5" means all the letters from "a" to "k", the single letter m, and the numerals 1 through 5. To specify a literal hyphen character, precede it with two backslashes (\\-). Space characters are ignored. At least 10 different characters must be allowed. Multiple characters or ranges can be specified in any order.

The following example specifies a character set consisting of only the uppercase letters, numerals, and underscore character.

prompt> **define_name_rules UC_ONLY -allowed "A-Z 0-9 _"**

In the following example, some punctuation characters are disallowed, and the lowercase letters are disallowed as the first character of a name.

prompt> **define_name_rules NOPUNC** \
-restricted "!@#$%^&*()\-" -first_restricted "a-z"

The hyphen character (-) is disallowed by the character sequence \-. The quotation marks character (") is disallowed by the sequence \".

If an object name contains a disallowed character, the **change_names** command performs the following steps to modify the name:

1. Removes the character if the **-remove_chars** option was used in the rule definition.

2. Changes the case. For example, if lowercase letters are not allowed and uppercase characters are allowed, the name "sum4" is changed to "SUM4".

3. Replaces the character with an underscore character (by default) or the character specified by the **-replacement_char** option. For example, if punctuation characters are not allowed and the replacement character is an underscore, the name "U$1" is changed to "U_1".

4. Appends a number the name if necessary to make the name unique. If the previous steps create duplicate names, a number is appended to the new names to make them different.

Reserved Word Rules

To prevent specific names from being used as object names, specify the disallowed words using the **-reserved_words** option. For example, the following command prevents the words START and END from being used as names:

prompt> **define_name_rules MYWORDS -reserved_words {"START", "END"}**

Case Sensitivity Rule

By default, the naming rules are case-sensitive. The uppercase and lowercase versions of a letter are considered different characters.

To consider uppercase and lowercase letters as equivalent, use the **-case_insensitive** option in the rule definition. In that case, the words "END", "End", and "end" are all considered the same, so if the word "END" is disallowed, then "End and "end" are also disallowed.

Maximum Length Rule

To specify a maximum length for names, use the **-max_length** option to specify the maximum number of characters per name.

If an object name contains more than this number of characters, the **change_names** command performs the following steps to modify the name:

1. Truncation. For example, if the maximum name length is 16, the name THIS_NAME_IS_TOO_LONG_TO_BE_ACCEPTABLE is truncated to THIS_NAME_IS_TOO.

2. Truncation and appending an index. If truncation of names results in duplicate names, these names are truncated further and appended with a number. For example, if multiple names are truncated to make the name THIS_NAME_IS_TOO, the tool renames the objects THIS_NAME_IS_T1, THIS_NAME_IS_T2, and so on up to THIS_NAME_IS_T99.

3. Renaming using a prefix and index. When Step 1 and Step 2 fail to produce unique names, the tool creates an entirely new name in the form of a prefix appended with a numeric index. By default, the prefix is "P" for ports, "U" for cells, and "N" for nets. For example, nets are named N1, N2, and so on. You can specify the prefix by using the **-prefix** option.

If all three steps fail to generate a unique name, the original name is retained and a warning message is issued.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Irregular Bus Support

There are three modes of applying rules in the contest of handling irregular buses.

1. Rule **-flatten_port_bus** is enabled.

Ensure that all pins of a bused port have names of the form "*bus_name*[*i*]". This will typically rename buses whose HDL type involved VHDL records, SystemVerilog structs, or multidimensional arrays. Regular pin names permit write_verilog to netlist the bus as a one-dimensional bus port.

2. Rule **remove_irregular_port_bus** is enabled.

Bit-blasts any port bus that contains irregular members. The names of the bus pins would be retained in the resulting netlist.

3. Rule **flatten_multi_dimension_buses** is enabled.

Flattens multi-dimension ports, net buses, and arrays so writing out is easier. If only **-flatten_multi_dimension_buses** is turned on, then, **-remove_irregular_port_bus** would be enabled as well, to allow write_verilog to successfully write out single dimension buses with non-numeric indices.

End users could choose any of the above described modes.

EXAMPLES

The following commands change all occurrences "a" to "A" and "i" to "I" in port, cell, and net names.

```
prompt> define_name_rules UPPER_AI -map {{"a","A"},{"i","I"}}
1
prompt> report_name_rules      ; Report all defined name rules
...
Rules Name: UPPER_AI
   ...
   Report on user-defined UPPER_AI rule set
   ...
Rules Name: verilog
   ...
   Report on predefined verilog rule set
   ...
1
prompt> report_names -rules UPPER_AI  ; Report effect on names in design
                                      ; without actually changing them
```

```
  Design         Type    Object      New Name
  ------------------------------------------------------------
  leon3mp        port    reseta      resetA
  leon3mp        port    clk         clk
  ...            ...     ...         ...
```

```
prompt> change_names -rules UPPER_AI  ; Change names in design
 Information: Using name rules 'UPPER_AI'.
 Information: 908 objects (124 ports, ...) changed in design 'leon3mp'.
1
```

define_power_model

Defines a power model which describes the power intent of a reference library cell.

SYNTAX

string **define_power_model**
power_model_name
[-for *library_cells*]
{ UPF_commands }

Data Types

power_model_name	string
library_cells	list
UPF_commands	command list

ARGUMENTS

power_model_name

Specifies the name of the power model to be defined. The name should be a simple (non-hierarchical) name.

The name is scope-based, i.e., the power model cannot be defined if there is another power model with the same name in the scope where the **define_power_mode** command is executed.

-for *library_cells*

Specifies a collection of library cells that this power model can be applied to.

If this option is not specified, the power model can then be applied to any library cell.

{ UPF_commands }

UPF commands enclosed by braces will define the power intent of this power model. When the **apply_power_model** command is executed, these UPF commands will loaded in the scope of the target cells. Please see **apply_power_model(2)** for more details.

When the **define_power_model** command is executed, syntax legality of **UPF_commands** is not checked until the **apply_power_model** command is executed.

DESCRIPTION

The define_power_model command defines a power model containing other UPF commands contained within curly braces. A power model is used to define the power intent of a model and shall be used in conjunction with one or more model representations. The opening and closing curly braces encapsulating the UPF commands that describe the power model must be present in the same UPF file.

A power model can be referenced by its simple name from anywhere in a power intent description. It shall be an error to have two power models with the same name.

A power model can be applied to specific instances using **apply_power_model**.

One power model applied to a given instance may apply another power model to a descendant instance.

A power model that is not referenced by an **apply_power_model** command does not have any impact on the power intent of the design.

The **define_power_model** command provides a protected environment to the power model. Any Tcl variable used in the power model is not affected by the global variables defined outside the **define_power_model** command. Also, any Tcl variable defined inside the power model will not affect the environment outside the power model.

A power model can be parameterized by creating parameters using the **add_parameter** command. These parameters are represented as special Tcl variables which can be referenced within the power model. The parameters can be overridden with **-parameters** option of the **apply_power_model** command.

A power model can have nested hierarchy of other power models using the **apply_power_model** commands but it cannot have a nested definitions of power models, i.e. a nested **define_power_model** command.

EXAMPLES

The following example creates a power model for two library cells. Notice that there is a parameter for the top power domain name in the power model.

```
prompt> define_power_model MODEL -for {lib_cell_A lib_cell_B} {
  add_parameter DOMAIN -default domain -description "top power domain in model"
  create_supply_net VDD
  create_supply_net VSS
  create_supply_set SS -function {power VDD} -function {ground VSS}
  create_power_domain PD_$DOMAIN -supply {primary SS} -include_scope
}
```

define_proc_attributes

Defines attributes of a Tcl procedure, including an information string for help, a command group, a set of argument descriptions for help, and so on. The command returns the empty string.

SYNTAX

string **define_proc_attributes**
proc_name
[-info *info_text*]
[-define_args *arg_defs*]
[-define_arg_groups *group_defs*]
[-command_group *group_name*]
[-return *type_name*]
[-hide_body]
[-hidden]
[-dont_abbrev]
[-permanent]

Data Types

proc_name string
info_text string
arg_defs list
group_defs list
group_name string
type_name string

ARGUMENTS

proc_name

Specifies the name of the existing procedure.

-info *info_text*

Provides a help string for the procedure. This is printed by the **help** command when you request help for the procedure. If you do not specify *info_text*, the default is "Procedure".

-define_args *arg_defs*

Defines each possible procedure argument for use with **help -verbose**. This is a list of lists where each list element defines one argument.

-define_arg_groups *group_defs*

Defines argument checking groups. These groups are checked for you in parse_proc_arguments. each list element defines one group

-command_group ***group_name***

Defines the command group for the procedure. By default, procedures are placed in the "Procedures" command group.

-return ***type_name***

Specifies the type of value returned by this proc. Any value may be specified. Some applications use this information for automatically generated dialogs etc. Please see the type_name option attribute described below.

-hide_body

Hides the body of the procedure from **info body**.

-hidden

Hides the procedure from **help** and **info proc**.

-dont_abbrev

Specifies that the procedure can never be abbreviated. By default, procedures can be abbreviated, subject to the value of the **sh_command_abbrev_mode** variable.

-permanent

Defines the procedure as permanent. You cannot modify permanent procedures in any way, so use this option carefully.

-deprecated

Defines the procedure as deprecated i.e. it should no longer be called but is still available.

-obsolete

Defines the procedure as obsolete i.e. it used to exist but can no longer be called.

DESCRIPTION

The **define_proc_attributes** command associates attributes with a Tcl procedure. These attributes are used to define help for the procedure, locate it in a particular command group, and protect it.

When a procedure is created with the **proc** command, it is placed in the Procedures command group. There is no help text for its arguments. You can view the body of the procedure with **info body**, and you can modify the procedure and its attributes. The **define_proc_attributes** command allows you to change these aspects of a procedure.

Note that the arguments to Tcl procedures are all named, positional arguments. They can be programmed with default values, and there can be optional arguments by using the special argument name *args*. The **define_proc_attributes** command does not relate the information that you enter for argument definitions with **-define_args** to the actual argument names. If you are describing anything other than positional arguments, it is expected that you are also using **parse_proc_arguments** to validate and extract your arguments.

The *info_text* is displayed when you use the **help** command on the procedure.

Use **-define_args** to define help text and constraints for individual arguments. This makes the help text for the procedure look like the help for an application command. The value for **-define_args** is a list of lists. Each element has the following format:

arg_name option_help value_help data_type attributes

The elements specify the following information:

- *arg_name* is the name of the argument.
- *option_help* is a short description of the argument.
- *value_help* is the argument name for positional arguments, or a one word description for dash options. It has no meaning for a Boolean option.
- *data_type* is optional and is used for option validation. The *data_type* can be any of: string, list, boolean, int, float, or one_of_string. The default is string.
- *attributes* is optional and is used for option validation. The *attributes* is a list that can have any of the following entries:
  - "required" - This argument must be specified. This attribute is mutually exclusive with optional.
  - "optional" - Specifying this argument is optional. This attribute is mutually exclusive with "required."
  - "value_help" - Indicates that the valid values for a one_of_string argument should be listed whenever argument help is shown.
  - "values {<list of allowable values>}" - If the argument type is one_of_string, you must specify the "values" attribute.
  - "type_name <name>" - Give a descriptive name to the type that this argument supports. Some applications may use this information to provide features for automatically generated dialogs, etc. Please see product documentation for details. This attribute is not supported on boolean options.
  - "merge_duplicates" - When this option appears more than once in a command, its values are concatenated into a list of values. The default behavior is that the right-most value for the option specified is used.
  - "remainder" - Specifies that any additional positional arguments should be returned in this option. This option is only valid for string option types, and by default the option is optional. You can require at least one item to be specified by also including the required option.
  - "deprecated" - Specifying this option is deprecated i.e. it should no longer be used but is still available. A warning will be output if this option is specified. This attribute cannot be combined with obsolete or required.
  - "obsolete" - Specifying this option is obsolete i.e. it used to exist but can no longer be used. A warning will be output if this option is specified. This attribute cannot be combined with deprecated or required.
  - "min_value" <value> - Specify the minimum value for this option. This attribute is only valid for integer and float types.
  - "max_value" <value> - Specify the maximum value for this option. This attribute is only valid for integer and float types.
  - "default" <value> - Specify the default value for this option. This attribute is only valid for string, integer and float option types. If the user does not specify this option when invoking the command this default value will be automatically passed to the associated tcl procedure.

  The default for *attributes* is "required."

Use the **-define_arg_groups** to define argument checking groups. The format of this option is a list where each element in the list defines an option group. Each element has the following format:

{<type> {<opt1> <opt2> ...} [<attributes>]}

The types of groups are

- *"exclusive"* Only one option in an exclusive group is allowed. All the options in the group must have the same required/optional status. This group can contain any number of options.
- *"together"* If the first option in the group is specified then the second argument is also required. This type of group can contain at most two options.

- \fi"related" These options are related to each other. An automatic dialog builder for this command may try to group these options together.

The supported attributes are:

- *{"label" <text>}* An optional label text to identify this group. The label may be used by an application to automatically build a grouping in a generated dialog.
- *"bidirectional"* This is only valid for a together group. It means that both options must be specified together.

Change the command group of the procedure using the **-command_group** command. Protect the contents of the procedure from being viewed by using **-hide_body**. Prevent further modifications to the procedure by using **-permanent**. Prevent abbreviation of the procedure by using **-dont_abbrev**.

EXAMPLES

The following procedure adds two numbers together and returns the sum. For demonstration purposes, unused arguments are defined.

```
prompt> proc plus {a b} { return [expr $a + $b]}

prompt> define_proc_attributes plus -info "Add two numbers" \
? -define_args {
  {a "first addend" a string required}
  {b "second addend" b string required}
  {"-verbose" "issue a message" "" boolean optional}}

prompt> help -verbose plus
Usage: plus    # Add two numbers
   [-verbose]       (issue a message)
   a              (first addend)
   b              (second addend)

prompt> plus 5 6
11
```

In the following example, the argHandler procedure accepts an optional argument of each type supported by **define_proc_attributes**, then displays the options and values received. Note the only one of -Int, -Float, or -Bool may be specified to the command:

```
proc argHandler {args} {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo $argname = $results($argname)
  }
}

define_proc_attributes argHandler \
  -info "Arguments processor" \
  -define_args {
    {-Oos "oos help"      AnOos   one_of_string
      {required value_help {values {a b}}}}
    {-Int "int help"      AnInt   int     optional}
    {-Float "float help"  AFloat  float   optional}
```

```
    {-Bool "bool help"     ""      boolean optional}
    {-String "string help" AString string  optional}
    {-List "list help"     AList   list    optional}
    {-IDup "int dup help"  AIDup   int     {optional merge_duplicates}}
  } \
  -define_arg_groups {
    {exclusive {-Int -Float -Bool}}
  }
```

define_scaling_lib_group

Associates a set of related panes to form a scaling group.

SYNTAX

string **define_scaling_lib_group**
[-name *group_name*]
[-details *detail_list*]
[-reflib *lib*]
contributing_db_libraries

Data Types

group_name	string
detail_list	list
lib	collection
contributing_db_libraries	list

ARGUMENTS

-name *group_name*

Specifies the name for the group.

By default, the command assigns a name using the following naming convention: slg<*n*>, where *n* is a unique integer.

-details *detail_list*

Displays additional information when generating the scaling groups.

Valid values are

- **basic**

  Displays the panes that match the specified logic libraries; information about the power and ground rails, including constant and dependent rails; a summary of the unscalable objects; and detailed information about each pane, including voltage, temperature, and associated logic library.

- **unscalable_objects**

  Displays the panes that match the specified logic libraries; information about the power and ground rails, including constant and dependent rails; detailed and summary information about the unscalable objects; and detailed information about each pane, including voltage, temperature, and associated logic library.

- **no_unscalable_summary**

Displays the panes that match the specified logic libraries; information about the power and ground rails, including constant and dependent rails; and detailed information about each pane, including voltage, temperature, and associated logic library. No information is provided about the unscalable objects.

- **all**

  Displays the panes that match the specified logic libraries; information about the power and ground rails, including constant and dependent rails; detailed and summary information about the unscalable objects; and detailed information about each pane, including voltage, temperature, and associated logic library.

If you do not specify this option, the command reports only a summary of the unscalable objects found in the specified logic libraries.

-reflib ***lib***

Specifies the reference library in which to search for panes.

By default, the command searches all reference libraries.

contributing_db_libraries

Specifies the logic libraries used to find the panes to group. Note that a logic library (pane) can be a part of multiple overlapping scaling groups.

This is a required option.

DESCRIPTION

The **define_scaling_lib_group** command uses the specified logic libraries to try to build a scaling group that allows interpolation in the voltage and temperature dimensions.

The command searches the reference libraries in memory for panes that match the specified logic libraries. The command assumes that the logic libraries were used to build a reference library that has been loaded into memory, and all of the logic libraries are in the same reference library.

Each logic library must be at a different characterization point and infer a single pane. Each pane must have the same process label and process number. Each reference library must have matching values for the nine library threshold values. The reference libraries must also cover all of the needed PVTs to form a full grid. For example, if you have two values for rail1, two for rail2, and two for temperature, then either contributing logic libraries are needed. If these requirements are not met, the command cannot create the group.

Given a set of panes that meet the basic requirements, determination of a valid group starts with rails and temperature. A *constant* rail or temperature (where the value is the same across all panes) is eliminated from contention. In the case of *dependent* rails, where rail1=rail2 in each of the contributing panes, one of the two is eliminated. For as many dimensions (rails or temperature) that remain, the required PVT values are listed, and then the command verifies that each required PVT is present.

The final step of creating a group is to verify which objects are scalable and which are not. To be scalable, the object must exist in every contributing pane, and each table must be a function of the same variables. Unscalable objects are not a problem. When doing a calculation, in these cases, the application falls back to the nearest matching pane.

A successful scaling group is represented as a new pane, which can be seen with the **report_lib** command. These panes are added at the end for a good reason. If your corner specification is an exact match for a basic pane in the reference library, the application uses the simpler pane that requires a single interpolation in the basic table variables rather than multiple interpolations.

A scaling group is not particularly expensive to create. In terms of memory, the cost is about a byte per object. For example, to create a scaling group for a large library with a few thousand cells, tens of thousands of arcs, dynamic power records, and so on might cost

about 10MB. The most expensive part of creating the group is looking for unscalable objects. That might take a minute or two for a large library.

EXAMPLES

In the following example, a group is successfully created.

```
prompt> set dbs \
  {wc_v0p99_t0.db wc_v0p99_t-40.db wc_v0p81_t-40.db wc_v0p81_t0}
prompt> define_scaling_lib_group $dbs -details basic -name G1
 ...'wc_v0p99_t0.db' matched pane 0 in lib WC
 ...'wc_v0p99_t-40.db' matched pane 2 in lib WC
 ...'wc_v0p81_t-40.db' matched pane 3 in lib WC
 ...'wc_v0p81_t0.db' matched pane 1 in lib WC

 ...Rail 1 -  power (vdd)
 ...Rail 2 -  pwell (gnds)
 ...Rail 3 -  nwell (vdds)

* Removing constant rail 'gnds' from consideration
* Rails vdd/vdds are dependent, removing vdds from consideration
Information: For rail 'vdd', found values: 0.81, 0.99 (SLG-024)
Information: For temperature, found values: -40, 0 (SLG-024)

 ... checking for missing objects and incompatible tables...

Reference lib: WC
 pane 0: vdd=0.99; t=0    ; file wc_v0p99_t0.db
 pane 1: vdd=0.81; t=0    ; file wc_v0p81_t0.db
 pane 2: vdd=0.99; t=-40  ; file wc_v0p99_t-40.db
 pane 3: vdd=0.81; t=-40  ; file wc_v0p81_t-40.db

 ...created scaling lib group G1
G1
```

In the following example, the specified logic libraries do not form a complete grid, so the scaling group cannot be created.

```
prompt> set dbs {wc_v0p99_t0.db wc_v0p99_t-40.db wc_v0p81_t-40.db}
prompt> define_scaling_lib_group $dbs -details basic -name G2
 ...'wc_v0p99_t0.db' matched pane 0 in lib WC
 ...'wc_v0p99_t-40.db' matched pane 2 in lib WC
 ...'wc_v0p81_t-40.db' matched pane 3 in lib WC

 ...Rail 1 -  power (vdd)
 ...Rail 2 -  pwell (gnds)
 ...Rail 3 -  nwell (vdds)

* Removing constant rail 'gnds' from consideration
* Rails vdd/vdds are dependent, removing vdds from consideration
Information: For rail 'vdd', found values: 0.81, 0.99 (SLG-024)
Information: For temperature, found values: -40, 0 (SLG-024)
Error: Missing characterization point: vdd=0.81 temp=0 (SLG-023)
```

SEE ALSO

report_lib(2)

define_test_mode

Defines a test mode to be created during DFT synthesis.

SYNTAX

status **define_test_mode**
mode_name
-usage *mode_purpose*
[-encoding {*port_name* 0 | 1, ...}]
[-target *core_mode_pair_list*]
[-transparent_mode_of *parent_mode_name*]

Data Types

mode_name string
mode_purpose string
port_name string
core_mode_pair_list list
parent_mode_name string

ARGUMENTS

mode_name

Specifies a user-defined text string containing only alphanumeric characters (a-z, A-Z, 0-9) and the underscore (_).

-usage *mode_purpose*

Specifies the mode type for a test mode. The supported mode types are **scan_compression**, **scan**, **wrp_if**, **wrp_of**, **wrp_safe**, and **logicbist**.

- **scan** is the basic scan mode operation. The scan chains are driven directly by top-level scan-in ports and they in turn drive top-level scan-out ports. This mode is used for testing all logic internal to the core.
- **scan_compression** is the DFTMAX compressed scan mode of operation. In this mode, the compressed scan chains are driven by the load compressors and the scan chains drive the unload compressors. This mode is used for testing all logic internal to the core.

  For backward compatibility, you can also use this usage to define DFTMAX Ultra compression modes if the design does not also contain DFTMAX compression modes.
- **streaming_compression** is the DFTMAX Ultra compressed scan mode of operation. In this mode, the compressed scan chains are driven by the streaming load compressors and the scan chains drive the streaming unload compressors. This mode is used for testing all logic internal to the core.
- **wrp_if** is the inward facing, or **INTEST** mode of wrapper operation. This mode is used for testing all logic internal to the core.

In this mode, wrappers are enabled and configured to drive and capture data within the design in conjunction with the internal scan chains.

- **wrp_of** is the outward facing, or **EXTEST** mode of wrapper operation. This mode is used for testing all logic external to the design. Wrappers are enabled and configured to drive and capture data outside of the design. In this mode the internal chains are disabled.
- **wrp_safe** is the safe wrapper mode. In this mode the internal chains are disabled and the internal core is protected from toggle activity. This mode is optional and provides isolation of the core while other cores are being tested. When active, safe mode enables driving steady states into or out of the design.
- **logicbist** is the LogicBIST self-test compression mode, which implements a digital logic built-in self-test capability. In this mode, the compressed scan chains are driven by a pseudo-random pattern generator for a fixed number of patterns. A multiple-input signature register (MISR) captures the resulting scan data, then compares it against an expected signature value to generate a PASS/FAIL result.

-encoding {*port_name* 0 | 1, ...}

Specifies a list of ports and the binary values that select a particular test mode. The encoding argument consists of a port name and a binary value pair that specify the test-mode port and the bit values to be used in a particular test mode. The encoding port pairs for a test mode must contain all pairs to be used in the design. See the EXAMPLES section for more information.

Before a port can be used for a test-mode port, it must be defined as a test-mode port using the **set_dft_signal** command:

set_dft_signal -type TestMode

-target *core_mode_pairs*

Specifies test-mode assignments to use for DFT-inserted cores.

This option overrides the default test-mode assignment for DFT-inserted cores. Specify a list of core and test-mode pairs to use for the top-level test mode being defined; each pair consists of a core instance name and a core test-mode name separated by a colon (:). For designs with scan compression, you can also include the name of the current design, without a colon or test-mode name, to specify that the top-level logic should be active and tested.

If a core is targeted in some test modes but not others, it is inactive in the test modes where it is not targeted. This is known as sparse targeting. (To completely exclude a core from all top-level test modes, use the **-exclude_elements** option of the **set_scan_configuration command**.)

Untargeted cores (not included in any target list across all test modes) are tested in top-level modes where the top-level logic is tested.

-transparent_mode_of *parent_mode_name*

Specifies the parent mode for the transparent test mode being defined.

A transparent mode is derived from an inward-facing parent test mode of a core-wrapped design. It is identical to its parent mode, except that

- Wrapper chains are treated as regular scan chains.
- Dedicated wrapper cells are logically transparent, although their flip-flops remain in the wrapper chains and act as observe test points on I/O paths.
- Any scan compression codecs from the referenced inward-facing mode are reused.
- Feedthrough chains drive the outward-facing wrapper scan I/Os in transparent mode.

A transparent mode allows a core-wrapped design to be tested top-down flat from a higher hierarchy level.

A transparent mode inherits all DFT configuration information from its parent mode. Do not apply any other DFT configuration

commands specifically to a transparent test mode; they are ignored. Do not specify a base mode for a transparent compressed scan mode.

DESCRIPTION

The **define_test_mode** command allows you to define a test mode for DFT synthesis. Inference for existing scan multimode designs is not supported at this time.

The information associated with a *spec* mode is interpreted as a specification of a test mode to be synthesized. This information is used during the DFT architect and insertion process. The specification information for a mode consists of protocols, port attributes, and the configuration information specific to the DFT to be inserted.

Perform multimode specifications in the following order:

1. Define TestMode signals with **set_dft_signal -test_mode all**.
2. Define all test modes, their usage, and their encoding with **define_test_mode**.
3. Define clocks, asynchronous signals, and constants common to all test modes with **set_dft_signal -test_mode all**.
4. Define mode-specific signals with **set_dft_signal -test_mode test_mode_name**.
5. Specify scan paths to be used in all test modes with **set_scan_path -test_mode all**.
6. Specify scan paths to be used in specific test modes with **set_scan_path -test_mode test_mode_name**.

Note that when the **define_test_mode** command is used, it will set the current_test_mode. Then if any of the commands listed below are used without the **-test_mode** option, the spec will not be applied to all test modes. Instead, the spec will be applied only to the mode that was last defined with **define_test_mode**. The affected commands are

set_scan_configuration

set_scan_path

set_dft_signal

set_scan_compression_configuration

set_logicbist_compression_configuration

Be sure to use the **-test_mode** option with all of these commands once the **define_test_mode command has been issued. If the spec is to be applied to all modes use -test_mode all. If the spec is to be applied to a specific test mode, use -test_mode test_mode_name.**

EXAMPLES

The following example defines three test modes in a DFTMAX compressed scan flow. The modes are ScanCompression_mode, Internal_scan1, and Internal_scan2. The encoding values are also specified.

```
prompt> set_dft_signal -view spec -type TestMode \
    -port [list i_trdy_de i_trdy_dd i_cs]
```

```
prompt> define_test_mode ScanCompression_mode \
    -usage scan_compression \
    -encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1}

prompt> define_test_mode Internal_scan1 -usage scan \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0}

prompt> define_test_mode Internal_scan2 -usage scan \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1}
```

The following example defines 9 wrapper modes:

```
prompt> set_dft_signal -view spec -type TestMode \
    -port [list i_trdy_de i_trdy_dd i_cs]

prompt> define_test_mode burn_in -usage scan  \
    -encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 0 i_wr 1}

prompt> define_test_mode domain -usage scan \
    encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1 i_wr 0}

prompt> define_test_mode my_wrp_if -usage wrp_if \
    encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1 i_wr 1}

prompt> define_test_mode my_wrp_if_delay -usage wrp_if \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0 i_wr 0}

prompt> define_test_mode my_wrp_if_scl_delay -usage wrp_if \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0 i_wr 1}

prompt> define_test_mode my_wrp_of -usage wrp_of \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1 i_wr 0}

prompt> define_test_mode my_wrp_of_delay -usage wrp_of \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1 i_wr 1}

prompt> define_test_mode my_wrp_of_scl_delay -usage wrp_of \

define_user_attribute

Defines a new user-defined attribute.

SYNTAX

status **define_user_attribute**
-type string | int | float | double | boolean
-classes *class_list*
[-range_min *min*]
[-range_max *max*]
[-one_of *values*]
[-non_persistent]
[-quiet]
-name *attribute_name*
pos_attribute_name

Data Types

class_list list
min double
max double
values list
attribute_name string
pos_attribute_name string

ARGUMENTS

-type string | int | float | double | boolean

Specifies the data type of the attribute.

-classes *class_list*

Specifies the classes to which the new user-defined attribute applies. To see the valid classes, use the following command:

define_user_attribute -help

-range_min *min*

Specifies the minimum value for numeric ranges. If you specify a minimum constraint without a maximum constraint, the tool creates an attribute that accepts a value greater than or equal to *min*.

This option is valid only when the data type of the attribute is int, float, or double.

-range_max *max*

Specifies the maximum value for numeric ranges. If you specify a maximum constraint without a minimum constraint, the tool creates an attribute that accepts a value less than or equal to *max*.

This option is valid only when the data type of the attribute is int, float, or double.

-one_of *values*

Specifies a list of allowable strings.

This option is valid only when the data type of the attribute is string.

-non_persistent

Specifies that the attribute is not saved in the design library, and therefore is not persistent.

By default, user-defined attributes are saved in the design library.

-quiet

Disables warning messages that would otherwise be issued if the attribute or classes are incorrect.

-name *attribute_name*

Specifies the name of the attribute.

This option is mutually exclusive with the *pos_attribute_name* argument. You must specify either this option or the *pos_attribute_name* argument.

pos_attribute_name

Specifies the name of the attribute.

This argument is provided for compatibility with other tools. It is mutually exclusive with the **-name** option. You must specify either this option or the **-name** option.

DESCRIPTION

The **define_user_attribute** command defines a new attribute.

By default, the definition for a user-defined attribute is saved in the design library and is persistent. To make a user-defined attribute non-persistent, use the **-non_persistent** option.

To list the user-defined attributes, use the **list_attributes** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines an attribute named attr_1 that has a data type of double with a minimum value of 2 and a maximum value of 3.2 and can be set on cells or nets.

```
prompt> define_user_attribute -classes {cell net} -type double \
```

```
  -range_max 3.2 -range_min 2 -name attr_1
1
```

The following example defines an attribute named attr_2 that has a data type of string with valid values of true or false and can be set on nets.

```
prompt> define_user_attribute -classes net -type string \
  -one_of {true false} -name attr_2
1
```

The following example shows how to list the attribute definitions using the **list_attributes** command:

```
prompt> list_attributes
****************************************
Report : List of Attribute Definitions
Version:
Date   : Thu Jul 14 14:16:40 2011
****************************************

Properties:
   A - Application-defined
   U - User-defined
   I - Importable from design/library (for user-defined)
   S - Settable
   B - Subscripted

Attribute Name   Object   Type    Properties  Constraints
-------------------------------------------------------------
attr_1          cell    double   U          2 to 3.2
attr_1          net     double   U          2 to 3.2
attr_2          net     string   U          true, false
```

derive_3d_interface

Creates a derived set of bump cell, TSV (Through-Silicon Via), or bond pad objects based on an existing set of bump cell, TSV, or bond pad objects. This command maintains a one-to-one correspondence between the from_object and the derived_object, while honoring user-specified x_offset and y_offset for placement of the derived object.

SYNTAX

int **derive_3d_interface**
-from *from_object_collection*
-to_object_ref *to_object_collection*
[-x_offset *x_offset*]
[-y_offset *y_offset*]
[-coord_spec {[bl|br|tl|tr|c] [bl|br|tl|tr|c]}]
[-connect true | false]
[-name_prefix *name_prefix*]
[-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90]
[-bond_pad_width *bond_pad_width*]
[-bond_pad_height *bond_pad_height*]

Data Types

from_object_collection collection
to_object_collection collection
x_offset float
y_offset float
name_prefix string
bond_pad_width float
bond_pad_height float

ARGUMENTS

-from *from_object_collection*

Specifies the collection of from_objects which are used to derive the new objects to be created. The collection can contain any one of the following three type of objects:

a) Collection of bump cell instances, or

b) Collection of TSV cell instances, or

c) Collection of bond pad terminal objects The collection must contain at least one object. This is a required option.

-to_object_ref *to_object_collection*

Specifies a collection of exactly one object which is used as a reference object for creating the derived object. The collection also

indicates the type of object that is derived.

a) If TSVs are to be derived, the collection object is a via def object

b) If bump cells are to be derived, the collection object is a lib_cell object

c) If bond pad objects are to be derived, the collection object is a layer object This is a required option.

-x_offset *x_offset*

Specifies the horizontal spacing from each from_object to the corresponding derived object. A negative value indicates the placement of derived_object is to the left of the from_object. Unit for this specification is micron. If not specified, the default value of 0.0 micron is used.

-y_offset *y_offset*

Specifies the vertical spacing from each from_object to the corresponding derived object. A negative value indicates the placement of derived_object is to the bottom of from_object. Unit for this specification is micron. If not specified, default value of 0.0 micron is used.

-coord_spec {bl|br|tl|tr|c bl|br|tl|tr|c}

Specifies the corner or center of the from_object which is matched against the corner or center of the derived object for applying the x_offset and y_offset specification. The specified value is a list of exactly two keywords, which must be one of the following:

a) bl - indicates the bottom-left corner of the from_object or derived_object

b) br - indicates the bottom-right corner of the from_object or derived_object

c) tl - indicates the top-left corner of the from_object or derived_object

d) tr - indicates the top-right corner of the from_object or derived_object

e) c - indicates the center of the from_object or derived_object

The first keyword is used for the from_object, and second keyword is used for the derived object. This is an optional argument. If not specified, a default value of "{c c}" is assumed.

-connect true | **false**

Specifies whether the derived object is to be connected to its corresponding from_object. This is an optional argument. If not specified, a default value of true is assumed. If from_object is connected to an existing net, it uses the same net to connect to the derived object. Otherwise, it creates a new net and connects both from_object and derived_object to this net. The newly created net is named "<from_object_name>_net". If a net with this name already exists, the command adds a unique suffix to generate a unique net name.

-name_prefix *name_prefix*

Specifies the prefix to be used for naming derived objects. This is an optional argument. If not specified, the command uses the following specification for determining the name prefix.

a) default_tsv_array<uniqueId>_<viadef> for derived TSVs

b) default_bondpad_array<uniqueId>_<layer_name> for derived Bond Pads

c) default_bump_array_<uniqueId> for derived Bumps

The full name of derived object depends on how the from_objects are named. If all from_objects have names of the form: "<from_prefix>_index1_index2", then the derived objects are named "<name_prefix>_index1_index2". Otherwise, derived objects are named "<name_prefix>_<from_object_name>".

-orientation R0 | **R90** | **R180** | **R270** | **MY** | **MXR90** | **MX** | **MYR90**

Specifies the orientation of the derived objects to be created. If this option is not specified, the default orientation is R0.

-bond_pad_width *bond_pad_width*

Specifies the width of Bond Pad shape created on specified bond pad layer. If the "-to_object_ref" argument specifies a bond pad layer name, this argument is mandatory, and it must specify a positive value for derived bond pad shape width. The value is specified in microns. If the derived object is not of bond pad type, this argument is ignored.

-bond_pad_height *bond_pad_height*

Specifies the height of bond pad shape created on a specified bond pad layer. If the "-to_object_ref" argument specifies a bond pad layer name, this argument is mandatory, and it must specify a positive value for derived bond pad shape height. Value is specified in microns. If derived object is not of bond pad type, this argument is ignored.

DESCRIPTION

This command creates a set of derived bump cell, TSV, bond pad objects based on an existing set of bump cell, TSV, or bond pad objects. The command maintains a one-to-one correspondence between the from_object and the derived_object, while honoring user-specified x_offset and y_offset for placement of the derived object.

EXAMPLES

The following example creates a set of TSV objects based on existing bump cell objects.

```
set bumpcell_coll   [get_cells bump_array_name*]
set tsv_viadef_coll [get_via_defs -tech [get_techs *] VIAB1]
derive_3d_interface -from $bumpcell_coll -to_object_ref $tsv_viadef_coll  \
  -x_offset 10.0 -y_offset -10.0 -coord_spec {br tl}
```

The following example creates a set of bond pad objects based on existing TSV objects. The center of the bond pad is aligned with the center of corresponding TSV instance.

```
set tsvcell_coll      [get_cells THROUGH* -within { {8999 1999} {10000 3000} }]
set bondpad_layer_coll [get_layers AP]
derive_3d_interface -from $tsvcell_coll -to_object_ref $bondpad_layer_coll \
  -bond_pad_width 0.8 -bond_pad_height 0.5
```

The following example creates a set of bump cell objects based on existing Bond pad objects. In this example, the bump cell instances are not connected to the corresponding Bond pad terminals.

```
set bond_pad_coll     [get_terminals bond_pad_AP_0_*]
set bump_lib_cell_coll [get_lib_cells */BUMP]
derive_3d_interface -from $bond_pad_coll -to_object_ref $bump_lib_cell_coll \
  -x_offset 10.0 -name_prefix xyzPAD22 -connect false
```

SEE ALSO

create_bump_array(2)
create_bond_pad_array(2)

derive_cell_snap_data

Constructs data used for snapping multi height standard cells.

SYNTAX

status **derive_cell_snap_data**
[-force]

ARGUMENTS

-force

Forces the cell snapping data to rebuild, even if the data is already constructed. If this option is not specified the command will not rebuild existing snapping data.

DESCRIPTION

The **derive_cell_snap_data** command derives a snapping data used to snap standard cells to placement sites when assigned site definitions does not match the cell size.

EXAMPLES

The following command derives data used for snapping cells into placement sites.

prompt> **derive_cell_snap_data**

derive_clock_balance_constraints

Generate clock balance groups based on cross clock timing relations.

SYNTAX

string **derive_clock_balance_constraints**
[-slack_less_than]

ARGUMENTS

-slack_less_than

Specify the threshold for interclock timing slack to consider.

DESCRIPTION

This command collects a set of clocks which have timing slack smaller than the threshold

Multicorner-Multimode Support

EXAMPLES

prompt> **derive_clock_balance_constraints -slack_less_than 0.1**

SEE ALSO

create_clock_balance_group(2)

remove_clock_balance_groups(2)
balance_clock_groups(2)

derive_clock_balance_points

Derive set_clock_balance_points constraints at the clock sinks from ideal SDC clock latencies. The clock balance point constraints will instruct CTS to maintain the clock arrival time differences between pairs of sinks when switching from ideal to propagated clocks.

SYNTAX

status **derive_clock_balance_points**
[-clocks *clock_list]*
[-corners *corner_list*]
[-reference_latency *latency*]
[-output *file*]

Data Types

clock_list collection
corner_list collection
latency float
file string

ARGUMENTS

-clocks *clock_list*

Balance point constraints will be generated for the sinks of these clocks. If this options is not specified, balance points will be created for all ideal primary clocks of all active scenarios that have hold and/or setup analysis enabled.

-corners *corner_list*

Only generate balance point constraints for these corners. Only scenarios with the clock's mode and one of the specified corners will be considered.

-reference_latency *latency*

Balance point constraints will reflect the difference between ideal clock latencies at sinks and this reference latency at the sinks.

-output *file*

Instead of applying the clock balance points to the design, write the balance point constraints to the named file. The balance points are written out in Tcl format. This allows for inspection and modification of the balance points.

DESCRIPTION

The **derive_clock_balance_points** command will create *set_clock_balance_point* constraints based on the ideal latencies as specified by the SDC *set_clock_latency* command. The clocks to be processed should be primary clocks in ideal mode. Generated clocks or clocks that are in propagated mode are not supported. The command will convert the ideal pre-CTS latency modeling of the clock sinks to CTS goals. The command uses a reference latency per clock. The default reference latency is the sum of the source- and network-latency as specified for the clock. The source- and network latency can be specified using SDC's *set_clock_latency* on the clock objects. In order to derive the balance point delay value, the ideal mode total clock latency at a sink is subtracted from the reference latency. The result of the subtraction is applied as the *-delay* value of *set_clock_balance_point*. Each created set_clock_balance_point constraint is clock- and corner-specific. If the resulting delay value is 0.0, then the balance point constraint will only be created if there is already an existing balance point constraint active for that (pin,clock,corner). Note that the existing balance point constraint may be clock-independent or corner-independent. A user-specified reference latency will override the default reference latency.

In a standard situation where only set_clock_latency assertions are defined at the clock objects, the default reference latency will match the ideal total latency at all sinks. In that case, all -delay values will be 0.0. As a consequence, no balance point constraints will be generated. If a selected number of sinks have a total ideal latency that differs from the reference latency, then only for those sinks clock balance point constraints will be generated.

Multicorner-Multimode Support

EXAMPLES

The following example creates two balance point constraints.

```
prompt> set_clock_latency -source 0.5 [get_clock clk]
prompt> set_clock_latency 1.0 [get_clock clk]
prompt> set_clock_latency 1.5 [get_pin reg1/CK]
prompt> set_clock_latency 0.5 [get_pin reg2/CK]
prompt> derive_clock_balance_points -clocks [get_clock clk]
```

Created balance points:

```
set_clock_balance_point -delay -0.5 -corner default -balance_points \
        [get_pin reg1/CK] -clock clk
set_clock_balance_point -delay 0.5 -corner default -balance_points \
        [get_pin reg2/CK] -clock clk
```

The following example uses 0.0 as the reference latency.

```
prompt> set_clock_latency -source 0.5 [get_clock clk]
prompt> set_clock_latency 1.0 [get_clock clk]
prompt> set_clock_latency 1.5 [get_pin reg1/CK]
prompt> set_clock_latency 0.5 [get_pin reg2/CK]
prompt> derive_clock_balance_points -clocks [get_clock clk] \
    -reference_latency 0.0
```

Created balance points:

```
set_clock_balance_point -delay -2.0 -corner default -balance_points \
        [get_pin reg1/CK] -clock clk
set_clock_balance_point -delay -1.0 -corner default -balance_points \
        [get_pin reg2/CK] -clock clk
set_clock_balance_point -delay -1.5 -corner default -balance_points \
        <all_sinks_except_reg1_and_reg2> -clock clk
```

SEE ALSO

derive_clock_cell_references

Generate a list of LEQ references for the clock gates and ICGs in the design and make it available for CTS.

SYNTAX

string **derive_clock_cell_references**
[-output *filename*]

Data Types

filename string

ARGUMENTS

-output *filename*

Writes the list of LEQ references for clock gates and ICGs in the output file provided.

DESCRIPTION

The command identifies the clock gates and ICGs in the design. This does not include buffers or inverters in the design. It identifies the logically equivalent references for these cells. These references are then made available to CTS for usage.

Before running the **derive_clock_cell_references** command, if references have been excluded for CTS usage these will not be considered by **derive_clock_cell_references**. Exclusion could have been made either by marking references as 'dont_use' during library preparation or by marking dont_touch on these references or by calling **set_lib_cell_purpose -exclude cts** for the concerned references.

When output option is used, the settings will be written to specified file instead of applying to the design. The file will also list of references which are disabled due to dont_touch, dont_use or user driven exclude in the comments format. You can then review this script and source it to provide the clock tree references required for the CTS engine. Generated output file will contain following sections:

- References enabled for CTS: Logical equivalent references of clock gates and ICG of current design which does not have dont_touch, dont_use or user exclude(include_purpose doesn't have CTS) for CTS."

Following options will be in comment format. User can review the tcl file and enable by uncommenting command for enabling library cell if required:

- References already available for CTS: Library cells which are already available for CTS either by user setting or library setting.

- Dont touch references: Library cell with dont_touch attribute
- Dont use references: Library cell with dont_use attribute
- User driven exclude references: User has explicitly excluded this lib cell for CTS purpose

EXAMPLES

The following example shows that all the lib_cells other than 'and02d8' and 'and02d16' are made available for CTS.

```
prompt> set_lib_cell_purpose -exclude cts [get_lib_cells {tech_lib/and02d8 tech_lib/and02d16}]
prompt> derive_clock_cell_references
```

The following example shows how user can control the references enabled for CTS as a part of **derive_clock_cell_references** command.

```
prompt> derive_clock_cell_references -output cts_leq_set.tcl
```

SEE ALSO

set_lib_cell_purpose(2)

derive_hier_antenna_property

Derives the hierarchical antenna properties of all the top-level ports in the specified cell. You should use this command for designs routed with router.

SYNTAX

status **derive_hier_antenna_property**
-design_name *design_name*

Data Types

design_name string

ARGUMENTS

-design_name *design_name*

Specifies the design name from which to derive antenna properties.

DESCRIPTION

This command derives the hierarchical antenna properties of all the top-level ports in the given design. It is recommended that you use this command for designs routed with router. The hierarchical antenna properties include gate size, routing area, and diode protection.

This command should be run within the child cell of each macro and saved. When antenna analysis is done at the top level, the properties that were previously set can be seen in each macro pin. When nets connecting to macro pins are analyzed, the antenna information from each macro pin is used for analyzing that pin. This eliminates repetitive calculation of antenna properties of each macro or flattening the design.

The hierarchical antenna properties are calculated based on the following information:

- Routing contained in the DESIGN view of the top-level cell.
- The hierarchical antenna properties of the design
- The gate sizes and the diode protection for each port of the library cells.

The hierarchical antenna properties are stored in the FRAME view of the cell. Both the DESIGN and FRAME views must exist before you execute this command.

Perquisites

The design library must be opened first.

Both the DESIGN view and the FRAME view of the cell must exist and be writable before the command is run.

The antenna properties of all port instances in the cell must be properly set. Otherwise, the antenna property calculated will not be accurate. The antenna properties can be set by:

- Running the **derive_hier_antenna_property** command on child cells, if the child cell is routed by router.
- Set the gate size and diode protection value of each port, if the child cell is a standard cell.

Limitations

The **derive_hier_antenna_property** command does not work on standard library cells or hard macros because the tool does not read the diffusion layer in the layout. The results might not be accurate if hard macros exist in the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the use of the command on a cell instance named my_cell.

```
prompt> derive_hier_antenna_property -design_name my_design
```

derive_macro_relative_location

Derives a set of relative location constraints for hard macros and writes out **set_macro_relative_location** commands to describe the constraints.

SYNTAX

status **derive_macro_relative_location**
[-cells *macro_list*]
[-offset_type { auto|fixed|scalable auto|fixed|scalable }]
[-anchor_corner bl | tl | tr | br | *corner_index*]
[-anchor_object *anchor_object*]
[-use_bbox]
[-cluster_spacing *xy_distance* | {*x_distance y_distance*}]
[-hierarchical]
[-output_file *file_name*]

Data Types

macro_list list
corner_index integer
anchor_object core_area, move_bound, voltage_area, voltage_area_shape
xy_distance float
x_distance float
y_distance float
file_name string

ARGUMENTS

-cells *macro_list*

Specifies the macros for which to derive relative location constraints. If not specified, the command derives constraints for all macros which are not marked physical-only in a hierarchical design when you specify the **-hierarchical** option. If want physical-only macros to be included as well then use -cells option to pass the macro cell list to the command.

-offset_type { auto|fixed|scalable auto|fixed|scalable }

Specifies the preference for the offset type when writing out the location constraints. Valid offset type values are: auto, fixed and scalable as follows:

- fixed: Command writes out offsets as absolute values.
- scalable: Command writes out offset values as ratios between the absolute offset values and the corresponding dimensions of the block/core_area/move_bound/voltage_area_shape's size.

- auto: Command automatically determines the offset type: fixed or scalable. This is the default.

The constraints happen in one macro cluster (For macro1 anchor to macro2, if macro1+its_keepout_margin+finfet/litho_grid_pitch touches macro2+its_keepout_margin+finfet/litho_grid_pitch, the two macros are one macro cluster) are fixed type. The constraints happen in one macro array are fixed type. For macro anchor to block/core_area corner, if macro+its_keepout_margin+finfet/litho_grid_pitch touches the block_corner-its_inner_keepout_margin/core_area_corner, the constraint's offset type is fixed. Option -cluster_spacing is used to control/set the user specified macro spacing. The hard/hard_macro/placement_blockage keepout margin and block's inner keepout margin are considered. The offset type can be specified separately on X and Y dimension.

-anchor_corner bl | tl | tr | br | *corner_index*

Restricts the eventual anchor corner on the block of all specified macros. Valid values for this option are: bl, tl, tr, br, or a positive integer no larger than the total corner count of the current design block. The corner index of a block starts from 1, corresponding to the bottom leftmost corner, and increases in the clockwise direction proceeding around the macro. If **-anchor_corner** is one of bl, tl, tr or br, the command derives constraints based on the bounding box of the current block, as if **-use_bbox** option were specified.

-anchor_object *anchor_object*

Specifies the core_area/move_bound/voltage_area/voltage_area_shape as the eventual anchor object for all specified or derived macros in it to anchor on. For move_bounds and voltage_areas, the first shape is used. If this option is not specified, the default anchor object is the hard macros' parent block.

-use_bbox

Specifies that the command uses the bounding box instead of the rectilinear boundary of the shape when deriving location constraints. If not specified, the command derives constraints based on the rectilinear boundary of the block.

-cluster_spacing

This option is used to control the macro cluster. For macro1 anchor to macro2, if macro1+its_keepout_margin+cluster_spacing touches macro2+its_keepout_margin+cluster_spacing, the two macros are in one macro cluster, and the constraint between these two macros is fixed offset type. For macro anchor to block/core_area corner, if macro+its_keepout_margin+cluster_spacing touches the block_corner-its_inner_keepout_margin/core_area_corner, the constraint's offset type is fixed. Default cluster_spacing value is finfet/litho_grid_pitch.

-hierarchical

The command derives constraints for all hard macros in hierarchical design with this option.

-output_file *file_name*

Specifies the output file name in which to write the constraints. By default, relative locations are written to the console and not saved to a file.

DESCRIPTION

This command prints out macro relative location constraints as a set of **set_macro_relative_location** commands. You can limit the output to only a specified set of macros with the **-cells** option, otherwise by default the tool writes out macro relative location constraints for all macros which are not marked as physical-only in hierarchical design with the **-hierarchical** option. If want physical-only macros to be included as well then use -cells option to pass the macro cell list to the command.

EXAMPLES

The following example writes out relative location constraints for all hard macros in the hierarchical design to the console.

```
prompt> derive_macro_relative_location -hierarchical
set_macro_relative_location -target_object [get_cells cmem0/ddata0_0/x0_t0]
 -target_orientation MX -target_corner bl -anchor_object [get_cells cmem0/idata0_1/x0_t0]
 -anchor_corner tr -offset {0.0000 10.7200}
[ more set_macro_relative_location commands printed to console ]
Derived relative location constraints for 38 macros.
1
```

The following example writes out the relative location constraints only for hard macros U1 and U2 in the current design and save results to **relative_locations.out**.

```
prompt> set macros {U1 U2}
prompt> derive_macro_relative_location -cells [get_cells $macros] \
  -output_file relative_locations.out
Derived relative location constraints for 2 macros.
1
```

derive_mask_constraint

Derives mask constraint for a specified shapes and vias from underlying tracks.

SYNTAX

status **derive_mask_constraint**
[*object_list*]
[-derive_cut_mask]
[-follow_pin_mask]
[-follow_wider_object_mask]
[-verbose]

Data Types

object_list collection

ARGUMENTS

object_list

Specifies the collection or selection set containing objects to derive mask constraint. If this option is not specified, the global selection set is used.

-derive_cut_mask

Specified if cut mask constraints should be derived. By default, the command only derives mask constraints for shapes and via enclosures.

-follow_pin_mask

Specified if shape mask constraints should be derived from overlapping/touching pins or ports. By default the shape mask is derived from track only. This option works only for shapes and via enclosures, via cuts are not affected.

-follow_wider_object_mask

Specified if shape mask constraints should be derived from wider overlapping/touching objects. By default the shape mask is derived from track only. This option works only for shapes and via enclosures, via cuts are not affected.

-verbose

Specified if detailed messages should be print.

DESCRIPTION

This command derives the color mask for given wires and vias from the nearest underlying tracks. In case of wide wires that occupy multiple tracks, it takes the mask color opposite to next unoccupied track. The latter is guaranteed to work only for two mask scenarios.

This command ignores the global edit setting *get_edit_setting -update_color_mask*.

EXAMPLES

The following example updates color mask of net ABC shapes.

```
prompt> change_selection [get_shapes -of_object [get_net ABC]]
prompt> derive_mask_constraint
```

The alternative syntax uses collection to specify objects.

```
prompt> derive_mask_constraint [get_shapes -of_object [get_net ABC]]
```

derive_metal_cut_routing_guides

Creates metal cut allowed and forbidden preferred grid extension routing guides. Metal cut allowed routing guides cover the area taken up by all the placable site rows reduced by the vertical and horizontal shrink factor. The vertical shrink factor is expressed as a percentage of the smallest site row height and the default is 50%. It can be set using the chipfinishing.metal_cut_allowed_vertical_shrink_factor app option. The horizontal shrink factor is expressed as a percentage of the smallest site row width. It can be set using the chipfinishing.metal_cut_allowed_horizontal_shrink_factor app option. Finally, forbidden preferred grid extension routing guides are created to cover the remaining area up to the boundary.

SYNTAX

collection **derive_metal_cut_routing_guides**
[-site_def *site_def*]
[-boundary_cells *lib_cell_names*]
[-treat_fixed_as_blockage]
[-add_metal_cut_allowed]
[-add_standard_cell_region]
[-check_only]
[-error_view *file_name*]]

Data Types

site_def string or collection
lib_cell_names collection
file_name string
percentage float

ARGUMENTS

-site *site_def*

Specifies the site definition that the shrink factors are calculated from.

-boundary_cells *lib_cell_name*

Specifies the list of boundary cells.

-treat_fixed_as_blockage

Specifies whether existing fixed cells are treated as blockage.

-add_metal_cut_allowed

Specifies to add metal cut allowed routing guide underneath standard cell placable area.

-add_standard_cell_region

Specifies to add standard cell region routing guide underneath standard cell placable area.

-check_only

The command checks route guides with this option.

-error_view

Specifies the output file name for error browser.

-standard_cell_region_vertical_shrink_factor ***percentage***

Specifies the vertical area between place-able area for route guide creation as a percentage of the unit tile. The default value is 0.5.

-standard_cell_region_horizontal_shrink_factor ***percentage***

Specifies the horizontal area between place-able area for route guide creation as a percentage of the unit tile. The default value is 0.0.

-boundary_cells ***lib_cell_name***

Specifies the list of boundary cells.

DESCRIPTION

The **derive_metal_cut_routing_guides** command enables you to create metal cut allowed and forbidden preferred grid extension routing guides.

EXAMPLES

The following example derives routing guides using the site definition unit.

prompt> **derive_metal_cut_routing_guides -site_def unit** {abc}

SEE ALSO

create_boundary_cells(2)

derive_perimeter_constraint_objects

Generate the specified perimeter constraint objects to constraint detailed routing.

SYNTAX

int **derive_perimeter_constraint_objects**
-perimeter_objects {metal_preferred | mpndrg_nonpreferred | route_blockage_preferred | route_blockage_nonpreferred}
[-layers {*layer_name*}]
[-short_metal_length {*layer_length_pair*}]
[-metal_spacing {*layer_spacing_pair*}]
[-spacing_from_boundary {*layer_spacing_pair*}]
[-pin_cutout]
[-spacing_preferred *spacing_value*]
[-width_preferred *width_value*]
[-spacing_nonpreferred *spacing_value*]
[-width_nonpreferred *width_value*]
[-stub *stub_value*]
[-spacing_cut_layer_horizontal *spacing_value*]
[-width_cut_layer_horizontal *width_value*]
[-spacing_cut_layer_vertical *spacing_value*]
[-width_cut_layer_vertical *width_value*]
[-hierarchical]
[-check_only]
[-error_view *file_name*]]

Data Types

layer_name list
layer_length_pair list
layer_spacing_pair list
spacing_value float
width_value float
stub_value list
file_name string

ARGUMENTS

-perimeter_objects {metal_preferred | mpndrg_nonpreferred | route_blockage_preferred | route_blockage_nonpreferred}

Specifies the objects to be generated along the preferred and nonpreferred perimeter edges of a block or design. More than one type of objects can be specified. This option must be provided. The route blockage and mpndrg (max pattern nonpreferred direction route guide) objects serve certain routing objectives due to process technology requirements.

-layers {*layer_name*}

Specifies the metal routing layers or via cut layers where objects should be generated. The default value is all metal routing layers or via cut layers.

-short_metal_length {*layer_length_pair*}

Specifies the length for the short metal object at the preferred routing direction perpendicular to the edge at the non-preferred direction as {{layer_name length_value} ...}

-metal_spacing {*layer_spacing_pair*}

Specifies the spacing between the metal objects perpendicular to the edge at the non-preferred routing direction as {{layer_name spacing_value} ...}

-spacing_from_boundary {*layer_spacing_pair*}

Specifies the spacing (from the edge) for the object perpendicular to the edge at the non-preferred routing direction as {{layer_name spacing_value} ...}

-pin_cutout

Specifies that when routing blockages are generated, cutout will be applied when I/O pins are present on the corresponding edge of the blockage. The cutout allows routing access to the pins. By default, no cutout is applied.

-spacing_preferred *spacing_value*

Specifies the spacing (from the edge) for the object along an edge at the preferred routing direction. The unit is micron. All layers have the same value if specified. If this option is not specified, the minimum metal spacing of the layer from the tech file will be used. When metal_preferred is specified, if this option is not specified, the created metal runs along the closest wire track of the edge while keeping the metal shape within the boundary of the design, and if this option is specified, the created metal shape will be snapped to wire track.

-width_preferred *width_value*

Specifies the width of the object along an edge at the preferred routing direction. The unit is micron. All layers have the same value if specified. If this option is not specified, the default metal width of the layer from the tech file will be used.

-spacing_nonpreferred *spacing_value*

Specifies the spacing (from the edge) for the object along an edge at the non-preferred routing direction. The unit is micron. All layers have the same value if specified. If this option is not specified, the minimum metal spacing of the layer from the tech file will be used.

-width_nonpreferred *width_value*

Specifies the width of the object along an edge at the non-preferred routing direction. The unit is micron. All layers have the same value if specified. If this option is not specified, the default metal width of the layer from the tech file will be used.

-stub {*stub_value*}

Specifies the offset (from the center), starting position (from the edge), the length, and the spacing between adjacent stubs for metal stubs at the preferred routing direction as {offset_value start_value length_value spacing_value}. The unit is micron. All layers have the same values if specified. The created metal stubs run along the edge while keeping the preferred spacing. If this option is not specified, the metal rectangle will be created. This option can only be specified when metal_preferred is specified.

-spacing_cut_layer_horizontal *spacing_value*

Specifies the spacing (from the edge) for the object along an edge at the horizontal direction. The unit is micron. All via cut layers have the same value if specified. If this option is not specified, the max value of spacing_preferred and spacing_nonpreferred will be used.

-width_cut_layer_horizontal *width_value*

Specifies the width of the object along an edge at the horizontal direction. The unit is micron. All via cut layers have the same value if specified. If this option is not specified, the max value of width_preferred and width_nonpreferred will be used.

-spacing_cut_layer_vertical *spacing_value*

Specifies the spacing (from the edge) for the object along an edge at the vertical direction. The unit is micron. All via cut layers have the same value if specified. If this option is not specified, the max value of spacing_preferred and spacing_nonpreferred will be used.

-width_cut_layer_vertical *width_value*

Specifies the width of the object along an edge at the vertical direction. The unit is micron. All via cut layers have the same value if specified. If this option is not specified, the max value of width_preferred and width_nonpreferred will be used.

-hierarchical

The command derives perimeter constraint objects for all soft macros in hierarchical design with this option.

-check_only

The command checks route guides with this option.

-error_view

Specifies the output file name for error browser.

DESCRIPTION

Generate the specified perimeter constraint objects to constraint detailed routing. The size and locations of the objects are specified by the Techfile by default. Command options can specify parameter values that override the Techfile.

EXAMPLES

The following example creates the perimeter constraint objects for metal_preferred and mpndrg_nonpreferred.

prompt> **derive_perimeter_constraint_objects -perimeter_objects { metal_preferred mpndrg_nonpreferred } -layers { M1 M3**

The following example creates the perimeter constraint objects for metal stubs.

prompt> **derive_perimeter_constraint_objects -perimeter_objects { metal_preferred } -layers { M1 } -width_preferred 0.2 -st**

The following example creates the perimeter constraint objects for route_blockage_preferred and route_blockage_nonpreferred.

prompt> **derive_perimeter_constraint_objects -perimeter_objects { route_blockage_nonpreferred route_blockage_preferred**

SEE ALSO

derive_boundary_routing_blockages(2)
derive_metal_cut_routing_guides(2)

derive_pin_access_route_guides(2)

derive_pg_mask_constraint

Derives mask constraint for PG shapes, vias, via matrixes and shape patterns.

SYNTAX

status **derive_pg_mask_constraint**
[-nets *netname_list*]
[-overwrite]
[-derive_cut_mask]
[-always_align_color_layers *layer_name_list*]
[-verbose]
[-ignore_std_cell]
[-color_off_track_shape]
[-check_fix_shape_drc]

Data Types

netname_list list
layer_name_list list

ARGUMENTS

-nets *netname_list*

Specifies a list of PG nets on which to derive mask constraints. If not specified, mask constraints will be derived for all PG nets.

-overwrite

Specifies that the existing mask constraints of PG objects should be removed. If specified, existing mask constraints will be erased and reassigned.

-derive_cut_mask

Specifies that cut mask constraints should be derived. By default, the command only derives mask constraints for shapes and via enclosures.

-always_align_color_layers

Specifies layers on which non-default width wires have same color as aligned routing tracks. By default, the nondefault width wires have opposite color to aligned routing tracks.

-verbose

Specifies that detailed messages should be printed.

-ignore_std_cell

Specifies that DRC checking against standard cells should be ignored for cut mask constraint assignment.

-color_off_track_shape

Specifies to derive mask of shape not aligned on track. By default assigns color mask only for shapes which center is aligned with colored track. If to be colored shape overlaps with already colored shape without a conflict, color is derived from overlapping shape rather than colored track.

-check_fix_shape_drc

Specifies to check shape DPT drc and fix by rotating mask of shape when mask is derived from track color. If flipping mask doesn't resolve drc, mask will retain its color from track. This flow is recommended to use with off-track shapes, but it will impact runtime for drc checking. By default this option is off.

DESCRIPTION

This command derives the mask constraints for PG wires, vias, via matrixes and shape patterns of specified nets. For wires and via enclosures, the mask constraint assignment follows these two rules: 1) assign same mask constraint for touching shapes if possible, and 2) assign mask constraint based on the underlying routing track mask constraint. For via cuts, the command will assign mask_one or mask_two if no DRC violation is seen. For shape patterns the limitations are: Support only "uniform type", and not "non-uniform type" shape pattern coloring; Overlap with colored shapes condition is not supported now, only shapes that are centered on tracks are supported; DRC will not be checked when color mask to shape patterns is assigned..

EXAMPLES

The following example assigns mask_constraint for VDD wires, vias, via matrixes and shape patterns.

```
prompt> derive_pg_mask_constraint -nets VDD -derive_cut_mask
```

SEE ALSO

remove_pg_mask_constraints(2)
report_pg_mask_constraints(2)
set_pg_mask_constraint(2)

derive_pin_access_routing_guides

Generates a set of routing guides and routing blockages around the specified hard macros to improve routability to their pins.

SYNTAX

status **derive_pin_access_routing_guides**
-cells *cells*
-layers *layers*
-x_width *distance*
-y_width *distance*
[-boundary_threshold *distance*]
[-pin_extension *ext_value*]
[-nonpreferred_direction]

Data Types

cells collection
layers collection
distance float
ext_value float

ARGUMENTS

-cells *cells*

Specifies the hard macros for which to create the pin access routing guides. This is a required option.

-layers *list*

Specifies the layers on which to create the pin access routing guides. This is a required option.

-x_width *distance*

Specifies the x-direction width in microns of the routing guide. This is a required option.

-y_width *distance*

Specifies the y-direction width in microns of the routing guide. This is a required option.

-boundary_threshold *distance*

Specifies a distance threshold to include an internal macro pin for processing. By default, a pin not touching an edge of the macro is excluded. If the distance of an internal macro pin is within the threshold value, it will be included. The unit is micron.

-pin_extension *ext_value*

Generate pin extension on the metal routing layers. The *ext_value* specifies the protrusion of the pin extension beyond the routing guide specified by either the **-x_width** or **-y_width** options. The unit is microns. Negative values for *ext_value* are not allowed. The width of the pin extension is the same as the width of the corresponding pin. Pin extension on the non-preferred routing direction is also generated if the **-nonpreferred_direction** option is specified. No pin extension is generated if this option is omitted. Pin extension is not generated for logically unconnected pins.

-nonpreferred_direction

Specifies that the cutout of the metal layer blockage should also be done on the nonpreferred routing direction to access the macro pins. By default only the preferred routing direction pin access are allowed.

DESCRIPTION

The **derive_pin_access_routing_guides** command creates pin access routing guides for the specified hard macros. The pin access routing guides enable the router to connect to the macro pins. It is often necessary to create pin access routing guides when reusing hard macros in a smaller technology node. Use this command after placing the macros and before routing.

This command performs the following tasks:

- Creates a pin access routing guide along the boundary of the specified macros

  The routing guide enables straight routing to the pin using preferred direction routing.

- Creates a zero-spacing metal blockage on the specified layers that forms a ring around each specified macro, including its keepout margin; the metal blockage has a cutout for each pin on the layer

  The metal blockage prevents unrelated routing near the macro, while the cutouts enable routing access to the pins.

- Creates a zero-spacing via blockage on the via layers adjacent to the specified layers that covers each macro, including its keepout margin

  The via blockage prevents routing direction changes when connecting to the macro pins.

- Sets the placement status of each macro to fixed so that it cannot be moved by the automatic macro placement command

- Sets the **is_rectangle_only_rule_waived** attribute on the macro pins to **true**

  This attribute waives the rectangle-only rule to allow proper routing to pins with different sizes.

- Reports pins that violate the minimum spacing rules specified with the **minSpacingForMacroPin** attribute in the Layer section of the technology file

- Places the generated routing guides and blockages in an edit group with their associated macro so that you can move the objects together in the GUI editor

EXAMPLES

The following example creates pin access routing guides and blockages on the Metal2 and Metal 3 layers for the myMacro1 and mylp2 macros. The routing guides are 0.6um wide in the x-direction and 0.7um wide in the y-direction.

```
prompt> derive_pin_access_routing_guides \
  -cells { myMacro1 mylp2 } -layers { Metal2 Metal3 } \
  -x_width 0.6 -y_width 0.7
```

SEE ALSO

create_routing_guide(2)

route_detail(2)

derive_placement_blockages

Used to automatically create blockages and route blockages to cover thin channels, based on current placement.

SYNTAX

status **derive_placement_blockages**
[-hierarchical]
[-force]

ARGUMENTS

-hierarchical

Specifies that the command should also work on the blocks in the design. By default, it will stop at block boundaries.

-force

Specifies that the command should always create the blockages. By default, it will not create the blockages it thinks utilization might get too high after blockages are inserted.

DESCRIPTION

This command is used to create placement blockages covering thin channels between hard macros and block boundaries. This command also creates routing blockages for all user created route blockages (created using **create_keepout_margin -type route_blockage**). This is useful to set up the block for block implementation.

For the thin channel placement blockages, if the **place.floorplan.sliver_size** application option is set, then this is used as the maximum size for a thin channel. If this application option is not set, the tool estimates the size of a thin channel based on hard_macro keepout margins. These keepouts are either user created using **create_keepout_margin -type hard_macro** or auto generated. See the for **plan.place.default_keepout** man page.

To remove these derived blockages use the following command:

remove_placement_blockages [get_placement_blockages -filter is_derived==true]

EXAMPLES

The following example derives placement blockages for the top-level design.

```
prompt> derive_placement_blockages
1
```

SEE ALSO

create_keepout_margin(2)
create_placement(2)

derive_preferred_macro_locations

Extracts the current macro locations as preferred macro locations. If specified, the command writes to locations to a constraint file as **set_macro_constraints** commands. The file can be sourced in a subsequent session and used to guide the macro placement. Use this command to capture a "good" macro placement achieved in one session and use the placement in a subsequent session to reduce sensitivity to small netlist modifications and other changes.

SYNTAX

status **derive_preferred_macro_locations**
[*hard_macro_list*]
[-file *file_name*]

Data Types

hard_macro_list list
file_name string

ARGUMENTS

hard_macro_list

Specifies the list of hard macros for which preferred location constraints are calculated. When omitted, all the macros in the current design are considered.

-file *file_name*

Writes the resulting preferred location constraints to *file_name*. By default, the preferred location constraints are set in the current session.

DESCRIPTION

This command generates preferred location constraints based on the current macro locations. Use this command to write out the result to a file, or to set the constraints internally in the current session. The resulting preferred location constraints can be reported with the **report_macro_constraints** command. Note that this command works incrementally and does not overwrite existing preferred location constraints. Use the **remove_macro_constraints** command to delete any existing preferred location constraints.

EXAMPLES

The following example captures of the macro locations in one session and applies them in another session.

```
prompt> set macros [get_cells -filter "design_type == macro" -hier *]
prompt> derive_preferred_macro_locations $macros -file preferred.tcl
```

The tool writes the preferred.tcl file, which contains **set_macro_constraints** commands for each specified macro.

```
set_macro_constraints \
  -preferred_location {0.261 0.858} \
  [get_cells I_ORCA_TOP/I_PCI_TOP/I_PCI_WRITE_FIFO/PCI_FIFO_RAM_7]

set_macro_constraints \
  -preferred_location {0.287 0.817} \
  [get_cells I_ORCA_TOP/I_PCI_TOP/I_PCI_WRITE_FIFO/PCI_FIFO_RAM_6]
...
```

The following example loads the constraints generated in the previous example. Source the preferred placement constraints before running the **create_placement -floorplan** command.

```
prompt> source preferred.tcl
prompt> report_macro_constraints $macros
****************************************
Report : report_macro_constraints
Design : ORCA
****************************************

 macro            preferred
 name             location
 --------------------------------------------------------------------------------
I_ORCA_TOP/I_PCI_TOP/I_PCI_WRITE_FIFO/PCI_FIFO_RAM_7
                  {0.261 0.858}
I_ORCA_TOP/I_PCI_TOP/I_PCI_WRITE_FIFO/PCI_FIFO_RAM_6
                  {0.287 0.817}
```

report_macro_constraints(2)
set_macro_constraints(2)

derive_route_connection

Derive connection of a set of disjoint dangling routes.

SYNTAX

status **derive_route_connection**
list_of_nets

Data Types

list_of_nets collection

ARGUMENTS

list_of_nets

List of nets to derive.

DESCRIPTION

This command is used to derive connection of disjoint dangling routes.

It will connect these routes to make connected routes from driver to loads. It will derive terminal for un-assigned block pins at end of route inside their blocks. It will break multiple points paths into two points paths.

Deriving terminal will fail if there are multiple un-assigned block pins of same block. Please manually create terminals before using this command. It may also fail if there are multiple ends of wires in that block, because this command does not know end of which wire is the expected location of the terminal. If user has multiple wire ends inside the block, please make sure other wire ends, which are not expected to be derived as the terminal, be close enough to the wire it will connect.

When connecting routes, this command just follows shortest path without honor anything, e.g. routing rules, blockages or routing DRCs.

EXAMPLES

The following examples show usage of command options.

prompt> **derive_route_connection {net_1 net 2}**

SEE ALSO

add_buffer_on_route(2)

describe_state_transition

Specifies the legality of a transition from one object's named power state to another.

SYNTAX

status **describe_state_transition**
transition_name
-object *object_name*
[-from *from_list* -to *to_list*]
[-paired {*from_state to_state*}]
[-through *through_list*]
[-legal]
[-illegal]

Data Types

transition_name string
object_name string
from_list list
to_list list
through_list list
from_state string
to_state string

ARGUMENTS

transition_name

Specifies the simple name of transition.

-object *object_name*

Specifies simple name of any UPF object which contains the power state.

-from *from_list*

Specifies an unordered list of power state names active before a state transition. Empty list expands to all named power states for the specified object.

-to *to_list*

Specifies an unordered list of power state names active after a state transition. Empty list expands to all named power states for the specified object.

-paired {*from_state to_state*}

Specifies a list of from-state name and to-state name pairs.

-through *through_list*

Specifies list of intermediate states. This option is only applicable when -from/-to options are specified. The effective transition sequence is -from, -through, -to.

-legal | **-illegal**

Specify the legality of the transition being defined as either legal or illegal. The default is -legal.

DESCRIPTION

The describe_state_transition command specifies the legality of a transition from one object's named power state to another.

This command will be deprecated in UPF 3.0 and be replaced by add_state_transition.

EXAMPLES

The following example shows how to describe an illegal state transition, turn_on:

```
prompt> describe_state_transition turn_on \
 -object PdA -from {SLEEP_MODE} -to {HIGH_SPEED_MODE} -illegal
```

SEE ALSO

add_power_state(2)
add_state_transition(2)

dft_drc

Checks the current design against test design rules.

SYNTAX

status **dft_drc**
[-test_mode test_mode_label]
[-verbose]
[-coverage_estimate]
[-gui]

Data Types

test_mode_label string

ARGUMENTS

-test_mode

Specifies the mode in which we are running dft_drc. Examples of options are Internal_scan and ScanCompression_mode

-verbose

Controls the amount of detail when displaying violations. If specified, every violation instance is displayed. By default, only the first instance and the number of instances are displayed.

-coverage_estimate

Generates a test coverage estimate at the end of post-DFT DRC design rule checking.

-gui

Opens the DRC violation browser in the application GUI. The GUI is started if not already running.

DESCRIPTION

This command checks the current design against the test design rules used for scan insertion. If there are unconnected test modes and functional Autofix clocks, they are constrained as needed.

If design rule violations are found, the appropriate messages are generated.

Perform test design rule checking on a design before performing any other DFT operations, such as **insert_dft**.

This command requires the existence of a valid test protocol. The test protocol can be generated using the **create_test_protocol** command.

The severity of violations falls under one of the following categories:

- Information indicates no action is required.
- Warning indicates that you should analyze the violations. These might violate sequential cells resulting in their exclusion from scan chains. However, they do not prevent you from running certain DFT Compiler commands.
- Fatal violations stop you from proceeding. Certain DFT Compiler commands cannot be run.

If you start with a design with pre-existing scan structures, the scan information for inference must be specified with **-view** as **existing_dft** for the **set_dft_signal** and **set_scan_path** commands and run the **create_test_protocol** command.

The \fb-coverage option generates test coverage statistics for the current design. The option does not allow you to save or write out test patterns. The number generated is only an estimate and might be different from the one generated by an ATPG tool.

If you are running the command in the Design Vision environment, you can use the violation browser to analyze violations.

EXAMPLES

The following command performs test design-rule checking for the current design, and illustrates the types of messages that are printed:

```
dft_drc -verbose

disconnect_3d_bumps

Removes logical connections between bumps and I/O drivers.

SYNTAX

status **disconnect_3d_bumps**
[-nets *nets*]

Data Types

nets list

ARGUMENTS

-nets *nets*

Specifies the nets for logical connection removal. By default, logical connections for all top-level nets between bumps and I/O drivers are removed.

DESCRIPTION

This command removes logical connection between bumps and I/O driver.

EXAMPLES

The following example removes the logical connections between bumps and I/O ports for net VDD.

prompt> **disconnect_3d_bumps -nets VDD**

SEE ALSO

create_3d_mirror_bumps(2)
propagate_3d_connections(2)
set_3d_chip_placement(2)

disconnect_net

Disconnects a net or scalar nets of net_bus from ports, scalar ports of port_bus and pins.

SYNTAX

int **disconnect_net**
[-design *design*]
[-net *net*]
[*net*]
[-all]
terms

Data Types

design collection
net list
terms list

ARGUMENTS

-design *design*

Specifies the design in which to disconnect the net or net_bus. If no design is specified, the net or net_bus is disconnected in the current design.

-net *net*

Specifies the net or net_bus to be disconnected. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified along with terms, then terms must contain the same width port_bus or length of the scalar port list must be same as bus width of the net_bus.

net

Specifies the net or net_bus to be disconnected. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified along with terms, then terms must contain the same width port_bus or length of the scalar port list must be same as bus width of the net_bus. This positional argument is provided for compatibility with other tools.

-all

Specifies to break all connections on the net.

terms

Specifies the ports,port_bus and pins to disconnect from the net. Only objects existing in the current design can be specified.

DESCRIPTION

The **disconnect_net** command breaks the connections between the specified ports,scalar ports of port_bus and pins from its net. The net, net_bus, ports,port_bus and pins must reside in the same hierarchy. The net, net_bus, pins,ports and port_bus are not removed.

Either *terms* or **-all** must be specified. If **-all** is specified, then **-net** must be specified as well.

If the *terms* is specified without the **-net** option, then the specified ports, scalar ports of port_bus and pin are disconnected from its currently connected net.

If a port or pin cannot be disconnected, the port or pin is skipped. And a warning message will be printed. The remaining ports and pins in the *terms* are disconnected.

The number of disconnected ports and pins are returned.

To connect nets, use the **connect_net** command. To display the ports and pins connected to a net, use the **all_connected** command.

EXAMPLES

The following examples show nets being disconnected using the **disconnect_net** command.

```
prompt> disconnect_net -net NET0 [get_ports A1]
prompt> disconnect_net [get_pins U1/A]
```

The following example shows all connections on a net being broken using **disconnect_net**.

```
prompt> disconnect_net -net MY_NET_1 -all
prompt> all_connected [get_nets MY_NET_1]
{}
```

The following example disconnects net_bus *N[7:0]* to port_bus *P[7:0]* so that N[7] is disconnected from P[7], N[6] is disconnected from P[6] ..,N[0] from P[0].

```
prompt> disconnect_net -net N P
prompt> 8
prompt> all_connected [get_net_buses N]
{}
prompt> all_connected [get_port_buses P]
{}
```

The following example shows the result of disconnecting an open pin *OPEN_PIN* (the pin which is not connected to any net) from net *NET*.

```
prompt> disconnect_net -net NET OPEN_PIN
Warning: Object 'OPEN_PIN' is not connected to net 'NET'. (NDMUI-916)
```

SEE ALSO

connect_net(2)
all_connected(2)

distribute_objects

Distributes the specified objects.

SYNTAX

status **distribute_objects**
[*object_list*]
[-anchor *object_list*]
[-parent]
[-to {*x1 y1*}]
[-to_box {{*x1 y1*} {*x2 y2*}}]
[-side left | right | top | bottom | hcenter | vcenter]
[-anchor_side auto | ll | ur | center]
[-spacing *spacing*]
[-pitch *pitch*]
[-group]
[-margin]
[-space_anchor]

Data Types

object_list collection
x1 float
y1 float
x2 float
y2 float
spacing float
pitch float

ARGUMENTS

object_list

Collection or selection set containing objects to distribute. If this option is not specified, global selection set is used.

-anchor *object_list*

Specifies the first object that other objects are distributed from.

-parent

Specifies that objects are distributed starting at the parent edge.

For terminals and I/O pads the parent object is the die. For soft macro pins the parent object is the soft macro. For all other objects the parent is the core.

-to {*x1 y1*}

Specifies that objects are distributed starting at the specified position.

-to_box {{*x1 y1*} {*x2 y2*}}

Specifies that objects are distributed starting at the specified rectangle.

-side left | **right** | **top** | **bottom** | **hcenter** | **vcenter**

Specifies the side of the object to be used for placing distributed objects. The valid values are as follows:

left - Use the left side
right - Use the right side
top - Use the top side
bottom - Use the bottom side
hcenter - Use the horizontal center
vcenter - Use the vertical center

The default is **left**.

-anchor_side auto | **ll** | **ur** | **center**

Specifies anchor object side to be distributed from. The valid values are as follows:

auto - Determine the anchor side automatically
ll - Use the low left side
ur - Use the upper right side
center - Use the center

The default is auto.

-spacing *spacing*

Specifies the spacing between distributed objects. The default is **0.0**.

-pitch *pitch*

Specifies the pitch between distributed objects. The default is **0.0**.

-space_anchor

Specifies that spacing should be also applied for placement of objects relatively to the anchor.

-group

Specifies that objects should be treated as if it was single object.

-margin

Use extended objects boundaries. The block boundaries are extended with keepout margins. The voltage areas boundaries are extended with guard bands. To exclude certain block keepout margins from consideration, use the following command:

```
prompt> win_set_filter -class cell \
  -filter {hard_macro_margin hard_margin route_blockage_margin soft_margin}
```

DESCRIPTION

This command distributes a list of unfixed objects to place them side by side horizontally or vertically with an optional spacing between each object.

You can specify an anchor object, anchor position, or let the command automatically determine the anchor object from the supplied list of objects using the following algorithm:

- If any objects are marked as fixed, the anchor objects is selected from the set of fixed objects. The rightmost, leftmost, bottommost or topmost fixed object for alignment of left, right, top and bottom respectively.
- If no objects are marked as fixed, the anchor object is the leftmost, rightmost, topmost or bottommost object for alignment of left, right, top and bottom respectively.

NOTES

Snapping is done automatically using global snap settings.

EXAMPLES

The following example moves the currently selected objects so that they are placed side by side in the horizontal direction with 20 units between each.

```
prompt> distribute_objects -parent -spacing 20
```

The alternative syntax uses a collection to specify the objects.

```
prompt> distribute_objects [get_selection] -parent -spacing 20
```

drive_of

Determines the drive resistance of the specified library cell pin.

SYNTAX

float **drive_of**
[-rise]
[-fall]
lib_cell_pin

Data Types

lib_cell_pin collection

ARGUMENTS

-rise

Gets rise drive value.

-fall

Gets fall drive value.

lib_cell_pin

Specifies the name of the library cell pin, or a collection that contains the library cell pin, for which to get the drive resistance. But the tool wrill only return the drive resistance for first lib pin in the collection.

DESCRIPTION

The **drive_of** command returns the drive resistance of of the first given library cell pin. If neither the *-rise* nor *-fall* option is specified, the greater value of rise and fall is returned. The calculation of the driver resistance is based on current corner.

echo

Echos arguments to standard output.

SYNTAX

string **echo**
  [-n]
  [*arguments*]

Data Types

arguments string

ARGUMENTS

-n

Suppresses the new line. By default, **echo** adds a new line.

arguments

Specifies the arguments to be printed.

DESCRIPTION

The **echo** command prints out the value of the given arguments. Each of the arguments are separated by a space. The line is normally terminated with a new line, but if the **-n** option is specified, multiple **echo** command outputs are printed onto the same output line.

The **echo** command is used to print out the value of variables and expressions in addition to text strings. The output from **echo** can be redirected using the **>** and **>>** operators.

EXAMPLES

The following are examples of using the **echo** command:

prompt> **echo**

```
"Running version" $sh_product_version
Running version v3.0a

prompt> echo -n "Printing to" [expr (3 - 2)] > foo
prompt> echo " line." >> foo
prompt> sh cat foo
Printing to 1 line.
```

SEE ALSO

sh(2)

eco_netlist

Performs name-based netlist comparison between a working design and the golden input.

SYNTAX

status **eco_netlist**
  -write_changes *write_changes_file_name* |
    -write_changes_per_module *directory_name*
  { [-by_verilog_file *verilog_file_name*] |
    [-by_block *golden_block[/label_name]*
    [-golden_lib *golden_library*]
    [-working_block *working_block[/label_name]*]
    [-working_lib *working_library*]
    ]
  }
  [-compare_physical_only_cells]
  [-extract_timing_eco_changes]
  [-compare_target_modules *target_module_name_list* |
    -compare_module_subsets | -top_module *module_name*]
  [-write_summary *summary_file_name*]
  [-compare_pg]
  [-cross_physical_hierarchy]

Data Types

write_changes_file_name string
directory_name string
verilog_file_name string
golden_block string
label_name string
golden_library string
working_block string
working_library string
target_module_name_list list
summary_file_name string
module_name string

ARGUMENTS

-write_changes *write_changes_file_name*

Specifies a file name to write the comparison result in. This option is mutually exclusive with **-write_changes_per_module**. You must specify one of this option or **-write_changes_per_module**.

-write_changes_per_module ***directory_name***

Writes changes for each module separately. The change files are written to the specified directory with the module name as the file name. This option is mutually exclusive with **-write_changes**. You must specify one of this option or **-write_changes**.

When this option is specified, a source file "source_sequence.tcl" will be created for each block, which can be used to source all changes per module in this block with the correct sequence. When this option is used with **-cross_physical_hierarchy**, a single file named "full_chip_source_sequence.tcl" will be created under the specified directory, which can be used to source all changes per block with the correct sequence.

-by_verilog_file ***verilog_file_name***

Specifies a Verilog file as the golden input. You must specify this option or by_block. They are mutually exclusive with each other. The Verilog file can contain part of modules when **-compare_target_modules** or **-compare_module_subsets** is specified.

-by_block ***golden_block/label_name***

Specifies an existed block as the golden input. It is optional to append a label name after the block name. You must specify this option or by_verilog_file. They are mutually exclusive with each other.

-golden_lib ***golden_library***

Specifies the library which the golden block is in. It is optional and if it is not specified, the golden block will be found in current library. This option must be used together with **-by_block**.

-working_block ***working_block/label_name***

Specifies the working block and optional with a label name. It is optional and can let you choose a non-current block as the working block. If this option is not specified, the current block will be used as working block. This option must be used together with by_block.

-working_lib ***working_library***

Specifies the library name which the working block is in. It is optional and if unspecified, the working block will be found in current library. This option must be used together with **-by_block** and **-working_block**.

-compare_physical_only_cells

Specifies that physical-only cells are included in comparison. By default, this option is off and the command will ignore the changes of physical-only cells.

-extract_timing_eco_changes

Extracts the timing ECO changes such as **size_cell**, **add_eco_repeater** and **remove_eco_repeater**. Except the timing ECO changes, if there still are some functional ECO changes between the working block and golden input, the command will also write out the changes together with the timing ECO changes.

-compare_target_modules ***target_module_name_list***

Compares only the specified modules. This option is mutually exclusive with **-compare_module_subsets** and **-top_module**.

-compare_module_subsets

Compares only the modules provided in the golden input. This option is mutually exclusive with **-compare_target_modules** and **-top_module**.

-top_module

Specify the top module for loading the golden verilog file when there are multiple top modules in this verilog file. This option is mutually exclusive with **-compare_target_modules** and **-compare_module_subsets**.

-write_summary ***summary_file_name***

Specifies the file name to use for writing a detail summary of the comparison. By default, the command displays only a simple comparison result.

-compare_pg

Specifies that PG objects (nets, ports, pins) are included in the comparison. Comparison rules for non-PG objects are used. By default, PG objects are excluded.

-cross_physical_hierarchy

Specifies that the command crosses physical hierarchy and also compares the child blocks. This option must be used together with **-write_changes_per_module** and it is mutually exclusive with **-write_changes**. By default, this option is off and the comparison will not cross physical hierarchy.

DESCRIPTION

This command identifies netlist changes in Verilog flow or tracks netlist changes before and after certain operations. This command does a name-based comparison between working and golden and only logical netlist changes are involved. The working and golden designs must be synthesized. This command will not apply the comparison result on working block. You should source the output change list manually if you want to apply the changes on working block.

This command can output the netlist changes in Tcl format of module-based ECO editing commands. You must specify the file name or the directory name for the output.

EXAMPLES

The following example shows the usage of input Verilog file as golden.

```
prompt> eco_netlist by_verilog_file after_eco.v \
  -write_changes eco.tcl
```

The following example show the usages of input existed block as golden. Use the current block as working and another block in current library as golden.

```
prompt> eco_netlist -by_block golden_block \
  -write_changes eco.tcl
```

The following example uses the current block as working and another block in another library as golden.

```
prompt> eco_netlist -by_block golden_block \
  -golden_lib golden_library -write_changes eco.tcl
```

The following example uses the block in another libraries as the working and golden.

```
prompt> eco_netlist -by_block golden_block \
  -golden_lib golden_library -working_block working_block \
  -working_lib working_library -write_changes eco.tcl
```

The following example uses the blocks with label name.

```
prompt> eco_netlist -by_block golden_block/after_buffering \
  -write_changes eco.tcl
```

The following example shows the usages of involving physical only cells in comparison.

```
prompt> eco_netlist -by_block golden_block/spare_cells \
  -compare_physical_only_cells -write_changes eco.tcl
```

The following example shows the usage of extracting timing ECO changes.

```
prompt> eco_netlist -by_block golden_block \
  -extract_timing_eco_changes -write_changes eco.tcl
```

The following examples show the usage of doing partial netlist diff to compare module A and B

```
prompt> eco_netlist -by_verilog_file golden.v \
  -write_changes eco.tcl -compare_target_modules {A B}
```

The following example compares modules in golden as subset modules:

```
prompt> eco_netlist -by_verilog_file golden.v \
  -write_changes eco.tcl -compare_module_subsets
```

The following examples show the usage of the summary options.

```
prompt> eco_netlist -by_verilog_file golden.v \
  -write_changes eco.tcl -write_summary eco.sum
```

The detail summary in file eco.sum is as follows:

```
=========================
eco_netlist Diff Summary
=========================
Total 2 modules compared, 100.00% modules have difference.
  0 modules created.

  0 modules deleted.

  2 modules changed.
    Module sub has max changes: 6
    Average changes per module: 6
    sub: 6 changes (60.00%)
      Instance changed  : 0 (0.00%)
      Port changed      : 3 (150.00%)
      Connection changed: 3 (50.00%)
    top: 6 changes (60.00%)
      Instance changed  : 0 (0.00%)
      Net changed       : 0 (0.00%)
      Port changed      : 3 (150.00%)
      Connection changed: 3 (50.00%)
```

The following examples show the usage of **-write_changes_per_module**.

```
prompt> eco_netlist -by_verilog_file golden.v -write_changes_per_module changes
```

Consider the case where there are two modules, A and B, that have differences. The preceding command generates a directory named "changes". In the directory, the files A.tcl and B.tcl contain the changes of module A and B respectively. The file source_sequence.tcl contains the source commands in correct sequence.

The file A.tcl might look like this:

```
# sourcing follow files in order before sourcing this file
# B.tcl
```

```
  [changes of module A]
```

The file source_sequence.tcl might look like this:

```
source B.tcl
source A.tcl
```

The dependency is represented by indent. In this example it means B is a sub module of A and you must source B.tcl before sourcing A.tcl.

eco_opt

Optimizes the current routed design with PrimeTime timing and PrimeTime ECO.

SYNTAX

status **eco_opt**
[-types *type_list*]
[-pba_mode none | path | exhaustive]
[-physical_mode open_site | occupied_site]
[-training_data_directory *directory_name*]
[-pre_eco_script *file_name*]
[-eco_script *file_name*]
[-write_change_file_only]
[-no_eco_place_and_route]
[-hold_margin *margin*]
[-setup_margin *margin*]
[-punch_port]
[-save_session *directory_name*]
[-size_only]

Data Types

type_list list
directory_name string
file_name string
margin float

ARGUMENTS

-types *type_list*

Specifies the optimization types. Specify one or more of the following optimization types:

- **timing** - Fix setup and hold timing violations.
- **setup** - Fix setup timing violations.
- **hold** - Fix hold timing violations by selecting hold buffers and delay cells and passing them to PrimeTime ECO.
- **sequential_timing** - Fix setup and hold violations for sequential cells. Must be specified with the **setup**, **hold**, or **timing** type.
- **useful_skew** - Fix setup and hold timing violations on the clock network.
- **drc** - Fix maximum transition and maximum capacitance violations.
- **max_transition** - Fix maximum transition violations.

- **max_capacitance** - Fix maximum capacitance violations.
- **max_clock_transition** - Fix maximum transition violations on the clock network.
- **leakage_power** - Reduce leakage power by sizing and swapping cells. The tool selects the worst leakage power scenario based on PrimeTime-PX power analysis, and passes the information to PrimeTime ECO for power optimization.
- **dynamic_power** - Reduce dynamic power by downsizing cells. The tool selects the worst dynamic power scenario based on PrimeTime-PX power analysis, and passes the information to PrimeTime ECO for power optimization.
- **total_power** - Reduce total power by sizing and swapping cells. The tool selects the worst total power scenario based on PrimeTime-PX power analysis, and passes the information to PrimeTime ECO for power optimization.
- **buffer_removal** - Remove redundant buffers for power reduction.
- **noise** - Fix noise violations.
- **power_integrity** - Fix power integrity violations. User will need to provide path to rail database generated by RedHawk analysis to use this feature. Cannot be combined with other fixing types.

When multiple types are specified, the tool determines the optimum order of the different types of optimization.

The default is **{setup hold drc total_power buffer_removal}**. The default DRC fixing includes both **max_transition** and **max_capacitance**.

-pba_mode none | path | exhaustive

Controls the use of path-based analysis (PBA). The effort value can be

- **none** (the default)

  Performs graph-based analysis (GBA).

- **path**

  Path-based analysis is applied to paths after they are gathered.

- **exhaustive**

  An exhaustive path-based analysis path search algorithm is applied to determine the worst path set in the block.

These meanings are the same as in the PrimeTime **report_timing** and **get_timing_paths** commands.

Path-based analysis (PBA) removes pessimism and provides more accurate timing but spends more time than graph-based analysis (GBA). When the current block is optimized with PBA, it can reduce power more than GBA-based optimization as more positive slacks are available for downsizing or swapping. PBA-based optimization can also reduce the number of changes as the number of violations is smaller than the number of violations in GBA.

PBA-based optimization might increase runtime. Moreover, PBA runtime might increase if your block has a large number of violations.

When this option is specified, the fixing process uses the specified path-based analysis type to determine the timing fixes needed. If combined with the **-eco_script** option for user-specified PrimeTime ECO commands, the **-pba_mode** determines only the path-based analysis type for the built-in QoR reports within the **eco_opt** command, not affecting the user-specified script. In this way, the intermediate QoR reports' path-based analysis mode match the user-specified ECO script.

-physical_mode none | open_site | occupied_site

Specifies the use of physical data to resize cells or place buffers.

The valid values are

- **none**

  Does not use physical data to resize cells or place buffers.

- **open_site** (default)

  Sizes a cell if there is enough room available around the cell and inserts a buffer if there is an empty site. This mode avoids moving existing cells; it places cells only in empty sites.

- **occupied_site**

  The PrimeTime tool considers the layout density in the cell neighborhood and can place or resize a cell overlapping existing neighbor cells when the local placement density can accommodate the change. This mode places or resizes a cell even if no empty site is available; later place and route commands move existing cells to create room for the new or sized cells and change routing accordingly for the best results.

-training_data_directory *directory_name*

Specifies the directory for storing the training data for PrimeTime power optimization.

-pre_eco_script *file_name*

Specifies a Tcl script file to be sourced in the PrimeTime tool before the **check_eco** command is executed.

-eco_script *file_name*

Specifies a file that contains PrimeTime ECO commands.

The following example shows a custom ECO script file that contains PrimeTime ECO commands and a custom Tcl procedure, apply_my_custom_dont_touch.

```
# apply custom dont touch
apply_my_custom_dont_touch
# perform ECO
fix_eco_drc
fix_eco_timing -type setup -slack_greater_than 0.1
fix_eco_power -pattern {HVT LVT}
```

When this option is specified, the **-types** option is ignored. Instead, the current block is optimized with the PrimeTime commands specified in the file.

-write_change_file_only

Writes the PrimeTime ECO changes to a file instead of sourcing them.

Use this option carefully as the design status in the immplementation tool would be different from that of the PrimeTime tool.

-no_eco_place_and_route

Does not perform ECO placement and routing after making changes.

By default, the command runs ECO placement and routing.

-setup_margin *margin*

Specifies a margin applied to setup timing slack during PrimeTime ECO fixing, in library time units.

-hold_margin *margin*

Specifies a margin applied to hold timing slack during PrimeTime ECO fixing, in library time units.

-punch_port

Performs port punching for maximum transition and noise violation fixing.

-save_session ***directory_name***

Specifies the directory in which to save the PrimeTime session.

-size_only

Only sizing methods will be deployed with the specified fixing types. **max_fanout** and **buffer_removal** fixing types will not be executed when *-size_only* is specified.

DESCRIPTION

This command optimizes the current block with PrimeTime timing and PrimeTime ECO features. By default, the command invokes the PrimeTime tool, runs PrimeTime ECO including timing and DRC fixing as well as power optimization, brings back the changes to the implementation tool, followed by ECO placement and routing. The command also provides the ability to specify custom PrimeTime ECO commands for flexibility and to meet complex ECO requirements.

When the **eco_opt** command executes, the following actions happen:

- Generates PrimeTime setup based on the tool's multi scenario
- Invokes Distributed Multiscenario Analysis (DMSA) PrimeTime under the hood unless PrimeTime has already started
- Runs multiscenario timing updates
- Performs the specified types of PrimeTime ECO
- Brings the changes back to the implementation tool by sourcing the change list generated by the PrimeTime tool
- Performs incremental placement and routing with the recommended minimal physical impact (MPI) settings

EXAMPLES

The following example performs setup fixing followed by incremental place and route.

```
prompt> eco_opt -types setup
```

The following example performs setup and hold timing fixing followed by incremental place and route, and checks the PrimeTime timing with the **check_pt_qor** command.

```
prompt> eco_opt -types {setup hold}
prompt> check_pt_qor
```

The following example performs total-power optimization with path-mode PBA.

```
prompt> eco_opt -types total_power -pba_mode path
```

The following example performs the custom ECO commands defined in the my_eco.tcl file and checks the PrimeTime QoR.

```
prompt> eco_opt -eco_script my_eco.tcl
prompt> check_pt_qor -type summary
```

The following example runs the predetermined fixing types followed by a custom ECO script. Note that placement and routing are

performed only once, after the last command that sources all changes made by the three **eco_opt** commands.

```
prompt> eco_opt -types setup -write_change_file_only
prompt> eco_opt -types total_power -write_change_file_only
prompt> eco_opt -eco_script my_pteco.tcl
```

eco_update_supply_net

This command updates supply nets for eco buffers.

SYNTAX

status **eco_update_supply_net**
[-cells *cells*]

Data Types

cells collection

ARGUMENTS

-cells *cells*

Specify cells to update supply nets. The specified cells and the cells in their "eco buffer trees" will be updated. Here "eco buffer tree" means a group of connected timing eco cells, separated by cells of other types. If this option is not specified, all cells added by timing eco commands will be updated, including add_buffer, add_eco_repeater, split_fanout, add_buffer_on_route and size_cell(in freeze_silicon).

DESCRIPTION

This command update supply nets for eco buffers. If there is any violation when updating the MV supply nets, the command will give warning messages and not apply supply nets for related cells. But the command will not remove the cells which have violations during updating supply nets.

The command may handle multiple buffer trees, if some trees failed, the failed cells will be added to the collection $ecoUpdateSupplyFailedCells, and for each failed buffer tree, a warning message will be issued .

This command does not support undo.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples shows how to using the eco_update_supply_net command to update supply nets for the specified cells.

prompt> **eco_update_supply_net -cells {eco_cell_0}**

The following examples shows how to using the eco_update_supply_net command to update supply nets for all eco buffers which have no supply updated yet.

prompt> **eco_update_supply_net**

SEE ALSO

add_buffer_on_route(2)
check_mv_design(2)

edit_block

Run specified commands editing the block

SYNTAX

edit_block
command_list

Data Types

command_list string list

ARGUMENTS

command_list

Specifies the design modification commands to run.

DESCRIPTION

The **edit_block** command allows a list of commands to run within one together, minimizing the runtime needed to for computation to keep the database consistent, which is normally done at the end of every command.

Certain operations, for example, collection cleanup are required to be performed at the end of every command, and can get expensive when a lot of collections are active. Using **edit_block** will help in such cases as well.

Following are the eco commands supported by **edit_block**:

- create_cell
- remove_cell
- change_link
- create_port
- remove_port
- create_net

- remove_net
- connect_net
- disconnect_net
- set_attribute
- remove_port_buses
- create_port_bus
- remove_net_buses
- create_net_bus
- add_eco_repeater
- remove_eco_repeater
- size_cell

The usage of command **set_attribute** in **edit_block** is limited to netlist objects only.

EXAMPLES

The following example edits the block, creating a new cell and connecting a net to one of the pins of the new cell.

```
prompt> edit_block {
  create_cell iAnd [get_lib_cells lib/AND2]
  connect_net -net n2 iAnd/a1
}
```

The following example runs the source command

```
prompt> edit_block {
  source -e -v  commands.tcl
}
```

SEE ALSO

edit_module(2)

edit_ems_rule

Edits an user-defined EMS rule.

SYNTAX

edit_ems_rule
-name *rule_name*
[-severity *rule_severity*]
[-message *message_template*]
[-parameters *parameter_properties*]

Data Types

rule_name string
rule_severity string
message_template string
parameter_properties string

ARGUMENTS

-name *rule_name*

This is a mandatory option. This name is used to identify the rule to be edited. The rule name should obey regular expression [A-Z]+[-][0-9]+ i.e one or more upper-case alphabets, followed by hyphen character and which should be followed by one or more numerals. If rule name does not obey this regular expression then an error message is displayed. User should have already created an EMS rule by this name using command **create_ems_rule** before using this command. If an EMS message is already created using this rule then the rule is considered frozen. One cannot edit a frozen rule, it results in an error message.

-severity *rule_severity*

This is an optional option. This option is used to specify whether the rule corresponds to an error, warning or information. The valid string arguments are **error**, **information**, **info**, **warning** and **warn**. These string values can be in upper or lowercase or a mix of both. But it is advisable to stick to one convention for the sake of uniformity. But when the EMS message is displayed in the shell or in the EMS GUI message browser, the severity string displayed will be one of **Error**, **Warning** or **Information**.

-message *message_template*

This is an optional option. This option is used to specify the message template for the rule. The message template can contain placeholders referred to as **parameters**. Parameters begin with a **%** character. The parameter name should obey regular expression [A-Za-z0-9_]+ i.e it should contain one or more of upper or lower case alphabets or numerals or underscore character. There should not be any whitespace between **%** and parameter name. To use a literal percent sign (**%**), specify **%%**.

-parameters *parameter_properties*

This is an optional option. If there are no EMS parameters for the rule being defined then this option need not be used. But if there

are EMS parameters specified in message template this option can be used to define the parameter properties. This option takes a string as an argument which is a sequence of fields separated by semi-colon (;) describes properties of an EMS parameter, which again is a sequence of pairs of format <name>:<value>. Currently, an EMS parameter can have at-most three properties namely, name-property, type-property and command-property. Here type-property and command-property are optional and name-property is mandatory. name-property will take a valid parameter name as value and which helps EMS to know properties of which parameter are defined. type-property can take one of **string**, **int**, **float** and **double** values. type-property is used to define the type of the EMS parameter. The command-property of the EMS parameter can take value as any of the **get_*** commands such as get_pins, get_cells etc., which take an object name as argument and return the object handle. This property is used to get the object handle corresponding to the EMS parameter name.

DESCRIPTION

Command **edit_ems_rule** edits an already existing user-defined EMS rule. An EMS rule is a message template with some auxiliary information used to create the EMS message. The user-defined rules created are not persistent across sessions. This command can be used to add or override information related to an already created user-defined rule. But if an EMS message is already created for the user-defined rule to be edited, then editing fails displaying an error message.

EXAMPLES

```
prompt> create_ems_rule -name "TEMP-001" -severity "Info" -message "Pin:%pin has capacitance:%cap"
prompt> edit_ems_rule -name "TEMP-001" -parameters "name:pin type:string command:get_pins"
prompt> edit_ems_rule -name "TEMP-001" -parameters "name:cap type:double"
prompt> create_ems_rule -name "TEMP-002" -severity "Error" -message "Cell %cell is not placed"
prompt> edit_ems_rule -name "TEMP-002" -severity "Info"
prompt> edit_ems_rule -name "TEMP-002" -message "The Cell %cell is not placed."
prompt> edit_ems_rule -name "TEMP-002" -parameters "name:cell type:string command:get_cells"
prompt> create_ems_database a.ems
{a.ems}
prompt> set cap 0.0004
prompt> create_ems_message -rule "TEMP-001" -parameters "pin:U1/I cap:$cap"
prompt> set cell U23
prompt> create_ems_message -rule "TEMP-002" -parameters "cell:$cell"
prompt> report_ems_database
 ...
Information: Pin:U1/I has capacitance 0.0004 (TEMP-001)
Information: The Cell U23 is not placed. (TEMP-002)
```

create_ems_message(2)

edit_module

Edits a Verilog module in the module aspect to modify the netlist aspects.

SYNTAX

edit_module
module_list
command_list

Data Types

module_list collection
command_list list

ARGUMENTS

module_list

Specifies the list of modules to edit for different netlist modifications. *module_list* can be specified as a string (name of objects) or the collection of objects.

command_list

Specifies the netlist modification commands to apply to the specified modules. Commands are listed sequentially with each command on one line. The commands that operate at the module scope are **create_cell**, **remove_cells**, **create_net**, **remove_nets**, **create_port**, **remove_ports**, **connect_net**, **disconnect_net**, **change_link**, **get_cells**, **get_nets** and **get_ports**.

DESCRIPTION

The **edit_module** command edits a Verilog module directly in the module scope and propagates the changes to all its instances. All the Tcl commands that are used to modify a netlist can be used within this *edit_module* scope, including creating and deleting of cells, ports and nets, connecting and disconnecting of nets and changing reference of module instance.

When cells are created or reference of module instance is changed, the corresponding hier aspect instances are set respectively with an ECO status of **create_cell** or **change_link**.

The getter commands related to cells/nets/ports (get_cells/get_nets/get_ports) can also be used within *edit_module* scope. They will behave exactly similar to hier aspect get_cells/get_nets/get_ports commands. Attributes can be queried on returned objects of these getter commands. Outputs of these getter commands can be passed on to other commands as well.

The commands passed into *edit_module* are not screened; take care with the commands that you use.

EXAMPLES

The following example edits a module 'abc' where module instance iAnd is created and net n2 is connected with pin a1 of iAnd.

```
prompt> edit_module abc {
  create_cell iAnd [get_lib_cells lib/AND2]
  connect_net -net n2 iAnd/a1
}
```

The following example edits a module 'abc' where module port A1 is created, net n2 is created and module instance iBuf's reference is changed.

```
prompt> edit_module [get_modules abc] {
  create_port A1
  create_net n2
  change_link iBuf BUF2
}
```

The following example shows usage of getter commands within **edit_module**.

```
prompt> edit_module [get_modules abc] {
  get_nets -of_objects [get_cells]
  remove_cells [get_cells iAnd]
  get_attribute [get_ports in2] port_type
}
```

SEE ALSO

create_module(2)
remove_modules(2)

edit_via_matrix

Edit a via matrix in the current design.

SYNTAX

int **edit_via_matrix**
[-delete *box*]
[-add *box*]
[-update *box*]
[-lower_mask_constraint *lower_mask*]
[-cut_mask_constraint *cut_mask*]
[-upper_mask_constraint *upper_mask*]
[-force]
[-verbose]
via_matrix

Data Types

box rectangle
via_matrix collection

ARGUMENTS

-add *bounding_box*

Specifies the box region which overlaps or touch base vias to be added. *-add*, *-delete* and *-update* are mutually exclusive options.

-delete *bounding_box*

Specifies the box region which overlaps or touch base vias to be deleted. *-add*, *-delete* and *-update* are mutually exclusive options.

-update *bounding_box*

Specifies the box region which overlaps or touch base vias whose mask(s) to be updated. *-add*, *-delete* and *-update* are mutually exclusive options.

-lower_mask_constraint *lower_mask*

Updates the lower mask constraint of the base vias specified by *-update*. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. No matter what the via_matrix mask_pattern is, the specified base via lower mask is to be updated as *lower_mask*.

-cut_mask_constraint *cut_mask*

Updates the cut mask constraint of the base vias specified by *-update*. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, mask_five, mask_six, mask_seven, mask_eight, mask_nine, mask_ten, mask_eleven, mask_twelve, mask_thirteen, mask_fourteen, mask_fifteen and same_mask. No matter what the via_matrix mask_pattern is, the specified base via cut mask is to be updated as *cut_mask*.

-upper_mask_constraint *upper_mask*

Updates the upper mask constraint of the base vias specified by *-update*. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. No matter what the via_matrix mask_pattern is, the specified base via upper mask is to be updated as *upper_mask*.

-force

Edit locked or fixed a via_matrix. By default, such via_matrixes are not re sized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-verbose

Display verbose deletion information.

via_matrix

Specifies a via matrix to edit. It may be via matrix collections, specified using the **get_via_matrixes** command.

DESCRIPTION

This command edits a via matrix.

EXAMPLES

For example to exclude all base vias overlapping or touching the specif ed bounding-box.

```
prompt> edit_via_matrix -delete {{8.0600 9.2800} {8.2545 9.4345}} $viaMatrix
```

For example to include all base vias overlapping or touching the specif ed bounding-box.

```
prompt>edit_via_matrix -add {{8.0300 9.1850} {8.0302  9.19}} $viaMatrix
```

For example to update masks of all base vias overlapping or touching the specif ed bounding-box.

```
prompt>edit_via_matrix -update {{8.28 9.50} {8.40 9.5}} $viaMatrix -lower_mask_constraint mask_three
```

SEE ALSO

elaborate

Builds a new design using an analyzed module, entity or configuration template from an *hdl_library*.

SYNTAX

status **elaborate**
template_name
[-architecture *arch_name*]
[-hdl_library *hdl_library_name*]
[-parameters *param_list*]

Data Types

template_name string
arch_name string
hdl_library_name string
param_list string (comma-separated list)

ARGUMENTS

template_name

Specifies the name of an analyzed module, entity, or configuration for which a template is available from the specified *hdl_library*.

-architecture *arch_name*

Specifies the name of an architecture for the entity *template_name* as declared in an analyzed VHDL source. The default architecture is the one most recently analyzed.

-hdl_library *hdl_library_name*

Specifies the name of the *hdl_library* in which to find the template. When the -**hdl_library** option is not used, or it specifies "default", then the *hdl_library_name* is taken from **hdlin.hdl_library.default_name**.

-parameters *param_list*

Specifies a string of design parameter mappings. Parameters within the list must be separated by commas. A specification can be based on parameter declaration order (for example, "8,7,5") or on parameter names (for example, "N=>8,M=>6", or "N=8,M=6"). It is acceptable to mix ordered and named parameter specifications, if the ordered parameters are listed first. The full *param_list* syntax is summarized in the "DESCRIPTION" section below.

DESCRIPTION

The **elaborate** command builds the indicated design from its analyzed (template) representation using the specified parameter value substitutions. The elaborated *block_name* becomes the **current_block** in your session; its containing library becomes the **current_lib** of the session.

The syntax of parameter specification includes VHDL conventions plus the 'h, 'b, 'd, 'o constant literal forms from Verilog. Verilog accepts strings, integers, and "verilog number" values. VHDL also allows the concatenation operator ampersand (&) between two arrays or strings. Concatenating an array with a scalar is not supported. Define each named-parameter only one time; an error message issues if a name is defined more than one time.

Parameters are not case-sensitive, so NUM is the same as num. Characters inside string-values are case-sensitive, however.

The **-parameters** option must arrive as a single Tcl string token, but there are many ways to delimit it, split it across multiple input lines, and even to let the shell compute it. Typical parameter specifications are enclosed in double quotation marks ("), but this is not advised if the specification itself includes string values. Instead it can be written as a Tcl list \{inside curly braces\}. Even when using Tcl list notation, parameter specifications must be separated by a comma (,).

The formal syntax for the -parameter option is as follows:

```
param_option::=  [ param_list ] [ suffix ]

param_list::=  param_spec [ , param_spec ]*
        |   value_spec [ , param_list ]

param_spec::=  parameter_name => value_spec
        |   parameter_name = value_spec

value_spec::=  " string_value "
        |   ' character_value '
        |   integer_value
        |   enum_value
        |   ( value_spec [ , value_spec ]* )
        |   array_value_spec & array_value_spec
        |   integer_value 'h hex_value
suffix::=      | interface port, config, & defparam info
               (not user-settable)
```

EXAMPLES

The following example builds the design *mult* with *N* parameter set to 8, and *M* set to 3 leaving the result and also the templates with which to generate other variations inside a library called ELEMENTARY.

```
prompt> create_lib /remote/projects/function_libs/ELEMENTARY
prompt> analyze -format verilog \
   ~/my_function_designs/asymmetric/multiplier.v
prompt> elaborate -hdl_library LOGICAL mult -param "N=8,M=3"
```

enable_runtime_improvements

Enables off-by-default runtime improvement features to reduce place and route flow runtimes.

SYNTAX

status **enable_runtime_improvements**

DESCRIPTION

The **enable_runtime_improvements** command enables off-by-default runtime improvement features. Some of the runtime improvements are on-by-default and do not require any special settings to enable them. However, some of the runtime improvements are not yet on-by-default and this command enables those improvements. The improvements enabled by this command will be on-by-default in a future release.

This command can be run any time in the flow including before open_block.

EXAMPLES

The following example shows usage.

```
prompt> enable_runtime_improvements
```

SEE ALSO

error_info

Prints extended information on errors from the last command.

SYNTAX

string **error_info**

ARGUMENTS

This **error_info** command has no arguments.

DESCRIPTION

The **error_info** command is used to display information after an error has occurred. Tcl collects information showing the call stack of commands and procedures. When an error occurs, the **error_info** command can help you to focus on the exact line in a block that caused the error.

EXAMPLES

This example shows how **error_info** can be used to trace an error. The error is that the iterator variable "s" is not dereferenced in the 'if' statement. It should be '$s == "a" '.

```
prompt> foreach s $my_list {
?       if { s == "a" } {
?         echo "Found 'a'!"
?       }
?     }
Error: syntax error in expression " s == "a" "
      Use error_info for more info. (CMD-013)
shell> error_info
Extended error info:
syntax error in expression " s == "a" "
   while executing
"if { s == a } {
    echo "Found 'a'"
}"
   ("foreach" body line 2)
```

```
    invoked from within
"foreach s [list a b c] {
  if { s == a } {
    echo "Found 'a'"
}
}"
 -- End Extended Error Info
```

estimate_delay

Predicts endpoint slack per scenario at post-route in pre-route stages using machine learning (ML), and drives an incremental clock-opt optimization using ML-adjusted endpoint slack.

SYNTAX

status **estimate_delay**
[-training_labels "lStage"]
[-training_features "fStage lStage"]
[-train_model "fStage lStage"]
[-enable_model "fStage lStage"]
[-disable model]
[-output_dir "dir_path"]

Data Types

lStage string
fStage string
dir_path string

ARGUMENTS

-training_labels \flStage

Collects training labels (or, ground truth data for training) and stores it based on "lStage" tag provided by the user.
 User must specify "-output_dir <dir_path>" as well.

-training_features \ffStage lStage

Collects training features from "fStage", based on endpoints collected from "lStage" tag provided by the user in "-training_labels". User must specify "-output_dir <dir_path>" as well.

-train_model \ffStage lStage

Trains model based on features collected at "fStage", and labels at "lStage", tags provided by the user in "-training_labels" and "-training_features", respectively. User must specify "-output_dir <dir_path>" as well.

-enable_model \ffStage lStage

Enables model based on "fStage", and labels at "lStage", tags provided by the user in "-training_labels" and "-training_features", respectively. User must specify "-output_dir <dir_path>" as well. First, features are extracted. Second, endpoint slack values are predicted. Third, endpoint slack values are adjusted based on model predictions. User will see QoR summary before and after ML adjustments. Last, clock_opt engine is configured to run ML incremental clock_opt. Now, the user can run "clock_opt -from final_opto -to final_opto".

-disable model

Disables ML adjustments. User will see QoR summary before and after ML adjustments are removed.

DESCRIPTION

The **estimate_delay** command applies machine learning-based (ML-based) technology to adjust endpoint slack values at pre-route to post-route / route_opt values. The command is MCMM-aware, i.e., slack values are predicted per-scenario for each endpoint.

EXAMPLES

The following command collects labels or ground truth.

prompt> **estimate_delay -training_labels "lStage" -output_dir "dir_path"**

Currently, training labels are stored in "$dir_path/mlDelay/train/tLabels.lStage.NA.{min,max}.csv".

The following command collects training features.

prompt> **estimate_delay -training_features "fStage lStage" -output_dir "dir_path"**

Currently, training features are stored in "$dir_path/mlDelay/train/tFeatures.fStage_lStage.NA.{min,max}.csv".

The following command trains model.

prompt> **estimate_delay -train_model "fStage lStage" -output_dir "dir_path"**

Currently, model is stored in
"$dir_path/mlDelay/model/mlDelay.fStage_lStage.NA.{min,max}.pkl".

The following command enables the model.

prompt> **estimate_delay -enable_model "fStage lStage" -output_dir "dir_path"**

Extracted features are stored in "$dir_path/mlDelay/predict/pFeatures.fStage_lStage.NA.{min,max}.csv".
Predicted slack values are stored in "$dir_path/mlDelay/predict/pred.fStage_lStage.NA.{min,max}.csv".

The following command disables the model.

prompt> **estimate_delay -disable_model -output_dir "dir_path"**

estimate_timing

Performs virtual in-place optimization on the current design.

SYNTAX

status **estimate_timing**
[-host_options *host_options_name*]
[-pins *list_of_pins_or_ports*]
[-nets *list_of_nets*]

Data Types

list_of_blocks list
host_options_name string

ARGUMENTS

-host_options *host_option_name*

Specifies that the specified host option should be used for distributed processing. The host option is created with the **set_host_options** command. Note that only the part of **estimate_timing** that updates child blocks' views supports distributed processing so this option's effect depends on the design condition.

-pins *list_of_pins_or_ports*

Specifies the pins or ports for corresponding paths to run timing estimation. The switch is only applicable in the incremental mode, by default estimate_timing does timing estimation on the whole design.

-nets *list_of_nets*

Specifies the nets to run timing estimation. The switch is only applicable in the incremental mode, by default estimate_timing does timing estimation on the whole design.

DESCRIPTION

Performs virtual in-place optimization on the current design by simulating the effects of removing repeaters, building repeater trees and sizing cells. The simulated effects are stored as back-annotated transition times, delays and total net capacitances on the internally created artificial corner **estimated_corner**.

User can also specify **-nets** option or **-pins** option to do incremental timing estimation only on specific nets, or on paths through specific pins or ports. There should be a previous full *estimate_timing* run on the design prior to running in the incremental mode.

When the command is issued on a hierarchical design with child blocks, it first checks whether the reference view of the child blocks are acceptable to perform the virtual optimization at the current block level. Acceptable child block views are design view and timing abstract view with child level *estimate_timing* data. The timing abstract view with child level *estimate_timing* data are generated by *create_abstract -estimate_timing* command done at the child block level.

If the tool finds any child block that does not reference to one of the acceptable views, the command would open the child block's design view and run *add_feedthrough_buffer* to buffer any unbuffered feedthrough nets, then run *create_abstract -estimate_timing* to generate the appropriate timing abstract view, use change the block instance to reference to this timing abstract view, and continue with virtual optimization. The reference view change would happen to any child block unless the child block has *set_editability -value false* setting.

The *add_feedthrough_buffer* operation, which would be performed on a child block if *estimate_timing* needs to generate a new timing abstract view for it, would change the netlist. There are several app options which can be used to control the *add_feedthrough_buffer* done inside *estimate_timing*. You can do *report_app_options plan.estimate_timing.abstract** to find them.

This command returns 1 on success, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example performs virtual in-place optimization by using the artificial corner **estimated_corner**.

```
prompt> estimate_timing
```

SEE ALSO

current_corner(2)

plan.estimate_timing.abstract_add_feedthrough_buffer(3)
plan.estimate_timing.abstract_feedthrough_buffer_side(3)
plan.estimate_timing.abstract_feedthrough_logical(3)
plan.estimate_timing.abstract_feedthrough_user_buffer(3)

estimate_topology_timing

Estimate the timing of topology plans using net estimation rule information.

SYNTAX

longest_delay **estimate_topology_timing**
[-detail_level *level_value*]
[-routing *type*]
[-cell *type*]
[-significant_digits *digits_range*]
[-width *width_range*]
[-full_names]
[-list]

[*topology plans*]

Data Types

longest_delay float (in time units)
level_value 0 (default), 1 or 2
type "real" or "virtual"
digits_range integer, range 1 to 8
width_range integer >= 1

topology plans collection or list of names of topology plans to estimate

estimate_topology_timing.

ARGUMENTS

-detail_level *level_value*

Determines the amount of detail printed by **estimate_topology_timing**. The default value of 0 returns the longest delay of any given stage as the return value of the **estimate_topology_timing** command with no additional output.

Detail level 1 displays a header with the name of the plan, how many bits were timed (see *-cell* and *-routing* options) and the number of endpoints (for branching paths). A separate start-to-endpoint report is displayed for each unique start-to-endpoint path (i.e. each branch of the topology plan). For each segment, the "start" and "end" points of that segment are displayed, along with the incremental timing delay computed for this segment of the plan and the total cumulative delay to this point of the stage.

A stage is a set of segments that starts at the start pin/node and ends at the end pin/node or an intermediate topology repeater of type sequential (register or latch). Buffer/inverter segments are printed separately, but they do not end a stage. Cumulative timing is reset to 0.0 at the end of each stage.

The letter "F" is appended to any segment that ends in a sequential element (topology repeater of type "sequential"). The letter "W" is appended to the stage that has the worst overall delay of any stage in the plan. Incremental delay for each branch-path is the sum of the worst delay of each separate segment of the branch-path, and is reset at each sequential element (stage). This means that the estimated stage delay may be somewhat pessimistic, if the worst bit of each segment or stage is a different bit.

Detail level 2 adds display of the worst/best/average delay found for each of the bits tested for this segment, the "virtual" wire length for this segment, total "virtual" wire length for this stage as well as each virtual wire for this segment.

If more than one plan is estimated and detail is set to > 0, the worst plan name and its delay are also reported at the end of the report.

-routing *type*

Specifies the type of routing analysis to use - real or virtual. Virtual routing simply takes the topology edge points as actual routing data for each path. In virtual mode, every topology repeater has the same routing. In real mode, the actual routing shape associated with the nets of the topology plan are used to determine horizontal and vertical wire lengths, which have their delays measured using the net estimation rule for the associated topology edge.

If this parameter is not specified, the command tries to determine if real routing analysis is possible, and if so, uses real routing analysis. If it is not available, virtual routing analysis is performed. If real routing is specified and is not available, an error will be printed. If virtual routing analysis is specified, virtual routing analysis is performed with no check for real routing.

-cell *type*

Similar to the **-routing** option, this determines if actual repeater locations or topology repeater locations are used. There are several possible operating modes, between routing and cell options. for a more detailed explanation, read the "Analysis Summary" section. If real cells exist in the netlist and are associated with the appropiate topology repeater in the topology plan (for EVERY topology repeater in the plan), and each such cell is placed, real cell analysis is possible, otherwise only virtual cell analysis is possible.

If this parameter is not specified, the command tries to determine if real cell analysis is possible, and if so, uses real cell analysis. If it is not available, virtual cell analysis is performed. If real cell is specified and is not available, an error will be printed. If virtual cell analysis is specified, virtual cell analysis is performed with no check for real cell status.

-significant_digits *digits_range*

Rounds off all delay values to the specified number of significant digits. Default is 5, valid range is from 1 to 8.

-width *width_range*

Uses this many characters to print the names of the netlist elements at each segment (pins/ports/nodes/repeaters). Default is to use only as many as necessary. This can be used to increase that size for visual appeal or standardize on a specific size. If the given width is smaller than the required size, a warning is printed and the width value is ignored.

-full_names

By default, topology node and repeater names are printed only with the name of that topology plan element. However, if a reference node is encountered (a reference to a node that is part of another plan), all elements from that other plan are merged into the current plan. All such merged elements are printed with the "full" name format: block/plan/name. Specifying the -full_names option will use the full block/plan/name format for EVERY element in the report.

-list

Instead of returning the single worst delay of the plans that were estimated, returns a Tcl list of the form "{plan1 0.15} {plan2 -1.0} ... {planN 0.325}". If an error occurs (any delay is set to -1.0), the list is still returned, but an error condition is also set. To capture the return value in this case, it is suggested to use: set rc [catch {estimate_topology_timing ...} output] and the value of the variable output will contain the list of delays.

topology plans

The default is to report on all topology plans in the current block. To estimate specific plans, including plans in other blocks, use

this option with either exact plan names or wildcards

DESCRIPTION

This command builds a simplified timing graph of a topology plan, and uses net estimation rules to estimate the delay through the various parts of this topology plan.

Each sequential repeater (register/flip flop or latch) ends a timing stage. At the end, the worst timing stage is reported as the worst delay of the topology plan.

Net estimation rule timing (similar to estimate timing and the timing ruler) is used. A net estimation rule must have valid layers set, register/buffer cells set (not "--ideal--"), a valid corner set and parasitics must be loaded in order to use this command.

Resistive and capacative values are obtained from the net estimation rule layer information, as well as the specific buffer pin and register pin delay values.

Launch and capture budgets specified on the initial topology plan are added to the first and last stage, respectively.

Empty nodes / virtual nodes / tap nodes (nodes without any pins/cells) are modeled simply as additional wires that are then associated with each of their child edges. Since these nodes are used for routing purposes, their only contribution to the computed delay is a wire-type delay. Therefore, not all nodes that are part of the original topology plan will be explicitly printed in a detail report.

Analysis Summary

There are several routing/cell modes possible for analyzing a plan.

Virtual routing / virtual cells ***In this mode, the points of the edge are used as the route points, and the origin of each node and repeaters are used as the origin. No special offsets of any kind are used, and only 1 bit per segment is timed.***

Virtual routing / real cells ***In this mode, an offset from the origin of each std cell is added as an additional horizontal and/or vertical wire to the actual node/repeater origins. In this way, std cells in a repeater array that are further from the origin of the virtual repeater will have longer delays added to estimate a worse overall timing delay. One bit per repeater is timed per segment, so the command will time all n bits of the plan.***

Real routing / virtual cells ***Since there is no actual indication of which part of the routing is associated with each repeater, a ratio of "virtual routing length" (topology edge length) to actual routing shape length is computed, and then each repeater is given the portion of the real route shapes/lengths that are associated with that repeater. For example, suppose a topology edge has a virtual length of 100, with virtual repeaters at offset 20, 50 and 75 and the routing shapes for the actual net have real length 150. Then, the first (150 / 100) * 20 = 30 units of the real route are allocated to the first repeater, the next 45 units to the second repeater, the next 37.5 units to the third repeater, and the last 37.5 units from the last repeater to the end pin/port.***

If the edge has no repeaters, then the route shapes are used, and an offset is added if the route shapes do not start/end at the pins associated with the start/end nodes of the edge.

One bit per route is timed, so the command will time all n bits of the plan.

Real routing / real cells ***Actual route shapes for all the nets of each stage are added up. All n bits of the plan are timed.***

KNOWN LIMITATIONS

Currently, all folded edges in the topology plan must have the same number of folds.

This report is NOT intended to correlate to the report_timing command, since significantly less information is used to compute the delay in order to improve the performance of the computation. The values returned by this command are only an estimate. If the

uesr inputs inappropriate values for register/buffer cells or spacing values or uses incorrect parasitic data, the computed delay values can be significantly different from actual delays.

EXAMPLES

The following example estimates topology timing for plan_1 with default detail level (level 0):

```
prompt> estimate_topology_timing topo_1
0.10882
prompt>
```

The following example estimates topology timing for plan_1,
with detail level 1, width 25 and significant digts 3. This plan has only
virtual repeaters and virtual routing, so only 1 bit is timed.

```
prompt> estimate_topology_timing topo_1 -detail 1 -width 25 -significant_digits 3

eval_checkpoint

Creates a checkpoint on a block of Tcl commands.

SYNTAX

integer **eval_checkpoint**
checkpoint_name
tcl_commands

Data Types

checkpoint_name string
tcl_commands list

ARGUMENTS

checkpoint_name

Specifies the name of the checkpoint for the checkpoint system.

tcl_commands

Specifies the Tcl command block that is defined as a checkpoint.

DESCRIPTION

Creates a checkpoint name for a block of Tcl commands, and evaluates that block of commands. When a block of Tcl is checkpointed, the user can then associate a set of actions or reports to run at that checkpoint.

The checkpoint name should be a Tcl string (without spaces) that is descriptive of the Tcl command steps being checkpointed. Every checkpoint name in the system must be unique. If a non-unique name is given, a number is automatically incremented and appended to the end until a unique name is achieved. For example: if a checkpoint named place_design already exists and a new eval_checkpoint is executed with the same checkpoint name, it will use the name place_design2 instead.

The Tcl command list that is executed by the checkpoint can be any valid Tcl. This includes a single Tcl command (with or without options), a block of multiple Tcl commands, or no Tcl commands (either exclude the command_list option or provide an empty Tcl string with "" or {}).

If an eval_checkpoint statement is nested inside another eval_checkpoint statement, then the inner one will be ignored. The enclosed Tcl commands for the inner eval_checkpoint will be evaluated as though no eval_checkpoint statement was present.

When an eval_checkpoint command is evaluated, the following sequence of steps occur in order:

- Runs any reports specified to run before the checkpoint using associate_checkpoint_report -before
- Runs any actions specified to run before the checkpoint using associate_checkpoint_action -before
- Runs the checkpointed block of Tcl commands. Alternately, this is skipped and any actions specified to run as a replacement for the checkpointed Tcl using associate_checkpoint_action -replace are run.
- Runs any actions specified to run after the checkpoint using associate_checkpoint_action -after
- Runs any reports specified to run after the checkpoint using associate_checkpoint_report -after

EXAMPLES

Creates a checkpoint named multibit and evaluates the identify_multibit command.

```
prompt> eval_checkpoint multibit { identify_multibit -register -apply }
```

Creates a checkpoint called placement_constraints and evaluates multiple Tcl commands.

```
prompt> eval_checkpoint placement_constraints {
  source ./scripts/placement_app_options.tcl
  source ./scripts/placement_blockages.tcl
  source ./scripts/placement_bounds.tcl
}
```

Creates a checkpoint named route_final and evaluates no Tcl. This checkpoint only exists as a reference point to associate with ac

```
prompt> eval_checkpoint route_final {}
```

eval_pg_ml_model

Evaluate the quality of the trained PG ML model for fixability prediction.

SYNTAX

status **eval_pg_ml_model**

Data Types

ARGUMENTS

DESCRIPTION

This command evaluates the quality of the trained PG ML model by outputing the following ML prediction results: true_negative, false_negative, true_positive, and false_positive based on ML model and ML data in memory.

For example,

---------- testing report ---------- Unfixable: 1078 , Fixable: 346 True Negative: 1078, Ratio: 100.00% False Negative: 0, Ratio: 0.00% True Positive: 341, Ratio: 98.55% False Positive: 5, Ratio: 1.45%

EXAMPLES

The following example evaluates PG ML model stored in the directory ./pg_model with respect to ML data in memory.

```
prompt> compile_pg -create_ml_data
prompt> eval_pg_ml_model
```

SEE ALSO

compile_pg(2)
train_pg_ml_model(2)

eval_with_undo

Executes a command or set of commands with undo-related settings applied.

SYNTAX

string **eval_with_undo**
[-atomic *name*]
[-disable]
commands

Data Types

name string
commands string

ARGUMENTS

-atomic *name*

Make the execution of *commands* appear on the undo command stack as though it were a single command level with name *name*.

-disable

Disable the recording of undo history during the execution of *commands*.

commands

The Tcl command or set of commands to execute with the applied undo settings.

DESCRIPTION

This command executes a set of Tcl commands as a single unit, with the option of disabling undoability of the commands in *commands*. If you use the **-atomic** option, the execution of the commands in *commands* appears as a single command with name *name* in the undo stack, and undoing *name* restores the database to the state before the execution of this command.

If you use the **-disable** option, undo is disabled for the duration of the command. It has the side effect of clearing the undo history. It is used in situations where it is known a priori that undo will not be necessary, and hence eliminates the runtime and memory overhead necessary to build and store undo data for the command. This option is most useful in cases where the magnitude of the expected changes is large. This command with the **-disable** option is the equivalent to the following sequence:

```
set undo [get_app_option_value -name shell.undo.enabled]
set_app_options -name shell.undo.enabled -value false
eval {commands}
if { $undo == "true" } { set_app_options -name shell.undo.enabled -value true }
```

The return value is that returned by the last Tcl command in *commands*.

EXAMPLES

The following example executes link_design with undo temporarily disabled:

```
prompt> eval_with_undo -disable { link_design }
```

SEE ALSO

undo(2)
redo(2)
create_undo_marker(2)

exec_gds2rh

Generates a Redhawk macro model using the RedHawk *gds2rh* utility.

SYNTAX

status **exec_gds2rh**
-config_file *config_file*

Data Types

string *config_file*

ARGUMENTS

-config_file *config_file*

Specifies a configuration file for RedHawk *gds2rh* utility.

DESCRIPTION

This command generates a Redhawk macro model by using RedHawk *gds2rh* utility with user-provided configuration file. This command does not check if there is any syntax error in the user configuration file.

EXAMPLES

The following example generates a RedHawk macro model using the user-provided configuration file as an input.

```
prompt> set_app_options -rail.redhawk_path -value /install_path/bin
prompt> exec_gds2rh user.config
```

SEE ALSO

analyze_rail(2)
set_app_options(2)

exit

Terminates the application.

SYNTAX

integer **exit**
[*exit_code*]

Data Types

exit_code integer

ARGUMENTS

exit_code

Specifies the return code to the operating system. The default value is 0.

DESCRIPTION

This command exits from the application. You have the option to specify a code to return to the operating system.

If there are pending jobs from **redirect -bg, then exit will wait for the jobs to complete before exiting.**

EXAMPLES

The following example exits the current session and returns the code 5 to the operating system. At a UNIX operating system prompt, verify (**echo**) the return code as shown.

```
prompt> exit 5

% echo $status
5
```

SEE ALSO

quit(2)

expand_objects

Expands the specified objects by moving each side out until it touches another object or the core boundary; in this case the number of sides is retained. Alternatively, the command expands the object to fill available space around it; in this case the number of sides is not retained.

SYNTAX

status **expand_objects**
[*object_list*]
[-side left | right | top | bottom | all]
[-offset *offset*]

Data Types

object_list collection
offset float

ARGUMENTS

object_list

Collection or selection set containing objects to expand. If this option is not specified, the global selection set is used.

-side left | **right** | **top** | **bottom** | **all**

Specifies the side of the object to expand. Use multiple **expand_objects** commands to expand the object on more than one side. The default is all, which expands the object to all sides.

-offset *offset*

Specifies the spacing between the sides and the surrounding objects. The offset value can be a negative or positive float value. The default is 0.0.

DESCRIPTION

This command expands an object's sides until they touch another object or the core boundary.

The expansion is done by moving each specified object side outwards until it hits one the specified object types. The types of objects considered for collisions can specified by **set_edit_settings** command.

If an offset is specified then the resultant shape's selected sides are shrunk (or grown in the case of negative offsets) by this offset after expansion.

If the operation results in an invalid object boundary (self overlapping) the command will fail.

Snapping is done automatically using global snap settings.

EXAMPLES

The following example resizes the alu1 cell so that it's bounding box is 20 units from any of the collision objects in all directions.

prompt> **expand_objects -side all -offset 10**

The alternative syntax uses collection to specify objects.

prompt> **expand_objects [get_selection] -side all -offset 10**

get_edit_setting(2)
get_selection(2)
set_edit_setting(2)

expand_outline

Expands the outline representation for a design into the full design representation. The command reads the original Verilog netlist to perform the expansion.

SYNTAX

string **expand_outline**
[-design *design_name*]
[-force]
[-strip *prefix_list*]
[-keep]
[-no_def]

Data Types

design_name string
prefix_list list

ARGUMENTS

-design *design_name*

Specifies the name of the design to expand.

-force

Forces the tool to reread the Verilog file.

-keep

Keeps the outline design open after expansion.

-no_def

Prevents reading of the DEF file during design expansion.

-strip *prefix_list*

Specifies a list of path names to remove from file names when searching.

DESCRIPTION

The **expand_outline** command rereads the Verilog files containing the modules for an outline design and generates a full design representation. The tool reads only the parts of the Verilog files containing the modules in the specified outline design.

The original Verilog files must be in the same location as when the **read_verilog_outline** command was run. If the files are not found in their original location, the tool searches for them by using the *search_path*. The **-strip** option removes file path name prefixes when searching with the *search_path*. If the files are modified, the tool skips them unless you specify the **-force** option.

After successful expansion, the tool closes the outline design representation. If the outline design is not referenced or modified, it is removed from memory. Specify the **-keep** option to retain both the outline design and the expanded design in memory.

Use the **-force** option with caution. The modules in each Verilog file are referenced by their original line numbers assigned by the **read_verilog_outline** command. If the line number location of a module changes for any reason, such as inserting a comment or deleting a blank line, the **expand_outline** command will fail to expand the module.

The **expand_outline** command behaves in a similar way to the **read_verilog** command. See the **read_verilog** command documentation for more information on options and variable settings.

EXAMPLES

In the following example, the **read_verilog_outline** command reads the r4000.v compressed Verilog netlist and creates an outline design. The **commit_block** command creates a separate design for the alu. The **expand_outline** command rereads the Verilog netlist and expands the top design.

```
prompt> set_ref_libs -ref_libs {"tcbn90ghvt" "tcbn90glvt"}
tcbn90ghvt tcbn90glvt
prompt> read_verilog_outline -top r4000 r4000.v.gz

search_path(3)

explore_logic_hierarchy

Creates or removes module boundaries in the GUI to help analyze the logical hierarchy and prepare for committing blocks. The command converts all top-level logical hierarchies, or only specified hierarchies, and displays the result in the GUI. Use this command to determine which logical hierarchies should be converted to physical hierarchies by analyzing the module boundaries sizes, macro contents, and connectivity. For a flattened design, use **set_app_options -list { plan.place.hierarchy_by_name true}** to extract the name-based virtual hierarchies and create the corresponding move bounds of the virtual hierarchies for exploration.

SYNTAX

collection **explore_logic_hierarchy**
[-cell *cell_names*]
[-threshold *percent_value*]
[-utilization *utilization_value*]
[-virtual_group *module_boundary_names*]
[-name *new_module_boundary_name*]
[-virtual_ungroup *module_name*]
[-output *file_name*]
[-create_module_boundary |
-expand |
-collapse |
-remove |
-organize |
-force |
-place |
-use_existing_placement |
-rectangular]
[-nested]

Data Types

cell_names string
percent_value float
utilization_value float
module_boundary_names collection
new_module_boundary_name string
module_name string
file_name string

ARGUMENTS

-cell *cell_names*

Specifies the cell names of the logical hierarchies to process. You must specify one or more valid cell names together with the **-expand** or **-collapse** option. By default, the command processes all logical hierarchies at the top level. For a flattened design with

set_app_options -list { plan.place.hierarchy_by_name true}, specify virtual hierarchy names to be explored.

-threshold *percent_value*

Specifies the minimum block size to process. This option is valid only when option **-create_module_boundary** or option **-expand** is specified. If the *percent_value* is less than zero, the tool issues a warning message and sets the value to zero. By default, the *percent_value* is 0.03 and any logical hierarchy whose size is smaller than 3 percent of total size is ignored with option **-create_module_boundary**, and any child hierarchy whose size is smaller than 3 percent of the size of current expanding hierarchy is ignored with option **-expand**.

The default value of 0.03 can be changed using the global application option **plan.explore.default_threshold**.

If the **-cell** option is specified together with option **-create_module_boundary**, the **-threshold** option is ignored as the cells to be processed have been explicitly specified.

-utilization *utilization_value*

Specifies the utilization value when creating the boundary for a logic hierarchy. If the specified value is less than zero, this option is ignored and the design utilization is used. Valid utilization values are between 0.01 and 10. By default, the design utilization value is used. This option only works with the **-create_module_boundary** and **-expand** options.

-virtual_group *module_boundary_names*

Creates a module boundary by combining the specified module boundaries. The module boundaries specified in *module_boundary_names* are not required to belong to a single logical hierarchy. This option needs to be used together with the **-name** option. For the flattened design with **set_app_options -list { plan.place.hierarchy_by_name true}**, the existing virtual hierarchy move bounds to be grouped are specified.

-name *new_module_boundary_name*

Specifies the name of the new module boundary to be created. This option can only be used together with the **-virtual_group** option.

-virtual_ungroup *module_name*

Specifies the name of a grouped module boundary to ungroup.

-output *file_name*

Writes a file that contains the module boundary names and virtual group names.

-create_module_boundary

Creates a module boundary for the input hierarchy specified by the **-cell** option. If the **-cell** option is omitted, the **-create_module_boundary** option removes all module boundaries and re-creates the module boundaries for all top-level logic hierarchies, based on the **-threshold** option setting.

-expand

Expands an existing module boundary into subhierarchies. The command removes the existing module boundary for the specified hierarchy and creates a new hierarchical boundary for each subhierarchy. The tool creates new module boundaries for subhierarchies with a size larger than the threshold. The input logical hierarchy must be a module boundary, otherwise it cannot be expanded.

The tool removes the original module boundary and creates the new hierarchical boundaries on top of the original location. The new boundaries might overlap other existing module boundaries. The expanded module boundaries are selected in GUI; you can hand edit the locations to remove overlaps.

-collapse

Collapses the input hierarchy into its parent hierarchy. The tool removes all child module boundaries of the parent hierarchy and

creates a new module boundary for the parent.

-remove

Removes one or more module boundaries. If you specify **-cell cell_names**, the tool removes only the specified boundaries. If you do not specify the **-cell** option, the tool removes all module boundaries. The tool places macros from the module boundary to the upper-right of the design boundary.

-organize

Rearranges the existing module boundaries, top-level macros, and pads of which the physical status is unplaced into three predefined regions. After experimenting with different module boundary placements, you can use this option to set the module boundary to rectangular and reset the placements.

-force

Forces the tool to expand the hierarchy, even if it has no connectivity.

-place

Shows a placement of the module boundaries into the floorplan boundary. The module boundaries with "fixed" attribute and the blocks (committed cells) are treated as fixed (i.e., location is not changed) when other module boundaries are placed.

-use_existing_placement

Places module boundaries based on their existing placement, rather than using the result from a new placement run. This option is valid only when used with the **-place** option.

-rectangular

Restricts the shape of the module boundaries to be rectangular shapes only. Use this option together with the **-place** option. If you specify the **-place** option without the **-rectangular** option, the tool can create nonrectangular module boundaries to reduce the overlap between boundaries.

-nested

By default nested module boundaries are not allowed. For example, you cannot use "-create_module_boundary" to create module boundaries for hierarchy A and hierarchy A/B at the same time. With this option, nested module boundaries are allowed. Behavior of other options like "-expand", "-collapse", and "-place" are changed to create a nested result.

DESCRIPTION

The **explore_logic_hierarchy** command creates, removes, and places module boundaries to enable hierarchy and floorplan exploration in the GUI. You can create module boundaries for all top-level logical hierarchies, or select specific hierarchies by using the **-cell** option. Use this command to determine which logical hierarchies should be converted to physical hierarchies based on the size of the module boundaries, number of macros, and connectivity.

You can specify only one of the **-expand**, **-collapse**, **-remove**, and **-create_module_boundary** options.

This command returns TCL_OK on success with a collection of created objects, TCL_Error otherwise.

EXAMPLES

The following example creates module boundaries for all top-level logical hierarchies with a cell size larger than 1 percent of the total cell size. This is normally the first exploration option to apply.

```
prompt> explore_logic_hierarchy -create_module_boundary -threshold 0.01
```

The following example expands the input logical hierarchy named "I_ORCA_TOP".

```
prompt> explore_logic_hierarchy -cell I_ORCA_TOP -expand
```

The following example collapses the input logical hierarchy "I_ORCA_TOP/I_PCI_TOP" into its parent "I_ORCA_TOP".

```
prompt> explore_logic_hierarchy -cell I_ORCA_TOP/I_PCI_TOP -collapse
```

The following example removes the module boundary for "I_ORCA_TOP/I_PCI_TOP".

```
prompt> explore_logic_hierarchy -cell I_ORCA_TOP/I_PCI_TOP -remove
```

The following example places the module boundaries of the design.

```
prompt> explore_logic_hierarchy -place
```

SEE ALSO

initialize_floorplan(2)

export_advanced_technology_rules

Exports advanced technology placement rules from the current design for consumption by PrimeTime-ECO.

SYNTAX

status **export_advanced_technology_rules**
output_file
[-exclude_lib_cells *lib_cells*]
[-use_implant_layer_names]
[-attach]

Data Types

output_file string
lib_cells collection

ARGUMENTS

output_file

File name for output.

-exclude_lib_cells

Collection of library cells to exclude from color-based spacing rule processing. This option may be used to reduce command runtime if you know that certain library cells are not intended for use. By default, the command processes all library cells from all reference libraries attached to the current block.

-attach

Attaches the output of the command to the NDM design library for the design. This option does not affect the creation of the output file. By default, the command output is not attached to the NDM.

-use_implant_layer_names

Uses the VT implant layer names that correspond to the names in the technology file. By default, the command writes out abstracted layer names.

DESCRIPTION

This command exports all advanced technology placement rules, as well as all inter-cell spacing rules that have been set by the user, in the current design. The output of the command is encrypted. You can optionally choose to attach the output of the command

to the NDM of the current design as well.

SEE ALSO

report_placement_spacing_rules(2)
set_placement_spacing_label(2)
set_placement_spacing_rule(2)

extract_model

Creates Extracted Timing Model (ETM) library for the current block.

SYNTAX

status **extract_model**
[-lib_name *lib_name*]
[-etm_lib_work_dir *dir_name*]

Data Types

lib_name string
dir_name string

ARGUMENTS

-lib_name *lib_name*

Specifies the ETM library name. By default, the tool will generate ETM library with the same name as the top module name of the current block.

-etm_lib_work_dir *dir_name*

Specifies the directory where ETM library creation files and logs are generated. If you don't specify a working directory, a directory with the name ETM_Lib_work_dir is created under your current working directory.

DESCRIPTION

This command generates Extracted Timing Model (ETM) Library.

When the extract_model command executes, the following actions happen:

- Generates PrimeTime setup based on IC Compiler II multi scenario
- Invokes Distributed Multi Scenario Analysis (DMSA) PrimeTime under the hood unless PrimeTime has started already
- Runs multi scenario timing updates
- Generates Extracted Timing Model (ETM). If you want to influence ETM generation using any PrimeTime extract_model* variables, include the same in a file and provide the file as an argument to set_pt_options -post_link_script option.
- Invokes IC Compiler II Library Manager (icc2_lm_shell) to assemble ETM.db with the frame view to create ETM library. By

default, the tool will write out the generated ETM library into [pwd]/ETM_Lib_work_dir/block_name/label_name/ directory for labelled blocks and [pwd]/ETM_Lib_work_dir/block_name/ for non-labelled blocks. If you specify a value to etm_lib_work_dir, the tool will then write into [pwd]/<etm_lib_work_dir>/block_name/label_name/ for labelled blocks and [pwd]/etm_lib_work_dir/block_name/ for non-labelled blocks.

Multi-Level Hierarchy Support To generate an ETM library at the parent level, the child blocks must be linked to design views. In addition, full chip timing constraints should be provided using set_pt_options -scenario_constraints.

EXAMPLES

The following example script shows how to use extract_model to generate ETM library. The ETM library name would be the top module name of block block.design which would be created in [pwd]/ETM_Lib_work_dir/block/

```
icc2_shell> open block.nlib:block.design
icc2_shell> create_frame <options>  ;# extract_model needs Frame for library preparation
icc2_shell> set_pt_options -pt_exec_path <> \
        -post_link_script <tcl script with extract_model* variables> \
        -work_dir ETM_work_dir
icc2_shell> extract_model
```

The following example shows the creation of ETM library with user specified name using -lib_name. The ETM library my_etm_lib would be created in [pwd]/ETM_Lib_work_dir/block/test/

```
icc2_shell> open block.nlib:block/test.design
icc2_shell> create_frame <options> ;# extract_model needs Frame for library preparation
icc2_shell> set_pt_options -pt_exec_path <> \
        -post_link_script <tcl script with extract_model* variables> \
        -work_dir ETM_work_dir
icc2_shell> extract_model -lib_name my_etm_lib
```

The following example shows how to redirect ETM library creation data using -etm_lib_work_dir option. The ETM library my_etm_lib would be created in [pwd]/<my_etm_work_dir>/block/test/

```
icc2_shell> open block.nlib:block/test.design
icc2_shell> create_frame <options> ;# extract_model needs Frame for library preparation
icc2_shell> set_pt_options -pt_exec_path <> \
        -post_link_script <tcl script with extract_model* variables> \
        -work_dir ETM_work_dir
icc2_shell> extract_model -lib_name my_etm_lib -etm_lib_work_dir my_etm_work_dir
```

extract_svf

Extracts checkpoints from the specified .svf file.

SYNTAX

status **extract_svf**
[-dir *directory*]
[-ckpt *checkpoints*]
[-list]
file_name

Data Types

file_name string
directory string
checkpoints list

ARGUMENTS

-dir

Specifies the directory to save the extracted checkpoints. This option is mutually exclusive with the **-list** option.

-ckpt

Specifies a list of checkpoints to extract. If this option is not specified, all checkpoints will be extracted.

-list

Lists available checkpoints with the specified *file_name*. This option is mutually exclusive with the **-dir** option.

file_name

Specifies the .svf file that contains the checkpoints to extract.

DESCRIPTION

This command extracts checkpoints within the .svf file if there are any.

EXAMPLES

In the following example, the **extract_svf** command extracts the ckpt_logic_opt checkpoints and saves them to the directory named output.

```
prompt> extract_svf -ckpt "ckpt_logic_opt" -dir output my.svf
1
```

SEE ALSO

set_svf(2)

filter_collection

Filters an existing collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

collection **filter_collection**
[-regexp]
[-nocase]
collection1
expression

Data Types

collection1	collection
expression	string

ARGUMENTS

-regexp

Specifies that the =~ and !~ filter operators will use real regular expressions. By default, the =~ and !~ filter operators use simple wildcard pattern matching with the * and ? wildcards.

-nocase

Makes the pattern match case-insensitive.

collection1

Specifies the base collection to be filtered. This collection is copied to the result collection. Objects are removed from the result collection if they are evaluated as **false** by the conditional *expression* value. Substitute the collection you want for *collection1*.

expression

Specifies an expression with which to filter *collection1*. Substitute the string you want for *expression*.

DESCRIPTION

Filters an existing collection, resulting in a new collection. The base collection remains unchanged. In many cases, application commands that create collections support a *-filter* option that filters as part of the collection process, rather than after the collection has been made.

This type of filtering is almost always more efficient than using the **filter_collection** command after a collection has been formed. The **filter_collection** command is most useful if you plan to filter the same large collection many times using different criteria.

The **filter_collection** command results in either a new collection or an empty string. A resulting new collection contains the subset of the objects in the input *collection1*. A resulting empty string (the empty collection) indicates that the *expression* filtered out all elements of the input *collection1*.

The basic form of the conditional expression is a series of relations joined together with AND and OR operators. Parentheses () are also supported. The basic relation compares an attribute name with a value through a relational operator.

For example,

```
is_hierarchical == true and area <= 6
```

If an attribute is a collection attribute that contains a single object, then you can query an attribute value from that object using "." to name the attribute on the other object. The "." operator can be chained. For example.

```
owner.is_hierarchical == true and owner.area <= 6
shape.net.name==reset
```

The value side of a relation can be a simple string, quoted string, or an attribute name prefixed with "@". For example:

```
input_delay<=@output_delay
input_delay<=0.24
name=="@literal_name"
```

The relational operators are

```
==   Equal
!=   Not equal
>    Greater than
<    Less than
>=   Greater than or equal to
<=   Less than or equal to
=~   Matches pattern
!~   Does not match pattern
```

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only either *true* or *false*.

Existence relations determine if an attribute is defined or not defined for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
!defined
```

These operators apply to any attribute as long as it is valid for the object class.

Collection attributes support a special sizeof(attrName) operator that returns the number of objects in the attribute. If the attribute is not set then 0 is returned.

The **filter_collection** command has a *-regexp* option that uses regular expressions when matching for string attributes. Regular

expression matching is done in the same way as in the Tcl **regexp** command. When using the *-regexp* option, take care in the way you quote the filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended.

Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed. You can make the regular expression search case-insensitive by using the *-nocase* option.

If the application variable filter_collection_extended_syntax is true then mathematical expressions are supported too. All function names must be prefixed with the '#' in order to disambiguate the function names from subscripted attribue names (i.e. "#sin(attr)"). In order to use a math expression on the right hand side of a comparison, the expression must be contained in parenthesis. This is required for backward compatibility with the legacy expression syntax as strings on the right do not require quoting.

When extended syntax is on filters can also match against glob style subscript patterns (i.e. "input_delay(*)<1.0"). In that case the term evaluates to true if any subscript satisfies the condition.

Additionally when extended syntax is on, a filter may refer to nested attributes that may imply multiple objects in a collection (i.e. "pins.capacitance==0.2"). In that case the term returns true if any of the objects referred to in the have an attribute value satisfying the condition.

EXAMPLES

The following example from PrimeTime creates a collection of only hierarchical cells.

```
pt_shell> set a [filter_collection [get_cells *] \
"is_hierarchical == true"]
{"Adder1" "Adder2"}
```

The following example from PrimeTime uses existence operators to create a collection of all nonmoded cell timing_arc objects in the current design.

```
pt_shell> set b [filter_collection \
        [get_timing_arcs -of_objects [get_cells *]] \
        "undefined(mode)"]
```

The following example finds all cells from {U0(1) U1(1) U0(0) U1(0)}
with the index (0). Notice the round brackets used for the index.

```
pt_shell> filter_collection -regexp [get_cells] {full_name =~ "U.*\(0\)"}
{U0(0) U1(0)}
```

The following example finds all ports from in[18] to in[23]. The placement of double quotes and backslashes is necessary to avoid syntax errors.

```
pt_shell> filter_collection [get_ports] -regexp {name=~ "in\[(1[8-9]|2[0-3])\]"}
{in[23] in[22] in[21] in[20] in[19] in[18]}
```

The following example finds the U2 and U4 cells, using the -nocase option:

```
pt_shell> filter_collection [get_cells] -regexp -nocase {name =~ u[24]}
{U2 U4}
```

find_objects

Finds logical hierarchy objects within a scope. This is a UPF query command.

SYNTAX

list **find_objects**
scope
-pattern *pattern_string*
[-object_type inst | port | net | model | supply_port | process]
[-direction in | out | inout]
[-transitive true | false]
[-traverse_macros]
[-non_leaf]
[-leaf_only]
[-exact]
[-regexp]
[-ignore_case]

Data Types

scope string
pattern_string string

ARGUMENTS

scope

Specifies the scope within which to search for logical hierarchy objects.

-pattern *pattern_string*

Specifies a search pattern. By default, the pattern is treated as a Tcl glob expression.

-object_type inst | port | net | model | supply_port | process

Searches only for the specified object type.

The keyword values have the following definitions:

- **inst** (cell instance)
- **port** (design port)
- **net** (net)
- **model** (model or lib cell)

- **supply_port** (supply port)
- **process** (named process)

If **-object_type model** is specified, **find_objects** searches for instances of any model or lib cell whose name matches the *pattern_string*.

If you do not specify the **-object_type** option, instances, named processes, ports, and nets are searched.

-direction in | **out** | **inout**

Restricts the direction of the searched ports and supply ports.

This option has an effect only when ports and supply ports are included in the search.

-transitive true | **false**

Controls whether the descendants of the elements are included in the search.

By default (**false**), the descendants are not included in the search.

-traverse_macros

Controls whether the command would descend and traverse all hierarchies without stopping at any boundary marked as "soft_macro" or "terminal_boundary" by **set_design_attribute**.

If **-traverse_macros** is specified, then **-transitive TRUE** is implicitly specified.

By default, the searching will be stopped at any boundary marked as "soft_macro" or "terminal_boundary".

-non_leaf

Limits the search to only nonleaf design elements (elements that have child elements).

If you do not specify the **-non_leaf** or **-leaf_only** option, both leaf and non-leaf design elements are searched.

-leaf_only

Limits the search to only leaf-level design elements (elements without child elements).

If you do not specify the **-non_leaf** or **-leaf_only** option, both leaf and non-leaf design elements are searched.

-exact

Disables the default Tcl glob pattern matching. For use when searching for objects that contain the * and ? wildcard characters as part of their names.

The **-regexp** option is mutually exclusive with the **-exact** option

-regexp

Option to interpret and match the given pattern as a regular expression rather than a Tcl glob expression

The **-regexp** option is mutually exclusive with the **-exact** option

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *pattern*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name.

Note that the use of the "/" to match the hierarchy separator is only allowed with "glob" type matching; it is not allowed with **-regexp**. Even though the "/" is not treated as hierarchical separator in regular expression mode, it will be treated as normal alphabet to compare base name. In the EXAMPLES section you can find an example to show this.

-ignore_case

Performs case insensitive searches. By default, all matches are case sensitive.

DESCRIPTION

The **find_objects** command finds logical hierarchy objects within a scope. It returns a list of the found hierarchical names relative to the active scope; when nothing is found, it returns a null string.

This is a UPF query command. The command would use of the "/" to match the hierarchy separator with "glob" type matching, and this behavior is different from other netlist query command, like **get_cells**, **get_pins**, etc.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Here are some examples of usage of the command.

```
prompt> find_objects a -pattern * -object_type inst \
  -transitive TRUE -non_leaf
a/b1 a/b2
```

Suppose we have "bot" module/lib_cell instantiated in the design with instances "a/b1", "a/b2", and "b1". With find_objects we can see following results.

```
prompt> find_objects . -object_type model -pattern bot -non_leaf \
 -transitive TRUE
a/b1 a/b2 b1
```

Suppose we have a design which has instances "a1", "x1", "a2/b2/c" and "x2". "x1" has "a1", "a1" has "b1", and "b1" has "c"; "x2" has "a2/b2/c". With find_objects, we can see the results as follows. With **-transitive true** we can get all leaf instance names in the design with pattern *a*/b*/c*.
Note that in case of transitive, the pattern should match the last string, that's to say, when we use pattern x1/a1/b1*, we can't get the instance x1/a1/b1/c:

```
prompt> find_objects . -pattern a*/b*/c -object_type inst -transitive true
a1/b1/c a2/b2/c x1/a1/b1/c x2/a2/b2/c
prompt> find_objects . -pattern a*/b*/c -object_type inst -transitive false
a1/b1/c a2/b2/c
prompt> find_objects . -pattern x1/a1/b1* -object_type inst -transitive true -leaf_only
prompt> find_objects . -pattern a2/b2/c -object_type inst -regexp
Warning: The use of the '/' to match the hierarchy separator is only allowed
with glob type matching; it is not allowed with -regexp. (UPF-366)
a2/b2/c
prompt> find_objects . -pattern a1/b1/c -object_type inst -regexp
Warning: The use of the '/' to match the hierarchy separator is only allowed
with glob type matching; it is not allowed with -regexp. (UPF-366)
```

Use the design in the previous example. Suppose we mark instance x2 as "terminal_boundary" using **set_design_attribute**. We can see the command won't return the instances below **x2** without **-traverse_macros**.

```
prompt> find_objects . -pattern a*/b*/c -object_type inst -transitive true
a1/b1/c a2/b2/c x1/a1/b1/c
prompt> find_objects . -pattern a*/b*/c -object_type inst -traverse_macros
a1/b1/c a2/b2/c x1/a1/b1/c x2/a2/b2/c
```

fix_floorplan_rules

Move macros or create routing or placement blockages to fix violations of related floorplan spacing, enclosure, halo, area and width rules, and output a Tcl file to record the changes.

SYNTAX

collection **fix_floorplan_rules**
[-derive_macro_keepout]
[-adjust_hard_macros]
[-derive_routing_blockages]
[-adjust_std_cell_areas]
[-file *file_name*]
[-prefix *blockage_prefix*]
[-objects *macros*]
[-bbox *bounding_box*]

Data Types

file_name string
blockage_prefix string
macros list
bounding_box rectangle

ARGUMENTS

-derive_macro_keepout

Fix hard macro and std_cell_area spacing & halo rule violations by deriving hard keepout margin on hard macro.

-adjust_hard_macros

Fix hard macro to hard macro spacing/length rule violation, and block boundary to hard macro enclosure/location rule violation.

-derive_routing_blockages

Fix hard macro and routing blockage enclosure/halo rule violation.

-adjust_std_cell_areas

Fix hard macro to std_cell_area spacing/length rule violation, std_cell_area to std_cell_area spacing rule violation, block boundary to std_cell_area enclosure/location rule violation, std_cell_area width rule violation, std_cell_area poly rule violation and std_cell_area area rule violation.

-file *file_name*

Name of tcl script to record changes.

-prefix ***blockage_prefix***

Name of prefix to automatically added blockages.

-objects ***macros***

List of macro instances for which we will fix violations. If provided, only the violations that related to specified macros will be fixed. Mutually exclusive with -bbox.

-bbox ***bounding_box***

Bounding box of macros to consider for fixing violations. If provided, only macros that are completely covered by the box will be selected, then only the violations that related to selected macros will be fixed. Mutually exclusive with -objects.

DESCRIPTION

After the floorplan rule checker is done, you can use this command to fix the following violations:

- Derive the macros' hard keepout margin to satisfy the macro to std_cell_area spacing/halo rule.
- Move macros to satisfy all grid-type spacing/length rules, and enclosure/location rules from the block boundary.
- Create routing blockages after macro placement to satisfy all routing blockage to hard macro enclosure and halo rules.
- Create placement blockages after macro placement to make the standard cell area satisfy all width rules, poly rules, area rules, spacing/length rules to hard macro, enclosure rules from the block boundary and spacing rules to standard cell area.

EXAMPLES

The following commands fix violations of floorplan rule_1 on hard macros to the block boundary.

```
prompt> set_floorplan_spacing_rule -name rule_1 \
  -from_object_types hard_macro -to_object_types block_boundary
prompt> fix_floorplan_rules -adjust_hard_macros
```

report_floorplan_rules(2)

fix_mv_design

Fix Multi-Voltage and PVT violations of buffers/inverters/diodes in the design

SYNTAX

fix_mv_design
[-buffer]
[-diode]
[-from *driver_list*]
[-cells *cell_list*]
[-lib_cells *lib_cell_list*]
[-minimize_dual_rail]
[-level_shifter]
[-report_only]
[-report_all]
[-output *output_file*]
[-html]
[-csv]
[-verbose]
[-no_split]

Data Types

driver_list list of {driver_pins or driver_nets}
cell_list list of {cells}
lib_cell_list list of {library cells}
output_file string

ARGUMENTS

-buffer

Specify **fix_mv_design** to work on buffer trees. In the current release, either -buffer or -diode has to be specified.

-diode

Specify **-diode** to work on all diodes in the netlist.

-from

Specify the buffer trees that **fix_mv_design -buffer** should work on. If input is a pin, it specifies the driver pin of a full or partial buffer tree. If input is a net, its driver pin will specify a full or partial buffer tree. Wild cards can be used to match pins and nets.

-cells

Specify a list of cells that **fix_mv_design** can only work on. **fix_mv_design** will not modify any other cells outside of this list.

If both **-cells** and **-from** are specified, **fix_mv_design -buffer** will only work on buffers and inverters from the specified cell list which are present in the buffer trees specified by **-from**. Other cells in the cell list will not be modified.

-lib_cells

Specify a list of single-rail and dual-rail buffer/inverter lib cells that **fix_mv_design -buffer** can use. The command will not use any lib cells that are not found in this list. Tool will keep existing lib cells used by buffers/inverters if they don't need to be fixed.

-minimize_dual_rail

By default, **fix_mv_design -buffer** will not swap dual-rail buffers/inverters with single-rail lib cells if it does not fix any isolation violations. But if **-minimize_dual_rail** option is specified, **fix_mv_design** will minimize dual-rail buffers/inverters whenever possible without introducing new isolation violations.

-level_shifter

By default, buffer trees stop at level shifters and enable level shifters. If **-level_shifter** option is specified, buffer trees will include level shifters and the command can modify input/output supplies of these level shifters. However, library cells of these level shifters will not be changed.

-report_only

Do not modify netlist but print report only.

-report_all

Display detailed information of all buffer trees no matter they have been modified by the command or not. The **-verbose** option must also be specified.

-output <*output_file*>

Print report into <*output_file*>.

-html

Print report in HTML format.

-csv

Print report in CSV (Comma-Separated Value) format.

-verbose

Display detailed information of each buffer tree modified by the command.

-no_split

Display text in table without splitting lines.

DESCRIPTION

The **fix_mv_design** command with **-buffer** option will perform the following changes in buffer trees if feasible:

- Fix isolation violations by changing buffer/inverter lib cells and their supply net connections. No isolation cells will be inserted.

- Fix voltage violations by changing buffer/inverter lib cells and their supply net connections. No level shifter cells will be inserted.
- Fix PVT, bias, set_target_library_subset, set_libcell_subset, and set_lib_cell_purpose violations by swapping buffer/inverter lib cells with legal ones.
- Fix MV-058 violations (which complain about the backup supply of a dual-rail buffer/inverter being connected to the power domain primary supply) by replacing dual-rail with single-rail buffer/inverter lib cells.
- Assign physical/logical feedthrough buffer/inverter to a correct power domain which is consistent with its voltage area.
- Minimize number of dual-rail buffer/inverter lib cells by swapping them with single-rail counterparts without introducing new voltage or isolation violations if **-minimize_dual_rail** option is specified.

If the original buffer/inverter lib cell has already been placed, **fix_mv_design** will put the new lib cell in the same location. But **fix_mv_design** does not guarantee that the new placement is legal or timing is met. Please run optimization and legalization commands again.

PG net connections to the original buffer/inverter will be removed if the lib cell is changed by **fix_mv_design**. Please run **connect_pg_net** to reconnect the PG nets.

If **-diode** is specified, fix_mv_design will check all diodes in the current netlist. If the diode sits in the voltage area which is not matching the diode's power domain, then power domain of its voltage area will be assigned to the diode. If **-report_only** is specified, fix_mv_design will only report that certain power domain will need to be assigned to diodes without making any actual power domain assignment.

EXAMPLES

The following example runs **fix_mv_design** on a buffer tree driven by input pin 'in' to fix isolation violation and minimize number of dual-rail buffers. It does not modify the netlist but only reports what would have been modified:

```
prompt> fix_mv_design -buffer -from {in} -minimize_dual_rail -report_only -verbose
****************************************
Report : fix_mv_design
        -buffer

fix_pg_missing_vias

Creates PG vias to fix missing vias by given DRC error objects that are written by the **analyze_rail** command. If PG vias are inserted successfully for a missing via error object, the error object's status will be updated to fixed.

SYNTAX

status **fix_pg_missing_vias**
  error_objects
  -error_data *drc_error_data*
  [-via_masters *via_master_list*]
  [-allow_parallel_objects]
  [-drc no_check | check_but_no_fix]
  [-mark_as *usage_type*]
  [-tag *tag_name*]

Data Types

error_objects collection
fldrc_error_data collection
via_master_list list
usage_type string
tag_name string

ARGUMENTS

error_objects

A collection of error objects to insert PG vias.

-error_data *drc_error_data*

Specifies the error data where the error object collection is from.

-via_masters *via_master_list*

Specifies the list of via masters to be used during via creation. You can specify via masters with the following information:

- Contact code names defined in the technology file
- Via rule names defined by **set_pg_via_master_rule**
- Custom via definitions
- The **default** keyword

Given one intersection, the tool uses the following rules for via creation in an order from high to low:

1. Via rules
2. Specified custom via contact definitions
3. Specified contact codes in the technology file
4. Specified contact codes or custom via definitions

For example, the tool first tries feasible via rules for via creation. If all via rules do not apply to this intersection, the tool uses the specified custom via contact definitions for via creation, and so on. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable. By default, the first DRC-clean default contact code is used for via insertion for each intersection.

-allow_parallel_objects

Specifies that vias are created between parallel objects. By default, vias are only created between orthogonal objects.

-drc no_check | **check_but_no_fix**

Specifies the DRC option for PG via creation. The argument following -drc must be either *no_check* or *check_but_no_fix*. When *no_check* is specified, the command will not perform DRC check while creating vias. When *check_but_no_fix* is specified, the command performs DRC check and reports DRC errors without fixing DRC errors. By default, DRC is checked and fixed for the inserted PG vias.

-mark_as *usage_type*

Specifies the type of the created vias. The argument must be one of the following:

- **stripe**: Power strap
- **ring**: Power ring
- **lib_cell_pin_connect**: Standard cell connection
- **macro_pin_connect**: Macro connection
- **user_route**: User route
- **follow_pin**: Standard cell connection
- **shield_route**: Shield route

If you do not specify this option, the tool uses the shape used on the bottom layer shape for the created vias.

-tag *tag_name*

Specifies a tag name to be assigned to all new vias and shapes created by this command. This tag name is used as a user attribute for filtering collections at later design stages. By default, no tags are assigned.

DESCRIPTION

The **fix_pg_missing_vias** command creates PG vias by a given error object collection. This command only supports error objects which are generated by the **analyze_rail -check_missing_via** command. For each error object, this command invokes **create_pg_vias** to insert PG vias. If PG vias are inserted successfully, the error object's status will be updated to "fixed". Or the status will be "ignored".

EXAMPLES

The following example creates PG vias for all error objects.

```
prompt> set errdm [open_drc_error_data miss_via.VDD.err]
prompt> set errs [get_drc_errors -error_data $errdm]
prompt> fix_pg_missing_vias -error_data $errdm $errs
```

analyze_rail(2)
open_drc_error_data(2)
get_drc_errors(2)

fix_placement_color_mask

Perform color mask swapping of violated cell instances from the current design for consumption by PrimeTime-ECO.

SYNTAX

status **fix_placement_color_mask**

DESCRIPTION

This command swaps the maskShift attribute of cell instances that violated color rule. This command is for consumption by PrimeTime-ECO in conjunction with the export_advanced_technology_rules command. This command does not displace cells.

SEE ALSO

export_advanced_technology_rules(2)

fix_signal_em

Fixes signal electromigration violations.

SYNTAX

fix_signal_em
[-nets *net_list*]

Data Types

net_list list

ARGUMENTS

-nets *net_list*

Specifies the list of net names for which to fix signal EM violation. By default, all nets with EM violations are fixed.

DESCRIPTION

The **fix_signal_em** command performs automatic fixing of signal (interconnect) electromigration violations for the current design or for specified nets.

The command invokes electromigration analysis for nets, which calculates the current on every segment of the net and compares the result with the current thresholds defined in the design library. EM fixing strategies are applied on the violations.

Before using the **fix_signal_em** command, make sure the design is detail routed and has signal electromigration constraints. Also, make sure the switching activity has been defined for all boundary nets.

By default, the command repairs all EM violations in the whole design, including clock nets and signal nets. To restrict fixing to specified nets, list those nets in the command. You can use the **get_nets** command to create a collection of nets on which to perform EM fixing.

This command uses information from current mode and corner.

Multicorner-Multimode Support

This command works only on the current scenario.

EXAMPLES

The following example runs signal electromigration fixing.

```
prompt> fix_signal_em
```

SEE ALSO

report_signal_em(2)

flip_objects

Flips one or more objects in the current design.

SYNTAX

status **flip_objects**
-x *x* | -y *y* | -flip x | y
[-anchor center | ll | lr | ul | ur]
[-group]
[-force]
[-simple]
[*object_list*]

Data Types

x	float
y	float
object_list	collection or selection

ARGUMENTS

-x *x*

Specifies, in user units, either the x-coordinate of the anchor point (if you do not specify the **-anchor** or **-group** option) or the x-offset from the x-coordinate (if you specify the **-anchor** or **-group** option).

The resultant x-coordinate specifies the position of the vertical line to flip the objects about.

-y *y*

Specifies, in user units, either the y-coordinate of the anchor point (if you do not specify the **-anchor** or **-group** option) or the y-offset from the y-coordinate (if you specify the **-anchor** or **-group** option).

The resultant y-coordinate specifies the position of the horizontal line to flip the objects about.

-flip x | **y**

Specifies the axis around which to flip the object. Use the **-anchor** option to specify a corner of the object around which to flip. By default, each object is flipped around its center point.

-anchor center | **ll** | **lr** | **ul** | **ur**

Specifies the anchor point for rotation.

The anchor values are:

center is center
ll is lower left
lr is lower right
ul is upper left
ur is upper right

The option cannot be specified together with the **-group** option.

-group

Specifies the center point of a group as an anchor for rotation.

The option cannot be specified together with the **-anchor** option.

object_list

Collection or selection set containing objects to rotate. If this option is not specified, the global selection set is used.

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

DESCRIPTION

The **flip_objects** command flips one or more objects in the current design.

Note that snapping is done automatically by using global snap settings.

Flipping at X

To flip objects about an x-coordinate, the x-values of the boundaries of each object are mirrored about the x-value of the vertical line specified by the **-x** and **-anchor** options. The object then has its boundary set to the new values.

Flipping at Y

To flip objects about a y-coordinate, the y-values of the boundaries of each object are mirrored about the y-value of the horizontal line specified by the **-y** and **-anchor** options. The object then has its boundary set to the new values.

EXAMPLES

The following example flips all selected objects around the y-axis using center as an anchor.

```
prompt> flip_objects -flip y
```

The alternative syntax uses collection to specify objects.

```
prompt> flip_objects [get_selection] -flip y
```

foreach_in_collection

Iterates over the elements of a collection.

SYNTAX

string **foreach_in_collection**
itr_var
collections
body

Data Types

itr_var	string
collections	list
body	string

ARGUMENTS

itr_var

Specifies the name of the iterator variable.

collections

Specifies a list of collections over which to iterate.

body

Specifies a script to execute per iteration.

DESCRIPTION

The **foreach_in_collection** command is used to iterate over each element in a collection. You cannot use the Tcl-supplied **foreach** command to iterate over collections because the **foreach** command requires a list, and a collection is not a list. Also, using the **foreach** command on a collection causes the collection to be deleted.

The arguments for the **foreach_in_collection** command parallel those of the **foreach** command: an iterator variable, the collections over which to iterate, and the script to apply at each iteration. All arguments are required.

Note: The **foreach_in_collection** command does not allow a list of iterator variables.

During each iteration, the *itr_var* option is set to a collection of exactly one object. Any command that accepts *collections* as an

argument also accepts *itr_var* because they are of the same data type (collection).

You can nest the **foreach_in_collection** command within other control structures, including another **foreach_in_collection** command.

Note that if the body of the iteration is modifying the netlist, it is possible that all or part of the collection involved in the iteration will be deleted. The **foreach_in_collection** command is safe for such operations. If a command in the body causes the collection to be removed, at the next iteration, the iteration ends with a message indicating that the iteration ended prematurely.

An alternative to collection iteration is to use complex filtering to create a collection that includes only the desired elements, then apply one or more commands to that collection. If the order of operations does not matter, the following are equivalent. The first is an example without iterators.

```
set s [get_cells {U1/*}]
command1 $s
command2 $s
unset s
```

The following is a similar approach using the **foreach_in_collection** command:

```
foreach_in_collection itr [get_cells {U1/*}] {
  command1 $itr
  command2 $itr
}
```

For collections with large numbers of objects, the non-iterator version is more efficient, though both produce the same results if the commands are order-independent.

EXAMPLES

The following example from PrimeTime removes the wire load model from all hierarchical cells in the current instance.

```
pt_shell> foreach_in_collection itr [get_cells *] {
?         if {[get_attribute $itr is_hierarchical] == "true"} {
?           remove_wire_load_model $itr
?         }
?       }
Removing wire load model from cell 'i1'.
Removing wire load model from cell 'i2'.
```

SEE ALSO

collections(2)
foreach(2)

generate_hot_spots

Generates voltage drop hot spots by dividing the whole design into multiple grids within which voltage drop hot spots can be analyzed. All grids will be sorted by voltage drop values. Each grid will be assigned with an index number start from 0, where the smaller the number, the bigger voltage drop the grid has.

SYNTAX

status **generate_hot_spots**
[-net *net_name*]
[-percentage *percentage*]
[-site_row *site_row_height_multiplier*]
[-row *number_of_rows*]
[-column *number_of_columns*]

Data Types

net_name string
percentage float
site_row_height_multiplier integer
number_of_row integer
number_of_columns integer

ARGUMENTS

-net *net_name*

Specifies a power or ground net name on which hot spot analysis is performed.

-percentage *percentage*

Specifies a percentage threshold which is used to generate hot spot error cells. Default is 0.1 which means 10%.

-site_row *site_row_height_multiplier*

By default the whole design is divided into multiple grids by using the standard cell row height and vertical PG straps on the lowest metal layer. This option allows users to use multiple row heights to divide hot spot rows while keeping columns separated by vertical PG straps.

-row *number_of_rows*

Specifies the number of row to construct grid boxes.

-column *number_of_columns*

Specifies the number of columns to construct grid boxes.

DESCRIPTION

The **generate_hot_spots** command generates voltage drop hot spot analysis by dividing the whole design into multiple grid boxes from which voltage drop hot spots can be analyzed. This command is needed for the **report_hot_spots** command.

EXAMPLES

The following example generates hot spot grid boxes using the default standard cell row height and vertical PG straps. Users can open the error browser to browse those voltage drop error cells.

```
prompt> generate_hot_spots -net VDD
Information: 1015 of instance effective voltage drop error cells created
```

The following example divides the whole design to 100 by 200 grid boxes:

```
prompt> generate_hot_spots -net VDD -row 100 -column 200
Information: 2314 of instance effective voltage drop error cells created
```

SEE ALSO

report_hot_spots(2)
remove_hot_spots(2)

generate_mv_constraints

Derives MV constraints automatically.

SYNTAX

status **generate_mv_constraints**
-elements *objects*
[-no_isolation]
[-apply | -output *file_name*]

Data Types

objects list
file_name string

ARGUMENTS

-elements *objects*

Specifies the objects on which to generate MV constraints. The objects can be pins of the root cells of power domains or ports of the top-level design for the top power domain, or hierarchical instances.

-no_isolation

Optional argument which enables the tool to derive UPF *-no_isolation* isolation strategies based on electrical needs. At least one of the *-no_isolation* options must be used.

-apply

Optional argument which instructs the tool to apply the newly-derived strategies to the design in memory.

-output *file_name*

Optional argument which instructs the tool where to write out the newly-derived strategies. If the file specified already exists, it is overwritten.

DESCRIPTION

The generate_mv_constraint utility automatically generates *-no_isolation* strategies for power domain boundary pins where an isolation strategy has been specified, but is not needed based on the power states defined in the UPF. The command has no effect on domain boundary pins where isolation cells have already been inserted.

When the tool-derived *-no_isolation* strategies are applied on top of existing user strategies, it prevents unnecessary isolation cells from being inserted.

At least one of the *-output* or *-apply* options must be specified. If the *-apply* option is not used, you are expected to load the output UPF file specified in the *-output* option manually.

EXAMPLES

The following example generates no_isolation strategies and writes the output to a user-specified file:

```
prompt> generate_mv_constraints -elements {B1 B2} no_isolation -output no_iso.upf
```

The output file no_iso.upf looks as follows:

```
set derived_upf true
if ($derived_upf) {
set_isolation snps_no_iso__0 -domain PD_P1 -no_isolation \
  -elements {B1/in  B1/out}
set_isolation snps_no_iso__0 -domain B2/PD_P2 -no_isolation \
  -elements B2/in
}
set derived_upf false
```

SEE ALSO

load_upf(2)
create_mv_cells(2)

generate_net_pattern

Generate automatic resistance scaling factors with net pattern.

SYNTAX

status **generate_net_pattern**
-output <file_name>
-route_mode <mode>
[-apply]

Data Types

file_name string
mode string

ARGUMENTS

-output *file_name*

Specifies the name of the output file to which pattern based resistance scaling table for the current design is written.

-route_mode *mode*

Specifies the routing stage that you want to run net pattern generation. For faster run time and good accuracy, track assign is the default. If you'd like to use full detail route, you can use *"-route_mode detail"*. If you have run routing, you can use *"-route_mode skip"*.

-apply

Once this option is used, the net pattern based scaling resistane table will be applied immediately so the next virtual route extraction will be using the table to adjust the resistance.

DESCRIPTION

For designs using advanced nodes, high metal layers show much smaller resistance compared to lower metal layers. In preroute extraction, the tool uses a weighted approach to estimate preroute resistance because it does not know which metal layers a net will eventually go on during detail routing.

To improve resistance correlation, the tool uses a resistance scaling approach based on the wire length net pattern. The router tends to route long nets on upper layers, which typically means a smaller resistance unit for long nets, so virtual routing can be pessimistic for long nets. For short nets, the router uses lower metal layers, which means that virtual route estimation can be optimistic. In this scaling approach, the tool scales the net's virtual route estimation based on scaling factors for each net pattern.

The default pattern generation will run global route and track assign, and then run pattern generator to create the net pattern based resistance scaling table for all corners. You can use -apply option to apply the generated net pattern immediately for the next virtual route extraction and future steps or you can save the pattern table to a file called "file_name" if option *-output* is used. If you have a routed design (for example, a detailed routed design using route_auto), you can use *"-route_mode skip"* option so that we will start the pattern generation without going through the routing steps. If you dont use *"-route_mode skip"* option, routes will be removed after pattern generation.

In theory, you can use the above command anywhere in your flow. You can either just create a pattern for future use using *"-output"* option (which will create a tcl file that you can source later on), or you can generate the pattern and use it immediately to drive later flows. In practice, a better flow may be to run your first flow all the way to route_auto and then create the net pattern there and reuse it to drive your future preroute optimization like place_opt and clock_opt. The following is a sample flow:

```
place_opt
clock_opt
route_auto
generate_net_pattern -route_mode skip -output my_pattern_r.tcl
```

Then restart your place_opt flow using the generated pattern tcl file:

```
source my_pattern_r.tcl
place_opt
clock_opt
route_auto
route_opt
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example generates and writes the net pattern resistane scaling table to an output file.

```
prompt> generate_net_pattern -output pattern.tcl
```

generate_pg_script

Creates a configuration file or a Tcl script that includes the syntax for pattern-based PG network synthesis.

SYNTAX

status **generate_pg_script**
[-input *file_name*]
[-outut *file_name*]
[-template]

Data Types

file_name string

ARGUMENTS

-input *file_name*

Specifies the name of the PG configuration file. This is a required option when the **-template** option is not specified.

-output *file_name*

Specifies the name of the PG script file that is written out. If the option is not specified, the default script name is ppns_script.tcl.

-template

Creates a PG configuration file. When this option is specified, all other options are ignored.

DESCRIPTION

This command creates a configuration file or a Tcl script that includes the syntax for pattern-based PG network synthesis.

Two configurations are supported in the PG configuration file: StrapConfig and ViaConfig. See the following descriptions for details.

TargetConfig: Specifies which configurations are used to create the PG script. Without it, all the configurations in the configuration file are used to create the PG script.

I. StrapConfig:

1. Mesh (with category mesh) Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage, extension. Required keywords for layer: widths, direction, spacings, pitch. Optional keywords for layer: offset, alignTrack, trim.

2. Std Rail (with category rail) Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage. Optional

keywords for layer: widths.

3. Alignment straps for switch cells (with category switch_alignment). Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage, extension. Required keywords for layer: alignCell. Optional keywords for layer: widths, direction, alignPinLayer, alignWireNumber, alignTrack, trim, offset.

4. Alignment straps for physical cells (with category physical_cell_alignment). Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage, extension. Required keywords for layer: alignCell. Optional keywords for layer: widths, alignPinLayer, alignPinName, alignWireNumber, alignTrack, offset.

5. Macro connection for long pin (with category macros and pintype long_pin). Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage. Required keywords for layer: pintype, pitch, direction. Optional keywords for layer: widths, spacings, pinlayer.

5. Macro connection for scattered pin (with category macros and pintype scattered_pin). Required keywords: target_area, category, nets, layer. Optional keywords: tag, blockage. Required keywords for layer: pintype. Optional keywords for layer: widths, pinlayer.

II. ViaConfig:

1. Via between wires (with category wire_to_wire). Required keywords: category, nets. conditionally required keywords: upper_layer, lower_layer. Optional keywords: via_def, tag, allow_parallel.

2. Via between wires and pins (with category wire_to_pin) Required keywords: category, nets, pin_name. conditionally required keywords: upper_layer, lower_layer. Optional keywords: via_def, tag, allow_parallel.

III. Keyword syntax:

1. target_area: Supported setting: core, design_boundary, voltage_areas, polygon, macros, blocks, pg_regions. Please see the man page of the command set_pg_strategy for details.

2. category: Supported setting: mesh, rail, switch_alignment, physical_cell_alignment, macros, wire_to_wire, wire_to_pin.

3. nets: Supported setting: names of power/ground nets.

4. layer: Supported setting: names of routing layers.

5. blockage: Supported setting: please see the man page of the option -blockgae of the command set_pg_strategy for details

6. extension: Supported setting: please see the man page of the option -extension of the command set_pg_strategy for details

7. tag: Supported setting: any name.

8. widths: Supported setting: values (in micron).

9. direction: Supported setting: horizontal, vertical.

10. spacings: Supported setting: values (in micron), minimum, interleaving.

11. pitch: Supported setting: values (in micron).

12. offset: Supported setting: values (in micron).

13. alignTrack: Supported setting: true, false

14. trim: Supported setting: true, false

15. alignCell: Supported setting: master name of cell.

16. alignPinLayer: Supported setting: name of layer.

17. alignWireNumber: Supported setting: integer.

18. pintype: Supported setting: long_pin, scattered_pin.

19. pinlayer: Supported setting: name of layer.
20. upper_layer: Supported setting: name of layer.
21. lower_layer: Supported setting: name of layer.
22. via_def: Supported setting: name of viaDef or contact code.
23. allow_parallel: Supported setting: true, false.

EXAMPLES

The following example creates a PG configuration file:

```
prompt> generate_pg_script -template
```

The following example creates a PG script file named test.tcl from the dp_pgConfigExample.txt PG configuration file:

```
prompt> generate_pg_script -input dp_pgConfigExample.txt -output test.tcl
```

generate_rm

Generate the IC Compiler II Reference Methodology Scripts

SYNTAX

status **generate_rm**
-rm_script <version_name>
-node <node_name>
[-foundry *foundry_name*]
-output <output_dir>
[-synopsys_library]

Data Types

version_name string
node_name string
foundry_name string
output_dir string

ARGUMENTS

-rm_script *version_name*

Specifies the script version of the IC Compiler II Reference Methodology to generate.

The *"Full RM Version"* is the script version that gives users control to configure with optional features, their flat place and route flow.

The *"JumpStart Version"* is the starting point for new users that have a block ready for place_opt. It will run the default recommended flat place and route flow.

-node *node_name*

Specifies the technology node version of the scripts to generate. Supported technology nodes are "established, 20nm, 16nm, 14nm, 12nm, 10nm, 7nm, and 5nm". The user must specify one of the supported names.

-foundry *foundry_name*

Specifies the name of the foundry for the technology node if applicable.

-output *output_dir*

Specifies the output directory location for the reference scripts. By default the output directory is the current working directory.

-synopsys_library

Specifies to generate the Synopsys Logic Library configuration of the scripts when applicable.

DESCRIPTION

This command will generate the IC Compiler II Reference Methodology scripts in the configuration that the user specifies. The user must configure for the technology node as well as foundry name and Synopsys Logic Library version when applicable.

The perferred method of generating these scripts are through the GUI of this command that can be accessed through the *Help* menu dropdown and selected with *Generate RM Scripts*.

EXAMPLES

In the following example the generate_rm command will generate the JumpStart Version of the 20nm technology node scripts in the current working directory.

prompt> **generate_rm -node 20nm -rm_script {JumpStart Version} -output ./**
File ./ICC2-RM_Q-2019.12.tar.gz is generated. Please unpack the file to get IC Compiler II Reference Methodology scripts.

SEE ALSO

generate_sadp_tracks

Creates tracks based on self-aligned double patterning (SADP) track rules.

SYNTAX

collection **generate_sadp_tracks**
-rule_name *track_pattern_rule*
-layer *layer_name*
[-start *point*]
[-stop *point*]
[-count *number_of_repeats_using_rule*]
[-pitch *pitch_between_patterns*]
[-auto_fill intra_pattern | inter_pattern | all | none]
[-exact]
[-create_pg_route]
[-color mask_one | mask_two]

Data Types

track_pattern_rule string
layer_name string
point float
number_of_repeats_using_rule int
pitch_between_patterns float

ARGUMENTS

-rule_name *track_pattern_rule*

Specifies the track rule to use to create the tracks.

-layer *layer_name*

Specifies the layer to use for the tracks created by this track rule.

-start *point*

Specifies the location where the first track of the current pattern can start. If the tracks are vertical, the starting point specifies a x-coordinate. If the tracks are horizontal, the starting point specifies a y-coordinate.

The actual starting point depends on the locations of the previous SADP tracks on the given layer and the interactions between the different SADP tracks.

By default, the starting point is the left bottommost edge of the design.

-stop *point*

Specifies the location of the last track in the current pattern. If the tracks are vertical, the stopping point specifies an x-coordinate. If the tracks are horizontal, the stopping point specifies a y-coordinate.

The actual stopping point depends on the locations of the previous SADP tracks on the given layer and the interactions between different SADP tracks.

By default, the stopping point is the right topmost edge of the design.

-count ***number_of_repeats_using_rule***

Specifies the number of times the track rule is to be repeated.

-pitch ***pitch_between_patterns***

Specifies the spacing between the first track of adjacent track_patterns. The pitch should be used together with **count**.

-auto_fill intra_pattern | **inter_pattern** | **all** | **none**

Specifies how to fill spaces between routes that are large enough to accommodate one or more default tracks. Fill values are one of *intra_pattern*, *inter_pattern*, *all* or *none*.

Specify *intra_pattern* to create tracks between track groups or in between SADP tracks based on the same rule when there is sufficient space.

Specify *inter_pattern* to create tracks between two SADP tracks based on different SADP rules when there is sufficient space.

Specify *all* to fill all the intervening space with default width tracks.

Specify *none* to avoid filling intervening space.

By default, the auto fill value is *all*.

-exact

Start the SADP track exactly at the startpoint. You must specify **-start** together with this option. By default, the tool calculates the nearest allowed SADP location based on the track plan and other SADP tracks on the same layer.

-create_pg_route

Creates shapes for the entire length of track if the netname in the track pattern rule matches a PG netname.

-color mask_one | **mask_two**

Specifies the mask pattern for the track pattern.

DESCRIPTION

This command creates self-aligned double patterning (SADP) on the specified layer based on the track rule for the current block.

EXAMPLES

The following examples creates SADP tracks in the current block.

prompt> **generate_sadp_tracks -rule_name tr1 -start 40 -layer M7 -count 3**

{TRACK_0 TRACK_1 TRACK_2 TRACK_3 TRACK_4 TRACK_5}

SEE ALSO

check_sadp_tracks(2)
create_sadp_track_rule(2)
remove_sadp_track_rule(2)
report_sadp_track_rule(2)

generate_via_ladder_template

This command generates via ladder template according to input config file and current block.

SYNTAX

status **generate_via_ladder_template**
-config_file *name*
[-template_file *name*]
[-association_file *name*]

Data Types

name string

ARGUMENTS

-config_file *name*

Specifies the file-name of high-level input configuration in XML format. This option is required. An example of XML file is shown in EXAMPLES section.

-template_file *name*

Specifies the file-name of output via rule definition in TCL format. User can directly source the file to set via rule into data-base. The default file-name is auto_gen_via_ladder_template.tcl.

-association_file *name*

Specifies the file-name of output via ladder constraint association in TCL format. User can directly source the file to set the association into data-base. The default file-name is auto_gen_via_ladder_association.tcl.

DESCRIPTION

This command generates via ladder template according to input config file and current opened block. The config file should describe the structure of via ladder template in XML format. By taking design rules defined in the technology file into consideration, this command would generate corresponding TCL commands in side files, which could be sourced by user in later stage.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> generate_via_ladder_template \
   -config_file input.config \
   -template_file output_via_rule.tcl \
   -association_file output_via_association.tcl
```

Content of input.config :

```
<EmRule>
   <!—template definition -->
   <Template name="template_1_3231">
      <Layer name="M1" row_number="3"/>
      <Layer name="M2" row_number="2"/>
      <Layer name="M3" row_number="3"/>
      <Layer name="M4" row_number="1"/>
   </Template>

... more templates

   <!-- Pin to template association -->
   <Pin name="*/BCELLD5A11*/Z">
      <Template name="template_1_3231"/>
   </Pin>

.... more associations

</EMRule>
```

Content of output_via_rule.tcl :

```
create_via_rule -name template_1_3231 \
   -cut_layer_names {VIA1 VIA2 VIA3} -cut_names {Vs Vs Vs}
   -cut_rows {2 3 1} -cuts_per_row {3 2 3}
set viaRule [get_via_rules template_1_3231]
set_attribute $viaRule upper_metal_min_length_table {0.3 0.2 0.4}
set_attribute $viaRule cut_x_min_spacing_table {0.07 0.11 0.11}
set_attribute $viaRule cut_y_min_spacing_table {0.06 0.06 0.15}
set_attribute $viaRule max_num_stagger_tracks_table {1 2 0}
set_attribute $viaRule for_electro_migration true
```

output_via_association.tcl :

```
foreach_in_collection pin [get_lib_pins -quiet */BCELLD5A11*/Z] {
      set_attribute -quiet $pin is_em_via_ladder_required true
set_via_ladder_candidate $pin -ladder_name "template_1_3231"
}
```

SEE ALSO

generate_via_rules_for_performance

Generate via rules based on the analysis of routing layers.

SYNTAX

status **generate_via_rules_for_performance**
-max_layer layer_name pins
-rule_file rule_file_name
-stagger

Data Types

layer_name string
rule_file_name string

ARGUMENTS

-max_layes *layer_name*

Specifies max_layer of via ladders. This should not be higher layer than the max_layer in the routing rule.

-rule_file *rule_file_name*

Specifies output via rule file name. (Default: auto_perf_via_ladder_rule.tcl)

-stagger

Generate stagger table

DESCRIPTION

This command generates via rules based on the analysis of routing layers. This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following is the usage examples.

```
prompt> generate_via_rules_for_performance
1

prompt> generate_via_rules_for_performance -stagger
1
```

SEE ALSO

create_via_rule(2)
remove_via_rules(2)
report_via_rules(2)
setup_performance_via_ladder(2)

get_abstract_type

Get the type of an abstract view design

SYNTAX

string **get_abstract_type**
[design]

ARGUMENTS

design

The abstract view design to get type from. Only abstract view design is accepted.

DESCRIPTION

Get the type of the specified abstract view design.

EXAMPLES

The following example gets the type of the abstract view of design BlkA:

prompt> **get_abstract_type [get_designs BlkA -filter "view_name == abstract"]**

SEE ALSO

create_abstract(2)

get_alternative_lib_cell

Creates a collection of equivalent library cells for the specified cell or library cell.

SYNTAX

collection **get_alternative_lib_cells**
[-current_library]
[-libraries *libraries*]
[-skip_pg]
[-skip_timing]
object

Data Types

libraries list
object list

ARGUMENTS

-current_library

If this option is specified, then searches for library cells in the cell's current library or library cell's current library only. You cannot specify this option with the -libraries option.

-libraries *libraries*

Specifies a list of libraries from which to select alternative library cells. The default is to select from all libraries in the link path. The libraries option can be a list of library names, or collections of libraries loaded; the latter can be obtained using the get_libs command. You cannot specify this option with the -current_library option.

-skip_pg

Skip pg pin consistency checking while searching the alternative cell. Then the return alternative lib cell pg pin setting could be different with the specified lib cell.

-skip_timing

Skip timing consistency checking while searching the alternative cell. Then the return alternative lib cell timing arcs could be different with the specified lib cell.

object

Specifies the cells or library cell for which to return equivalent library cells. This is a required option. Patterns is allowed, but the specified cell or library cell must be unique. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the wildcards man page.

DESCRIPTION

The **get_alternative_lib_cells** command creates a collection of library cells that are logically similar to the specified cell or library cell and pass the filter, if specified. This collection can be used to replace or resize the specified cell in the current design.

The command returns a collection if any library cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use the **get_alternative_lib_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_alternative_lib_cells** result to a variable.

When issued from the command prompt, **get_alternative_lib_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_alternative_lib_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_alternative_lib_cells** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the equivalent library cells for the slow/AND2X2 library cell

```
prompt> set libcelsel [get_lib_cells slow/AND2X2]
{slow/AND2X2}

prompt> [get_alternative_lib_cells $libcelsel]
{slow/AND2X1 slow/AND2X6 slow/AND2X12}
```

The following example queries the equivalent library cells for the top/U21 cell instance.

```
prompt> set celsel [get_cell top/U21]
{top/U21}

prompt> [get_alternative_lib_cells $celsel]
{slow/AND2X1 slow/AND2X2 slow/AND2X6 slow/AND2X12}
```

SEE ALSO

shell.common.collection_result_display_limit(3)

get_alternative_lib_cells

Creates a collection of equivalent library cells for the specified cell or library cell.

SYNTAX

collection **get_alternative_lib_cells**
[-current_library]
[-libraries *libraries*]
[-skip_pg]
[-skip_timing]
object

Data Types

libraries list
object list

ARGUMENTS

-current_library

If this option is specified, then searches for library cells in the cell's current library or library cell's current library only. You cannot specify this option with the -libraries option.

-libraries *libraries*

Specifies a list of libraries from which to select alternative library cells. The default is to select from all libraries in the link path. The libraries option can be a list of library names, or collections of libraries loaded; the latter can be obtained using the get_libs command. You cannot specify this option with the -current_library option.

-skip_pg

Skip pg pin consistency checking while searching the alternative cell. Then the return alternative lib cell pg pin setting could be different with the specified lib cell.

-skip_timing

Skip timing consistency checking while searching the alternative cell. Then the return alternative lib cell timing arcs could be different with the specified lib cell.

object

Specifies the cells or library cell for which to return equivalent library cells. This is a required option. Patterns is allowed, but the specified cell or library cell must be unique. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the wildcards man page.

DESCRIPTION

The **get_alternative_lib_cells** command creates a collection of library cells that are logically similar to the specified cell or library cell and pass the filter, if specified. This collection can be used to replace or resize the specified cell in the current design.

The command returns a collection if any library cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use the **get_alternative_lib_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_alternative_lib_cells** result to a variable.

When issued from the command prompt, **get_alternative_lib_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_alternative_lib_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_alternative_lib_cells** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the equivalent library cells for the slow/AND2X2 library cell

```
prompt> set libcelsel [get_lib_cells slow/AND2X2]
{slow/AND2X2}

prompt> [get_alternative_lib_cells $libcelsel]
{slow/AND2X1 slow/AND2X6 slow/AND2X12}
```

The following example queries the equivalent library cells for the top/U21 cell instance.

```
prompt> set celsel [get_cell top/U21]
{top/U21}

prompt> [get_alternative_lib_cells $celsel]
{slow/AND2X1 slow/AND2X2 slow/AND2X6 slow/AND2X12}
```

get_antenna_rule_names

Name

get_antenna_rule_names

Creates a list of antenna rule names defined in the library.

SYNTAX

list **get_antenna_rule_names**
[-mode *antenna_mode*]
[-library *library*]

Data Types

antenna_mode integer
library collection

ARGUMENTS

-mode *antenna_mode*

An integer value between 1 and 6, that represents the way the antenna areas are computed. When this option is specified, only the antenna rules names that use the given mode for antenna area calculation, are returned. This is an optional option. When not specified all the antenna rule names defined in the library are returned.

-library *library*

Specifies the library from which the antenna rule names are to be returned. This is an optional option. By default the command returns the antenna rule names defined in the current library.

DESCRIPTION

This command returns the antenna rule names for the specified mode that are defined in the given library.

EXAMPLES

The following example returns all the antenna rule names in the current library.

```
prompt> get_antenna_rule_names
{r1 r2 r3 r4 r5 r6}
```

The following example returns all the antenna rule names from the library lib1, that use mode 1 for antenna area calculation.

```
prompt> get_antenna_rule_names -mode 1 -library lib1
r1
```

get_app_option_value

Returns the value or the information of the specified application option.

SYNTAX

string **get_app_option_value**
[-block *block*]
[-user_default]
[-system_default]
[-details]
-name *name*

OLD SYNTAX

[-design *design*]
[-global]
[-default]
[-details]
-name *name*

Data Types

block block name or collection
name string

ARGUMENTS

-block *block*

Specifies the block for which the option values to be returned are set on. This option cannot be specified with the *-user_default* or the *-system_default* option. If this option is not specified, the application option value will be obtained from the current design, if any. If there is no current design or the specified option is not explicitly set on the design, then the option value will be obtained from the user-default or system-default (if the user-default is not set).

-user_default

Returns the user default value of the application option if set. If the user-default does not exist, then nothing is returned. This option is mutually exclusive with the *-system_default* option.

-system_default

Returns the system default value of the application option. This option is mutually exclusive with the *-user_default* option.

-details

Indicates that detailed information about the specified option is returned. If this option is specified, the command will return a list containing name and value pairs related to the option definition. This option cannot be specified with any of the *-user_default*, *-system_default* or *-block* options.

-name *name*

Specifies the name of the application option whose values is to be returned. For application options that are of type "list of {name value} pairs", this option also accepts the subscripts for pointed modifications. The subscripts should be encolsed within braces " ()" (e.g. optionName(subscript)). This is a mandatory option.

-design *design*

Specifies the design which the option values to be returned are set on. This option cannot be specified with the *-global* option. If neither *-design* nor *-global* is specified, option value will be obtained from the current design, if any. If there is no current design or the specified option is not explicitly set on the design, then the option value will be obtained from the global scope. This option is deprecated, use *-block* option instead.

-global

Indicates that the option values in the global scope will be returned. This option cannot be specified with the *-design* option. This option is deprecated.

-default

Indicates that the default value of the option is returned. This option cannot be specified with the *-details* option. This option will be obsolete, use *-user_default* or *-system_default* instead.

DESCRIPTION

This command returns the value of the specified application option. If the application option is design scoped, then the value for the block specified with *-block* is returned. With the *-details* option specified, this command returns the information of the option definition as a list of name and value pairs.

Each design will store only the options explicitly set on it. Any design scoped application option values not set on the design will be obtained from the user-default or system-default (if user-default is not set). When a default value is being returned, the value will first be validated for the block and if the value is valid, then it will be returned. If the value turns out to be not valid for the block, then an empty value is returned. For application options that are of type list, the default value returned for the block may have lesser values, since the invalid values are trimmed off.

For application options of type "list of {name value} pairs", values for keys can be selectively obtained by using the subscript mechanism.

For backward compatibility the older syntax of the command will still be supported, but the options are made hidden. The options '-design', '-global' and '-default' are made hidden.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following example gets the value of the *time.enable_preset_clear_arcs* option on the current design (or in the global scope if there is no current design).

```
prompt> get_app_option_value -name time.enable_preset_clear_arcs
false
```

The following example gets the system-default value of the **shell.tmp_dir_path** application option.

```
prompt> get_app_option_value -system_default -name shell.tmp_dir_path
/tmp
```

The following example gets the user-default value of the **shell.tmp_dir_path** application option.

```
prompt> get_app_option_value -user_default -name shell.tmp_dir_path
/user/temp/
```

The following example gets the value for the M4 key of the **test.layer_name_number_pair_list** application option on the current block.

```
prompt> get_app_option_value -name test.layer_name_number_pair_list(M4)
34
```

The following example reports information about the **time.all_clocks_propagated** application option.

```
prompt> get_app_option_value -details -name time.all_clocks_propagated
name time.all_clocks_propagated value_type bool default_value false
help {Determines whether or not all clocks are created as propagated clocks}
status basic is_obsolete false is_persistent true
```

SEE ALSO

get_app_options(2)
report_app_options(2)
set_app_options(2)
reset_app_options(2)
help_app_options(2)

get_app_options

Returns a list of valid application option names.

SYNTAX

list **get_app_options**
[-block *block*]
[-global]
[-non_default]
[-quiet]
[*pattern*]

OLD SYNTAX

list **get_app_options**
[-design *design*]
[*pattern*]
[-quiet]

Data Types

block block name or collection
pattern string

ARGUMENTS

-block *block*

Specifies the block which the application options to be returned are set on. If this option is specified, the command returns only those options whose values are explicitly set on the specified block.

-global

Returns only the global scoped application options. This is an optional option. This option is mutually exclusive with the *-block* option. This option is deprecated.

-non_default

Returns app options set to different behavior than the system-default. This includes:

- Block-scope app options set to a non-default setting with set_app_options

- Global-scope app options set to a non-default setting with set_app_options
- Block-scope app options given a user default setting with set_app_options -as_user_default

-quiet

Suppresses warning or error messages.

pattern

Specifies a pattern for the option names. A pattern can include the wildcard characters asterisk (*) and question mark (?). "*" will match zero or more of any character, and "?" will match any single character. If this option is specified, the command returns those option names that match the specified pattern. If not specified, includes all options.

-design *design*

Specifies the design which the application options to be returned are set on. If this option is specified, the command returns only those options whose values are explicitly set on the specified design. This option is deprecated, use *-block* option instead.

DESCRIPTION

This command returns a list of application options whose names match the specified pattern. If a block is specified, only those options that are explicitly set on the block will be returned. The return value may be an empty list if there are no such options.

The default behavior is to return all the application options.

For backward compatibility the older syntax of the command will still be supported, but the options are made hidden. The option '-design', is made hidden.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets the list of all options that contain "dir" in their names.

```
prompt> get_app_options *dir*
shell.tmp_dir_path
```

The following example gets the list of all options in the *timer* category, which are explicitly set on the current block.

```
prompt> get_app_options timer.* -block [current_block]
time.all_clocks_propagated time.enable_preset_clear_arcs
```

The following example gets the list of all global scoped application options whose value is different from the default.

```
prompt> get_app_options -global -non_default
shell.man_path time.enable_preset_clear_arcs
```

SEE ALSO

get_app_option_value(2)
report_app_options(2)
set_app_options(2)
reset_app_options(2)
help_app_options(2)

get_app_var

Gets the value of an application variable.

SYNTAX

string **get_app_var**
[-default | -details | -list]
[-only_changed_vars]
var

Data Types

var string

ARGUMENTS

-default

Gets the default value.

-details

Gets additional variable information.

-list

Returns a list of variables matching the pattern. When this option is used, then the *var* argument is interpreted as a pattern instead of a variable name.

-only_changed_vars

Returns only the variables matching the pattern that are not set to their default values, when specified with **-list**.

var

Specifies the application variable to get.

DESCRIPTION

The **get_app_var** command returns the value of an application variable.

There are four legal forms for this command:

- get_app_var *<var>*
  Returns the current value of the variable.

- get_app_var *<var>* -default
  Returns the default value of the variable.

- get_app_var *<var>* -details

Returns more detailed information about the variable. See below for details.

- get_app_var -list [-only_changed_vars] *<pattern>*

Returns a list of variables matching the pattern. If *-only_changed_vars* is specified, then only variables that are changed from their default values are returned.

In all cases, if the specified variable is not an application variable, then a Tcl error is returned, unless the application variable **sh_allow_tcl_with_set_app_var** is set to true. See the **sh_allow_tcl_with_set_app_var** man page for details.

When **-details** is specified, the return value is a Tcl list that is suitable as input to the Tcl **array set** command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key, and each even-numbered element in the list is the value of the previous key.

The supported keys are as follows:

name

This key contains the name of the variable. This key is always present.

value

This key contains the current value of the variable. This key is always present.

default

This key contains the default value of the variable. This key is always present.

help

This key contains the help string for the variable. This key is always present, but sometimes the value is empty.

type

This key contains the type of the application variable. Legal values of for this key are: string, bool, int, real. This key is always present.

constraint

This key describes additional constraints placed on this variable. Legal values for this key are: none, list, range. This key is always present.

min

This key contains the min value of the application variable. This key is present if the constraint is range. The value of this key may be the empty string, in which case the variable only has a max value constraint.

max

This key contains the max value of the application variable. This key is present if the constraint is "range". The value of this key may be the empty string, in which case the variable only has a min value constraint.

list

This key contains the list of legal values for the application variable. This key is present if the constraint is "list".

EXAMPLES

The following are examples of the **get_app_var** command:

```
prompt> get_app_var sh_enable_page_mode
1

prompt> get_app_var sh_enable_page_mode -default
false

foreach {key val} [get_app_var sh_enable_page_mode -details] {   echo "$key: $val"
}
=>  name: sh_enable_page_mode
    value: 1
    default: false
    help: Displays long reports one page at a time
    type: bool
    constraint: none

prompt> get_app_var -list sh_*message
sh_new_variable_message
```

SEE ALSO

report_app_var(2)
set_app_var(2)
write_app_var(2)

get_attribute

Returns attribute values on the specified objects.

SYNTAX

```
list get_attribute
  [-class class_name]
  [-quiet]
  [-value_list]
  -objects object_list
  -name attribute_name
  pos_object_list
  pos_attribute_name

class_name          string
object_list         list
attribute_name      string
pos_object_list     list
pos_attribute_name  string
```

ARGUMENTS

-class *class_name*

Specifies the first class object type name used for implicit search of objects. This can be used when objects are specified as string and its object type is not among the predefined types in the search order set by app option *shell.common.implicit_find_mode*.

-quiet

Indicates that error and warning messages are not to be reported.

-value_list

Indicates that the result should always be returned as a list.

-objects *object_list*

Specifies a list of objects from which to get the attribute values. Each element in the list is a collection of objects. This option is mutually exclusive with *pos_object_list*. Either one (and only one) of *-objects* or *pos_object_list* must be specified.

-name *attribute_name*

Specifies the name of the attribute whose value is returned. This option is mutually exclusive with *pos_attribute_name*. Either one (and only one) of *-name* or *pos_attribute_name* must be specified.

pos_object_list

Specifies a list of objects from which to get the attribute values. Each element in the list is a collection of objects. This positional option is provided for compatibility with other tools.

pos_attribute_name

Specifies the name of the attribute whose value is returned. This positional option is provided for compatibility with other tools.

DESCRIPTION

This command searches the *object_list* for the specified attribute and returns a list of attribute values. An empty list is returned if the attribute is not found on any of the specified objects.

The *object_list* can be specified as strings in which case objects will be implicitly searched based on object type search order as specified by app option *shell.common.implicit_find_mode*. If none of the predefined object type matches specified input string then the command will fail. If the object type is known then user can use *-class* to provide that input.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets the value of the *rise_drive* attribute for the IN1 port.

```
prompt> get_attribute -objects [get_ports IN1] -name rise_drive
0.25
```

The above result can also be achieved by using implicit search with string input as shown below.

```
prompt> get_attribute -objects IN1 -name rise_drive
0.25
```

The following example gets the value of *is_primary* attribute for voltage area VA1 by specifying VA1 as string and using *-class* option since voltage area is not among predefined object types for implicit find search order.

```
prompt> get_attribute -objects VA1 -name is_primary -class voltage_area
true
```

The following example gets the value of the *load* attribute for all ports whose names begin with OUT:

```
prompt> get_attribute -objects [get_ports OUT*] -name load
1.0 2.0 2.5 1.0
```

The following example sets a user-defined attribute named X on some cells and then uses **get_attribute** commands to retrieve this attribute value, as well as the value of an application attribute.

```
prompt> define_user_attribute -type int -classes cell -name X
prompt> set_attributes -objects [get_cells *] -name X -value 30
{"i1", "i2"}
prompt> foreach_in_collection sel [get_cells *] {
?       echo -n "On '[get_attribute -objects $sel -name full_name]', "
?       echo "X =  [get_attribute -objects $sel -name X]"
```

```
?      }
On 'i1', X =  30
On 'i2', X =  30
```

The following example shows how the command works when some objects fail to get their attributes.

```
prompt> get_attribute -objects [get_cells {cell1 cell2 cell3}] -name area
Warning: Attribute 'area' does not exist on cell 'cell2' (ATTR-3)
79.833600 {} 79.833600
```

The following example shows the warning that is issued because the U9 cell is not found:

```
prompt> get_attribute -objects [get_cells {U1 U9}] -name dont_touch
Warning: No cell objects matched 'U9' (SEL-004)
true
```

get_blackbox_generated_clocks

Returns a blackbox generated clock object that is created by the **create_blackbox_generated_clock** command.

SYNTAX

int **get_blackbox_generated_clocks**
[-filter *expression*]
[-quiet]
pattern

Data Types

expression string
pattern string

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any clocks that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the clock. If the expression evaluates to true, the clock is included in the result.

-quiet

Suppresses warning and error messages if no objects match.

patterns

Matches clock names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

This command returns blackbox generated clock objects as previously created by the **create_blackbox_generated_clock** command. Use this command in Tcl scripts to explore the characteristics of blackbox generated clock that you created. And you can use **get_attributes** to examine its attribute values.

EXAMPLES

The following example retrieves some attributes for the blackbox generated clock.

```
prompt> get_attribute -name master_clock [get_blackbox_generated_clocks GCK]
prompt> get_attribute -name master_source [get_blackbox_generated_clocks GCK]
prompt> get_attribute -name network_delay_max [get_blackbox_generated_clocks GCK]
prompt> get_attribute -name network_delay_min [get_blackbox_generated_clocks GCK]
prompt> get_attribute -name source_pin [get_blackbox_generated_clocks GCK]
prompt> get_attribute -name period [get_blackbox_generated_clocks GCK]
```

SEE ALSO

create_blackbox_generated_clock(2)

get_block_objects

Creates a collection of physical objects by making the input block as the top block.

SYNTAX

collection **get_block_objects**
[-filter *expression*]
[-quiet]
[-block *block_name*]
[*objects*]

Data Types

expression string
block_name string
objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on physical object's attributes. You can determine the corresponding physical object's attributes by using the **list_attributes** command. If the expression evaluates to **true**, the object is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-block *block_name*

Specifies the block to use as the top block for returning the physical objects. The block should be in the instance tree of the physical objects been passed, otherwise it will be an error condition.

objects

Specifies name or collection of objects in the top design's context.

DESCRIPTION

This command creates a collection of physical objects by selecting objects from a homogeneous collection of objects after

converting it to input block's context and after that meet the selection criteria. It returns a collection handle if one or more physical objects meet the selection criteria. If no object match the selection criteria, it returns an empty string.

You can use the **get_block_objects** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable. See the **collections** command man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets the shape in the input block's context.

```
prompt> set result [get_block_objects -block [get_blocks MID] TOP/MID/shape1]
prompt> get_attribute -objects $result -value full_name
{MID/shape1}
```

SEE ALSO

collections(2)
filter_collection(2)
get_blocks(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_blocks

Creates a collection of one or more blocks in memory. You can assign these blocks to a variable or pass them into another command

SYNTAX

collection **get_blocks**
[-open | -explicit | -implicit | -all]
[-lib_cells]
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
block_patterns | -of_objects *objects*

Data Types

expression string
exact_count int
minimum_count int
block_patterns list
objects list

ARGUMENTS

-open

Returns only blocks that are currently open. This is the default.

-explicit

Returns only blocks that were explicitly opened with open_block.

-implicit

Returns only blocks that were implicitly opened.

-all

Includes unopened blocks, if matched.

-lib_cells

Includes lib_cell blocks, if matched.

-hierarchical

Searches only physical blocks in the current block hierarchy. Does not force an auto link.

-filter *expression*

Filters the collection with *expression*. For any modules that match *patterns*, the expression is evaluated based on the attributes for the design. If the expression evaluates to true, the design is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of blocks associated with the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a lib, module or a design. **-of_objects** and *patterns* are mutually exclusive. You can specify only one of the two. If the specified object is a lib, blocks contained in the library are returned otherwise blocks which own the specified module or design is returned.

patterns

A collection of blocks, or a pattern to match block names against. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type block

DESCRIPTION

The **get_blocks** command creates a collection of blocks from those currently loaded into memory that match certain criteria. The command returns a collection if any blocks match the patterns and pass the filter (if specified). If no objects matched your criteria, the empty string is returned.

The pattern is of the form [[path_name/]lib_name:]block_name[/label_name][.view_name]. If the path_name is not given, all libraries that match the lib_name (if a lib_name specified), are searched. If the lib_name is not given, the current library is searched. If the view_name is not given, design views will be returned. If the label_name is not given, the default unnamed label will be returned. If the block_name is not given the pattern "*" is used.

Path_name can be absolute or relative. If a path name starts with a slash '/', it is interpreted as an absolute path name. If it starts with a tilde '~' or '~user', then it represents a user's home directory. If it starts with a '.', then it is relative to the current directory. Otherwise the path name is interpreted relative to the first component of the Tcl search_path variable which locates a file.

It is an error to use patterns and **-of_objects** option together.

The **-all** option allows get_blocks to return blocks that are not open. The **get_blocks** command will not open those blocks. Very little can be done with a block that is not open. An unopened block can be opened with **open_block**, or can be removed from its library with **remove_blocks**. Some attributes are available with **get_attribute**. An unopened block cannot be made the current block.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_blocks** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_blocks** result to a variable.

When issued from the command prompt, **get_blocks** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_blocks** provides a fast, simple way to display modules in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_blocks** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the modules that begin with 'mpu.'

```
prompt> get_blocks mpu*
{lib1:mpu_0_0.design lib1:mpu_0_1.design lib1:mpu_1_0.design}
```

The following example shows that, given a collection of blocks, you can remove those blocks.

```
prompt> remove_blocks [get_blocks mpu*]
```

```
Removing block lib1:mpu_0_0.design...
Removing block lib1:mpu_0_1.design...
Removing block lib1:mpu_1_0.design...
```

get_bound_shapes

Creates a collection by selecting bound shapes from the current design.

SYNTAX

collection **get_bound_shapes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any bound shapes that match *patterns*, the expression is evaluated based on the bound shape's attributes. If the expression evaluates to true, the bound shape is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for bound shapes level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the bound shapes of the specified move bound. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

patterns

Matches the bound shape names in the current design against the specified patterns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-at *point*

Creates a collection that contains all bound shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all bound shapes that are completely inside the specified region and doesn't include bound shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all bound shapes that are completely inside the specified region and the bound shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all bound shapes which are abut/touching from inside or outside to the specified region and the bound shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of bound shapes of the specified move bounds. It returns a collection handle if one or more bound shapes are found. If no bound shapes are found, it returns an empty string.

You can use the **get_bound_shapes** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of bound shapes of the move bound "movebound1".

```
prompt> get_bound_shapes -of_objects "movebound1"
{"BOUND_SHAPE_1", "BOUND_SHAPE_2"}
```

get_bounds

Creates a collection by selecting bounds from the current design.

SYNTAX

collection **get_bounds**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the bound attributes. You can determine the bound attributes by using the **list_attributes** command. If the expression evaluates to **true**, the bound is included

in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for bounds level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect**, and **-at**, but not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the bounds of the specified cells, ports, or bound shapes. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

patterns

Matches the bound names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-at *point*

Creates a collection that contains all bounds at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all bounds that are completely inside the specified region and doesn't include bounds which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all bounds that are completely inside the specified region and the bounds which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all bounds which are abut/touching from inside or outside to the specified region and the bounds whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of bounds by selecting bounds that meet the selection criteria. It returns a collection handle if one or more bounds meet the selection criteria. If no bounds match the selection criteria, it returns an empty string.

You can use the **get_bounds** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of bounds by name pattern matching.

```
prompt> get_bounds movebound*
{"movebound1", "movebound2", "movebound3"}
```

The following example creates a collection of bound with attribute filtering.

```
prompt> get_bounds -filter {type == hard}
{"movebound1"}
```

The following example creates a collection of all bounds.

```
prompt> get_bounds *
{"movebound1", "movebound2", "movebound3", "groupboundA"}
```

The following example creates a collection of all bounds containing the cells "inv*" and port "reset".

```
prompt> get_bounds -of_objects "inv* reset"}
{"movebound1", "movebound2"}
```

get_budgets

Returns attributes, settings, and analysis for timing budgeting.

SYNTAX

int **get_budgets**
[-blocks]
[-clocks]
[-path_types]
[-all_segments]
[-pin]
[-all_pins]
[-pin_data]
[-all_pin_data]
[-pin_constraints]
[-all_pin_constraints]
[-fanin_segments *pin_data*]
[-fanout_segments *pin_data*]
[-fanin_cone *segments_or_pin_data*]
[-fanout_cone *segments_or_pin_data*]
[-of_pin *budgeted_block_pin*]
[-input]
[-output]
[-filter *expression*]

Data Types

pin_data budget_pin_data object
segments_or_pin_data collection
budgeted_block_pin string or list
expression string

ARGUMENTS

-blocks

Returns a Tcl collection of cells which have been selected for budgeting by the **set_budget_options -add_blocks** command.

-clocks

Returns a Tcl collection of budget_clock objects representing each budgeted clock in each budgeted block of the design. You can use collection and attribute commands to query data similar to that shown in the Clock summaries section of the **report_budget** report. See the budget_attributes man page for details on what data can be queried from a budget_clock_object. You can use the **-filter** to select certain objects, based on their attribute values.

-path_types

Returns a Tcl collection of budget_path_type objects representing each type of timing path in the budgeted design. You can use collection and attribute commands to query data similar to that shown by the **report_budget -path_type** command. See the budget_attributes man page for details on what data can be queried from a budget_path_type object. You can use the **-filter** to select certain objects, based on their attribute values.

-all_segments

Returns a Tcl list with the name of all segments in the budgeted design. A segment represents any subpath between two budgeted pins, or the worst timing path from/to a timing path startpoint/endpoint. You can use collection and attribute commands to query data similar to that shown by the **report_budget -fanin_segments** or **report_budget -fanout_segments** commands. See the budget_attributes man page for details on what data can be queried from a budget_segment object. You can use the **-filter** to select certain objects, based on their attribute values.

-pin

Returns a Tcl budget_pin object associated with the given budgeted pin of your design. A budget_pin object contains budget summary information for every pin on a budgeted block. You can use the budget_pin to query data similar to that shown by the **report_budget -pins** command. See the budget_attributes man page for details on what data can be queried from a budget_pin_data object. The **-pin** option must be accompanied by the by the **-of_pin** option.

-all_pins

Returns a collection of Tcl budget_pin objects that cover all pins of all budget blocks. These are the same type of objects return by the **-pin** option. You can use the **-filter** to select certain objects, based on their attribute values.

-pin_data

Returns a Tcl collection of budget_pin_data objects associated with the given budgeted pin of your design. A budget_pin_data object represents the derived budget for a single timing path through a budgeting pin. Note that one pin can have many timing paths passing through it, so this option might return many pin_data objects. You can use collection and attribute commands to query data similar to that shown by the **report_budget -pins** command. See the budget_attributes man page for details on what data can be queried from a budget_pin_data object. The **-pin_data** option must be accompanied by the **-of_pin** option.

-all_pin_data

Returns a collection of Tcl budget_pin_data objects that cover all data where a path passes through a budget pin. These are the same type of objects return by the **-pin_data** option. You can use the **-filter** to select certain objects, based on their attribute values.

-pin_constraints

Returns a Tcl collection of budget_pin_constraint objects associated with the given budgeted pin of your design. The command returns one budget_pin_constraint object for each unique constraint that has been specified with the **set_pin_budget_constraints** command. You can use collection and attribute commands to query data similar to that shown by the **report_budget -pins** command. See the budget_attributes man page for details on what data can be queried from a budget_pin_constraint object. The **-pin_constraints** option must be accompanied by the **-of_pin** option.

-all_pin_constraints

Returns a collection of Tcl budget_constraint objects that cover all constraints applied to budgeted pins. These are the same type of objects return by the **-pin_constraints** option. You can use the **-filter** option to select certain objects, based on their attribute values.

-fanin_segments ***pin_data***

Returns a collection of budget_segment objects that "fan into" the given budget_pin_data object. You can use this option to trace from segments at the end of a budget path to segments nearer to the beginning of a budget path. You can use collection and attribute commands to query data similar to that shown by the **report_budget -fanin_segments** or **report_budget -**

fanout_segments commands. See the budget_attributes man page for details on what data can be queried from a budget_segment object.

-fanout_segments ***pin_data***

Returns a collection of budget_segment objects that "fan out of" the given budget_pin_data object. You can use this option to trace from segments at the beginning of a budget path toward segments nearer to the end of a budget path. You can use collection and attribute commands to query data similar to that shown by the **report_budget -fanin_segments** or **report_budget -fanout_segments** commands. See the budget_attributes man page for details on what data can be queried from a budget_segment object.

-fanin_cone ***segments_or_pin_data***

Returns a collection of budget_segment objects that occur in the transitive fanin of the given budget_segment or budget_pin_data objects. If you give segments to this option, those segments will be included in the resulting collection. The fanin_cone option can be combined with the fanout_cone option to get all budget_segments between two sets of budget_segment or budget_pin_data objects.

-fanout_cone ***segments_or_pin_data***

Returns a collection of budget_segment objects that occur in the transitive fanout of the given budget_segment or budget_pin_data objects. If you give segments to this option, those segments will be included in the resulting collection. The fanout_cone option can be combined with the fanin_cone option to get all budget_segments between two sets of budget_segment or budget_pin_data objects.

-of_pin ***budgeted_block_pin***

Specify a pin or a list of pins to be used with the **-pin**, **-pin_data** or **-pin_constraints** option. This option can be specified with the **-input** or **-output** options.

-input

Returns data for the "input" direction of a bidirectional pin. Specify this option with the **-of_pin** option.

-output

Returns data for the "output" direction of a bidirectional pin. Specify this option with the **-of_pin** option.

-filter ***expression***

Filters the collection with *expression*. Only objects that conform to the expression will be included in the output collection. The **-filter** option can be used with the **-clocks**, **-path_types**, **-all_segments**, **-all_pins**, **-all_pin_data**, or **-all_pin_constraints** option.

DESCRIPTION

Queries attributes, settings, and analysis information for budgeting. Almost any data that can be obtained from the **report_budget** command can be accessed as Tcl objects and attributes by the **get_budgets** command. See the different option descriptions for details.

Use commands such as **foreach_in_collection**, **index_collection**, and **get_attribute** to access the raw data. See the budget_attributes man page for details of what attributes are available on what objects.

EXAMPLES

The following example prints a list of segments that have frozen constraints.

```
set fpins [get_budgets -all_pins -filter internal_frozen==true]
foreach_in_collection pin $fpins {
   echo [get_attribute $pin pin.full_name]
}
```

The following example prints a list of pins on budgeted blocks that have no timing paths.

```
set upins [get_budgets -all_pins -filter undefined(pin_data)]
foreach_in_collection pin $upins {
   echo [get_attribute $pin pin.full_name]
}
```

The following example prints a list of budget path types that are launched from CLK2.

```
set pts [get_budgets -path_types -filter launch_clock.clock.name==CLK2]
foreach_in_collection pt $pts {
   echo [get_attribute $pt full_name]
}
```

The following example prints a list of budget segments that are constrained by the "fast_rule" net_estimation_rule.

```
set pts [get_budgets -all_segments -filter rule_name==fast_rule]
foreach_in_collection pt $pts {
   echo [get_attribute $pt full_name]
}
```

The following example prints the number of budgeted paths in the design that start in "block1" and end in "block2".

```
set count 0
foreach_in_collection pin [get_pins block1/*] {
 foreach_in_collection pin_data [get_budgets -pin_data -of_pin $pin] {
  foreach_in_collection segment [get_budgets -fanout_segments $pin_data] {
   set to_cell [get_cells -of_objects [get_attribute $segment to_pin]]
   if {[get_attribute $to_cell name] == "block2"} {
    set count [expr $count + 1]
   }
  }
 }
}
puts $count
```

The following example prints the name of any budgeted pin where a multicycle path through the pin is not meeting the current budget.

```
foreach_in_collection pin_data [get_budgets -all_pin_data] {
 set path_type [get_attribute $pin_data path_type]
 set is_multicycle [string equal -length 19 \
  [get_attribute $path_type exception] "set_multicycle_path"]
 if {$is_multicycle && (
    ([get_attribute $pin_data launch_slack] < 0.0) ||
    ([get_attribute $pin_data capture_slack] < 0.0))} {
  puts $pin
 }
}
```

The following example returns all segments on paths between block1 and block2.

```
set from_segs [get_budget -all_segments -filter \
  "from_block==block1 AND undefined(from_pin)"]
set to_segs [get_budget -all_segments -filter \
  "to_block==block2 AND undefined(to_pin)"]
set between_segs [get_budgets -fanout_cone $from_segs -fanin_cone $to_segs]
```

get_bump_cluster_name

Returns a string of one or more bump cluster names which match the specified pattern, or which contain any of the specified *-of_objects*. If more than one bump cluster match input criteria, the return string contains space-separated name of all bump clusters.

SYNTAX

string **get_bump_cluster_name**
[*patterns*
| -of_objects *objects*]

Data Types

patterns string or collection
objects collection

ARGUMENTS

patterns

Specifies the name pattern for finding bump clusters. This is an optional argument. If a wildcard expression is specified, it is used to match against all bump clusters in current design.

-of_objects *objects*

Specifies a collection of one or more objects for which a bump cluster containing such object is matched. Allowed objects are only those objects which can be contained in an edit group. This is an optional argument. This argument is mutually exclusive with *patterns* argument. If no argument is specified, command returns the name of all bump clusters.

DESCRIPTION

This command returns a space-separated string containing the names of all bump clusters which match the input criteria. Bump clusters can be matched either by their name for given wildcard expression, or by the *-of_objects* option. If no bump cluster matches the input criteria, the command issues a warning message and returns an empty string.

EXAMPLES

The following example returns a space-separated string of all bump clusters with a name that begins with bump_cluster_1:

```
prompt> get_bump_cluster_name bump_cluster_1*
"bump_cluster_1 bump_cluster_10 bump_cluster_11 bump_cluster_12"
```

The following examples returns a space-separated string of all bump clusters with name that contain specified **-of_objects**:

```
prompt> get_bump_cluster_name -of_objects [get_cells bump_cluster_xyz_bump23]
"bump_cluster_xyz"
```

SEE ALSO

create_bump_cluster(2)
get_bump_cluster_objects(2)

get_bump_cluster_objects

Creates a collection by selecting specified type of objects from given bump cluster(s).

SYNTAX

collection **get_bump_cluster_objects**
cluster_name_or_collection
[*-bumps*
| *-tsvs*
| *-vias*
| *-route_shapes*]

Data Types

cluster_name_or_collection string or collection

ARGUMENTS

cluster_name_or_collection

Specifies the bump cluster name or collection for finding objects. This is a required argument. If a wildcard expression is specified, it is used to match against all bump clusters in the current design.

-bumps

Returns all bump cell instances for given bump cluster collection. This is an optional argument. However, if none of the other optional arguments is specified, command selects this option as default behavior.

-tsvs

Returns all TSV cell instances for a given bump cluster collection. This is an optional argument.

-vias

Returns all vias for a given bump cluster collection. Note, vias do not include TSV instances. This is an optional argument.

-route_shapes

Returns all route shapes for a given bump cluster collection. This is an optional argument.

DESCRIPTION

This command creates a collection of the specified type of objects from the bump clusters that match the bump cluster name, or are defined by the bump cluster collection. It returns a collection handle if one or more specified type of objects are found. If no objects are found, it issues a warning message and returns an empty string.

Use the **get_bump_cluster_objects** command as an argument to another command or assign its result to a variable. See the example below for more information.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of all non-TSV cells contained in bump cluster bump_cluster_123:

```
prompt> get_bump_cluster_objects bump_cluster_123
{"bump_cluster_123_bump1", "bump_cluster_123_bump2", "bump_cluster_123_bump3",
"bump_cluster_123_bump4"}
```

The following examples creates a collection of all TSV cells contained in bump clusters whose name begins with bump_cluster_xyz:

```
prompt> get_bump_cluster_objects bump_cluster_xyz* -tsvs
{"THROUGH_SILICON_VIA_0", "THROUGH_SILICON_VIA_1"}
```

The following examples creates a collection of all non-TSV vias contained in all bump clusters:

```
prompt> get_bump_cluster_objects * -vias
{"VIA_S_0", "VIA_S_1"}
```

The following examples creates a collection of all route shapes contained in bump clusters of given collection:

```
prompt> get_bump_cluster_objects [get_edit_groups bump_cluster_xyz] -route_shapes
{"RECT_74_1", "RECT_74_2"}
```

SEE ALSO

create_bump_cluster(2)
get_bump_cluster_name(2)
get_edit_groups(2)

get_bundles

Creates a collection of bundles. You can assign these bundles to a variable or pass them into another command.

SYNTAX

collection **get_bundles**
[-design *design*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
patterns | -of_objects *objects*

Data Types

design collection
exact_count int
minimum_count int
expression string
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-filter *expression*

Filters the collection with *expression*. For any bundles that match *patterns* (or *objects*) the expression is evaluated based on the bundle's attributes. If the expression evaluates to true, the bundle is included in the result.

patterns

Matches bundle names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type bundle.

-of_objects *objects*

Creates a collection of bundles containing the specified objects. Each object is a named bundle or net, or bundle collection or net collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_bundles** command creates a collection of bundles in the current design, that match certain criteria. The command returns a collection if any bundles match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_bundles** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_bundles** result to a variable.

When issued from the command prompt, **get_bundles** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_bundles** provides a fast, simple way to display bundles in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_bundles** as an

argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the bundles that begin with "o" and reference an FD2 library bundle. Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_bundles "BUNDLE*"
{"BUNDLE_0", "BUNDLE_3"}
```

remove_from_bundle(2)
report_bundles(2)

get_busplans

Get busplan_bus objects as defined by the **create_busplans** command.

SYNTAX

int **get_busplans**
[-of_object pin_port]
[pattern] [-filter *expression*]
[-quiet]

Data Types

pattern string
expression string

ARGUMENTS

-of_object *pin_or_port*

Returns the busplan that passes through the given pin or port, if any.

patterns

Matches bus names against patterns. Patterns can include the wildcard characters "*" and "?". If no pattern is specified, it defaults to "*". Patterns can also include collections of type busplan_bus. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

-filter *expression*

Filters the collection with *expression*. For any buses that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the bus. If the expression evaluates to true, the bus is included in the result.

-quiet

Suppresses warning and error messages if no matching busplans are found.

DESCRIPTION

Return busplan_bus objects as previously defined by the **create_busplans** command.

EXAMPLES

Get the busplan named bus1.

prompt> **get_busplans bus1**

Get all busplans with a rule named "fast_rule".

prompt> **get_busplans * -filter "rule_name==fast_rule"**

SEE ALSO

set_net_estimation_rule(2)
create_busplans(2)

get_cell

Creates a collection of cells from the current design relative to the current instance. You can assign these cells to a variable or pass them into another command.

SYNTAX

collection **get_cells**
[-design *design*]
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
[-hsc *separator*]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
exact_count int
minimum_count int
expression string
patterns list
separator string
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-hierarchical

Searches for cells level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a cell block1/adder, a hierarchical search finds it using "adder". This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-physical_context

Specifies that only the physical cells be searched and returned. This option can also be used with **-of_objects**. If *objects* argument to **-of_objects** is a pin, than the cell owning the pin is returned. If *objects* argument to **-of_objects** is a net, than a collection of cells owning the physical pins connected to the net is returned. If *objects* argument to **-of_objects** is a physical hierarchical cell, a collection of physical cells contained in the hierarchical cell is returned. If **-of_objects**, is not used than physical cells matching the specified *patterns* are returned.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-filter *expression*

Filters the collection with *expression*. For any cells that match *patterns* (or *objects*) the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

-hsc *separator*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects *objects*

Creates a collection of cells connected or associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a cell, pin, net, bound, io_guide, io_ring, lib_cell, module, voltage_area, voltage_area_shape, edit_group, rp_group, power_strategy, placement attraction, stub_chains, scan_chains, safety register rule,

or safety register group.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, **-hierarchical** with **-of_objects**, only makes sense if the objects are cells or rp_groups.

patterns

Matches cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type cell.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all cells at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within ***region***

Creates a collection that contains all cells that are completely inside the specified region and doesn't include cells which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching ***region***

Creates a collection that contains all cells that are completely inside the specified region and the cells which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect ***region***

Creates a collection that contains all cells which are abut/touching from inside or outside to the specified region and the cells whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

The **get_cells** command creates a collection of cells in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any cells match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_cells** result to a variable.

When issued from the command prompt, **get_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_cells** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the cells that begin with "o" and reference an FD2 library cell. Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_cells "o*" -filter "ref_name == FD2"
{"o_reg1", "o_reg2", "o_reg3", "o_reg4"}
```

The following example shows that, given a collection of pins, you can query the cells connected to those pins.

```
prompt> set pinsel [get_pins o*/CP]
{"o_reg1/CP", "o_reg2/CP"}
prompt> query_objects [get_cells -of_objects $pinsel]
{"o_reg1", "o_reg2"}
```

The following example sets a timing derate on cells i1 and i2.

```
prompt> set_timing_derate -late 1.1 [get_cells {i1 i2}]
1
```

regexp(2)
shell.common.collection_result_display_limit(3)

get_cell_array_patterns

Creates a collection by selecting cell array_patterns from the current block.

SYNTAX

collection **get_cell_array_patterns**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the cell array pattern attributes. You can determine the cell array pattern attributes by using the **list_attributes** command. If the expression evaluates to **true**, the cell array pattern is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for cell array patterns.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are

mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for cell array patterns level-by-level relative to the current instance.

patterns

Matches the cell array pattern names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

DESCRIPTION

This command creates a collection of cell array patterns that meet the selection criteria. It returns a collection handle if one or more cell array patterns meet the selection criteria. If no cell array patterns match the selection criteria, it returns an empty string.

You can use the **get_cell_array_patterns** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of cell_array_patterns by matching the name against the pattern:

```
prompt> get_cell_array_patterns CELL_ARRAY_PATTERN*
{CELL_ARRAY_PATTERN0 CELL_ARRAY_PATTERN1 CELL_ARRAY_PATTERN2}
```

The following example creates a collection of all cell_array_patterns:

```
prompt> get_cell_array_patterns *
{mycap0 mycap1 CELL_ARRAY_PATTERN0 CELL_ARRAY_PATTERN1 CELL_ARRAY_PATTERN2}.in -0.25in
```

SEE ALSO

create_cell_array_pattern(2)
remove_cell_array_patterns(2)
report_cell_array_patterns(2)

get_cell_buses

Creates a collection of cell_buses from the current design relative to the current instance. You can assign these cell_buses to a variable or pass them into another command.

SYNTAX

collection **get_cell_buses**
[-design *design*]
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
[-hsc *separator*]
patterns | -of_objects *objects*

Data Types

design collection
exact_count int
minimum_count int
expression string
patterns list
separator string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-hierarchical

Searches for cell_buses level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-filter *expression*

Filters the collection with *expression*. For any cell_buses that match *patterns* (or *objects*) the expression is evaluated based on the cell_bus's attributes. If the expression evaluates to true, the cell_bus is included in the result.

-hsc *separator*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects *objects*

Creates a collection of cell_buses associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a cell or pin_bus. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both. In addition, **-hierarchical** with **-of_objects**, only makes sense if the objects are cells or rp_groups.

patterns

Matches cell_bus names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type cell_bus. Supports patterns containing hierarchical separator when **-hierarchical** is specified.*patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_cell_buses** command creates a collection of cell_buses in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any cell_buses match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

A cell_bus represents an array of cells created with the same base name. This is typically accomplished in the source HDL using an

array notation.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_cell_buses** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_cell_buses** result to a variable.

When issued from the command prompt, **get_cell_buses** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_cell_buses** provides a fast, simple way to display cell_buses in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_cell_buses** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the cell_buses that begin with "reg_bus". Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_cell_buses "reg_bus*"
{"reg_bus_x", "reg_bus_y"}
```

get_cells

Creates a collection of cells from the current design relative to the current instance. You can assign these cells to a variable or pass them into another command.

SYNTAX

collection **get_cells**
[-design *design*]
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
[-hsc *separator*]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
exact_count int
minimum_count int
expression string
patterns list
separator string
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-hierarchical

Searches for cells level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a cell block1/adder, a hierarchical search finds it using "adder". This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-physical_context

Specifies that only the physical cells be searched and returned. This option can also be used with **-of_objects**. If *objects* argument to **-of_objects** is a pin, than the cell owning the pin is returned. If *objects* argument to **-of_objects** is a net, than a collection of cells owning the physical pins connected to the net is returned. If *objects* argument to **-of_objects** is a physical hierarchical cell, a collection of physical cells contained in the hierarchical cell is returned. If **-of_objects**, is not used than physical cells matching the specified *patterns* are returned.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-filter *expression*

Filters the collection with *expression*. For any cells that match *patterns* (or *objects*) the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

-hsc *separator*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects *objects*

Creates a collection of cells connected or associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a cell, pin, net, bound, io_guide, io_ring, lib_cell, module, voltage_area, voltage_area_shape, edit_group, rp_group, power_strategy, placement attraction, stub_chains, scan_chains, safety register rule,

or safety register group.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, **-hierarchical** with **-of_objects**, only makes sense if the objects are cells or rp_groups.

patterns

Matches cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type cell.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all cells at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within ***region***

Creates a collection that contains all cells that are completely inside the specified region and doesn't include cells which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching ***region***

Creates a collection that contains all cells that are completely inside the specified region and the cells which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all cells which are abut/touching from inside or outside to the specified region and the cells whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

The **get_cells** command creates a collection of cells in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any cells match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_cells** result to a variable.

When issued from the command prompt, **get_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_cells** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the cells that begin with "o" and reference an FD2 library cell. Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_cells "o*" -filter "ref_name == FD2"
{"o_reg1", "o_reg2", "o_reg3", "o_reg4"}
```

The following example shows that, given a collection of pins, you can query the cells connected to those pins.

```
prompt> set pinsel [get_pins o*/CP]
{"o_reg1/CP", "o_reg2/CP"}
prompt> query_objects [get_cells -of_objects $pinsel]
{"o_reg1", "o_reg2"}
```

The following example sets a timing derate on cells i1 and i2.

```
prompt> set_timing_derate -late 1.1 [get_cells {i1 i2}]
1
```

get_cells_of_scan_chain

Returns a collection containing all scan cells of the specified SCANDEF stub chain.

SYNTAX

collection **get_cells_of_scan_chain**
-chain *chain_name*

Data Types

chain_name string

ARGUMENTS

-chain *chain_name*

Specifies the name of the SCANDEF stub chain.

DESCRIPTION

This command returns a Tcl collection containing all scan cells for the specified scan chain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example gets all scan cells of the *chain1* scan chain:

prompt> **get_cells_of_scan_chain -chain "chain1"**

SEE ALSO

get_scan_chain_count(2)

get_checkpoint_data

Queries the checkpoints and the associated actions and reports.

SYNTAX

string **get_checkpoint_data**
[-list_names]
[-name *checkpoint_name*]
[-list_reports]
[-report *report_name*]
[-list_actions]
[-action *action_name*]

Data Types

checkpoint_name string
report_name string
action_name string

ARGUMENTS

-list_names

Specifies a time-ordered list of previously executed checkpoints.

-name *checkpoint_name*

Specifies detailed information about a previously executed checkpoint.

-list_reports

Lists all defined checkpoint system reports.

-report *report_name*

Specifies detailed information about a defined checkpoint report.

-list_actions

Lists all defined checkpoint system actions.

-action *action_name*

Returns detailed information about a defined checkpoint action.

DESCRIPTION

This command queries information about the checkpoint system, including previously executed checkpoints, defined reports and actions, as well as details about those checkpoints, reports, and actions.

Use -list_names, -list_reports, or -list_actions to get a Tcl list of all executed checkpoints or defined reports or actions. Use -name, -report, or -action to get detailed information about a specific checkpoint, report, or action. Specify only one of those six options at a time; all are mutually exclusive with each other.

The -name, -report, and -action options all return a Tcl dictionary consisting of key / value pairs of a particular property of that checkpoint / report / action, and the value for that property.

- memory: The peak memory up through execution of the checkpoint
- start_time: The starting clock time of that checkpoint's execution
- end_time: The ending clock time of that checkpoint's execution
- before_runtime: The runtime from the end of the previous checkpoint to the start of this checkpoint. For the first checkpoint in the tool session, it is the runtime from tool startup until the start of this checkpoint.
- before_report_runtime: The runtime of all before phase reporting for this checkpoint
- self_runtime: The runtime of the checkpointed block of Tcl commands, as well as any before/after/replace actions associated to that checkpoint
- after_report_runtime: The runtime of all after phase reporting for this checkpoint
- after_runtime: The runtime from the end of this checkpoint until the start of the next checkpoint. For the last checkpoint in an active tool session, it will always show zero. For the last checkpoint in an exited tool session, it will show the runtime from teh end of this checkpoint until the end of the tool session.
- before_reports: A time-ordered Tcl list of all reports that were executed before this checkpoint
- after_reports: A time-ordered Tcl list of all reports that were executed after this checkpoint
- before_actions: A time-ordered Tcl list of all actions that were executed before this checkpoint
- after_actions: A time-ordered Tcl list of all actions that were executed after this checkpoint

  after_patterns: A ordered Tcl list of association constraints to run before this report or action
- replace_patterns: A ordered Tcl list of association constraints to run before this action. -report does not return the replace_patterns property, since reports cannot be associated to replace a checkpoint.

  Each of the three *_patterns properties returns with this format:

  {{enable|disable1 pattern1} {enable|disable2 pattern2} ...}

  For example, this indicates the report or action was enabled for all checkpoints (*), and then disabled only for the create_placement checkpoint. {{enable *} {disable create_placement}}

EXAMPLES

The following example returns a time-ordered list of previously executed checkpoints.

```
prompt> get_checkpoint_data -list_names
```

The follow example returns information about the multibit report

```
prompt> get_checkpoint_data -report multibit
```

get_clock_balance_groups

Create a collect of clock_balance_groups in the current design.

SYNTAX

collection **get_clock_balance_groups**
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

design collection
mode collection
expression string
exact_count integer
minimum_count integer
objects collection
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-filter *expression*

Filters the collection with *expression*. For any clock_balance_group that matches *patterns* (or *objects*) the expression is evaluated based on the clock_balance_group's attributes. If the expression evaluates to true, the clock_balance_group is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of clock_balance_groups associated with the specified objects. The object can be a clock. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches clock_balance_group names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type clock_balance_group. *patterns* and **-of_objects** are mutually exclusive.

DESCRIPTION

This command will create a collection of clock balance groups in the current design and current mode.

EXAMPLES

The following example gets all clock_balance_groups in the mode "mode1".

prompt> **get_clock_balance_groups -mode mode1**

SEE ALSO

create_clock_balance_group(2)
report_clock_balance_groups(2)
remove_clock_balance_groups(2)
balance_clock_groups(2)

get_clock_gate_pins

Creates a collection of clock gate pins of the specified type.

SYNTAX

collection **get_clock_gate_pins**
[-type *pin_type*]
[-of_objects *clock_gates*]

Data Types

pin_type list
clock_gates list

ARGUMENTS

-type *pin_type*

Specifies pin type of the clock gating cells to be returned. The values can be:

gated_clock gated clock output pin
clock clock input pin
enable enable input pin
test test input pin
observation observation output pin

If you do not specify this option, the command returns gated_clock output pins.

-of_objects *clock_gates*

Specifies the clock gating cells whose pins are returned. If you do not specify this option, the command searches all clock gates.

DESCRIPTION

The **get_clock_gate_pins** command creates a collection of specified pins of clock gate cells in the current design. If no clock gate cells with the specified pin are found, an empty collection is returned.

You can use the **get_clock_gate_pins** command at the command prompt, or you can nest it as an argument to another command, such as **connect_net**. In addition, you can assign the **get_clock_gate_pins** result to a variable.

When issued from the command prompt, **get_clock_gate_pins** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the

collection_result_display_limit variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The first example gets the gated clock output pin (default pin type) of the clockGateA cell.

prompt> **get_clock_gate_pins -of_objects {clockGateA}**

{clockGateA/ECK}

The next example returns the clock input pin and the enable pin of clockGateA and clockGateB.

prompt> **get_clock_gate_pins -type {clock enable}**

{clockGateA/CK clockGateA/E clockGateB/CK clockGateB/E}

SEE ALSO

collections(2)
get_clock_gates(2)
report_clock_gating(2)

get_clock_gates

Creates a collection of clock gate cells that meet the specified criteria.

SYNTAX

collection **get_clock_gates**
[-clock *clocks*]
[-level *levels*]
[-stage *stages*]
[-type {*clock_gate* | *self_gate*}]
[-origin {*tool_inserted* | *pre_existing*}]
[*patterns*]

Data Types

clocks list
levels list
patterns list

ARGUMENTS

-clock *clocks*

Searches for clock gate cells whose base clock matches *clocks*. If you do not specify this option, all clocks are searched.

-level *levels*

Searches for clock gates cells whose level matches the entry of *levels*. If you do not specify this option, all levels are searched.

-stage *stages*

Searches for clock gates cells whose stage matches the entry of *stages*. If you do not specify this option, all stages are searched.

-type {*clock_gate* | *self_gate*}

Specifies the type of gate cells to be obtained. The type can be *clock_gate*, *self_gate*, or both. With *clock_gate* the command searches for regular clock gate cells. With *self_gate* the command searches for self gate cells. If *clock_gate* and *self_gate* are used together, or neither are used, it searches for regular clock gates and self gates.

-origin {*tool_inserted* | *pre_existing*}

Specifies the origin of the clock gates to be obtained. The origin can be *tool_inserted*, *pre_existing*, or both. With *tool_inserted* the command searches for clock gate cells that are inserted by the tool. With *pre_existing* the command searches for clock gate cells that are manually inserted by the user. If *tool_inserted* and *pre_existing* are used together, or neither are used, it searches for pre-existing and tool inserted clock gates.

patterns

Matches clock gate names against *patterns*. Patterns can include the wildcard characters asterisk(*) and question mark(?). For more details about using and escaping wildcards, refer to the **wildcards** man page. If you do not specify any pattern, the tool uses (*).

DESCRIPTION

The **get_clock_gates** command creates a collection of clock gate cells in the current design that match the specified criteria. If no clock gate cells match the criteria, an empty collection is returned.

You can use the **get_clock_gates** command at the command prompt, or you can nest it as an argument to another command, such as **get_clock_gate_pins**. In addition, you can assign the **get_clock_gates** result to a variable.

When issued from the command prompt, **get_clock_gates** behaves as though **query_objects** is called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns clock gate cells in the design with the following configuration:

- Two clock gate cells manually inserted at level 1, clockGateA and clockGateB.
- Two clock gate cells inserted by the tool at level 2, clock_gate_mid_A/out_reg_0 and clock_gate_mid_B/out_reg_1.
- clockGateA is driving clock_gate_midA/out_reg_0.
- clockGateB is driving clock_gate_midB/out_reg_1.
- The clock source of clockGateA is CLKA.
- The clock source of clockGateB is CLKB.

```
prompt> get_clock_gates
{clockGateA clockGateB clock_gate_mid_A/out_reg_0 clock_gate_mid_B/out_reg_1}

prompt> get_clock_gates clock_gate_mid_A/*
{clock_gate_mid_A/out_reg_0}

prompt> get_clock_gates -level 1
{clockGateA clockGateB}

prompt> get_clock_gates -origin {tool_inserted}
{clock_gate_mid_A/out_reg_0 clock_gate_mid_B/out_reg_1}

prompt> get_clock_gates -clock CLKA
{clockGateA clock_gate_mid_A/out_reg_0}
```

get_clock_group_groups

Creates a collection of the clock group groups (groups of a clock group) in a clock_group in the current scenario.

SYNTAX

collection **get_clock_group_groups** [-quiet]
clock_group

string *clock_group*

ARGUMENTS

clock_group

The clock group object for which to return the clock group group objects. Only one clock group object is allowed in this command.

DESCRIPTION

The **get_clock_group_groups** command creates a collection of clock group group objects of a specific clock group object in the current scenario. You can assign these clock group groups to a variable or pass them into another command. The clock groups were previously created by the **set_clock_groups** command.

The command returns a collection if the specified clock group object exists, else returns an empty string.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command works on the mode of the specified clock group.

EXAMPLES

In the following example a variable named cg is set to a clock group object. It then sets a variable named cg_groups with the clock group group objects of that clock group.

```
prompt> set cg_groups [get_clock_group_groups $cg]
```

SEE ALSO

collections(2)
set_clock_groups(2)
shell.common.collection_result_display_limit(3)

get_clock_groups

Creates a collection of clock groups in the current scenario.

SYNTAX

collection **get_clock_groups** [-quiet]
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
mode collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-of_objects *of_objects*

Creates a collection of clock groups that contain the specified objects. Each object is a named clock or clock collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

-filter *expression*

Filters the collection with *expression*. For any clock group that match the pattern or the of_objects criteria, the expression is evaluated based on the clock group's attributes. If the expression evaluates to true, the clock group is included in the result.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches clock group names against patterns. Patterns can include the wildcard characters "*" and "?". *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_clock_groups** command creates a collection of clock groups in the current scenario that match certain criteria. You can assign these clock groups to a variable or pass them into another command. The clock groups are created with the **set_clock_group** command. by default, a clock is not in a clock group.

The command returns a collection if any clock group object matches the pattern or the **-of_objects** specifiers and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

You can use the **get_clock_groups** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_clock_groups** result to a variable.

When issued from the command prompt, the **get_clock_groups** command behaves as though the **query_objects** command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this

maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_clock_groups** provides a fast, simple way to display clock groups in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_clock_groups** as an argument to **query_objects**. Note that the name shown for a clock group is either the one given during this clock group's specification and if not then its generated by the tool.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following example sets the variable cg to a collection of asynchronous clock groups which contains the clock clk1.

```
prompt> create_clock_group -asynchronous -group {clk1 clk2 clk3} -group {clk1a clk2a, clk3a}
prompt> set cg [get_clock_groups -of_objects {clk1} -filter "clock_group_type==asynchronous"]
```

get_clock_skew_groups

Creates a collection of skew groups for a design. You can assign these skew groups to a variable or pass them into another command.

SYNTAX

collection **get_clock_skew_groups**
[-design *design*]
[-mode *mode_list*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
patterns | -of_objects *objects*

Data Types

design string
mode_list list
exact_count integer
minimum_count integer
expression string
patterns list
objects collection

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode_list*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, it modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

When combined with the *-regexp* option, it makes matches case-insensitive.

-filter *expression*

Filters the collection with the *expression* value. For any skew groups that match the *patterns* values, the expression is evaluated based on the skew group's attributes. If the expression evaluates to true, the skew group is included in the result.

patterns

Matches skew_group names against patterns. Patterns can include the wildcard characters "*" and "?". *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

-of_objects *objects*

Creates a collection of skew_groups created on the specified objects. Objects can be pin and/or port and/or clock. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_clock_skew_groups** command creates a collection of skew groups that match certain criteria. The command returns a collection if any skew groups match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

You can use the **get_clock_skew_groups** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_clock_skew_groups** result to a variable.

When issued from the command prompt, the **get_clock_skew_groups** command behaves as though the **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_clock_skew_groups** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_clock_skew_groups** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following returns all the skew groups that are on the clock clk1.

```
prompt> get_clock_skew_groups -of_objects clk1
{"SG_clk11", "SG_clk2"}
```

[-total *string*]

[-unique_cells]

[-unique_nets]

[-scan_all_hierarchical_pins]

[-expect *int* | -expect_at_least *int*]
[-verbose]
[-quiet]

Data Types

extended_attribute_expression string
comma_separated_expression_list list
pin_specifying_list collection
start_index integer
end_index integer
range_list list
from_list list
through_list list
to_list list

ARGUMENTS

-clocks *clock_list*

Reports the clock trees specified in *clock_list*. By default, the command reports for clocks in the current scenario. Note that a clock object returned by "get_clocks" is bound to a scenario, so if "get_clocks" command is used, a clock from a different scenario may be searched. If a textual clock name is supplied as an option, it is equivalent to using "get_clocks" on that name with no options. This option may not be used with the scenarios, modes or corners options.

-scenario *scenario_list*

Specifies the scenarios used for resolving which clock and mode to be employed.

-mode *mode_list*

Do not process any scenario that does not incorporate a mode from this list.

-corner *corner_list*

Do not process any scenario that does not incorporate a corner from this list.

-from *from_list*

Only clock elements that are driven, directly or indirectly, by these pins will be considered. Using -from will impact the way that the clock trees are traversed. Please see discussion below. Hierarchical pins are valid inputs to **-from** option.

-through *through_list*

Only clock elements on paths through these pins will be considered.

-to *to_list*

Only paths that go to these elements these pins will be considered.

-groups_from *from_list*

Return a list of collections, one collection for each pin listed here.

-of_objects *pin_specifying_list*

Returns only the pins connected to the specified pins, ports, cells, and nets.

-filter *extended_attribute_expression*

Specifies the expression with which to filter the results. The expression must use the standard pin attributes or the ephemeral pin attributes provided by this command.

The command evaluates the expression for each pin, and eliminates any pin where the value is zero or negative. This is similar

to the **-filter** option of the **get_pins** command, but additional ephemeral attributes are available, as described below.

If the expression has an unrecogized attribute name in it, the command prints a list of available attributes and error and return nothing.

-sort_by ***extended_attribute_expression***

Specifies the expression with which to sort the results. The expression must use the standard pin attributes or the ephemeral pin attributes provided by this command.

The command evaluates the expression for each pin, and sorts the pins based on its value.

-index_range { start end }

Allows you to access a subset of the pins. The starting index is 0 and the index of the end member is the size of the set minus 1. If the start value is negative, the range is interpreted as being relative to the end of the set.

-value_for_undefined_attributes ***float***

By default, if the filter or sorting operation accesses an attribute that is undefined on a pin, such as the height of a pin that has no downstream loads, that pin will be excluded from the active set of pins. This can be overridden by the "value_for_undefined_attributes" parameter, in which case the attribute is replaced by the specified value. If this is not specified, undefined attributes have a value of -999.0. Note that an undefined attribute is different than an unknown attribute.

-metrics ***comma_separated_expression_list***

The -metrics option allows you to gather many attributes at once. The results are formed into a Tcl list and stored in the Tcl array variable specified with the -assign option. Note that if -assign is used without -metrics, the expression specified in -sort_by is stored. Any number of expressions may be specified in the -metrics option, such as "is_net_driver", "depth_max-depth_min", "toggle_rate*capacitance_max". Most commonly, the attributes are simply listed, without arithmetic operators, and calculations are done after the command is finished. The -metrics option must be used with the -assign_to_variable option.

-assign_to_variable ***tcl_variable_name***

By specifying a Tcl variable name with the assign_to_variable option, the tool will create an associative array variable by that name. This is a way to capture the value of attribute expressions. The keys of this array will be the full name of each pin returned. If used with -sort_by, this stores the floating point value of the attribute expression used to sort the pins. If used with -metrics, any number of attribute expressions may be specified. The resulting floating point values will be stored as a Tcl list in each element of the array.

-statistics_variable ***tcl_variable_name***

The -sort_by and -metrics options compute the floating point value of expressions for each clock pin output. Some statistics computed over these values, such as their max, min and mean, will be captured as a Tcl list in the variable specified by the statistics_variable option.

-total ***string***

This must be used with a -sort_by option. It computes the total of all sort_by expressions and assigns the result into the specified Tcl variable. Note that the command will also print this total, along with the smallest, largest, mean, and standard drivation of these values, whenever the command is run with a -sort_by expression.

-unique_cells

If the tool encounters multiple pins on the same cell more than once in the filtered output list, only the first occurance will be considered, and subsequent pins on the same cell will be discarded. This is useful for getting totals of attribute values, since totaling the attribute values of both inputs and outputs leads to double counting.

-unique_nets

If the tool encounters multiple pins on the same net more than once in the filtered output list, only the first occurance will be

considered, and subsequent pins on the same net will be discarded. This is useful for getting totals of attribute values, since totaling the attribute values of both the inputs and outputs of a cell causes double counting.

-scan_all_hierarchical_pins

By default, the tool skips over hierarchical pins unless they have a clock source defined on them. If -scan_all_hierarchical_pins is specified, the tool scans them, and if they are not filtered out, they are returned. Note that the value of some attributes, such as latency_max, are not defined on hierarchical pins.

-expect *exact_count*

Expect exactly this many matching objects, and raise a Tcl exception if this is not found. (Value of exact_count must be >= 0)

-expect_at_least *minimum_count*

Expect at least this many matching objects, and raise a Tcl exception if this is not found. (Value of minimum_count must be >= 0)

-verbose

Print more information about the pins found. If used with the "-sort_by" option, print a report of all the pins found and the value of the "sort_by" expression.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

DESCRIPTION

The **get_clock_tree_pins** command returns selected pins from the clock trees in the design. By default, all pins on all clock trees will be returned. The options allow you to restrict the set to a smaller set of pins. It can be used before or after CTS.

The command operates in up to seven phases:

1) Clock tree traversal, and construction of the working set of pins

2) Removing any pins from the working set if they not on paths specified by the from, through or to options.

3) Removing any pins from the working set if they were not included in the -of_objects option.

4) Removing any pins from the working set if the "filter" option expression cannot be evaluated or evaluates to false.

5) Sorting the working set according to the attribute expression specified.

6) Selecting a sub-set of the sorted pins by index.

7) Returning the working set as a collection of pins, and optionally by Tcl variable.

The -clocks, -scenario, -from, and -mode options control the way that the tool traverses the clock tree(s). In a large design with many clocks, using these options may speed up execution. As it traverses the tree(s) it builds up a set of pins internally. The other options control which of these pins will be returned.

The -from, -through, and -to options can be used to discard any pins that are not on paths that are from, or though, or to specified pins. In order to qualify, a path must meet all the from, through, to requirements simultaneously. That is, if a pin is on the "from" list in one clock and on the "to" list in another clock, those pins would not quality and would be filtered out.

The -groups_from option returns not just one collection of pins, but a list of collections. The tool works through each specified pin,

and finds the clock pins that are driven from it. This is typically used to find the sinks driven by each of a list of driver pins. Each of these collections is appended into a list, which is returned by the command. If the fanouts of the pins listed overlap each other, the downstream driver is "preferred", so sinks, for example, will appear associated with the pin that drives them most closely. This is mutually exclusive with the -from, -through, and -to options.

The "-of_objects" option allows you to restrict the set of clock pins to pins related to the specified objects. The objects may be cells, nets, ports or other pins. This makes it possible, for example, to identify which pins on a given cell are "active" in the specified clock tree(s). This may not be obvious if the cell is a macro or a large multi-input gate. Note that you can pass the output of one invocation of get_clock_tree_pins to be the input to a second invocation by using this option.

The -filter option allows you to deselect pins based on the standard attributes of pins (as is done with the get_pins commands), and/or a set of ephemeral attributes available only in this command. The ephemeral attributes provide access to clock specific information, so, for example, you can filter out pins based on their latency.

The -sort_by option controls the way the set of pins is sorted. Once sorted, the pins are ordered and you can select a sub-range of them.

Please note that you can assemble groups of pins using get_clock_tree_pins several times and joining the results with "add_to_collection -unique".

Attributes available only in this command

Many of the normal pin attributes such as is_net_driver and is_net_load are available for use with the -filter option. These are listed in the next section. This section describes some additional ephemeral attributes that are available inside get_clock_tree_pins command only: they can be used to control inclusion or exclusion from the results, and can be made available for design analysis.

The ephemeral attributes include:

capacitance_limit transition_limit

These are float attributes that may be defined on all pins. CTS has several ways of specifying max capacitance, max transition rules based on clock and designs. These attributes return the value that is in effect for CTS under the specified set of clocks and scenarios. If there is no rule, the attribute is undefined.

capacitance_max

This is an ephemeral float attribute that may not be defined on all pins. The attribute represents a simple, lumped model of the pin's total load capacitance, including the net and the load pins. If a pin is inside a physical macro or for some other reason has no meaningful capacitance, this value will be undefined.

ccd_offset

This attribute represents the offset set by ccd for sinks as part of balance point. For sinks with no -offset component, it reports a "0" value. For non-sinks and intermediate pins on clock network, it report a garbage value, -999

cell_num_pins

The number of pins on the cell that the pin is attached to.

cell_internal_power_max cell_leakage_power_max cell_switching_power_max cell_total_power_max

These are ephemeral float attributes that may not be defined on all pins. Since power is associated with cells, not pins, these attributes refer to the power disappated by the cell that the pin belongs to. The total power is the sum of leakage, internal and switching power. Power is the highest power rate observed on the cell across all scenarios accessed by the command. (Note that the leakage_power, internal_power, switching_power and total_power attributes are also available at the shell level with get_attribute. These access the power in the current scenario.) Note that if a cell is accessed from more than one pin, the power attribute will be accessed twice. If you are trying to compute the total power of cells, use the "-unique_cells" option with these

attributes.

center_x center_y

These are ephemeral distances (i.e. float) attributes that are defined on all physical pins. They are the XY coordinates for the center of the pin. It may be useful for filtering out pins that are not in the region of interest, or for sorting the results from left to right, for example.

depth_max depth_min height_max height_min

These are ephemeral integer attributes that may not be defined on all pins. The depth of pin is the number of nets between it and the clock tree source. All the pins on a (single driver) net have the same depth_max and depth_min, and the pins on the net attached to the root have a depth_max and depth_min of 0. Each pin as a max and min depth because there may be reconvergence in the tree (but on most pins the depth_max will equal the depth_min). If there is no path from a clock root to the pin, the depth attributes are undefined.

The height of pin is the number of nets between it and a clock balanced pin (sink) below it in the tree. In general, the pins on a net will have different heights, and the pins attached to a sink have a height_min and height_max of 0. If there is no path from a pin to a timing balanced pin, the height attributes are undefined.

downstream_delay_max downstream_delay_min

These are ephemeral float attributes that may not be defined on all pins. The downstream delay (aka "phase delay") is computed from a pin to all of the time balanced sink pins that it drives, and includes any float pin timing. It does not include any time to "drc only" pins downstream. If no sinks are found downstream of a pin, the downstream delays are undefined.

The rise/fall times cannot be accessed independently with these attributes.

fanout_max

This is an ephemeral integer attribute that is defined on output pins. The fanout of a pin is the number of loads it drives. The fanout_max is the max fanout over all paths that pass though the output pin.

is_beyond_clock_boundary

This is an ephemeral integer (0 or 1) attribute defined on all pins. This is 1 for pins encountered while traversing the clock tree after a clock balance point has been encountered.

is_cell_sizable

This is an ephemeral integer (0 or 1) attribute defined on all pins. This has the value 1 if the cell that the pin is attached to can be resized by CTS.

is_clock_source

This is an ephemeral integer (0 or 1) attribute defined on all pins. If a generated clock lists this pin as its source, the is_generated_clock_source attribute will be 1. Note that if the command is run with several scenarios/modes and a pin is considered a clock source in any mode, then this attribute will be 1.

is_clock_to_data

This is an ephemeral integer (0 or 1) attribute defined on all pins. If a clock path transitions from being a clock element to data elements, the pin where this happens will have the clock_to_data attribute equal to 1.

is_connected_to_multidriven_net

This is an ephemeral integer (0 or 1) attribute defined on all pins. This is 1 for all driver and load pins connected to a multi-driven

net (including disabled mesh drivers). Given a pin, if its net has multiple drivers, then it will be filtered by this attribute.

is_cts_added

This an ephemeral integer (0 or 1) attribute defined on all pins. This attribute is 1 for pins on buffers and inverters that were added by clock tree synthesis.

is_float_pin is_explicit_ignore

These are ephemeral integer (0 or 1) attributes defined on all pins. A float pin may have a balance_point stop on it with an explicit time, or without a time (aka a stop pin). A pin may be explicitly ignored, or it may be ignored because of traversal rules.

is_generated_clock_source

This is an ephemeral integer (0 or 1) attribute defined on all pins. If a generated clock lists this pin as its source, the is_generated_clock_source will be 1. Note that if the command is run with several scenarios/modes and a pin is considered a generated clock source in any mode, then this attribute will be 1.

is_global_routed

This is a integer (0 or 1) attribute defined on all pins. After global routing, most nets will have some global routing associated with them. But other nets (such as very short ones), may not. Also, depending on the flow, your script may have routed a subset of clock nets, or the design might have been modified after global routing was run. The is_globally_routed property can filter nets based on this.

is_ignored

This is an ephemeral integer (0 or 1) attribute defined on all pins. Ignored pins do not participate in CTS.

is_inside_etm

This is an ephemeral integer (0 or 1) attribute defined on all pins. It is 1 for pins found inside an ETM object.

is_internal

This is an ephemeral integer (0 or 1) attribute defined on all pins. An internal pin is neither an net_driver nor a net_load.

is_leaf is_sink

These are ephemeral integer (0 or 1) attributes defined on all pins. All the pins that transition as a result of a root pin transition, and which do not drive any further pins are leaf pins. All pins that have a controlled timing relationship between them and a root are sinks. For a simple tree with no exceptions, these attributes are the same. Balance points are sinks. Note that if the command is run with several scenarios/modes and a pin is considered a sink in any mode, then this attribute will be 1.

is_mscts_subtree_driver_object

This is an ephemeral integer (0 or 1) attribute defined on all pins. This is 1 for all pins/ports specified with set_multisource_clock_subtree_options -driver_objects or set_multisource_clock_tap_options -driver_objects.

is_on_buffer is_on_icg is_on_inverter is_on_repeater

These are ephemeral integer (0 or 1) attributes defined on all pins. If a pin is on either a buffer or an inverter it is considered to be a on a repeater. Or a pin may be on an ICG, or on a gate other than an ICG (such as a NAND gate). For ports of the current design none of these attributes would be 1.

is_on_global_clock_tree

This is an ephemeral integer (0 or 1) attribute defined on all pins. This is 1 for all pins whose cell is inserted by create_clock_drivers or synthesize_multisource_global_clock_trees command

is_on_macro

This an ephemeral integer (0 or 1) attribute defined on all pins. If a pin is on a macro (physical block) this attribute will be 1.

is_on_physical_boundary

This is an ephemeral integer (0 or 1) attribute defined on all pins. If a pin is an hierarchical pin and resides on a physical boundry, this attribute will be 1. Note that this attribute should be used with the -scan_all_hierarchical_pins.

is_reconvergent

This is an ephemeral integer (0 or 1) attribute defined on all pins. A point driven by two clocks is called a convergent pin, and a point driven by two paths from the same clock is called a reconvergent pin. This attribute is 1 at the point of reconvergence and at pins below it in the tree.

is_removable

This is an integer (0 or 1) attribute defined on all pins. Pins on dont_touch cells are not removable.

is_root

This is an integer (0 or 1) attribute defined on all pins. This is 1 for all the pins where traversal starts for this command. Generally this is clock root pins, but if the -from option is used, the pins in the -from option have a is_root attribute value of 1.

latency_max latency_min

These are ephemeral float attributes that may not be defined on all pins. The max delay from a transition to a pin is available with the latency_max attribute and the latency_min is similarly defined. The latency of the root is the clock latency, which may be zero. If there is no path from the root, the value is undefined. After synthesis, latency is generally defined on all pins, even those that are not balanced by CTS such as DRC only pins past exceptions. Before synthesis, the latency value may be large, random or undefined (because of huge fanouts or massive DRC violations, for example.)

The rise/fall times cannot be accessed independently with these attributes.

load_pin_capacitance_max

This is an ephemeral float attribute that is defined on input pins. This is the max load capacitance of the pin.

net_num_pins

This is an ephemeral integer attribute defined on all pins. This is the number of pins on the net that the pin belongs to.

net_switching_power_max

This is an ephemeral float attribute that may not be defined on all pins. The power of a net is the charging/discharging power associated with the net. The power is the highest power rate observed on the net across all scenarios accessed by the command. Note that if a net is accessed from more than one pin, the power attribute will be reported twice. If you are trying to compute the total power of nets, use the "-unique_nets" option to avoid double counting.

num_edges_from_root_max

This is an ephemeral integer attribute defined on all pins. As a tree is traversed from the root, each timing arc is counted. The value is stored in this attribute. Sorting on this attribute and using the -to and -verbose options results in a list something like "report_clock_timing".

num_icgs_from_root_max

This is an ephemeral integer attribute defined on all pins. As a tree is traversed from the root, each time an ICG is encountered this value is incremented.

num_nonrepeaters_from_root_max

This is an ephemeral integer attribute defined on all pins. As a tree is traversed from the root, each time an ICG, MUX, or other clock gate is encountered this value is incremented.

routing_skew_max

This is an ephemeral float attribute that is defined on output pins. If the pin has only one fanout, its routing_skew is 0. If it has multiple fanouts, the routing_skew is the difference between the earliest and latest arrival times (which must be due to routing delays).

skew_max skew_min

This is an ephemeral float attribute that may not be defined on all pins. The skew of a pin is equal to the downstream delay max - downstream delay min that is observed as the CTS engine scans the tree. If the pin is encounted several times (e.g. is is part of several scenarios or clocks) then the skew_max may not equal the downstream_delay_max attribute - downstream_delay_min attribute. If there is one sink below the pin, the skew is 0.0. If there is no sink with a valid latency, the skew is undefined. Before synthesis, the skew attribute is generally random or undefined.

subtree_num_repeaters_max subtree_total_area_max

These are ephemeral attributes defined on the root pin of each subtree traversed. A subtree begins at the output of a non repeater (e.g. an ICG) and ends at a sink, a generated_clock, or the input of a non-repeater. The subtree_num_repeaters metric returns the number of repeater cells (inverters + buffers) in the subtree. If the subtree consists of an ICG that drives sinks directly this number will be zero. The subtree_total_area_max attribute returns the area of all repeaters plus the area of the root cell.

subtree_total_leakage_power_max subtree_total_internal_power_max subtree_total_switching_power_max

These are ephemeral float attributes defined on the root pins of subtrees. A subtree begins at the output of a non repeater (e.g. an ICG) and ends at a sink, a generated_clock, or the input of a non-repeater. These metrics return the total leakage, internal and switching power of the subtree, including the clock cell at its root. If the tool scans the driver pin and its subtree more than once and finds multiple values for the power, the largest value is returned.

toggle_rate_max

This is an ephemeral float attribute that may not be defined on all pins. It is equal to the highest switching toggle rate observed on the pin across all scenarios accessed by the command.

total_load_pin_capacitance_max

This is an ephemeral float attribute defined on net driver pins. This is the sum of the load pin capacitances.

toggle_rate_reduction_min

This is an ephemeral float attribute defined in the output of ICGs. This is the toggle rate of the output of an ICG divided by the the toggle rate of the input. If the ICG is not enabled, this will be zero. If it is enabled all the time, this rate will be 1.0. Most ICGs will have values between 0 and 1. If the value is greater than 1, there is probably an error in the SAIF file.

transition_max transition_min

These are ephemeral float attributes that may not be defined on all pins. These attributes represent the pin's max and min transition times, considering rise and fall, and early and late transitions.. The rise/fall times cannot be accessed independently with these attributes.

undefined

This is defined on all pins for convenience. When the tool must return a value for an undefined attribute, it returns -999 (or whatever value has been set with the -value_for_undefined_attributes option). Using "==undefined" in your filter express to handle undefined attributes (instead of "==-999") makes it a little easier to read. For example "-filter is_hierarchical==undefined" will return all pins for which the is_hierarchical attribute is not defined: e.g. ports.

Access to Persistent (non ephemeral) Attributes

In addition to the attributes listed above, the command provides access to some of the standard pin attributes. This can be useful when sorting or filtering pins. (The "is_net_driver" and "is_net_load" attributes are particularly useful.):

case_value clock_latency_fall_max clock_latency_fall_min clock_latency_rise_max clock_latency_rise_min clock_source_latency_early_fall_max clock_source_latency_early_fall_min clock_source_latency_early_rise_max clock_source_latency_early_rise_min clock_source_latency_late_fall_max clock_source_latency_late_fall_min clock_source_latency_late_rise_max clock_source_latency_late_rise_min constant_value dont_touch_network dont_touch_network_no_propagate hold_uncertainty is_async_pin is_clear_pin is_clock_gating_clock is_clock_gating_enable is_clock_gating_pin is_clock_pin is_clock_used_as_clock is_clock_used_as_data is_data_pin is_fall_edge_triggered_clock_pin is_fall_edge_triggered_data_pin is_feedthrough_port is_fixed is_hierarchical is_ideal is_latch_loop_breaker is_negative_level_sensitive_clock_pin is_negative_level_sensitive_data_pin is_net_driver is_net_load is_positive_level_sensitive_clock_pin is_positive_level_sensitive_data_pin is_preset_pin is_rise_edge_triggered_clock_pin is_rise_edge_triggered_data_pin is_scan is_three_state is_three_state_enable_pin is_three_state_output_pin is_user_latch_loop_breaker max_capacitance_constraint max_rise_input_cap max_rise_load_cap max_slack max_time_borrow max_transition_constraint min_capacitance_constraint min_slack propagated_clock setup_uncertainty user_case_value user_case_value user_clock_sense

Sorting by an Attribute Expression

The default behavior is to sort the pins in increasing alphabetical order before returning them. In addition, they may also be sorted by an expression using any boolean, integer or float attribute. For example, sorting on latency_max will yield a collection with the lowest latency pins first. For attributes such as is_sink and is_on_repeater which would normally be thought of as booleans, "false" has a value of 0, and is therefore smaller than "true" which has a value of 1, so pins with the false attribute value will appear in the output before pins with a "true" value. In addition to 0 and 1 values, some attributes may be undefined on some pins and when this occurs, they will have the value of -999 (or whatever value was set with the "-value_for_undefined_attributes" option). Pins with the same attribute value will be sorted alphabetically (i.e. "ba3/reg7/clk" before "g1/clk"). Note that you can reverse the sort by putting a minus sign in front of the expression. For example, sorting on -latency_max will yield a collection with the highest latency pins first. Pins with the same latency value will still be sorted forward alphabetically.

Selecting a subset of pins by index

If you don't want the whole set, you can specify which members you want by index. The starting index is 0, and if there are 7 members, the index of the last pin is 6. The range {0 9} will try to return the first 10 members, but if there are not 10 members it will return the whole set. A range of {5 6} would return the last two members. The default end option is the end of the set, so this could be written as {5}. If the start value is negative, the range is interpreted as being relative to the end of the set, so a range of { -2 -1 } would also specify the last two elements (as would just {-2}).

EXAMPLES

In the following example, the **get_clock_tree_pins** finds sink pins clock tree called clk1.

```
prompt> set sss [get_clock_tree_pins -filter is_sink -clock clk1]
{DFF4/CP DFF3/CP DFF2/CP DFF1/CP DFF0/CP DFF7/CP DFF6/CP DFF5/CP clk1iv1/Z
CTS_BUF_R__14911490/Z CTS_BUF_R__14871486/Z CTS_BUF_R__14861485/Z
clk1iv4/Z CTS_BUF_14841483/Z AFF1/CP AFF3/CP AFF6/CP AFF7/CP CP FF36/CP
FF35/CP FF34/CP FF33/CP FF32/CP FF31/CP FF46/CP FF45/CP FF44/CP
FF43/CP FF42/CP FF41/CP FF40/CP FF39/CP FF54/CP FF53/CP FF52/CP
FF51/CP FF50/CP FF49/CP FF48/CP FF47/CP FF62/CP FF61/CP FF60/CP FF59/CP FF58/CP ...}
```

In the following example, the **get_clock_tree_pins** finds ICG pins on the clock tree named clk1.

```
prompt> set sss [get_clock_tree_pins -filter is_on_icg -clock clk1]
{icg1/CK  icg1/ENCK }
```

This command can be used with the **change_selection** command to highlight parts of the clock tree. Here the command highlights any sinks 8 or more down.

```
prompt> change_selection \
  [get_clock_tree_pins -filter is_sink&&depth_max>=8]
1
```

The -expect option can be used as a simple validation check. This command checks for synthesized delay buffers with 200ps or more of cumulative delay. If such a structure is found, it raises a Tcl exception; otherwise, it is silent. For example, the following command raises an exception if any pin in the tree has a latency of 0.200 time units or greater.

```
prompt> get_clock_tree_pins -quiet -expect 0 -filter latency_max>0.200
1
```

In some cases, it might be useful to identify pins where an attribute is undefined, such as the skew at a pin with no balanced sinks below it. For example, in a simple, well-defined clock tree, all drive pins should have a defined, non-negative skew. This test finds any that did not.

```
prompt> get_clock_tree_pins -value_for_undefined -1 \
  -filter is_net_driver&&skew_max==undefined
```

If you need to access the skew, depth, height, or any other ephemeral attribute value after the command has executed, you can do so by sorting on that attribute and using the **-assign_to_variable** option. Each of the pins in the final sort list will correspond to one entry in this Tcl variable, and you can access it with the standard Tcl array syntax.

```
prompt> set slowest_pin [get_clock_tree_pins -filter is_sink \
  -sort_by latency_max -index_range -3 -assign_to_variable lat_values]
{block1/reg17/clk block1/reg52/clk block2/reg203/clk}
prompt> echo $lat_values(block1/reg52/clk)
0.0142
```

To get the pins of skew groups based on their ICG output pins, use the **-groups_from** option. In this example, the list returned as been indented to highlight the fact that it is a list of two collections.

```
prompt> set skew_groups_list [get_clock_tree_pins -filter is_sink \
  -groups_from { icg1.out  icg2.out} ]
{SUB2/FF0/CP SUB2/FF1/CP SUB3/FF0/CP SUB3/FF1/CP SUB4/FF0/CP SUB4/FF1/CP
SUB4/SUB5/FF0/CP SUB4/SUB5/FF1/CP SUB4/SUB6/FF0/CP SUB4/SUB6/FF1/CP
SUB7/FF0/CP SUB7/FF1/CP}
{SUB1/FF0/CP SUB1/FF1/CP SUB1/FF2/CP SUB1/FF3/CP SUB1/FF4/CP SUB1/FF5/CP
SUB1/FF6/CP SUB1/FF7/CP SUB1/FF8/CP SUB1/FF9/CP}

prompt> query [lindex $skew_groups 1]
{SUB1/FF0/CP SUB1/FF1/CP SUB1/FF2/CP SUB1/FF3/CP SUB1/FF4/CP SUB1/FF5/CP
SUB1/FF6/CP SUB1/FF7/CP SUB1/FF8/CP SUB1/FF9/CP}
```

The **-metrics** option can be used to gather many metrics at the same time. You can use Tcl to extract the values for further processing.

```
## gather some power related metrics and put them in a variable called "subs"
prompt> set met_names "height_max, subtree_delay_longest, \
  subtree_num_repeaters_max, subtree_total_area_max, \
  subtree_total_switching_power_max, toggle_rate_max"
prompt> get_clock_tree_pins -metrics $met_names \
  -filter is_net_driver -assign subs -clock CORE_CLK
...

## pick up the first element of the array
prompt> echo lindex [array names subs] 0] \
  $subs([lindex [array names subs] 0])
SUB1/FF5/latch/Q 2 3.2 3.0 3 21.23 35442112.22 0.4444
```

Note that with some Tcl code you can collate the elements in the lists returned with the "met_names" option string. You can also convert the output to CSV format and write it into a file, as shown in the following example:

```
echo  pin_name, $met_names > subs.csv
foreach indx [array names subs] {
 echo  -n $indx >> subs.csv
 foreach e $subs($indx) {
    echo -n  ", $e" >> subs.csv
 }
 echo  "" >> subs.csv
}
```

To get the hierarchical pins in a design, you must use the **-scan_all_hierarchical_pins** option.

```
prompt> get_clock_tree_pins -scan_all_hierarchical_pins \
  -filter is_on_physical_boundary

prompt> get_clock_tree_pins -statistics stats \
  -metrics latency_max,latency_min -sort_by depth_max
SFF6/CP SFF7/CP U02/B U27/D0 U28/A U28/B U28/C U29/A U90/B U91/A
clk1 clk2 clk3 ...

prompt> lindex $stats 0
{expression   {depth_max}}   {count 174} {total 679} {mean 3.90229893}
{std_dev 1.74259639} {max 7} {min 0}

prompt> lindex $stats 1
{ expression {latency_max}}   {count 174} {total 133.08136945265142}
{mean 0.764835477} {std_dev 0.247443825} {max 0.99067997932434082} {min 0}

prompt> lindex $stats 2
{ expression {latency_min}}   {count 174} {total 129.66261979239789}
{mean 0.745187461} {std_dev 0.244880974} {max 0.9508100152015686} {min 0}
```

get_clocks

Creates a collection of clocks from the current design. You can assign these clocks to a variable or pass them into another command.

SYNTAX

collection **get_clocks**
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns

Data Types

design	collection
mode	collection
expression	string
exact_count	int
minimum_count	int
patterns	list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-filter *expression*

Filters the collection with *expression*. For any clocks that match *patterns*, the expression is evaluated based on the clock's attributes. If the expression evaluates to true, the clock is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches clock names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_clocks** command creates a collection of clocks in the current design that match certain criteria. The command returns a collection if any clocks match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

You can use the **get_clocks** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_clocks** result to a variable.

When issued from the command prompt, **get_clocks** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_clocks** provides a fast, simple way to display clocks in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_clocks** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page. In addition, see the man page for **all_clocks**, which also creates a collection of clocks.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following example applies the **set_max_time_borrow** command to all clocks in the design matching "PHI*".

prompt> **set_max_time_borrow 0 [get_clocks "PHI*"]**

The following example sets the variable clock_list to a collection of clocks that have period of 15.

prompt> **set clock_list [get_clocks * -filter "period==15"]**

get_command_hooks

Get registered hooks for this command

SYNTAX

string **get_command_hooks** *commandName*

string *commandName*

ARGUMENTS

commandName

Command to query

DESCRIPTION

The **get_command_hooks** command returns information about any hooks registered on the specified command. The data returned is in Tcl dict format and may be queried using that command.

EXAMPLES

When a command has both before and after hooks registered the data will look like this

```
prompt> get_command_hooks place_opt
before {before0 report_timing}
after {after0 {echo "Done with placement"}}
```

SEE ALSO

add_command_hook(2)
remove_command_hook(2)
get_current_hook_command(2)
dict(2)

get_command_option_values

Queries current or default option values.

SYNTAX

get_command_option_values
[-default | -current]

-command *command_name*

Data Types

command_name string

ARGUMENTS

-default

Gets the default option values, if available.

-current

Gets the current option values, if available.

-command *command_name*

Gets the option values for this command.

DESCRIPTION

This command attempts to query a default or current value for each option (of the command) that has default and/or current-value-tracking enabled. Details of how the option value is queried depend on whether one of the **-current** or **-default** options is specified (see below).

A "Tcl array set compatible" (possibly empty) list of option names and values is returned as the Tcl result. The even-numbered entries in the list are the names of options that were enabled for default-value-tracking or current-value-tracking and had at least one of these values set to a not-undefined value). Each odd-numbered entry in the list is the default or current value of the option name preceding it in the list.

Any options that were not enabled for either default-value-tracking nor current-value-tracking are omitted from the output list.

Similarly, options that were enabled for default-value-tracking or current-value-tracking, but for which no (not-undefined) default or current value is set, are omitted from the result list.

If neither **-current** nor **-default** is specified, then for each command option that has either default-value-tracking or current-value-tracking (or both) enabled, the value returned is as follows:

- The current value is returned if current-value-tracking is enabled and a (not-undefined) current value has been set;
- Otherwise the default value is returned if default-value-tracking is enabled and a (not-undefined) default value has been set;
- Otherwise the name and value pair for the option is not included in the result list.

If **-current** is specified, the value returned for an option is the current value if current-value-tracking is enabled, and a (not-undefined) current value has been set; otherwise the name and value pair for the option is omitted from the result list.

If **-default** is specified, the value returned for an option is the default value if default-value-tracking is enabled, and a (not-undefined) default value has been set; otherwise the name and value pair for the option is omitted from the result list.

The result list from **get_command_option_values** includes option values of both dash options and positional options (assuming that both kinds of options of a command have been enabled for value-tracking).

The command issues a Tcl error in a variety of situations, such as if an invalid command name was passed in with **-command**.

EXAMPLES

The following example shows the use of **get_command_option_values**:

```
prompt> test -opt1 10 -opt2 20
1

prompt> get_command_option_values -command test
-bar1 10 -bar2 20
```

SEE ALSO

set_command_option_value(2)

get_connected_routing

Creates a collection of net shapes and vias that are physically connected to the specified collection of objects on the same nets. The specified objects can be of type net, shape, via, pin, terminal, and port.

SYNTAX

collection **get_connected_routing**
[-hierarchical]
[-cross_net]
[*objects*]

Data Types

objects collection

ARGUMENTS

-hierarchical

Traces connections across hierarchical module boundaries. For example, all net shapes of a connected feedthrough net are included in result collection when this option is specified.

-cross_net

Traces physically connected shapes across different nets, except PG nets. For example, short circuit net shapes will be included in the results.

DESCRIPTION

This command creates a collection of net shapes and vias by tracing the physical connectivity of the specified objects. If no such objects are specified as command arguments, the selected objects in layout view will be used. Routing corridor shapes are also supported, but are treated specifically. For them, this command creates a collection of routing corridor shapes that are physically connected and belong to the same routing corridor. The **-hierarchical** and **-cross_net** command options have no effect in this case.

EXAMPLES

The following example gets the connected routing objects of the selected net shapes.

```
prompt> change_selection [get_shapes PATH_31_0]
prompt> get_connected_routing
```

The following example creates a collection of shapes and vias that connect to the specified hierarchical net of the specified shape.

```
prompt> get_connected_routing -hierarchical [get_shapes PATH_31_0]
```

The following example creates a collection of the short circuit shapes and vias that connect to the specified shape.

```
prompt> get_connected_routing -cross_net [get_shapes PATH_31_0]
```

SEE ALSO

change_selection(2)
get_shapes(2)
gui_select_connected_net_shapes(2)

get_constraint_groups

Returns a collection of constraint groups from the current design.

SYNTAX

collection **get_constraint_groups**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-type string]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any constraint group that match the patterns option, the expression is evaluated based on the constraint group's attributes. If the expression evaluates to *true*, the constraint group is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for constraint groups level-by-level relative to the current instance. This option is useful only with *patterns* and not with **-of_objects**.

-type *string*

Specifies the type of constraint groups to be searched. By default all types of constraint groups are searched.

-of_objects *of_objects*

Creates a collection containing the constraint groups of the specified nets and bundles. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches constraint group names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_constraint_groups** command creates a collection of constraint groups from the current design that match certain criteria. The command returns a collection of constraint groups if any constraint group matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_constraint_groups** command at the command prompt, or you can nest it as an argument to another command,

such as **report_attributes**. In addition, you can assign the **get_constraint_groups** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the constraint groups in the current design.

```
prompt> get_constraint_groups
{differential_pair_1 shielding_2 net_priority_3}
```

The following example returns a collection of all the constraint groups tied to a net.

```
prompt> get_constraint_groups -of_objects net12
{shielding_2 net_priority_3}
```

get_core_area

Creates a collection containing the core area of the current design.

SYNTAX

collection **get_core_area**
[-design design]

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

DESCRIPTION

This command returns a collection containing the core area of the current design. If the core area is not defined, the command returns an empty string.

The core area is a box that contains all rows. It represents the placeable area for standard cells. The core area is typically smaller than the cell boundary. Pads, I/O pins, and top-level power and ground rings are typically found outside the core area. Standard cells, macros, and wire tracks are typically found inside the core area. There should be only one core area in a design.

The core_area object is a first class object,and it has multiple attributes, such as bbox, cell_id, name and so on.You can use **list_attributes** and **report_attributes** to browse attributes.You can use **get_attribute** and **lindex** to get coordinates of the current design die area.

EXAMPLES

The following example gets the core area of the current design.

```
prompt> get_core_area
{unit_core}
```

The following example shows how to list the attributes of the core_area class by using **list_attributes** command.

```
prompt> list_attributes -application -class core_area
```

The following example shows how to get the attribute values of the core_area object by using **report_attributes** command.

```
prompt> report_attributes -application -class core_area [get_core_area]
```

The following example shows how to get coordinates of the current design die area,by using **get_attribute** command.

```
prompt> get_attribute [get_core_area] bbox
{0.000 0.000} {300.480 396.620}
```

SEE ALSO

get_attribute(2)
list_attributes(2)

get_corners

Creates a collection of corners in the current design. You can assign these corners to a variable or pass them into another command.

SYNTAX

collection **get_corners**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the corners of the specified modes. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches corner names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_corners** command creates a collection of corners matching *patterns* in the current design and which pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Multicorner-Multimode Support

This command works on all corners.

SEE ALSO

all_corners(2)
collections(2)
create_corner(2)
current_corner(2)

get_cputime

Retrieves the overall user time associated with the current process.

SYNTAX

float **get_cputime**
  [-all]
  [-format]

string *format*

ARGUMENTS

all

If specified then it gives cpu time for this process and it's children.

format

This argument takes a *printf* style formatting string for a floating point number.

DESCRIPTION

The *get_cputime* command returns the accumulated user time, in seconds, for the current process. If the *format* string is omitted, an integer number of seconds is returned. If the format string is specified, a floating point number is returned. The number includes fractions of a second elapsed and is formatted in accordance with given specifier. Refer to the Unix man page for *printf* for a detailed description of how to format a floating point argument.

```
prompt> get_cputime "%g"
3.74
```

SEE ALSO

get_mem(2)

get_cross_probing_info

Gets cross-probing information about cells, ports, modules and blocks and returns the results as a string.

SYNTAX

string **get_cross_probing_info**
[-unique_source]
objects

Data Types

objects collection

ARGUMENTS

-unique_source

Prevents duplicate source file and line number combinations from being returned in the result.

If you specify this option, the string that is returned follows a different format; it does not use a pair of braces between the different source positions of an object or the results between different objects. Instead, the tool returns the results in the following format:
obj1_file1:obj1_line1 obj2_file1:obj2_line1 obj2_file2:obj2_line2
If an object has no known source position or valid file and line number, nothing is returned for the object.

objects

Specifies the cell, port, module and block objects to query.

DESCRIPTION

This command provides cross-probing information about specified cells, ports, modules and blocks and returns the results as a string.

You must have a design that was analyzed and elaborated or synthesized using this tool. The tool provides information about where the cell or port or module or block was created, specifying which file and line number the object came from. Some objects in the design might have been merged, which can result in an object with multiple source locations. In this case, multiple results are returned for the object.

The results of each object are separated by a pair of braces between each source position and between each object. For example, if you specify two objects with the **get_cross_probing_info** command, obj1 and obj2, where obj1 has one source position and obj2 has two source positions, the tool returns the results in the following format:

{ { obj1_file1:obj1_line1 } } { { obj2_file1:obj2_line1 } {obj2_file2:obj2_line2 } }

You can prevent duplicate file and line number combinations in the results by using the **-unique_source** option. In this case, the tool returns the results in the following format:

obj1_file1:obj1_line1 obj2_file1:obj2_line1 obj2_file2:obj2_line2

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows results from the **get_cross_probing_info** command:

```
prompt> get_cross_probing_info [get_cells -hierarchical]
{ {/usr/joe/design/m.v:21} } { {/usr/joe/design/m.v:22} } { {/usr/joe/design/m.v:21} }
{ {/usr/joe/design/m.v:22} } { {/usr/joe/design/m.v:28} } { {/usr/joe/design/m.v:12} }
{ {/usr/joe/design/m.v:13} } { {/usr/joe/design/m.v:14} } { {/usr/joe/design/m.v:4} }
```

The following example shows results from the **get_cross_probing_info** command with the **-unique_source** option:

```
prompt> get_cross_probing_info [get_cells -hierarchical] -unique_source
/usr/joe/design/m.v:21 /usr/joe/design/m.v:22 /usr/joe/design/m.v:28 /usr/joe/design/m.v:12
/usr/joe/design/m.v:13 /usr/joe/design/m.v:14 /usr/joe/design/m.v:4
```

The following example shows results from the **get_cross_probing_info** command for modules:

```
prompt> get_cross_probing_info [get_modules]
{ {/usr/joe/design/top.v:1} } { {/usr/joe/design/top.v:14} } { {/usr/joe/design/top.v:32} }
```

The following example shows results from the **get_cross_probing_info** command for modules with the **-unique_source** option:

```
prompt> get_cross_probing_info [get_modules] -unique_source
/usr/joe/design/top.v:1 /usr/joe/design/top.v:14 /usr/joe/design/top.v:32
```

The following example shows results from the **get_cross_probing_info** command for blocks:

```
prompt> get_cross_probing_info [get_blocks]
{ {/usr/joe/design/top.v:1} }
```

The following example shows results from the **get_cross_probing_info** command for blocks with the **-unique_source** option:

```
prompt> get_cross_probing_info [get_blocks] -unique_source
/usr/joe/design/top.v:1
```

SEE ALSO

report_cross_probing(2)

cross_probing_filter(2)

get_current_checkpoint

Get information about the current active checkpoint.

SYNTAX

string **get_current_checkpoint**
[-name]
[-position]
[-script]

Data Types

ARGUMENTS

-name

Returns the name of the current checkpoint name

-position

Returns the name of the stage depending on if the execution is currently at before/after/replace.

-script

Returns the name of the checkpointed TCL script

DESCRIPTION

Provides introspection into the current checkpoint. This command must be called with one and only one of the -name, -position, and -script options. This command should be executed within a checkpoint, either directly in the block of Tcl enwrapped by the eval_checkpoint command, or indirectly within a checkpoint action or report.

The -name option returns the name of the current checkpoint. A typical application is to use the checkpoint name as part of the filename when writing out reports to disk from a checkpoint report. This ensures unique names for the reports and identifies at which checkpoint that report was generated.

The -position option returns the position within the current checkpoint. While executing a before action or report, it returns 'before'. While executing the checkpointing block of Tcl commands, or substituting it with a replacement action, it returns 'self'. While executing an after action or report, it returns 'after'. A typical application is to use the position in a filename written to disk by a checkpoint report. This ensures that if a report is associated to run before and after the same checkpoint, it writes to two unique filenames.

The -script option returns the full block of Tcl command/s enwrapped by the eval_checkpoint statement. A typical application is to use this command information in a replacement action, for example to modify the arguments passed to a Tcl command within the checkpoint.

EXAMPLES

This example defines a checkpoint report to write report_qor to a file on disk. It then associates this report to run before and after the place_opt checkpoint. When the place_opt checkpoint runs, two report_qor files are written with unique names by using the get_current_checkpoint -name and -position options.

```
## In ./checkpoint.config.tcl
create_checkpoint_report qor {
 set name [get_current_checkpoint -name]
 set pos [get_current_checkpoint -position]
 redirect -file ./checkpoint/$name.$pos.qor.rpt { report_qor }
}

associate_checkpoint_report -enable qor -before place_opt
associate_checkpoint_report -enable qor -after place_opt

## In the flow script place_opt.tcl
eval_checkpoint place_opt { place_opt }

## Writes two files:
## ./checkpoint/place_opt.before.qor.rpt
## ./checkpoint/place_opt.after.qor.rpt
```

This example defines a checkpoint action run high-effort congestion-driven placement on all create_placement* and refine_placement* checkpoints. get_current_checkpoint -command is used to access and modify the original command options to force high congestion effort. associate_checkpoint_action uses the -replace option to replace the original checkpoint command contents with the modified command contents.

```
## In ./checkpoint.config.tcl
 create_checkpoint_action high_eff_cong {
 eval [get_current_checkpoint -command] -congestion -congestion_effort high
 }
associate_checkpoint_action -enable high_eff_cong -replace "create_placement* refine_placement*"

## In the flow script place_opt.tcl
eval_checkpoint create_placement { create_placement -timing_driven }

## Upon execution, that create_placement command will instead run:
create_placement -timing_driven -congestion -congestion_effort high
```

get_current_ems_database

Returns a collection containing the current EMS database.

SYNTAX

collection **get_current_ems_database**

ARGUMENTS

The **get_current_ems_database** command takes no arguments.

DESCRIPTION

The **get_current_ems_database** command returns the current EMS database as part of a collection. An EMS database is called "current", if it is opened in memory and is the currently active database.

EXAMPLES

The following example returns a collection containing the current EMS database.

```
prompt> create_ems_database test.ems
prompt> get_current_ems_database
{test.ems}
```

SEE ALSO

get_current_hook_command

Get the currently running command string

SYNTAX

string **get_current_hook_command**

ARGUMENTS

DESCRIPTION

The **get_current_hook_command** command may only be run from within a command hook. The command returns the command string used to invoke the command.

Note that option values may have been abbreviated when the hooked command was executed. In that case the information returned will also include abbreviated option values.

SEE ALSO

add_command_hook(2)
remove_command_hook(2)
get_command_hooks(2)

get_current_mismatch_config

Obtains the current mismatch config.

SYNTAX

string **get_current_mismatch_config**

ARGUMENTS

The **get_current_mismatch_config** command has no arguments.

DESCRIPTION

The **get_current_mismatch_config** command returns the name of the current config in the session. By default, a session has **default** config as current config. Use command **set_current_mismatch_config** to change current config.

EXAMPLES

The following example gets the name of the current config:

```
prompt> get_current_mismatch_config
default

prompt> set_current_mismatch_config auto_fix
1

prompt> get_current_mismatch_config
auto_fix
```

SEE ALSO

report_design_mismatch(2)
get_mismatch_types(2)
get_mismatch_objects(2)
set_current_mismatch_config(2)
create_mismatch_config(2)
report_mismatch_configs(2)

get_defined_attributes

Returns attribute names currently defined for the specified class.

SYNTAX

string **get_defined_attributes**
-class *class_name*
-return_classes
[-details]
[-application]
[-user]
[*attr_pattern*]

Data Types

class_name string
attribute_names list
data_type string

ARGUMENTS

-class *class_name*

Specifies the class for which to get the attributes. Valid classes are application defined. Note legal with the *-return_classes* option.

-return_classes

Return the set of application defined classes. Not legal with the *-class* option.

-details

Gets additional information on a single attribute.

-application

Returns application-defined attributes only. This option is mutually exclusive with the *-user* option.

-user

Returns user-defined attributes only. This option is mutually exclusive with the *-application* option.

attr_patterns

Specifies a list of attribute names or glob style patterns to check on the existences of.

DESCRIPTION

This command returns a list of attribute names that are defined for the specified class.

There are three legals forms for this command:

- get_defined_attributess -return_classes

Returns the application defined object classes

- get_defined_attributes -class cell [<pattern>] Returns all the attributes matching the optional pattern
- get_defined_attributes -class cell -details <attrName> Returns more detailed information about the attribute. See below for details

  When **-details** is specified, the return value is a Tcl list that is suitable as input to the Tcl **array set** command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key, and each even-numbered element in the list is the value of the previous key.

  The supported keys are as follows:

name

This key contains the name of the attribute

infor

The short help defined for the attribbute

type

The type of value the attribute storesn

settable

The value is settable with the set_attribute command.

application

The value is 1 if the attribute is application defined, else 0.

subscripted

The value is 1 if the attribute is subscripted, else 0.

min_value

Not always present. If present value is the minimum allowed value.

max_value

Not always present. If present value is the maximum allowed value.

allowd_values

Not always present. If present value is the set of allowed values

allowed_subscripts

Present if the attribute is subscripted. Contains list of legal subcripts for the attribute if the attribute uses global subscripts. If empty, then the subscripts vary per object.

smart_subscripts

Present if the attribute is subscripted. Contains the list of supported smart subscripts if the attribute supports smart subscripts.

EXAMPLES

The following are examples of the **get_defined_attributes** command:

```
prompt> get_defined_attributes -class cell
name full_name object_class ....

prompt> get_defined_attributes -class cell *name*
name full_name reference_name ...

prompt> get_defined_attributes -class cell name
name name info {The simple name of the cell} type string application 1
settable 0 subscripted 0
```

SEE ALSO

get_attribute(2)
help_attributes(2)

get_defined_commands

Get information on defined commands and groups.

SYNTAX

string **get_defined_commands** [-details]
  [-groups]
  [*pattern*]

string *pattern*

ARGUMENTS

-details

Get detailed information on specific command or group.

-groups

Search groups rather than commands

pattern

Return commands or groups matching pattern. The default value of this argument is "*".

DESCRIPTION

The **get_defined_commands** gets information about defined commands and command groups. By default the command returns a list of commands that match the specified pattern.

When **-details** is specified, the return value is a list that is suitable as input to the **array set** command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key name, and each even-numbered element in the list os the value of the previous key. The **-details** option is only legal if the pattern matches exactly one command or group.

When **-group** is specified with **-details**, the supported keys are as follows:

name

This key contains the name of the group.

info

This key contains the short help for the group.

commands

This key contains the commands in the group

When **-details** is used with a command, the supported keys are as follows:

name

This key contains the name of the command.

info

This key contains the short help for the command.

groups

This key contains the group names that this command belongs to.

options

This key contains the options defined for the command. The value is a list.

return

This key contains the return type for the command.

Each element in the *options* list also follows the key value pattern. The set of available keys for options are as follows:

name

This key contains the name of the option.

info

This key contains the short help for the option.

value_info

This key contains the short help string for the value

type

The type of the option.

required

The value will be 0 or 1 depending if the option is optional or required.

is_list

Will be 1 if the option requires a list.

list_length

If a list contains the list length constraint. One of any, even, odd, non_empty or a number of elements.

allowed_values

The allowed values if the option has specified allowed values.

min_value

The minimum allowed value if the option has specified one.

max_value

The maximum allowed value if the option has specified one.

EXAMPLES

prompt> **get_defined_commands *collection**
add_to_collection append_to_collection copy_collection filter_collection
foreach_in_collection index_collection sort_collection
prompt> **get_defined_commands -details sort_collection**
name sort_collection info {Create a sorted copy of the collection}
groups {} options {{name -descending info {Sort in descending order}
value_info {} type boolean required 1 is_list 0} {name -dictionary info
{Sort strings dictionary order.} value_info {} type boolean required 1
is_list 0} {name collection info {Collection to sort} value_info
collection type string required 0 is_list 0} {name criteria info {Sort
criteria - list of attributes} value_info criteria type list required 0
is_list 1 list_length non_empty}}

SEE ALSO

help(2)
man(2)

get_density_rules

Creates a collection by selecting density rules from a lib or tech.

SYNTAX

collection **get_density_rules**
[-design *design*]
[-library *library*]
[-tech *tech*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *of_objects*

Data Types

design collection
library collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-design *design*

Specifies the block in which to find density rules.

If you do not specify a block or technology data, the command searches for density rules in the current block.

-library *library*

Specifies the library in which to find density rules. The command searches the technology data of the specified library to find density rules.

If you do not specify a block or technology data, the command searches for density rules in the current block.

-tech *tech*

Specifies the technology data in which to find density rules.

If you do not specify a block or technology data, the command searches for density rules in the current block.

-filter *expression*

Filters the collection with *expression*. For any density rule that matches the patterns option, the expression is evaluated based on the density rule's attributes. If the expression evaluates to *true*, the density rule is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the density rule attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive. **-nocase** and **-exact** are mutually exclusive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the density rules associated with the specified objects. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the density rule names against the patterns in the specified block or technology data.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

This command creates a collection of density rules by selecting density rules from the specified block or technology data that meet the selection criteria. It returns a collection if one or more density rules meet the selection criteria. If no density rules match the selection criteria, it returns an empty string.

Use the **get_density_rules** command as an argument to another command or assign its result to a variable.

See the **collections** man page for information about working with collections.

EXAMPLES

The following example creates a collection of all density rules defined in the current block that are associated with objects whose name starts with VIA_C:

```
prompt> get_density_rules -of_objects VIA_C*
{FATVIA12_230_530 FATVIA12_530_230}
```

The following example creates a collection of all density rules from the technology data named test with a maximum density limit of 100:

```
prompt> get_density_rules -tech test -filter "max_density == 100"
{DENSITY_RULE_0 DENSITY_RULE_2 DENSITY_RULE_4 DENSITY_RULE_6 DENSITY_RULE_8
DENSITY_RULE_10 DENSITY_RULE_12 DENSITY_RULE_14 DENSITY_RULE_16}
```

SEE ALSO

report_density_rules(2)
get_attribute(2)
query_objects(2)

get_design_checks

Creates a collection of both user-defined and pre-defined checks.

SYNTAX

collection **get_design_checks**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on check attributes. You can determine check attributes by using the **list_attributes** command and option **-class ems_check** to it. If the expression evaluates to **true**, the check is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this option is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Takes a collection or list of objects which are checks.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the check names in the current design against the specified patterns. You can specify the patterns by using the following formats:

(1) A collection of checks

(2) An asterisk (*), which indicates all checks

(3) Specific check names

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

This command returns a collection of both pre-defined and user-defined checks that helps the user in knowing which checks are currently available.

EXAMPLES

(1) The following example shows how get_design_checks is used to create a list of available checks.

```
prompt> get_design_checks

   { routes mib_alignment pg_drc pg_missing_vias pin_placement
    analyze_design_violations rp_constraints finfet_grid cts_qor
```

feedthroughs pre_route_stage legality scan_chain design_mismatch
design_extraction clock_trees unbound pre_clock_tree_stage
pre_placement_stage timing mv_design routability }

(2) The following example shows how to get a collection of available checks ending with "_stage".

prompt> **get_design_checks *_stage**

{ pre_placement_stage pre_clock_tree_stage pre_route_stage }

SEE ALSO

get_design_rules

Returns a collection of design rules from the technology data.

SYNTAX

collection **get_design_rules**
[-tech *tech_object*]
[-library *library*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

tech_object collection
library string or collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-tech *tech_object*

Specifies the technology data in which to search for design rules.

By default, the command searches for design rules in the technology data of the current library.

The **-tech** and **-library** options are mutually exclusive; you can specify only one.

-library *library*

Specifies the library in which to search for design rules. The command searches the technology data of the specified library to find design rules.

By default, the command searches for design rules in the technology data of the current library.

The **-tech** and **-library** options are mutually exclusive; you can specify only one.

-filter *expression*

Filters the collection with *expression*. For any design rule that matches the patterns option, the expression is evaluated based on the design rule's attributes. If the expression evaluates to *true*, the design rule is included in the result.

-quiet

Suppresses warning and error messages if no object matches. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the design rules of the specified techs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches design rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_design_rules** command creates a collection of design rules from the tech that match certain criteria. The command returns a collection of design rules if any design rule matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_design_rules** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_design_rules** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the design rules in the tech of current library.

```
prompt> get_design_rules
{DESIGN_RULE_0 DESIGN_RULE_1 DESIGN_RULE_2 DESIGN_RULE_3 DESIGN_RULE_4 DESIGN_RULE_5}
```

SEE ALSO

create_pr_rule(2)
remove_pr_rules(2)
report_design_rules(2)

get_designs

Creates a collection of one or more designs in memory. You can assign these designs to a variable or pass them into another command.

SYNTAX

collection **get_designs** [-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns

Data Types

expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-hierarchical

Searches for designs inferred by the design hierarchy relative to the current instance. The full name of the object at a particular level must match the patterns. The use of this option does not force an auto link.

-filter *expression*

Filters the collection with *expression*. For any designs that match *patterns*, the expression is evaluated based on the design's attributes. If the expression evaluates to true, the design is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are

mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches design names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type design.

DESCRIPTION

The **get_designs** command creates a collection of designs from those currently loaded into memory that match certain criteria. The command returns a collection if any designs match the *patterns* and pass the filter (if specified). If no objects matched your criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_designs** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_designs** result to a variable.

When issued from the command prompt, **get_designs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_designs** provides a fast, simple way to display designs in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_designs** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the designs that begin with 'mpu.' Although the output looks like a list, it is just a display. A complete listing of designs is available using the **list_blocks** command.

```
prompt> get_designs mpu*
{"mpu_0_0", "mpu_0_1", "mpu_1_0", "mpu_1_1"}
```

The following example shows that, given a collection of designs, you can remove those designs.

```
prompt> remove_block [get_designs mpu*]
Removing design mpu_0_0...
Removing design mpu_0_1...
Removing design mpu_1_0...
Removing design mpu_1_1...
```

remove_blocks(2)
shell.common.collection_result_display_limit(3)

get_dff_connections

Get dff_connection objects representing the results of **compute_dff_connections**.

SYNTAX

status **get_dff_connections**
[-filter *expression*]
[-max_reg *register_count*]
[-max_gate *gate_count*]

[-from *list_of_connection_points*]
[-to *list_of_connection_points*]
[-through *list_of_connection_points*] [-through *list_of_connection_points*] [...]

[-no_from_to_through]

[-quiet]
[*path pattern list*]

Data Types

expression string
register_count int
gate_count int
list_of_connection_points collection or list of names of ports, pins, blocks, module boundaries or virtual groups. Connection points can be ports, pins (hierarchical or not), cells (blocks), module boundaries or virtual module boundary groups. These can be specified as a collection or a name, such as *-from "BlOCK_1"* or *-from "BLOCK_1/bus1*"*. Any cells/modulle boundaries specified (without a pattern specifying specific pins) will be turned into a list of ALL pins belonging to that object.

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any dff_connection objects that match *patterns* or *objects*, the expression is evaluated based on the attributes of the dff_connection. If the expression evaluates to true, the dff_connection is included in the result.

-max_reg *register_count*

Specifies the maximum number of registers a path can contain and still be returned. It is an error to specify a larger value than

used during **compute_dff_connections**.

-max_gate *gate_count*

Specifies the maximum number of gates a path can contain and still be returned. It is an error to specify a larger value than used during **compute_dff_connections**.

-from *list_of_connection_points*

Return only paths starting at one of the specified connection points. See Data Types.

-to *list_of_connection_points*

Return only paths ending at one of the specified connection points. See Data Types.

-through *list_of_connection_points*

Return only paths going through one of the specified connection points. See Data Types. *-through* can be specified more than once. If *-through* is specified more than once, then a path must match one connection point from the each of the *-through* lists in order.

By default, start and end points of a path are also searched when *-through* is specified (see next option).

See **NOTES** and **KNOWN LIMITATIONS** for more information about *-through*.

-no_from_to_through

Do not check start or end points of the dff_connection against *-through* patterns. The default is to check start and end points against *-through* patterns.

-quiet

Do not report errors/warnings when the patterns specified for *-from*, *-to* or *-through* do not match any netlist objects.

path pattern list

A list of patterns used to match the name of paths. Only paths matching one or more of the patterns are returned. If not specified, this filter is inactive.

DESCRIPTION

This command returns dff_connection objects representing paths from the Data Flow Flylines (DFF) tracer (**compute_dff_connections**). For the attributes of dff_connection objects, see dff_connection_object_attributes(3).

By default, all connections are returned. The returned paths can be filtered using **-from**, **-to**, **-through**, **-no_from_to_through** and **[path pattern list]** as well as the standard collection filtering option **-filter**. .

Calling *compute_dff_connections* will invalidate existing dff_connection objects/collections.

The results of *get_dff_connections* with various block/macro/bound/pin options should closely match those of *report_dff_connections*. However, be aware that for blocks and bounds, *report_dff_connections* does the equivalent of a *-through* search, not *-from* or *-to*. Since the tracer stops at macros and ports, paths generally stop there, so *-through* is not needed if trying to do a *-from* or *-to* equivalent search.

NOTES

The *-through* option can be very useful. However, since the entire contents of the **detail** attribute of each path must be searched

(and potentially **start** and **end** fields), it is definitely slower than *-from* and *-to*. Exact performance of *-through* depends directly on the number of objects in the **detail** attribute. Multiple *-through* options will not increase this penalty significantly, since the detail field of each dff_connection is searched only once in order to match all *-through* arguments.

KNOWN LIMITATIONS

There is one significant limitation to *-through*. Due to the tracer technology, the **detail** field contains actual pin instances that correspond to the entries of the **hierarchy_pins** field. All other entries in the detail field are **cells**, NOT **pins**. Searching for a path that goes through a particular pin of a specific register will fail, EVEN if the **detail** field contains that register, since some objects will have multiple pins. Therefore, *-through* can be used to search for specific hierarchy pins (or their parent cells) and non-hierarchical cells only. Specifying non-hierarchical pins to *-through* will fail to match anything.

EXAMPLES

The following example traces the current design using default constraints, and then the first call to *get_dff_connections* gets paths starting from a block BLOCK_A. The second example assumes *compute_dff_connections* was already called, and gets paths ending at any port.

```
prompt> compute_dff_connections
prompt> get_dff_connections -from "BLOCK_A"

prompt> set port_list [get_ports]
prompt> get_dff_connections -to $port_list
```

SEE ALSO

collections(2)
compute_dff_connections(2)
dff_connection_object_attributes(3)
filter_collection(2)
report_dff_connections(2)

get_dft_hierarchical_pins

Returns a collection of ports and hierarchical pins created during DFT insertion.

SYNTAX

collection **get_dft_hierarchical_pins**

ARGUMENTS

The **get_dft_hierarchical_pins** command has no arguments.

DESCRIPTION

This command returns a collection of ports and hierarchical pins created during DFT insertion command in the current design.

EXAMPLES

The following example shows how to use the **get_dft_hierarchical_pins** command to show that the queried objects also have the attribute "created_during_dft":

```
prompt> set ports [ get_dft_hierarchical_pins ]
{mid1/test_se mid1/bot1/test_se mid1/bot1/c1/test_se mid1/test_si mid1/bot1/test_si mid1/bot1/c1/test_si}

prompt> foreach_in_collection p $ports {puts [get_attribute $p created_during_dft]}
true
true
true
true
true
true
```

SEE ALSO

current_design(2)
insert_dft(2)

get_domain_elements

Creates a collection of elements of power domains.

SYNTAX

collection **get_domain_elements**
[*power_domains*]

Data Types

power_domains list

ARGUMENTS

power_domains

Returns a collection of domain elements associated with the specified power domains. If no power domains are specified, the tool returns the domain elements of all power domains.

DESCRIPTION

The **get_domain_elements** command creates a collection of elements of power domains in the current design.

Until commit_upf command is executed and power intent is finalized, power domains of subblocks are not propagated and will not be included in the result.

EXAMPLES

The following example creates a power domain, then queries the elements of the power domain.

```
prompt> create_power_domain SUB_DOMAIN -elements [get_cells mid1]
1
prompt> get_domain_elements SUB_DOMAIN
{mid1}}
```

SEE ALSO

create_power_domain(2)
report_power_domains(2)

get_drc_error_data

Creates a collection of DRC error data objects.

SYNTAX

collection **get_drc_error_data**
[-all]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-all

Includes unopened DRC error data objects, if matched. The default is to return only DRC error data objects that are currently open.

-filter *expression*

Filters the collection with *expression*.

For any DRC error data objects that match the *patterns* or *objects* argument, the expression is evaluated based on the DRC error data object's attributes. If the expression evaluates to true, the DRC error data object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* argument and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters.

The **-regexp** and **-exact** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find.

If the command finds a different number of objects, it raises a Tcl error and stops processing.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find.

If the command finds fewer objects, it raises a Tcl error and stops processing.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object.

If one or more patterns does not match, the command raises a Tcl error and stops processing.

-of_objects *objects*

Creates a collection of DRC error data objects connected to the specified objects. You can specify the following types of objects: DRC error types (drc_error_type), DRC errors (drc_error), and blocks.

The **-of_objects** option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

patterns

Matches DRC error data object names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of DRC error data objects.

The **-of_objects** option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

DESCRIPTION

The **get_drc_error_data** command creates a collection of DRC error data objects that match certain criteria. The command returns a collection if any DRC error data objects match the *patterns* or *objects* and pass the filter (if specified). If no objects match the

criteria, the command returns the empty string.

To include DRC error data objects that are not open, use the **-all** option. The **get_drc_error_data** command creates a collection that contains the DRC error data object, but does not open the DRC error data object. To query or modify the error type objects and error objects in the DRC error data object, you must open the DRC error data object with the **open_drc_error_data** command.

You can use the **get_drc_error_data** command at the command prompt or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_drc_error_data** result to a variable.

When issued from the command prompt, **get_drc_error_data** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by using the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_drc_error_data** command provides a fast, simple way to display the DRC error data objects in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_drc_error_data** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a collection that contains the DRC error data object named "dppinassgn.err", and then opens it.

```
prompt> set data [get_drc_error_data -all dppinassgn.err]
{"dppinassgn.err"}
prompt> open_drc_error_data $data
{"dppinassgn.err"}
```

The following example creates a collection that contains the DRC error data object associated with the block named "my_design".

```
prompt> get_drc_error_data -of_objects my_design
{"dppinassgn.err"}
```

get_drc_error_types

Creates a collection of physical DRC error types from the given error data. You can assign these physical DRC error types to a variable or pass them into another command.

SYNTAX

collection **get_drc_error_types**
-error_data *drc_error_data*
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]
[-of_objects *objects*]

Data Types

drc_error_data collection
expression string
exact_count int
minimum_count int
patterns list
objects list

ARGUMENTS

-error_data *drc_error_data*

Specifies the error data in which to find objects.

-filter *expression*

Filters the collection with *expression*. For any physical DRC error types that match *patterns* (or *objects*) the expression is evaluated based on the physical DRC error type's attributes. If the expression evaluates to true, the physical DRC error type is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a true regular expression rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with true regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of physical DRC error types connected to the specified objects. In this case, each object is either a named drc_error or a drc_error collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches physical DRC error type names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of drc_error_type. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both. If both the *patterns* and **-of_objects** are omitted, then the wildcard "*" is used as the *pattern*

DESCRIPTION

The **get_drc_error_types** command creates a collection of physical DRC error types in the given error data that match certain criteria. The command returns a collection if any physical DRC errors match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_drc_error_types** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_drc_error_types** result to a variable.

When issued from the command prompt, **get_drc_error_types** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.commmon.collection_result_display_limit** application option.

The "implicit query" property of **get_drc_error_types** provides a fast, simple way to display physical DRC error types in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_drc_error_types** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the physical DRC error type that is named "route short". Although the output looks like a list, it is not. The output is just a display. The quotation marks around (route short) are required because the type name contains a space.

```
prompt> set data [open_drc_error_data -file_name my_design.err]
prompt> get_drc_error_types -error_data $data {"route short"}
{"route short"}
```

The following example shows that, given a collection of physical DRC errors, you can query the physical DRC error types connected to those errors.

```
prompt> set error [get_drc_errors -error_data $data 9]
{"9"}
prompt> query_objects [get_drc_error_types -error_data $data -of_objects $error]
{"route short"}
```

The following example gets the physical DRC errors associated with an error type.

```
prompt> get_drc_errors -error_data $data -of_objects \
      [get_drc_error_types -error_data $data {"route short"}]
{"9", "10", "11"}
1
```

SEE ALSO

shell.common.collection_result_display_limit(3)

get_drc_errors

Creates a collection of physical DRC errors from the given error data. You can assign these physical DRC errors to a variable or pass them into another command.

SYNTAX

collection **get_drc_errors**
-error_data *drc_error_data*
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]
[-of_objects *objects*]
[-boundary *region*]

Data Types

drc_error_data collection
expression string
exact_count int
minimum_count int
objects list
region region
patterns list

ARGUMENTS

-error_data *drc_error_data*

Specifies the error data for finding objects.

-filter *expression*

Filters the collection with *expression*. For any physical DRC errors that match *patterns* (or *objects*) the expression is evaluated based on the physical DRC error's attributes. If the expression evaluates to true, the physical DRC error is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of physical DRC errors connected to the specified objects. In this case, each object is either a named drc_error_type, net, pin, port, cell, pin guide, voltage area, or a collection of these objects. **-of_objects** and *patterns* are mutually exclusive; you may specify one, but not both.

-boundary *region*

Creates a collection of physical DRC errors with shapes within or touching the specified boundary shape. The region may be entered as a bounding box or as a list of coordinates. **-boundary** and **-filter can both be specified together.**

patterns

Matches physical DRC error names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type drc_error. *patterns* and **-of_objects** are mutually exclusive; you may specify one, but not both. *patterns* is also mutually exclusive with **-of_objects**; you may specify one, but not both. If both the *patterns* and **-of_objects** are ommitted, then the wildcard "*" is used as the *pattern*

DESCRIPTION

The **get_drc_errors** command creates a collection of physical DRC errors in the given error data that match certain criteria. The command returns a collection if any physical DRC errors match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of

an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_drc_errors** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_drc_errors** result to a variable.

When issued from the command prompt, **get_drc_errors** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_drc_errors** provides a fast, simple way to display physical DRC errors in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_drc_errors** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the physical DRC errors that is associated with an error type named "route short". Although the output looks like a list, it is not. The output is just a display. Note the required quotes because the type name contains a space.

```
prompt> set data [open_drc_error_data -file_name my_design.err]
prompt> get_drc_errors -error_data $data -filter {type_name == "route short"}
{"9", "10", "11"}
```

The following example shows that, given a collection of error types, you can query the physical DRC errors connected to those error types.

```
prompt> set type [get_drc_error_types -error_data $data {{route short}}]
{"route short"}
prompt> query_objects [get_drc_errors -error_data $data -of_objects $type]
{"9", "10", "11"}
```

The following example gets the **objects** attribute for physical DRC error 9, which in this case are two nets associated with the error.

```
prompt> get_attribute [get_drc_errors -error_data $data 9] objects
{"F_12_", "F_11_"}
1
```

SEE ALSO

regexp(2)
shell.common.collection_result_display_limit(3)

get_eco_bus_buffer_patterns

Creates a collection of ECO bus buffer patterns. You can assign these ECO bus buffer patterns to a variable or pass them into another command.

SYNTAX

collection **get_eco_bus_buffer_patterns**
patterns

Data Types

patterns list

ARGUMENTS

patterns

Matches ECO bus buffer pattern names against patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type ECO bus buffer pattern.

DESCRIPTION

The **get_eco_bus_buffer_patterns** command creates a collection of ECO bus buffer patterns.

EXAMPLES

The following example returns ECO bus buffer patterns that begin with "o".

prompt> **get_eco_bus_buffer_patterns "o*"**
{o_p1 o_p2}

SEE ALSO

add_buffer_on_route(2)
create_eco_bus_buffer_pattern(2)
remove_eco_bus_buffer_patterns(2)
report_eco_bus_buffer_patterns(2)

get_edit_groups

Creates a collection by selecting edit groups from the current design.

SYNTAX

collection **get_edit_groups**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the edit group attributes. You can determine the edit group attributes by using the **list_attributes** command. If the expression evaluates to **true**, the edit group is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for edit groups.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for edit groups level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at** but not with **-of_objects**.

patterns

Matches the edit group names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects *of_objects*

Creates a collection containing the edit groups that contain the specified objects. If the objects are edit groups, the command returns the edit groups which the objects contain. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-at *point*

Creates a collection that contains all edit_groups at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all edit_groups that are completely inside the specified region and doesn't include edit_groups which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all edit_groups that are completely inside the specified region and the edit_groups which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all edit_groups which are abut/touching from inside or outside to the specified region and the edit_groups whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of edit groups that meet the selection criteria. It returns a collection handle if one or more edit groups meet the selection criteria. If no edit groups match the selection criteria, it returns an empty string.

You can use the **get_edit_groups** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of edit_groups by matching the edit group name against the pattern.

```
prompt> get_edit_groups EDIT_GROUP*
{"EDIT_GROUP_1", "EDIT_GROUP_2", "EDIT_GROUP_3"}
```

The following example creates a collection of edit groups with attribute filtering.

```
prompt> get_edit_groups -filter {ungroup_on_remove == last}
{"EDIT_GROUP_2"}
```

The following example creates a collection of all edit groups.

```
prompt> get_edit_groups *
{"EDIT_GROUP_1", "EDIT_GROUP_2", "EDIT_GROUP_3", "my_top_edit_group"}
```

The following example creates a collection of all edit groups containing the cells "U33" and "U60".

```
prompt> get_edit_groups -of_objects "U33 U60"
{"EDIT_GROUP_1", "EDIT_GROUP_2"}
```

The following example creates a collection of all edit groups with names that begin with "ED".

```
prompt> get_edit_groups -expect_each_pattern_matches ED*
{"EDIT_GROUP_1", "EDIT_GROUP_2", "EDIT_GROUP_3"}
```

get_edit_setting

Returns common edit settings.

SYNTAX

string **get_edit_setting**
[-ignore_fixed]
[-ignore_locked]
[-keep_pin_on_edge]
[-self_intersection]
[-update_floorplan]
[-update_color_mask]
[-auto_display_hidden]
[-select_partial_object]
[-select_edge]
[-select_vertex]
[-select_center_line]
[-select_center_vertex]
[-expand_hit_macro_cell]
[-expand_hit_blockage]
[-expand_hit_constraint]
[-honor_ndr]
[-hierarchical_routing]
[-pin_layer_policy]
[-specified_pin_layer]

ARGUMENTS

-ignore_fixed

Return the setting for the ignore locked ort fixed objects flag. The option is synonym of **-ignore_locked** option.

-ignore_locked

Return the setting for the ignore locked and modify locked objects flag. Use The option is synonym of **-ignore_fixed** option.

-keep_pin_on_edge

Return the setting for keeping pins on the parent edge.

-self_intersection

Return the setting for allowing shape self intersection.

-update_floorplan

Return the setting for updating the floorplan when cell boundary is changed.

-update_color_mask

Return the setting for updating the color mask for a net shapes to match the tracks they are snapped to (if the track has a specified mask color).

-auto_display_hidden

Return the setting for displaying hidden objects automatically.

-select_partial_object

Return the setting for allowing selection of partial object.

-select_edge

Return the setting for allowing object edge selection.

-select_vertex

Return the setting for allowing object vertex selection.

-select_center_line

Return the setting for allowing wire center line selection.

-select_center_vertex

Return the setting for allowing wire center point selection.

-expand_hit_macro_cell

Return the setting for expand hit type macro cell.

-expand_hit_blockage

Return the setting for expand hit type blockage.

-expand_hit_constraint

Return the setting for expand hit type placement or routing constraint.

-honor_ndr

Return the setting for honoring nondefault width and spacing during editing.

-hierarchical_routing

Return the setting for treating hierarchical nets as same net for routing and tracing.

-pin_layer_policy

Return the setting for layer policy while moving pins on the edge.

-specified_pin_layer

Return the setting for pin layer when layer policy is set to 'specified'.

DESCRIPTION

This command return the current edit setting for the specified option. Use this command to query one setting at a time.

EXAMPLES

The following example returns the current edit setting for self intersection.

```
prompt> get_edit_setting -self_intersection
1
```

SEE ALSO

set_edit_setting(2)

get_editability

Returns the hierarchical edit control of specified blocks.

SYNTAX

list **get_editability**
[-blocks *list_of_blocks*]

Data Types

list_of_blocks string or collection

ARGUMENTS

-blocks *list_of_blocks*

The hierarchical edit control of specified blocks would be reported with respect to the current top-level context. If this option is not specified, the default behavior shall report the hierarchical editability of the current_block.

DESCRIPTION

This command returns a list containing the true/false value of hierarchical edit controls corresponding to each of the specified blocks. A true value means the block is editable and false value means the block is uneditable.

EXAMPLES

The following example gets the hierarchical edit control of a single block:

```
prompt> get_editability -blocks blk1
false
```

The following example gets the hierarchical edit control of multiple blocks:

```
prompt> get_editability -blocks [get_blocks {blk1 blk2 blk3}]
{false true false}
```

SEE ALSO

set_editability(2)
report_editability(2)

get_edrc_setting

Returns common Editor DRC settings.

SYNTAX

string **get_edrc_setting**
[-name *rule_name*]
[-rules]
[-enclosed_via_spacing_rule]
[-general_via_spacing_rule]
[-minimum_edge_rule]
[-minimum_length_and_area_rule]
[-rdl_acute_angle_rule]
[-rdl_right_angle_rule]
[-via_density_rule]
[-honor_ndr]
[-dpt_odd_cycle]
[-dpt_precolor]
[-end_of_line_spacing_rule]
[-via_enclosure_rule]
[-metal_width_rule]
[-metal_span_spacing_rule]
[-end_of_line_keepout_rule]
[-filter_same_net_spacing]
[-check_fill]
[-max_error_limit]
[-max_shape_limit]
[-max_processing_time]
[-show_error_browser]
[-check_drc]

Data Types

rule_name string

ARGUMENTS

-name *string*

Returns the current setting for the specified rule name.

-rules

Returns a list of rule name and value pairs.

-enclosed_via_spacing_rule

Returns the current setting for the enclosed via spacing rule.

-general_via_spacing_rule

Returns the current setting for the general via spacing rule.

-minimum_edge_rule

Returns the current setting for checking the following minimum edge rules: maximum total number of short edge, maximum total short edge length, convex-concave minimum edge length, adjacent minimum edge length and special notch.

-minimum_length_and_area_rule

Returns the current setting for checking the minimum length and general minimum area rules.

-rdl_acute_angle_rule

Returns the current setting for checking acute angle violations for RDL routes.

-rdl_right_angle_rule

Returns the current setting for checking right angle violations for RDL routes.

-via_density_rule

Returns the current setting for checking the via density rule.

-honor_ndr

Returns the current setting for checking the following nondefault routing rules: metal spacing and via spacing.

-dpt_odd_cycle

Returns the current setting for checking the existence of DPT odd cycles.

-dpt_precolor

Returns the current setting for checking DPT spacing violation for colored shapes.

-end_of_line_spacing_rule

Returns the current setting for checking the following end-of-line spacing rules: end-of-line to end-of-line, one-neighbor end-to-end table-based, one-neighbor end-of-line and two-neighbor end-of-line.

-via_enclosure_rule

Returns the current setting for checking the following via enclosure rules: minimum enclosure, zero-neighbor end-of-line enclosure, and T-shape metal extension end-of-line enclosure.

-metal_width_rule

Returns the current setting for checking the following metal width rules: discrete metal width rule and signal routing maximum metal width rule.

-metal_span_spacing_rule

Returns the current setting for checking the following metal span spacing rules: metal span spacing and metal span orthogonal spacing rule.

-end_of_line_keepout_rule

Returns the current setting for the end of line keepout rule.

-filter_same_net_spacing

Skips spacing violations between shapes of the same net.

-check_fill

Returns the current setting for checking shapes inside fill cells.

-max_error_limit

Returns the current setting for the maximum number of DRC errors to report. The default is 200.

-max_shape_limit

Returns the current setting for the maximum number of shapes for DRC checking. The default is 400.

-max_processing_time

Returns the maximum time (in seconds) to allow for DRC checking.

-show_error_browser

Returns the current setting for whether to show the error browser when errors are detected.

-check_drc

Returns whether DRC checking is enabled for interactive editing.

DESCRIPTION

This command queries additional rules and settings for Editor DRC. By default, Editor DRC checks shorts and the following spacing rules: minimum spacing, via corner spacing, u-shape spacing, fat metal spacing and minimum width, net-type based spacing and via farm spacing.

EXAMPLES

This command queries the current setting for DPT odd cycle.

```
prompt> get_edrc_setting -name {DPT Odd Cycle}
1
```

SEE ALSO

set_edrc_setting(2)

get_ems_databases

Returns a collection of all opened EMS databases in memory.

SYNTAX

collection **get_ems_databases**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

expression string
exact_count int
minimum_count int
patterns list
objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the EMS database attributes. You can determine the EMS database attributes by using the **list_attributes** command and **-application -class ems_database** options. If the expression evaluates to **true**, the EMS database is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. The **-regexp** option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Specifies that matching is case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches the EMS database names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Matches EMS database names against patterns. Patterns can include the wildcard characters the * (asterisk) and ? (question mark) wildcard characters or regular expressions, depending on the use of the **-regexp** option. For more details about using and escaping wildcards, see the **wildcards** man page. The **-of_objects** and *patterns* options are mutually exclusive; you can use only one. By default, the command uses * (asterisk) as the *pattern*.

-of_objects *objects*

Creates a collection containing the EMS databases associated with the specified objects. -of_objects works with objects of type ems_message.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

The **get_ems_databases** command creates a collection of EMS databases that match certain criteria. The command returns a collection handle (identifier) if any EMS databases match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns false.

You can use the **get_ems_databases** command at the command prompt or nest it as an argument to another command. You can also assign the **get_ems_databases** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example uses a regular expressions to get a collection of EMS databases that end with *_0.ems:

```
prompt> get_ems_databases -regexp *_0.ems
{EMS_DB_0.ems}
```

SEE ALSO

close_ems_databases(2)
create_ems_database(2)
get_current_ems_database(2)
open_ems_database(2)
save_ems_database(2)
set_current_ems_database(2)

get_ems_rules

Returns a collection of EMS rules.

SYNTAX

collection **get_ems_rules**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

expression string
exact_count int
minimum_count int
patterns list
objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the EMS rule attributes. You can determine the EMS rule attributes by using the **list_attributes** command and **-application -class ems_rule** options. If the expression evaluates to **true**, the EMS rule is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. The **-regexp** option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Specifies that matching is case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches the EMS rule names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Matches EMS rule names against patterns. Patterns can include the wildcard characters the * (asterisk) and ? (question mark) wildcard characters or regular expressions, depending on the use of the **-regexp** option. For more details about using and escaping wildcards, see the **wildcards** man page. The **-of_objects** and *patterns* options are mutually exclusive; you can use only one. By default, the command uses * (asterisk) as the *pattern*.

-of_objects *objects*

Creates a collection containing the EMS rules associated with the specified objects.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

The **get_ems_rules** command creates a collection of EMS rules that match certain criteria. The command returns a collection handle (identifier) if any EMS rules match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns false.

You can use the **get_ems_rules** command at the command prompt or nest it as an argument to another command. You can also assign the **get_ems_rules** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example uses a regular expressions to get a collection of EMS rules that begin with EMS:

```
prompt> get_ems_rules EMS*
{EMS-001 EMS-002 EMS-003 EMS-004 EMS-005}

get_equivalent_power_domains

Create a collection of power domains that are equivalent and satisfy the criteria to share a voltage area.

SYNTAX

status **get_equivalent_power_domains**
power_domain
[-functional_equivalence]

Data Types

power_domains string

ARGUMENTS

power_domain

Returns a collection of power domains that are equivalent and satisfy the criteria to share a primary voltage area the with the specified power domain.

-functional_equivalence

Specifies that domain supplies are considered as equivalent based on functional equivalence. If this options is not specified, by default, domain supplies are considered as equivalent based on electrical equivalence.

DESCRIPTION

The **get_equivalent_power_domains** command create a collection of equivalent power domains in the current design that can share a voltage area with the specified power domain.

This command supports the shared voltage area flow only with mv.upf.multi_pd_shared_voltage_area_flow set to new.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the equivalent power domains to share a primary voltage area with the specified power domain.

```
prompt> get_equivalent_power_domains pd1
 {pd2 pd3}
```

SEE ALSO

report_power_domains(2)
create_voltage_area(2)
set_voltage_area(2)
check_equivalent_power_domains(2)

get_essential_points

Lists the essential points that influence a specified set of objects.

SYNTAX

int **get_essential_points**
[*object_list*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]

Data Types

object_list list
mode_list list
corner_list list
scenario_list list

ARGUMENTS

-objects *object_list*

List of objects - pins/ports/nets/cells - for which to list the activity influencing essential points. For a net, we consider any essential point in its fanin. For pins/ports, we consider any essential point in the fanin; if the pin/port happens to be an essential point, we list the pin/port itself. For cells, we consider any essential point that is in the fanin of its input pins.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes occurs.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering occurs on corners.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Output of the command is generated separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options is specified, the command lists for the current scenario in the design.

DESCRIPTION

This command takes a set of objects and for each specified scenario, generates a list of the essential points that influence these objects. To filter for scenarios, the *-modes*, *-corners* and *-scenarios* options can be used.

EXAMPLES

The following example shows the usage of the **get_essential_points** command to get the essential points of all the nets in the design .

```
prompt> get_essential_points [get_nets -hier]
Information: Activity for scenario scenario1 was cached, no propagation required. (POW-005)
****************************************
Report : get_essential_points

get_estimated_wirelength

Estimates the net wire length by using a virtual router.

SYNTAX

float **get_estimated_wirelength**
[-nets *nets*]

Data Types

nets collection

ARGUMENTS

-nets *nets*

Specifies a list of nets for wire length estimation. By default, wire length estimation is performed for all nets in the current design and the command returns the total wire length.

DESCRIPTION

The **get_estimated_wirelength** command returns the estimated wire lengths for the nets. It uses a fast virtual router to build Steiner trees for the nets, taking consideration of the standard cell pins and block pins connected to them. The sum of the edge lengths of the Steiner trees are used as estimates for the wire lengths. The virtual router is multilevel physical hierarchy aware and blockages aware. However, the virtual router is not congestion aware and does not build an internal congestion map. Note that the **get_estimated_wirelength** command does not guarantee an accurate wire length calculation, rather it is just a quick estimation of the wire length.

For each given net, the wire length is calculated for the whole net as it traverses across all the hierarchies from top to bottom. Use the **set_editability** command to disable one or more blocks (may or may not include the top block itself) for planning. If a block is disabled, then the wire length estimation for the net segments inside this block is skipped. However, if a disabled block contains a sub-block that is still enabled for planning, then the wire length estimation for the net segments inside this planning enabled sub-block is still performed. With properly set **set_editability**, you can include or exclude specific net segments when creating the wire length estimate.

If a net connects to a block pin or a top port without a corresponding physical pin shape, the command ignores wire length estimates for the net segments connecting to this block pin or top port. The command issues a warning message to notify you of the problem.

If a net connects to a block pin or a top port that has multiple physical pin shapes, then the wire length estimation will randomly pick one. The command issues a warning message to notify you of the problem.

To get an accurate wire length estimation, the blocks in the top design should be a design view. If the blocks are with other views, such as an abstract view, the wire length estimation can be very different from the design view estimate, due to missing cells in the abstract view. The tool issues a warning message to notify you that net segments inside abstract views were encountered.

EXAMPLES

The following command performs wire length estimation for net **n1**.

```
prompt> get_estimated_wirelength -nets n1
```

SEE ALSO

place_pins(2)
set_editability(2)

get_exception_groups

Creates a collection of exception_groups from a collection of exceptions. You can assign the result collection to a variable or pass them into another command.

SYNTAX

collection **get_exception_groups**
[-filter *expression*]
collection1

Data Types

expression string
collection1 collection

ARGUMENTS

collection

Specifies the collection of exceptions to be filtered.

-filter *expression*

Filters the collection with the *expression* option. For any exception_groups that match the *patterns* option, the expression is evaluated based on the exception_group's attributes. If the expression evaluates to true, the exception_group is included in the result. If this option is not give, then all exception_groups in *collection* will be added to the result collection.

DESCRIPTION

The **get_exception_groups** command creates a collection of exception_groups from the *collection1* collection. The command returns a collection containing all exception_groups matching the *expression* argument of the -filter option.

You can use the **get_exception_groups** command at the command prompt, or you can nest it as an argument to another command. In addition, you can assign the **get_exception_groups** result to a variable.

For information about getting collection of exceptions, see the **get_exceptions** man page.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command works on the mode of the specified exceptions.

EXAMPLES

The following command sequence first get a collection of exceptions with from pins "**a***". The result collection is assigned to a variable named **exp_obj**.

The second command then, from **exp_obj**, gather a collection of exception_groups with **type** equal to "through". The result is assigned to a variable named **through_groups_clct**.

```
prompt> set exp_obj [get_exceptions -from a*]
prompt> set through_groups_clct \
  [get_exception_groups $exp_obj -filter "type==through"]
```

SEE ALSO

get_exceptions(2)
shell.common.collection_result_display_limit(3)
list_attributes(2)
report_attributes(2)
exception_group_attributes(3)

get_exceptions

Creates a collection of exceptions in the current scenario. You can assign these exceptions to a variable or pass them into another command.

SYNTAX

collection **get_exceptions**
[-design *design*]
[-from *from_list*
  | -rise_from *rise_from_list*
  | -fall_from *fall_from_list*]
[-through *through_list*]*
[-rise_through *rise_through_list*]*
[-fall_through *fall_through_list*]*
[-to *to_list*
  | -rise_to *rise_to_list*
  | -fall_to *fall_to_list*]
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]

Data Types

design collection
expression string
exact_count int
minimum_count int

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-from *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from ***fall_from_list***

Same as the **-from** option, except that the path must fall from the objects specified.If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through ***through_list***

Specifies a list of pins, ports, and nets through which the paths must pass that are to be reset. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-rise_through ***rise_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-rise_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-fall_through ***fall_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-fall_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-to ***to_list***

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-filter ***expression***

Filters the collection with *expression*. For any exceptions that match the from/through/to criteria, the expression is evaluated based on the exception's attributes. If the expression evaluates to true, the exception is included in the result.

-expect ***exact_count***

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

DESCRIPTION

The **get_exceptions** command creates a collection of exceptions in the current scenario that match certain criteria. You can assign these exceptions to a variable or pass them into another command.

The command returns a collection if any exceptions match the from/through/to specifiers and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

You can use the **get_exceptions** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_exceptions** result to a variable.

When issued from the command prompt, **get_exceptions** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_exceptions** provides a fast, simple way to display exceptions in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_exceptions** as an argument to **query_objects**. Note that the name shown for an exception is a brief id for printing only. You cannot search for exceptions by this name.

For information about collections and the querying of objects, see the **collections** man page. In addition, see the man page for **all_exceptions**, which also creates a collection of exceptions.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example sets the variable e1 to a collection of false_path exceptions with OUT1 as a to_pin.

prompt> **set e1 [get_exceptions -to OUT1 -filter "type==false_path"]**

SEE ALSO

set_max_delay(2)

set_min_delay(2)
shell.common.collection_result_display_limit(3)

get_fill_cells

Creates a collection of fill_cells. You can assign these fill_cells to a variable or pass them into another command.

SYNTAX

collection **get_fill_cells**
[-design *design*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-filter *expression*]
patterns

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any fill_cells that match *patterns* the expression is evaluated based on the fill_cell's attributes. If the expression evaluates to true, the fill_cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-hierarchical

Searches for fill_cells in the full **fill cell** hierarchy in the top-level design. By default, the search is limited to the top-level design.

Using this option allows the hierarchical fill data to be searched. It does not enable search across child physical blocks.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches fill_cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type fill_cell.

DESCRIPTION

The **get_fill_cells** command creates a collection of fill_cells in the current design, that match certain criteria. The command returns a collection if any fill_cells match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_fill_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_fill_cells** result to a variable.

When issued from the command prompt, **get_fill_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_fill_cells** provides a fast, simple way to display fill_cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_fill_cells** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the fill cells in the current block.

```
prompt> get_fill_cells
{FILL_INST_0}
```

The following example queries the fill cells in the FILL_INST_0 instance whose names start with FILL_INST_2.

```
prompt> get_fill_cells -hierarchical FILL_INST_0/FILL_INST_2*
{FILL_INST_0/FILL_INST_2 FILL_INST_0/FILL_INST_20}
```

SEE ALSO

collections(2)
filter_collection(2)
remove_fill_cells(2)

get_flat_cells

Creates a collection of leaf cells that match certain criteria in the current design.

SYNTAX

collection **get_flat_cells**
[-design *design*]
[-all]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-hsc *separator*]
patterns | -of_objects *objects*

Data Types

design collection
expression string
exact_count int
minimum_count int
separator string
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top-level block for finding objects.

The default is the current design.

-hierarchical

Expands the search expanded to the entire physical hierarchy.

By default, the command searches only in the current physical hierarchy.

-all

Includes physical-only cells in the collection. Physical cells are cells that either do not have any ports or have only power and ground ports.

By default, physical-only cells are not included in the collection.

-filter *expression*

Filters the collection with *expression*.

The command evaluates the cells that match *patterns* or *objects* based on the attributes of the cell. If the expression evaluates to true, the cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are never suppressed.

-regexp

Views the *patterns* argument as regular expressions rather than simple wildcard patterns.

This option also modifies the behavior of the =~ and !~ filter operators to compare with regular expressions rather than simple wildcard patterns.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Performs case-insensitive pattern matching.

-exact

Disables simple pattern matching.

Use this option to search for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find.

If the command finds a different number of objects, it issues an error message and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find.

If the command finds fewer objects, it issues an error message and command processing stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object.

If one or more patterns does not match, the command issues an error message and command processing stops.

-hsc *separator*

Specifies the hierarchical separator character.

The default is /. Valid values are /, @, ^, #, ., and |.

patterns

Matches cell names against patterns.

Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of cells.

-of_objects ***objects***

Creates a collection of leaf cells connected to or associated with the specified objects.

Each object in the list is a name, pattern, or collection. The objects can be a cell, pin, net, bound, io_guide, io_ring, voltage_area, voltage_area_shape, edit_group, rp_group, or power_strategy.

The **-of_objects** argument and *patterns* option are mutually exclusive; you must specify one, but not both.

In addition, you can use the **-hierarchical** option with the **-of_objects** option only if the objects are cells or rp_groups.

DESCRIPTION

The **get_flat_cells** command creates a collection of leaf cells from the current design that match the specified criteria. Leaf cells are those cells processed during place and route. They are shown and can be selected in the GUI layout window.

If the *patterns* or *objects* argument fails to match any objects and the design is not linked, the command automatically links the design.

The **get_flat_cells** and **get_cells** commands both return cell objects. The collections returned by both commands are interchangeable and can be passed along to any command that accepts cell objects. However, the **get_flat_cells** command differs from the **get_cells** command in several ways.

- The **get_cells** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis in the Design Compiler, IC Compiler, and PrimeTime tools.

  The **get_flat_cells** command searches all leaf cells to match the *patterns* argument on their full names relative to the current design; it does not depend on the current instance. It performs pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the Fusion Compiler flow.

You can choose to use either command, depending on the type of search you are doing.

Regular expression matching is the same as in the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_flat_cells** command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the **get_flat_cells** result to a variable.

When entered at the command prompt, the **get_flat_cells** command behaves as though the **query_objects** command is called to display the objects in the collection. By default, a maximum of 100 objects are displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_flat_cells** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, to display the object class), use the **get_flat_cells** command as an argument to the **query_objects** command. For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following examples query all soft macro cells in the current design. Although the output looks like a list, it is only a text display.

```
prompt> get_flat_cells * -filter {is_soft_macro==true}
{I_ORCA_TOP/I_BLENDER_1 I_ORCA_TOP/I_BLENDER_2 I_ORCA_TOP/I_BLENDER_3
I_ORCA_TOP/I_BLENDER_4 I_ORCA_TOP/I_BLENDER_5}
```

The following examples query all black box cells in the current design. Although the output looks like a list, it is only a text display.

```
prompt> get_flat_cells * -filter {is_black_box == true }
{I_CLOCK_GEN/I_PLL_SD I_CLOCK_GEN/I_PLL_PCI
I_CLOCK_GEN/I_CLKMUL I_ORCA_TOP/I_BLENDER/latched_clk_en_reg I_ORCA_TOP/I_
CONTEXT_MEM/CONTEXT_RAM_3 I_ORCA_TOP/I_CONTEXT_MEM/CONTEXT_RAM_2 ...}
```

The following example queries the leaf cells whose full name begins with "BLOCK/". It includes all leaf cells any number of logical levels below the BLOCK hierarchical cell.

```
prompt> get_flat_cells BLOCK/*
{BLOCK/SB/U1 BLOCK/SB/U2 BLOCK/SB/U3 BLOCK/SB/U4 BLOCK/U5 BLOCK/U6
BLOCK/U7 BLOCK/U8 BLOCK/U9}
```

As a comparison to the previous example, the following example finds only cells that are direct children of the BLOCK hierarchical cell.

```
prompt> get_cells BLOCK/*
{BLOCK/SB BLOCK/U9 BLOCK/U5 BLOCK/U8 BLOCK/U7 BLOCK/U6}
```

The following example shows that, given a collection of nets, you can select the leaf cells connected to those nets. These cells are selected in a GUI layout view open for the current design.

```
prompt> set netsel [get_flat_nets r1_2_ ]
{r1_2_}
prompt> change_selection [get_flat_cells -of_objects $netsel ]
```

Data Types

design string
expression string
exact_count integer
minimum_count integer
separator character
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. The default is the current design.

-all

Includes power and ground nets.

-filter *expression*

Filters the collection with *expression*. For any nets that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the net. If the expression evaluates to true, the net is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are never suppressed.

-regexp

Considers the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Performs case-insensitive pattern matching.

-exact

Disables simple pattern matching. Use this option to search for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, an error is reported and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, an error is reported and command processing stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, an error is reported and command processing stops.

-hierarchical

Search will be expanded to multi-level physical hierarchy. By default, searches only in the current physical hierarchy.

-hsc *separator*

Specifies the hierarchical separator character. The default is /. Valid values are /, @, ^, #, ., and |.

patterns

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions, based on the **-regexp** option. Patterns can also include collections of type net. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expression pattern matching.

-of_objects *objects*

Creates a collection of nets connected to the specified objects. Each object is a named pin, a pin collection, a named cell, a cell collection, a named net or a net collection, or a routing corridor or a bundle.

The **-of_objects** and *patterns* arguments are mutually exclusive; you must specify one, but not both. In addition, **-hierarchical** and **-of_objects** can be used together only when **-physical_context** is also used and the *objects* argument to **-of_objects** are nets.

DESCRIPTION

The **get_flat_nets** command creates a collection of top-level nets of hierarchical net groups in the current design that match the specified criteria.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design is automatically linked.

The **get_flat_nets** and **get_nets** commands both return net objects. The collections returned by both commands are interchangeable and can be passed along to any command that accept net objects. However, the **get_flat_nets** command differs from the **get_nets** command in several ways.

The **get_nets** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis in Design Compiler, IC Compiler, PrimeTime, and SDC. The **get_flat_nets** command searches the top-level nets of hierarchical net groups to match the *patterns* argument on their full names relative to the current design; it does not depend on the current instance. It performs pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the Fusion Compiler flow. You can choose to use either command, depending on the type of search you are doing.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching.

Bus subscripting is specified with the format "*name*[*begin_index*:*end_index*:*step_n*]", and returns every nth bus net inclusively between the begin and end indexes. Note that the "[]" characters must be escaped because they are Tcl special characters (for example, A\[0:15:2\] or {A[0:15:2]}).

Name expansion subscripting is specified with the format "*name*(*begin_index*:*end_index*:*step_n*)", and returns every nth net inclusively between the begin and end indexes, which has a matching name without the delimiters characters (that is, net names do not actually contain the '(' and ')' characters). Note that ":*step_n*" is optional; the default step size is 1. Multiple "*begin_index*:*end_index*:*step_n*" patterns can be specified, separated with a ',' character.

You can use the **get_flat_nets** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_flat_nets** result to a variable.

When entered at the command prompt, **get_flat_nets** behaves as though **query_objects** is called to display the objects in the collection. By default, a maximum of 100 objects are displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_flat_nets** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, to display the object class), use **get_flat_nets** as an argument to **query_objects**. For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the top-level nets whose full name begins with "BLOCK/". Although the output looks like a list, it is just a text display.

```
prompt> get_flat_nets BLOCK/*
{BLOCK/SB/n76}
```

The following example shows that there is no top-level net whose full name begins with "BLOCK/" and ends with "n1".

```
prompt> get_flat_nets BLOCK/*n1
Warning: No nets matched 'BLOCK/*n1' (SEL-004)
```

As a comparison to the previous example, the following example shows that there is a net whose full name begins with "BLOCK/" and ends with "n1".

```
prompt> get_nets BLOCK/*n1
{BLOCK/n1}
```

The following selects the top-level nets of hierarchical net groups that connect to cells. You can see that these nets are selected in a GUI layout view open for the current design.

```
prompt> set cellsel [get_flat_cells I_ORCA_TOP/I_SDRAM_IF/U23276]
{I_ORCA_TOP/I_SDRAM_IF/U23276}

prompt> change_selection [get_flat_nets -of_objects $cellsel]
```

[-hierarchical]
patterns | -of_objects *objects*

Data Types

design_name string
expression string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects list

ARGUMENTS

-design *design_name*

Specifies the name of the design in which to find pins. The default is the current design.

-all

Includes power and ground pins.

-filter *expression*

Filters the collection with *expression*. For any pins that match *patterns* or *objects*, the expression is evaluated based on the attributes of the pin. If the expression evaluates to true, the pin is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are never suppressed.

-regexp

Views the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option modifies the behavior of the =~ and !~ filter operators to compare with true regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Performs case-insensitive pattern matching.

-exact

Disables simple pattern matching. Use this option to search for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an exact number of objects to find. If the command finds a different number of objects, an error is reported and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, an error is reported and command processing stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, an error is reported and command processing stops.

-hierarchical

Search will be expanded to multi-level physical hierarchy. By default, searches only in the current physical hierarchy.

-hsc separator_character

Specifies the hierarchical separator character. The default is /. Valid values are /, @, ^, #, ., and |.

patterns

Matches pin names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions, based on the **-regexp** option. Patterns can also include collections of type pin. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expression pattern matching.

-of_objects *objects*

Creates a collection of pins connected to the specified objects. Each object is a named cell, net, cell collection, or pin collection. The **-of_objects** and *patterns* options are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_flat_pins** command creates a collection of pins on leaf cells from the current design that match the specified criteria. Leaf cells are those processed during place and route. They are shown and can be selected in the GUI layout window

If any *patterns* (or *objects*) fail to match any objects and the design is not linked, the design is automatically linked.

The **get_flat_pins** and **get_pins** commands both return pin objects. The collections returned by both commands are interchangeable and can be passed along to any command that accepts pin objects. However, the **get_flat_pins** command differs from the **get_pins** command in several ways.

The **get_pins** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis in Design Compiler, IC Compiler, PrimeTime, and SDC. The **get_flat_pins** command searches all pins of leaf cells to match the *patterns* argument on their full names relative to the current design; it does not depend on the current instance. It performs pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the Fusion Compiler flow. You can choose to use either command, depending on the type of search you are doing.

When a cell has bus pins, **get_flat_pins** can find them in several ways. For example, if cell u1 has a bus "A" with indexes 2 to 0, and the design.bus_delimiters for your design is "%s[%d]", use "u1/A[*]" as the pattern. You can also find the same three pins with "u1/A" as the pattern.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching.

Bus subscripting is specified with the format "*name*[*begin_index*:*end_index*:*step_n*]", and returns every nth bus pin inclusively between the begin and end indexes. Note that the "[]" characters must be escaped because they are Tcl special characters (for example, A\[0:15:2\] or {A[0:15:2]}).

Name expansion subscripting is specified with the format "*name*(*begin_index*:*end_index*:*step_n*)", and returns every nth pin inclusively between the begin and end indexes, which has a matching name without the delimiters characters (that is, pin names do not actually contain the '(' and ')' characters). Note that ":*step_n*" is optional; the default step size is 1. Multiple "*begin_index*:*end_index*:*step_n*" patterns may be specified, separated with a ',' character.

You can use the **get_flat_pins** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_flat_pins** result to a variable.

When entered at the command prompt, **get_flat_pins** behaves as though **query_objects** in called to display the objects in the collection. By default, a maximum of 100 objects are displayed. You can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_flat_pins** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, to display the object class), use **get_flat_pins** as an argument to **query_objects**. For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the I pins of leaf cells that begin with "I_CLK". Although the output looks like a list, it is just a text display.

```
prompt> get_flat_pins I_CLK*/I
{I_CLK_SOURCE_SDRAM_CLK/I I_CLK_SOURCE_SYS_2x_CLK/I
I_CLK_SOURCE_SYS_CLK/I I_CLK_SOURCE_PCLK/I}
```

The following example selects pins of leaf cells whose name begins with "O_1". You can see that these pins are selected in a GUI layout view open for the current design.

```
prompt> set csel [get_flat_cells O_1*]
{O_10__reg O_11__reg O_12__reg O_13__reg O_1__reg}
prompt> change_selection [get_flat_pins -of_objects $csel]
```

get_generated_clock

Creates a collection of generated clocks.

SYNTAX

collection **get_generated_clocks**
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns

Data Types

design	collection
mode	collection
expression	string
exact_count	int
minimum_count	int
patterns	list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

When combined with the *-regexp* option, makes matches case-insensitive.

-filter *expression*

Filters the collection with the *expression* option. For any generated clocks that match the *patterns* option, the expression is evaluated based on the generated clock's attributes. If the expression evaluates to true, the generated clock is included in the result.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches generated clock names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_generated_clocks** command creates a collection of generated clocks from the current design that match certain criteria. The command returns a collection if any generated clocks match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

To create a generated clock in the design, use the **create_generated_clock** command. To remove a generated clock from the design, use the **remove_generated_clocks** command. To show information about clocks and generated clocks in the design, use the **report_clocks** command.

You can use the **get_generated_clocks** command at the command prompt, or you can nest it as an argument to another command (for example, the **query_objects** command). In addition, you can assign the **get_generated_clocks** command result to a variable.

When issued from the command prompt, the **get_generated_clocks** command behaves as though the **query_objects** command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_generated_clocks** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the the **query_objects** command, use the **get_generated_clocks** command as an argument to the **query_objects** command. For example, use this to display the object class.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following command applies the **set_clock_latency** command on all generated clocks in the design matching the "GEN*".

prompt> **set_clock_latency 2.0 [get_generated_clocks "GEN*"]**

The following command removes all the generated clocks in the design matching "GEN1*".

prompt> **remove_generated_clocks [get_generated_clocks "GEN1*"]**

[-expect_each_pattern_matches]
patterns

Data Types

design collection
mode collection
expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

When combined with the *-regexp* option, makes matches case-insensitive.

-filter *expression*

Filters the collection with the *expression* option. For any generated clocks that match the *patterns* option, the expression is evaluated based on the generated clock's attributes. If the expression evaluates to true, the generated clock is included in the result.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches generated clock names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_generated_clocks** command creates a collection of generated clocks from the current design that match certain criteria. The command returns a collection if any generated clocks match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

To create a generated clock in the design, use the **create_generated_clock** command. To remove a generated clock from the design, use the **remove_generated_clocks** command. To show information about clocks and generated clocks in the design, use the **report_clocks** command.

You can use the **get_generated_clocks** command at the command prompt, or you can nest it as an argument to another command (for example, the **query_objects** command). In addition, you can assign the **get_generated_clocks** command result to a variable.

When issued from the command prompt, the **get_generated_clocks** command behaves as though the **query_objects** command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_generated_clocks** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the the **query_objects** command, use the **get_generated_clocks** command as an argument to the **query_objects** command. For example, use this to display the object class.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following command applies the **set_clock_latency** command on all generated clocks in the design matching the "GEN*".

prompt> **set_clock_latency 2.0 [get_generated_clocks "GEN*"]**

The following command removes all the generated clocks in the design matching "GEN1*".

prompt> **remove_generated_clocks [get_generated_clocks "GEN1*"]**

get_geometry_result

Returns a list of geometry-based rail results based on the type of result specified. The result is sorted by the voltage or resistance values in the order from high to low.

SYNTAX

list **get_geometry_result**
-type *result_type*
-net *net_name*
-touching *region*
[-layer *layer*]
[-top *top_num*]
[-threshold *threshold*]
[-percentage *percentage*]
[-histogram]

Data Types

result_type string
net_name string
layer string
region list
top_num integer
threshold float
percentage float

ARGUMENTS

-type *result_type*

Specifies the rail result type to report. The accepted types are voltage_drop and min_path_resistance. This option is a required option.

-net *net_name*

Specifies a power or ground net name for which rail results are to be returned. This option is a required option.

-layer *layer*

Specifies the layer name or layer number on which to return the rail result.

-touching *region*

Specifies a region such that geometries which are completely inside the specified region are returned with rail results. The region boundary can be a rectangle or a polygon. This is a required option to prevent returning all geometries in the whole design.

Users have to specify a region for the results to return.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

This option is mutually exclusive with the -top, -threshold, -percentage, or -histogram option.

-top ***top_num***

Returns the top number of geometries for the result type specified. This option is mutually exclusive with the -touching, -threshold, -percentage, or -histogram option.

-threshold ***threshold***

Returns geometries with the rail result value greater than the specified threshold. This option is mutually exclusive with the -touching, -top, -percentage, or -histogram option.

-percentage ***percentage***

Returns geometries with the rail result value such that its percentage ratio (calculated over the ideal supply voltage) is greater than the specified percentage. This option is mutually exclusive with the -touching, -top, -threshold, or -histogram option.

-histogram

Returns a histogram of rail results. The default histogram has 10 bins, which are expanded from the smaller value to the biggest value. This option is mutually exclusive with the -touching, -top, -threshold, or -percentage option.

The **get_geometry_result** command returns a list of geometry-based rail results. This command has to be run after the **analyze_rail** or **open_rail_result** command.

EXAMPLES

The following example returns a list of geometries within a rectangle area:

```
prompt> get_geometry_result -net VDD -type voltage_drop -touching {{1610 1968} {1620 1969}}
{ { 1616.475 1967.000 } { 1617.525 1969.800 } } metal5 0.00448
{ { 1608.810 1946.000 } { 1611.190 1974.000 } } metal7 0.00446
{ { 1608.000 1946.000 } { 1612.000 1974.000 } } metal9 0.00446
```

The following example returns the top 5 geometries on voltage drops within a rectangle region:

```
prompt> get_geometry_result -net VDD -type voltage_drop -top 5 -touching {0 0} {1000 1000}}
{ { 425.120 180.800 } { 432.720 181.860 } } M1 -0.0306
{ { 651.920 195.740 } { 659.120 196.800 } } M1 -0.0304
{ { 417.120 180.800 } { 425.120 181.860 } } M1 -0.03
{ { 432.720 180.800 } { 439.520 181.860 } } M1 -0.0297
{ { 409.120 180.800 } { 417.120 181.860 } } M1 -0.0287
```

SEE ALSO

analyze_rail(2)
open_rail_result(2)

get_grids

Creates a collection of grids from the current design.

SYNTAX

collection **get_grids**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-type block | user]
patterns

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the grid attributes. You can determine the grid attributes by using the **list_attributes** command. If the expression evaluates to **true**, the specific grid is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~

and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-type block | **user**

Specifies the type of grid to return. This option can be used to get specific type of grids. It can take as value either *block*, for block grids or *user*, for user grids.

patterns

Matches the grid names against *patterns*. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

DESCRIPTION

This command creates a collection of grids from the current design that match certain criteria. The command returns a collection handle (identifier) if any grid matches the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_grids** command at the command prompt or nest it as an argument to another command, such as **report_grids**. You can also assign the **get_grids** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns a grid named gr1

prompt> **get_grids gr1**

{gr1}

The following returns all grids with names that begin with "gr"

prompt> **get_grids gr***
{gr1 gr2 gr3 gr4}

The following returns all block grids with name matching gr

prompt> **get_grids -type block gr***
{gr1 gr2}

The following returns all user grids with names that begin with "gr"

prompt> **get_grids -type user gr***
{gr3 gr4}

get_groups

Creates a collection by selecting groups from the current design.

SYNTAX

collection **get_groups**
[-design *design_name*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hdl_of_module *module*]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
module string
patterns list
of_objects list

ARGUMENTS

-design *design_name*

Specifies the design in which to search for groups.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the group attributes. You can determine the group attributes by using the **list_attributes** command. If the expression evaluates to **true**, the group is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hdl_of_module

Matches the HDL groups contained in the specified module.

patterns

Matches the group names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Support hierarchical pattern when **-hdl_of_module** option is specified.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

-of_objects *of_objects*

Creates a collection containing the groups that contain the specified objects. If the objects are groups, the command also returns the groups which the objects contain. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

This command creates a collection of groups that meet the selection criteria. It returns a collection handle if one or more groups meet the selection criteria. If no groups match the selection criteria, it returns an empty string.

You can use the **get_groups** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of groups by matching the group name against the pattern.

```
prompt> get_groups GROUP*
{"GROUP_1", "GROUP_2","GROUP_3" }
```

The following example creates a collection of groups with attribute filtering.

```
prompt> get_groups -filter {type == collection}
{"GROUP_2"}
```

The following example creates a collection of all groups.

```
prompt> get_groups
{"GROUP_1", "GROUP_2", "GROUP_3", "my_group"}
```

The following example creates a collection of all groups containing the shape "RECT_14_0".

```
prompt> get_groups -of_objects RECT_14_0
{"GROUP_1", "my_group"}
```

The following example creates a collection of all groups with names that begin with "GR".

```
prompt> get_groups -expect_each_pattern_matches GR*
{"GROUP_1", "GROUP_2", "GROUP_3"}
```

The following example creates a collection of HDL groups of module ORCA.

```
prompt> get_groups -hdl_of_module ORCA
{"hdl_blk_1", "hdl_blk_2","hdl_blk_3" }
```

The following example creates a collection of HDL group with the name HDL in the module ORCA.

```
prompt> get_groups -hdl_of_module ORCA HDL
{"HDL" }
```

get_gui_stroke_bindings

Queries the data for stroke bindings.

SYNTAX

get_gui_stroke_bindings
[-dictionary *dict_name*]
[-builtin]

ARGUMENTS

-dictionary *dictionary_name*

Report only the bindings for the specified dictionary.

-builtin

Return information on the built-in commands that are available for use in bindings.

DESCRIPTION

This command queries the current state of stroke bindings for the application. If no options are specified, the application returns data for all dictionaries. The **-dictionary** option limits the data returned to only that for a given dictionary. The **-builtin** option queries for the built-in commands that are available for use with bindings.

A user does not typically use this command. The tool provides built-in reporting commands that produce human-readable reports from the information returned by this command. You can use the **report_gui_stroke_bindings** and **report_gui_stroke_builtins** commands for report generation.

This command returns its data as a Tcl list, suitable for further processing into reports or command streams by Tcl procedures.

DATA FORMAT

The command returns data differently depending on the options that are provided.

The data for a dictionary is a list of entries where each entry contains the stroke sequence and the data for the command invoked by that sequence. If the command queries more than one dictionary, another level of lists is added with dictionary name followed by dictionary data.

Built-in command data is formatted as a list of commands. Each command has the name of the built-in command followed by the data for the command.

EXAMPLES

The following example returns all binding information for all dictionaries.

```
psyn_gui-t> get_gui_stroke_bindings
```

The following example returns the bindings for the Graphics dictionary.

```
psyn_gui-t> get_gui_stroke_bindings -dictionary Graphics
```

The following example returns the built-in commands available for use in bindings.

```
psyn_gui-t> get_gui_stroke_bindings -builtin
```

get_input_delays

Creates a collection of input delays for the current scenario. You can assign these input delays to a variable or pass them into another command.

SYNTAX

collection **get_input_delays**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
-of_objects *objects*
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]

Data Types

mode_list collection
corner_list collection
scenario_list collection
objects collection
expression string
exact_count int
minimum_count int

ARGUMENTS

-modes *mode_list*

Specifies the scenarios from which to retrieve the input delays. If this option is given, all scenarios of the specified modes will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners *corner_list*

Specifies the scenarios from which to retrieve input delays. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios *scenario_list*

Specifies the scenarios from which to retrieve input delays. The **-modes** or **-corners** option must not be specified with this option.

-of_objects *objects*

Creates a collection of input delays defined on the specified objects. Each object is either a named pin, a pin collection, a named port or port collection.

-filter *expression*

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

DESCRIPTION

The **get_input_delays** command creates a collection of input delays matching *patterns* in the current scenario and which pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Input delays are managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is specified, the command applies to all of the specified scenarios.

If the **-modes** option is specified, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is specified, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are specified, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

This example sets the variable inDel to the collection of input delays defined on ports IN* in the current scenario.

```
prompt> set inDel [get_input_delays -of_objects [get_ports IN*]]
```

SEE ALSO

collections(2)
set_input_delay(2)

get_instance_result

Returns a list of cell instances with rail results based on the type of result specified. The command lists the instances in the order of values from high to low.

When the -collection option is selected, this command creates a collection of cells which can be assigned to a variable or pass to another command.

SYNTAX

list **get_instance_result**
-type *result_type*
[-net *net_name*]
[-touching *region*]
[-top *top_num*]
[-threshold *threshold*]
[-percentage *percentage*]
[-histogram]
[-collection]

Data Types

result_type string
net_name string
region list
top_num integer
threshold float
percentage float

ARGUMENTS

-type *result_type*

Specifies the rail result type to report. Accepted types are effective_voltage_drop, current, effective_resistance, min_path_resistance, or power. This option is a required option.

-net *net_name*

Specifies a power or ground net name for which rail results to report. When not specified, results from all power nets will be returned.

-touching *region*

Specifies a region such that cell instances which are completely inside the specified region are returned with rail results. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

This option is mutually exclusive with the -top, -threshold, -percentage, or -histogram option.

-top ***top_num***

Returns the top number of cell instances for the result type specified. This option is mutually exclusive with the -touching, -threshold, -percentage, or -histogram option.

-threshold ***threshold***

Returns cell instances with rail result values greater than the specified threshold. This option is mutually exclusive with the -touching, -top, -percentage, or -histogram option.

-percentage ***percentage***

Returns cell instances with rail results values such that its percentage ratio (calculated over ideal supply voltage) is greater than the specified percentage. This option is mutually exclusive with the -touching, -top, -threshold, or -histogram option.

-histogram

Returns a histogram of rail results. The default histogram has 10 bins, which are expanded from the smaller value to the biggest value. This option is mutually exclusive with the -touching, -top, -threshold, or -percentage option.

-collection

Returns a collection of cell instances with the result type. This option can be used with the -touching, -top, -threshold, or -percentage option. This option is mutually exclusive with the -histogram option.

The **get_instance_result** command returns a list of cell instances with rail result. This command has to be run after command **analyze_rail** or **open_rail_result**.

EXAMPLES

The following example returns a list of cell instances within a rectangle area:

```
prompt> get_instance_result -net VDD -type voltage_drop -touching {{1610 1968} {1620 1969}}
lsw2/lsw2_pktpro/U179070 -0.053533
lsw2/lsw2_pktpro/U64076 -0.0535949
lsw2/lsw2_pktpro/U83035 -0.0535949
lsw2/lsw2_pktpro/U181017 -0.0535949
lsw2/lsw2_pktpro/U103335 -0.05366
```

The following example returns a collection of cell instances within a rectangle area:

```
prompt> get_instance_result -net VDD -type voltage_drop -touching {{1610 1968} {1620 1969}}
{lsw2/lsw2_pktpro/U179070 lsw2/lsw2_pktpro/U64076 lsw2/lsw2_pktpro/U83035 lsw2/lsw2_pktpro/U181017 lsw2/lsw2_pktpro/U1
```

The following example returns the top 5 cell instances on the effective voltage drop:

```
prompt> get_instance_result -net VDD -type voltage_drop -top 5
lsw2/lsw2_pktpro/I12653 -0.1022
```

lsw2/latch12 -0.101123
lsw2/l123422 -0.0988
lsw2/lsw2_pktpro/U112 -0.08765
lsw2/lsw2_pktpro/U123 -0.06542

SEE ALSO

analyze_rail(2)
open_rail_result(2)

get_io_guides

Creates a collection by selecting I/O guides from the current design.

SYNTAX

collection **get_io_guides**
[-design *design_name*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design_name string
expression string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-design *design_name*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the I/O guide attributes. You can determine the I/O guide attributes by using the **list_attributes** command. If the expression evaluates to **true**, the I/O guide is

included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies the expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for I/O guides level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at** but not with **-of_objects**.

patterns

Matches the I/O guide names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *objects*

Creates a collection containing the I/O guides of the specified pad cells. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all io_guides at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all io_guides that are completely inside the specified region and doesn't include io_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all io_guides that are completely inside the specified region and the io_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all io_guides which are abut/touching from inside or outside to the specified region and the io_guides whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of I/O guides by selecting I/O guides that meet the selection criteria. The command returns a collection handle if one or more I/O guides meet the selection criteria. If no I/O guides match the selection criteria, the command returns an empty string.

You can use the **get_io_guides** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of I/O guides by name pattern matching.

```
prompt> get_io_guides io_guide*
{"io_guide1", "io_guide2", "io_guide3"}
```

The following example creates a collection of io_guide with attribute filtering.

```
prompt> get_io_guides -filter {side == left}
{"io_guide1"}
```

The following example creates a collection of all I/O guides.

```
prompt> get_io_guides *
{"io_guide1", "io_guide2", "io_guide3", "groupio_guideA"}
```

The following example creates a collection of all I/O guides containing the pad cells "pad1" and "pad5".

```
prompt> get_io_guides -of_objects "pad1 pad5"
{"io_guide1", "io_guide2"}
```

get_io_rings

Creates a collection by selecting I/O rings from the current design.

SYNTAX

collection **get_io_rings**
[-design *design_name*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design_name string
expression string
exact_count integer
minimum_count integer
patterns list
of_objects list
region list
point list

ARGUMENTS

-design *design_name*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the I/O ring attributes. You can determine the I/O ring attributes by using the **list_attributes** command. If the expression evaluates to **true**, the I/O ring is included

in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for I/O rings level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

patterns

Matches the I/O ring names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *of_objects*

Creates a collection containing the I/O rings of the specified pad cells. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all IO rings at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all IO rings that are completely inside the specified region and doesn't include IO rings which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all IO rings that are completely inside the specified region and the IO rings which are abut/touching from inside with the specified region. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all IO rings which are abut/touching from inside or outside to the specified region and the IO rings whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of I/O rings by selecting I/O rings that meet the selection criteria. It returns a collection handle if one or more I/O rings meet the selection criteria. If no I/O rings match the selection criteria, it returns an empty string.

You can use the **get_io_rings** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of I/O rings by name pattern matching.

```
prompt> get_io_rings io_ring*
{"io_ring1", "io_ring2", "io_ring3"}
```

The following example creates a collection of I/O ring with attribute filtering.

```
prompt> get_io_rings -filter {"outer_ring == io_ring2"}
{"io_ring1"}
```

The following example creates a collection of all I/O rings.

```
prompt> get_io_rings *
{"io_ring1", "io_ring2", "io_ring3", "groupio_ringA"}
```

The following example creates a collection of all I/O rings containing the io_rings "io_ring1.bottom" and "io_ring2.left".

```
prompt> get_io_rings -of_objects "io_ring1.bottom io_ring2.left"
{"io_ring1", "io_ring2"}
```

The following example creates a collection of all I/O rings containing the pad cells "pad1" and "pad5" (through an I/O guide associated with the I/O ring)

```
prompt> get_io_rings -of_objects "pad1 pad5"
{"io_ring1", "io_ring2"}
```

get_keepout_margins

Creates a collection of keepout margins from the current design.

SYNTAX

collection **get_keepout_margins**
[-filter *expression*]
[-quiet]
[-design *design*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-type hard | soft | hard_macro | routing_blockage]
[*patterns* | -of_objects *objects*]

Data Types

expression string
design string
exact_count integer
minimum_count integer
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the keepout attributes. You can determine the keepout attributes by using the **list_attributes** command. If the expression evaluates to **true**, the keepout is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Returns the keepout margins of blocks and its instances hierarchically. This option is useful only with *patterns* and not with **-of_objects**.

-type hard | **soft** | **hard_macro** | **routing_blockage**

Returns the keepout margins of specific type only. The valid values for the options are: hard, soft, hard_macro and routing_blockage

-of_objects *objects*

Creates a collection containing the keepout margins associated with the specified objects. The objects can be designs, cells and lib cells. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the keepout names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

This command creates a collection of keepouts from the current design that match certain criteria. The command returns a collection

handle (identifier) if any keepouts match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_keepout_margins** command at the command prompt or nest it as an argument to another command (such as **report_keepout_margin**). You can also assign the **get_keepout_margins** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example returns keepout margins from the current_design

```
prompt> get_keepout_margins
{lib1:design1.design/KEEPOUT_hard_INNER_0
lib1:design1.design/KEEPOUT_soft_INNER_0
lib1:design1.design/KEEPOUT_hard_macro_INNER_0
lib1:design1.design/KEEPOUT_routing_blockage_INNER_0
lib1:design1.design/KEEPOUT_hard_OUTER_0
lib1:design1.design/KEEPOUT_soft_OUTER_0
lib1:design1.design/KEEPOUT_hard_macro_OUTER_0
lib1:design1.design/KEEPOUT_routing_blockage_OUTER_0}
```

The following example returns keepout margins of type 'hard' from all cells in the design

```
prompt> get_keepout_margins -of_objects [get_cells -hierarchical] -type hard
{cntrl/KEEPOUT_hard_OUTER_0 cntrl/KEEPOUT_hard_INNER_0
cntrl/U151/KEEPOUT_hard_OUTER_3 cntrl/U121/KEEPOUT_hard_OUTER_4 ...}
```

The following example returns keepout margins from the cell 'U280'

```
prompt> get_keepout_margins -of_objects {U280}
{U280/KEEPOUT_soft_OUTER_2196}
```

The following example returns keepout margins of lib cell 'abc'

```
prompt> get_keepout_margins -of_objects [get_lib_cells */abc/frame]
{lib1:abc.frame/KEEPOUT_hard_OUTER_1968}
```

SEE ALSO

create_keepout_margin(2)
remove_keepout_margins(2)
report_keepout_margins(2)

get_label_switch_list

Gets the value of the switch list for the specified design, if set.

SYNTAX

status **get_label_switch_list**

DESCRIPTION

This command gets the label switch list of a design. A designs' label switch list is used during linking if block is the top design.

The label switch list is a precedence-ordered list of labels that is applied when binding a design. If the top design has its label switch list explicitly set, then that label switch list is used. If not, then the top design label is used.

SEE ALSO

set_label_switch_list(2)

get_latch_loop_groups

Returns a list of collections of pins. Each collection contains the transparent latch data pins for one latch loop group.

SYNTAX

list **get_latch_loop_group**
[-of_objects *pin_list*]
[-loop_breakers_only]

Data Types

pin_list list

ARGUMENTS

-of_objects *pin_list*

Specifies a collection of data pins of transparent latches. This option returns only pins of loop groups containing the specified pins. By default, the command returns one collection for each loop group in the design.

-loop_breakers_only

Specifies that the returned collection contains only pins that are loop breaker latch data pins (that have a **true** value for the **is_latch_loop_breaker** pin attribute). By default, all transparent latch data pins within the loop group are returned in the collections.

DESCRIPTION

When sequential loops of transparent latches exist in a design, a loop group containing all latch data pins of intersecting loops is formed. The **get_latch_loop_groups** command analyzes the design and returns a collection for each loop group formed. The collection contains the latch data pins of the loop group. Combinational pins are not included in the results.

You can use the results of the **get_latch_loop_groups** command to find paths within loops that violate timing. For an example, see the EXAMPLES section.

EXAMPLES

The following example reports violating paths within latch loops by using the **get_latch_loop_groups** command. No paths outside

the loops are reported.

```
prompt> foreach a_loop_group [get_latch_loop_groups -loop_breakers_only] {
          report_timing -from $a_loop_group -to $a_loop_group -slack_lesser_than 0.0
        }
```

SEE ALSO

report_latch_loop_groups(2)
set_latch_loop_breaker(2)

get_layers

Creates a collection of one or more layers.

SYNTAX

collection **get_layers**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-all_purposes]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*. For any layers that match, the expression is evaluated based on the layer's attributes. If the expression evaluates to true, the layer is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-all_purposes

If this is specified, not just the tech layers, but all the layer purposes including layerDataTypes from tech file are also returned. All the layer purposes are stilll considered for a match, when the pattern contains a purpose name or purpose number. For example, if the pattern is "M1:signal" or "M1:2" or "M1:*", then all the layer purposes are also searched for a match.

-of_objects *of_objects*

Creates a collection containing the layers of the specified libs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches layer names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark) or regular expressions, depending on whether or not you also use the **-regexp** option.

DESCRIPTION

This command creates a collection of layers defined in the technology file for the current library.

You can use the **get_layers** command at the command prompt or as an argument nested in another command (for example, in the **query_objects** command). You can also assign its result to a variable.

The layer name printed for returned collection will have following format.

layer_name:purpose_name

The same format can be used to find layers with a specific purpose. If a layer **M1** with purpose **signal** is required, following can be used to get the required layer.

```
get_layers M1:signal
```

If the purpose **signal** has the purpose number **3**, the following will also work.

```
get_layers M1:3
```

When no purpose is specified in the layer name pattern, then the layer with default purpose **drawing** will be returned. If a layer with

all its purposes is needed, then wildcard "*" can be used in the pattern name, as following.

```
get_layers M1:*
```

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a layer for the name M1R.

```
prompt> get_layers M1R
{M1R}
```

SEE ALSO

collections(2)
filter_collection(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_lib

Creates a collection of libraries loaded into memory. You can assign these libraries to a variable or pass them into another command.

SYNTAX

collection **get_libs**
[-implicit | -explicit | -all]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

string *expression*
list *objects*
list *patterns*

ARGUMENTS

-implicit

Returns reference libraries implicitly opened through the ref_lib_list. Exclusive with -explicit and -all

-explicit

Returns main libraries explicitly opened with the open_lib command. Exclusive with -implicit and -all

-all

Returns both main and reference libraries. This is the default, exclusive with -implicit and -explicit.

-filter *expression*

Filters the collection with *expression*. For any libraries that match *patterns* (or *objects*), the expression is evaluated based on the library's attributes. If the expression evaluates to true, the library is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of libraries that contain the specified objects. In this case, each object is either a named library cell or a library cell collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches library names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type lib.

DESCRIPTION

The **get_libs** command creates a collection of libraries from those currently loaded into memory that match certain criteria. The command returns a collection if any libraries match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_libs** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_libs** result to a variable.

When issued from the command prompt, **get_libs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_libs** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_libs** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example creates a design library with two reference libraries.

```
prompt> create_lib top_lib -ref_libs {ref_lib1 ref_lib2}
{top_lib}
prompt> get_libs -all *
{top_lib ref_lib1 ref_lib2}
prompt> get_libs -explicit *
{top_lib}
prompt> get_libs -implicit *
{ref_lib1 ref_lib2}
```

The following example queries all loaded libraries. Although the output looks like a list, it is just a display.

```
prompt> get_libs -all *
{misc_cmos misc_cmos_io}
```

shell.common.collection_result_display_limit(3)

get_lib_cell

Creates a collection of library cells from the reference libraries loaded in memory.

SYNTAX

collection **get_lib_cells**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hsc *separator_character*]
[-include_subcells]
[*patterns*]
[-of_objects *objects*]

Data Types

expression string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any library cells that match *patterns* (or *objects*), the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

Regular expression matching is the same as in the Tcl **regexp** command. When using the **-regexp** option, take care in the way

you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find.

If the command finds a different number of objects, it raises a Tcl error and stops processing.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find.

If the command finds fewer objects, it raises a Tcl error and stops processing.

-expect_each_pattern_matches

Requires that each pattern in *patterns* must match at least one object.

If one or more patterns does not match, the command raises a Tcl error and stops processing.

-hsc *separator_character*

Specifies the hierarchy separator character.

The default is /. Valid values are /, @, ^, #, ., and |.

-include_subcells

Includes child cells in the results for hierarchical library cells.

By default, the results include only the top-level library cells.

patterns

Matches library cell names against patterns.

Patterns can include the wildcard characters '*' and '?' or regular expressions, based on the **-regexp** option. Patterns can also include collections of library cells.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either the *patterns* argument or the **-of_objects** option, the command assumes a default pattern of '*/*'.

-of_objects *objects*

Creates a collection of library cells that are referenced by the specified cells, own the specified library cell pins, or are in the specified libraries.

The **-of_objects** option and the *patterns* option are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_lib_cells** command creates a collection of library cells that match certain criteria. The command looks for the library cells in the reference libraries currently loaded in memory. The command returns a collection if any library cells match the specified criteria. If no objects match the criteria, the command returns an empty string.

In general, the command returns only library cells with timing views. If a library does not contain any cells with timing views, the command returns library cells with frame or design views. If you specify the view type (for example '*/*/frame' or '*/OR2/frame'), the library cells with that view type are returned, if found. If a library cell does not have a timing view and the library cell name does not contain a wildcard (for example '*/FILL4'), the command returns the frame view, if it exists. Otherwise, the command returns the design view. The command returns the layout view only if you explicitly specify that view type (for example '*/FILL8/layout').

You can use **get_lib_cells** commnad with lib cell name only which will treat as */lib_cell_name

You can use the **get_lib_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_lib_cells** result to a variable.

When issued from the command prompt, **get_lib_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_lib_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_lib_cells** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example creates a collection of the library cells in the misc_cmos library whose names begin with AN2. Although the output looks like a list, it is just a display.

```
prompt> get_lib_cells misc_cmos/AN2*
{misc_cmos/AN2 misc_cmos/AN2P}
```

The following example shows one way to determine the library cell used by a particular cell instance.

```
prompt> get_lib_cells -of_objects [get_cells o_reg1]
{misc_cmos/FD2}
```

objects list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any library cells that match *patterns* (or *objects*), the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

Regular expression matching is the same as in the Tcl **regexp** command. When using the **-regexp** option, take care in the way

you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find.

If the command finds a different number of objects, it raises a Tcl error and stops processing.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find.

If the command finds fewer objects, it raises a Tcl error and stops processing.

-expect_each_pattern_matches

Requires that each pattern in *patterns* must match at least one object.

If one or more patterns does not match, the command raises a Tcl error and stops processing.

-hsc *separator_character*

Specifies the hierarchy separator character.

The default is /. Valid values are /, @, ^, #, ., and |.

-include_subcells

Includes child cells in the results for hierarchical library cells.

By default, the results include only the top-level library cells.

patterns

Matches library cell names against patterns.

Patterns can include the wildcard characters '*' and '?' or regular expressions, based on the **-regexp** option. Patterns can also include collections of library cells.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either the *patterns* argument or the **-of_objects** option, the command assumes a default pattern of '*/*'.

-of_objects *objects*

Creates a collection of library cells that are referenced by the specified cells, own the specified library cell pins, or are in the specified libraries.

The **-of_objects** option and the *patterns* option are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_lib_cells** command creates a collection of library cells that match certain criteria. The command looks for the library cells in the reference libraries currently loaded in memory. The command returns a collection if any library cells match the specified criteria. If no objects match the criteria, the command returns an empty string.

In general, the command returns only library cells with timing views. If a library does not contain any cells with timing views, the command returns library cells with frame or design views. If you specify the view type (for example '*/*/frame' or '*/OR2/frame'), the library cells with that view type are returned, if found. If a library cell does not have a timing view and the library cell name does not contain a wildcard (for example '*/FILL4'), the command returns the frame view, if it exists. Otherwise, the command returns the design view. The command returns the layout view only if you explicitly specify that view type (for example '*/FILL8/layout').

You can use **get_lib_cells** commnad with lib cell name only which will treat as */lib_cell_name

You can use the **get_lib_cells** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_lib_cells** result to a variable.

When issued from the command prompt, **get_lib_cells** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_lib_cells** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_lib_cells** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example creates a collection of the library cells in the misc_cmos library whose names begin with AN2. Although the output looks like a list, it is just a display.

```
prompt> get_lib_cells misc_cmos/AN2*
{misc_cmos/AN2 misc_cmos/AN2P}
```

The following example shows one way to determine the library cell used by a particular cell instance.

```
prompt> get_lib_cells -of_objects [get_cells o_reg1]
{misc_cmos/FD2}
```

SEE ALSO

get_lib_pin

Creates a collection of library cell pins from libraries loaded into memory.

SYNTAX

collection **get_lib_pins**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hsc *separator_character*]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*
| -all]

Data Types

expression string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects collection
point list
region list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any library cell pins that match *patterns* (or *objects*), the expression is evaluated based on the library cell pin's attributes. If the expression evaluates to true, the library cell pin is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hsc separator_character

Specifies a separator character. Valid values are /, @, ^, #, ., |.

The default is /.

-of_objects *objects*

Creates a collection of library cell pins referenced by the specified netlist pins or owned by the specified library cells. In this case, each object is either a named library cell, a named netlist pin, a library cell collection, or a netlist pin collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

patterns

Creates a collection that contains all library cell pins that match the specified patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-at *point*

Creates a collection that contains all library cell pins at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-within *region*

Creates a collection that contains all library cell pins that are completely inside the specified region, not including library cell pins that abut the specified region from the inside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-touching *region*

Creates a collection that contains all library cell pins that are either completely inside the specified or abut the specified region from the inside. the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-intersect *region*

Creates a collection that contains all library cell pins that abut the specified region from the inside or outside and the library cell pins that are partially outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-all

Creates a collection that contains all library cell pins in the libraries loaded in memory. This is the same as using "*/*/*" as the *pattern*.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

DESCRIPTION

The **get_lib_pins** command creates a collection of library cell pins from the libraries loaded into memory that match certain criteria. The command returns a collection if any library cell pins match the *patterns* or *objects* arguments and pass the filter (if specified). If no objects matched the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_lib_pins** command at the command prompt, or you can nest it as an argument to another command such as the **query_objects** command. In addition, you can assign the **get_lib_pins** result to a variable.

When issued from the command prompt, the **get_lib_pins** command behaves as though the **query_objects** command had been called to display the objects in the collection. By default, the command displays a maximum of 100 objects. To change this maximum, set the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_lib_pins** command provides a fast, simple way to display the pins in the collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_lib_pins** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries all pins of the AN2 library cell in the misc_cmos library. Although the output looks like a list, it is just a display.

```
prompt> [get_lib_pins misc_cmos/AN2/*
{misc_cmos/AN2/A misc_cmos/AN2/B misc_cmos/AN2/Z}
```

The following example shows one way to find out how the library pin is used by a particular pin in the netlist.

```
prompt> get_lib_pins -of_objects o_reg1/Q
{misc_cmos/FD2/Q}
```

| -intersect *region*
| -all]

Data Types

expression string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects collection
point list
region list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any library cell pins that match *patterns* (or *objects*), the expression is evaluated based on the library cell pin's attributes. If the expression evaluates to true, the library cell pin is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hsc separator_character

Specifies a separator character. Valid values are /, @, ^, #, ., |.

The default is /.

-of_objects *objects*

Creates a collection of library cell pins referenced by the specified netlist pins or owned by the specified library cells. In this case, each object is either a named library cell, a named netlist pin, a library cell collection, or a netlist pin collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

patterns

Creates a collection that contains all library cell pins that match the specified patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-at *point*

Creates a collection that contains all library cell pins at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-within *region*

Creates a collection that contains all library cell pins that are completely inside the specified region, not including library cell pins that abut the specified region from the inside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-touching *region*

Creates a collection that contains all library cell pins that are either completely inside the specified or abut the specified region from the inside. the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-intersect *region*

Creates a collection that contains all library cell pins that abut the specified region from the inside or outside and the library cell pins that are partially outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

-all

Creates a collection that contains all library cell pins in the libraries loaded in memory. This is the same as using "*/*/*" as the *pattern*.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, **-at**, and **-all** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses "*/*/*" as the *pattern*.

DESCRIPTION

The **get_lib_pins** command creates a collection of library cell pins from the libraries loaded into memory that match certain criteria. The command returns a collection if any library cell pins match the *patterns* or *objects* arguments and pass the filter (if specified). If no objects matched the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_lib_pins** command at the command prompt, or you can nest it as an argument to another command such as the **query_objects** command. In addition, you can assign the **get_lib_pins** result to a variable.

When issued from the command prompt, the **get_lib_pins** command behaves as though the **query_objects** command had been called to display the objects in the collection. By default, the command displays a maximum of 100 objects. To change this maximum, set the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_lib_pins** command provides a fast, simple way to display the pins in the collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use the **get_lib_pins** command as an argument to the **query_objects** command.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries all pins of the AN2 library cell in the misc_cmos library. Although the output looks like a list, it is just a display.

```
prompt> [get_lib_pins misc_cmos/AN2/*
{misc_cmos/AN2/A misc_cmos/AN2/B misc_cmos/AN2/Z}
```

The following example shows one way to find out how the library pin is used by a particular pin in the netlist.

```
prompt> get_lib_pins -of_objects o_reg1/Q
{misc_cmos/FD2/Q}
```

SEE ALSO

get_lib_cells(2)
query_objects(2)
regexp(2)
shell.common.collection_result_display_limit(3)

get_lib_timing_arcs

Creates a collection of library arcs for custom reporting and other processing. You can assign these library arcs to a variable and get the desired attribute for further processing.

SYNTAX

string **get_lib_timing_arcs**
[-from *from_list*]
[-to *to_list*]
[-of_objects *object_list*]
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]

Data Types

from_list list
to_list list
of_objects list
expression string
exact_count int
minimum_count int

ARGUMENTS

-to *to_list*

Specifies the "to" library pins, or ports. All backward library arcs from the specified library pins or ports are considered.

-from *from_list*

Specifies the "from" library pins, or ports. All forward library arcs from the specified library pins or ports are considered.

-of_objects *object_list*

Specifies library cells or timing arcs. If a library cell is specified, all library cell arcs of that cell are considered. If a timing arc collection is given in the object list, the corresponding library timing arc is considered.

-filter *expression*

Specifies the filter expression. A filter expression is a string that comprises a series of logical expressions describing a set of constraints you want to place on the collection of library arcs. Each subexpression of a filter expression is a relation contrasting an attribute name with a value, by means of an operator.

-quiet

Specifies that all messages are to be suppressed.

-expect ***exact_count***

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

DESCRIPTION

Creates a collection of library arcs for custom reporting and other processing. You can assign these library arcs to a variable and get the desired attribute for further processing. Use the **foreach_in_collection** command to iterate among the library arcs in the collection. You can use the **get_attribute** command to obtain information about the paths. You can also use the filter expression to filter the library arcs that satisfy the specified conditions. The following attributes are supported on library timing arcs:

from_lib_pin
is_disabled
is_user_disabled
mode
object_class
sdf_cond
sense
to_lib_pin

One attribute of a library timing arc is the **from_lib_pin**, which is the library pin from which the timing arc begins. In the same way, **to_lib_pin** is the library pin to which the timing arc ends. To get more information on **from_lib_pin** and **to_lib_pin**, use the **get_attributes** command. The **object_class** attribute holds the class name of library timing arcs: **lib_timing_arc**.

See the **collections** and **foreach_in_collection** man pages for more information.

Multicorner-Multimode Support

EXAMPLES

The following procedure is an example of how the collection returned from an invocation of **get_lib_timing_arcs** can be utilized to provide useful and readable cell level arc information.

```
proc show_lib_arcs {args} {
  set lib_arcs [eval [concat get_lib_timing_arcs $args]]
  echo [format "%15s    %-15s  %18s" "from_lib_pin" "to_lib_pin" \
        "sense"]
  echo [format "%15s    %-15s  %18s" "------------" "----------" \
        "-----"]

  foreach_in_collection lib_arc $lib_arcs {
    set fpin [get_attribute $lib_arc from_lib_pin]
    set tpin [get_attribute $lib_arc to_lib_pin]
```

```
    set sense [get_attribute $lib_arc sense]
    set from_lib_pin_name [get_attribute $fpin base_name]
    set to_lib_pin_name [get_attribute $tpin base_name]
    echo [format "%15s -> %-15s  %18s" \
       $from_lib_pin_name $to_lib_pin_name \
       $sense]
  }
}
```

prompt> **show_lib_arc -of_objects [get_timing_arcs -of_objects ffa]**

```
  from_lib_pin    to_lib_pin                sense
  ------------    ----------                -----
          CP -> D                setup_clk_rise
          CP -> D                 hold_clk_rise
          CP -> Q                   rising_edge
          CP -> QN                  rising_edge
          CD -> Q                   clear_low
          CD -> QN                   preset_low
```

prompt> **show_lib_arc -of_objects mylib/AN2**

```
  from_lib_pin    to_lib_pin                sense
  ------------    ----------                -----
          A -> Z                positive_unate
          B -> Z                positive_unate
```

prompt> **show_lib_arc -from mylib/AN2/A**

```
  from_lib_pin    to_lib_pin                sense
  ------------    ----------                -----
          A -> Z                positive_unate
```

get_libs

Creates a collection of libraries loaded into memory. You can assign these libraries to a variable or pass them into another command.

SYNTAX

collection **get_libs**
[-implicit | -explicit | -all]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

string *expression*
list *objects*
list *patterns*

ARGUMENTS

-implicit

Returns reference libraries implicitly opened through the ref_lib_list. Exclusive with -explicit and -all

-explicit

Returns main libraries explicitly opened with the open_lib command. Exclusive with -implicit and -all

-all

Returns both main and reference libraries. This is the default, exclusive with -implicit and -explicit.

-filter *expression*

Filters the collection with *expression*. For any libraries that match *patterns* (or *objects*), the expression is evaluated based on the library's attributes. If the expression evaluates to true, the library is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of libraries that contain the specified objects. In this case, each object is either a named library cell or a library cell collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches library names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type lib.

DESCRIPTION

The **get_libs** command creates a collection of libraries from those currently loaded into memory that match certain criteria. The command returns a collection if any libraries match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_libs** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_libs** result to a variable.

When issued from the command prompt, **get_libs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_libs** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_libs** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example creates a design library with two reference libraries.

```
prompt> create_lib top_lib -ref_libs {ref_lib1 ref_lib2}
{top_lib}
prompt> get_libs -all *
{top_lib ref_lib1 ref_lib2}
prompt> get_libs -explicit *
{top_lib}
prompt> get_libs -implicit *
{ref_lib1 ref_lib2}
```

The following example queries all loaded libraries. Although the output looks like a list, it is just a display.

```
prompt> get_libs -all *
{misc_cmos misc_cmos_io}
```

get_license

Obtains a license feature.

SYNTAX

status **get_licenses**
feature_name
[-quantity *num_licenses*]

Data Types

feature_name	string
num_licenses	integer

ARGUMENTS

feature_name

Specifies the feature name to be obtained.

-quantity *num_licenses*

Specifies the total number of licenses to be checked out for the feature. If some licenses have already been checked out, the command acquires only the additional licenses needed to bring the total to the specfied quantity. If this option is not specified, only one license is checked out for the feature.

DESCRIPTION

This command checks out a license for the specified feature. The features remain checked out until the **remove_licenses** command is used or until the program exits.

If multiple licenses are required, you can use the **-quantity** option to specify the total number of licenses needed. You can use this option to reserve the required number of licenses early in the session, rather than risking a failure later in the session if the licenses are not available.

The **list_licenses** command provides a list of the features that you are currently using.

EXAMPLES

The following example obtains the requested feature:

```
prompt> get_licenses Fusion-Compiler-BE
1
```

The following example obtains two licenses of the feature:

```
prompt> get_licenses Fusion-Compiler-BE -quantity 2
1
```

SEE ALSO

get_licenses

Obtains a license feature.

SYNTAX

status **get_licenses**
feature_name
[-quantity *num_licenses*]

Data Types

feature_name	string
num_licenses	integer

ARGUMENTS

feature_name

Specifies the feature name to be obtained.

-quantity *num_licenses*

Specifies the total number of licenses to be checked out for the feature. If some licenses have already been checked out, the command acquires only the additional licenses needed to bring the total to the specfied quantity. If this option is not specified, only one license is checked out for the feature.

DESCRIPTION

This command checks out a license for the specified feature. The features remain checked out until the **remove_licenses** command is used or until the program exits.

If multiple licenses are required, you can use the **-quantity** option to specify the total number of licenses needed. You can use this option to reserve the required number of licenses early in the session, rather than risking a failure later in the session if the licenses are not available.

The **list_licenses** command provides a list of the features that you are currently using.

EXAMPLES

The following example obtains the requested feature:

```
prompt> get_licenses Fusion-Compiler-BE
1
```

The following example obtains two licenses of the feature:

```
prompt> get_licenses Fusion-Compiler-BE -quantity 2
1
```

get_macro_group_packing_clone_candidates

Get macro group packing canditates.

SYNTAX

collection_of_objects **get_macro_group_packing_clone_candidates**
-group macro_group

ARGUMENTS

-group macro_group

Specifies source macro group.

DESCRIPTION

This command returns a collection of macro groups which the packing of source macro group can be copied to. The command goes over every macro group in the ndm database, and determine whether the source macro group can be copied to it using following steps.

\n+[step]. If the number of macros of source macro group and destination macro group are not the same, it will not copy the packing from source to desitination and the skip the group.
\n+[step]. Sorting macros of source macro group and destinaiton macro group based on macro names. Each macro in the source macro list corresponds to the macro of destinaiton macro list at the same location in the list.
\n+[step]. Comparing corresponding macros from these two macro list one by one. If any two macros have different size, the packing cannot be copied and the group is skipped.
\n+[step]. Add the macro group to the result.

EXAMPLES

The following command returns a list of macro groups which can be copied from macro group G1.

prompt> **get_macro_group_packing_clone_candidatess** -group G1

SEE ALSO

create_macro_group(2)
clone_macro_group_packing(2)

get_matching_types

Creates a collection by selecting matching types from the current block.

SYNTAX

collection **get_matching_types**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the matching type attributes. You can determine the matching type attributes by using the **list_attributes** command. If the expression evaluates to **true**, the matching type is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the matching types of the specified cells, pins, or terminals. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the matching type names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

This command creates a collection of matching types by selecting matching types that meet the selection criteria. It returns a collection handle if one or more matching types meet the selection criteria. If no matching types match the selection criteria, it returns an empty string.

You can use the **get_matching_types** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of matching types by name pattern matching.

```
prompt> get_matching_types myMatchingType*
{"myMatchingType1", "myMatchingType2", "myMatchingType3"}
```

The following example creates a collection of matching types with attribute filtering.

```
prompt> get_matching_types -filter {uniquify_number == 3}
{"myMatchingType2"}
```

The following example creates a collection of all matching types.

```
prompt> get_matching_types *
{"myMatchingType1", "myMatchingType2", "myMatchingType3", "yourMatchingType1"}
```

The following example creates a collection of all matching_types containing the cells "inv1".

```
prompt> get_matching_types -of_objects [get_cells inv1]
{"myMatchingType3"}
```

get_mem

Retrieves the total memory allocated by the current process.

SYNTAX

int **get_mem**

DESCRIPTION

The *get_mem* command returns the size of memory currently allocated by the current process for the purposes of storing design netlist, design annotations, and constraints information as well as computed timing information. The value printed represents the amount in kilobytes (kB).

Note that the value reported would not match values obtained by the user through Unix process tracking commands, such as *top*. This is the case because the *get_mem* command does not track memory used to load the executable and maintain process stack space. Also, it does not differentiate between resident and swapped memory.

```
prompt> get_mem
8092
```

SEE ALSO

get_cputime(2)

get_message_ids

Get application message ids

SYNTAX

string **get_message_ids** [-type *severity*]
[*pattern*]

string *severity*
string *pattern*

ARGUMENTS

-type *severity*

Filter ids based on type (Values: Info, Warning, Error, Severe, Fatal)

pattern

Get IDs matching pattern (default: *)

DESCRIPTION

The **get_message_ids** command retrieves the error, warning and informational messages used by the application. The result of this command is a Tcl formatted list of all message ids. Information about the id can be queried with the **get_message_info** command.

EXAMPLES

The following code finds all error messages and makes the application stop script execution when one of these messages is encountered.

```
foreach id [get_message_ids -type Error] {
  set_message_info -stop_on -id $id
}
```

SEE ALSO

print_message_info(2)
set_message_info(2)
suppress_message(2)

get_message_info

Returns information about diagnostic messages.

SYNTAX

integer **get_message_info**
[-error_count | -warning_count | -info_count
| -limit l_id | -occurrences o_id | -suppressed s_id | -id i_id]

Data Types

l_id string
o_id string
s_id string
i_id string

ARGUMENTS

-error_count

Returns the number of error messages issued so far.

-warning_count

Returns the number of warning messages issued so far.

-info_count

Returns the number of informational messages issued so far.

-limit *l_id*

Returns the current user-specified limit for a given message ID. The limit was set with the **set_message_info** command.

-occurrences *o_id*

Returns the number of occurrences of a given message ID.

-suppressed *s_id*

Returns the number of times a message was suppressed either using **suppress_message** or due to exceeding a user-specified limit.

-id *i_id*

Returns information about the specified message. The information is returned as a Tcl list compatible with the array set command.

DESCRIPTION

The **get_message_info** command retrieves information about error, warning, and informational messages. For example, if the following message is generated, information about it is recorded:

```
Error: unknown command 'wrong_command' (CMD-005)
```

It is useful to be able to retrieve recorded information about generated diagnostic messages. For example, you can stop a script after a certain number of errors have occurred, or monitor the number of messages issued by a single command.

You can also find out how many times a specific message has occurred, or how many times it has been suppressed. Also, you can find out if a limit has been set for a particular message ID.

EXAMPLES

The following example uses the **get_message_info** command to count the number of errors that occurred during execution of a specific command, and to return from the procedure if the error count exceeds a given amount:

```
prompt> proc \
  do_command {limit} {
    set current_errors [get_message_info -error_count]
    command
    set new_errors [get_message_info -error_count]
    if {[expr $new_errors - $current_errors] > $limit} {
      return -code error "Too many errors"
    }
    ...
  }
```

The following example uses the **get_message_info** command to retrieve information on the CMD-014 message:

```
prompt> get_message_info -id CMD-014
id CMD-014 severity Error limit 0 occurrences 0 suppressed 0 message
{Invalid %s value '%s' in list.}
```

SEE ALSO

print_message_info(2)
set_message_info(2)
suppress_message(2)
get_message_ids(2)

get_mib_objects

Creates a collection of multiply instantiated blocks (MIBs) from the current design relative to the current instance. You can assign these objects to a variable or pass them into another command.

SYNTAX

collection **get_mib_objects**
[-quiet]
[-add]
object_list

Data Types

object_list list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-add

Include original selected pins and/or cells in returned MIB objects.

object_list

A collection or selection set of objects to get MIB from.

DESCRIPTION

The **get_mib_objects** command creates a collection of multiply instantiated blocks (MIBs) from the current design relative to the current instance.

You can use the **get_mib_objects** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_mib_objects** result to a variable.

EXAMPLES

The following example get the MIB objects for the cell named block_0.

```
prompt> get_mib_objects [get_cell block_0]
{"block_0" "block_1"}
```

The following example gets the MIB objects of a specified pin.

```
prompt> set pinsel [get_pin o_reg1/CP]
{"o_reg1/CP"}
prompt> get_mib_objects $pinsel
{"o_reg1/CP", "o_reg2/CP"}
```

SEE ALSO

get_mismatch_objects

Create a collection of mismatch objects from the current design and its ref_libs. This collection does not contain mismatch objects of **accepted** mismatch state. To obtain **accepted** mismatch objects, use **repair_status** option. You can assign these objects to a variable or pass them into another command.

SYNTAX

collection **get_mismatch_objects**
[-filter *expression*]
[-repair_status *status*
[-mismatch_type *type*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *objects*

Data Types

expression string
status string
type string
exact_count int
minimum_count int
patterns list
of_objects list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any cells that match *patterns* the expression is evaluated based on the mismatch object's attributes. If the expression evaluates to **true**, the mismatch object is included in the result.

-repair_status

Specifies the list of mismatch states to return mismatches. Valid values are **repaired**, **not_repaired**, **accepted**, **deleted**, and **ignored**.

-mismatch_type *type*

Specifies the list of mismatch types to return mismatches. Valid values are **bus_blast_type**, **lib_missing_logical_port**,

lib_missing_physical_port, **lib_missing_physical_reference**, **lib_name_case**, **lib_port_direction**, **lib_port_name_synonym**, **lib_port_type**, **missing_logical_reference**, **missing_port**, **port_name_case**, **cell_name_case**, **port_name_synonym**, and **empty_logic_module**.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of mismatch objects associated to the specified object. In this case, each object in the list is a name, pattern, or collection. The objects can be design, lib_cell and libs. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches mismatch object names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. By default, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

The get_mismatch_objects command creates a collection of mismatch objects that match certain criteria. The command returns a collection handle (identifier) if any mismatch object match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns Error.

By default, this command returns mismatch objects having any mismatch state except **accepted**. To get **accepted** mismatch objects, use **repair_status** option.

When **mismatch_type** option is used, this command will return mismatches for specified mismatch type.

You can use the **get_mismatch_objects** command at the command prompt or nest it as an argument to another command . You can also assign the **get_mismatch_objects** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example returns all mismatch objects from current design and ref libs.

```
prompt> get_mismatch_objects
{port_name_case_ORCA_inv0d1/i port_name_case_ORCA_invbd2/i}
```

The following example returns all mismatch objects from all designs.

```
prompt> get_mismatch_objects -of_objects [get_designs]
{port_name_case_REG_FILE_inv0d1/i port_name_case_ORCA_inv0d1/i port_name_case_ORCA_invbd2/i}
```

The following example returns mismatch objects having repair state as "accepted" from current design and ref libs.

```
prompt> get_mismatch_objects -repair_status accepted
{port_name_case_REG_FILE_inv0d2/i}
```

The following example returns mismatch objects of specified mismatch states from current design and ref libs.

```
prompt> get_mismatch_objects -repair_status {accepted repaired}
{port_name_case_REG_FILE_inv0d2/i}
```

The following example returns mismatch objects of specified mismatch types from current design and ref libs.

```
prompt> get_mismatch_objects -mismatch_type port_name_case
{port_name_case_REG_FILE_inv0d2/i}
```

get_mismatch_types

Create a collection mismatch types from the current design. You can assign these to a variable or pass them into another command.

SYNTAX

collection **get_mismatch_types**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns

Data Types

expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any cells that match *patterns* the expression is evaluated based on the mismatch object's attributes. If the expression evaluates to **true**, the mismatch object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect ***exact_count***

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches mismatch object names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. By default, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

The get_mismatch_types command creates a collection of mismatch types that match certain criteria. The command returns a collection handle (identifier) if any mismatch types match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns Error.

You can use the **get_mismatch_types** command at the command prompt or nest it as an argument to another command . You can also assign the **get_mismatch_types** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example returns all mismatch types.

```
prompt> get_mismatch_types
{lib_missing_physical_reference lib_missing_logical_port
lib_missing_physical_port lib_port_type lib_port_direction
lib_port_name_synonym missing_logical_reference reference_name_case
missing_port port_name_case port_name_synonym bus_bit_naming
lib_cell_name_case lib_port_name_case lib_missing_rail_pg
layer_missing_prefer_direction lib_port_missing_via_region
lib_port_missing_access_edge macro_cell_contain_too_many_obs
exceed_ndr_limitation empty_logic_module}
```

The following example queries the mismatch types which start with "lib".

```
prompt> get_mismatch_types "lib*"
{lib_missing_physical_reference lib_missing_logical_port
```

```
lib_missing_physical_port lib_port_type lib_port_direction
lib_port_name_synonym lib_cell_name_case lib_port_name_case
lib_missing_rail_pg lib_port_missing_via_region lib_port_missing_access_edge}
```

The following example returns the current repair subscript attribute for the specified mismatch type.

```
prompt> get_attr [get_mismatch_types lib_missing_logical_port] \
  current_repair
auto_fix create_placeholder_logic_lib_port default null
```

The following example returns the current repair subscript attribute for the specified configuration and mismatch type.

```
prompt> get_attr [get_mismatch_types lib_missing_logical_port] \
  current_repair(auto_fix)
create_placeholder_logic_lib_port
```

get_modes

Creates a collection of modes in the current design. You can assign these modes to a variable or pass them into another command.

SYNTAX

collection **get_modes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches mode names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_modes** command creates a collection of modes matching *patterns* in the current design and which pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Multicorner-Multimode Support

This command works on all modes.

EXAMPLES

This script performs **report_clock** one time for each mode beginning with "Test".

```
foreach_in_collection mode [get_modes Test*] {
 current_mode $mode
 report_clock
}
```

SEE ALSO

all_modes(2)

collections(2)
create_mode(2)
current_mode(2)
report_clocks(2)

get_modules

Creates a collection of one or more modules in a block. You can assign these modules to a variable or pass them into another command.

SYNTAX

collection **get_modules**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns

Data Types

design string or collection
expression string
exact_count int
minimum_count int
patterns list

ARGUMENTS

-design

Specifies the block for finding objects. If this is not specified, objects will be found in the current block.

-filter *expression*

Filters the collection with *expression*. For any modules that match *patterns*, the expression is evaluated based on the design's attributes. If the expression evaluates to true, the design is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches design names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type design.

DESCRIPTION

The **get_modules** command creates a collection of modules from the specified block or the current block that match certain criteria. The command returns a collection if any modules match the *patterns* and pass the filter (if specified). If no objects matched your criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_modules** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_modules** result to a variable.

When issued from the command prompt, **get_modules** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_modules** provides a fast, simple way to display modules in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_modules** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the modules that begin with 'mpu.'

```
prompt> get_modules mpu*
{"mpu_0_0", "mpu_0_1", "mpu_1_0", "mpu_1_1"}
```

get_msg

Gets message properties.

SYNTAX

integer **get_msg**
[*msgTag*]
[-level]
[-default_level]
[-print_count]
[-trigger_count]
[-limit]
[-format]
[-last]
[-total_print_count off | debug | verbose | info | warning | error | fatal]

Data Types

msgTag string

ARGUMENTS

msgTag

Specifies the unique message tag to query.

-level

Returns the current level of the message.

-default_level

Returns the system default level of the message.

-print_count

Returns the number of times the message was printed.

-trigger_count

Returns the number of times the messages was encountered. Messages can be triggered but not printed due to their level.

-limit

Returns the print limit of the message.

-format

Returns the message format string.

-last

Returns the output of the last time the message was printed.

-total_print_count off | debug | verbose | info | warning | error | fatal

Returns the total amount of messages printed for the specified message level. Valid values are off, debug, verbose, info, warning, error, or fatal.

DESCRIPTION

The following example returns the message level for message ABC-1234.

EXAMPLES

```
prompt> get_msg ABC-1234 -level
Warning
```

The following example returns how often the specified message was printed.

```
prompt> get_msg ABC-1234 -print_count
2
```

The following example returns how often the message was triggered.

```
prompt> get_msg ABC-1234 -trigger_count
5034
```

SEE ALSO

report_msg(2)
set_msg(2)

get_multisource_clock_sink_groups

Returns a collection of sink groups defined for multisource clock tap assignment

SYNTAX

collection **get_multisource_clock_sink_groups**
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
patterns | -of_objects *objects*

Data Types

exact_count integer
minimum_count integer
expression string
patterns string
objects collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no sink groups match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for sink groups that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of sink groups to find. If the command finds a different number of sink groups, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of sink groups to find. If the command finds fewer sink groups, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one sink group. If one or more patterns do not match, a Tcl error will be raised and command processing will stop.

-filter ***expression***

Filters the collection with *expression*. For any sink group that match *patterns* (or *objects*) the expression is evaluated based on the sink group's attributes. If the expression evaluates to true, the sink group is included in the result.

patterns

Matches sink group names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type multisource_sink_group. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

-of_objects ***objects***

Creates a collection of sink groups associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be pin or ports and refer to the driver object or collection of sinks. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_multisource_clock_sink_groups** command is used to return a collection of sink groups defined for multisource clock tap assignment. The command returns a collection if any sink groups match the *patterns* or *objects* and pass the filter (if specified). If no sink group matches the criteria, the empty string is returned.

Regular expression matching using option *-regexp* is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

This example returns a sink groups that start with e prefix my_sinks.

prompt> **get_multisource_clock_sink_groups my_sinks***

This example returns the sink group that is associated with pin reg1/CK.

prompt> **get_multisource_clock_sink_groups -of_objects [get_pin reg1/CK]**

get_net

Creates a collection of nets from the netlist. You can assign these nets to a variable or pass them to another command.

SYNTAX

collection **get_nets**
[-design *design*]
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-physical_context]
[-top_net_of_hierarchical_group]
[-segments]
[-boundary_type lower | upper | both]
[-hsc *separator*]
[-include_shielded]
[-shielded_only]]
patterns | -of_objects *objects*

Data Types

design string
expression string
exact_count integer
minimum_count integer
separator character
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this option is not specified, objects will be found in the current design.

-hierarchical

Searches for nets within the hierarchy relative to the current instance, when used without the **-physical_context** option. The full

name of the object at a particular level of hierarchy must match *patterns*. The search is similar to the UNIX **find** command. For example, if there is a net u1/muxsel, a hierarchical search would find it using "muxsel". **-hierarchical** and **-of_objects**, can be used together only when **-physical_context** is also used and the *objects* argument to **-of_objects** are nets. When used together with **-physical_context** option, the search is performed level-by-level, where each level is a physical hierarchy. So, if u1 is a logical hierarchical instance, then the search will **not** find the net "muxsel". However, search for "*muxsel", would find the net physical net u1/muxsel.

-filter *expression*

Filters the collection with *expression*. For any nets that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the cell. If the expression evaluates to true, the net is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Considers the *patterns* argument as true regular expressions rather than a simple wildcard pattern. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-physical_context

Searches only for physical nets. This option can also be used with **-of_objects**. If the *objects* argument to **-of_objects** is a pin, the physical net connected to the pin is returned. If the *objects* argument to **-of_objects** is a cell, a collection of physical nets connected to the pins of the cell is returned. If *objects* argument to **-of_objects** is a net, the physical net corresponding to the net is returned. If **-of_objects** is not used, the physical nets matching the specified *patterns* are returned. When **-hierarchical** is used, the patterns are matched against the name of the physical nets, which typically correspond to full hierarchical name of logical nets. Therefore, a search for "net*" will only find nets in the topmost logical hierarchy, matching the pattern "net*". To find physical nets in lower levels of the logical hierarchy, prefix the expression with an asterisk (*), for example, "*net*".

-top_net_of_hierarchical_group

Keeps only the top net of a hierarchical group. When more than one hierarchical net of the same group is specified (local nets at various hierarchical levels of the same physical net), only the net closest to the top of the hierarchy is saved with the collection. In the case of multiple nets at the same level, the first net specified is kept. Although this option can be used when there are multiple

nets specified, it is best used in combination with **-segments** and with a single net.

-segments

Returns all global segments for given nets. This modifies the initial search which matches *patterns* or *objects*. It is applied before the **-top_net_of_hierarchical_group** is determined. For each net, all global segments which are part of that net will be added to the result collection. Global net segments are all those physically connected across all hierarchical boundaries. Although this option can be used with other options and when there are multiple nets specified, it is best used with a single net. When combined with the **-top_net_of_hierarchical_group** option, you can isolate the highest net segment of a physical net.

-boundary_type lower | **upper** | **both**

Specifies what to do when getting nets of boundary pins. This option requires the **-of_objects** option. Allowed values are lower, upper, and both, meaning the net inside the hierarchical block, outside the hierarchical block, or both nets, respectively. The option has no meaning for non-hierarchical pins. Note that the "upper" value is less useful, as getting pins of a hierarchical net will return the pin outside the hierarchical block, and a subsequent **get_nets** commands find the upper hierarchical net. Using "upper" on a hierarchical pin is the same as omitting the option.

-hsc ***separator***

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects ***objects***

Creates a collection of nets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell, cell collection, a named net or a net collection, a named via or a via collection, a shape collection, a routing corridor, a bundle, a net bus,a named via_matrix or a via_matrix collection.

The **-of_objects** and *patterns* arguments are mutually exclusive; you must specify one, but not both. In addition, **-hierarchical** and **-of_objects** can be used together only when **-physical_context** is also used and the *objects* argument to **-of_objects** are nets.

-include_shielded

Specifies to include the shielded nets when **-of_objects** contains shapes. It is only valid when **-of_objects** contains shapes.

This option is mutually exclusive with **-shielded_only**.

-shielded_only

Specifies to get the shielded nets only when **-of_objects** contains shapes. It is only valid when **-of_objects** contains shapes.

This option is mutually exclusive with **-include_shielded**.

patterns

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions based on the **-regexp** option. Patterns can also include collections of type net. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_nets** command creates a collection of nets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any nets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus net inclusively between the begin_index and end_index indexes. Note that the "[]" characters must be escaped, because they are Tcl special characters (e.g., A\[0:15:2\] or {A[0:15:2]}). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth net inclusively between the begin and end indexes, which has a matching name without the delimiters characters (that is, net names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns can be specified, separated with a ',' character.

You can use the **get_nets** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_nets** result to a variable.

When issued from the command prompt, **get_nets** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_nets** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_nets** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the nets that begin with 'NET' in block 'block1'. Although the output looks like a list, it is just a display.

```
prompt> get_nets block1/NET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example queries nets by using bus subscripting.

```
prompt> get_nets {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

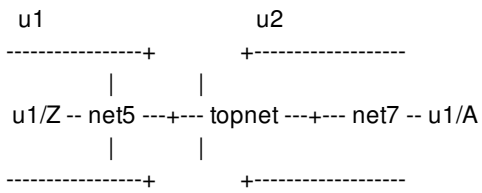
The following example queries nets by using name expansion subscripting.

```
prompt> get_nets B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example queries the nets connected to a collection of pins returned by the **get_pins** command.

```
prompt> current_instance block1
block1
prompt> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
prompt> query_objects [get_nets -of_objects $pinsel]
{"NET1QNX", "NET2QNX"}
```

This example shows how to use the **-top_net_of_hierarchical_group** and **-boundary_type** options. Given the following circuit:



There are hierarchical cells u1 and u2 at this level, connected by a net *topnet*. Within u1 is a pin u1/Z driving *net5*, and within u2 is a pin u1/A being driven by *net7*. These three nets are physically the same net. Assume these are the only nets in the design. Notice the difference in the results of the following two **get_nets** commands:

```
prompt> get_nets * -hierarchical
{topnet u1/net5 u2/net7}
prompt> get_nets * -hierarchical -top_net_of_hierarchical_group
{topnet}
prompt> get_nets -physical_context
{topnet}
prompt> get_nets -physical_context -of_objects [get_nets u2/net7]
{topnet}
```

Assume that at the top level, topnet is connected to pins u2/in and u1/out. Here are some examples of **-boundary_type**. Notice now in this case, the "upper" type does not add value.

```
prompt> get_nets -of_objects u2/in
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type upper
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type lower
{u2/net7}
prompt> get_nets -of_objects u2/in -boundary_type both
{u2/net7 topnet}
prompt> get_nets -boundary_type lower -of_objects \
  [get_pins -of_objects [get_nets topnet]]
{u1/net5 u2/net7}
```

get_net_buses

Creates a collection of net buses from the current design. You can assign these net buses to a variable or pass them into another command.

SYNTAX

collection **get_net_buses**
[-design *design*]
[-hierarchical]
[-physical_context]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *objects*

Data Types

design string or collection
expression string
exact_count integer
minimum_count integer
patterns list
objects string or collection

ARGUMENTS

-design *design_name*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

-hierarchical

Searches for bus nets within the hierarchy relative to the current instance. The full name of the object at a particular level of hierarchy must match *patterns*. The search is similar to the UNIX **find** command. For example, if there is a bus net block1/bus1, a hierarchical search would find it using "bus1"

-physical_context

This option is needed when a cell object is provided as input to the **-of_objects** option. The net buses of the cells are returned, if the cell is a physical hierarchical cell.

-filter *expression*

Filters the collection with *expression*. For any net buses that match *patterns*, the expression is evaluated based on the net's attributes. If the expression evaluates to true, the cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Specifies that the *patterns* argument is a real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *objects*

Creates a collection of net buses connected to the specified objects. Each object is a named cell, cell collection, named net, net collection, named block or block collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type net. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_net_buses** command creates a collection of net buses in the current design that match the specified criteria. The command returns a collection if any net buses match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the **regexp** Tcl command. When using **-regexp**, take care in the way you quote the

patterns and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_net_buses** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_net_buses** result to a variable.

When issued from the command prompt, **get_net_buses** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_net_buses** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_net_buses** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page. In addition, refer to the man pages for **all_inputs** and **all_outputs**, which also create collections of net buses.

EXAMPLES

The following example queries all input net buses beginning with 'bus'. Although the output looks like a list, it is just a display.

```
prompt> get_net_buses "bus*"
{"bus1", "bus2"}
```

get_net_estimation_rules

Returns a net_estimation_rule object as defined by the **set_net_estimation_rule** command.

SYNTAX

int **get_net_estimation_rules**
[pattern] [-filter *expression*]
[-quiet]
[-cell *cell*]

Data Types

expression string
pattern string
cell collection

ARGUMENTS

patterns

Matches rule names against patterns. Patterns can include the wildcard characters "*" and "?". If no pattern is specified, it defaults to "*". Patterns can also include collections of type net_estimation_rule.

-filter *expression*

Filters the collection with *expression*. For any rules that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the rule. If the expression evaluates to true, the rule is included in the result.

-quiet

Suppresses warning and error messages if no matching net_estimation_rules are found.

-cell *cell*

Specifies the physical cell from which to find the net estimation rule.

By default, the current block is searched for the specified net estimation rule(s)..

DESCRIPTION

This command returns net_estimation_rule objects as previously defined by the **set_net_estimation_rule** command. The object is useful for querying many attributes, which can be specified or derived automatically by the tool. For example, you can specify a

buffer chain of size 12 buffers and query the calculated attributes of the buffer chain; the command returns the delay of the buffer chain. Use this command in Tcl scripts to explore the characteristics of your technology.

Alternatively you can use **report_net_estimation_rules** to examine the attribute values.

NET ESTIMATION RULES AND HIERARCHY

Net estimation rules can be created in any physical block at any level of the hierarchy and multiple blocks can have different rules with the same name. However, rules are often stored/retrieved by name, and doing this can cause confusion as to which rule is being used by a given command. Generally, the "current" (top) block's list of rules is searched by commands such as *estimate_timing*. This means that if you define rule R1 in "top" and rule R1 in block "B1", if you make block B1 the current block, commands will use B1's R1. When you go back to top, top's R1 is used. To avoid confusion, use globally unique rule names and define them at the top - they will be propagated to child blocks during distributed commands as necessary. Rules in child blocks that have the same name as rules in top may also be overwritten during distributed commands.

EXAMPLES

The following example retrieves all attributes for the "default" rule.

```
prompt> report_attributes -application [get_net_estimation_rules default]
```

The following example returns the horizontal buffer spacing for the "M5_M6" rule.

```
prompt> get_attribute [get_net_estimation_rules M5_M6] h_buffer_spacing
```

SEE ALSO

report_net_estimation_rules(2)
set_net_estimation_rule(2)

get_nets

Creates a collection of nets from the netlist. You can assign these nets to a variable or pass them to another command.

SYNTAX

collection **get_nets**
[-design *design*]

[-boundary_type lower | upper | both]
[-hsc *separator*]
[-include_shielded]
[-shielded_only]]
patterns | -of_objects *objects*

Data Types

design string
expression string
exact_count integer
minimum_count integer
separator character
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this option is not specified, objects will be found in the current design.

-hierarchical

Searches for nets within the hierarchy relative to the current instance, when used without the **-physical_context** option. The full

name of the object at a particular level of hierarchy must match *patterns*. The search is similar to the UNIX **find** command. For example, if there is a net u1/muxsel, a hierarchical search would find it using "muxsel". **-hierarchical** and **-of_objects**, can be used together only when **-physical_context** is also used and the *objects* argument to **-of_objects** are nets. When used together with **-physical_context** option, the search is performed level-by-level, where each level is a physical hierarchy. So, if u1 is a logical hierarchical instance, then the search will **not** find the net "muxsel". However, search for "*muxsel", would find the net physical net u1/muxsel.

-filter *expression*

Filters the collection with *expression*. For any nets that match *patterns* (or *objects*), the expression is evaluated based on the attributes of the cell. If the expression evaluates to true, the net is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Considers the *patterns* argument as true regular expressions rather than a simple wildcard pattern. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-physical_context

Searches only for physical nets. This option can also be used with **-of_objects**. If the *objects* argument to **-of_objects** is a pin, the physical net connected to the pin is returned. If the *objects* argument to **-of_objects** is a cell, a collection of physical nets connected to the pins of the cell is returned. If *objects* argument to **-of_objects** is a net, the physical net corresponding to the net is returned. If **-of_objects** is not used, the physical nets matching the specified *patterns* are returned. When **-hierarchical** is used, the patterns are matched against the name of the physical nets, which typically correspond to full hierarchical name of logical nets. Therefore, a search for "net*" will only find nets in the topmost logical hierarchy, matching the pattern "net*". To find physical nets in lower levels of the logical hierarchy, prefix the expression with an asterisk (*), for example, "*net*".

-top_net_of_hierarchical_group

Keeps only the top net of a hierarchical group. When more than one hierarchical net of the same group is specified (local nets at various hierarchical levels of the same physical net), only the net closest to the top of the hierarchy is saved with the collection. In the case of multiple nets at the same level, the first net specified is kept. Although this option can be used when there are multiple

nets specified, it is best used in combination with **-segments** and with a single net.

-segments

Returns all global segments for given nets. This modifies the initial search which matches *patterns* or *objects*. It is applied before the **-top_net_of_hierarchical_group** is determined. For each net, all global segments which are part of that net will be added to the result collection. Global net segments are all those physically connected across all hierarchical boundaries. Although this option can be used with other options and when there are multiple nets specified, it is best used with a single net. When combined with the **-top_net_of_hierarchical_group** option, you can isolate the highest net segment of a physical net.

-boundary_type lower | **upper** | **both**

Specifies what to do when getting nets of boundary pins. This option requires the **-of_objects** option. Allowed values are lower, upper, and both, meaning the net inside the hierarchical block, outside the hierarchical block, or both nets, respectively. The option has no meaning for non-hierarchical pins. Note that the "upper" value is less useful, as getting pins of a hierarchical net will return the pin outside the hierarchical block, and a subsequent **get_nets** commands find the upper hierarchical net. Using "upper" on a hierarchical pin is the same as omitting the option.

-hsc ***separator***

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects ***objects***

Creates a collection of nets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell, cell collection, a named net or a net collection, a named via or a via collection, a shape collection, a routing corridor, a bundle, a net bus,a named via_matrix or a via_matrix collection.

The **-of_objects** and *patterns* arguments are mutually exclusive; you must specify one, but not both. In addition, **-hierarchical** and **-of_objects** can be used together only when **-physical_context** is also used and the *objects* argument to **-of_objects** are nets.

-include_shielded

Specifies to include the shielded nets when **-of_objects** contains shapes. It is only valid when **-of_objects** contains shapes.

This option is mutually exclusive with **-shielded_only**.

-shielded_only

Specifies to get the shielded nets only when **-of_objects** contains shapes. It is only valid when **-of_objects** contains shapes.

This option is mutually exclusive with **-include_shielded**.

patterns

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions based on the **-regexp** option. Patterns can also include collections of type net. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_nets** command creates a collection of nets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any nets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus net inclusively between the begin_index and end_index indexes. Note that the "[]" characters must be escaped, because they are Tcl special characters (e.g., A\[0:15:2\] or {A[0:15:2]}). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth net inclusively between the begin and end indexes, which has a matching name without the delimiters characters (that is, net names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns can be specified, separated with a ',' character.

You can use the **get_nets** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_nets** result to a variable.

When issued from the command prompt, **get_nets** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_nets** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_nets** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the nets that begin with 'NET' in block 'block1'. Although the output looks like a list, it is just a display.

```
prompt> get_nets block1/NET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example queries nets by using bus subscripting.

```
prompt> get_nets {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

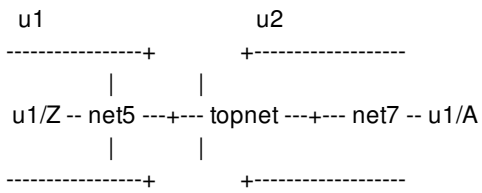
The following example queries nets by using name expansion subscripting.

```
prompt> get_nets B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example queries the nets connected to a collection of pins returned by the **get_pins** command.

```
prompt> current_instance block1
block1
prompt> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
prompt> query_objects [get_nets -of_objects $pinsel]
{"NET1QNX", "NET2QNX"}
```

This example shows how to use the **-top_net_of_hierarchical_group** and **-boundary_type** options. Given the following circuit:



There are hierarchical cells u1 and u2 at this level, connected by a net *topnet*. Within u1 is a pin u1/Z driving *net5*, and within u2 is a pin u1/A being driven by *net7*. These three nets are physically the same net. Assume these are the only nets in the design. Notice the difference in the results of the following two **get_nets** commands:

```
prompt> get_nets * -hierarchical
{topnet u1/net5 u2/net7}
prompt> get_nets * -hierarchical -top_net_of_hierarchical_group
{topnet}
prompt> get_nets -physical_context
{topnet}
prompt> get_nets -physical_context -of_objects [get_nets u2/net7]
{topnet}
```

Assume that at the top level, topnet is connected to pins u2/in and u1/out. Here are some examples of **-boundary_type**. Notice now in this case, the "upper" type does not add value.

```
prompt> get_nets -of_objects u2/in
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type upper
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type lower
{u2/net7}
prompt> get_nets -of_objects u2/in -boundary_type both
{u2/net7 topnet}
prompt> get_nets -boundary_type lower -of_objects \
  [get_pins -of_objects [get_nets topnet]]
{u1/net5 u2/net7}
```

get_num_scan_chains

Returns the number of chains in a given test mode.

SYNTAX

list **get_num_scan_chains**
[-test_mode *mode_name*]

Data Types

mode_name string

ARGUMENTS

-test_mode *mode_name*

Returns the number of chains for the specified test mode. By default, the tool reports on the current test mode. If this option is not specified and there is no current test mode, the command returns an error.

DESCRIPTION

This command returns the number of scan chains for the specified test mode, or the current test mode if a mode is not specified.

EXAMPLES

The following example reports the number of scan chains for some test modes.

```
prompt> get_num_scan_chains -test_mode Internal_scan
8
prompt> get_num_scan_chains -test_mode ScanCompression_mode
32
```

get_object_by_id

Creates a collection of objects from the current design relative to the current instance with the input of object_id(s). You can assign these objects to a variable or pass them into another command.

SYNTAX

collection **get_object_by_id**
object_list

Data Types

object_list list

ARGUMENTS

object_list

Need to pass a list of of object_ids to the command, otherwise the command reports nothing. The object types supported are cell, pin, port, lib_cell and net.

DESCRIPTION

The **get_object_by_id** command creates a collection of objects in the current design, relative to the current instance, that match certain criteria. The object types supported for the object_id attribute list passed to the command are cell/port/pin/lib_cell/net. If the object_id doestn't point to an object, then the object_id will be skipped. If no objects are found with the list of object_ids passed, the command doesn't report anything.

EXAMPLES

The following example tries to get the object collection given object_ids list passed to the command.

```
prompt>get_attribute [get_cells {U_0 r1_reg}] object_id
260628496 260628692
prompt> get_object_by_id {260628496 260628692}
{U_0 r1_reg}
```

SEE ALSO

collections(2)
filter_collection(2)
get_attribute(2)

get_object_name

Gets the name of the objects in a collection.

SYNTAX

string **get_object_name** *collection*

string *collection*

ARGUMENTS

collection

Specifies the collection.

DESCRIPTION

The **get_object_name** command is a convenient way to get the *full_name* attribute from any object or collection of objects.

EXAMPLES

The following example shows how to use **get_object_name**.

```
prompt> get_object_name [get_cells i1]
i1
prompt> get_attribute [get_cells i1] full_name
i1
prompt> get_object_name [get_cells i*]
i1 i2 i3
```

SEE ALSO

collections(2)
get_attribute(2)

get_object_occurrences

Creates a collection of all occurrences of a physical object in the hierarchy of the top design.

SYNTAX

collection **get_object_occurrences**
[-quiet]
[*object*]

Data Types

object list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

object

Specifies name or collection of a single physical object in the top design's context.

DESCRIPTION

This command creates a homogeneous collection of all occurrences of the physical object given a handle to one of the physical object. If there is only one occurrence of the physical object than it returns the same. You can use the **get_object_occurrences** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable. See the **collections** command man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example get all occurrences of the cell in the hierarchy of the top design given a single occurrence of the cell as input.

```
prompt> get_object_occurrences [ get_cells I_ORCA_TOP/I_BLENDER_2/U1664]
{I_ORCA_TOP/I_BLENDER_2/U1664 I_ORCA_TOP/I_BLENDER_5/U1664}
```

SEE ALSO

collections(2)
filter_collection(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_objects_by_location

Creates a homogeneous or heterogeneous collection of physical objects by using a region-based search criteria.

SYNTAX

collection **get_objects_by_location**
[-design *design*]
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-classes *classes*]
[-hierarchical]
[-include_fill_shapes]
[-at *point*]
[-within { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]
[-touching { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]
[-intersect { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]

Data Types

design string
expression string
exact_count int
minimum_count int
classes list
point coordinates
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection

ARGUMENTS

-design *design*

Specifies the top-level design in which to find objects. If this is not specified, the command searches for objects in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on attributes of the physical object. You can determine the attributes by using the **list_attributes** command. If the expression evaluates to **true**, the object is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-expect *exact_count*

Specifies an expected number of objects to return. If the command finds a different number of objects, the command raises a Tcl error and terminates.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and terminates.

-classes *classes*

Specifies the physical objects for which the search is performed. By default, all the supported physical objects are searched. The supported values are:

- "*routing_blockage*"
- "*placement_blockage*"
- "*bound*"
- "*edit_group*"
- "*fill_cell*"
- "*io_guide*"
- "*io_ring*"
- "*pg_region*"
- "*pin_blockage*"
- "*pin_guide*"
- "*routing_guide*"
- "*shape*"
- "*shape_pattern*"
- "*via*"
- "*via_region*"
- "*via_matrix*"
- "*site_row*"

- "*track*"
- "*voltage_area*"
- "*routing_corridor*"
- "*rp_group*"
- "*rp_blockage*"
- "*site_array*"
- "*cell*"
- "*port*"
- "*net*"
- "*terminal*"
- "*lib_pin*"
- "*pin*"
- "*bound_shape*"
- "*voltage_area_shape*"
- "*routing_corridor_shape*"

-hierarchical

Searches for physical objects in the full hierarchy below the top-level design. By default, the search is limited to the top-level design.

-include_fill_shapes

Search for fill shapes in hierarchy below the top-level design. By default, fill shapes search is limited to top-level design.

-at *point*

Searches all physical objects of given classes whose region completely contains the input point. This option is mutually exclusive with the **-within**, **-touching** and **-intersect** options. At least one of **-at**, **-within**, **-touching** or **-intersect** must be specified.

-within { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Searches all physical objects of the given classes whose region is completely contained by the specified regions. All objects which are abut/touching from inside and completely contained also get selected.

When the **design.enable_icc_region_query** application option is set to *true*, only the objects which are completely contained but not abut/touching from inside get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

This option is mutually exclusive with the **-at** and **-touching** options. At least one of **-at**, **-within** , **-touching** or **-intersect** must be

specified.

-touching { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Searches all physical objects of the given classes whose region is completely contained by the specified region. All objects which are touching from inside and completely contained also get selected.

The region may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

This option is mutually exclusive with the **-at** , **-within** and **-intersect** options. At least one of **-at**, **-within** , **-touching** or **-intersect** must be specified.

-intersect { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Searches all physical objects of the given classes whose region intersects the specified region. The certain portion of the region should be completely inside and certain portion outside of the input window to pass this test.

When the **design.enable_icc_region_query** application option is set to *true*, even the objects which are abut/touching from either inside or outside also get selected.

Region specified can be a disjointed rectangle or polygon.

This option is mutually exclusive with the **-at** and **-touching** options. At least one of **-at**, **-within** , **-touching** or **-intersect** must be specified.

DESCRIPTION

This command performs a physical search on specific classes of physical objects and returns a homogeneous/heterogeneous collection of the queried physical objects. A particular invocation of the command queries for the input user object classes. All the objects of the given classes which satisfy the search parameters and other filtering parameters are returned as a homogeneous/heterogeneous collection. The collection of homogeneous/heterogeneous objects is returned with respect to the context of the top-level design or to the design explicitly specified with **-design**. The input point or region is specified with respect to the top-level design coordinate space or the coordinate space of the design specified with **-design**. By default, the command searches for all supported physical objects for a point or region, unless the physical object classes are explicitly provided. In most cases, the command returns a heterogeneous collection. If no object matches the search criteria, it returns an empty string. You can use the **get_objects_by_location** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable. See the **collections** command man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns the cells in the top-level design that completely contain the point {830 70}.

```
prompt> get_objects_by_location -classes {cell} -at {830 70}
{MEM1}
```

get_output_delays

Creates a collection of output delays in the current scenario. You can assign these output delays to a variable or pass them to another command.

SYNTAX

collection **get_output_delays**
-of_objects *objects*
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]

Data Types

mode_list collection
corner_list collection
scenario_list collection
objects collection
expression string
exact_count int
minimum_count int

ARGUMENTS

-of_objects *objects*

Creates a collection of output delays defined on the specified objects. Each object is either a named pin, a pin collection, a named port or port collection.

-modes *mode_list*

Specifies the scenarios from which to retrieve the objects. If this option is given, all scenarios of the specified modes will be used. The **-scenarios** option must not be specified together with the **-modes** option. If both **-modes** and **-corners** are specified, the command uses all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners**.

-corners *corner_list*

Specifies the scenarios from which to retrieve the objects. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified together with the **-corners** option. If both **-modes** and **-corners** are specified, the command uses all scenarios whose mode is specified by **-modes** and whose corner is specified by **-**

corners.

-scenarios ***scenario_list***

Specifies the scenarios from which to retrieve the objects. The **-modes** or **-corners** option must not be specified together with the **-scenarios** option.

-filter ***expression***

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-expect ***exact_count***

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

DESCRIPTION

The **get_output_delays** command creates a collection of output delays matching *patterns* in the current scenario and which pass the filter, if specified. If no objects match the criteria, the empty string is returned.

Output delay data is managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is given, the command applies to all of the specified scenarios.

If the **-modes** option is given, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is given, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets the inDel variable to the collection of output delays defined on ports IN* in the current scenario.

```
prompt> set inDel [get_output_delays -of_objects [get_ports IN*]]
```

SEE ALSO

collections(2)
set_output_delay(2)

get_overlap_blockages

Creates a collection of overlap blockages from the current design.

SYNTAX

collection **get_overlap_blockages**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
of_objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any overlap blockages that match *patterns*, the expression is evaluated based on the overlap blockage's attributes. If the expression evaluates to true, the blockage is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for overlap blockages level-by-level relative to the current instance. This option is useful only with *patterns* and not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the overlap blockages of the specified cells or blocks. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the overlap blockage names in the current design against the specified patterns. You can specify the patterns by using the following formats:

- ***** (asterisk) or **OB_*** indicates all overlap blockages
- **OB_77** indicates one overlap blockage whose object_id is 77

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

DESCRIPTION

This command returns a collection of overlap blockages of the current design that meet the selection criteria. You can use this command to query the overlap blockages inside the database by area, by point, or by region. You can also use this command to query overlap blockages by filtering their attributes.

EXAMPLES

The following example returns the overlap blockages whose area is larger than 1000.

```
prompt> get_overlap_blockages * -filter "area > 1000"
{"OB_4683"}
```

The following example returns all overlap blockages that begin with "OB_".

```
prompt> get_overlap_blockages "OB_*"
{"OB_4683 OB_5389"}
```

The following three commands show how to use **get_attribute** to query the value of the overlap blockage attributes.

```
prompt> get_attribute [get_overlap_blockages OB_4683] overlap_layer_name
overlap

prompt> get_attribute [get_overlap_blockages OB_4683] bbox
{0.000 0.000{ {100.000 100.000}

prompt> get_attribute [get_overlap_blockages OB_4683] area
10000.000000
```

To get a complete report of all the attribute values of an overlap blockage, use the **report_attributes** command, as shown in the following example.

```
prompt> report_attributes -application [get_overlap_blockages OB_0]
Design   Object   Type       Attribute Name     Value
------------------------------------------------------------------------
CORE     OB_0     area       area               3.6864
CORE     OB_0     rect       bbox               {0.0000 0.0000}
  {2.5600 1.4400}
CORE     OB_0     coord_list boundary           {0.0000 0.0000}
  {0.0000 1.4400} {2.5600 1.4400} {2.5600 0.0000}
CORE     OB_0     string     full_name          OB_0
CORE     OB_0     string     name               OB_0
CORE     OB_0     string     object_class       overlap_blockage
CORE     OB_0     string     overlap_layer_name overlap
CORE     OB_0     collection parent_block       std_lib:CORE.design
```

SEE ALSO

report_attributes(2)

get_parasitic_techs

Get the parasitic tech object from a library.

SYNTAX

get_parasitic_techs
[-library *library_object*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

string *expression*
list *objects*

ARGUMENTS

-library

to specify one library object from other get command. If no library is specified, all open libraries will be searched to get parasitic techs.

-filter *expression*

Filters the collection with *expression*. For any parasitic_tech that match *patterns* (or *objects*) the expression is evaluated based on the parasitic_tech's attributes. If the expression evaluates to true, the parasitic tech is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of libraries that contain the specified objects. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches library names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type lib.

DESCRIPTION

The **get_parasitic_techs** command creates a collection of parasitic_techs in the specified library, that match certain criteria. The command returns a collection if any parasitic_techs match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_parasitic_techs** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_parasitic_techs** result to a variable.

When issued from the command prompt, **get_parasitic_techs** will report the itf_technology_name if found a match.

The "implicit query" property of **get_parasitic_techs** provides a fast, simple way to display parasitic_techs in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_parasitic_techs** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example will get a parasitic tech from library r4000.

prompt> **get_parasitic_techs -filter "itf_technology_name == crn40lp_1p06m+alrdl_4x1u_cworst"**

SEE ALSO

filter_collection(2)
read_parasitic_tech(2)

get_path_group

Creates a collection of path groups from the current design. You can assign these path groups to a variable or pass them into another command.

SYNTAX

collection **get_path_groups**
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

design	collection
mode	collection
expression	string
exact_count	int
minimum_count	int
patterns	list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-filter *expression*

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches path group names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_path_groups** command creates a collection of path groups from the current design that match certain criteria. The command returns a collection if any path groups match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Path groups control the optimization cost function and also affect timing reports.

You can use the **get_path_groups** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_path_groups** result to a variable.

When issued from the command prompt, the **get_path_groups** command behaves as though the **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_path_groups** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_path_groups** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following generates a timing report for each path group matching "Z*".

```
prompt> foreach_in_collection grp [get_path_groups Z*] { \
  report_timing -group $grp \
}
```

get_path_groups

Creates a collection of path groups from the current design. You can assign these path groups to a variable or pass them into another command.

SYNTAX

collection **get_path_groups**
[-design *design*]
[-mode *mode*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

design	collection
mode	collection
expression	string
exact_count	int
minimum_count	int
patterns	list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

-filter *expression*

Filters the collection with *expression*. For any objects that match, the expression is evaluated based on the object's attributes. If the expression evaluates to true, the object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches path group names against patterns. Patterns can include the wildcard characters "*" and "?".

DESCRIPTION

The **get_path_groups** command creates a collection of path groups from the current design that match certain criteria. The command returns a collection if any path groups match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Path groups control the optimization cost function and also affect timing reports.

You can use the **get_path_groups** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_path_groups** result to a variable.

When issued from the command prompt, the **get_path_groups** command behaves as though the **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of the **get_path_groups** command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_path_groups** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

get_pg_regions

Creates a collection of PG regions from the current design.

SYNTAX

collection **get_pg_regions**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design string *expression* string *exact_count* integer *minimum_count* integer *objects* collection *patterns* string *region* list *point* list

ARGUMENTS

-design *design*

Specifies the top-level design for finding objects. By default, objects are searched in the current design.

-filter *expression*

Filters the collection with *expression*. For any PG regions that match *patterns*, the expression is evaluated based on the attributes for the PG region. If the expression evaluates to true, the clock is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Enforces exact pattern matching and disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer than the specified number of objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Requires that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *of_objects*

Specifies the edit groups to use to search for PG regions.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches PG region names against patterns. Patterns can include the asterisk wildcard character (*) and the question mark character (?). For more information about using and escaping wildcards, see the **wildcards** man page.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all pg_regions at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-within *region*

Creates a collection that contains all pg_regions that are completely inside the specified region and doesn't include pg_regions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-touching *region*

Creates a collection that contains all pg_regions that are completely inside the specified region and the pg_regions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-intersect *region*

Creates a collection that contains all pg_regions which are abut/touching from inside or outside to the specified region and the pg_regions whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

This command returns a collection of PG regions in the current design that meet the selection criteria. You can use this command to query PG regions by filtering their attributes.

EXAMPLES

The following example returns all PG regions beginning with PGR_.

```
prompt> get_pg_regions "PGR_*"
{"PGR_4683 PGR_5389"}
```

The following example uses the **get_attribute** command to query the value of the PG region attributes.

```
prompt> get_attribute [get_pg_regions PGR_1123] name
PGR_1123

prompt> get_attribute [get_pg_regions PGR_4683] bbox
{0.000 0.000} {100.000 100.000}
```

SEE ALSO

collections(2)
create_pg_region(2)
remove_pg_regions(2)
report_pg_regions(2)

get_pin

Creates a collection of pins from the netlist. You can assign the collection to a variable or pass the collection to another command.

SYNTAX

collection **get_pins**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-leaf]
[-physical_context]
[-design *design_name*]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hsc *separator_character*]
patterns | -of_objects *objects*

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects list

ARGUMENTS

-hierarchical

Searches for pins level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a pin block1/adder/D[0], a hierarchical search finds it using "adder/D[0]". You cannot use **-hierarchical** with the **-of_objects** option.

-filter *expression*

Filters the collection with *expression*. For any pins that match *patterns* or *objects*, the expression is evaluated based on the attributes of the pin. If the expression evaluates to true, the pin is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as true regular expressions rather than as simple wildcard patterns. This option modifies the behavior of the =~ and !~ filter operators to compare with true regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Performs case-insensitive pattern matching.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-leaf

Includes only pins on leaf cells connected to the specified nets. You can use this option only with **-of_objects**. For any nets in the *objects* argument to **-of_objects**, only pins on leaf cells connected to those nets are included in the collection. In addition, hierarchical boundaries are crossed to find pins on leaf cells.

-physical_context

Searches only for physical pins. This option can also be used with **-of_objects**. For any nets in the *objects* argument to **-of_objects**, only pins on physical cells connected to those nets are included in the collection. In addition, hierarchical boundaries are crossed to find pins on physical cells. For any cells in the *objects* argument to **-of_objects**, pins of the cell are returned, if the cell is physical. If **-of_objects**, is not used than physical pins matching the specified *patterns* are returned.

-design *design_name*

Specifies the name of the design in which to find pins.

-expect *exact_count*

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and stops.

-hsc separator_character

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

patterns

Matches pin names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions, based on the **-regexp** option. Patterns can also include collections of type pin. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

-of_objects *objects*

Creates a collection of pins connected to the specified objects. Each object is a named cell, named net, named stub_chain,

named scan_chain, cell collection, net collection, stub_chain collection or scan_chain collection.

The **-of_objects** and *patterns* options are mutually exclusive; you must specify either option, but not both. In addition, you cannot use the **-hierarchical** option with **-of_objects**.

DESCRIPTION

The **get_pins** command creates a collection of pins in the current design, relative to the current instance, that match certain criteria. The command returns a collection of pins that match the specified *patterns* or *objects*, and pass the filter, if specified. If no objects match the criteria, the empty string is returned.

When used with **-of_objects**, **get_pins** searches for pins connected to any cells or nets specified in *objects*. For net objects, there are two variations of pins that are considered. By default, only pins connected to the net at the same hierarchical level are considered. When combined with the **-leaf** option, only pins connected to the net that are on leaf cells are considered. In this case, hierarchical boundaries are crossed to find pins on leaf cells. Note that **-leaf** has no effect on the pins of cells.

If no *patterns* (or *objects*) match any objects, and the current design is not linked, the design automatically links.

When a cell has bus pins, **get_pins** can find them in several ways. For example, if cell u1 has a bus "A" with indexes 2 to 0, and the verilog.bus_naming_style for your design is "%s[%d]", use "u1/A[*]" as the pattern. You can also find the same three pins with "u1/A" as the pattern.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus pin inclusively between the begin and end indices. Note that the "[]" characters must be escaped, because they are TCL special characters (e.g., A\[0:15:2\] or {A[0:15:2]}). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth pin inclusively between the begin and end indices, which has a matching name without the delimiters characters (i.e., pin names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns may be specified, separated with a ',' character.

You can use the **get_pins** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_pins** result to a variable.

When issued from the command prompt, **get_pins** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can increase or decrease the number of results that are displayed by setting the **shell.collection_result_display_limit** application option.

The "implicit query" property of **get_pins** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_pins** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the 'CP' pins of cells that begin with 'o'. Although the output looks like a list, it is just a display.

```
prompt> get_pins o*/CP
{"o_reg1/CP", "o_reg2/CP", "o_reg3/CP", "o_reg4/CP"}
```

The following example queries pins using bus subscripting.

```
prompt> get_pins {U1/A[0:1,3:7:2]}
{"U1/A[0]", "U1/A[1]", "U1/A[3]", "U1/A[5]", "U1/A[7]"}
```

The following example queries pins using name expansion subscripting.

```
prompt> get_pins U1/B(0:4:2)C(1:2,5)
{"U1/B0C1", "U1/B0C2", "U1/B0C5", "U1/B2C1", "U1/B2C2", "U1/B2C5",
 "U1/B4C1", "U1/B4C2", "U1/B4C5"}
```

The following example queries the pins connected to the specified cells.

```
prompt> set csel [get_cells o_reg1]
{"o_reg1"}
prompt> query_objects [get_pins -of_objects $csel]
{"o_reg1/D", "o_reg1/CP", "o_reg1/CD", "o_reg1/Q", "o_reg1/QN"}
```

The following example shows the difference between getting local pins of a net and getting the leaf pins of net. In this example, NET1 is connected to i2/a and reg1/QN. Cell i2 is hierarchical. Within i2, port a is connected to the U1/A and U2/A.

```
prompt> get_pins -of_objects [get_nets NET1]
{"i2/a", "reg1/QN"}
prompt> get_pins -leaf -of_objects [get_nets NET1]
{"i2/U1/A", "i2/U2/A", "reg1/QN"}
```

The following example shows how to create a clock using a collection of pins.

```
prompt> create_clock -period 8 -name CLK [get_pins o_reg*/CP]
1
```

get_pin_blockages

Creates a collection of pin blockages from the current design.

SYNTAX

collection **get_pin_blockages**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
design_name string
exact_count int
minimum_count int
patterns list
objects list
region list
point list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the pin blockage attributes. You can determine the pin blockage attributes by using the **list_attributes** command. If the expression evaluates to **true**, the pin blockage is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for pin blockages level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

patterns

Matches pin blockage names against patterns. Patterns can include the wildcard characters the * (asterisk) and ? (question mark) wildcard characters or regular expressions, depending on the use of the **-regexp** option. For more details about using and escaping wildcards, see the **wildcards** man page.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *of_objects*

Creates a collection containing the pin blockages associated with the specified objects. The objects can be pins, nets, or ports.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all pin_blockages at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all pin_blockages that are completely inside the specified region and doesn't include pin_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all pin_blockages that are completely inside the specified region and the pin_blockages which are abut/touching from inside with the specified region. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all pin_blockages which are abut/touching from inside or outside to the specified region and the pin_blockages whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of pin blockages from the current design that match certain criteria. The command returns a collection handle (identifier) if any pin blockages match the value of the *patterns* option and meet the filter criteria (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_pin_blockages** command at the command prompt or nest it as an argument to another command, such as **report_pin_blockages**. You can also assign the **get_pin_blockages** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns the pin blockages associated with the specified pins.

```
prompt> get_pin_blockages -of_objects [get_pins cellA/pin*]
{VA1}
```

SEE ALSO

add_to_pin_blockage(2)
create_pin_blockage(2)
remove_from_pin_blockage(2)
remove_pin_blockages(2)
report_pin_blockages(2)

get_pin_buses

Creates a collection of pin_buses from the current design relative to the current instance. You can assign these pin_buses to a variable or pass them into another command.

SYNTAX

collection **get_pin_buses**
[-design *design*]
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-filter *expression*]
[-hsc *separator*]
patterns | -of_objects *objects*

Data Types

design collection
exact_count int
minimum_count int
expression string
patterns list
separator string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-hierarchical

Searches for pin_buses level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-filter *expression*

Filters the collection with *expression*. For any pin_buses that match *patterns* (or *objects*) the expression is evaluated based on the pin_bus's attributes. If the expression evaluates to true, the pin_bus is included in the result.

-hsc *separator*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects *objects*

Creates a collection of pin_buses associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a pin or cell_bus. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches pin_bus names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type pin_bus. Supports patterns containing hierarchical separator when **-hierarchical** is specified.*patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_pin_buses** command creates a collection of pin_buses in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any pin_buses match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

A pin_bus represents an array of pins created with the same base name. This is typically accomplished in the source HDL using an

array notation.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_pin_buses** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_pin_buses** result to a variable.

When issued from the command prompt, **get_pin_buses** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_pin_buses** provides a fast, simple way to display pin_buses in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_pin_buses** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the pin_buses that begin with "reg_bus". Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_pin_buses "*reg_bus*"
{"reg_cell_bus/reg_bus_x", "reg_cell_bus/reg_bus_y"}
```

get_pin_constraints

Creates a collection of pin_constraints. You can assign these pin_constraints to a variable or pass them into another command.

SYNTAX

collection **get_pin_constraints**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *objects*

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns list
objects collection

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the search results to those matching the given expression. The filter expression must be a boolean expression based on the pin constraint attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are

mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches pin_constraint names against patterns. This command uses a default pattern of "*" if the user does not specify any arguments. Mutually exclusive with the **-of_objects** argument.

-of_objects *objects*

Specifies a list of objects from which to find associated pin constraints. Supported object types are block, which returns pin constraints owned by the given block, and pin/port/net/cell/bundle, which return the pin constraints that apply to the given objects. Mutually exclusive with the **patterns** argument.

DESCRIPTION

The **get_pin_constraints** command creates a collection of pin_constraints in the current design, that match certain criteria. The command returns a collection if any pin_constraints match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If any *patterns* fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_pin_constraints** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_pin_constraints** result to a variable.

When issued from the command prompt, **get_pin_constraints** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

The "implicit query" property of **get_pin_constraints** provides a fast, simple way to display pin_constraints in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_pin_constraints** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

get_pin_guides

Creates a collection of pin guides from the current design.

SYNTAX

collection **get_pin_guides**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
design_name string
exact_count int
minimum_count int
patterns list
objects list
region list
point list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the pin guide attributes. You can determine the pin guide attributes by using the **list_attributes** command. If the expression evaluates to **true**, the pin guide is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for pin guides level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

patterns

Matches pin guide names against patterns. Patterns can include the wildcard characters the asterisk (*) and question mark (?) wildcard characters or regular expressions, depending on the use of the **-regexp** option. For more details about using and escaping wildcards, see the **wildcards** man page.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *of_objects*

Creates a collection containing the pin guides associated with the specified objects. The objects can be pins, nets, or ports.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all pin_guides at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all pin_guides that are completely inside the specified region and doesn't include pin_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all pin_guides that are completely inside the specified region and the pin_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all pin_guides which are abut/touching from inside or outside to the specified region and the pin_guides whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of pin guides from the current design that match certain criteria. The command returns a collection handle (identifier) if any pin guides match the value of the *patterns* option and pass the filter criteria (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_pin_guides** command at the command prompt or nest it as an argument to another command (such as **report_pin_guides**). You can also assign the **get_pin_guides** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns the pin guides associated with the specified pins.

```
prompt> get_pin_guides -of_objects [get_pins cellA/pin*]
{VA1}
```

SEE ALSO

create_pin_guide(2)
remove_pin_guides(2)
report_pin_guides(2)
add_to_pin_guide(2)
remove_from_pin_guide(2)

get_pins

Creates a collection of pins from the netlist. You can assign the collection to a variable or pass the collection to another command.

SYNTAX

collection **get_pins**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-leaf]
[-physical_context]
[-design *design_name*]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hsc *separator_character*]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
separator_character string
patterns list
objects list
region list
point list

ARGUMENTS

-hierarchical

Searches for pins level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a pin block1/adder/D[0], a hierarchical search

finds it using "adder/D[0]". This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-filter *expression*

Filters the collection with *expression*. For any pins that match *patterns* or *objects*, the expression is evaluated based on the attributes of the pin. If the expression evaluates to true, the pin is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as true regular expressions rather than as simple wildcard patterns. This option modifies the behavior of the =~ and !~ filter operators to compare with true regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Performs case-insensitive pattern matching.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-leaf

Includes only pins on leaf cells connected to the specified nets. You can use this option only with **-of_objects**. For any nets in the *objects* argument to **-of_objects**, only pins on leaf cells connected to those nets are included in the collection. In addition, hierarchical boundaries are crossed to find pins on leaf cells.

-physical_context

Searches only for physical pins. This option can also be used with **-of_objects**. For any nets in the *objects* argument to **-of_objects**, only pins on physical cells connected to those nets are included in the collection. In addition, hierarchical boundaries are crossed to find pins on physical cells. For any cells in the *objects* argument to **-of_objects**, pins of the cell are returned, if the cell is physical. If **-of_objects**, is not used than physical pins matching the specified *patterns* are returned.

-design *design_name*

Specifies the name of the design in which to find pins.

-expect *exact_count*

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and stops.

-hsc separator_character

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

patterns

Matches pin names against patterns. Patterns can include the wildcard characters "*" and "?", or regular expressions, based on the **-regexp** option. Patterns can also include collections of type pin. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects ***objects***

Creates a collection of pins connected to the specified objects. Each object is a named cell, named net, named stub_chain, named scan_chain, cell collection, net collection, stub_chain collection, scan_chain collection, safety register rule, or safety register group

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all pins at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within ***region***

Creates a collection that contains all pins that are completely inside the specified region and doesn't include pins which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching ***region***

Creates a collection that contains all pins that are completely inside the specified region and the pins which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect ***region***

Creates a collection that contains all pins which are abut/touching from inside or outside to the specified region and the pins whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

The **get_pins** command creates a collection of pins in the current design, relative to the current instance, that match certain criteria. The command returns a collection of pins that match the specified *patterns* or *objects*, and pass the filter, if specified. If no objects match the criteria, the empty string is returned.

When used with **-of_objects**, **get_pins** searches for pins connected to any cells or nets specified in *objects*. For net objects, there are two variations of pins that are considered. By default, only pins connected to the net at the same hierarchical level are considered. When combined with the **-leaf** option, only pins connected to the net that are on leaf cells are considered. In this case, hierarchical boundaries are crossed to find pins on leaf cells. Note that **-leaf** has no effect on the pins of cells.

If no *patterns* (or *objects*) match any objects, and the current design is not linked, the design automatically links.

When a cell has bus pins, **get_pins** can find them in several ways. For example, if cell u1 has a bus "A" with indexes 2 to 0, and the **design.bus_delimiters** application option is set to [], use "u1/A[*]" as the pattern. You can also find the same three pins with "u1/A" as the pattern.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus pin inclusively between the begin and end indices. Note that the "[]" characters must be escaped, because they are Tcl special characters (e.g., A\[0:15:2\]). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth pin inclusively between the begin and end indices, which has a matching name without the delimiters characters (i.e., pin names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns can be specified, separated with a ',' character.

You can use the **get_pins** command at the command prompt, or you can nest it as an argument to another command (for example,

query_objects). In addition, you can assign the **get_pins** result to a variable.

When issued from the command prompt, **get_pins** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can increase or decrease the number of results that are displayed by setting the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_pins** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_pins** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the 'CP' pins of cells that begin with 'o'. Although the output looks like a list, it is just a display.

```
prompt> get_pins o*/CP
{"o_reg1/CP", "o_reg2/CP", "o_reg3/CP", "o_reg4/CP"}
```

The following example queries pins using bus subscripting.

```
prompt> get_pins {U1/A[0:1,3:7:2]}
{"U1/A[0]", "U1/A[1]", "U1/A[3]", "U1/A[5]", "U1/A[7]"}
```

The following example queries pins using name expansion subscripting.

```
prompt> get_pins U1/B(0:4:2)C(1:2,5)
{"U1/B0C1", "U1/B0C2", "U1/B0C5", "U1/B2C1", "U1/B2C2", "U1/B2C5",
 "U1/B4C1", "U1/B4C2", "U1/B4C5"}
```

The following example queries the pins connected to the specified cells.

```
prompt> set csel [get_cells o_reg1]
{"o_reg1"}
prompt> query_objects [get_pins -of_objects $csel]
{"o_reg1/D", "o_reg1/CP", "o_reg1/CD", "o_reg1/Q", "o_reg1/QN"}
```

The following example shows the difference between getting local pins of a net and getting the leaf pins of net. In this example, NET1 is connected to i2/a and reg1/QN. Cell i2 is hierarchical. Within i2, port a is connected to the U1/A and U2/A.

```
prompt> get_pins -of_objects [get_nets NET1]
{"i2/a", "reg1/QN"}
prompt> get_pins -leaf -of_objects [get_nets NET1]
{"i2/U1/A", "i2/U2/A", "reg1/QN"}
```

The following example shows how to create a clock using a collection of pins.

```
prompt> create_clock -period 8 -name CLK [get_pins o_reg*/CP]
1
```

get_placement_attractions

Find and return existing placement_attraction objects

SYNTAX

collection **get_placement_attractions**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the placement_attraction attributes. You can determine the placement_attraction attributes by using the **list_attributes** command. If the expression

evaluates to **true**, the placement_attraction is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for placement_attractions level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect**, and **-at**, but not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the placement_attractions of the specified cells, ports, or placement_attraction shapes. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

patterns

Matches the placement_attraction names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-at *point*

Creates a collection that contains all placement_attractions at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all placement_attractions that are completely inside the specified region and doesn't include placement_attractions which are abut/touching from inside with the specified region. The region placement_attractionary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all placement_attractions that are completely inside the specified region and the placement_attractions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all placement_attractions which are abut/touching from inside or outside to the specified region and the placement_attractions whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If

you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of placement_attractions that meet the selection criteria. It returns a collection handle if one or more placement_attractions meet the selection criteria. If no attractions match the selection criteria, it returns an empty string.

You can use the **get_placement_attractions** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of placement_attractions by name pattern matching.

```
prompt> get_placement_attractions attract*
{"attract1", "attract2", "attract3"}
```

The following example creates a collection of placement_attractions with attribute filtering.

```
prompt> get_placement_attractions -filter {effort == medium}
{"attact1"}
```

The following example creates a collection of all placement_attractions.

```
prompt> get_placement_attaractions *
{"attract1", "attract2", "attract3", "attactA"}
```

The following example creates a collection of all placement_attaractions containing the cells "inv*" and port "reset".

```
prompt> get_placement_attaractions -of_objects "inv* reset"}
{"attract1", "attract2"}
```

get_placement_blockages

Creates a collection of placement blockages from the current design.

SYNTAX

collection **get_placement_blockages**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count integer
minimum_count integer
patterns list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with expression. For any placement blockages that match the *patterns* argument, the expression is evaluated based on the attributes of the placement blockages. If the expression evaluates to *true*, the placement blockage is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for placement blockages level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**.

patterns

Specifies the placement blockages. The patterns can be a collection handle of blockages or other formats, similar to the following:

- * (asterisk) indicates all placement blockages
- *xx** indicates any placement blockage whose name begins with *xx*
- PB_77 indicates one placement blockage that does not yet have a name and its object_id is 77
- PB_* indicates any placement blockage that does not yet have a name.

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all placement_blockages at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the

pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all placement_blockages that are completely inside the specified region and doesn't include placement_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all placement_blockages that are completely inside the specified region and the placement_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all placement_blockages which are abut/touching from inside or outside to the specified region and the placement_blockages whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical

hierarchies.

DESCRIPTION

This command creates a collection of placement blockages that meet the selection criteria. It returns a collection of placement blockages if one or more blockages meet the selection criteria. If no blockages match the selection criteria, it returns an empty string. You can use the **get_placement_blockages** command as an argument to another command or assign its result to a variable. Refer to the example below for details.

You can use the **get_placement_blockages** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** man page for information about working with collections.

EXAMPLES

The following examples show some uses of this command to create placement blockages:

```
prompt> get_placement_blockages *
{"PB_1", "PB_2", "PB_3"}

prompt> get_placement_blockages * -filter "area > 1000"
{"PB_3"}
```

SEE ALSO

collections(2)
create_placement_blockage(2)
get_attribute(2)
query_objects(2)

get_placement_ir_drop_target

Get placer IR drop targets

SYNTAX

string **get_placement_ir_drop_target** *voltage_area*

list *voltage_area*

ARGUMENTS

voltage_area

Specifies the voltage area for settings the IR drop targets

DESCRIPTION

This command returns the IR aware placement target voltage drops for the given voltage areas. The result is a list of IR drop targets, each IR drop target itself is a list of three or four items: the voltage area name; "low" or "high" to denote the voltage drop target type, the voltage drop target (in percentage) and optionally the word "-irdrop" if the target number is not a populastion percentage but a voltage drop percentage.

EXAMPLES

The following example shows the use of **get_placement_ir_drop_target** command:

```
prompt> set_placement_ir_drop_target DEFAULT_VA low 1.0 -irdrop
prompt> set_placement_ir_drop_target DEFAULT_VA high 2.0
prompt> get_placement_ir_drop_target DEFAULT_VA
{ { DEFAULT_VA low 1.000000 -irdrop } { DEFAULT_VA high 2.000000 } }
```

get_port

Creates a collection of ports from the current design. You can assign these ports to a variable or pass them into another command.

SYNTAX

collection **get_ports** [-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any ports that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-of_objects ***objects***

Creates a collection of ports connected to or associated with the specified objects. Each object is a named cell, cell collection, named net, net collection, named port bus, port bus collection, named stub_chain, stub_chain collection, named scan_chain or scan_chain collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-physical_context

This option is needed when a cell object is provided as input to **-of_objects** option. The ports of the cells are returned, if the cell is a physical hierarchical cell.

-expect ***exact_count***

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and stops.

patterns

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all ports at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-within ***region***

Creates a collection that contains all ports that are completely inside the specified region and doesn't include ports which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-touching *region*

Creates a collection that contains all ports that are completely inside the specified region and the ports which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-touching** option.

-intersect *region*

Creates a collection that contains all ports which are abut/touching from inside or outside to the specified region and the ports whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

The **get_ports** command creates a collection of ports in the current design that match certain criteria. The command returns a collection if any ports match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus port inclusively between the begin and end indices. Note that the "[]" characters must be escaped, because they are Tcl special characters (e.g., A\[0:15:2\]). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth port inclusively between the begin and end indices, which has a matching name without the delimiters characters (i.e., port names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns may be specified, separated with a ',' character.

You can use the **get_ports** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_ports** result to a variable.

When issued from the command prompt, **get_ports** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the application option **shell.common.collection_result_display_limit**.

The "implicit query" property of **get_ports** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_ports** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page. In addition, refer to the man pages for **all_inputs** and **all_outputs**, which also create collections of ports.

EXAMPLES

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
prompt> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

The following example queries ports using bus subscripting.

```
prompt> get_ports {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

The following example queries ports using name expansion subscripting.

```
prompt> get_ports B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example sets the driving cell for ports beginning with "in" to an FD2.

```
prompt> set_driving_cell -cell FD2 -library my_lib [get_ports in*]
```

The following example reports ports connected to nets matching the pattern "bidir*".

```
prompt> report_port [get_ports -of_objects [get_nets "bidir*"]]
```

get_port_antenna_property

Get antenna attribute values on the specified port.

SYNTAX

antenna_prop_list **get_port_antenna_property**
-port *port*
[-layer *pin_layer*]

antenna_prop_list *collection*

Data Types

port blk port or lib-pin
layer layer object

ARGUMENTS

-port *port*

Specify the port or lib_pin from which the antenna property is to be retrieved.

This option is required.

-layer *search_layer*

Specifies the layer only for which the antenna properties for the port will be returned.

If you do not specify this option, the tool will return all the antenna properties on all the layers. If you specify this option, only those antenna properties on the specified layer will be returned.

DESCRIPTION

This command gets antenna property data from the specified port or lib_pin. It returns the data as a Tcl array of the form:

{[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size gate_data
mode1_area mode1_data mode2_ratio mode2_data mode3_area mode3_data
mode4_area mode4_data mode5_ratio mode5_data mode6_area mode6_data}

In the event no layer is given, the data for all metal layers that have antenna data is returned in the following form (abbreviated here for clarity):

```
{
 {[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size gate_data1 ...}
 {[well_type] [oxide_model <type>] metalLayer metalLayer2 gate_size gate_data1 ...}
 ...
}
```

Note that the returned data is a Tcl array and as such can be easily modified.

RETURN VALUE

antenna_prop_list if successful, empty list otherwise

EXAMPLES

The following examples depict the behavior.

```
prompt> get_port_antenna_property -port p3 -layer metal3
{{metalLayer metal3 gate_size 0.3436 mode1_area 6.664
  mode2_ratio 2.05346 mode3_area 12.708 mode4_area 17.5392
  mode5_ratio 7.04044 mode6_area 12.682} {well1 metalLayer metal3
  gate_size 0.8436 mode1_area 7.164 mode2_ratio 2.55346 mode3_area
  13.208 mode4_area 18.0392 mode5_ratio 7.54044 mode6_area 13.182}}

prompt> get_port_antenna_property -port p3 -layer metal3
{}
```

get_port_buses

Creates a collection of port buses from the current design. You can assign these port buses to a variable or pass them into another command.

SYNTAX

collection **get_port_buses**
[-design *design*]
[-physical_context]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *objects*

Data Types

design string or collection
expression string
exact_count integer
minimum_count integer
patterns list
objects string or collection

ARGUMENTS

-design *design_name*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

-physical_context

This option is needed when a cell object is provided as input to the **-of_objects** option. The port buses of the cells are returned, if the cell is a physical hierarchical cell.

-filter *expression*

Filters the collection with *expression*. For any port buses that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Specifies that the *patterns* argument is a real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *objects*

Creates a collection of port buses connected to the specified objects. Each object is a named cell, cell collection, named port, port collection, named block or block collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_port_buses** command creates a collection of port buses in the current design that match the specified criteria. The command returns a collection if any port buses match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the **regexp** Tcl command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_port_buses** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_port_buses** result to a variable.

When issued from the command prompt, **get_port_buses** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_port_buses** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_port_buses** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page. In addition, refer to the man pages for **all_inputs** and **all_outputs**, which also create collections of port buses.

EXAMPLES

The following example queries all input port buses beginning with 'bus'. Although the output looks like a list, it is just a display.

```
prompt> get_port_buses "bus*"
{"bus1", "bus2"}
```

get_ports

Creates a collection of ports from the current design. You can assign these ports to a variable or pass them into another command.

SYNTAX

collection **get_ports** [-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

expression string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any ports that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-of_objects ***objects***

Creates a collection of ports connected to or associated with the specified objects. Each object is a named cell, cell collection, named net, net collection, named port bus, port bus collection, named stub_chain, stub_chain collection, named scan_chain or scan_chain collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-physical_context

This option is needed when a cell object is provided as input to **-of_objects** option. The ports of the cells are returned, if the cell is a physical hierarchical cell.

-expect ***exact_count***

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

-expect_each_pattern_matches

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and stops.

patterns

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all ports at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-within ***region***

Creates a collection that contains all ports that are completely inside the specified region and doesn't include ports which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-touching ***region***

Creates a collection that contains all ports that are completely inside the specified region and the ports which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-touching** option.

-intersect ***region***

Creates a collection that contains all ports which are abut/touching from inside or outside to the specified region and the ports whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

The **get_ports** command creates a collection of ports in the current design that match certain criteria. The command returns a collection if any ports match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching. Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus port inclusively between the begin and end indices. Note that the "[]" characters must be escaped, because they are Tcl special characters (e.g., A\[0:15:2\]). Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth port inclusively between the begin and end indices, which has a matching name without the delimiters characters (i.e., port names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1. Multiple "begin_index:end_index:step_n" patterns may be specified, separated with a ',' character.

You can use the **get_ports** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_ports** result to a variable.

When issued from the command prompt, **get_ports** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the application option **shell.common.collection_result_display_limit**.

The "implicit query" property of **get_ports** provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_ports** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page. In addition, refer to the man pages for **all_inputs** and **all_outputs**, which also create collections of ports.

EXAMPLES

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
prompt> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

The following example queries ports using bus subscripting.

```
prompt> get_ports {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

The following example queries ports using name expansion subscripting.

```
prompt> get_ports B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example sets the driving cell for ports beginning with "in" to an FD2.

```
prompt> set_driving_cell -cell FD2 -library my_lib [get_ports in*]
```

The following example reports ports connected to nets matching the pattern "bidir*".

```
prompt> report_port [get_ports -of_objects [get_nets "bidir*"]]
```

get_power_budget

Returns the power budget for either the current design or a list of cells in the current design.

SYNTAX

status **get_power_budget**
[-scenarios *scenario_list*]
[-cell *cell_list*]

Data Types

scenario_list list
cell_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the budget values are returned. If no scenario is specified the current_scenario is used.

-cell *cell_list*

Specifies a list of cells on which the power budget values are reported.

DESCRIPTION

This command is used to return the budget values either on the design or on specific cells in the design. If this command is called without any option, the power budget value for the current design is returned.

If the command is called with the -cell option, then budget values will only be reported for the instances specified in the cell list.

Returns the requested numbers as a tagged list.

Multicorner-Multimode Support

EXAMPLES

In the following example, power budget value has been set globally on the design.

```
prompt> set_power_budget 5.92e+05
prompt> get_power_budget

{{Scenario SC1} {Design Top} {Power_Budget 5.92e+05}}
```

In the following example power budget has been set globally on the design, as well as on the hierarchical cell H1/H2.

```
prompt> set_power_budget 3.9e+05
prompt> set_power_budget -cell [get_cell H1/H2] 2.3e+03
prompt> get_power_budget [get_cells H1/H2]

{{Scenario SC1} {Cell H1/H2} {Power_Budget 2.3e+03}}
```

SEE ALSO

get_power_budget(2)
reset_power_budget(2)
report_power_budget(2)
report_power(2)

get_power_clock_scaling

Returns the clock frequency scaling values stored.

SYNTAX

status **get_power_clock_scaling**
[-scenarios *scenarios*]
[clock_list]

Data Types

scenarios list
clock_list list

ARGUMENTS

-scenarios *scenarios*

Specify a list of scenarios for which the scaling factor is to be retrieved, if found. If not specified, then scaling data is filtered for only the clock objs specified through clock_list option. If both scenarios and clocks are not specified then complete scaling data is printed. If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this option can take atmost one value. If the app option is set to true, and if this option is not used, the current scenario is assumed.

clock_list

Specify a list of clocks in the design for which the scaling factor is to be retrieved, if found. If not specified, then scaling data is filtered for only the scenarios specified through -scenarios option. If both scenarios and clocks are not specified then complete scaling data is printed. If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this option can take atmost one value. If the app option is set to true, and if this option is not used, the non-clock specific ratio value will be returned for the scenario.

DESCRIPTION

Clock frequency used in Switching Activity Interchange Format (SAIF) files, from logic simulation for functional verification can differ from the clock frequency used in Synopsys Design Constraints (SDC) file for timing and power analysis. This command retrieves the scaling factors stored in the set_power_clock_scaling command.

The clock_objects option in this command is a list of clocks in the design that have the specified period or ratio values used in simulation for SAIF generation. The scenarios are the ones for which the scaling factors are to be retrieved and displayed. Note that if both the scenario and the clock options are not specifed then the complete scaling data for all the scenarios is displayed.

When period value is specified for a clock, then the scaling ratio is calculated as the ratio of (period of the clock from set_power_clock_scaling cmd) / (period of the fastest clock of an object).This ratio is applied to the retrieved simulated activity of the object. If the ratio value is specified then it is directly applied as the scaling ratio.This ratio is applied to the retrieved simulated activity of the object.

If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this command will return only a tuple containing the scaling value. The value returned will be clock specific value if clock is specified and will be global ratio value if clock is not specified. If the scenario option is not specified & the app option is true, the current scenario is assumed for fetching the tuple.

EXAMPLES

The following examples describe the behaviour of the cmd.

```
prompt> set_power_clock_scaling {CLK CLK2 C_A} -period 2.6
prompt> set_power_clock_scaling -ratio 1
prompt> get_power_clock_scaling
------------------------------------------------------------
      Clock Scaling Data
------------------------------------------------------------
Scenario:default, Clock name:CLK, Period:2.600000
Scenario:default, Clock name:CLK2, Period:2.600000
Scenario:default, Clock name:C_A, Period:2.600000
------------------------------------------------------------
Scaling Ratios for Scenarios without Clocks
------------------------------------------------------------
Scenario:default, Ratio:1.000000
```

SEE ALSO

set_power_clock_scaling(2)
report_power_clock_scaling(2)
power.get_power_clock_scaling_single_objects_only(3)

get_power_derate

Returns the power derating factors for either the current design, a list of cells, library cells or all cells in a power group in the current design.

SYNTAX

status **get_power_derate**
[-scenarios *scenario_list*]
[-leakage]
[-switching]
[-internal]
[-user]
[*object_list*]

Data Types

scenario_list list
object_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

-leakage

Returns the leakage specific derating values only.

-switching

Returns the switching specific derating values only.

-internal

Returns the internal specific derating values only.

-user

Returns the actually stored power derating attributes if and only if they exist.

object_list

Specifies current a list of cells or library cells on which the power derating factors are reported.

DESCRIPTION

This command is used to return the derate factors either on the design, specific cells or library cells contained in the design. If this command is called without any option the current design power derating factors are returned.

If this command is called with option -user it will return the actually stored attributes if and only if they exist. Without -user, the command will return the used (inherited) derating factors. If the command is called with the object_list specified then derating factors will only be issued for the instances specified in the object list.

Returns requested numbers as a tagged list. If none of -leakage, -internal or -switching is specified it returns all three.

Multicorner-Multimode Support

EXAMPLES

In the following example, power derating factors have been set globally on the design.

```
prompt> set_power_derate -switching 0.92
prompt> set_power_derate -internal 1.15
prompt> set_power_derate -leakage 0.75
prompt> get_power_derate

{ {scenario default} {object Top} {leakage 0.75} {switching 0.92 } {internal 1.15 } }
```

In the following example power derating factors have been set globally on the design. More restrictive derates have been set on the hierarchical cell H1.

```
prompt> set_power_derate 0.95
prompt> set_power_derate -switching 1.06
prompt> set_power_derate -internal -leakage 0.82 [get_cell H1]
prompt> get_power_derate [get_cells H1/U1]

{ {scenario default} {object H1/U1} {leakage 0.82 } {switching 1.06} {internal 0.82 } }
```

In the following example only the power derating factors set specifically by the user are returned for the hierarchical cell H1.

```
prompt> get_power_derate -user [get_cells H1/U1]

{ {scenario default} {object H1/U1} {leakage 0.82 } {internal 0.82 } }
```

SEE ALSO

get_power_derate(2)
reset_power_derate(2)
report_power_derate(2)

get_power_domains

Creates a collection of power domains that meet the specified criteria.

SYNTAX

collection **get_power_domains**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-hierarchical

Searches for power domains in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for power domains only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical power domain names relative to the current scope.

You cannot specify this option when you use the **-of_objects** option.

-filter *expression*

Filters the collection with *expression*. For any power domains that match *patterns*, the expression is evaluated based on the power domain's attributes. If the expression evaluates to true, the power domain is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Returns a collection of power domains associated with the specified objects. The objects can be cells, power strategies, voltage areas, or voltage area shapes.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

patterns

Matches power domain names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the **wildcards** man page.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses "*".

DESCRIPTION

The **get_power_domains** command creates a collection of power domains in the current design that match certain criteria. If no power domains match the criteria, an empty string is returned.

Until the **commit_upf** command is executed and power intent is finalized, power domains of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using **-regexp**, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_power_domains** command at the command prompt, or you can nest it as an argument to another command, such as **report_power_domains**. In addition, you can assign the **get_power_domains** result to a variable.

When issued from the command prompt, **get_power_domains** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example creates power domains, then queries them.

```
prompt> create_power_domain TOP_DOMAIN
1
prompt> create_power_domain SUB_DOMAIN -elements [get_cells mid1]
1
prompt> get_power_domains
{TOP_DOMAIN SUB_DOMAIN}
prompt> get_power_domains TOP*
{TOP_DOMAIN}
```

The following example gets all power domains under the current scope.

```
prompt> get_power_domains -hierarchical
{PD1 SUB_INST/PD2}
```

SEE ALSO

create_power_domain(2)
report_power_domains(2)

get_power_group

Returns list of all power groups the specified cell or libcell is in.

SYNTAX

status **get_power_group**
object
[-user]
[-default]

Data Types

object object

ARGUMENTS

-user

Returns user specified power groups for the specified *object* if exist, else an error message is reported stating no user specified power group found on that object.

-default

Returns default power group for the specified *object*.

object

Specifies cell or libcell for which power group needs to be reported.

DESCRIPTION

This command returns list of all power groups on the specified object. If '-user' is specified then user specified power groups are reported. If '-default' is specified then default power group is reported. If neither '-user' nor '-default' is specified then return value depends on the app option 'power.report_user_power_groups'. If the app option is set as 'exclusive' then command returns Actual power group. Actual power group is the user specified power group present for that cell. If multiple user power groups are specified then first power group in the specified list is Actual power group. If user specified power group is not present for that cell then actual power group is the user specified power group present for the libcell of that cell. If multiple user power groups are present for the libcell then first power group in the specified list is Actual power group. If user specified power group is not present for that libcell then actual power group is the default power group of that cell. If app option value is 'inclusive' then list of all user specified power groups and default power group of that cell is returned. If cell has no user power groups specified then the corresponding libcell is checked for user specified power groups. It is to be noted that '-user' and '-default' options can not be specified together.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example returns default power group of a cell.

prompt> **get_power_group u3/S_reg_0 -default**

SEE ALSO

set_power_group(2)
reset_power_group(2)
report_power_groups(2)
get_power_group_objects(2)
report_power(2)
power.report_user_power_groups(3)

get_power_group_objects

Returns a collection of cells for the specified power groups.

SYNTAX

status **get_power_group_objects**
group_names

Data Types

group_names list

ARGUMENTS

group_names

Specifies the power groups for which the collection of cells will be returned.

DESCRIPTION

The get_power_group_objects command returns a collection of cells contained by the specified power groups. The return value depends on app option 'power.report_user_power_groups'. The collection will have no duplicate objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example returns collection of cells present in power group macro1 and register.

prompt> **get_power_group_objects {macro1 register}**

SEE ALSO

set_power_group(2)
reset_power_group(2)
get_power_group(2)
report_power_groups(2)
report_power(2)
power.report_user_power_groups(3)

get_power_strategies

Creates a collection of power strategies.

SYNTAX

collection **get_power_strategies**
[-domain *power_domain*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[*patterns*]

Data Types

power_domain string
expression string
exact_count integer
minimum_count integer
patterns list

ARGUMENTS

-domain *power_domain*

Specifies the name of the power domain in which to collect this UPF power strategy.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the power strategies attributes. You can determine the power strategies attributes by using the **list_attributes** command. If the expression evaluates to **true**, the power strategy is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~

and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *objects*

Returns a collection of power strategies associated with the specified objects. The objects can be cells or power domains.

patterns

Matches the power strategy names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument is not specified, the command uses asterisk (*) as the *pattern*.

DESCRIPTION

This command creates a collection of power strategies that match certain criteria. The command returns a collection handle (identifier) if any power strategies match the value of the *patterns* option and pass the filter criteria (if specified). If no objects match the criteria, the command returns an empty string.

Until the **commit_upf** command is executed and power intent is finalized, strategies of subblocks are not propagated and are not included in the result.

You can use the **get_power_strategies** command at the command prompt or nest it as an argument to another command (such as **get_cells**, **set_power_strategy**). You can also assign the **get_power_strategies** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns isolation strategies defined in specified power domain.

```
prompt> get_power_strategies -domain TOP -filter {type==ISO}
{iso_stra1 iso_stra2}
```

SEE ALSO

create_power_switch(2)
set_isolation(2)
set_level_shifter(2)
set_power_strategy_attribute(2)
set_retention(2)

get_power_switch_patterns

Creates a collection of power switch patterns that meet the specified criteria.

SYNTAX

collection **get_power_switch_patterns**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any power switch patterns that match *patterns*, the expression is evaluated based on the attributes of the power switch pattern. If the expression evaluates to true, the power switch pattern is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches power switch pattern names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the **wildcards** man page.

DESCRIPTION

The **get_power_switch_patterns** command creates a collection of power switch patterns in the current design, that match certain criteria. If no power switch pattern match the criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl regexp command. When using **-regexp**, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_power_switch_patterns** command at the command prompt, or you can nest it as an argument to another command, such as **report_power_switch_patterns**. In addition, you can assign the **get_power_switch_patterns** result to a variable.

When issued from the command prompt, **get_power_switch_patterns** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example gets all power switch patterns in the current design.

```
prompt> get_power_switch_patterns
{PSW_PATTERN_INST_pattern2_0 PSW_PATTERN_INST_pattern2_1 PSW_PATTERN_INST_pattern2_2}
```

The following example gets all power switch patterns matching a given pattern.

```
prompt> get_power_switch_patterns *pattern2_7*
{PSW_PATTERN_INST_pattern2_7 PSW_PATTERN_INST_pattern2_70 PSW_PATTERN_INST_pattern2_71}
```

SEE ALSO

report_power_switch_patterns(2)

get_pr_rules

Returns a collection of cell row spacing rules (pr_rules) from the specified technology object.

SYNTAX

collection **get_pr_rules**
[-tech *tech_object*]
[-library *library*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *of_objects*]
[*patterns*]

Data Types

tech_object collection
library collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-tech *tech_object*

Specifies the technology object in which to search for the cell row spacing rules.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is searched in the technology object of the current library.

-library *library*

Specifies the library in which to search for the cell row spacing rules. The command searches for the rules in the technology object associated with the specified library. In an implementation tool, the library is a design library. In the library manager, the library is a cell library. You can specify the library using the library's name or a collection that contains the library.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is

searched in the technology object of the current library.

-filter *expression*

Filters the collection with *expression*. For any rules that match the *patterns* or *objects* option, the expression is evaluated based on the attributes of the rule. If the expression evaluates to true, the rule is included in the result.

-quiet

Suppresses warning and error messages if no object matches. Syntax error messages are not suppressed.

-regexp

Considers the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The **-regexp** and **-exact** options are mutually exclusive; you can specify only one.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-regexp** and **-exact** options are mutually exclusive; you can specify only one.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, it raises a Tcl error and stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, it raises a Tcl error and stops.

-expect_each_pattern_matches

Requires each pattern in the *patterns* argument to match at least one object. If one or more patterns do not match, the command raises a Tcl error and stops.

-of_objects *of_objects*

Creates a collection that contains the cell row spacing rules of the specified technology objects. Each object in the list is a name, pattern, or collection.

The **-of_objects** option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

patterns

Matches the rule names against the *patterns* argument. The *patterns* argument can include the "*" wildcard character.

The **-of_objects** option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

DESCRIPTION

The **get_pr_rules** command creates a collection of cell row spacing rules from the specified technology object that match certain

criteria. The rules include both the rules specified in the PRRule section of the technology file and the rules created with the **create_pr_rule** command.

The command returns a collection of rules if at least one cell row spacing rule matches the criteria; otherwise, it returns an empty string.

You can use the **get_pr_rules** command at the command prompt or nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_pr_rules** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the cell row spacing rules in the technology object of the current library.

```
prompt> get_pr_rules
{PR_RULE_0}
```

SEE ALSO

create_pr_rule(2)
remove_pr_rules(2)
report_pr_rules(2)

get_purposes

Creates a collection of one or more purposes.

SYNTAX

collection **get_purposes**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*. For any purposes that match, the expression is evaluated based on the layer's attributes. If the expression evaluates to true, the layer is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect ***exact_count***

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least ***minimum_count***

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects ***of_objects***

Creates a collection containing the purposes of the specified libs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches layer names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark) or regular expressions, depending on whether or not you also use the **-regexp** option.

DESCRIPTION

This command creates a collection of purposes defined in the technology file for the current library.

You can use the **get_purposes** command at the command prompt or as an argument nested in another command (for example, in the **query_objects** command). You can also assign its result to a variable.

The layer name printed for returned collection will have following format.

layer_name:purpose_name

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a layer for the name M1R.

```
prompt> get_purposes M1R
{drawing}
```

SEE ALSO

collections(2)
filter_collection(2)
query_objects(2)
create_purpose(2)
shell.common.collection_result_display_limit(3)

get_related_supply_nets

Creates a collection of related supply nets of signal pins or ports.

SYNTAX

collection **get_related_supply_nets**
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expand]
[-ground]
[-in_block_upf]
objects

Data Types

expression string
exact_count int
minimum_count int
objects list

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For each related supply net, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expand

Do not merge and combine duplicated related supply nets of signal pins.

-ground

Specifies that the ground supply net should be returned.

-in_block_upf

This is for boundary ports of linked blocks only. Return the related supply net in block UPF. The return value shows the related supply net for this block boundary port when the linked block is opened as current block.

objects

Returns a collection of related supply nets associated with the signal pins or ports.

DESCRIPTION

The **get_related_supply_nets** command creates a collection of related supply nets of the specified collection of pins or ports. Power supply net is returned by default. If the -ground option is specified, ground supply net is returned.

Until commit_upf command is executed and power intent is finalized, power intent of subblocks are not propagated and will not be included in the result.

EXAMPLES

The following example gets the related supply nets of all pins of a level-shifter cell.

```
prompt> get_related_supply_nets [get_pins Multiplier/mult_on_UPF_LS/*]
{VDDL}
```

SEE ALSO

create_supply_net(2)
connect_supply_net(2)
set_related_supply_net(2)

get_repeater_group_info

Get detailed information for input repeater group.

SYNTAX

status **get_repeater_group_info**
-group_id *group_id*
-type cutline | driver_group_id

Data Types

group_id integer

ARGUMENTS

-group_id *group_id*

Specifies the group id set by set_repeater_group.

-type

Specifies the type to query, cutline or driver_group_id.

DESCRIPTION

This command gets detailed information for input repeater group.

EXAMPLES

The following examples show the usages of command.

prompt> **get_repeater_group_info -group_id 4 -type driver_group_id**
prompt> **get_repeater_group_info -group_id 4 -type cutline**

SEE ALSO

set_repeater_group(2)
report_repeater_groups(2)

get_routes_between_objects

Returns net shapes that connect two ports or pins on the same net.

SYNTAX

status **get_routes_between_objects**
[-quiet]
[*object_list*]

Data Types

object_list collection or selection

ARGUMENTS

object_list

Specifies a collection or selection set that contains objects to get routes between. If this option is not specified, global selection set is used.

-quiet

Suppresses all output messages.

DESCRIPTION

This command returns a collection of net shapes that connect two ports or pins on the same net.

If the selection contains two objects of port or leaf pin on the same net, and the two objects are physically connected by routes of the net, this command returns a collection of net shapes that connect these two objects. Otherwise the command returns an empty collection.

EXAMPLES

The following example selects routes that connect the two leaf pins A0_12__reg/Q and RES_I109/ADD_6/A1.

prompt> **change_selection [get_pins {A0_12__reg/Q RES_I109/ADD_6/A1}]**
prompt> **change_selection [get_routes_between_objects]**

The alternative syntax uses collection to specify objects.

prompt> **change_selection [get_routes_between_objects [get_pins {A0_12__reg/Q RES_I109/ADD_6/A1}]]**

SEE ALSO

change_selection(2)

gui_select_connections_of_selected(2)

get_routing_blockages

Creates a collection of routing blockages from the current design.

SYNTAX

collection **get_routing_blockages**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_lib_cell]

[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any routing blockages that match *patterns*, the expression is evaluated based on the routing blockage's attributes. If the expression evaluates to true, the routing_blockage is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for routing blockages level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-include_lib_cell

Search for routing blockages in the **lib_cell**. By default, **lib_cell** routing_blockages are excluded from search.

This option must be used with **-hierarchical** option.

-of_objects *of_objects*

Creates a collection containing the routing blockages of the specified edit groups or cells. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together.

patterns

Matches the routing blockage names in the current design against the specified patterns. You can specify the patterns by using the following formats:

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses *

(asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all routing_blockages at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all routing_blockages that are completely inside the specified region and doesn't include routing_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all routing_blockages that are completely inside the specified region and the routing_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all routing_blockages which are abut/touching from inside or outside to the specified region and the routing_blockages whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command returns a collection of routing blockages of the current design that meet the selection criteria. You can also use this command to query routing blockages by filtering their attributes.

EXAMPLES

The following example returns the routing blockages whose area is larger than 1000.

```
prompt> get_routing_blockages * -filter "area > 1000"
{"RB_4683"}
```

The following example returns all routing blockages.

```
prompt> get_routing_blockages "RB_*"
{"RB_4683 RB_5389"}
```

The following example shows how to use **get_attribute** to query the value of the routing blockage attributes.

```
prompt> get_attribute [get_routing_blockages  RB_4683] layer
via3Blockage

prompt> get_attribute [get_routing_blockages RB_4683] bbox
{0.000 0.000{ {100.000 100.000}

prompt> get_attribute [get_routing_blockages RB_4683] area
10000.000000
```

To get a complete report of the attribute values of all routing blockages, use the **report_attributes** command, as shown in the following example.

```
prompt> report_attributes -application [get_routing_blockages RB_4683]
Design  Object   Type   Attribute Name   Value
------------------------------------------------------------------------
CORE    RB_4683  float    area         10000.000000
CORE    RB_4683  string   bbox         {0.000 0.000} {100.000 100.000}
CORE    RB_4683  string   full_name    CORE/RB_4683
CORE    RB_4683  string   layer        via3Blockage
CORE    RB_4683  string   name         RB_4683
CORE    RB_4683  string   object_class  route_guide
```

get_routing_corridor_shapes

Creates a collection of routing corridor shapes from the current design.

SYNTAX

collection **get_routing_corridor_shapes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns list
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design in which to find objects. If this option is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing corridor shape attributes. You can determine the routing corridor shape attributes by using the **list_attributes** command. If the expression

evaluates to **true**, the routing corridor shape is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

Checks whether each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and command processing will stop.

-hierarchical

Searches for routing corridor shapes level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *objects*

Creates a collection containing the routing corridor shapes of the specified routing corridors. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the routing corridor shape names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

IP "-at *point*" Creates a collection that contains all routing_corridor_shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all routing_corridor_shapes that are completely inside the specified region and doesn't include routing_corridor_shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all routing_corridor_shapes that are completely inside the specified region and the routing_corridor_shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all routing_corridor_shapes which are abut/touching from inside or outside to the specified region and the routing_corridor_shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of routing corridor shapes in the current design that match the specified criteria.

The command returns a collection if any routing corridor shapes match the specified criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples return the routing corridor shapes that match the specified patterns.

```
prompt> get_routing_corridor_shapes CORRIDOR_SHAPE_528896
{ CORRIDOR_SHAPE_528896 }

prompt> get_routing_corridors "CORRIDOR_SHAPE_*"
{ CORRIDOR_SHAPE_6 CORRIDOR_SHAPE_7 CORRIDOR_SHAPE_8
  CORRIDOR_SHAPE_9 }
```

The following example returns the routing corridor shapes that are associated with the corridor_a routing corridor.

```
prompt> get_routing_corridor_shapes \
   -of_objects [get_routing_corridor corridor_a]
{ CORRIDOR_SHAPE_528896 CORRIDOR_SHAPE_528897 CORRIDOR_SHAPE_528898
  CORRIDOR_SHAPE_528899 CORRIDOR_SHAPE_528900 CORRIDOR_SHAPE_528901
  CORRIDOR_SHAPE_528902 CORRIDOR_SHAPE_528903 CORRIDOR_SHAPE_528904
  CORRIDOR_SHAPE_528905 }
```

get_routing_corridors

Creates a collection of routing corridors from the current design.

SYNTAX

collection **get_routing_corridors**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns list
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design in which to find objects. If this option is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing corridor attributes. You can determine the routing corridor attributes by using the **list_attributes** command. If the expression evaluates to **true**, the

routing corridor is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

Checks whether each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and command processing will stop.

-hierarchical

Searches for routing corridor shapes level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *objects*

Creates a collection containing the routing corridors of the specified routing corridor shapes, nets and supernets. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the routing corridor names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all routing_corridors at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all routing_corridor_shapes which are abut/touching from inside or outside to the specified region and the routing_corridor_shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all routing_corridors that are completely inside the specified region and the routing_corridors which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all routing_corridors which are abut/touching from inside or outside to the specified region and the routing_corridors whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses *

(asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of routing corridors in the current design that match the specified criteria.

The command returns a collection if any routing corridors match the specified criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples return the routing corridors that match the specified patterns.

```
prompt> get_routing_corridors corridor_a
{ corridor_a }

prompt> get_routing_corridors "*"
{ corridor_a corridor_b }
```

The following example returns the routing corridors that are associated with the nets named N1, N2, and N3.

```
prompt> get_routing_corridors -of_objects [get_nets "N1 N2 N3"]
{ corridor_a }
```

get_routing_guides

Creates a collection of routing guides from the current design.

SYNTAX

collection **get_routing_guides**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design string
expression string
exact_count integer
minimum_count integer
patterns list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing guide attributes. You can determine the routing guide attributes by using the **list_attributes** command. If the expression evaluates to **true**, the routing guide is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. The option can be used when searching for objects that contain * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for routing guides level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**.

patterns

Matches routing guide names against patterns. Patterns can include the wildcard characters "*" and "?".

The *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all routing_guides at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*,**-within**,**-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all routing_guides that are completely inside the specified region and doesn't include routing_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,**-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all routing_guides that are completely inside the specified region and the routing_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,**-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all routing_guides which are abut/touching from inside or outside to the specified region and the routing_guides whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,**-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of routing guides that meet the selection criteria. It returns a collection of routing guides if one or more routing guides meet the selection criteria. If no routing guides match the selection criteria, it returns an empty string.

You can use the **get_routing_guides** command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the **collections** man page for information about working with collections.

EXAMPLES

The following example returns all routing guides:

```
prompt> get_routing_guides *
{RG_0 RG_1 RG_2}
```

The following example uses the **-hierarchical** option to return routing guides within child physical blocks.

```
prompt> get_routing_guides -hierarchical
{RG_0 RG_1 RG_2 mid/RG_0 mid/RG_1 mid/bot/RG_0}
```

The following example returns routing guides with an area greater than 1000.

```
prompt>get_routing_guides * -filter "area > 1000"
{RG_2}
```

SEE ALSO

collections(2)
create_routing_guide(2)
remove_routing_guides(2)

get_routing_rules

Returns a collection of routing rules from the current design.

SYNTAX

collection **get_routing_rules**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any routing rule that match the patterns option, the expression is evaluated based on the routing rule's attributes. If the expression evaluates to *true*, the routing rule is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are

mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the routing rules of the specified nets. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches routing rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_routing_rules** command creates a collection of routing rules from the current design that match certain criteria. The command returns a collection of routing rules if any routing rule matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_routing_rules** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_routing_rules** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the routing rules in the current design.

```
prompt> get_routing_rules
{ndr1 test3}
```

The following example returns a collection of all the routing rules corresponding to a net.

```
prompt> get_routing_rules -of_objects Reset
{ndr3}
```

SEE ALSO

create_routing_rule(2)
collections(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_rp_blockages

Creates a collection by selecting relative placement blockages from the current design.

SYNTAX

collection **get_rp_blockages**
[*patterns* | -of_objects *of_objects*]
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list or collection
patterns list

ARGUMENTS

patterns

Matches the relative placement blockage names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

-of_objects *of_objects*

Creates a collection containing the relative placement blockages of the specified relative placement groups. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the relative placement blockage attributes. You can determine the relative placement blockage attributes by using the **list_attributes** command. If the expression evaluates to **true**, the relative placement blockage is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for relative placement blockages level-by-level relative to the current design. This option is useful only with *patterns* and not with **-of_objects**.

DESCRIPTION

This command creates a collection of relative placement blockages by selecting relative placement blockages that meet the selection criteria. It returns a collection handle if one or more relative placement blockages meet the selection criteria. If no relative placement blockages match the selection criteria, it returns an empty string.

You can use the **get_rp_blockages** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of relative placement blockages by name pattern matching.

```
prompt> get_rp_blockages rp_blockage*
{rp_blockage1 rp_blockage2 rp_blockage3}
```

The following example creates a collection of relative placement blockages with attribute filtering.

```
prompt> get_rp_blockages -filter {height == 2}
{rp_blockage1}
```

The following example creates a collection of all relative placement blockages.

```
prompt> get_rp_blockages *
{rp_blockage1 rp_blockage2 rp_blockage3 rp_blkg4}
```

The following example creates a collection of parent relative placement blockages of relative placement group rp_group1.

```
prompt> get_rp_blockages -of_objects rp_group1}
{rp_blockage1}
```

SEE ALSO

create_rp_group(2)
add_to_rp_group(2)
remove_from_rp_group(2)
remove_rp_groups(2)

filter_collection(2)
query_objects(2)
regexp(2)
shell.common.collection_result_display_limit(3)

get_rp_group_objects

Creates a collection by selecting cells or relative placement groups or blockages of given relative placement groups.

SYNTAX

collection **get_rp_group_objects**
rp_group_list
[-cell] | [-rp_group] | [-blockage]
[-hierarchical]
[-row row_number]
[-column column_number]

Data Types

rp_group_list list or collection
row_number integer
column_number integer

ARGUMENTS

rp_group_list

Specifies the list of names or collection of a relative placement groups, from which objects needs to be collected.

-cell

Specifies that cells of given relative placement groups must be collected.

-rp_group

Specifies that relative placement groups of given relative placement groups must be collected.

-blockage

Specifies that relative placement blockages of given relative placement groups must be collected.

-hierarchical

Specifies that objects from all sub-groups of relative placement groups in *rp_group_list* are to be collected. By default, objects in sub-groups are not collected.

-row

Specifies the row from which objects must be collected. By default, objects are collected from all rows of the relative placement group.

-column

Specifies the column from which objects must be collected. By default, objects are collected from all columns of the relative placement group.

DESCRIPTION

The **get_rp_group_objects** command returns a collection of cells, relative placement groups and/or blockages. By default, all objects of relative placement group are collected. If user provides *-cell* or *-rp_group* or *-blockage* then cells or relative placement groups or relative placement blockages will be collected respectively.

EXAMPLES

The following example uses **get_rp_group_objects** to create collection cells.

```
prompt> get_rp_group_objects grp_ripple -cell
{U0 U1 U2 U3}
```

The following example uses **get_rp_group_objects** to create collection relative placement groups.

```
prompt> get_rp_group_objects grp_ripple -rp_group
{grp_ripple_hier1 grp_ripple_hier2}
```

The following example uses **get_rp_group_objects** to create collection relative placement blockages.

```
prompt> get_rp_group_objects grp_ripple -blockage
{grp_ripple_blkg}
```

The following example uses **get_rp_group_objects** to get object at given row and column location.

```
prompt> get_rp_group_objects grp_ripple -row 1 -column 1
{grp_ripple_blkg}
```

The following example uses **get_rp_group_objects** to get objects of a row.

```
prompt> get_rp_group_objects grp_ripple -row 1
{grp_ripple_blkg grp_ripple_hier2 U2 U3}
```

The following example uses **get_rp_group_objects** to get objects of a column.

```
prompt> get_rp_group_objects grp_ripple -column 1
{grp_ripple_blkg grp_ripple_hier1 U0 U1}
```

The following example uses **get_rp_group_objects** to get all objects of relative placement group.

```
prompt> get_rp_group_objects grp_ripple
{grp_ripple_blkg U0 U1 U2 U3 grp_ripple_hier1 grp_ripple_hier2}
```

The following example uses **get_rp_group_objects** to get all objects of relative placement group and its hierarchical relative placement groups.

```
prompt> get_rp_group_objects grp_ripple -hierarchical
{grp_ripple_blkg U0 U1 U2 U3 grp_ripple_hier1 grp_ripple_hier2 U5 U6 U7}
```

SEE ALSO

create_rp_group(2)
get_rp_groups(2)
add_to_rp_group(2)
write_rp_groups(2)

get_rp_groups

Creates a collection by selecting relative placement groups from the current design.

SYNTAX

collection **get_rp_groups**
[*patterns* | -of_objects *of_objects*]
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-top]
[-hierarchical]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list or collection
patterns list

ARGUMENTS

patterns

Matches the relative placement group names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

-of_objects *of_objects*

Creates a collection containing the parent relative placement group of the specified cells, relative placement groups or relative placement blockages. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the relative placement group attributes. You can determine the relative placement group attributes by using the **list_attributes** command. If the expression evaluates to **true**, the relative placement group is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-top

If specified with *patterns* then it specifies that only top level relative placement groups must be collected. The option when specified with *of_objects* collects top most relative placement group in parent hierarchy instead of parent relative placement group.

-hierarchical

Searches for relative placement groups level-by-level relative to the current design. This option is useful only with *patterns* and not with **-of_objects**.

DESCRIPTION

This command creates a collection of relative placement groups by selecting relative placement groups that meet the selection

criteria. It returns a collection handle if one or more relative placement groups meet the selection criteria. If no relative placement groups match the selection criteria, it returns an empty string.

You can use the **get_rp_groups** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of relative placement groups by name pattern matching.

```
prompt> get_rp_groups rp_group*
{rp_group1 rp_group2 rp_group3}
```

The following example creates a collection of relative placement groups with attribute filtering.

```
prompt> get_rp_groups -filter {tiling_type == bit_slice}
{rp_group1}
```

The following example creates a collection of all relative placement groups.

```
prompt> get_rp_groups *
{rp_group1 rp_group2 rp_group3 rp_group4}
```

The following example creates a collection of parent relative placement group of cell inv.

```
prompt> get_rp_groups -of_objects inv
{rp_group1}
```

get_safety_register_groups

Creates a collection of safety register groups.

SYNTAX

status **get_safety_register_groups**
[*patterns*]
[-of_objects *cells*]
[-filter *expr*]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect *count*]
[-expect_at_least *count*]
[-expect_each_pattern_matches]

Data Types

cells	collection
count	int

ARGUMENTS

patterns

Finds safety register groups with names matching these patterns

-of_objects *cells*

Gets safety register groups associated with these registers or pins

-filter *expression*

Filters collection with *expression*

-quiet

Does not print any messages

-regexp

Specifies that patterns are full regular expressions

-exact

Specifies that wildcards are considered as plain characters

-nocase

Performs case-insensitive matching

-expect *count*

Expects exactly these many matching objects: count >= 0

-expect_at_least *count*

Expects at least these many matching objects: count >= 1

-expect_each_pattern_matches

Specifies that each pattern must match at least one object

DESCRIPTION

Finds and creates a collection of safety_register_group objects based on the options and filters specified. If no options are specified, it returns all the safety register groups of the current design.

EXAMPLES

The following example creates a collection of safety register group objects based on given pattern with case insensitive matching.

prompt> **get_safety_register_groups -nocase group1***

SEE ALSO

create_safety_register_group(2)
report_safety_register_groups(2)
write_safety_register_script(2)

get_safety_register_rules

Creates a collection of safety register rules.

SYNTAX

status **get_safety_register_rules**
[*patterns*]
[-of_objects *registers*]
[-filter *expr*]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect *count*]
[-expect_at_least *count*]
[-expect_each_pattern_matches]

Data Types

registers collection
count int

ARGUMENTS

patterns

Finds safety register rules with names matching these patterns

-of_objects *registers*

Gets safety register rules associated with these registers or pins

-filter *expression*

Filters collection with *expression*

-quiet

Does not print any messages

-regexp

Specifies that patterns are full regular expressions

-exact

Specifies that wildcards are considered as plain characters

-nocase

Performs case-insensitive matching

-expect *count*

Expects exactly these many matching objects: count >= 0

-expect_at_least *count*

Expects at least these many matching objects: count >= 1

-expect_each_pattern_matches

Specifies that each pattern must match at least one object

DESCRIPTION

Finds and creates a collection of safety register rule objects based on the options and filters specified. If no options are specified, it returns all the safety register rules of the current design.

EXAMPLES

The following example creates a collection of safety_register_rule objects based on given pattern with case insensitive matching.

prompt> **get_safety_register_rules -nocase rule1***

SEE ALSO

create_safety_register_rule(2)
report_safety_register_rules(2)
write_safety_register_script(2)

get_scan_cell_names

Returns a list containing the names of scan cells for the specified option filters.

SYNTAX

list **get_scan_cell_names**
[-chain *chain_name_list*]
[-test_mode *mode_name_list* | all]

Data Types

chain_name_list list
mode_name_list list

ARGUMENTS

-chain *chain_name_list*

When specified, retrieves and returns a list of scan cell names contained in the specified scan chains. By default, the scan cells for all chains are returned.

-test_mode *mode_name_list* | all

Reports only on the specified test mode(s), or on all test modes if **all** is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

DESCRIPTION

This command returns a Tcl list of scan cell names (as strings), according to the specified options. The information can include scan paths defined by the **set_scan_path** command, as well as scan paths created by the tool.

By default, the command returns the scan cell names for all chains.

SEE ALSO

current_test_mode(2)
get_scan_chain_names(2)

report_dft(2)
set_dft_configuration(2)
set_dft_signal(2)
set_scan_configuration(2)
set_scan_path(2)

get_scan_cells_of_chain

Returns a collection containing all scan cells of the specified scan chain.

SYNTAX

collection **get_scan_cells_of_chain**
-chain *chain_name*

Data Types

chain_name string

ARGUMENTS

-chain *chain_name*

Specifies the name of the scan chain.

DESCRIPTION

This command returns a Tcl collection containing all scan cells for the specified scan chain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example gets all scan cells of the *chain1* scan chain:

prompt> **get_scan_cells_of_chain -chain "chain1"**

SEE ALSO

get_scan_chains(2)

get_scan_chain_collection

Returns a Tcl list containing the names of the SCANDEF stub chains of the design.

SYNTAX

list **get_scan_chain_collection**

ARGUMENTS

This command does not receive any arguments.

DESCRIPTION

This command returns a Tcl list containing the names of the SCANDEF stub chains of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example gets the scan chain names of the design:

```
prompt> get_scan_chain_collection
{ chain1 2 3 4 }
prompt>
```

SEE ALSO

get_scan_chain_count(2)

get_scan_chain_count

Returns the number of SCANDEF stub chains in the current design.

SYNTAX

int **get_scan_chain_count**

DESCRIPTION

This command returns the number of SCANDEF stub chains in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example returns the number of scan chains in the design:

```
prompt> get_scan_chain_count
203
```

SEE ALSO

get_cells_of_scan_chain(2)

get_scan_chain_names

Returns a list containing the names of scan chains for the specified option filters.

SYNTAX

list **get_scan_chain_names**
[-test_mode *mode_name_list* | all]

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list* | all

Reports only on the specified test mode(s), or on all test modes if **all** is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

DESCRIPTION

This command returns a Tcl list of scan chain names (as strings), according to the specified options. The information can include scan paths defined by the **set_scan_path** command, as well as scan paths created by the tool.

SEE ALSO

current_test_mode(2)
get_scan_cell_names(2)
report_dft(2)
set_dft_configuration(2)
set_dft_signal(2)
set_scan_configuration(2)
set_scan_path(2)

get_scan_chain_of_cell

Returns a Tcl list containing the name of the SCANDEF stub chain to which the given cell belongs.

SYNTAX

string **get_scan_chain_of_cell**
-cell *cell_name*

Data Types

cell_name string

ARGUMENTS

-cell *cell_name*

Specifies the name of the cell whose scan chain is looked for.

DESCRIPTION

This command returns a Tcl list containing the name of the SCANDEF stub chain corresponding to the given cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example gets the chain name *chain1* corresponding to the cell *blockA/a_cell*.

```
prompt> get_scan_chain_of_cell -cell blockA/a_cell
{ chain1 }
prompt>
```

SEE ALSO

get_scan_chain_count(2)

get_scan_chains

Returns a collection of scan chains from the current design.

SYNTAX

collection **get_scan_chains**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*
| -of_objects *objects*

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any scan chain that matches the patterns option, the expression is evaluated based on the scan chain's attributes. If the expression evaluates to *true*, the scan chain is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *objects*

Creates a collection containing the scan chains of the specified stub_chains, ports, pins or cells. Each object in the list is a name, pattern, or collection.

patterns

Matches scan chains names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, **-of_objects** arguments are mutually exclusive; you can specify only.

DESCRIPTION

The **get_scan_chains** command creates a collection of scan chains from the current design that match certain criteria. The command returns a collection of scan chains if any scan chain matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_scan_chains** command at the command prompt, or you can nest it as an argument to another command, such as **report_scan_chains**. In addition, you can assign the **get_scan_chains** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the scan chains in the current design.

```
prompt> get_scan_chains
{scan1 scan2}
```

The following example returns a collection of all the scan chains associated with a specified pin.

```
prompt> get_scan_chains -of_objects u1/pin1
{scan1 scan2}
```

SEE ALSO

create_scan_chain(2)

get_scenarios

Creates a collection of scenarios in the current design.

SYNTAX

collection **get_scenarios**
[*patterns* | -of_objects *of_objects*]
[-modes *mode_list*]
[-corners *corner_list*]
[-design *design*]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-quiet]
[-regexp]
[-nocase]
[-filter *expression*]
string *expression*
list *patterns*
list *of_objects*
list *mode_list*
list *corner_list*

ARGUMENTS

patterns

Matches scenario names against patterns. Patterns can include the wildcard characters "*" and "?".

The *patterns* argument; **-of_objects** option; and **-modes** and **-corners** options are mutually exclusive; you can specify only one. If you do not specify any of these, the generated collection contains all scenarios.

-of_objects ***of_objects***

Creates a collection of scenarios that are associated with the specified objects. Each object is a named mode or corner, or mode or corner collection.

The *patterns* argument; **-of_objects** option; and **-modes** and **-corners** options are mutually exclusive; you can specify only one. If you do not specify any of these, the generated collection contains all scenarios.

-modes ***mode_list***

Creates a collection of scenarios that are associated with the specified modes.

If you use both the **-modes** and **-corners** options, the scenarios are associated with one of the specified modes and one of the

specified corners.

You cannot use the **-modes** or **-corners** options with the **-of_objects** option or *patterns* argument. If you do not specify any of these, the generated collection contains all scenarios.

-corners *corner_list*

Creates a collection of scenarios that are associated with the specified corners.

If you use both the **-modes** and **-corners** options, the scenarios are associated with one of the specified modes and one of the specified corners.

You cannot use the **-modes** or **-corners** options with the **-of_objects** option or *patterns* argument. If you do not specify any of these, the generated collection contains all scenarios.

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-filter *expression*

Filters the collection with *expression*. For any scenarios that match *patterns*, the expression is evaluated based on the scenario's attributes. If the expression evaluates to true, the scenario is included in the result.

DESCRIPTION

The **get_scenarios** command creates a collection of scenarios in the current design that match the *patterns* argument, the **-of_objects** option, or the **-modes** and **-corners** options, and that pass the filter (if specified). If no objects match the criteria, the empty string is returned.

With the correct combination of options, this command can return all the scenarios of a given mode or corner, or the single scenario (if any) of a given mode and corner.

EXAMPLES

The following example returns all scenarions.

```
prompt> get_scenarios
{func::corner_S1_max func::corner_S1_min func::corner_S5_max
func::corner_S5_min func::corner_S7_max func::corner_S7_min}
```

The following example returns all scenarios whose name matches the pattern *min.

```
prompt> get_scenarios *min
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}
```

The following example returns all active setup scenarios.

```
prompt> get_scenarios -filter setup&&active
{func::corner_S1_max func::corner_S5_max func::corner_S7_max}
```

The following examples return all scenarios that use a corner that matches the pattern *min.

```
prompt> get_scenarios -corners *min
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}

prompt> get_scenarios -of_objects [get_corners *min]
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}
```

The following example returns the scenarios that use a corner named *min or a mode named func (or both).

```
prompt> get_scenarios -of_objects [add_to_collection \
  [get_corners *min] [get_modes func]]
{func::corner_S1_min func::corner_S5_min func::corner_S7_min
func::corner_S1_max func::corner_S5_max func::corner_S7_max}
```

The following example returns the scenarios that use the func mode and the corner_S7_max corner.

```
prompt> get_scenarios -corners corner_S7_max -modes func
{func::corner_S7_max}
```

SEE ALSO

all_scenarios(2)
report_scenarios(2)

create_scenario(2)
current_scenario(2)

get_selection

Returns a collection containing the current selection in the GUI.

SYNTAX

collection **get_selection**
[-slct_targets *target_selection_bus*
[-slct_targets_operation *operation*]]
-create_slct_buses
[-name *selection_bus*]
[-type *object_type*]
[-design *design*]
[-more_than *more*]
[-fewer_than *fewer*]
[-count]
[-num *num*]
[-type_list]

Data Types

target_selection_bus string
operation string
selection_bus string
object_type string
design string
more integer
fewer integer
num integer

ARGUMENTS

-slct_targets *target_selection_bus*

Specifies the name of a selection bus in which to store the result. When you use this option, the *target_selection_bus* value is also returned as result of the command. By default, the result is returned in a collection.

-slct_targets_operation *operation*

Specifies which operation should be used when storing the result in the selection bus specified by the *target_selection_bus* argument. The valid values for the *operation* argument are **clear**, **add**, and **remove**. You can use the **-slct_targets_operation** option only if you also use the **-slct_targets** option.

-create_slct_buses

Specifies to create a new selection bus in which to store the result. Using this option is equivalent to using the

create_selection_bus command to create a selection bus and then providing the created selection bus to the **-slct_targets** option.

-name *selection_bus*

Specifies the selection bus from which the selection is taken.

-type *object_type*

Specifies the type of selected object with which to filter the selection. The valid values for *object_type* and their descriptions are as follows:

design -design object
port -port object
net -net object
cell -cell object
pin -pin object
path -timing path object

-design *design*

Returns only objects in the filter specified by the value of *design*.

-more_than *more*

Returns true if the selection bus contains more than the number of objects specified by *more*.

-fewer_than *fewer*

Returns true if the selection bus contains more than the number of objects specified by *fewer*.

-count

Returns the number of elements contained in the selection bus.

-num *num*

Returns only the number of objects specified by *num* or fewer.

-type_list

Returns a Tcl list of the types of elements contained in the selection bus.

DESCRIPTION

This command returns the current selection in the tool as a collection. It returns a collection handle (identifier) if any objects are selected. If no objects are selected, the command returns an empty string. If you do not use the **-type** option, the command returnS a heterogeneous collection of all objects currently selected. If you use **-type**, the collection is filtered to a homogeneous one containing only objects of the type you specify.

You can use the **get_selection** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**), or assign the **get_selection** result to a variable.

When issued from the command prompt, **get_selection** behaves as if you had called **query_objects** to display the objects in the collection. By default, the command displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

The "implicit query" property of **get_selection** provides a fast, simple way to display cells in a collection. However, if you want the

flexibility provided by the options of the **query_objects** command (for example, if you want to display the object class), use **get_selection** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns the collection of the selected cell objects.

```
prompt> get_selection -type cell
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

The following example assigns the collection to a variable named **collect_a** that is passed to the **query_objects** command.

```
prompt> set collect_a [get_selection -type cell]
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
prompt> query_objects $collect_a
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

geometric_objects
| -touching { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects
| -intersect { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]

Data Types

design collection
expression string
exact_count integer
minimum_count integer
patterns string
objects list
point list
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection

ARGUMENTS

-design *design*

Specifies the block in which to find shape_patterns.

By default, the tool finds objects in the current block.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on shape_pattern attributes. You can determine the shape_pattern attributes by using the **list_attributes -class shape_pattern** command. If the expression evaluates to **true**, the shape_pattern is included in the collection.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for shape_patterns level-by-level relative to the current instance. You can use this option with the *patterns*, **-within**, **-touching**, **-intersect**, and **-at** arguments, but not with the **-of_objects** option.

-of_objects *of_objects*

Creates a collection that contains the shape_patterns connected to the specified net, layer, edit group, or group. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command

uses * (asterisk) as the *pattern*.

patterns

Matches the shape_pattern names against the patterns in the current block. You can specify the patterns by using the following formats:

- *** (asterisk) specifies all shape_patterns
- *PATH_PATTERN_** specifies all shape_patterns with shape_pattern_type path_pattern
- *RECT_PATTERN_** specifies all shape_patterns with shape_pattern_type rect_pattern

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at ***point***

Creates a collection that contains all shape_patterns whose region completely contains the input point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-within ***region***

Creates a collection that contains all shape_patterns completely contained inside the specified region. All objects which are abut/touching from inside and completely contained also get selected.

When the *design.enable_icc_region_query* application option is set to *true*, only the objects which are completely contained but not abut/touching from inside get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-touching ***region***

Creates a collection that contains all shape_patterns completely contained by the specified region. All objects which are touching from inside and completely contained also get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-intersect *region*

Creates a collection that contains all shape_patterns whose region intersects the specified region. A certain portion of the region should be completely inside and a certain portion outside of the input window to pass this test.

When the *design.enable_icc_region_query* application option is set to *true*, even the objects which are abut/touching from either inside or outside also get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

DESCRIPTION

This command creates a collection of shape_patterns by selecting shape_patterns from the nets, layer, edit group, or group that meet the selection criteria. It returns a collection if one or more shape_patterns meet the selection criteria. If no shape_patterns match the selection criteria, it returns an empty string.

You can use the **get_shape_patterns** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all shape_patterns connected to the specified net.

```
prompt> get_shape_patterns * -of_objects [get_nets VDD]
{PATH_PATTERN_31_0 PATH_PATTERN_31_1}
```

The following example creates a collection of shape_patterns on the M2 layer.

```
prompt> get_shape_patterns -of_objects [get_layers M2]
{RECT_PATTERN_32_0 RECT_PATTERN_32_1 PATH_PATTERN_32_99 ...}
```

get_shapes

Creates a collection by selecting shapes from the block.

SYNTAX

collection **get_shapes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_fill]
[-include_lib_cell]
[-include_shield]
[-shield_only]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count integer
minimum_count integer
patterns string
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the block in which to find shapes.

By default, the tool finds objects in the current block.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on shape attributes. You can determine the shape attributes by using the **list_attributes -class shape** command. If the expression evaluates to **true**, the shape is included in the collection.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for shapes level-by-level relative to the current instance. You can use this option with the *patterns*, **-within**,\ fB-touching, **-intersect**, and **-at** arguments, but not with the **-of_objects** option.

-include_fill

Search for fill shapes. You must specify the **-hierarchical** option to search the **fill cell hierarchy** instance in the current block.

By default, fill shapes are excluded from search.

-include_lib_cell

Search for shapes in library cells. You must specify the **-hierarchical** option to search for shapes in the library cells.

By default, library cell shapes are excluded from search.

-include_shield

Includes shield shapes when the **-of_objects** option specifies nets. This option is valid only when the **-of_objects** option specifies nets.

This option is mutually exclusive with the **-shield_only** option.

-shield_only

Search only for shield shapes when the **-of_objects** option specifies nets. This option is valid only when the **-of_objects** option specifies nets.

This option is mutually exclusive with the **-include_shield** option.

-of_objects *of_objects*

Creates a collection that contains the shapes connected to the specified net, port, pin, terminal, library cell pin, layer, edit group, or fill cell. Each object in the list is a name, pattern, or collection.

When you specify ports, the **get_shapes** command searches for shapes attached to the terminals associated with the specified ports.

When you specify pins, the **get_shapes** command searches for shapes attached to the terminals of the ports associated with the specified pins.

When you specify fill cells, the **get_shapes** command searches for shapes contained in the specified fill cells.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the shape names against the patterns in the current block. You can specify the patterns by using the following formats:

- *** (asterisk) specifies all shapes
- *PATH_** specifies all path shapes
- *RECT_** specifies all rectangle shapes

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-within *region*

Creates a collection that contains all shapes that are completely inside the specified region and does not include shapes that abut the specified region or touch it from the inside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-touching ***region***

Creates a collection that contains all shapes that are completely inside the specified region and the shapes that abut the specified region or touch it from the inside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

-intersect ***region***

Creates a collection that contains all shapes that abut the specified region or touch it from the inside or outside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. However, you can specify the **-within** and **-intersect** options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the **-hierarchical** option.

DESCRIPTION

This command creates a collection of shapes by selecting shapes from the nets, ports, pins, or layers that meet the selection criteria. It returns a collection if one or more shapes meet the selection criteria. If no shapes match the selection criteria, it returns an empty string.

You can use the **get_shapes** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all shapes connected to the specified net.

```
prompt> get_shapes -of_objects [get_nets net1]
{PATH_31_0 PATH_31_1}
```

The following example creates a collection of shapes on the M2 layer.

```
prompt> get_shapes -of_objects [get_layers M2]
{RECT_32_0 RECT_32_1 PATH_32_99 ...}
```

The following example creates a collection of path shapes.

```
prompt> get_shapes -filter {number_of_points > 2}
{PATH_31_2375 PATH_31_2396 PATH_32_2294 PATH_32_2301}
```

SEE ALSO

filter_collection(2)
query_objects(2)
regexp(2)
shell.common.collection_result_display_limit(3)

get_shaping_blockages

Creates a collection of shaping blockages from the current design.

SYNTAX

collection **get_shaping_blockages**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any shaping blockages that match *patterns*, the expression is evaluated based on the shaping blockage's attributes. If the expression evaluates to true, the blockage is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for shaping blockages level-by-level relative to the current instance. This option is useful only with *patterns* and not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the shaping blockages of the specified cells or blocks. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the shaping blockage names in the current design against the specified patterns. You can specify the patterns by using the following formats:

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

DESCRIPTION

This command returns a collection of shaping blockages of the current design that meet the selection criteria. You can use this command to query the shaping blockages inside the database by area, by point, or by region. You can also use this command to query shaping blockages by filtering their attributes.

EXAMPLES

The following example returns the shaping blockages whose area is larger than 1000.

```
prompt> get_shaping_blockages * -filter "area > 1000"
{"SB_4683"}
```

The following example returns all shaping blockages that begin with "SB_".

```
prompt> get_shaping_blockages "SB_*"
{"SB_4683 SB_5389"}
```

The following three commands show how to use **get_attribute** to query the value of the shaping blockage attributes.

```
prompt> get_attribute [get_shaping_blockages SB_4683] layer
via3Blockage

prompt> get_attribute [get_shaping_blockages SB_4683] bbox
{0.000 0.000{ {100.000 100.000}

prompt> get_attribute [get_shaping_blockages SB_4683] area
10000.000000
```

To get a complete report of the attribute values of all shaping blockages, use the **report_attributes** command, as shown in the following example.

```
prompt> report_attributes -application [get_shaping_blockages SB_4683]
Design  Object    Type   Attribute Name   Value
------------------------------------------------------------------------
CORE    SB_4683   float    area         10000.000000
CORE    SB_4683   string   bbox         {0.000 0.000} {100.000 100.000}
CORE    SB_4683   string   full_name    CORE/SB_4683
CORE    SB_4683   string   name         SB_4683
CORE    SB_4683   string   object_class  route_guide
```

get_shaping_channels

Get a collection of channels in the current block.

SYNTAX

collection **get_shaping_channels**
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[-types type list]
[patterns]

Data Types

design design
expression filter_expression
exact_count int
minimum_count int
of_objects collection
type list list of shaping constraint typesi

ARGUMENTS

-design

The -design argument specifies the top design for finding objects.

-filter

The -filter argument filters the collection based on the criteria given in the filter expression.

-quiet

The -quiet argument suppresses all messages.

-regexp

The -regexp argument causes the command to treat the patterns as full regular expressions.

-nocase

The -nocase argument performs case-insensitive matching.

-exact

The -exact argument treats wildcards as plain characters.

-expect exact_count

The -expect argument tells the command to expect exactly this many matching objects.

-expect_at_least minimum_count

The -expect argument tells the command to expect at least this many matching objects.

-expect_each_pattern_matches

The -expect_each_pattern_matches argument requires that each pattern match at least one object.

-of_objects of_objects

The -of_objects argument specifies a list of objects from which to gather the shaping channel objects. The objects may be of type shaping_constraint, in which case the command gathers the shaping channels associated with the given shaping_constraint objects. The objects may also be of types voltage_area, move_bound, cell, shaping group, or block, in which case the command gathers the shaping channels associated with any shaping constraints defined for the given objects.

-types type list

The -types argument specifies a list of channel types to filter the result. The valid types are object and neighbor.

patterns

The patterns argument gives the patterns to match channel names against.

DESCRIPTION

Gathers a returns a collection of channel objects in the current design that match the set of collection criteria.

EXAMPLES

The following command gets all the channel objects.

prompt> get_shaping_channels

The following command gets all the channel objects of type object.

prompt> get_shaping_channels -type object

SEE ALSO

create_shaping_channel(2)
remove_shaping_channels(2)
channel(3)

get_shaping_constraints

Get a collection of shaping_constraint objects

SYNTAX

collection **get_shaping_constraints**
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[-types type list]
[patterns]

Data Types

design design
expression filter_expression
exact_count int
minimum_count int
of_objects collection
type list list of shaping constraint types

ARGUMENTS

-design

The -design argument specifies the top design for finding objects.

-filter

The -filter argument filters the collection based on the criteria given in the filter expression.

-quiet

The -quiet argument suppresses all messages.

-regexp

The -regexp argument causes the command to treat the patterns as full regular expressions.

-nocase

The -nocase argument performs case-insensitive matching.

-exact

The -exact argument treats wildcards as plain characters.

-expect exact_count

The -expect argument tells the command to expect exactly this many matching objects.

-expect_at_least minimum_count

The -expect argument tells the command to expect at least this many matching objects.

-expect_each_pattern_matches

The -expect_each_pattern_matches argument requires that each pattern match at least one object.

-of_objects of_objects

The -of_objects argument specifies a list of objects from which to gather the shaping_constraint objects.

-types type list

The -types argument specifies a list of shaping constraint types to filter the result. The valid types are alignment_point, allowable_orientation, array_layout, aspect_ratio, boundary_area, boundary_channels, boundary_status, child_default_channels, child_default_utilization, external_channels, is_rigid_boundary, parent_object, reference_region, target_location, utilization.

patterns

The patterns argument gives the patterns to match shaping_constraint names against.

DESCRIPTION

Gathers and returns a collection of shaping_constraint objects in the current design that match the set of selection criteria.

EXAMPLES

The following command gets all the shaping_constraint objects.

```
prompt> get_shaping_constraints
```

The following command gets all the shaping_constraint objects of types target_location and alignment_point.

```
prompt> get_shaping_constraints -types "target_location alignment_point"
```

SEE ALSO

create_shaping_constraint(2)
remove_shaping_constraints(2)

get_site_arrays

Returns a collection of site arrays from the current design.

SYNTAX

collection **get_site_arrays**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any site array that matches the patterns option, the expression is evaluated based on the site array's attributes. If the expression evaluates to *true*, the site array is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for site arrays level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *objects*

Creates a collection containing the site arrays of the specified voltage areas and site rows. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches site array names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all site_arrays at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all site_arrays that are completely inside the specified region and doesn't include site_arrays which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all site_arrays that are completely inside the specified region and the site_arrays which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all site_arrays which are abut/touching from inside or outside to the specified region and the site_arrays whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical

hierarchies.

DESCRIPTION

The **get_site_arrays** command creates a collection of site arrays from the current design that match certain criteria. The command returns a collection of site arrays if any site array matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_site_arrays** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_site_arrays** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the site arrays in the current design.

```
prompt> get_site_arrays
{array_1 array_2 array_3}
```

The following example returns a collection of all the site arrays associated with a specified voltage area.

```
prompt> get_site_arrays -of_objects VA1
{SA1_1 SA1_2}
```

SEE ALSO

create_site_array(2)
collections(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_site_defs

Returns a collection of site defs from the tech of current or specified library.

SYNTAX

collection **get_site_defs**
[-library *library*]
[-tech *tech_object*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

library string or collection
tech_object collection
expression string
exact_count int
minimum_count int
of_objects list
patterns string

ARGUMENTS

-library *library*

Site definition will be searched in the technology of this library. Default is current library's tech. This is mutually exclusive with -tech option.

-tech *tech_object*

Site definition will be searched in this technology. Default is current library's tech. This is mutually exclusive with -library option.

-filter *expression*

Filters the collection with *expression*. For any site def that match the patterns option, the expression is evaluated based on the site def's attributes. If the expression evaluates to *true*, the site def is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the site defs of the specified site rows, site arrays and lib cells. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches site def names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_site_defs** command creates a collection of site defs from the tech of the current or specified library that match certain criteria. The command returns a collection of site defs if any site def matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_site_defs** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_site_defs** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the site defs in the tech of current library.

```
prompt> get_site_defs
{SD_1 SD_2 SD_3}
```

The following example returns a collection of all the site defs belonging to a site array.

```
prompt> get_site_defs -of_objects SA1
{SD1_1}
```

SEE ALSO

collections(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_site_rows

Returns a collection of site rows from the current design.

SYNTAX

collection **get_site_rows**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-first_row]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any site row that match the patterns option, the expression is evaluated based on the

site row's attributes. If the expression evaluates to *true*, the site row is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for site rows level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-first_row

This will give first site-row with respect to core area. First site-row will be left-most for vertical site-rows, or the bottom-most for horizontal site-rows with respect to core area bounding box.

-of_objects *of_objects*

Creates a collection containing the site rows of the specified edit groups and site arrays. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches site row names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all site_rows at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all site_rows that are completely inside the specified region and doesn't include site_rows which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all site_rows that are completely inside the specified region and the site_rows which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all site_rows which are abut/touching from inside or outside to the specified region and the site_rows whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

The **get_site_rows** command creates a collection of site rows from the current design that match certain criteria. The command returns a collection of site rows if any site row matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_site_rows** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_site_rows** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the site rows in the current design.

```
prompt> get_site_rows
{ROW_1 ROW_2 ROW_3}
```

The following example returns a collection of all the site rows that belong to site array SA1.

```
prompt> get_site_rows -of_objects SA1
{SA1_1 SA1_2}
```

SEE ALSO

collections(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_snap_setting

Returns the current snap setting for the specified option.

SYNTAX

status **get_snap_setting**
-enabled |
-class *obj_class* |
-cursor_edge |
-object_edge |
-edge_radius |
-preferred_track |
-fix_orientation |
-macro_by_color |
-user_grid

Data Types

obj_class string

ARGUMENTS

-enabled

Returns the current setting for **set_snap_setting -enabled**: 1 if snapping is enabled, 0 if snapping is disabled.

-class *obj_class*

Returns the current setting for **set_snap_setting -class class_name -snap object**. Valid class values are std_cell, macro_cell, io_cell, metal_shape, edit_group, placement_constraint, wiring_constraint, or other.

-cursor_edge

Returns the current setting for **set_snap_setting -cursor_edge**: 1 if objects should be snapped to visible object edges, 0 otherwise.

-object_edge

Returns the current setting for **set_snap_setting -object_edge**: 1 if moved or stretched object should be snapped to other object edges, 0 if not.

-edge_radius

Returns the current integer value setting for **set_snap_setting -edge_radius**, which specifies the search radius for snapping to object edges.

-preferred_track

Returns the current setting for **set_snap_setting -preferred_track**: 1 if only preferred tracks should be used if snapping to tracks is on, 0 otherwise.

-fix_orientation

Returns the current setting for **set_snap_setting -fix_orientation**: 1 if cell orientation should be fixed to match site rows or I/O guides, 0 otherwise.

-macro_by_color

Returns the current setting for **set_snap_setting -macro_by_color**: 1 if soft and hard macros should be snapped so that their colored pins are snapped to matching colored tracks, 0 otherwise.

-user_grid

Returns the current setting for **set_snap_setting -user_grid**: the command returns nothing if this option is not set.

DESCRIPTION

The command queries the current snap settings in the GUI. You can only query one option at a time.

EXAMPLES

The following example returns 1 if snapping is enabled, 0 if snapping is disabled.

```
prompt> get_snap_setting -enabled
1
```

SEE ALSO

set_snap_setting(2)

get_stub_chains

Returns a collection of stub chains from the current design.

SYNTAX

collection **get_stub_chains**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*
| -of_objects *objects*

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

-filter *expression*

Filters the collection with *expression*. For any stub chain that matches the patterns option, the expression is evaluated based on the stub chain's attributes. If the expression evaluates to *true*, the stub chain is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-of_objects *objects*

Creates a collection containing the stub chains of the specified scan_chains, ports, pins or cells. Each object in the list is a name, pattern, or collection.

patterns

Matches stub chains names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, **-of_objects** arguments are mutually exclusive; you can specify only.

DESCRIPTION

The **get_stub_chains** command creates a collection of stub chains from the current design that match certain criteria. The command returns a collection of stub chains if any stub chain matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_stub_chains** command at the command prompt, or you can nest it as an argument to another command, such as **report_stub_chains**. In addition, you can assign the **get_stub_chains** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the stub chains in the current design.

```
prompt> get_stub_chains
{stub1 stub2}
```

The following example returns a collection of all the stub chains associated with a specified pin.

```
prompt> get_stub_chains -of_objects u1/pin1
{stub1 stub2}
```

SEE ALSO

create_stub_chain(2)

get_supernets

Creates a collection of supernets from the netlist. You can assign these supernets to a variable or pass them into another command.

SYNTAX

collection **get_supernets**
[-design *design*]
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hsc *separator*]
patterns | -of_objects *objects*

Data Types

design string
expression string
exact_count integer
minimum_count integer
separator character
patterns list
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this option is not specified, objects will be found in the current design.

-hierarchical

Searches for supernets level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a supernet block1/snet1, a hierarchical search finds it using "snet1". This option is useful with *patterns* but not with **-of_objects**.

-filter *expression*

Filters the collection with *expression*. For any supernets that match *patterns* (or *objects*), the expression is evaluated based on the attributes on the supernet. If the expression evaluates to true, the supernet is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Considers the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hsc *separator*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

-of_objects *objects*

Creates a collection of supernets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell, cell collection, a named net or a net collection, a named bundle or a bundle collection, a named routing corridor or a routing corridor collection. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches supernet names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option. Patterns can also include collections of type supernet. *patterns* and **-of_objects** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **get_supernets** command creates a collection of supernets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any supernets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_supernets** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_supernets** result to a variable.

When issued from the command prompt, **get_supernets** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the **shell.common.collection_result_display_limit** application option.

The "implicit query" property of **get_supernets** provides a fast, simple way to display supernets in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_supernets** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the supernets that begin with 'SUPERNET' in block 'block1'. Although the output looks like a list, it is just a display.

```
prompt> get_supernets block1/SUPERNET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example queries the supernets that are anchored to a collection of pins.

```
prompt> current_instance block1
block1
prompt> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
prompt> query_objects [get_supernets -of_objects $pinsel]
{"SUPERNET1QNX", "SUPERNET2QNX"}
```

get_supply_net_probability

Gets switching probability on selected supply nets in the current design.

SYNTAX

string **get_supply_net_probability**
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
object_list

Data Types

scenario_list	list
mode_list	list
corner_list	list
object_list	list

ARGUMENTS

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Output of the command is generated separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command reports for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

object_list

Specifies a supply net in the current design for which the value of the static probability are to be reported.

DESCRIPTION

Use this command to report the static probability of supply nets in the current design.

The supply nets that are reported can be specified explicitly as a list of objects.

If a combination of a mode and corner is specified that does not represent a valid scenario, those are ignored.

Multicorner-Multimode Support

EXAMPLES

The following **get_supply_net_probablity** command reports the static probability on supply net VSS.

```
prompt> get_supply_net_probability [get_supply_net VSS]
(mode = default, corner = default, probability = 1, type = default)
```

get_supply_nets

Creates a collection of supply nets that meet the specified criteria.

SYNTAX

collection **get_supply_nets**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[-top_net_of_hierarchical_group]
[-segments]
[[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-hierarchical

Searches for supply nets in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply nets only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply net names relative to the current scope.

You cannot specify this option when you use the **-of_objects** option.

-filter *expression*

Filters the collection with *expression*. For any supply nets that match *patterns*, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Returns a collection of supply nets associated with the specified objects. The objects can be supply ports, pg leaf pins, voltage_areas, or supply sets.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

-top_net_of_hierarchical_group

Keeps only the top supply_net of a hierarchical group. When more than one hierarchical supply_net of the same group is specified (equivalent supply_net at various hierarchical levels), only the supply_net closest to the top of the hierarchy is saved with the collection. In the case of multiple supply_nets at the same level, the first supply_net specified is kept. Although this option can be used when there are multiple nets specified, it is best used in combination with **-segments** and with a single supply_net.

-segments

Returns all equivalent supply_nets for given supply_nets. This modifies the initial search which matches *patterns* or *objects*. It is applied after filtering, but before the **-top_net_of_hierarchical_group** is determined. For each net, all equivalent supply_nets will be added to the result collection. Although this option can be used with other options and when there are multiple supply_nets specified, it is best used with a single net. When combined with the **-top_net_of_hierarchical_group** option, you can isolate the highest scope of equivalent supply_net.

patterns

Matches supply net names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the **wildcards** man page.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses "*".

DESCRIPTION

The **get_supply_nets** command creates a collection of supply nets in the current design, that match certain criteria. If no supply nets match the criteria, an empty string is returned.

Until the **commit_upf** command is executed and power intent is finalized, supply nets of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using **-regexp**, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_supply_nets** command at the command prompt, or you can nest it as an argument to another command, such as **report_supply_nets**. In addition, you can assign the **get_supply_nets** result to a variable.

When issued from the command prompt, **get_supply_nets** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by setting the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example gets all supply nets under the current scope.

```
prompt> get_supply_nets -hierarchical
{"VDD", "SUB_INST/VDD"}
```

SEE ALSO

create_supply_net(2)
report_supply_nets(2)

get_supply_ports

Creates a collection of supply ports that meet the specified criteria.

SYNTAX

collection **get_supply_ports**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[-exclude_power_switch]
[[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-hierarchical

Searches for supply ports in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply ports only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply port names relative to the current scope.

You cannot specify this option when you use the **-of_objects** option.

-filter *expression*

Filters the collection with *expression*. For any supply ports that match *patterns*, the expression is evaluated based on the supply port's attributes. If the expression evaluates to true, the supply port is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Returns a collection of supply ports associated with the specified supply net objects.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

-exclude_power_switch

Exclude the supply ports of power switches. By default, supply ports of power switches are included in the result.

patterns

Matches supply port names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the **wildcards** man page.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses "*".

DESCRIPTION

The **get_supply_ports** command creates a collection of supply ports in the current design, that match certain criteria. If no supply ports match the criteria, an empty string is returned.

Until commit_upf command is executed and power intent is finalized, supply ports of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using **-regexp**, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_supply_ports** command at the command prompt, or you can nest it as an argument to another command, such as **report_supply_ports**. In addition, you can assign the **get_supply_ports** result to a variable.

When issued from the command prompt, **get_supply_ports** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

get_supply_sets

Creates a collection of supply sets that meet the specified criteria.

SYNTAX

collection **get_supply_sets**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-of_objects *objects*]
[[*patterns*]

Data Types

expression string
exact_count int
minimum_count int
objects list
patterns list

ARGUMENTS

-hierarchical

Searches for supply sets in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply sets only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply net names relative to the current scope.

You cannot specify this option when you use the **-of_objects** option.

-filter *expression*

Filters the collection with *expression*. For any supply sets that match *patterns*, the expression is evaluated based on the attributes of the supply set. If the expression evaluates to true, the supply set is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Returns a collection of supply sets associated with the specified objects. The objects can be power domains and supply nets.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

patterns

Matches supply set names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the **wildcards** man page.

The *patterns* argument and **-of_objects** option are mutually exclusive. If you do not specify either, the tool uses "*".

DESCRIPTION

The **get_supply_sets** command creates a collection of supply sets in the current design, that match certain criteria. If no supply sets match the criteria, an empty string is returned.

Until commit_upf command is executed and power intent is finalized, supply sets of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using **-regexp**, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_supply_sets** command at the command prompt, or you can nest it as an argument to another command, such as **report_supply_sets**. In addition, you can assign the **get_supply_sets** result to a variable.

When issued from the command prompt, **get_supply_sets** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the **shell.common.collection_result_display_limit** application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example gets all supply sets under the current scope.

```
prompt> get_supply_sets
{SS1 SS2 SS3 SS4 SS5 new_sset_1}
```

The following example gets all supply sets matching a given pattern.

```
prompt> get_supply_sets SS*
{SS1 SS2 SS3 SS4 SS5}
```

SEE ALSO

report_supply_sets(2)
shell.common.collection_result_display_limit(3)

get_svf

Get the name of the current SVF directory.

SYNTAX

boolean **get_svf**

DESCRIPTION

This command prints the name of the SVF directory that is currently open for recording SVF guidance for Formality. If no SVF directory has been specified using the **set_svf** command, a message is printed.

EXAMPLES

In this example, we query the name of the SVF directory and find out that setup information is not being recorded yet. Then we specify the directory name and repeat the query.

```
prompt> get_svf
SVF guidance is not enabled.
1
prompt> set_svf cache_ctrl_svf
1
prompt> get_svf
The current SVF directory is /project/chip/cache_ctrl/cache_ctrl_svf.
1
```

SEE ALSO

set_svf(2)
Formality User Guide

get_switching_activity

Gets switching activity information on nets, pins, ports and cells in the current design.

SYNTAX

string **get_switching_activity**
[-state_condition *state_condition*]
[-path_sources *path_sources*]
[-rise]
[-fall]
[-related_clock]
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
object_list

Data Types

state_condition	string
path_sources	list
scenario_list	list
mode_list	list
corner_list	list
object_list	list

ARGUMENTS

-state_condition *state_condition*

Specifies the state condition for reporting state-dependent activities. State dependent activities can be reported when the object is already annotated with state-dependent activities. The state condition specified with this argument must match to a state condition already annotated for this object. Use -state_condition default to specify the default state condition.

-path_sources *path_sources*

Specifies the path sources when reporting path-dependent activities. This can be used when the object is already annotated with path-dependent activities. The path sources specified with this argument must be the same as those annotated for this object. If -path_sources option is used to specify the path_sources value, then -state_condition option must be specified to specify the value of the path_sources.

-rise

This option is used with the **-state_condition** option. It reports rise transition.

-fall

This option is used with the **-state_condition** option. It reports fall transition.

-related_clock

This option is used to print the clock domain of the objects.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Output of the command is generated separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command reports for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

object_list

Specifies a net, pin, port or cell in the current design for which the values of static probability, the toggle rate and the type of activity are to be reported.

DESCRIPTION

This command is used to report switching activity information on nets, ports, pins and cells. Switching activity information includes toggle rate, static probability and activity type.

Note that *object_list* argument should always be provided to the command. The activity type reported by the command can only be one of 'annotated', 'simulated', 'propagated', 'sta' or 'default'.

For more statistics on the switching activity annotation on the current design, use the **report_switching_activity** command.

Multicorner-Multimode Support

EXAMPLES

The following **get_switching_activity** command reports the toggle rate and static probability values on a pin for the current scenario in the design.

```
prompt> get_switching_activity {H1/p1}
 (mode = default, corner = default, probability = 0.9, toggle_rate = 0.3, type = annotated)
```

The following **get_switching_activity** command reports the activity information for a list of objects for the default state_condition for the current scenario scn1. If the object_list contains nets then the tool will ignore the state_condition option for those nets.

```
prompt> get_switching_activity {H1 H1/p1 H1/n1} -state_condition default
scn1 {{condition default probability 1}}
```

```
scn1 {{condition default rise_toggle_rate 0 fall_toggle_rate 0}}
(mode = scn1.mode, corner = scn1.corner, probability = 0.5,
toggle_rate = 0.0333333, type = default)
```

SEE ALSO

read_saif(2)
report_power(2)
report_switching_activity(2)
reset_switching_activity(2)
set_switching_activity(2)

get_taps

Retrieves a collection of tap objects.

SYNTAX

collection **get_taps**
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

string *expression*
list *patterns*
int *exact_count*
int *minimum_count*

ARGUMENTS

-filter *expression*

Filters the collection with the value specified by expression. For any taps that match the *patterns* argument, the expression is evaluated based on the specified tap attributes. If the expression is evaluated to be true, the tap is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the value of the pattern arguments as real regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions, rather than with simple wildcard patterns. Note that the -regexp and -exact options are mutually exclusive.

-nocase

Makes the pattern matching case-insensitive.

-exact

Disables the simple pattern matching. This is used when searching for objects that contain wildcard characters, like asterisks (*) and question marks (?) symbols. The -exact and -regexp options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

Matches each pattern in *patterns* at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

patterns

Matches tap names against patterns. Patterns can include wildcard characters asterisks (*) and question marks (?) symbols or regular expressions, depending on the use of the -regexp option.

DESCRIPTION

The **get_taps** command retrieves a collection of taps that are currently in the session context of the current design. The command returns a collection of the taps that match the patterns and pass the filter criteria (if specified). If no object matches the criteria, an empty collection is returned.

Use the -regexp option to enable regular expression matching in the same way as using the TCL regexp command. When using the -regexp option, be careful of the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression matching begins at the beginning of an object name and stops at the end of an object name. You can widen the search simply by adding the period and asterisk symbols (.*) to the beginning or end of the expressions as needed.

You can use the **get_taps** command at the command prompt, or nest it as an argument to another command, like the **query_objects** command. In addition, you can assign the result of the **get_taps** run to a variable.

When issued from the command prompt, the **get_taps** command behaves as though the **query_objects** command has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. To change the setting, use the *collection_result_display_limit* variable.

The "implicit query" property of the **get_taps** command provides a fast and simple way to display cells in a collection. However, if you want the flexibility provided by **query_objects** (for example, if you want to display the object class), use the **get_taps** command as an argument to the **query_objects** command.

EXAMPLES

The following example queries all taps that match a pattern TAP?2, except for the TAP_42.

```
prompt> get_taps -filter full_name!=TAP_42 TAP_?2
{"TAP_12", "TAP_22", "TAP_32", "TAP_52"}
```

The following example queries all taps.

```
prompt> get_taps

{"TAP_1", "TAP_2", "TAP_3", "TAP_4"}
```

SEE ALSO

create_taps(2)
remove_taps(2)
report_taps(2)

get_techs

Creates a collection of technology data objects loaded into memory. You can assign these technology data objects to a variable or pass them into another command.

SYNTAX

collection **get_techs**
[-all]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *objects*]

Data Types

expression string
objects list
patterns list

ARGUMENTS

-all

Returns the technology data objects of both the explicitly opened libraries and their reference libraries.

By default, the command returns only the technology data objects of the explicitly opened libraries.

-filter *expression*

Filters the collection with *expression*.

For any technology data objects that match *patterns* (or *objects*), the expression is evaluated based on the technology data object's attributes. If the expression evaluates to true, the technology data object is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~

and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The **-regexp** and **-exact** options are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The **-exact** and **-regexp** options are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *objects*

Creates a collection of technology data objects of the specified objects. In this case, each object is either a library or a block collection. In case of block, the technology data object of the containing library will be returned. **-of_objects** and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches technology data object names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

DESCRIPTION

The **get_techs** command creates a collection of technology data objects from those currently loaded into memory that match certain criteria. The command returns a collection if any of the technology data objects match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_techs** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_techs** result to a variable.

When issued from the command prompt, **get_techs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the

shell.common.collection_result_display_limit application option.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example creates a technology data object in the specified library. The following **get_techs** command returns the created technology data object.

```
prompt> create_tech -library r4000 tcbn90g
{r4000}
prompt> get_techs -of_objects [get_libs r4000]
{tcbn90g}
```

The following example replaces the existing technology data object by creating a new technology data object in the current library. The following **get_techs** command returns the created technology data object.

```
prompt> create_tech -force tcbn90g
{tcbn90g}
prompt> get_techs -of_objects [current_lib]
{tcbn90g}
```

get_terminals

Creates a collection by selecting terminals from the design.

SYNTAX

collection **get_terminals**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_lib_cell]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
of_objects list
patterns list
region list
point list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the specified expression. For each terminal in the collection, the expression is evaluated based on the

terminal's attributes. If the expression evaluates to true, the terminal is included in the result.

To see the list of terminal attributes that you can use in the expression, use the **list_attributes -application -class terminal** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive. use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the ==, =~, and !~ filter operators.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for terminal level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-include_lib_cell

Search for terminals in the **lib_cell**. By default, **lib_cell** vias are excluded from search.

This option must be used with the **-hierarchical** option.

patterns

Creates a collection of terminals whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *port_list*

Creates a collection of terminals connected to the specified ports.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all terminals at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all terminals that are completely inside the specified region and doesn't include terminals which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all terminals that are completely inside the specified region and the terminals which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all terminals which are abut/touching from inside or outside to the specified region and the

terminals whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of terminals by selecting terminals from the specified design or the current design.

The command returns a collection if any terminals match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **get_attribute**. In addition, you can assign the result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of terminals named reset or with a prefix of clock:

```
prompt> get_terminals [list reset clock*]
{reset clock}
```

The following example creates a collection of terminals with attribute filtering.

```
prompt> get_terminals  -filter {port_name == reset}
{reset}
```

The following example creates a collection of all terminals belonged to the port "reset".

```
prompt> get_terminals -of_objects {reset}
{reset}
```

SEE ALSO

query_objects(2)
remove_terminals(2)
shell.common.collection_result_display_limit(3)
wildcards(3)

get_timing_arcs

Creates a collection of timing arcs for custom reporting and other processing.

SYNTAX

collection **get_timing_arcs**
[-design *design*]
[-to *to_list*]
[-from *from_list*]
[-of_objects *object_list*]
[-filter *expression*]
[-quiet]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]

Data Types

design collection
to_list list
from_list list
object_list list
expression string
exact_count integer
minimum_count integer

ARGUMENTS

-design *design*

Specifies the top-level design for finding objects.

By default, objects are found in the current design.

-to *to_list*

Specifies the to pins or to ports to get the timing arcs for. All backward arcs from the specified pins or ports are considered.

You must specify one of the following options: **-to**, **-from**, or **-of_objects**.

-from *from_list*

Specifies the from pins or from ports to get the timing arcs for. All forward arcs from the specified pins or ports are considered.

You must specify one of the following options: **-to**, **-from**, or **-of_objects**.

-of_objects *object_list*

Specifies the cells or nets for which to get the timing arcs. If you specify a cell, all cell arcs of that cell are considered. If you specify a net, all net arcs of that net are considered.

You must specify one of the following options: **-to**, **-from**, or **-of_objects**.

-filter *expression*

Filters the collection with the specified expression.

For any objects that match, the command evaluates the expression based on the timing arc's attributes. If the expression evaluates to true, the timing arc is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-expect *exact_count*

Specifies the expected number of objects to find. If the command finds a different number of objects, it raises a Tcl error and stops processing.

-expect_at_least *minimum_count*

Specifies the minimum number of objects to find. If the command finds fewer objects, it raises a Tcl error and stops processing.

DESCRIPTION

The **get_timing_arcs** command creates a collection of timing arcs for custom reporting or other operations. Use the **foreach_in_collection** command to iterate among the arcs in the collection. You can use the **get_attribute** command to obtain information about the timing arcs. You can also use a filter expression to filter the arcs that satisfy the specified conditions. To see the attributes supported on timing arcs, use the **list_attributes -application -class timing_arc** command.

Multicorner-Multimode Support

This command works only on the mode associated with the current scenario.

EXAMPLES

The following example reports the to-pin and from-pin for the timing arcs of the ffa cell.

```
prompt> set arcs [get_timing_arcs -of_objects [get_cells ffa]]
prompt> foreach_in_collection arc $arcs {
? set fpin [get_attribute $arc from_pin]
? set tpin [get_attribute $arc to_pin]
? set from_pin_name [get_attribute $fpin full_name]
? set to_pin_name [get_attribute $tpin full_name]
? echo $from_pin_name -> $to_pin_name
? }
ffa/CP -> ffa/D
ffa/CP -> ffa/D
ffa/CP -> ffa/Q
ffa/CP -> ffa/QN
```

ffa/CD -> ffa/Q
ffa/CD -> ffa/QN

rise_exclude_list list
fall_exclude_list list
paths_per_endpoint int
max_path_count int
lesser_slack_limit float
mode_list list
corner_list list
scenario_list list
group_list list

ARGUMENTS

-from *from_list*

Specifies a list of from pins, ports, cells, or clocks to be processed. Path startpoints are typically the input ports or clock pins of registers. If you specify a clock, all startpoints are considered if they are clocked by the clock.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-to *to_list*

Specifies a list of to pins, ports, cells, or clocks to be processed. Path endpoints are typically the output ports or data pins of registers. If you specify a clock, all endpoints are considered if they are constrained by the clock.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

-fall_to *fall_to_list*

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-through *through_list*

Specifies a list of through pins, ports, cells, or nets to be processed. Only paths through the named objects are considered.

You can specify many *through_list* groups by using multiple **-through** options. The objects specified within one **-through** option are assumed to be in OR mode. The group of objects specified with multiple **-through** options is assumed to be in AND mode.

If you specify **-through** only one time, the tool generates only the paths that travel through one or more of the objects in the list.

If you specify multiple **-through** options, the tool generates only the paths that travel through one or more of the objects in each list. the tool uses the exact order in which the **-through** options are listed; so to obtain correct results, you must ensure that this

order is the same as that followed by the actual paths in the circuit.

-rise_through *rise_through_list*

Similar to the **-through** option, except that the path must rise through the objects specified.

-fall_through *fall_through_list*

Similar to the **-through** option, except that the path must fall through the objects specified.

-exclude *exclude_list*

Excludes all data paths from, through, or to specified list of pins, ports, nets, and cell instances. If a cell instance is specified, all pins of the cell are excluded. The **-exclude** option

o Takes precedence over the **-from**, **-through**, and **-to** options.

o Is exclusive with the **-rise_exclude** and **-fall_exclude** options.

o Does not apply to borrowing path from the **-trace_latch_borrow** option or clock path from the **-path full_clock** or **full_clock_expanded** option.

Note that this option is intended for use in conjunction with **-from**, **-through** and **-to** options and can lead to long runtime when used on its own, i.e. without other such topological options.

-rise_exclude *rise_exclude_list*

This option is the same as the **-exclude** option, but applies only to paths rising at the named pins, ports, nets, or cell instances.

-fall_exclude *fall_exclude_list*

This option is the same as the **-exclude** option, but applies only to paths falling at the named pins, ports, nets, or cell instances.

-delay_type max | **min** | **min_max** | **max_rise** | **max_fall** | **min_rise** | **min_fall**

Specifies the type of path delay. Valid values are **max** (the default), **min**, **min_max**, **max_rise**, **max_fall**, **min_rise**, or **min_fall**. The "rise" or "fall" suffix in the delay type refers to a rising or falling transition at the path endpoint.

-path_type full_clock | **full_clock_expanded**

Specifies the structure of the generated timing path objects. The allowed values are **full_clock** and **full_clock_expanded**, which create clock objects for the timing_path's **launch_clock_paths** and **capture_clock_paths** attributes. The **full_clock_expanded** value creates clock path objects that include the path between a primary clock and related generated clocks.

-report_by design | **mode** | **corner** | **scenario** | **group**

Specifies the grouping criteria for generating paths. The default is **design**. It is an error to specify both the **-report_by** and **-sort_by** options.

-sort_by group | **slack**

Specifies the sorting criteria for generating paths. Valid values are: **group** or **slack**. It is an error to give both the **-report_by** and **-sort_by** options. This option is deprecated, use the **-report_by** option instead.

-nworst *paths_per_endpoint*

Retrieves the *n* worst paths to endpoint, where *paths_per_endpoint* is >= 1. The default is 1, meaning that only the worst path to an endpoint is considered. Specifying larger values of *paths_per_endpoint* increases runtime.

-max_paths *max_path_count*

Specifies the maximum number of paths to retrieve per path group, where *max_path_count* is >= 1. The default is 1.

-slack_lesser_than *lesser_slack_limit*

Retrieves only paths with a slack less than **lesser_slack_limit**. With this filtering in effect, it might not be possible to find enough paths to satisfy the **-max_paths** and **-nworst** parameters. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not have a defined slack.

-pba_mode none | path | exhaustive

Specifies one of the following path-based analysis modes:

- **none** - Disables path-based analysis.
- **path** - Performs path-based analysis on paths after they have been gathered.
- **exhaustive** - Performs an exhaustive path-based analysis to determine the worst path-based analysis path set in the design. You cannot use the **exhaustive** mode together with the **-start_end_pair** or option.

-start_end_pair

Retrieves paths for each pair of startpoint and endpoint based on connectivity. This option can lead to long runtime and can lead to generating a huge number of paths depending on the design. By default, this option searches only for paths that are violating. This default can be changed by having an explicit -slack_lesser_than option. The options that do not work with this option are -nworst, -max_paths, -report_by. Unlike other options of the get_timing_paths command, this option causes the paths returned to no longer be sorted based on slack. Instead, paths are arranged based on the endpoint with those sharing the same endpoint appearing next to one another. The maximum number of paths returned is limited to 2000000.

-modes *mode_list*

Specifies the modes for which to generate paths. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option will be processed. If this option is not given, the command will process scenarios of all modes. If none of the **-modes**, **-corners**, or **-scenarios** options are given, the command will process every active scenario of the design. It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to generate paths. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option will be processed. If this option is not given, the command will process every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to generate paths. Each of the specified scenarios is processed. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, every scenario of the design will be processed.

-groups *group_list*

Specifies the list of path group names for generating paths. The default is all path groups. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not belong to any path group.

-exception *exception_type*

Prints user-specified timing exceptions, namely false paths, multicycle paths, and minimum and maximum delays, that are satisfied per timing path being reported. Only "dominant" exception type is acceptable, which is to report the dominant exception constraint used for the reported path.

Note: The additional analysis required per path with the -exceptions option is not trivial. Therefore, using a report_timing command with the -exceptions option is expected to execute slower than the exact same command without this option. The -exceptions option does not work with -path_type short/end/end_detailed option and forces the -input_pins option.

-include_hierarchical_pins

Includes any hierarchical pins that the generated paths pass through. By default, the paths include only ports and actual leaf cell driver and load pins. If a hierarchical pin is a path start or end point, it will of course always be included.

DESCRIPTION

The **get_timing_paths** command creates a collection of timing path objects for custom reporting or other operations. Use the **foreach_in_collection** command to iterate among the timing paths in the collection. You can use the **get_attribute** and **collection** commands to obtain information about the timing paths. A collection of timing_paths can easily be printed by passing it to the **report_timing** command.

If the **time.report_unconstrained_paths** application option is set to **true**, the command will search for unconstrained paths to endpoints for which constrained paths cannot be found. Searching for unconstrained paths can cause significantly longer runtimes.

The following attributes are among those supported on timing path objects:

arrival
capture_clock_paths
check_value
clock_uncertainty
common_path_pessimism
corner
corner_name
crpr_common_point
design_name
driving_cell_adjustment
endpoint
endpoint_clock
endpoint_clock_arrival_close_edge_type
endpoint_clock_arrival_open_edge_type
endpoint_clock_close_edge_arrival
endpoint_clock_close_edge_type
endpoint_clock_close_edge_value
endpoint_clock_is_inverted
endpoint_clock_is_propagated
endpoint_clock_latency
endpoint_clock_name
endpoint_clock_open_edge_arrival
endpoint_clock_open_edge_type
endpoint_clock_open_edge_value
endpoint_clock_period
endpoint_name
full_name
input_delay
launch_clock_paths
lib_name
mode
mode_name
name
network_latency
object_class
path_group
path_group_name
path_type

points
propagation_type
required
slack
source_latency
startpoint
startpoint_clock
startpoint_clock_arrival_open_edge_type
startpoint_clock_is_inverted
startpoint_clock_is_propagated
startpoint_clock_latency
startpoint_clock_name
startpoint_clock_open_edge_arrival
startpoint_clock_open_edge_type
startpoint_clock_open_edge_value
startpoint_clock_period
startpoint_name

Note that the launch_clock_paths and capture_clock_paths attributes are set only if specified by the **-path_type** option.

The following attributes are among those supported on clock_path objects:

clock
clock_edge_type
clock_edge_value
clock_latency
clock_name
corner
corner_name
design_name
driving_cell_adjustment
endpoint
endpoint_name
full_name
lib_name
mode
mode_name
name
object_class
path_type
points
propagation_type
source_clock
source_clock_edge_type
source_clock_edge_value
source_clock_name
source_latency
startpoint
startpoint_name

One attribute of a timing path or clock path is the *points* collection. A timing point object corresponds to a pin or port along the path. Iterate through these points with **foreach_in_collection** and get attributes on them by using the **get_attribute** command. The following attributes are among those for timing points of a timing path or clock path:

arrival
capacitance
delay

delta_delay
fanout
full_name
name
object
object_class
object_name
rise_fall
transition

For information about creating collections and iterating over the elements of a collection, see the **collections** and **foreach_in_collection** man pages.

For a complete list and descriptions of the attributes on timing_path, clock_path, and timing_port objects, see the **timing_path_attributes**, **clock_path_attributes**, and **timing_point_attributes** man pages.

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following command returns the two worst timing paths that rise from reg/latch/CP with slack less than 20.0.

```
prompt> get_timing_paths -nworst 2 -path_type full_clock -permanent \
  -rise_from reg/latch/CP -slack_lesser_than 20.0 -report_by group
```

If you use the **-pba_mode** option, path recalculation (path-based analysis) is used during the path search, and the worst recalculated paths meeting your criteria are returned. This option requires that a path search is performed to ensure that the paths being returned truly are the worst paths. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing improvement from path-based analysis increases, the runtime for the path search increases. Large **-nworst** values can significantly increase the time needed for the search.

get_topological_constraints

Creates a collection of topological pin feedthrough constraints from the current design.

SYNTAX

collection **get_topological_constraints**
[-hierarchical]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
exact_count integer
minimum_count integer
patterns list
of_objects list

ARGUMENTS

-hierarchical

Returns topological pin constraints for the entire design hierarchy. By default, the command returns constraints for the current level.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the topological constraint attributes. You can determine the topological constraint attributes by using the **list_attributes** command. If the expression evaluates to **true**, the topological constraint is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the

=~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the topological constraints associated with the specified objects. The objects can be constraint owner objects of type net/bundle, or the objects can be the start/end objects. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the topological constraint names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

This command creates a collection of topological constraints from the current design that match certain criteria. The command returns a collection handle (identifier) if any topological constraints match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_topological_constraints** command at the command prompt or nest it as an argument to another command (such as **report_topological_constraint**). You can also assign the **get_topological_constraints** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example returns the topological constraints from the current_design

```
prompt> get_topological_constraints
{TPF_CONSTRAINT_0 TPF_CONSTRAINT_1 TPF_CONSTRAINT_3 TPF_CONSTRAINT_4}
```

The following example returns the topological constraints owned by net \'net1\'

```
prompt> get_topological_constraints -of_objects net1
{TPF_CONSTRAINT_1 TPF_CONSTRAINT_3}
```

The following example returns the topological constraints that have the 'start_sides' attribute set

```
prompt> get_topological_constraints -filter "start_sides!=\"\""
{TPF_CONSTRAINT_1 TPF_CONSTRAINT_4}
```

SEE ALSO

create_topological_constraint(2)
remove_topological_constraints(2)
report_topological_constraints(2)

get_topology_edges

Creates a collection by selecting topology edges from the current block.

SYNTAX

collection **get_topology_edges**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list
of_objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology edge attributes. You can determine the topology edge attributes by using the **list_attributes** command. If the expression evaluates to **true**, the topology edge is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for topology edges.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for topology edges level-by-level relative to the current instance. Use this option with *patterns* and not with the **-of_objects** option.

patterns

Matches the topology edge names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

-of_objects *of_objects*

Creates a collection containing the topology edges that are associated with the specified objects.

If the objects are topology nodes, the command returns the topology edges which the topology nodes are connected to, i.e. the set of topology edges which have the specified topology nodes as their start_node or end_node.

If the objects are topology plans, the command returns the topology edges owned by the plans.

If the objects are topology repeaters, the command returns the topology edges which own the repeaters.

If the objects are nets, supernets, or bundles, the command returns the topology edges that have one or more of those objects in their "objects" attribute collection.

If the objects are constraint groups, the command returns the topology edges which are members of the specified constraint groups.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

This command creates a collection of topology edges that meet the selection criteria. It returns a collection handle if one or more topology edges meet the selection criteria. If no topology edges match the selection criteria, it returns an empty string.

You can use the **get_topology_edges** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of topology_edges by matching the name against the pattern:

```
prompt> get_topology_edges TOPOLOGY_EDGE*
{curplan/TOPOLOGY_EDGE0 curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2}
```

The following example creates a collection of all topology_edges:

```
prompt> get_topology_edges *
{curplan/TOPOLOGY_EDGE0 curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2 plan0/medge0 plan0/medge1}
```

The following example creates a collection of all topology_edges connected to topology_node "mynode":

```
prompt> get_topology_edges -of_objects [get_topology_nodes mynode]
{curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2}
```

get_topology_nodes

Creates a collection by selecting topology nodes from the current block.

SYNTAX

collection **get_topology_nodes**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *of_objects* | -of_ref_nodes *node_list*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list
of_objects list
node_list list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology node attributes. You can determine the topology node attributes by using the **list_attributes** command. If the expression evaluates to **true**, the topology node is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for topology nodes.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for topology nodes level-by-level relative to the current instance. Use this option with *patterns* and not with the **-of_objects** option.

patterns

Matches the topology node names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

-of_objects *of_objects*

Creates a collection containing the topology nodes that are associated with the specified objects.

If the objects are topology edges, the command returns the topology nodes which are connected as endpoints of the objects, i.e. the set of topology nodes which are either the start_node or end_node of the specified topology edges.

If the objects are topology_plans, the command returns the topology nodes owned by the plans.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

-of_ref_nodes *node_list*

Creates a collection topology nodes that reference the nodes in *node_list*.

DESCRIPTION

This command creates a collection of topology nodes that meet the selection criteria. It returns a collection handle if one or more topology nodes meet the selection criteria. If no topology nodes match the selection criteria, it returns an empty string.

You can use the **get_topology_nodes** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of topology_nodes by matching the name against the pattern:

```
prompt> get_topology_nodes TOPOLOGY_NODE*
{curplan/TOPOLOGY_NODE0 curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2}
```

The following example creates a collection of all topology_nodes:

```
prompt> get_topology_nodes *
{curplan/TOPOLOGY_NODE0 curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2 plan0/mnode0 plan0/mnode1}
```

The following example creates a collection of all topology_nodes that are endpoints of a collection of topology_edges:

```
prompt> get_topology_nodes -of_objects [get_topology_edges myedge*]
{curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2}
```

SEE ALSO

get_topology_plans

Creates a collection by selecting topology plans from the current block.

SYNTAX

collection **get_topology_plans**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list
of_objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology plan attributes. You can determine the topology plan attributes by using the **list_attributes** command. If the expression evaluates to **true**, the topology plan is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for topology plans.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for topology plans level-by-level relative to the current instance. Use this option with *patterns* and not with the **-of_objects** option.

patterns

Matches the topology plan names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

-of_objects *of_objects*

Creates a collection containing the topology plans that are associated with the specified objects.

If the objects are topology nodes or topology edges, the command returns the topology plans own those nodes and edges.

If the objects are topology_repeaters, the command returns the topology plans which own the edges that own the repeaters.

If the objects are nets, supernets, or bundles, the command returns the topology plans that have one or more of those objects in their "objects" attribute collection.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

This command creates a collection of topology plans that meet the selection criteria. It returns a collection handle if one or more topology plans meet the selection criteria. If no topology plans match the selection criteria, it returns an empty string.

You can use the **get_topology_plans** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of topology_plans by matching the name against the pattern:

```
prompt> get_topology_plans TOPOLOGY_PLAN*
{TOPOLOGY_PLAN0 TOPOLOGY_PLAN1 TOPOLOGY_PLAN2}
```

The following example creates a collection of all topology_plans:

```
prompt> get_topology_plans *
{myplan0 myplan1 TOPOLOGY_PLAN0 TOPOLOGY_PLAN1 TOPOLOGY_PLAN2}.in -0.25in
```

SEE ALSO

create_topology_plan(2)
remove_topology_plans(2)
current_topology_plan(2)
report_topology_plans(2)

get_topology_repeaters

Creates a collection by selecting topology repeaters from the current block.

SYNTAX

collection **get_topology_repeaters**
[-filter *expression*]
[-quiet]
[-design *design_name*]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns* | -of_objects *of_objects*]

Data Types

expression string
design_name string
exact_count integer
minimum_count integer
patterns list
of_objects list

ARGUMENTS

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology repeater attributes. You can determine the topology repeater attributes by using the **list_attributes** command. If the expression evaluates to **true**, the topology repeater is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-design *design_name*

Specifies the design module in which to search for topology repeaters.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

-expect_each_pattern_matches

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

-hierarchical

Searches for topology repeaters level-by-level relative to the current instance. Use this option with *patterns* and not with the **-of_objects** option.

patterns

Matches the topology repeater names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

-of_objects *of_objects*

Creates a collection containing the topology repeaters that are associated with the specified objects.

If the objects are topology edges, the command returns the topology repeaters which are owned by the edges.

If the objects are topology plans, the command returns the topology repeaters owned by the topology edges owned by the plans.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

DESCRIPTION

This command creates a collection of topology repeaters that meet the selection criteria. It returns a collection handle if one or more topology repeaters meet the selection criteria. If no topology repeaters match the selection criteria, it returns an empty string.

You can use the **get_topology_repeaters** command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example creates a collection of topology_repeaters by matching the name against the pattern:

```
prompt> get_topology_repeaters TOPOLOGY_REPEATER*
{curplan/edge0/TOPOLOGY_REPEATER0 curplan/edge0/TOPOLOGY_REPEATER1
curplan/edge0/TOPOLOGY_REPEATER2}
```

SEE ALSO

create_topology_repeater(2)
remove_topology_repeaters(2)
get_topology_edges(2)
get_topology_plans(2)
report_topology_plans(2)

get_trace_option

Get the current option value controlling behavior of command tracing and output annotation..

SYNTAX

get_trace_option [-command name
|-profile
|-memory_threshold
|-cpu_threshold
|-time_treshold]
[-annotate | -is_traced]

string *name*

ARGUMENTS

-command *name*

This option is mutually exclusive with -profile, -memory_threshold, -cpu_threshold, and -time_threshold. The option identifies the command for which tracing or annotation option is returned.

-annotate

If this option is given, then the *annotate* setting for the given command is returned. This option is mutually exclusive with -is_traced and is meaningful only in combination with the -command option.

-is_traced

If this option is given, then returns 1 if the given command is traced and logged, 0 otherwise. This option is mutually exclusive with -annotate and is meaningful only in combination with the -command option.

-profile

This option is mutually exclusive with all others. The option returns a list of the currently enabled profile metrics, or "all" if all metrics are enabled.

-memory_threshold

This option is mutually exclusive with all others. The option returns the currently set memory profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

-cpu_threshold

This option is mutually exclusive with all others. The option returns the currently set cpu profile threshold, if any, in seconds. If no threshold is set, then it returns the string "unset".

-time_threshold

This option is mutually exclusive with all others. The option returns the currently set wall clock time profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

DESCRIPTION

The command is used to query the current setting for the command annotation option that is set with the set_trace_option command, or profile metric settings.

EXAMPLES

The following example sets the annoation type of the **get_attribute** command.

```
prompt> get_trace_option -command get_attribute -annotate
annotate
```

The following example sets, then gets, the currently enabled profile metrics.

```
prompt> set_trace_topion -profile {cpu time}
prompt> get_trace_topion -profile
cpu time
```

The following example gets the threshold for memory profile metric before one has been set.

```
prompt> get_trace_option -memory_threshold
unset
```

The following example will list the commands in the Builtins command group that are not traced and logged.

```
prompt> foreach cmd [dict get [get_defined_commands -details -groups Builtins] commands] {
?  if {![get_trace_option -command $cmd -is_traced]}
?    {echo $cmd}
?  }
```

SEE ALSO

log_trace(2)
annotate_trace(2)
set_trace_option(2)

get_tracks

Creates a collection of tracks from the current design.

SYNTAX

collection **get_tracks**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count integer
minimum_count integer
patterns string
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on bound attributes. You can determine the shape attributes by using the **list_attributes** command. If the expression evaluates to **true**, the shape is included in

the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for tracks level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *of_objects*

Creates a collection of tracks that are located on the specified layers or in the specified edit groups. Each object in the list can be a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the track names in the current design against the specified patterns. You can specify the patterns by using the following formats:

- A collection of tracks
- An asterisk (*), which indicates all tracks
- Track names, which are in the format TRACK_*object_id*

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all tracks at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all tracks that are completely inside the specified region and doesn't include tracks which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all tracks that are completely inside the specified region and the tracks which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all tracks which are abut/touching from inside or outside to the specified region and the tracks whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input

polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command returns a collection of tracks of the current design that meet the selection criteria. You can use this command to query the tracks inside the database by layer, by point, or by region. You can also use this command to query tracks by filtering their attributes.

EXAMPLES

The following example returns the tracks that are located on the METAL2 layer.

```
prompt> get_tracks * -filter "layer~=METAL2"
{"TRACK_4683"}
```

The following example returns all tracks.

```
prompt> get_tracks "TRACK_*"
{"TRACK_4683 TRACK_5389"}
```

The following examples shows how to use the **get_attribute** command to query the value of a track attribute.

```
prompt> get_attribute [get_tracks  TRACK_43] layer_name
METAL2
prompt> get_attribute [get_tracks  TRACK_43] layer
{"METAL"}

prompt> get_attribute [get_tracks TRACK_43] bbox
{{0.000 0.000} {100.000 100.000}}

prompt> get_attribute [get_tracks TRACK_43] start
0.000 0.000
```

To get a complete report of the attribute values of all tracks, use the **report_attributes** command.

SEE ALSO

get_attribute(2)

report_attributes(2)

get_undo_info

Returns information about the undo history and the undo system.

SYNTAX

array **get_undo_info**
[-name *marker_name* | -current | -system | -user | -all | -command *command_name*]
[-details]

Data Types

marker_name string
command_name string

ARGUMENTS

-name *marker_name*

Return information about the undo marker with the specified user or system name.

-current

Return information about the current undo marker. If the system is at its most recent state, then no marker is the current marker and an empty string will be returned.

-system

Return a list of all system-generated markers in the undo history.

-user

Return a list of all user-generated markers in the undo history.

-all

Return a list of all markers in the undo history.

-command *command_name*

Return information about the undoability of the specified command.

-details

When used with the *-all*, *-user*, or *-system*, include detailed information about each marker in the returned marker list.

DESCRIPTION

This command returns information about the undo system, the undo history, and the undoability of commands. If the *-name* or *-current* option is used, an array of information about the specified marker is returned. The *-name* option specifies the marker with user or system name *marker_name*. The *-current* option specifies the marker corresponding to the current point in undo history, being the point before the command represented by the marker in the case of system markers. If system is at its most recent state, then no marker is the current marker, and an empty string will be returned.

If the *-all*, *-user*, or *-system* option is used, then a list of names of all, user-generated, or system-generated markers will be returned, respectively. If the *-details* option is also used, then a list of arrays of complete information about the specified markers is returned.

The following attribute/value pairs are included in marker information arrays (note: user markers are created with the *create_undo_marker* command; system markers are automatically created whenever an undoable command is executed):

marker	System name - always non-empty
name	User name - non-empty for user markers
command_name	Name of the command this marker corresponds to - non-empty for system markers
memory	Memory used by the marker to store data required to transition system state to or from the next more recent marker or the latest state if there are no more recent markers.
current	True if this is the current marker, false otherwise.

If the *-command* option is used, this command returns 0, 1, or 2 if the command is not undoable, undoable, or unknown to the undo system, respectively.

If no options are specified, then this command returns an array of information about the undo system.

EXAMPLES

The following gets a detailed list of all undo markers:

```
prompt> get_undo_info -all -details
{marker "SNPS_MARKER_131923" name "my_marker" command_name "" memory 0 current false}
{marker "SNPS_MARKER_131924" name "" command_name "create_edit_group" memory 19932 current false}
{marker "SNPS_MARKER_131925" name "" command_name "add_to_edit_group" memory 20416 current false}
```

The following gets a list of all system markers:

```
prompt> get_undo_info -system
"SNPS_MARKER_131924" "SNPS_MARKER_131925"
```

The following gets a list of all user markers:

```
prompt> get_undo_info -user
"my_marker"
```

The following gets the undoability of the *place_and_optimize_design* command:

```
prompt> get_undo_info -command place_and_optimize_design
Information: The command 'place_and_optimize_design' is not undoable. (UNDO-015)
0
```

unset(2)

get_user_units

This command returns a string representing the input or output unit for one quantity type.

SYNTAX

string **get_user_units**
  -input | -output
  -type *unit_type*
  [-numeric]

string *unit_type*

ARGUMENTS

-input

Get the unit for data input. Either **-input** or **-output** must be specified.

-output

Get the unit for data output. Either **-input** or **-output** must be specified.

-type *unit_type*

Specifies the type of quantity, which must be one of "time", "resistance", "capacitance", "voltage", "power" or "current".

-numeric

If specified, return the value as a number representing the unit value in terms of the base unit for that quantity type. Base units are seconds, Ohms, Farads, Volts, and Amperes.

DESCRIPTION

This command returns a string representing the input unit for one quantity type. The tool maintains separate units for input and input. There are input unit values for time, resistance, capacitance, power, voltage and current.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example shows how to get the input unit for time. With the **-numeric** option, the value is returned in terms of the base unit for that quantity type (seconds, for time).

```
prompt> get_user_units -input -type time
1.00ps
prompt> get_user_units -input -type time -numeric
1e-12
```

SEE ALSO

report_user_units(2)
set_user_units(2)

get_utilization_configurations

Creates a collection of utilization configurations from the scopes lib, tech and block.

SYNTAX

collection **get_utilization_configurations**
[-block *block*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-scope scope]
[patterns]

Data Types

expression string
patterns list
scope string

DESCRIPTION

This command creates and returns a collection of all the existing utilization configurations.

ARGUMENTS

-block *block*

Specifies the block in which the configurations are to be found.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the utilization-configuration attributes. You can determine the utilization-configuration attributes by using the **list_attributes** command. If the expression evaluates to **true**, the specific configuration is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-scope *scope*

The values it can take are 'lib', 'tech' and 'block'. By default, the order of search is block, lib and then tech i.e. the configuration is first searched in the current block, then the current library and finally the tech associated with the current library.

patterns

Matches the configuration names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

EXAMPLES

The following example lists the configurations created through the **create_utilization_configuration** command.

```
prompt> create_utilization_configuration config_lib -capacity core_area -scope lib
prompt> create_utilization_configuration config_tech -capacity boundary -scope tech
prompt> create_utilization_configuration config_block -capacity site_array -scope block

prompt> get_utilization_configurations
{config_lib config_tech config_block}
prompt> get_utilization_configurations -scope lib
{config_lib}
prompt> get_utilization_configurations -scope tech
{config_tech}
prompt> get_utilization_configurations -scope block
```

{config_block}

SEE ALSO

create_utilization_configuration(2)
remove_utilization_configurations(2)
report_utilization(2)

get_via_defs

Creates a collection by selecting via_defs from a block or tech.

SYNTAX

collection **get_via_defs**
[-design *design*]
[-library *library*]
[-tech *tech*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns | -of_objects *of_objects*

Data Types

design collection
library collection
tech string
expression string
exact_count int
minimum_count int
patterns string
of_objects list

ARGUMENTS

-design *design*

Specifies the block for finding via_defs. If neither a design nor tech is specified, the current block is used.

-library *library*

Specifies the tech for finding via_defs. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used.

-tech *tech*

Specifies the tech for finding via_defs. If neither a design nor tech is specified, the current block is used.

-filter *expression*

Filters the collection with *expression*. For any via_def that matches the patterns option, the expression is evaluated based on the via_def's attributes. If the expression evaluates to *true*, the via_def is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the via_def attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive. **-nocase** and **-exact** are mutually exclusive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the via_defs of the specified vias. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches the via_def names against the patterns in the specified block or tech.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

This command creates a collection of via_defs by selecting via_defs from the specified block or tech that meet the selection criteria. It returns a collection handle if one or more via_defs meet the selection criteria. If no via_defs match the selection criteria, it returns

an empty string.

Use the **get_via_defs** command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

EXAMPLES

The following example creates the collection of all custom via_defs used in the current block:

```
prompt> get_via_defs -of_objects VIA_C*
{FATVIA12_230_530 FATVIA12_530_230}
```

The following example creates the collection of all via_defs from the tech of library 'test' with cut layer VIA1 :

```
prompt> get_via_defs -tech [get_techs -of_objects test] -filter "cut_layer_name == VIA1"
{VIA12 FATVIA12}
```

SEE ALSO

get_attribute(2)
query_objects(2)
report_via_defs(2)

get_via_ladders

Creates a collection by selecting via ladder from the design.

SYNTAX

collection **get_via_ladders**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any via ladder that match the patterns option, the expression is evaluated based on the attributes of the via ladder. If the expression evaluates to *true*, the via ladder is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the via ladder attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for vias level-by-level relative to the current instance. This option is useful only with *patterns* and not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the via ladders connected to the specified net. Each object in the list is a name, pattern, or collection.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via ladder names against the patterns in the current design. You can specify the patterns with the following formats:

- * (asterisk) indicates all via ladders

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

This command creates a collection of via ladders by selecting via ladders from the current design that meet the selection criteria. It returns a collection handle if one or more via ladders meet the selection criteria. If no via ladders match the selection criteria, it returns an empty string.

Use the **get_via_ladders** command as an argument to another command or assign its result to a variable. Refer to the example

below for more information.

See the collection command man page for information about working with collections.

EXAMPLES

The following example create via ladder collections of net MemData[31]:

```
prompt> get_via_ladders -of_objects MemData[31]
{VIA_LADDER_0}
```

The following example gets all via ladders using '*' :

```
prompt> get_via_ladders *
{VIA_LADDER_0 VIA_LADDER_1}
```

The following example gets via ladders using regular expression match :

```
prompt> get_via_ladders -regexp VIA_LADDER_.
{VIA_LADDER_0 VIA_LADDER_1}
```

SEE ALSO

get_attribute(2)
report_attributes(2)

get_via_matrixes

Creates a collection by selecting via matrixes from the design.

SYNTAX

collection **get_via_matrixes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*]
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any via matrix that match the patterns option, the expression is evaluated based on the via matrix's attributes. If the expression evaluates to *true*, the via matrix is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the via matrix attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for vias level-by-level relative to the current instance. This option is useful only with *patterns* and not with **-of_objects**.

-of_objects *of_objects*

Creates a collection containing the via matrixes connected to the specified net, or edit groups. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via matrix names against the patterns in the current design. You can specify the patterns with the following formats:

- * (asterisk) indicates all via matrixes

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all via_matrices at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-at** option.

-within *region*

Creates a collection that contains all via_matrices that are completely inside the specified region and do not overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

In addition, you cannot use the **-hierarchical** option with the **-within** option.

-touching *region*

Creates a collection that contains all via_matrices that are inside the specified region, including those that overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-touching** option.

-intersect *region*

Creates a collection that contains all via_matrices that intersect the boundary of the specified region and at least part of the via_matrix is outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-intersect** option.

DESCRIPTION

This command creates a collection of via matrixes by selecting via matrixes from the current design that meet the selection criteria. It returns a collection handle if one or more via matrixes meet the selection criteria. If no via matrixes match the selection criteria, it returns an empty string.

Use the **get_via_matrixes** command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

EXAMPLES

The following examples create via matrix collections of net MemData[31]:

```
prompt> get_via_matrixes -of_objects MemData[31]
{VIA_MATRIX_0}
```

The following examples get all via matrixes for the same via definition VIA12 :

```
prompt> get_via_matrixes -filter "via_def_name==VIA12"
{VIA_MATRIX_0 VIA_MATRIX_1}
```

SEE ALSO

get_attribute(2)
query_objects(2)

get_via_regions

Creates a collection of via regions in the frame block that match the specified criteria.

SYNTAX

collection **get_via_regions**
[-design *block*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
patterns
| -of_objects *of_objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

block collection
expression string
exact_count int
minimum_count int
patterns string
of_objects list
region list
point list

ARGUMENTS

-design *block*

Specifies the block for finding via_regions. If no design is specified, the current block is used.

-filter *expression*

Filters the collection with *expression*. For any via_regions that match the patterns option, the expression is evaluated based on the attributes for the via_region. If the expression evaluates to *true*, the via_region is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the via_region attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a real regular expression rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matching case-insensitive. **-nocase** and **-exact** are mutually exclusive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies the expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing terminates.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing terminates.

-expect_each_pattern_matches

Forces each pattern in *patterns* to match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing terminates.

-of_objects *of_objects*

Creates a collection containing the via_regions of the specified terminals. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via_region names against the patterns in the specified block.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all via_regions at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-within *region*

Creates a collection that contains all via_regions that are completely inside the specified region and doesn't include via_regions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-touching *region*

Creates a collection that contains all via_regions that are completely inside the specified region and the via_regions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-intersect *region*

Creates a collection that contains all via_regions which are abut/touching from inside or outside to the specified region and the via_regions whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

DESCRIPTION

This command creates a collection of via_regions by selecting via_regions from the specified block that meet the selection criteria. It returns a collection handle if one or more via_regions meet the selection criteria. If no via_regions match the selection criteria, it returns an empty string.

Use the **get_via_regions** command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

EXAMPLES

The following example creates the collection of all via_regions of terminal Reset in current block:

```
prompt> get_via_regions -of_objects Reset
{Reset/VR_0 Reset/VR_1}
```

The following example creates the collection of all system via_regions in current block:

```
prompt> get_via_regions * -filter "type == SYSTEM"
{D1/VR_0  D1/VR_1}
```

SEE ALSO

create_via_region(2)
get_attribute(2)
query_objects(2)
report_via_regions(2)

get_via_rules

Returns a collection by selecting via_rules from a block and tech.

SYNTAX

collection **get_via_rules**
[-design *design*]
[-library *library*]
[-tech *tech_object*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns* | -of_objects *of_objects*]

Data Types

design collection
library collection
tech_object collection
expression string
exact_count integer
minimum_count integer
patterns string
of_objects list

ARGUMENTS

-design *design*

Specifies the block for finding via_rules. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

-library *library*

Specifies the tech for finding via_rules. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

-tech *tech_object*

Specifies the tech for finding via_rules. If neither a design nor tech is specified, the current block is used. If current block is not set

then current lib is used.

-filter *expression*

Filters the collection with *expression*. For any via rule that match the patterns option, the expression is evaluated based on the via rule's attributes. If the expression evaluates to *true*, the via rule is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-of_objects *of_objects*

Creates a collection containing the via rules of the specified techs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches via rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_via_rules** command creates a collection of via rules from the specified block scope and the tech scope that match certain criteria. The command returns a collection of via rules if any via rule matches the criteria. If no objects match the criteria, the empty

string is returned. By default, the command returns the via rules in both block and tech scope. If the search is to be limited to either block or tech scope, the same can be specified as an option.

You can use the **get_via_rules** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_via_rules** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the via rules in the block and tech scope of the current block.

```
prompt> get_via_rules
{VR1 VL1 VL1}
```

SEE ALSO

collections(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

get_vias

Creates a collection by selecting vias from the design.

SYNTAX

collection **get_vias**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_shield]
[-shield_only]
[-include_lib_cell]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design collection
expression string
exact_count integer
minimum_count integer
patterns string
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with *expression*. For any via that match the patterns option, the expression is evaluated based on the via's attributes. If the expression evaluates to *true*, the via is included in the result. By default, this option is off.

Use the **list_attributes** command to determine the via attributes.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for vias level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-include_shield

Specifies to include the shielding vias when -of_objects contains nets. It is only valid when -of_objects contains nets.

This option is mutually exclusive with -shield_only.

-shield_only

Specifies to get the shielding vias only when -of_objects contains nets. It is only valid when -of_objects contains nets.

This option is mutually exclusive with -include_shield.

-include_lib_cell

Search for vias in the **lib_cell**. By default, **lib_cell** vias are excluded from search.

This option must be used with -hierarchical option.

-of_objects *of_objects*

Creates a collection containing the vias connected to the specified net, port, terminal, lib_pin, or edit groups. Each object in the list is a name, pattern, or collection.

When ports are specified by **-of_objects**, **get_vias** searches for vias attached to the terminals associated with the specified ports.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via names against the patterns in the current design. You can specify the patterns with the following formats:

- * (asterisk) indicates all vias
- *VIA** indicates all vias
- *VIA_S** indicates all simple vias
- *VIA_C** indicates all custom vias
- *VIA_C_120* indicates one simple via.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all vias at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all vias that are completely inside the specified region and doesn't include vias which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching ***region***

Creates a collection that contains all vias that are completely inside the specified region and the vias which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect ***region***

Creates a collection that contains all vias which are abut/touching from inside or outside to the specified region and the vias whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of vias by selecting vias from the current design that meet the selection criteria. It returns a collection handle if one or more vias meet the selection criteria. If no vias match the selection criteria, it returns an empty string.

Use the **get_vias** command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

EXAMPLES

The following examples create via collections of net n300:

```
prompt> get_vias -of_objects n300
{"VIA_C_67"}
```

The following examples get all vias from the same via definition VIA12 :

```
prompt> get_vias -filter "via_def_name==VIA12"
{"VIA_S_120", "VIA_S_122", "VIA_S_123"}
```

SEE ALSO

get_attribute(2)
query_objects(2)

get_view_switch_list

Returns the value of the specified design, library, or global view switch list.

SYNTAX

string **get_view_switch_list**
[-design *design* | -library *library* | -global]
[-explicit]

Data Types

design string
library string

ARGUMENTS

-design *design*

Specifies the design for which to return the view switch list. This option is mutually exclusive with the **-library** and **-global** options.

-library *library*

Specifies the library for which to return the view switch list. This option is mutually exclusive with the **-design** and **-global** options.

-global

Returns the global, session-wide view switch list. This option is mutually exclusive with the **-design** and **-library** options.

-explicit

Returns the view switch list that was explicit set on the specified entity. If this option is not specified, the command returns the effective view switch list that is applied to the entity in the case where no view switch list was explicitly set.

DESCRIPTION

This command returns the effective view switch list of a design, library, or global session.

The view switch list is a precedence-ordered list of design views that is applied when attempting to bind a design. If you explicitly set the switch list for the design, then that view switch list is used. If not explicitly set, the command returns the view switch list for the design's owning library. If the owning library does not have a view switch list that was explicitly set, then the global view switch list is used. The view switch list attribute is persistent for designs and libraries, but not for the global session.

It is an error to specify more than one of the **-global**, **-library**, or **-design** options. If none of these options are specified, the command returns the global view switch list. An empty view switch list is displayed as "{ }". If you specified the **-explicit** option and the command returns an empty view switch list, then no explicitly set view switch list exists on the entity. If you omitted the **-explicit** option and the command returns an empty view switch list, then the view switch list is empty for this entity and its owners. If the entity is a design in this case, then it cannot be bound.

EXAMPLES

The following example gets the effective view switch list of design "mydesign":

```
prompt> get_view_switch_list -design mydesign
abstract outline
```

The following example gets the effective view switch list of library "mylib":

```
prompt> get_view_switch_list -library mylib
frame abstract design
```

The following examples each get the global view switch list:

```
prompt> get_view_switch_list
design frame abstract outline
```

```
prompt> get_view_switch_list -global
design frame abstract outline
```

SEE ALSO

get_virtual_connections

Gets a list of virtual connection that match the specified input criteria.

SYNTAX

status **get_virtual_connections**
patterns
| -of_objects *objects*

Data Types

patterns list
objects list

ARGUMENTS

patterns

Matches virtual connection names against patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type virtual connection.

-of_objects *objects*

The command returns a list of virtual connection connected to the specified objects. Each object can be a pin, port and cell.

DESCRIPTION

This command gets a list of virtual connection that match the specified input criteria.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples get the virtual connection.

prompt> **get_virtual_connections SNPS_VC_1**

```
prompt> get_virtual_connections {SNPS_VC_1 SNPS_VC_2}

prompt> get_virtual_connections VC*

prompt> get_virtual_connections \
    -of_objects [get_pins {U212/ZN U256/I}]

prompt> get_virtual_connections \
    -of_objects [get_cells {U300 U391}]

prompt> get_virtual_connections \
    -of_objects [get_ports WriteAdd[0]]

prompt> get_virtual_connections \
    -of_objects {U300/ZN U212 MemData[0]}
```

SEE ALSO

add_pins_to_virtual_connection(2)

remove_virtual_connections(2)
set_attribute(2)

get_voltage_area_rules

Returns a collection of voltage_area_rules from the design.

SYNTAX

collection **get_voltage_area_rules**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[*patterns*]

Data Types

design collection
expression string
exact_count int
minimum_count int
patterns string

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the voltage_area_rule attributes. You can determine the voltage_area_rule attributes by using the **list_attributes** command. If the expression evaluates to **true**, the voltage_area_rule is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are

mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. Wildcards are considered as plain characters. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches voltage_area_rule names against *patterns*. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

This command creates a collection of voltage_area_rules from the design. The command returns a collection handle (identifier) if any voltage_area_rules match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_voltage_area_rules** command at the command prompt or nest it as an argument to another command (such as **report_voltage_area_rules**). You can also assign the **get_voltage_area_rules** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following example returns a collection of voltage_area_rules with names starting with "RULE".

prompt> **get_voltage_area_rules RULE***

The following example returns a collection of voltage_area_rules which allow physical feedthrough.

```
prompt> get_voltage_area_rules -filter is_physical_feedthrough_allowed
```

SEE ALSO

create_voltage_area_rule(2)
remove_voltage_area_rules(2)
report_voltage_area_rules(2)

get_voltage_area_shapes

Creates a collection of voltage_area shapes from the current design.

SYNTAX

collection **get_voltage_area_shapes**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design string
expression string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the voltage_area shapes attributes. You can determine the voltage_area shapes attributes by using the **list_attributes** command. If the expression

evaluates to **true**, the voltage area shapes are included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for voltage area shapes level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *objects*

Creates a collection containing the voltage_area shapes of the specified voltage_areas, power_domains, cells, or edit groups. Each object in the list is a name, pattern, or collection.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the *pattern*.

patterns

Matches the voltage_area shape names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all voltage area shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all voltage area shapes that are completely inside the specified region and doesn't include voltage area shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all voltage area shapes that are completely inside the specified region and the voltage area shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all voltage area shapes which are abut/touching from inside or outside to the specified region and the voltage area shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses *

(asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of voltage_area shapes from the current design that match certain criteria. The command returns a collection handle (identifier) if any voltage_area shapes match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_voltage_area_shapes** command at the command prompt or nest it as an argument to another command (such as **remove_voltage_area_shapes**). You can also assign the **get_voltage_area_shapes** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns voltage_area shapes of a voltage_area

```
prompt> get_voltage_area_shapes -of_objects [get_voltage_area VA_1]
{VA1}
```

get_voltage_areas

Creates a collection of voltage_areas from the current design.

SYNTAX

collection **get_voltage_areas**
[-design *design*]
[-filter *expression*]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect *exact_count*]
[-expect_at_least *minimum_count*]
[-expect_each_pattern_matches]
[-hierarchical]
[*patterns*
| -of_objects *objects*
| -at *point*
| -within *region*
| -touching *region*
| -intersect *region*]

Data Types

design string
expression string
exact_count integer
minimum_count integer
patterns list
objects list
point list
region list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-filter *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the voltage_area attributes. You

can determine the voltage_area attributes by using the **list_attributes** command. If the expression evaluates to **true**, the voltage_area is included in the collection. By default, this option is off.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

-hierarchical

Searches for voltage areas level-by-level relative to the current instance. This option is useful with *patterns*, **-within**,**-touching**, **-intersect** and **-at**, but not with **-of_objects**.

-of_objects *objects*

Creates a collection containing the voltage_areas associated with the specified objects. The objects can be voltage_area shapes, power domains, supply nets, cells, or edit groups. Each object in the list is a name, pattern, or collection.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the voltage_area names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the **-regexp** option.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all voltage_areas at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all voltage_areas that are completely inside the specified region and doesn't include voltage_areas which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-touching *region*

Creates a collection that contains all voltage_areas that are completely inside the specified region and the voltage_areas which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

-intersect *region*

Creates a collection that contains all voltage_areas which are abut/touching from inside or outside to the specified region and the voltage_areas whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one

except **-within** and **-intersect** can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. **-hierarchical** can be specified to query objects across physical hierarchies.

DESCRIPTION

This command creates a collection of voltage_areas from the current design that match certain criteria. The command returns a collection handle (identifier) if any voltage_areas match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the **get_voltage_areas** command at the command prompt or nest it as an argument to another command (such as **report_voltage_areas**). You can also assign the **get_voltage_areas** result to a variable.

See the **collections** command man page for information about working with collections.

EXAMPLES

The following returns voltage_area from its shapes

```
prompt> get_voltage_areas -of_objects [get_voltage_area_shapes VOLTAGE_AREA_SHAPE_1]
{VA_1}
```

SEE ALSO

create_voltage_area(2)

get_vsdc

Get the name of the current VSDC file.

SYNTAX

boolean **get_vsdc**

DESCRIPTION

This command prints the name of the VSDC file that is currently open for recording VSDC guidance for Formality. If no VSDC file has been specified using the **set_vsdc** command, a message is printed.

EXAMPLES

In this example, we query the name of the VSDC file and find out that setup information is not being recorded yet. Then we specify the file name and repeat the query.

```
prompt> get_vsdc
VSDC guidance is not enabled.
1
prompt> set_vsdc cache_ctrl.vsdc
1
prompt> get_vsdc
The current VSDC file is /project/chip/cache_ctrl/cache_ctrl.vsdc.
1
```

get_working_design_stack

Gets the current working design stack.

SYNTAX

collection **get_working_design_stack**
[-instance]

ARGUMENTS

-instance

When specified the command returns pushed instance of current block within top hierarchy

DESCRIPTION

The command returns a collection that contains the current working design stack or the pushed instance of current block within top hierarchy

The first object of the returned collection is the top-level design, the second is the child design of the top-level design, and so on. The last element of the returned collection is the current working design, which you can get by using the **current_design** command.

EXAMPLES

The following example uses the **get_working_design_stack** command to return the working design stack before and after running the **set_working_design** command.

```
prompt> get_working_design_stack
{ORCA}
prompt> set_working_design -push I_ORCA_TOP/I_BLENDER_4
1
prompt> get_working_design_stack
{ORCA BLENDER_2}
prompt> get_working_design_stack -instance
{I_ORCA_TOP/ORCA BLENDER_2}
```

SEE ALSO

current_design(2)
set_working_design(2)
set_working_design_stack(2)

getenv

Returns the value of a system environment variable.

SYNTAX

string **getenv**
variable_name

Data Types

variable_name string

ARGUMENTS

variable_name

Specifies the name of the environment variable to be retrieved.

DESCRIPTION

The **getenv** command searches the system environment for the specified *variable_name* and sets the result of the command to the value of the environment variable. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the **env** Tcl array variable. The **getenv**, **setenv**, and **printenv** environment commands are convenience functions to interact with this array.

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you set the variable to a new value using the **setenv** command, you see the new value within the application and within any new child processes you initiate from the application using the **exec** command. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the **exec** command, that value is not reflected in the current application.

See the **set**, **unset**, and **printvar** commands for information about working with non-environment variables.

EXAMPLES

In the following example, **getenv** returns you to your home directory:

```
prompt> set home [getenv "HOME"]
/users/disk1/bill

prompt> cd $home

prompt> pwd
/users/disk1/bill
```

In the following example, **setenv** changes the value of an environment variable:

```
prompt> getenv PRINTER
laser1

prompt> setenv PRINTER "laser3"
laser3

prompt> getenv PRINTER
laser3
```

In the following example, the requested environment variable is not defined. The error message shows that the Tcl variable **env** was indexed with the value UNDEFINED, which resulted in an error. In the second command, **catch** is used to suppress the message.

```
prompt> getenv "UNDEFINED"
Error: can't read "env(UNDEFINED)": no such element in array
       Use error_info for more info. (CMD-013)

prompt> if {[catch {getenv "UNDEFINED"} msg]} {
         setenv UNDEFINED 1
        }
```

group_cells

Creates a new level of hierarchy

SYNTAX

collection **group_cells**
[*cell_list*]
[-module_name *module_name*]
[-cell_name *cell_name*]
[-phys_wrapper]
[-hdl_block *block_name*]
[-hdl_all_blocks]
[-hdl_bussed]
[-enable_mim *mim_module_name*]
[-mim_strict]

Data Types

cell_list list
module_name string
cell_name string
block_name string
mim_module_name string

ARGUMENTS

cell_list

Specifies the list of cells that will be grouped into a new level of hierarchy. All of the cells must be instances in the same module. If more than one cell is specified, the list must be enclosed in braces ({}). Cell names cannot be specified with the following options: -hdl_block, -hdl_all_blocks, -hdl_bussed

-module_name *module_name*

Specifies the name to be given to the newly-created module. The specified name is taken as a suggestion; if it is not available, the tool generates a module name automatically and prints a warning message.

If *module_name* is not specified or if the specified name is not available, the tool automatically generates a name of the form "group_0", "group_1", etc.

-cell_name *cell_name*

Specifies the name to be given to the cell that instantiates the new hierarchy. The specified name is taken as a suggestion; if it is not available in the parent module, the tool generates a cell name automatically and prints a warning message.

If *cell_name* is not specified or if the specified name is not available, the tool automatically generates a name of the form "group_cell_0". Since a single counter is used for all tool-generated cell names, the number in the suffix might not start at 0 and might not be sequential across multiple invocations of the command.

-phys_wrapper

Specifies that a single hierarchical cell is being grouped for use with design planning, possibly as a step toward creating a new physical hierarchy. If this option is specified, the new module's ports and nets will have the same names as the corresponding ports and nets in the specified cell, rather than inheriting their names from the parent module's nets. It is an error to specify more than one cell, or to specify a non-hierarchical cell, when using this option.

While the wrapper cell inherits the port and net names from the inner cell, any constraints on those objects are not moved to the wrapper cell.

-hdl_block *block_name*

Groups all cells of a HDL block created in the RTL file. The -hdl_block option requires that you specify HDL block label name in the current instance. Nested HDL block labels are separated by a /(slash); for example, my_process/my_function. block_name must reference a single label name. Wildcards are supported for label names, but they do not match hierarchy characters. If wildcards match multiple labels, the first block with cells is used.

-hdl_all_blocks

Groups all HDL blocks into a level of hierarchy. If only -hdl_all_blocks option is used, it recursively groups all the HDL blocks in the current hierarchy. If used with -hdl_block, all HDL blocks from the block_name label down are recursively grouped.

-hdl_bussed

Places each group of bussed gates created from HDL into a level of hierarchy. If used with -hdl_block option, blocks specified by block_name are recursively grouped.

-enable_mim *mim_module_name*

Specifies the MIM module name for multi instance group_cells. The tool checks and tries to match the groupcells with the target MIM module. It even tries to match them by making possible connection changes. If they are not compatible, it errors out or continues with normal group_cells based on the switch '-mim_strict'.

-mim_strict

This switch directs the MIM group_cells flow to error out or disable in case of errors. If *-mim_strict* is present it errors out else gives warning and continues with the normal group_cells.

DESCRIPTION

This command groups any number of cells in the same parent module into a new module, and instantiates that module as a cell instance in the original parent module. The cells do not have to be in the current block or current instance, but all cells to be grouped have to be in the same parent module. A collection containing the newly-created cell is returned.

If *-phys_wrapper* is not specified, the new module's ports will have the same name as the nets to which they are connected in the parent module, and the connected nets inside the new module will have the same name as their ports. Cells and other nets within the new module retain their original names (but the hierarchical paths from the top module to the grouped nets and cells will be different).

The new module's port directions are determined automatically based on the driver and load pins connected both inside and outside the new hierarchy.

This command operates on a single instance of the parent module that contains the cells being grouped. If that module is multiply

instantiated, a separate, unique module will be created for this instance and the new hierarchy will appear only in that instance's module.

For -hdl_block, -hdl_all_blocks, and -hdl_bussed options, only HDL blocks within the current instance can be referenced. To reference HDL blocks inside submodules, use the current_instance command to change the current instance to the parent block containing the HDL block. References to recursive grouping in the ARGUMENTS section refer to nested labels within the current instance, not to logical design hierarchy.

EXAMPLES

The following example groups two cells in parent cell "mid1" into a new module "BOT" with cell instance "bot1":

```
prompt> group_cells -module_name BOT -cell_name bot1 {mid1/U1 mid1/U2}
{bot1}
prompt> get_cells mid1/bot1/*
{mid1/bot1/U1 mid1/bot1/U2}
```

The following example groups all cells named "decoder_*" into a new module, allowing the tool to generate the new module and cell names:

```
prompt> group_cells [get_cells decoder_*]
{group_cell_4}
prompt> current_instance group_cell_4
group_cell_4
prompt> get_cells
{group_cell_4/decoder_1 group_cell_4/decoder_0}
```

The following example groups all cells in all the HDL blocks into separate level of hierarchy (or modules);

```
prompt> current_instance bot1
prompt> group_cells -hdl_all_blocks
{group_cell_0 group_cell_1 ...}
```

The following example groups all cells in the HDL function named bar and the process named proc into a module:

```
prompt> current_instance bot1
prompt> group_cells -hdl_block proc/bar
{group_cell_0}
```

The following example groups all bussed gates under the process named proc into separate level of hierarchy (or modules):

```
prompt> current_instance bot1
prompt> group_cells -hdl_block proc -hdl_bussed
{group_cell_0 group_cell_1 ...}
```

The following example shows usage of group_cells with MIM and mim_strict;,

```
prompt> current_instance bot1
prompt> group_cells -cell_name mm1 -enable_mim hier1 -mim_strict
{group_cell_0 group_cell_1 ...}
prompt> group_cells -cell_name mm1 -enable_mim hier1 -mim_strict
{group_cell_3 group_cell_4 ...}
```

range_value float
from_list list
rise_from_list list
fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
priority_level list
comment string

ARGUMENTS

-name *group_name*

Specifies a name for the path group.

If a group with this name already exists, the paths are added to that group. If a group with this name does not exist, a new group is created.

The **-name** and **-default** options are mutually exclusive; you must specify one of these options.

-default

Removes the specified endpoints or paths and moves them to the default group.

The **-name** and **-default** options are mutually exclusive; you must specify one of these options.

-weight *weight_value*

Specifies a cost function weight for this group.

The *weight_value* argument must be a number between 0.0 and 100.0; the default is 1.0.

A weight of 0.0 eliminates the paths in this group from cost function calculations. Do not use very small values such as 0.0001. Smaller values can prevent the tool from implementing small improvements to the design.

If you use the **-weight** option when you add members to an existing group, the tool uses the new weight for the group.

-critical_range *range_value*

Specifies a margin of delay for this group during optimization.

The *range_value* argument must be positive or 0.0; the default is defined by the **set_critical_range** command, whose default is 0.0.

A range of 0.0 means that only the most critical paths (the ones with the worst violation) are optimized. If you specify a nonzero range, other near-critical violating paths (one per endpoint) within that amount of the worst path are also optimized if possible.

To optimize more than one critical path to an endpoint, use a separate **group_path** command for each distinct critical path to that endpoint. To optimize all violating paths, specify a range value that is larger than any expected path violation.

-from *from_list*

Specifies the timing path startpoints. A valid startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified.

If you specify a clock, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected.

You can use only one of the following options: **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Specifies the timing path startpoints. This option is similar to the **-from** option, except that the path must rise from the specified objects.

If you specify a clock object, this option selects the startpoints launched by the rising edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Specifies the timing path startpoints. This option is similar to the **-from** option, except that the path must fall from the specified objects.

If you specify a clock object, this option selects startpoints launched by the falling edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: **-from**, **-rise_from**, and **-fall_from**.

-through ***through_list***

Specifies the timing path throughpoints. A valid throughpoint is a port, pin, or leaf cell. If you specify more than one throughpoint, they must be enclosed in either quotation marks ("") or braces ({}).

The path grouping applies only to paths that pass through one of the throughpoints.

You can use multiple **-through** options in a single command. If you use multiple **-through** options, the path grouping applies to paths that pass through each set of throughpoints in the order in which they were specified. In other words, the path must first pass through a throughpoint specified in the first **-through** option, then through a throughpoint specified in the second **-through** option, and so on for every **-through** option.

If you the **-through** option with the **-from** or **-to** options, the path grouping applies only if all the conditions are satisfied.

-rise_through ***rise_through_list***

Specifies the timing path throughpoints. This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects.

You can use multiple **-rise_through** options in a single command.

-fall_through ***fall_through_list***

Specifies the timing path throughpoints. This option is similar to the **-through** option, but applies only to paths with a falling transition at the specified objects.

You can use multiple **-fall_through** options in a single command.

-to ***to_list***

Specifies the timing path endpoints. A valid endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified.

If you specify a clock, all registers and primary outputs related to that clock are used as path endpoints. If you specify a cell, one path endpoint on that cell is affected.

You can use only one of the following options: **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Specifies the timing path endpoints. This option is similar to the **-to** option, but applies only to paths that rise at the endpoint.

If you specify a clock object, this option selects the endpoints captured by the rising edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Specifies the timing path endpoints. This option is similar to the **-to** option, but applies only to paths that fall at the endpoint.

If you specify a clock object, this option selects the endpoints captured by the falling edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: **-to**, **-rise_to**, and **-fall_to**.

-priority ***priority_level***

Assigns a priority to the command to resolve conflicting path selections between different **group_path** commands. By default, different **group_path** commands follow ordinary rules of priority to resolve conflicting path selections. For example, a command

using **-from** and **-to** to select paths has priority over a conflicting command that selects a subset of those paths using **-through**, so the latter command is ignored for the paths that could be in either. By setting a higher priority in the command using the **-through** option, its path selection is honored, overriding the usual order of priority on paths in the intersection of the two groups. If unspecified, the priority is 0. You can set the priority for a **group_path** command to any integer 0 or greater.

-comment ***comment***

Specifies a comment string for the command.

The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out by the **write_sdc** or **write_script** command. The comment remains intact throughout the design flow.

DESCRIPTION

This command groups a set of paths or endpoints for cost function calculations in optimization and analysis. The delay cost function is the sum of all groups (weight * violation), where violation is the cost of the worst path in the path group. If no violation occurs within a group, the group cost is zero. The weight of the default group is 1.0.You can use path groups to optimize even though there might be larger violations in another group.

The **create_clock** command automatically creates a path group for a new clock with a weight of 1.0 and the same name as the clock name. By default, clock-gating check and asynchronous preset and clear check paths will be added to the clock group they relate to.

The **time.use_special_default_path_groups** application option may be used to alter this behavior.

In presence of special inbuild path group, the tool follows the following precedence rules for assigning group paths:

Order of precedence from highest to lowest is:

a) User defined group path

b) Special inbuilt group path (async and clock_gating only) **set_app_options -name time.use_special_default_path_groups -value true**

c) IO group path **set_app_options -name time.enable_io_path_groups -value true**

d) Default clock group

By default, the tool allows pulling paths from special built-in path groups like: **async_default**, **clock_gating_default** into user-defined path groups, which is different from PrimeTime. To match PrimeTime precedence rule for group path, use the following application option:

set_app_options -name time.special_path_group_precedence primetime

To remove a path group, use the **remove_path_groups** command. To report path group information for a design, use the **report_path_groups** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example groups all endpoints clocked by CLK1A or CLK1B into a new group named group1 with a weight of 2.0.

```
prompt> group_path -name group1 \
  -weight 2.0 -to {CLK1A CLK1B}
```

The following example adds OUT1 and ff34/D to the existing path group named ADDR.

```
prompt> group_path -name ADDR \
  -to {OUT1 ff34/D}
```

The following example removes OUT1 and CLK2 from existing groups and places them in the default group.

```
prompt> group_path -default \
  -to {OUT1 CLK2}
```

The following example groups all paths from inputs I1 and I2 to outputs O5 and O7 into a group named serious with a weight of 10.0.

```
prompt> group_path -name serious \
  -weight 10.0 -from {I1 I2} -to {O5 O7}
```

The following example groups the paths that begin at A1, pass through B1, then pass through C1, and end at D1 into a group named group2.

```
prompt> group_path -name group2 \
  -from A1 -through B1 -through C1 -to D1
```

The following example groups the paths that begin at A1, pass through either B1 or B2, then pass through either C1 or C2, and end at D1 into a group named group3.

```
prompt> group_path -name group3 \
  -from A1 -through {B1 B2} -through {C1 C2} -to D1
```

gui_add_annotation

Adds an annotation to the layout window.

SYNTAX

status **gui_add_annotation**
[-window *window_name*]
[-group *group_type*]
[-type *shape_type*]
[-symbol_type *symbol_type*]
[-symbol_size *symbol_size*]
[-text *text*]
[-color *color*]
[-pattern *pattern*]
[-width *line_width*]
[-line_style *line_style*]
[-info_tip *info_tip*]
[-query_text *query_text*]
[-query_command *query_command*]
[-radius *radius*]
points

Data Types

window_name string
group_type string
shape_type string
symbol_type string
symbol_size string
text string
color string
pattern string
line_width string
line_style string
info_tip string
query_text string
query_command string
radius float
points list

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window. If window name is omitted, the annotation will apply to all layout windows.

-group *group_type*

Specifies the annotation group. If group name is omitted, the **global** name is used.

-type *shape_type*

Specifies the type of annotation. The supported values for this option are

rect
line
arrow
polygon
polyline
text
symbol
ruler
manhattan_ruler
circle
circular_ruler

The default is rect.

-symbol_type *symbol_type*

Specifies the type of symbol annotation. This option is only valid when annotation type is symbol. The supported values for this option are

square
x
triangle
diamond

The default is square.

-symbol_size *symbol_size*

Specifies the size of symbol annotation. An even symbol size will grow one automatically to find the appropriate center point. The default symbol size is 3.

-text *text*

Specifies the annotation text.

-color *color*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes may be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette.

-pattern *pattern*

Specifies the annotation fill pattern. The default fill pattern is none. An empty value forces the tool to use the window default value, which is usually set to solid fill.

-width *line_width*

Specifies the annotation line width. The default line width is 1.

-line_style *line_style*

Specifies the annotation line style. The default line style is none. An empty value forces the tool to use the window default value, which is usually set to solid line.

-info_tip *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_text *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_command *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation
%x the x position clicked in design coordinates
%y the y position clicked in design coordinates

-radius *radius*

Specifies the radius of circle annotation. This option is only valid when annotation type is circle.

points

Specifies the points for the specified annotation type. The points are specified by a tool command language (Tcl) list in which each list element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.
- bbox_ul : the annotation is placed at the upper left of the bounding box of the object.
- bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

DESCRIPTION

This command defines a new annotation and returns a collection containing that annotation if it is successful.

EXAMPLES

Create a green rectangle annotation.

```
prompt> gui_add_annotation -window Layout.1 \
  -type rect -color green {{200 200} {777 777}}
```

Create a light_green rectangle annotation using light_green from the highcontrast palette.

```
prompt> gui_add_annotation -window Layout.1 \
  -type rect -color light_green:highcontrast {{200 200} {777 777}}
```

Create a light_green x annotation of size 100 using light_green from the highcontrast palette.

```
prompt> gui_add_annotation -window Layout.1 \
  -type x -symbol_size 100 -color light_green:highcontrast [list {1835.0010 119.2950}]
```

Create a red polyline annotation in the group Test1.

```
prompt> gui_add_annotation -window Layout.2 \
  -group Test1 -type polyline -color red \
  -width 2 {{123 456} {789 12} {200 200}}
```

Create a line between two cells A and B.

```
prompt> gui_add_annotation -window Layout.1 \
  -type line [list [get_cells A] [get_cells B]]
```

Create a line between the center of largest rectangle of cell A and the center of the largest rectangle of cell B.

```
prompt> gui_add_annotation -window Layout.1 \
  -type line [list [list [get_cells A] center] [list [get_cells B] center]]
```

Create a line between the bottom left of cell A's bounding box and the middle of the top of cell B's bounding box.

```
prompt> gui_add_annotation -window Layout.1 -type line \
  [list [list [get_cells A] bbox_ll] [list [get_cells B] bbox_center 0.0 0.5]]
```

Create a blue rectangle which displays the annotation points using the annotation_query tcl procedure.

```
prompt> proc annotation_query { object window view } { \
 return [get_attribute $object points] \
 }

prompt> gui_add_annotation -window Layout.1 -type rect -color blue \
 -query_text {=annotation_query %object %window %view} -info_tip {annotation points} \
 {{110 110} {160 160}}
```

Create a circle annotation whose center is {100 100} and radius is 10.

```
prompt> gui_add_annotation -type circle -radius 10 {{100 100}}
```

Create a circle annotation whose center is {100 100} and boundary is at point {120 120}

```
prompt> gui_add_annotation -type circle {{100 100} {120 120}}
```

Create a circular ruler annotation with 3 circles (radius 20, 40, 100) at 100, 100.

```
prompt> gui_add_annotation -type circular_ruler {{100 100} {120 100} {140 100} {200 100}}
```

SEE ALSO

gui_add_hotkey_binding

Add additional hotkey binding to a menu item.

SYNTAX

string **gui_add_hotkey_binding**
-menu *MenuName*
-hot_key *HotKey*
[-replace_current_hotkey]
[-menu_root *MenuRoot*]

MenuName *String*
HotKey *String*
MenuRoot *String*

ARGUMENTS

-menu *MenuName*

MenuName specifies the menu item that the hotkey is associated with.

-hot_key *HotKey*

HotKey specifies the accelerator to be associated with the specified menu item.

-replace_current_hotkey

Specifies that the specified hotkey will replace the existing hotkey of the specified menu item.

-menu_root *MenuRoot*

MenuRoot specifies the menu tree that the menu item belongs to.

DESCRIPTION

This command adds or replace a hotkey binding for the specified menu item.

EXAMPLES

The following example creates a menu item and add an additional hotkey to it with this command. Note that the -menu option value in gui_add_hotkey_binding can have the ampersands stripped.

```
gui_add_menu -menu "&Test->Sub&Menu->Echo Hi" -tcl_cmd "echo hi" -hot_key "Ctrl+5"
gui_add_hotkey_binding -menu "Test->SubMenu->Echo Hi" -hot_key "Ctrl+Y"  #add additional hotkey to the menu item.
```

gui_add_missing_vias

Adds missing vias for the selected wires or nets.

SYNTAX

status **gui_add_missing_vias**
[-min_layer *min_layer_name*]
[-max_layer *max_layer_name*]
[-between_adjacent_layers_only]
[-quiet]
[*object_list*]

Data Types

min_layer_name string
max_layer_name string
object_list collection

ARGUMENTS

-min_layer *min_layer_name*

Specifies the name of the minimum bottom layer to consider when adding vias.

-max_layer *max_layer_name*

Specifies the name of the maximum upper layer to consider when adding vias.

-between_adjacent_layers_only

Specifies that vias should be added only between adjacent routing layers. No generation of via stacks is allowed. This option is equivalent to using of sequence of gui_add_missing_vias with adjacent layers specified in -min_layer and -max_layer options for all pairs of adjacent layers

-quiet

Suppress all messages.

object_list

Specifies the net name or net shape for which to create the via. If *object_list* is not specified, the command uses the global selection. If *object_list* is not specified and nothing is selected, the command issues an error message and does not modify the design.

DESCRIPTION

This command adds missing vias for unconnected wires in the GUI. Specify the wires for via insertion by selecting them in the GUI or by specifying the net names or net shapes to the command. For each selected wire, or wire on the selected net, the tool checks for overlaps with another wire, a pin shape or a port shape/terminal on a different layer on the same net. If an overlap is found and no via is present, the command ensures that vias exist so that these objects are connected.

The command considers the following:

Route Type

The route type of the new via is taken from the route type of the existing wire being connected. If there are two wires then the route type of one of the wires is used - which one is chosen is indeterminate.

Connection Point

The new via will be centered on the connection point between the two objects: wire-to-wire, wire-to-pin shape, or wire-to-port shape/terminal. The connection point is calculated by determining the overlap of the two shapes. The command snaps the center of the overlap using the layers and widths of the connecting objects.

Limitations

Vias inserted by this command on PG net wires are limited to only the selected wires and are not allowed for the whole net. This allows you to perform minor repairs and reduces the chance that you will accidently attempt to repair the whole power mesh. Repairing the entire power mesh would be prohibitively slow with this command and is better achieved by using separate power planning commands.

The vias created between PG net wires only use the simplified algorithms available in other route editing tools, such as the Stretch Wire tool and Create Via auto mode. If you need more control over via creation, use the **create_pg_vias** command or other tools available in the GUI.

EXAMPLES

The following example adds missing wires for all the wires on the net N1 between METAL and METAL3 layers.

```
prompt> change_selection [get_nets N1]
prompt> gui_add_missing_vias -min_layer METAL -max_layer METAL3
```

gui_append_utable

Append data rows to an existing UserTable.

SYNTAX

string **gui_append_utable**
-name *Name*
-rows *TCL_Data_List*
-fill_file_column *Name*
-fill_file_suffix *Suffix*
-fill_file_dir *Directory*
-fill_label_column *Name*
-fill_label_value *Value*
-fill_date_column *Name*
-fill_tag_column *Name*
-fill_title_column \fiName

Name String
TCL_DataList TCL List of String List
Suffix File Suffix String
Directory Directory Path String
Value Value String

ARGUMENTS

-name *Name*

The name of an existing UserTable that the new data rows should be added to.

-rows *TCL_Data_List*

A TCL list of string lists that match the number of columns.

-fill_file_column *Name*

The column name that is filled with data from one of the fill options.

-fill_file_suffix *Name*

A file suffix/extension 'filter' used to fill file entries for the column defined by the -fill_column argument.

-fill_file_dir *Directory*

The directory path to search for files matching the file suffix option.

-fill_label_column *Name*

The column name that is filled with a label for each entry added.

-fill_label_value *Value*

The label value used to fill the -fill_label_column argument as each entry is added.

-fill_date_column *Name*

The column name used to fill in the date of the file that was added.

-fill_tag_column *Name*

The column name used to fill in the metadata tag of the file if it exists.

-fill_title_column *Name*

The column name used to fill in the metadata title of the file if it exists.

DESCRIPTION

This command takes a TCL list of lists and tries to append new rows of data to an existing UserTable given by name.

Row columns are filled left to right, first to last, in a given list of lists.
Extra data values in a row list are ignored and if the row list is too short on values it will fill the extra columns with empty fields.

If the **-rows** argument is just a single list of values, it is assumed to be only one row of values that will be added. Again extra row values are ignored and missing row values are filled with empty fields.

Alternatively one can generate rows of data that include columns for file names, file dates, labels and if available in the file the tag and title meta data for all files found according to the specified file suffix and directory.
For more information on Meta Data please see the command *gui_set_utable_meta*.

EXAMPLES

The following example appends two rows of static data given as a TCL list of lists to the given UserTable that has three columns of data.

```
shell> gui_append_utable -name my_table {
...     { /top/ModA  0.01  1000 }
...     { /top/ModB  0.03  5000 }
...   }
```

The following example first creates a TCL list of lists and then appends it to the given UserTable.

```
shell> set rows {}
```

```
shell> ... loop through collection and set vars and append to list...
shell> lappend rows [list $cellname $delay $area]
shell> ...
shell> gui_append_utable -name MyTable -rows $rows
```

gui_bin

Organizes a collection of objects into bins.

SYNTAX

string **gui_bin**
-clct *Clct*
[-attr *Attribute* | -cmd *Command*]
[-lower_bound *Lower_Bound*]
[-lower_bound_strict]
[-upper_bound *Upper_Bound*]
[-upper_bound_strict]
[-boundary *Boundary*]
[-num_bins *Number_of_Bins* | -bin_range *Range_per_Bin*]
[-underflow]
[-overflow]
[-nice_level *Nice_Level*]
[-small_is_good]
[-exact_binning]
[-ignore_values *Ignore_List*]
[-bar_brush *Brush_Pattern*]
[-create_slct_buses]
[-filter_cmd *Filter_Command*]
[-numBin *numBins*]
[-return_values]
[-slct_targets *Selection_Targets*]
[-slct_targets_operation *Selection_Operation*]
[-value_list *Element_Value_List*]

Data Types

Clct collection
Attribute string
Command string
Lower_Bound float
Upper_Bound float
Boundary float
Number_of_Bins integer
Range_per_Bin float
Nice_Level integer
Ignore_List list
Brush_Pattern string
Filter_Command string
numBins integer
Selection_Target list
Selection_Operation string
Element_Value_List list

ARGUMENTS

-clct *Clct*

Specifies the collection of objects that the tool partitions into bins.

-attr *Attribute*

Specifies the attribute that the tool uses to get a floating point value for each object in the collection. The tool places the objects in bins based on these attribute values.

The **-attr** and **-cmd** options are mutually exclusive.

-cmd *Command*

Specifies the tool command language (Tcl) command that the tool uses to get a floating point value for each object in the collection. The tool places the objects in bins based on these values.

The tool replaces all occurrences of %clct in the command with a collection that contains, as its only element, the object used to compute the floating point value for the object. If the tool cannot store the object in a collection, it uses the string "Error" instead.

The tool replaces all occurrences of %string in the command with the name of the object. If the tool cannot compute the name for an object, it uses the string "Error" instead.

The **-cmd** and **-attr** options are mutually exclusive.

-lower_bound *Lower_Bound*

Defines the lower bound for the range of floating point values that the tool uses to place the objects in bins.

If you specify the **-underflow** option, the tool places all the objects with a value that is less than *Lower_Bound* in a separate underflow bin. If you do not specify the -underflow option, the tool discards these objects.

-lower_bound_strict

Forces the tool to use the **-lower_bound** option value as the lower bound of the bin with the smallest values, not including the underflow bin.

If you do not specify the -lower_bound_strict option, the tool sets the lower bound of the bin with the smallest values, not including the underflow bin, to the smallest value that is greater than or equal to the value specified by the **-lower_bound** option.

-upper_bound *Upper_Bound*

Defines the upper bound for the range of floating point values that the tool uses to place the objects in the bins.

If you specify the **-overflow** option, the tool places all the objects with a value that is greater than *upper_Bound* in a separate overflow bin. If you do not specify the **-overflow** option, the tool discards these objects.

-upper_bound_strict

Forces the tool to use the **-upper_bound** option value as the upper bound of the bin with the largest values, not including the overflow bin.

If you do not specify the **-upper_bound_strict** option, the tool sets the upper bound of the bin with the largest values, not including the overflow bin, to the largest value that is less than or equal to the value specified by the **-upper_bound** option.

-boundary *Boundary*

Specifies the boundary value for one of the bins, not including the underflow and overflow bins. This value must fall within the range of values covered by the bins.

If the relevant value distribution has a specific value where the quality of the values change, such as 0 for slack, you can use this option to make sure that no bin contains values on both sides of the boundary value.

-num_bins ***Number_of_Bins***

Specifies the number of bins that this command generates, not counting underflow and overflow bins. The default value is 8.

The **-num_bins** and **-bin_range** options are mutually exclusive. If you specify both of these options, the tool ignores the **-bin_range** option. If you do not specify either of these options, the default value is 8.

-bin_range ***Range_per_Bin***

Specifies the size of the value range represented by each bin.

The **-bin_range** and **-num_bins** options are mutually exclusive. If you specify both of these options, the tool ignores the **-bin_range** option. If you do not specify either of these options, the default value is 8.

-underflow

Collects all the objects with values less than the lower bound value specified by the **-lower_bound** option, and places them in a separate underflow bin. Otherwise, these objects are discarded.

-overflow

Collects all the objects with values greater than the upper bound value specified by the **-upper_bound** option, and places them in a separate overflow bin. Otherwise, these objects are discarded.

-nice_level ***Nice_Level***

Determines how round the boundaries of the bins are. The default value is 10. For rounder boundaries, specify a higher value. If *Nice_Level* is -1, the tool does not attempt to make the boundaries round.

-small_is_good

Sorts the values in every bin in order of decreasing values. By default, the tool sorts the objects in order of increasing values.

In addition, bins with values that are less than the value specified by the **-boundary** option are colored green, and bins with values that are greater than this value are colored red. This is opposite from the default color markings.

-exact_binning

Sets exact boundaries on the left border of the furthest left bin and the right border of the furthest right bin. By default, the tool can adjust these limits to create bins with equal widths.

-ignore_values ***Ignore_List***

Discards the objects with values specified in *ignore_List*.

-bar_brush ***Brush_Pattern***

Specifies the brush pattern for painting bars in a histogram based on the result of the command. The *brush_Pattern* can be one of the following values:

NoBrush SolidPattern Dense1Pattern
Dense2Pattern Dense3Pattern Dense4Pattern
Dense5Pattern Dense6Pattern Dense7Pattern
HorPattern VerPattern CrossPattern
BDiagPattern FDiagPattern DiagCrossPattern

-create_slct_buses

Creates selection buses to return the objects instead of collections.

-filter_cmd *Filter_Command*

Specifies a Tcl command that the **gui_bin** command uses to determine whether a collection in a bin should be filtered out.

The *filter_Command* format is

cmd %clct %attr %value

where *cmd* is a Tcl command or procedure, *%clct* is a collection, *%attr* is the name of the attribute used to create the bins, and *%value* is the maximum value for *%clct*. If the command returns a nonzero value, **%clct** is not placed in a bin.

-numBin *numBins*

This option is obsolete. Do not use it. Use the **-num_bins** option instead.

-return_values

Causes the **gui_bin** command to return the values of elements.

-slct_targets *Selection_Target*

Specifies a list of selection containers to store the objects.

-slct_targets_operation *Selection_Operation*

Specifies an operation applied to the selection containers.

-value_list *Element_Value_List*

Specifies values for the elements in a list. The **gui_bin** command uses these values to create the bins.

DESCRIPTION

The **gui_bin** command creates a list of bins from a collection of objects that you specify with the **-clct** option. The command determines a floating point value for each of the objects by using either an attribute that you specify with the **-attr** option or a Tcl command that you specify with the **-cmd** option.

Each bin is represented by a list that contains the left boundary, the right boundary, the number of objects in the bin, a collection containing the objects in the bin, and the value green or red.

The widths of the bins are equal by default, which means that in some cases the furthest left and furthest right bins might extend the specified boundaries in order to get nice values for the boundaries. If you specify the **-exact_binning** option, the left border of the furthest left bin and the right border of the furthest right bin are set exactly to the specified boundaries.

The collections are sorted with ascending floating point values by default, and a bin is marked green only if the objects it contains have values greater than or equal to the value specified by the **-boundary** option. If you specify the **-small_is_good** option, the values in the collections are sorted with descending floating point values, and a bin is marked red only if the objects it contains have values greater than or equal to the value specified by the **-boundary** option.

The bins cover the complete range of floating point values by default. You can define the covered range by using the -lower_bound, -lower_bound_strict, -upper_bound, and **-upper_bound_strict** options. In this case, you can collect objects with floating point values that are too small or too big and place them into separate underflow and overflow bins by specifying the **-underflow** and **-overflow** options.

You can specify a list of objects with floating point values that can be ignored by using the **-ignore_values** option.

You can specify a bin range size that results in a very large number of bins by using the **-bin_range** option. However, this results in a histogram that is difficult to read and that might take a long time to compute and draw.

The preference variable **hist_max_num_bins** in the Histogram category allows you to set the maximum number of histogram bins. The default value is 100. If a specified range size value causes the number of bins to exceed the value set for this variable, the tool issues an error message and does not create a histogram. The error message includes information about the data range to aid you in specifying a better -bin_range value. This variable is used only in conjunction with the **-bin_range** option and is not used with the **-num_bins** option.

EXAMPLES

The following example creates a list of bins containing the 100 worst paths according to their slack distribution:

```
prompt> set binInfo [gui_bin -clct [get_timing_paths \
  -nworst 100 -max_paths 100] -cmd "get_attribute %clct slack"]
prompt> set bins  [lindex $binInfo 0]
```

SEE ALSO

gui_change_charts_model

Change data in model used in chart's plots

SYNTAX

status **gui_change_charts_model**
-model *model_id*
[-column *string*]
{ -add | -delete | -modify | -calc | -query }
[-header *string*]
[-type *string*]
[-expr *string*]

Data Types

model_id int

ARGUMENTS

-model *model_id*

Model to change (previously created by **gui_create_charts_model** command).

-column *string*

The column name or number to delete, modify, calculate or query.

-add

Add column to model. The *expr* option specifies the expression to use to calculate the values in the new column.

-delete

Delete column from model. Use the *column* option to specify the column to delete.

Note: the original columns of the model cannot be deleted, only newly added columns can be removed after they are created.

-modify

Modifies the values in an existing column. Use the *column* option to specify the column to modify and the *expr* option to specify the expression to use to calculate the new values in the column.

Note: the original columns of the model cannot be modified, only newly added columns can be modified are created.

-calc

Calculate values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the

expression to use to calculate the values.

The calculated values are returned by the command. The model is not modified.

-query

Query values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the expression to use to query the values.

The expression should return true or false and the returned values are those where the expression evaluates to true.

The queried values are returned by the command. The model is not modified.

-header *string*

Specifies the name of the header when adding or modifying a column.

-type *string*

Specify the type of the new column for *add*, *modify* options.

-expr *string*

Specifies the expression to use when adding, modifying, calculating or querying values of a column of the model.

The expression can use tcl variable names that match the column name (as long as the column name is a legal tcl variable name). A few extra variables are also allowed:

- column : current column
- row : current row
- pi : value of pi (3.141592653...)
- NaN : Special 'not a number' real value that can be used to indicate absence of data.

A number of extra functions are allowed as well as the normal tcl expression functions:

- column : get column value for row
- row : get row value for column
- cell : get cell value for row and column
- setColumn : set column value for row
- setRow : set row value for column
- setCell : set cell value for row and column
- header : get header value for column
- setHeader : set header value for column
- type : get type for column
- setType : set type for column
- map : map row number to range
- bucket : get bucket for column value
- norm : normalize column value

- rand : get random number
- rnorm : get normaized random number
- color : get color from name
- remap : map column value to range
- timeval : get time value from column with time format

Some special character sequences in the expression are replaced with model values before the expression is evaluated.

- @<n> : value for specified column number (<n>) for current row.
- @c : column number.
- @r : row number.
- @nc : number of columns.
- @nr : number of rows.
- @v : value for current row and column.
- @{<name>} : value for specified column name (<name>) for current row.
- #{<name>} : column number for specified column name (<name>)

Normally the '@' symbols return data in the value format but this can be forced to be a string by using '@#' instead of '@'.

DESCRIPTION

Change data in existing model to add, delete or modify columns for use in charts.

EXAMPLES

The following example adds a new column to the model where the value is the sum of the first two columns.

```
shell> gui_change_charts_model -model $model -add -expr {column(0) + column(1)} -header Sum
```

SEE ALSO

gui_create_charts_plot(2)
gui_define_charts_proc(2)

gui_change_error_highlight

Manipulates error objects highlight sets.

SYNTAX

string **gui_change_error_highlight**
-add | -remove
[-color *color_id*]
[-selected | -all | -all_visible]
[-type *error_type_list*]
[-layer *layer_strings*]
[-include_net *nets* | -exclude_net *nets*]

color_name A color name
error_type_list A Tcl list of error type names
layer_strings A Tcl list of layer strings
nets A Tcl list of net names or a collection of nets

ARGUMENTS

-add | -remove

Required mutually exclusive option which specifies that the errors are added or removed from the error highlight set. If -add, the specified errors become drawn in the given highlight color. If -remove, the specified errors become drawn in the default violation color.

-color <*color_id*>

This option specifies the color for the operation. If a color is given with the -color option, it must be one of the supported color names: blue, green, light_blue, light_green, light_orange, light_purple, light_red, orange, purple, red, yellow. If -color option is provided with the -add option, the specified color will be used to color the specified errors in the given color. If -color option is provided with the -remove option, errors in the specified color highlight set will be removed from the highlight set and will become drawn in the default violation color. When given with the -remove option, this option is mutually exclusive with -selected, -all, -all_visible, -type, -layer, -include_net, and exclude net options.

-selected

This option is mutually exclusive with -all, -all_visible, -type, -layer, -include_net and -exclude_net. If this option is present, currently selected errors in the current tab error list become highlighted in the specified color.

-all

This option is only meaningful with the -remove and is mutually exclusive with -color, -all_visible, and -selected. When given with the -remove option, removes highlight colors from all errors in all open error views.

-all_visible

This option is mutually exclusive with -selected, -type, -layer, -include_net and -exclude_net. If this option is given with the -add option, currently visible errors in the current tab error list become highlighted in the specified color. If this option is given with the -remove option, all error highlight colors are removed from currently visible errors in the current tab error list. They become drawn in the default violation color.

-type <*error_type_list*>

This option is mutually exclusive with -selected and -all_visible. It may be combined with -layer, and -include_net or -exclude_net. Errors that are of one of the given types become highlighted in the specified color. If combined with layer and/or net specifications, errors must match all given specifications to be selected for highlighting.

-layer <*layer_string_list*>

This option is mutually exclusive with -selected and -all_visible. It may be combined with -type, and -include_net or -exclude_net. Errors that are of one of the given layers become highlighted in the specified color. If combined with error type and/or net specifications, errors must match all given specifications to be selected for highlighting.

-include_net <*nets*>

This option is mutually exclusive with -selected, -all_visible and with -exclude_net. It may be combined with -type and -layer. Errors that are associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

-exclude_net <*nets*>

This option is mutually exclusive with -selected, -all_visible and with -include_net. It may be combined with -type and -layer. Errors that are not associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

DESCRIPTION

The command specifies the color to use in drawing the specified errors. Errors can be drawn in a highlight color by adding them to the error highlight color set. Errors can be removed from the error highlight color set and revert to being drawn in the default violation color. The command behavior is determined by combinations of the options as follows:

Adding errors to a highlight set:

If -color is given with the -add option, the specified errors are added to the error highlight color set and become draw in the specified color. The specified color becomes the current error highlight color.

If -color is omitted with the -add option, the specified errors are added to the current error highlight color set and become draw in the current error highlight color.

If -selected is given with the -add option, selected errors are added to the error highlight color set and become draw in the specified color.

If -all_visible is given with the -add option, all visible errors in the current tab error list are added to the error highlight color set and become draw in the specified color.

If -type, -layer -include_net or -exclude_net is given with the -add option, visible errors in the current tab error list matching the given criteria are added to the error highlight color set and become drawn in the specified color.

Removing errors from a highlight set:

If -color is given with the -remove option, all errors in the specified error highlight color set are removed and become drawn in the

default violation color.

If -selected is given with the -remove option, selected errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all is given with the -remove option, all errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all_visible is given with the -remove option, all visible errors in the current tab error list are removed from respective error highlight color sets and become drawn in the default violation color.

If -type, -layer -include_net or -exclude_net is given with the -remove option, visible errors in the current tab error list matching the given criteria are removed from the respective error highlight color set and become drawn in the default violation color.

EXAMPLES

The following example puts the currently selected errors in the blue error highlight set:

gui_change_error_highlight -add -color blue -selected

The following example puts "Short" type errors associated with a net named "C0_9_" in the red error highlight set:

gui_change_error_highlight -add -color red -type {Short} -include_net {C0_9_}

The following example puts "Floating Port" type errors not associated with NULL net in the green error highlight set. Please note the use of parentheses as delimiters. Since the expected argument for -type and -exclude_net options is a list of strings, multi-word strings or empty string signifying NULL net must be delimited:

gui_change_error_highlight -add -color green -type {{Floating Port}} -exclude_net {{}}

The following example adds all visible errors in the current tab error list to the light_red highlight set:

gui_change_error_highlight -add -color light_red -all_visible

The following example removes all errors from all error highlight sets:

gui_change_error_highlight -remove -all

The following example removes errors in the red color highlight set from the highlight set:

gui_change_error_highlight -remove -color red

The following example removes all visible errors in the current tab error list from highlight sets:

gui_change_error_highlight -remove -all_visible

SEE ALSO

gui_set_selected_errors(2)

gui_change_highlight

Manipulate the set of globally highlighted objects.

SYNTAX

string **gui_change_highlight**

[-add | -remove | -toggle]
[-color *color_id* | -all_colors]
[-collection *clct*]

string *color_id*
collection *clct*

ARGUMENTS

-add

Use -add to highlight a collection of objects in a color specified with color. If -color is not specified, the current color is used. You cannot use -all_colors with -add. You must specify a collection with -collection. If -remove or -toggle are not specified, then -add is implied.

-remove

Use -remove to remove highlighting from objects. Use -collection to remove highlighting from specific objects. Use -color to remove highlighting from objects of a specific color. Use -all_colors to remove all highlighting. If you specify a collection, you cannot specify colors.

-toggle

Use -toggle to toggle the highlight state of a collection of objects. You must use -collection with -toggle, and you cannot use -color or -all_colors. Toggling an object that is highlighted will cause it to no longer be highlighted. Toggling an object that is not highlighted with cause it to be highlighted with the current color. If no operation is specified, then -add is assumed.

-color *color_id*

Specifies the color to be used for the highlight operation. This is mutually exclusive with -all_colors. The allowed colors are blue, light_blue, yellow, purple, light_purple, orange, light_orange, red, light_red, green, and light_green. If neither -color nor -all_colors is specified, then the current highlight color is assumed. You cannot use -color with -toggle.

-all_colors

This option is only valid with -remove. Use this option to clear all highlight colors.

DESCRIPTION

The gui_change_highlight command is used to operate on the set of highlighted objects. Objects can be added or removed from the set, or their presence can be toggled as described above. The set has a current color that can be modified with gui_set_highlight_options(2). The current color is used as needed when no color is specified.

The tool provides eleven built in highlight colors with the names yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

The gui_change_highlight command uses colors from the highlight color palette.

EXAMPLES

Highlight in green all cells with names matching foo*.

```
shell> gui_change_highlight -color green -collection [get_cells foo* -hier -all]
```

Remove highlights from all objects in the collection returned by the get_cells command.

```
shell> gui_change_highlight -remove -collection [get_cells foo* -hier -all]
```

Clear all objects with blue highlights.

```
shell> gui_change_highlight -remove -color blue
```

Clear objects with the current highlight color.

```
shell> gui_change_highlight -remove
```

Clear all highlights.

```
shell> gui_change_highlight -remove -all_colors
```

Toggle the highlight state of all objects in a collection returned by the get_cells command.

```
shell> gui_change_highlight -toggle -collection [get_cells foo*]
```

SEE ALSO

gui_get_highlight(2)
gui_get_highlight_options(2)
gui_set_highlight_options(2)
gui_get_color_value(2)

gui_change_layer

Sets the layer of pins, ports, or net shapes.

SYNTAX

collection **gui_change_layer**

-object *object*
-layer *layer*

Data Types

object collection
layer string

ARGUMENTS

-object *object*

Specifies the collection of objects for which to change the layer.

-layer *layer*

Specifies the name of the layer to use.

DESCRIPTION

The **gui_change_layer** command is used to change the layer of block pins, ports/terminals, and net shapes. Changing the layer of net shapes and terminals creates new shape objects and deletes the existing shapes. The **gui_change_layer** command updates the selection to contain the new objects. Use the **set_object_layer** command instead to avoid updating the selection.

EXAMPLES

The following example changes the layer of the clk_enable block pin.

prompt> **gui_change_layer -object [get_pins TOP/LEVEL_1/clk_enable] -layer METAL2**

SEE ALSO

get_layers(2)
set_object_layer(2)

gui_change_schematic

Performs abstraction on the current or specified schematic view.

SYNTAX

string **gui_change_schematic**
  -type *abstraction_name*
  -operation *operation_name*
  -clct *objects*
  [-window *window_name*]

Data Types

abstraction_name	string
operation_name	string
objects	collection
window_name	string

ARGUMENTS

-type *abstraction_name*

Name of abstraction type. Currently supported types: "Hierarchy".

-operation *operation_name*

Name of operation to be applied for the specified abstraction type. Currently supported operations: "Expand", "Collapse".

-clct *objects*

The collection of objects in the target schematic to which the specified abstraction operation will be applied.

-window *window_name*

Optionally specifies the target schematic to which the abstraction is applied. If not specified, the current application schematic will be the target.

DESCRIPTION

The command applies the specified abstraction operation to the specified objects within the target schematic view.

EXAMPLES

The following example collapses currently selected modules within the current schematic view.

prompt> **gui_change_schematic -type Hierarchy -operation Collapse -clct [get_current_selection]**

gui_change_selection_utable

Change Current Selection by adding objects named in the given table.

SYNTAX

string **gui_change_selection_utable**
-name *Table_Name*
[-obj_col *Col_Name*]
[-filter *Filter*]

Table_Name String
Col_Name String
Filter Table Filter String

ARGUMENTS

-name *Table_Name*

The name of the user table to use for finding object names to add to the current selection.

-obj_col *Col_Name*

The column name containing object names with a data type set. By default it uses the full_name and object_class type or named columns.

-filter *Filter*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

DESCRIPTION

This command takes a table name and if a filter is given, reduces the rows to those that match the filter and then tries to add to the current selection any object names found in those table rows. The object names are searched for in the column given by the *-obj_col* command argument. By default it uses the full_name and object_class type or named columns to determine object names to add to the current selection.

EXAMPLES

The following example adds all object with the object names found in the column 'pins' that match the filter '*ALU*'.

```
shell> gui_change_selection_utable -name my_table -obj_col pins -filter {pins =~ *ALU*}
```

gui_write_utable(2)

gui_change_via_def

Sets the via definition for the specified vias.

SYNTAX

string **gui_change_via_def**
-via *via*
-via_def *via_def*

Data Types

via collection
via_def string

ARGUMENTS

-via *via*

Specifies the collection of vias for which to change the via definition.

-via_def *via_def*

Specifies the name of the new via definition.

DESCRIPTION

The **gui_change_via_def** command is used to change the via definition of vias. By changing the via definition, new vias with different via definitions might be created. The **gui_change_via_def** command updates the selection to contain the new vias. Use the **set_via_def** command instead to avoid updating selection.

EXAMPLES

The following example changes the via definitions on a via named VIA_S_92587 to VIA34.

prompt> **gui_change_via_def -via [get_vias VIA_S_92587] -via_def VIA34**

SEE ALSO

create_via_def(2)
get_via_defs(2)
get_vias(2)
report_via_defs(2)
set_via_def(2)

gui_change_via_size

Sets the attributes for the number of rows and columns in a via collection.

SYNTAX

status **gui_change_via_size**
-via *via*
[-rows *rows*]
[-columns *columns*]

Data Types

via collection
rows integer
columns integer

ARGUMENTS

-via *via*

Specifies the collection of vias for which to change the array size.

-rows *rows*

Specifies the number of rows in the via array.

-columns *columns*

Specifies the number of columns in the via array.

DESCRIPTION

The **gui_change_via_size** command changes the number of rows and columns of vias. By changing the via size, new vias with a different via definitions might be created. The **gui_change_via_size** command updates the selection to contain the new vias. Use the **set_via_def** command instead to avoid updating the selection.

EXAMPLES

The following example changes the array size on a via named VIA_S_92587 to two rows and two columns.

```
prompt> gui_change_via_size -via [get_vias VIA_S_92587] -rows 2 -columns 2
```

SEE ALSO

get_vias(2)
set_via_def(2)

gui_check_drc_errors

Checks for DRC errors on specified objects by using the same DRC mechanism that the interactive route editing tools use.

SYNTAX

int **gui_check_drc_errors**
[-of_objects *objects*]
[-limit_area {*{llx lly} {urx ury}*}]
[-layers *layer_list*]
[-honor_ndr true | false]
[-rules *rule_types*]
[-filter_same_net_spacing true | false]
[-check_fill true | false]
[-max_error_limit *error_limit*]
[-max_shape_limit *shape_limit*]
[-max_processing_time *time_limit*]
[-show]

Data Types

objects collection
llx float
lly float
urx float
ury float
layer_list collection
rule_types list
error_limit integer
shape_limit integer
time_limit integer

ARGUMENTS

-of_objects *objects*

Specifies a collection of net shape and via objects on which the tool performs the DRC checks. By default the DRC check is performed on the selection.

-limit_area {*{llx lly} {urx ury}*}

Specifies a rectangular area in which the tool performs the DRC checks. The tool checks only those shapes of the specified objects that are enclosed within the area or that intersect the bounding box that defines the area.

-layers *layer_list*

Specifies the layers which to check. By default, the tool checks objects on all layers.

-honor_ndr true | **false**

Specifies whether the tool checks the supported nondefault routing rules. If this is not specified, the return value from **get_edrc_setting -honor_ndr** is used as default.

-rules ***rule_types***

Specifies the types of DRC rules that the tool checks. The *rule_types* list can contain one or more of the following DRC error types:

Adjacent Min Edge Length
All
DPT Odd Cycle
DPT Pre-color
Enclosed Via Spacing
End-of-Line Spacing
General Via Spacing
Metal Span Spacing
Metal Width
Minimum Edge
Minimum Length and Area
Open
RDL Acute Angle
RDL Right Angle
Short
Spacing
Via Density
Via Enclosure

All can be used as the list of all other rules except *Open*. If you do not specify this option, the tool uses those relevant option values returned by the **get_edrc_setting** command.

-filter_same_net_spacing true | **false**

Specifies whether the tool ignores spacing violations between objects on the same net. If this is not specified, the return value from **get_edrc_setting -filter_same_net_spacing** is used as default.

-check_fill true | **false**

Specifies whether the tool to check shapes inside fill cells. If this is not specified, the return value from **get_edrc_setting -check_fill** is used as default.

-max_error_limit ***error_limit***

Overrides the maximum number of DRC errors that the tool reports.

A zero or a negative value allows an unlimited number of errors.

If this option is not specified, the return value from **get_edrc_setting -max_error_limit** is used as default.

If the *error_limit* or default limit is reached, the tool issues a warning message in the terminal window, the console log view, and output log file, and then stops writing out further messages.

-max_shape_limit ***shape_limit***

Overrides the maximum number of shapes that the tool can check.

A zero value allows an unlimited number of shapes.

If this option is not specified, the return value from **get_edrc_setting -max_shape_limit** is used as default.

If the number of objects to be checked exceeds *shape_limit*, the command exits without checking. A warning message is issued in the terminal window and the console log view.

-max_processing_time *time_limit*

Specifies the maximum processing time in seconds that the tool can check. If this is not specified, the return value from **get_edrc_setting -max_processing_time** is used as default. The DRC checking terminates when the time limit is reached.

-show

Open the error browser to show violations.

DESCRIPTION

This command performs design rule checks on the specified objects and returns the number of violations found.

The command uses the same DRC mechanism that the route editing tools use during interactive editing operations. The tool writes the violations in the editor DRC error view and loads it into the error browser when error browser opens.

The editor DRC error view is associated with the current top-level design. This error view remains open after error checking finishes to ensure the validity of the returned collection of objects with violations. The tool closes the editor DRC error view automatically if you close the design or end the GUI session.

The editor DRC error view associated with the top-design is named *current_top_design_CEL_name*_edrc.err by default. You can retrieve the name of the editor DRC error view, including the version, as an attribute of the top-level design. The attribute name is **editor_error_view_name**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example checks the selected objects for DRC errors, writes the violations into the editor DRC view, and loads the view into the error browser.

```
prompt> gui_check_drc_errors -show
```

The following example checks the net shapes inside the region *{{0 0} { 50 50} }* on METAL1 layer for *Minimum Edge* rule.

```
prompt> gui_check_drc_errors -limit_area {{0 0} { 50 50} }\
  -rules {"Minimum Edge"} -layers METAL1 -show
```

remove_drc_errors(2)
set_edrc_setting(2)

gui_clear_error_data_filter

Remove the filter from error data.

SYNTAX

string **gui_clear_error_data_filter**

DESCRIPTION

Remove the filter and restore visibility of errors. Errors may remain hidden based on null net association or fixed status state if the "Hide Null-Net Errors" option or the "Hide Fixed Errors" option has been set.

EXAMPLES

The following example removes the error data filter

```
gui_clear_error_data_filter
```

SEE ALSO

gui_error_browser(2)

gui_set_error_browser_option(2)

gui_clear_selected_errors

Clears selection in the Error Browser.

SYNTAX

string **gui_clear_selected_errors**

ARGUMENTS

DESCRIPTION

Clears selected errors in the Error Browser.

EXAMPLES

The following example clears selected errors:

```
gui_clear_selected_errors
```

SEE ALSO

gui_error_browser(2)
gui_set_current_errors(2)
gui_set_selected_errors(2)

gui_close_error_data

Removes an error data file from the error browser.

SYNTAX

status **gui_close_error_data**
[*error_data*]

Data Types

error_data collection

ARGUMENTS

error_data

A collection of physical DRC error data objects to remove from the error browser. A collection of the error data or the error data name can be used to remove it from the error browser.

DESCRIPTION

The **gui_close_error_data** command removes the given error data from the GUI error browser. If no error data is given, then the command removes all error data from the error browser and hides the error browser.

When a command opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The **gui_open_error_data** command opens an error data if necessary. It does not increment the open_count if the error data is already open and in memory. If the **gui_open_error_data** command increments the open_count, then a subsequent call to **gui_close_error_data** for the same error data decrements the open_count. Otherwise, a subsequent call to **gui_close_error_data** simply removes the error_data from the error browser without decrementing the open_count.

EXAMPLES

The following example removes the physical DRC error data file that is named "my_design_dppinassgn.err" from the error browser.

```
prompt> gui_close_error_data "my_design_dppinassgn.err"
1
```

The following example removes all physical DRC error data file from the error browser and hides the error browser.

```
prompt> gui_close_error_data
1
```

gui_close_utable

Close and free the given list of UserTables in memory.

SYNTAX

string **gui_close_utable**
-names *Table_Names*

Table_Names String List

ARGUMENTS

-names *Table_Names*

The list of table names to close and free in memory.

DESCRIPTION

This command closes and frees all the table names given by the user. If the table was in read only mode (streaming), then the connection to the table file is closed.

EXAMPLES

The following example closes a list of user tables.

shell> **gui_close_utable -names {my_table1 my_table2}**

SEE ALSO

gui_create_utable(2)

gui_export_utable(2)
gui_import_utable(2)
gui_open_utable(2)
gui_show_utable(2)
gui_write_utable(2)

gui_close_window

Close the specified window

SYNTAX

status **gui_close_window**
{ -window *window_id* | -type *window_type* | -all }
[-exact_type_match]

Data Types

window_id string
window_type string

ARGUMENTS

-window *window_id*

Specifies the window name id.

Any matching window of this name will be closed.

This option precludes the *-type* and *-all* options.

-type *window_type*

Specifies the window type id. Any matching window of this type will be closed.

If the *-exact_type_match* options is not specified then types derived from this window type will also be closed. Derived types are created with the **gui_create_window_type** command.

This option precludes the *-window* and *-all* options.

-all

Specifies that we want to close all the windows.

This option precludes the *-window* and *-type* options.

-exact_type_match

Specifies that types derived from the specified type are excluded when the *-type* option is specified.

Note: this option should only be used with the *-type* option.

DESCRIPTION

This command closes the specified window(s).

Windows can be specified by name, type or as all windows.

EXAMPLES

The following examples will create a toplevel window and a child layout view window, then close the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> gui_close_window -window $x
```

gui_connect_charts_signal

Connect to charts signal

SYNTAX

status **gui_connect_charts_signal**
{ -view *view_name* | -plot *plot_name* }
-from *signal_name*
-to *tcl_proc*

Data Types

view_name string
plot_name string
signal_name string
tcl_proc string

ARGUMENTS

-view *view_name*

Charts view to connect to.

-plot *plot_name*

Plot to connect to.

-from *signal_name*

Signal name to connect to.

Supported names are:

objIdPressed (id proc) plot object clicked on with mouse

annotationIdPressed (id proc) plot or view annotation clicked on with mouse

chartObjsAdded (non-id proc) objects added to chart

-to *tcl_proc*

Tcl procedure to call when the signal is emitted.

For plot an id procedure is called with three arguments (view, plot and object_id) and a non-id procedure is called with two arguments (view, chart).

For view an id procedure is called with two arguments (view, object_id) and a non-id procedure is called with one arguments

(view).

DESCRIPTION

Connects signals emitted from charts events to tcl callbacks.

EXAMPLES

The following example calls chartObjPressed proc when object in plot pressed.

shell> gui_connect_charts_signal -plot $plot -from objIdPressed -to chartObjPressed

SEE ALSO

gui_create_charts_plot(2)

gui_copy_charts_model

Copy existing charts model to new model

SYNTAX

status **gui_copy_charts_model**
-model *model_id*

Data Types

model_id int

ARGUMENTS

-model *model_id*

Charts model to copy.

DESCRIPTION

Copy data in existing charts model to a new model.

EXAMPLES

The following example copies an existing model to a new one.

shell> set model2 [gui_copy_charts_model -model $model1]

SEE ALSO

gui_create_charts_model(2)
gui_change_charts_model(2)

gui_create_attrgroup

Creates a group of attributes for an object type.

SYNTAX

status **gui_create_attrgroup**
-class *design_object*
-name *name*
[-attr_list {{*attr_1*}...{*attr_n*}}]

Data Types

design_object	string
name	string
attr_1	string
attr_n	string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be created for the specified object type.

-attr_list {{*attr_1*}...{*attr_n*}}

Lists and orders the attributes to be included in the group.

DESCRIPTION

The **gui_create_attrgroup** command creates a new attribute group for a specific type of design object. The command adds the attribute group to the display in GUI tools, such as the Properties dialog box, List views, layout view InfoTips, and other graphic windows.

An attribute can be assigned to more than one attribute group at the same time.

The order of the attributes in an attribute group is important and is set by the **-attr_list** option when you create the group. Use the **gui_update_attrgroup** command if you need to change or reorder the attribute list for an attribute group.

EXAMPLES

```
prompt> gui_create_attrgroup -class Cell -name "Hierarchy" \
  -attr_list { "Name" "Hierarchical" "Owning Cell"
  "isPhysConstraint" "Hard Macro" "Num Children" "Num Nets"
  "Num Pins" "Utilization" "Area" "Aspect Ratio" "Min Aspect"
  "Max Aspect" "Min Area" "Max Area" "Area / 1M" "Hier Req Area / 1M"
  "Reference" "Logical Name" "FullName" }

prompt> gui_create_attrgroup -class Cell -name "Edit" \
  -attr_list { "Name" "isPhysConstraint" "Orientation"
  "Location" "Bounding Box" "Fixed Location" "Is Resizable"
  "Hard Macro" "Placed" "Is IO" "Off Litho Grid" "FullName" }

prompt> gui_create_attrgroup -class Pin -name "Timing" \
  -attr_list { "Name" "Is Clock" "Slew"  "slack_max" }

prompt> gui_create_attrgroup -class Net -name "Timing" \
  -attr_list { "Name" "Lumped C" "Total Lumped C"
  "Lumped Resistance" }
```

SEE ALSO

gui_delete_attrgroup(2)
gui_list_attrgroups(2)
gui_update_attrgroup(2)

gui_create_block_diagram

Creates a block diagram view for the hierarchy cells specified by cell names or a collection. If no cell name or collection is specified, current selection is used. If there is no selection, the top-level design is used.

SYNTAX

string **gui_create_block_diagram**
[*collection*]
[-cells *cellNames*]
[-expanded]

Data Types

collection collection
cellNames list

ARGUMENTS

collection

Specifies a collection of hierarchy cells; the collection is used to initialize the block diagram view. If there is only one hierarchy cell in the collection, it is used as the root of the block diagram with all the hierarchy blocks it contains as the contents. If there are multiple hierarchy cells in the collection, a common hierarchy parent is determined and used as the root for block diagram and its contents are expanded to make the specified blocks visible.

This option is mutually exclusive with **-cells** option. Specify either a collection or a list of cell names but not both. If neither is specified, the current selection is used. In there is no selection, the top-level design is used.

-cells *cellNames*

Specifies a Tcl list of hierarchy cell names; the list is used to initialize the block diagram view. If only one hierarchy cell is specified, it is used as the root of the block diagram with all its child hierarchy blocks as the contents. If multiple hierarchy cells are specified, a common hierarchy parent is determined and used as the root for block diagram and its contents are expanded to make the specified blocks visible.

This option is mutually exclusive with the *collection* argument. Specify either a collection or a list of cell names but not both. If neither is specified, the current selection is used. In there is no selection, the top-level design is used.

-expanded

Display only buses in the block diagram without trying to bundle the buses together. By default, buses are bundled to create a more abstract block diagram view.

DESCRIPTION

The command generates a block diagram view of the currently selected design and hierarchy cells.

EXAMPLES

Each of the following examples generate a block diagram of hierarchical cell named RAM_1. The first command selects cell RAM_1. The second and third commands generate a block diagram of RAM_1 where its buses are bundled (not expanded). The last command generates a block diagram with buses the of RAM_1 unbundled.

```
prompt> change_selection [find cell RAM_1]
prompt> gui_create_block_diagram -cells {RAM_1}
prompt> gui_create_block_diagram [get_selection]
prompt> gui_create_block_diagram [get_selection] -expanded
```

SEE ALSO

get_selection(2)
change_selection(2)

gui_create_category_nodes

Creates one or more offspring category nodes under one or more parent category nodes by applying one or more category rules to the parent category nodes.

SYNTAX

gui_create_category_nodes
[-tree *category_tree*]
-parent_categories *category_nodes_list*
-rule_names *rule_names_list*

Data Types

category_tree	string or category_tree collection
category_nodes_list	list
rule_names_list	list

ARGUMENTS

-tree *category_tree*

The category tree in which the category node operation will happen; must be a category tree name or a category tree collection of size one; the most recently used category tree is used if the *-tree* option is omitted.

-parent_categories *category_nodes_list*

List of hierarchical (parent category node) name patterns and collections of parent category nodes under which one or more offspring category nodes will be created. A parent category node name is a unique hierarchical name of a category node in a Tcl list format.

-rule_names *rule_names_list*

List of one or more names of the category rules which will be applied incrementally to the parent category nodes to create new offspring category nodes.

DESCRIPTION

Creates one or more offspring category nodes under one or more parent category nodes by incrementally applying one or more category rules to the parent category nodes. Applying a single filter rule produces one new new offspring category node as well as an uncategorized offspring category labeled UNCAT (if UNCAT does not already exist under the parent category).

Applying a single dynamic category rule generates one or more new offspring category nodes. The command returns "1" if

successful; otherwise, an empty string is returned.

You should run this command only if at least one category tree is available. The command acts on the category tree specified.

EXAMPLES

This example shows the creation of one or more offspring category nodes by applying a single category rule to a single parent category node:

```
shell> gui_create_category_nodes \
? -parent_categories {{ALL **clock_gating_default**}} \
? -rule_names {{Start Point}} \
? -tree Tree1
1
```

This example is similar to the previous example; however, the optional *-tree* option is not specified. Therefore, the current category tree is used.

```
shell> gui_create_category_nodes \
? -parent_categories {{ALL **clock_gating_default**}} \
? -rule_names {{Start Point}}
1
```

This example shows the creation of one or more offspring category nodes by applying two category rules (in order) to a single parent category node:

```
shell> gui_create_category_nodes \
? -parent_categories {{ALL **clock_gating_default**}} \
? -rule_names {{Start Point} {Slack LT 0}}
1
```

This example shows the creation of offspring category nodes by applying a single category rule to multiple parent category nodes:

```
shell> gui_create_category_nodes \
? -parent_categories {{ALL {StartBlock: ALU}} {ALL {StartBlock: LAT}}} \
? -rule_names {EndBlock}
1
```

SEE ALSO

gui_remove_category_nodes(2)
gui_get_category_nodes(2)

gui_create_category_rule

Creates a category rule for automatic generation of one or more object categories.

SYNTAX

string **gui_create_category_rule**
[-name *rule_name*]
[-filter *filter_spec*]
-category *category_spec*
[-builtin]

Data Types

rule_name string
filter_spec string
category_spec string

ARGUMENTS

-name *rule_name*

Specifies the name of the category rule to be created. If this option is omitted, a unique new rule name is automatically generated.

-filter *filter_spec*

Specifies the filter. The basic form of a filter conditional expression is a series of relations joined together with && (and), || (or), and ! (not) operators. Parentheses are used to override precedence. The basic relation is either a Boolean attribute or a comparison of one non-Boolean attribute with another or with a constant value using relational operators.

For example, a filter expression can have any of the following forms:

- **-filter {endpoint_clock_is_propagated}** (Boolean attributes)
- **-filter {(slack < 0)}** (Comparison with a literal number)
- **-filter {(path_group.full_name == "inputs")}** (Comparison with a literal string)
- **-filter {(startpoint_clock.full_name == endpoint_clock.full_name)}** (Comparison of attributes)

Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection. The following relational operators are supported:

- **==** (Equal)
- **!=** (Not equal)
- **=~** (Matches pattern)

- **!~** (Does not match pattern)
- **&~** (Contains all elements)
- |~ (Contains some elements)
- **>** (Greater than)
- **<** (Less than)
- **>=** (Greater than or equal to)
- **<=** (Less than or equal to)

The matching operators are used to match wildcard regular expressions. The containment operators are used to compare space-separated set or list attributes.

-category *category_spec*

Specifies the category. The category specification can be fixed literal text, or it can include an optional object attribute name enclosed in angle brackets; for example, **-category <path_type>**. Additional literal text is optionally allowed to the left and to the right of the angle brackets; for example **-category {Path Type: <path_type>}**. Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection; for example, **-category <startpoint_clock.full_name>**.

When a category rule is "executed" later in the GUI, a separate category (bin of objects) is generated for each unique value of the attribute specified by the **-category** option. (The GUI "category-rule-execution engine" examines attribute values for an input set of objects.)

-builtin

Indicates that the rule being created belongs to the built-in group of category rules. If this option is omitted, the rule being created does not belong to the built-in group.

The built-in group of category rules is a group of category rules that are created before any non-built-in rules. This group of rules includes both built-in rules created by the tool (at tool startup time) and built-in rules that you create before creating any non-built-in rules.

DESCRIPTION

This command creates a category rule. If rule creation is successful, the command returns the name of the newly-created category rule; otherwise, it returns an empty string. After a category rule has been created, it can be used later (at "category-rule execution time" in the GUI) with other rules to generate one or more object categories.

EXAMPLES

This example creates a simple category rule:

```
prompt> gui_create_category_rule -name pathgroups \
    -category <path_group.full_name>
pathgroups
```

This example creates a simple filtering rule:

```
prompt> gui_create_category_rule -name {Negative Slack} \
    -category {Failing Paths} -filter {slack < 0}
Negative Slack
```

This example creates a regular expression filtering rule:

```
prompt> gui_create_category_rule -name {ATPG Sessions} \
    -category {ATPG Sessions} -filter {session_name =~ "atpg*"}
Negative Slack
```

This example creates a set or list containment filtering rule:

```
prompt> gui_create_category_rule -name {Through CPU and CTRL} \
    -category {Through CPU and CTRL} -filter { blocks &~ "CPU CTRL"}
Negative Slack
```

SEE ALSO

gui_list_category_rules(2)
gui_remove_category_rules(2)

gui_create_category_tree

Creates a new category tree and returns it in a collection of size one.

SYNTAX

category_tree_collection **gui_create_category_tree**
[-name *tree_name*]
-collections *collections_list*

Data Types

category_tree_collection collection (of one category tree object)
tree_name string
collections_list list (of collections)

ARGUMENTS

-name *tree_name*

Name of the category tree to be created. If this option is omitted, then a unique new category tree name will be automatically generated.

-collections *collections_list*

A list of collections of objects to be categorized. Each collection in the list should be homogeneous and each collection should be of the same object class, such as the timing path object class.

DESCRIPTION

Creates a new category tree and returns it as a collection of size one if category tree creation is successful (otherwise an empty string is returned). The new category tree holds onto the object collections passed to the command via -collections for future categorization.

A category tree is a collectible object of object class category_tree, and supports querying these attributes (which are defined only after gui_start) via get_attribute:

- name - The name of the category tree
- is_current - Is true if the category tree is the current category tree; is false otherwise.
  One and only one of the existing category trees is considered to be current at any time.

- object_class - This attribute always has the value "category_tree" for a category tree object.

EXAMPLES

This example show the creation of a category tree, and querying an attribute of the newly created category tree:

```
shell> set path_clct [get_timing_paths ...]
_sel18
shell> set path_clct2 [get_timing_paths ...]
_sel19
shell> set cat_tree \
?   [gui_create_category_tree -name tree0 -collections [list $path_clct $path_clct2]]
_sel20
shell> sizeof_collection $cat_tree
1
shell> get_attribute $cat_tree name
tree0
```

SEE ALSO

gui_get_category_trees(2)
gui_remove_category_trees(2)
get_attribute(2)

gui_create_charts_arrow_annotation

Create arrow annotation in view or plot

SYNTAX

arrow_id **gui_create_charts_arrow_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
-start *position*
-end *position*
[-angle *angle*]
[-back_angle *angle*]
[-fhead *sbool*]
[-thead *sbool*]
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position string
angle float
name_value_list string
arrow_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-start *position*

Start point of the arrow line.

-end ***position***

End point of the arrow line.

-angle ***angle***

Angle of arrow head.

-back_angle ***angle***

Back angle of arrow head.

-fhead ***sbool***

Is arrow drawn at start of line.

-thead ***sbool***

Is arrow drawn at end of line.

-properties ***name_value_list***

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

arrow_id

Returns id of created annotation.

DESCRIPTION

Add an arrow annotation to plot or view.

The arrow annotation is a line with optional arrow heads draw at each end.

The line and arrow heads can be customized.

EXAMPLES

The following example creates an arrow annotation on a plot from (0 0) to (100 100) with arrows at both ends.

shell> gui_create_charts_arrow_annotation -plot $plot -start {0 0} -end {100 100} -fhead 1 -thead 1

gui_get_charts_property(2)

gui_create_charts_correlation_model

Create correlation model from existing charts model

SYNTAX

status **gui_create_charts_correlation_model**
-model *model_id*

Data Types

model_id int

ARGUMENTS

-model *model_id*

Model to create correlation model for.

DESCRIPTION

Create correlation model from existing model.

The input model column values are compared to generate a symmetric correlation matrix of values between -1 and 1 where closely correlated column values have high values (positive or negative) and uncorrelated column values have low numbers.

The command returns the model index of the newly created model.

EXAMPLES

The following example creates a correlation of an existing model.

shell> gui_create_charts_correlation_model -model $model

SEE ALSO

gui_create_charts_model(2)

gui_create_charts_ellipse_annotation

Create ellipse annotation in view or plot

SYNTAX

ellipse_id **gui_create_charts_ellipse_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
-center *position*
-rx *length*
-ry *length*
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position string
length float
name_value_list string
ellipse_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-center *position*

Center of the ellipse.

-rx *length*

X Radius of the ellipse.

-ry ***length***

Y Radius of the ellipse.

-properties ***name_value_list***

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

ellipse_id

Returns id of created annotation.

DESCRIPTION

Add an ellipse annotation to plot or view.

The background and border of the ellipse can be customized.

EXAMPLES

The following example creates an ellipse annotation on a plot centered at (0 0) with a radius of 60 in x direction and 40 in y direction.

shell> gui_create_charts_ellipse_annotation -plot $plot -center {0 0} -rx 60 -ry 40

gui_remove_charts_annotation(2)
gui_set_charts_property(2)
gui_get_charts_property(2)

gui_create_charts_model

Create a model from data for use in charts

SYNTAX

model_id **gui_create_charts_model**
{ -csv *filename* | -clct *collection* |
-tcl *tcl_list* }
[{ -comment_header | -first_line_header }]
[-first_column_header]
[-transpose]
[-columns *column_names*]
[-column_type *column_type*]
[-name *string*]

Data Types

filename string
collection string
tcl_list string
column_names string
column_type string

ARGUMENTS

-csv *filename*

Create model from contents of specified csv filename.

A CSV file has comma separated fields.

The *comment_header*, *first_line_header* and *first_column_header* options can be used to determine which (if any) lines are used for horizontal and vertical headers.

-clct *collection*

Create model from contents of a collection. Each row consists of a list of attribute values from the collection object.

The *columns* option can be used to specified which attributes are used to populate the table from the collection. If the *columns* option is not specified then the attributes from the ALL attribute group are used.

-tcl *tcl_list*

Create model from the values in a tcl variable.

The tcl variable must be a list of lists. The data is a list of rows where each row is a list of column values.

The *transpose* option can be used to transpose the value array so lists of columns can be specified where each column is a list of row values.

-comment_header

Specifies that the first comment (line starting with a #) contains the names of the horizontal column headers.

Only used by the *csv* option.

-first_line_header

Specifies that the first line contains the names of the horizontal column headers.

Used by the *csv* and *tcl* options.

-first_column_header

Specifies that the first column (first field in each row) contains the names of the vertical row headers.

If the data also has a horizontal header then the first field of the horizontal header is ignored.

Used by the *csv* and *tcl* options.

-transpose

Specifies that the tcl value array from *tcl* option is transposed so lists of columns can be specified where each column is a list of row values.

-columns *column_names*

Specifies a list of names for the attributes to query from the collection to generate the columns of each row.

Used by the *clct* option.

-column_type *column_type*

Specifies the type and optional formatting of the values in the columns.

If the type of the column is not specified then the application will try to automatically determine it depending on whether the values can be all converted to real or integer values. If not the default string type is used.

The specified value is an ordered list of column type data. Each column type data is a list where the first element specifies the type and any extra elements specify extra name values to customize the type. By default, the type is associated with the column number matching the index of the item but a specific column can be specified by including the column name or number with the type value in the first element.

Syntax:

- column_type_data : { <column_type> [<name_values>]}
- column_type : { [<column>] <type> }
- column : column_name|column_index
- type : integer|real|string|...
- name_values : <name_value> <name_value> ...
- name_value : { <name> <value> }

The supported name values are dependant on the column type.

Column types can be queried using:

gui_get_charts_data -name column_types

The column types named values can be queried using:

gui_get_charts_data -name column_type.names -data $type

-name ***string***

Specifies the name of the model.

This can be used to annotate the model so the user can more easily identify what data it contains in the gui.

If the *csv* option is used then the filename is the default name.

RETURNS

model_id

The id of the created model.

This can be used as input to the **gui_create_charts_plot** command and other commands to do further processing on the model.

DESCRIPTION

This command creates a persistant model and loads data into it so it can be used as the data source for one or more plots.

The command returns a model id which can be used as input to the **gui_create_charts_plot** and other charts commands.

EXAMPLES

The following example creates a model from the csv file "test.csv" using the first line for the column headers.

shell> gui_create_charts_model -csv "test.csv" -first_line_header

The following example creates a model from a collection of all shapes with columns for the name and layer attributes.

shell> gui_create_charts_model -clct [get_nets] -columns [list name layer]

SEE ALSO

gui_create_charts_plot(2)

gui_create_charts_plot

Create a plot of the type using the supplied data

SYNTAX

plot_name **gui_create_charts_plot**
-view *view_name*
{ -clct *collection* | -model *model_id* }
-type *plot_type*
[-columns *column_names*]
[-title *string*]
[-properties *name_value_list*]
[-xmin *float*]
[-ymin *float*]
[-xmax *float*]
[-ymax *float*]

Data Types

view_name string
collection string
model_id int
plot_type string
column_names string
name_value_list string

ARGUMENTS

-view *view_name*

Parent view for plot.

-clct *collection*

Collection to use for input data. Each row consists of a list of attribute values from the collection object.

The *columns* option is used to specified which attributes are read from the collection to populate the table values.

Note: the resultant model is a snapshot of the specified collection's attribute values and will not updates as the collection is changed.

-model *model_id*

The model to use for input data.

-type *plot_type*

The type of plot to display:

The plot types can be queried using the command **gui_get_charts_data -name types**

-columns *column_names*

Specifies the columns to use for each plot column parameter.

The columns string is a command separated list of name value pairs of the form "<parameter name>=<column name>".

The parameter names are plot type dependent.

When the *model* option is specified the column names are column indices (0 based) or column header names.

When the *clct* option is specified the column names are attributes names.

-title *string*

Specifies the title for the plot.

-properties *name_value_list*

Specifies a list of name value pairs for the properties to set on the created plot.

-xmin *float*

User specified minimum x value (to override the auto calculated range).

-ymin *float*

User specified minimum y value (to override the auto calculated range).

-xmax *float*

User specified maximum x value (to override the auto calculated range).

-ymax *float*

User specified maximum y value (to override the auto calculated range).

RETURNS

plot_name

The id of the created plot.

DESCRIPTION

Create plot in a view using values in data model.

The view and model data must be created before the plot can be added.

EXAMPLES

The following example creates a distribution plot from the specified model using values from the first column.

```
shell> set window [gui_get_current_window -mru]
shell> set view [gui_create_window -parent $window -type Charts]
shell> gui_create_charts_plot -view $view -model $model -type distribution -columns "value=0"
```

SEE ALSO

gui_create_window(2)
gui_create_charts_model(2)

gui_create_charts_point_annotation

Create point annotation in view or plot

SYNTAX

point_id **gui_create_charts_point_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
-position *position*
[-size *length*]
[-type *symbol_type*]
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position string
length float
symbol_type string
name_value_list string
point_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-position *position*

Point position.

-size *length*

Point size.

-type *symbol_type*

Point symbol type.

One of: dot, cross, plus, y, triangle, itriangle, box, diamond, star5, star6, circle, pentagon, ipentagon, hline, vline.

-properties *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

point_id

Returns id of created point.

DESCRIPTION

Add a point annotation to plot or view.

The background and border of the point can be customized.

EXAMPLES

The following example creates a point annotation on a plot with a circle symbol at (0 0).

shell> gui_create_charts_point_annotation -plot $plot -position {0 0} -type circle

SEE ALSO

gui_get_charts_property(2)

gui_create_charts_polygon_annotation

Create polygon annotation in view or plot

SYNTAX

poly_id **gui_create_charts_polygon_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
-points *position_list*
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position_list string
name_value_list string
poly_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-points *position_list*

List of polygon points.

-properties *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

poly_id

Returns id of created polygon.

DESCRIPTION

Add a polygon annotation to plot or view.

The background and border of the polygon can be customized.

EXAMPLES

The following example creates a polygon annotation on a plot with a red background with 50% alpha.

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -background 1 -fill_color red -fill_alpha 0.5
```

gui_get_charts_property(2)

gui_create_charts_polyline_annotation

Create polyline annotation in view or plot

SYNTAX

poly_id **gui_create_charts_polyline_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
-points *position_list*
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position_list string
name_value_list string
poly_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-points *position_list*

List of polygon points.

-properties *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

poly_id

Returns id of created poly line.

DESCRIPTION

Add a multi-point line annotation to plot or view.

The background and border of the line can be customized.

EXAMPLES

The following example creates a polyline annotation on a plot with a red border with 50% alpha.

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -border 1 -stroke_color red -stroke_alpha 0.5
```

gui_create_charts_rectangle_annotation

Create rectangle annotation in view or plot

SYNTAX

rect_id **gui_create_charts_rectangle_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
[-rectangle *string*]
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
name_value_list string
rect_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-rectangle *string*

Rectangle bounding box

-properties *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

rect_id

Returns id of created rectangle.

DESCRIPTION

Add a rectangle annotation to plot or view.

The background and border of the rectangle can be customized.

EXAMPLES

The following example creates a rectangle annotation on a plot from (0 0) to (100 100).

```
shell> gui_create_charts_rectangle_annotation -plot $plot -start {0 0} -end {100 100}
```

gui_create_charts_summary_model

Create summary model from existing charts model

SYNTAX

status **gui_create_charts_summary_model**
-model *model_id*
[-max_rows *int*]
[-random]
[-sorted]
[-sort_column *int*]
[-sort_order *string*]
[-paged]
[-page_size *int*]
[-page_number *int*]

Data Types

model_id int

ARGUMENTS

-model *model_id*

Model to create summary model for.

-max_rows *int*

Maximum number of rows to extract from model.

-random

Select random rows.

-sorted

Use sorted rows.

-sort_column *int*

Specify sort column.

-sort_order *string*

Specify sort order.

-paged

Specify rows are paged.

-page_size ***int***

Specify page size (default 100).

-page_number ***int***

Specify page number.

DESCRIPTION

Create summary model from existing model.

EXAMPLES

The following example creates a summary of an existing model using random rows.

shell> gui_create_charts_summary_model -model $model -random

SEE ALSO

gui_create_charts_model(2)

gui_create_charts_text_annotation

Create text annotation in view or plot

SYNTAX

text_id **gui_create_charts_text_annotation**
{ -view *view_name* | -plot *plot_name* }
[-id *string*]
[-tip *string*]
{ -position *position* | -rectangle *bounding_box* }
-text *string*
[-properties *name_value_list*]

Data Types

view_name string
plot_name string
position string
bounding_box string
name_value_list string
text_id annotation_id

ARGUMENTS

-view *view_name*

Charts View to add annotation to.

-plot *plot_name*

Plot to add annotation to.

-id *string*

Optional identifier string for annotation.

-tip *string*

Optional tip string for annotation.

-position *position*

The position of the text.

-rectangle *bounding_box*

The bounding box of the text.

-text ***string***

The text to display.

-properties ***name_value_list***

Specifies a list of name value pairs for the properties to set on the created annotation.

RETURNS

text_id

Returns id of created text.

DESCRIPTION

Add a text annotation to plot or view.

The background, border and font of the text can be customized.

EXAMPLES

The following example creates a text annotation on a plot at (0 0) with the text "Test text".

```
shell> gui_create_charts_text_annotation -plot $plot -position {0 0} -text "Test text"
```

gui_create_clock_graph

Creates a clock graph.

SYNTAX

gui_create_clock_graph
-clct objects
[-levelized]
[-latency]

ARGUMENTS

-clct

Collection of objects to be used to generate a clock graph.

-levelized

Generates a levelized clock graph.

-latency

Generates a latency clock graph.

DESCRIPTION

The command generates a levelized or latency clock graph using a selected set of objects.

EXAMPLES

The following example generates a levelized clock graph using a collection of clock paths.

prompt> **gui_create_clock_graph -clct $clock_paths -levelized**

SEE ALSO

change_selection(2)

gui_create_clock_histogram

Create a histogram view for given clocks and corner.

SYNTAX

status **gui_create_clock_histogram**
-clocks *clocks*
-corner *corner*
-type *type*

Data Types

clock collection
corner collection
type string

ARGUMENTS

-clocks *clocks*

Specifies the clocks on which the latency histograms are calculated. This is a required option.

-corner *corner*

Specifies the corner from which the latency histogram is traced. This is a required option.

-type *type*

Specifies the latency histogram type. The option value could be one of "launch" or "capture". This is a required option.

DESCRIPTION

Create a new view to show the latency histogram of specified clocks at specified corner.

EXAMPLES

The following example create the launch latency histogram of clock CLK3 with corner cr1.

```
prompt> gui_create_clock_histogram \
  -clocks [get_clocks CLK3] -corner cr1 \
  -type launch
```

SEE ALSO

gui_create_menu

Create a menu item for the toplevel menubar or a context menu item. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item.

SYNTAX

string **gui_create_menu** -menu *HierMenuName*
<-tcl_cmd *TclCmd*|-separator|-heading headingText>
[-enable_cmd *EnableCmd*]
[-get_state_cmd *GetStateCmd*]
[-icon *IconFilePath*]
[-hot_key *HotKey*]
[-tooltip *ToolTip*]
[-help_string *HelpStr*]
[-anchor_item *AnchorItem*]
[-anchor_offset *AnchorOffset*]
[-position *MenuPos*]
[-window_type *WindowTypeName*]
[-root *ContextMenuRoot*]
[-reference *RefMenuItem*]

HierMenuName *String*
TclCmd *String*
EnableCmd *String*
GetStateCmd *String*
IconFilePath *String*
HotKey *String*
ToolTip *String*
HelpStr *String*
AnchorItem *String*
AnchorOffset *Integer*
MenuPos *Integer*
WindowTypeName *String*
ContextMenuRoot *String*
RefMenuItem *String*

ARGUMENTS

-menu *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to create. If a level of the hierarchy does not exist in the menu structure it will be created automatically by this command. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do

so.

-tcl_cmd *TclCmd*

TclCmd specifies the tcl command to execute when the menu item is selected. This option is mutually exclusive with the -separator and -heading options.

-separator

This option creates a menu item separator. It is mutually exclusive with the -tcl_cmd and -heading options.

-heading *headingText*

This option creates a text heading in the menu with the specified **headingText**. It is visually distinct from actual menu items, and it is not selectable like an actual menu item is. This is used to provide general grouping information without requiring an additional level of sub menu. This option is mutually exclusive with the -separator and -tcl_cmd options.

-enable_cmd *EnableCmd*

EnableCmd specifies the tcl command to evaluate whether the menu item should be enabled or disabled. The tcl command should return "true" or "1" to enable, and return "false" or "0" to disable. If the enable_cmd is not specified then the menu item will always be enabled.

-get_state_cmd *GetStateCmd*

GetStateCmd specifies the tcl command that will be executed to determine whether the menu item should be in an on (checked or pushed-in) or off (unchecked or normal) state. Most menu items don't have persistent state, and for those the get_state_cmd should not be specified. This tcl command returns "true" or "1" for the "on" state, and returns "false" or "0" for the "off" state.

-icon *conFilePath*

IconFilePath specifies the absolute pathname of the icon file. The file should be in *.xpm* format. Typical application-supplied icons are 16x16 pixels in size and use a transparent background (color 'None' in xpm format).

-hot_key *HotKey*

HotKey specifies the hotkey (accelerator) for the menu item.

-tooltip *ToolTip*

ToolTip specifies the tooltip for the menu item.

-help_string *HelpStr*

HelpStr specifies the help string for the menu item. The help string is displayed in the status bar.

-anchor_item *AnchorItem*

AnchorItem specifies the existing menu item that will be used as the anchor position for this new menu item. This option is used together with the -anchor_offset option to determine the location of the new menu item. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

-anchor_offset *AnchorOffset*

AnchorOffset specifies the offset from the anchor item position that will be used to determine the location of the new menu item in the menu hierarchy. The offset must be a positive or negative integer, and not zero. If positive, the new menu item will be placed below the anchor item by the specified offset. If negative, it will be placed above the anchor item position by the absolute value of the specified offset. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

-position *MenuPos*

MenuPos specifies the absolute menu position for the menu item within the parent popup menu. The -position option cannot be

used with the -anchor_item and -anchor_offset options.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

-root *ContextMenuRoot*

ContextMenuRoot specifies the context menu root to which the menu item being defined will be added. A context menu root groups menu items that share the same context menu root. The context menu root is used for context menu. Context menu, is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

-reference *RefMenuItem*

RefMenuItem specifies the menu item under the toplevel window's menu bar, which will be used to define the behavior of the menu item being defined. Often used with the -root option to help associate a context menu item with an already defined menu entry under the menu bar. Used with the -window_type option to completely specify the reference menu item under the menu bar. If the -window_type option is not specified, the default toplevel window type as specified with the tcl variable "::gui_default_window_type" will be used.

DESCRIPTION

This command creates a menu item for the menu bar of a top level window. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item. The menu hierarchy separator is denoted by "->".

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default empty value. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_icc_gui.tcl for IC Compiler.

EXAMPLES

The following simple example adds a new toplevel popup menu *&Favorite* in the menubar and add a submenu named *Preferences* then add an item named *My &Item* to that submenu. This menu item will be enabled if *enable_my_item* is set to 1 and disabled otherwise. A hotkey and tooltip are also provided.

```
set enable_my_item 1
proc enable_my_item {} {
   if { $::enable_my_item == 1 } {
      return 1
   }
   return 0
}
gui_create_menu -menu "&Favorite->Preferences->My &Item" \
```

```
    -tcl_cmd "echo {executing My Item}" \
    -enable_cmd "enable_my_item" \
    -hot_key "Ctrl+N" \
    -tooltip "short tooltip description for My Item" \
    -help_string "long status bar description for My Item" \
    -icon_file "/syn/sparc/my_item.xpm"
```

The following IC Compiler example illustrates creating a new menu item in the context menu of the layout window which will refer to the Zoom Fit Selection menu item from the Layout window main menu bar. This assumes that the tcl variable "gui_default_window_type" is set to the ICC window type "LayoutWindow" and thus it is not necessary to specify the -window_type option with the value of "LayoutWindow".

```
gui_create_menu -menu "Zoom Fit Selection" \ -root layout_view_menu_root \ -reference "View->Zoom->Zoom Fit Selection"
```

The following example create a new Tcl-based menu entry in the context menu which invokes a procedure # called do_my_thing.

```
gui_create_menu -menu "Do My Thing" \ -root layout_view_menu_root \ -tcl "do_my_thing"
```

The following IC Compiler example illustrates adding a context menu item to the path schematic context menu which refers to a menu item in the Main window. This example assumes that there is a context menu root called "path_schematic_contextmenu_root", a hierarchical menu item in the toplevel menu bar of the window type "MainWindow" with the hierarchical menu name "Schematic->Delete Selected".

```
gui_create_menu -menu "Remove Selected" \ -root path_schematic_contextmenu_root \ -reference "Schematic->Delete Selected" -window_type MainWindow
```

gui_create_message_waiver

Creates an EMS message waiver to waive matching messages in Message Browser.

SYNTAX

status **gui_create_message_waiver**
-name *waiver_name*
[-rule *EMS_check_rule_name*]
[-domain *EMS_domain_name*]
[-comment *comment_string*]
-filter *filter_list*

Data Types

waiver_name string
EMS_check_rule_name string
EMS_domain_name string
comment_string string
filter_list list

ARGUMENTS

-name *waiver_name*

Specifies the name of the waiver to create.

-rule *EMS_check_rule_name*

Specifies the name of EMS check rule whose error or warning messages will be matched against the filter. If not specified, the filter is applied to messages generated by all rules of a given domain, or on all messages of currently opened database, if no domain is specified. The default is empty.

-domain *EMS_domain_name*

Specifies the name of EMS domain whose error/warning messages will be matched against the filter. If not specified, the filter is applied to all messages of currently opened database. The default is empty.

-comment *comment_string*

Specifies the comments or notes to the waiver.

-filter *filter_list*

Specifies list of criteria for the filter. The criteria should contain column name, a match value, and match operation in list format {COULMN_NAME MATCH_OP MATCH_VALUE}. The column name should be exactly the same as visible param title defined in the EMS database for related checks, or the column name in message list of Message Browser. Each of matched values will be

converted to predefined EMS type for comparison, such as string, int, float, and so on. The possible matching operations are '==', '=~'(match), '<', '<=', '>', '>=' applied to suitable types. A filter can contain multiple criteria for different column fields. A messages is waived only when all criteria within this option are matched. This is a required option.

DESCRIPTION

The **gui_create_message_waiver** command creates a waiver with the filter list. The waiver is used to waive the matching EMS message from the Message Browser. The tool tests the messages against the filter strings defined in the waiver. When a string matches the criteria, the message status is set to 'waived'. If 'hide waived' preference is enabled, the waived messages are hidden from the message browser.

EXAMPLES

The following command creates waiver which will filter message generated by rule 'CTS_QOR_002' based on the filter list:

```
prompt> gui_create_message_waiver -name waiver_2 -rule CTS_QOR-002 \
  -filter { { Num <= 20 } { { Net Name } == gclk } { Capacitance == 0.45 } }
```

gui_create_pref_category

Create a preference category.

SYNTAX

string **gui_create_pref_category** -category *Category*

Category *String*

ARGUMENTS

-category *Category*

Category specifies the category to create.

DESCRIPTION

This command creates a preference service category with the specified name, which can be used to store and categorize key-value pairs that are created with the **gui_create_pref_key** command. If successful, the command returns the name of the category that is created.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool -value false
```

SEE ALSO

gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_create_pref_key

Create a preference key.

SYNTAX

string **gui_create_pref_key** -key *Key*
-value_type *ValueType*
-value *Value*
[-category *Category*]
[-keep_value_if_exist]
[-read_only]
[-description *Description*]
[-min *Minimum_Value*]
[-max *Maximum_Value*]
[-legal_value_list *Value_List*]
[-string_to_int_map *Value_Map*]
[-save_on_exit *Boolean_Value*]

Key *String*
Category *String*
ValueType *one of [bool|integer|double|color|string|rect|point|size]*
Value *Depends on the value type*
Description *String*
Minimum_value *Minimum integer or double value*
Maximum_value *Maximum integer or double value*
Value_List *String List*
Value_Map *A list of string pair lists, each mapping a string value to an integer value.*
Boolean_Value *true | false*

ARGUMENTS

-key *Key*

Key specifies the name of the key to create.

-value_type *ValueType*

ValueType specifies the data type of the value of the key. It must be one of [bool | integer | double | color | string].

-value *Value*

Value specifies the value of the key. The value should be set appropriately in accordance with its value type. The **bool** type accepts [true, false, 0, 1, on, off]. The **color** type accepts a named color, eg. "red" or a string specifying the color in this format

"#RRGGBB", for example, "#0000FF".

-category *Category*

Category specifies the category that the key belongs to. If not specified, a default category will be assigned.

-keep_value_if_exist

This Boolean option specifies to keep current value if the key already exists. The default is that the key will be assigned the value given in the **-value** option.

-read_only

If given, this flag specifies that the preference key value is read-only and its value cannot be set after the key has been created.

-description *Description*

If given, the given description string with the meaning of the key is assigned to the preference key.

-min *Minimum_Value*

If given, specifies the minimum value for an integer or double type preference key.

-max *Maximum_Value*

If given, specifies the maximum value for an integer or double type preference key.

-legal_value_list *Value_List*

If given, this option specifies discrete valid values for an iteger, double or string type preference key. Input the argument using Tcl list syntax: {{prefVal} ...}

-string_to_int_map *Value_Map*

If given, provides a map from a string key value to an integer value for preferences of integer type. Input the argument as a Tcl list of Tcl list where the internal list is a pair of the string value and the integer value: {{stringval intval} ...}

-save_on_exit *Boolean_Value*

If given, specifies whether the preference key value is saved to the user preference file upon existing the application. Acceptable argument is either **true** or **false**.

DESCRIPTION

This command creates a preference key with the specified key name. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to the default category. Returns the value of the preference key.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200.

```
gui_create_pref_category -category some_category
```

```
gui_create_pref_key -category my_category -key some_key -value_type integer -value 200
```

gui_create_schematic

Creates a schematic view.

SYNTAX

string **gui_create_schematic**
[-clct *objects*]
[-size *{w h}*]
[-be_specific *bool*]

Data Types

objects collection
{w h} string

ARGUMENTS

-clct *objects*

Generates a schematic for the specified object collection. The current selection is used if not specified.

-size *{w h}*

Generates a schematic for the specified width (w) and height (h). Application default view size is used if not specified.

-be_specific *bool*

Controls the behavior of the schematic generation as to whether additional objects beyond those specifed using -clct. If not specifed, or specifed as false, additional objects will be included in the new schematic to provide connectivity and context. If specified as true, only the objects specified will be included in the new schematic.

DESCRIPTION

The command generates a new schematic view from the current selection or an object collection if specified.

EXAMPLES

The following example generates a schematic view of the hierarchical cell named RAM_1.

```
prompt> gui_create_schematic -clct [find cell RAM_1]
```

SEE ALSO

change_selection(2)

gui_create_task

Create a task.

SYNTAX

gui_create_task
-name *TaskName*
-item_root *ItemRootName*
[-help_string] *HelpString*
[-menu_string] *MenuString*
[-icon] *IconFileName*
[-default]

TaskName *String*
ItemRootName *String*
HelpString *String*
MenuString *String*
IconFileName *String*

ARGUMENTS

-name *TaskName*

TaskName specifies the name of the new task. Task names must be unqiue.

-item_root *ItemRootName*

ItemRootName specifies the name of the task root that will be associated with the task. Item root names are unique. If the same item root is associated with multiple tasks, then the tasks share the same item root.

-help_string *HelpString*

HelpString specifies the string that will displayed as help to describe the task.

-menu_string *MenuString*

MenuString specifies the string that will be shown in a task selection menu for the task. If omitted, the task name is used.

-icon *IconFileName*

IconFileName specifies the name of the file with an icon definition for the icon to be displayed in the GUI for the task.

-default

This option specifies that this command will be the default task set as the current task. If another task is later created with this option, the the later setting overrides any previous settings.

DESCRIPTION

This command creates a task. A task defines the user task context for the whole application. Tasks may be used to configure menus and also to present a hierarchical list of task items to the user to navigate in the Task Assistant. The hierarhical list of task items is defined with the gui_create_task_item command.

EXAMPLES

The following simple example creates a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot

gui_create_tk_task_page -name InputFormPage -create_command create_widget_proc
gui_create_html_task_page -name AppDocument -path ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask -page AppDocument
```

SEE ALSO

gui_create_task_item(2)
gui_create_tk_task_page(2)
gui_create_html_task_page(2)

gui_create_task_item

Create an item in the task tree to access in the Task Assistant.

SYNTAX

gui_create_task_item
-name *ItemName*
<-task *TaskName* | -item_root *ItemRootName*>
-page *PageName*
[-search_terms *TermsList*]

ItemName *String*
TaskName *String*
ItemRootName *String*
PageName *String*
TermsList *List*

ARGUMENTS

-name *ItemName*

ItemName specifies the hierarchical name given to the task item being created. This is also the text displayed to the user in the Task Assistant.

-task *TaskName*

TaskName specifies the task in which this task item is created. If a task name is used to create the task item, the item is inserted into the task item root associated with the task in the create_task command. If other tasks use the same item root, they will also see the new task item created with this command. This option is mutually exclusive with the -item_root option. One must be specified but not both.

-item_root *ItemRootName*

ItemRootName specifies the task item root in which this task item is created. Item root names are associated with task names with the gui_create_task command and allows multiple tasks to share a single task item root. This option is mutually exclusive with the -item_root option. One must be specified but not both.

-page *PageName*

PageName specifies the page content factory associated with this task item. When the user selects the task item, the page specified by this option will be constructed and shown in the Task Assistant.

-search_terms *TermsList*

TermsList specifies additional terms that can be matched by the command search feature to find this task item. For example, if the task page allows the user to specify values for input parameters to a command, you may want to associate the name of that

command as additional search term for the task item.

DESCRIPTION

This command creates a task item in the given task. Task items are defined in a hierarchy with hierarchy levels delimited by the separator string "->". The hierarchy of task items are shown in the task item navigation tree in the Task Assistant.

When the user selects a leaf item in the task navigation tree, the Task Assistant will show the task page associated with the item by this command. Currently, the pages can either be constructed from an HTML document or from a Tk widget factory.

EXAMPLES

The following simple example adds a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot

gui_create_tk_task_page -name InputFormPage -create_command create_widget_proc
gui_create_html_task_page -name AppDocument -path ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask -page AppDocument
```

SEE ALSO

gui_create_task(2)
gui_create_tk_task_page(2)
gui_create_html_task_page(2)

gui_create_task_page

Creates a task page with Command Form, HTML content or Tk Command Form.

SYNTAX

gui_create_task_page
-name taskPageName
-format pageType
-source contentSource

Data Types

taskPageName string

pageType string

contentSource string

ARGUMENTS

-name *taskPageName*

taskPageName specifies the name of a new task page.

-format *pageType*

Define this new page as a specified Type Page. **pageType** can be command, html, tk or tab. Which specifies the Command Form Page, HTML Page, Tk Command Form Page or Tabs Page.

-source *contentSource*

Define the content to be shown in this page. If this page is a Command Form Page or a Tk Command Form Page, **contentSource** is the command name. If it is a HTML Page, **contentSource** specifies the full path to the file with HTML source for the task page. If it is a Tabs Page, **contentSource** specifies a list of existing page names or page&title pairs.

DESCRIPTION

The **gui_create_task_page** command creates several kinds of task pages which can be shown in the task assistant. The name option value is the unique name of the page. The format option defines which kind of page to be created and the source option defines what content to be shown in the task page.

EXAMPLES

The following simple example creates three new task pages, then show them in the task assistant.

```
prompt> gui_create_task_page -name page1 -format command -source gui_report_map
prompt> gui_create_task_page -name page2 -format html -source ./MyAppDocument.html
prompt> proc create_widget_proc {widgetName parentName} {
        p#populate $wigetName with Tk
       p}
prompt> gui_create_task_page -name page3 -format tk -source create_widget_proc
prompt> gui_create_task_page -name page4 -format tab -source {page1 page2 {page3 title} }
prompt> gui_create_task -task "Testing Task" -item_root test_task_item_root
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 1" -page page1
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 2" -page page2
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 3" -page page3
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 4" -page page4
prompt> gui_show_task -task "Testing Task:Testing Page"
```

SEE ALSO

gui_create_task(2)
gui_create_task_item(2)

gui_create_tk_palette_type

Create a type of Tk palette.

SYNTAX

status **gui_create_tk_palette_type**
-type *string*
-title *string*
[-icon *string*]
-window_types *string_list*
[-dock_edge *dock_edge*]
-create_command *string*

Data Types

dock_edge string

ARGUMENTS

-type *string*

Unique palette type name for the palette.

The type name must be non-empty, must start with a letter or underscore, and must only contain letter, number or underscore characters.

-title *string*

Title string for the palette.

-icon *string*

Icon to display for the palette.

-window_types *string_list*

List of window types which the palette is to be added to.

-dock_edge *dock_edge*

The default edge to add the palette

left - dock on left edge
right - dock on right edge
top - dock on top edge
bottom - dock on bottom edge

-create_command *string*

The option specifies the tcl command to be run when the palette is created so that the palette's tk widget can be populated with tk child widgets and any other initialization can be performed.

The tcl procedure takes two arguments 'windowName' and 'parentName' where 'windowName' is the tk palette widget to populate and 'parentName' is the name of the parent window.

DESCRIPTION

Creates a user defined tk palette when a window of any of the specified types is created.

EXAMPLES

The following example creates a palette of type 'mypalette', with a title of 'My Palette' which calls the 'build_my_palette' tcl procedure to populate the palette with tk widgets whenever a new window of type 'LayoutWindow' is created.

The 'build_my_palette' creates a text entry filed in a frame for the palette.

```
shell> proc build_my_palette {windowName parentName} {
  set top_frame [frame $windowName.frame]
  pack $top_frame -fill both -expand 1
  set entry [entry $top_frame.entry -textvariable $::var]
  pack $entry
}
shell> gui_create_tk_palette_type -type mypalette -title "My Palette" \
 -create_command build_my_palette -window_types "LayoutWindow" -dock_edge right
```

SEE ALSO

gui_execute_events(2)

gui_create_toolbar

Create a toolbar with the specified name.

SYNTAX

string **gui_create_toolbar** -name *ToolBarName*
[-title *Title*]
[-dock_side *DockSide*]
[-hidden]
[-window_type *WindowTypeName*]

ToolBarName *String*
Title *String*
DockSide *String*
WindowTypeName *String*

ARGUMENTS

-name *ToolBarName*

ToolBarName is the toolbar identifier for the new toolbar.

-title *Title*

Title specifies the title or caption of the toolbar.

-dock_side *DockSide*

DockSide specifies the side of the window the tool docks to by default. The legal values are top, bottom, left, right.

-hidden

-hidden specifies the toolbar should be hidden by default.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

DESCRIPTION

This command creates a toolbar with the given name and title. Returns the name of the toolbar created.

EXAMPLES

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

SEE ALSO

gui_delete_toolbar_item(2)
gui_get_toolbar_names(2)
gui_default_window_type(3)
gui_custom_setup_files(3)

gui_create_toolbar_item

Create a button in the specified toolbar.

SYNTAX

string **gui_create_toolbar_item** -toolbar *ToolBarName*
<-menu *MenuName*|-separator *SeparatorName*>
[-window_type *WindowTypeName*]

ToolBarName *String*
MenuName *String*
SeparatorName *String*
WindowTypeName *String*

ARGUMENTS

-toolbar *ToolBarName*

ToolBarName specifies the toolbar that the new toolbar item will be added to.

-menu *MenuName*

MenuName specifies the name of the menu item to be invoked from this toolbar button. The "name" of a menu is a string whcih specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -separator option.

-separator *SeparatorName*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -menu option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

DESCRIPTION

This command adds a toolbar button to the specified toolbar using information described in the -menu option. The -menu option specifies the hierarchical menu name for some menu item. Thus, the toolbar icon becomes another interface for a menu item. Returns the item name if successful.

EXAMPLES

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

gui_create_utable

Create a new UserTable.

SYNTAX

string **gui_create_utable**
-name *Table_Name*
-parent *Table_Name*
-columns *Column_List*
-timing_path *Tim_Clct*
[-meta_obj *MetaObj_Name*]

Table_Name String
Column_List List of Strings
Tim_Clct Timing Path Collection
MetaObj_Name String

ARGUMENTS

-name *Table_Name*

The name of the user table to create.

-parent *Table_Name*

The name of the parent table that is related to this user table.

-columns *Column_List*

A TCL list of column names for the table with optional data type postfix information.

-timing_path *Tim_Clct*

Create and fill a Timing Point Table with the given Timing Path Collection. This is exclusive with the -columns option.

-meta_obj *MetaObj_Name*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

DESCRIPTION

This command creates a new user table with the given list of column names.
In addition, column names can have postfixes that describe the data type of that column.
Or one can use a MetaData object to define the column data types.

Important: This command returns the actual table name created which might
be different if the given table name had bad characters or already exists.
So, capture the return value and use it in future calls to this table.

Supported column name postfixes are:

:string
:int
:double
:cell
:net
:port
:pin
:point
:endpoint
:file

EXAMPLES

The following example creates a new UserTable with the given list of columns. The last
two columns also have some data type postfixes.

```
shell> set table [gui_create_utable -name my_table -columns {colA colB:int colC:double}]
```

gui_show_utable(2)
gui_write_utable(2)

gui_create_var

Create a typed gui variable.

SYNTAX

string **gui_create_var** -name *VarName*
-value *Value*
[-value_type *ValueType*]
[-keep_value_if_exist]
[-read_only]

VarName *String*
Value *Depends on the value type*
ValueType *one of [bool|integer|double|color|string|point|size|rect]*

ARGUMENTS

-name *VarName*

VarName specifies the name of the typed tcl variable to create.

-value_type *ValueType*

ValueType specifies the data type of the value of the variable. It must be one of [bool | integer | double | color | string]. If not specified, default to "string".

-value *Value*

Value specifies the value of the tcl variable. The value should be set appropriately in accordance with its value type. The **bool** type accepts [true, false, 0, 1, on, off]. The **color** type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

-keep_value_if_exist

If this option is specified, the variable will keep its current value if it already exists.

-read_only

If this option is specified, the variable will be read_only.

DESCRIPTION

This command creates a typed tcl variable with the specified name, value type and value. Returns the value of the variable created.

EXAMPLES

The following example creates a typed variable named *my_var* of type integer with value 200.

```
gui_create_var -name my_var -value_type integer -value 200
```

SEE ALSO

gui_set_var(2)
gui_get_var(2)
gui_remove_var(2)
gui_exist_var(2)

gui_create_vm

Creates a new visual mode container for visual mode buckets. The buckets contain coloring attributes for a collections of design objects.

SYNTAX

string **gui_create_vm**
-name *identifier*
[-update_cmd *update_command*]
[-title *label*]
[-help_topic *subject*]
[-infotip *infotip*]
[-discrete true | false]
[-icon *string*]
[-netfilter *string*]
[-float *bool*]
[-top_exaggeration *float*]
[-mid_exaggeration *float*]
[-bot_exaggeration *float*]
[-show_only_pins_of_nets *bool*]
[-enable_bucket_delete *bool*]

Data Types

identifier string
update_command string
label string
subject string
infotip string
net_filter string
icon_spec string

ARGUMENTS

-name *identifier*

Specifies the name that identifies the visual mode. Use this name when another visual mode command requires a visual mode name.

-update_cmd *update_command*

Specifies a Tcl command to execute when the visual mode is accessed. Use this option to update the state of the visual mode if its contents are likely to change under certain circumstances.

-title *label*

Specifies an optional title that is used to label the visual mode in the GUI. The *label* string can contain space characters. By default, the title is the empty string, and the **-name** option value is used to provide the label.

-help_topic *subject*

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

-infotip *infotip*

Specifies the infoTip text string.

-discrete true | false

Specifies an optional true or false string indicating whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. By default, visual modes are continuous.

-icon *string*

Specifies the icon file. The file contains an icon image for the GUI menus.

-netfilter *string*

Specifies the net connection filtering.

-float true | false

Specifies whether the bucket contents have a floating point range. By default, this option is false.

-top_exaggeration *float*

Specifies the exaggeration for the top bucket. The value should be greater than or equal to zero. By default, the value is 0.

-mid_exaggeration *float*

Specifies the exaggeration for the middle bucket. The value should be greater than or equal to -1. By default, the value is -1.

-bot_exaggeration *float*

Specifies the exaggeration for the bottom bucket. The value should be greater than or equal to zero. By default, the value is 0.

-show_only_pins_of_nets true | false

Specifies whether the layout shows pins of net objects in buckets. By default, the value is false.

-enable_bucket_delete true | false

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

DESCRIPTION

The **gui_create_vm** command creates an instance of a visual mode. The visual mode provides a container for visual mode buckets, which associate coloring attributes with collections of design objects.

If the -update_cmd that you specify needs input from the user, then you can define the arguments to your procedure with define_proc_attributes, and then use the gui_show_command_form command for your procedure as the -update_cmd. This will show a form that will prompt for the arguments to your procedure and then it will call your proc to update the visual mode using those values. See the man pages for gui_show_command_form and define_proc_attributes for additional details.

EXAMPLES

The following example creates a new visual mode named mycoloring1 with the GUI label "Cells Colored By X":

```
prompt> gui_create_vm -name mycoloring1 -title {Cells Colored By X}
```

define_proc_attributes(2)

gui_create_vm_objects

Create objects to hold annotations in visual modes

SYNTAX

string **gui_create_vm_objects** *<clct>*

string *<clct>*

ARGUMENTS

<clct>

Objects to convert.

DESCRIPTION

Layout visual modes are used to color objects in the layout given certain criteria. Sometimes you want not only object coloring but some additional annotations displayed with the objects in a bucket.

In order to create this type of visual mode, you need special type of object that can hold annotations. Use this command to create these special objects.

Objects of this type support name and core_obj attribute. The core_obj attribute returns the object that was used to create this object.

EXAMPLES

shell> **set objs [gui_create_vm_objects $cells]**

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_update_vm_annotations(2)

gui_create_vmbucket

Create new Visual Mode Bucket

SYNTAX

string **gui_create_vmbucket** -vmname *mode_identifier*
-name *bucket_identifier*
[-infotip *infotip*]
[-netfilter *net_filter*]
[-color *color*]
[-pattern *pattern*]
[-exaggeration double]
[-number int]
[-maxval double]
[-minval double]
[-visible *visibility*]
[-title *label*]
[-collection *handle*]
[-above *bucket_identifier* | -below *bucket_identifier* -at *top|bottom*]

string *mode_identifier*
string *bucket_identifier*
string *infotip*
string *net_filter*
string *color*
string *pattern*
string *visibility*
string *label*
string *handle*
string *bucket_identifier*
string *bucket_identifier*
string *top|bottom*

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

-name *bucket_identifier*

Specifies the name by which the visual mode bucket will be identified. It is used as the argument when associated visual mode commands require a visual mode bucket name to be specified.

-infotip *infotip*

String for infotip.

-netfilter *net_filter*

Specifies net connection filtering.

-color *color*

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

-pattern *pattern*

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

-exaggeration double

Specifies bucket min pixel exaggeration value >= 0.

-number int

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

-maxval double

Specifies bucket maximum value.

-minval double

Specifies bucket minimum value.

-visible *visibility*

Specifies initial visibility of bucket. Valid values are TRUE and FALSE.

-title *label*

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

-collection *handle*

Tcl object collection to be colored by this visual mode bucket.

-above *bucket_identifier*

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

-below *bucket_identifier*

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

-at *top*|*bottom*

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

DESCRIPTION

The gui_create_vmbucket command creates an instance of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The visual mode bucket can be assigned coloring styles and a collection of design objects to which the coloring will be applied when they are rendered as a part of the visual mode.

EXAMPLES

Create a visual mode with two buckets, one whose objects will be colored red, and another whose objects will be colored blue:

shell> **gui_create_vm -name foo1 -title "My Visual Mode"**

shell> **gui_create_vmbucket -vmname foo1 -name red -title "Red" -color red**

shell> **gui_create_vmbucket -vmname foo1 -name blue -title "Blue" -color blue -below red**

SEE ALSO

gui_set_vm(2)
gui_set_vmbucket(2)
gui_update_vm(2)

gui_create_window

Creates a window of the specified window type.

SYNTAX

string **gui_create_window**
-type *window_type*
[-parent *parent_window_id*]
[-show_state *window_state*]
[-title *title*]
[-rect *rect* | -size {*width height*}]
[-icon *icon*]

Data Types

window_type string
parent_window_id string
window_state string
title string
rect rectangle
width integer
height integer
icon string

ARGUMENTS

-type *window_type*

Specifies the type of window you are creating. The tool creates an instance of this window type.

You can display a list of the supported window types by using the **gui_get_window_types** command.

-parent *parent_window_id*

Specifies the window ID of the parent top-level window for the view window you are creating.

If you do not specify a window ID and the window type is not a top-level window type, the tool uses the current top-level window. If there is no current top-level window, the tool creates a new top-level window automatically to host the window you are creating.

-show_state *create_window_state*

Specifies the window state in which to display the window you are creating. The result varies depending on whether the window is a top-level window or a view window.

For a top-level window, you can specify one of the following states:

maximized -- show maximized (fill whole screen)
minimized -- show iconified
normal -- show at preferred size

Note that the window manager might not fully honor the specified state. See your window manager documentation for more details.

For a view window, you can specify one of the following states:

maximized -- show maximized in view area and raise to top
minimized -- show iconified in view area
normal -- show at preferred size in view area and raise to top

If you display a view window in its maximized state, the tool also maximizes any existing view windows. If you display a view window in its minimized or normal state, the tool changes any maximized view windows to their normal states.

The default is -show_state normal.

-title *title*

Specifies the title for the top-level or view window you are creating.

Note that the window manager might not fully honor the specified top-level window title string. See your window manager documentation for more details.

-rect *rect*

Specifies the size and position of the window in the following format:

{{*x1 y1*} {*x2 y2*}}

The coordinates {*x1 y1*} specify the location of the top-left corner, and the coordinates {*x2 y2*} specify the location of the bottom-right corner. These coordinates are relative to the top-left corner of the screen, for a top-level window, or to the top-right corner of the view area in the parent top-level window, for a view window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The **-rect** option and the **-size** option are mutually exclusive.

-size {*width height*}

Specifies the width and height of the window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The **-size** option and the **-rect** option are mutually exclusive.

-icon *icon*

Specifies the image to be used for the top-level or view window icon.

For a view window, the icon appears in the top-left corner of the title bar when the window is in its normal or minimized state and at the left side of the menu bar when the window is maximized.

For a top-level window, the icon might not be displayed when the window is in its normal, minimized, or maximized state. See your window manager documentation for more details.

DESCRIPTION

This command creates a window of the specified type and returns the window ID. The window type that you specify controls whether the window is a top-level window or a view window.

EXAMPLES

The following example creates a top-level layout window and a minimized layout view window.

```
prompt> set top [gui_create_window -type LayoutWindow]
LayoutWindow.1
prompt> gui_create_window -type Layout -parent $top \
  -show_state minimized
layout.1
```

gui_define_charts_proc

Define tcl command to use in charts expression evaluation

SYNTAX

status **gui_define_charts_proc**
name
args
body

Data Types

ARGUMENTS

name

Name of the procedure.

The procedure name must be non-empty, start with an underscore or a letter and contain only underscore or letter characters.

args

The arguments of the procedure.

body

The body of the procedure.

DESCRIPTION

Define custom tcl command to use in charts expression evaluation.

The syntax and arguments are the same as the standard tcl **proc** command.

If the arguments and body strings are empty then any existing procedure of that name is deleted.

To list all the defined charts procedures you can use the command:

shell> gui_get_charts_data -name procs

To get the args and body for an existing procedure you can use the command:

shell> gui_get_charts_data -name proc_data -data <proc_name>

EXAMPLES

The following example changes a model to create a new column with the square root of values in the first column.

```
shell> gui_define_charts_proc test_proc { arg } { return [expr {$arg/2.0}] }
shell> gui_change_charts_model -model $model -add -expr "test_proc(column(0))" -type real
```

SEE ALSO

gui_change_charts_model(2)
gui_get_charts_data(2)

gui_delete_attrgroup

Removes a group of attributes or all attribute groups for an object type.

SYNTAX

status **gui_delete_attrgroup**
-class *design_object*
-name *name*
[-all]

Data Types

design_object string
name string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be removed for the specified object type.

-all

Removes all attribute groups defined for the specified object type.

DESCRIPTION

The **gui_delete_attrgroup** command removes the specified attribute group or all attribute groups for the specified object type.

EXAMPLES

prompt> **gui_delete_attrgroup -class Cell -name "Hierarchy"**

prompt> **gui_delete_attrgroup -class Cell -all**

SEE ALSO

gui_create_attrgroup(2)
gui_list_attrgroups(2)
gui_update_attrgroup(2)

gui_delete_menu

Delete a menu item for the toplevel menubar or a context menu

SYNTAX

string **gui_delete_menu**
[-menu *HierMenuName* | -all]
[-window_type *WindowTypeName* | -root *ContextMenuRoot*]

HierMenuName *String*
WindowTypeName *String*
ContextMenuRoot *String*

ARGUMENTS

-menu *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to be deleted. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -all option.

-all

This option flag specifies all menu items in a menu root to be deleted. The option cannot be given with the -window_type option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

-root *ContextMenuRoot*

ContextMenuRoot specifies the context menu root to from which the menu item will be added. A context menu root name groups menu items to be included in a pop-up context menu. A context menu is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

DESCRIPTION

This command deletes a menu item for the menu bar of a top level window. The menu hierarchy separator is denoted by "->". If there

is a toolbar button or hotkeys defined for the menu being deleted they will also be deleted. If the path to the menu is a submenu that menu item and all its sub-items will be deleted.

The option -all may be used with a menu root name to remove all menu items from a menu. This is useful if a user wishes to customize or modify an entire context menu.

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default value of $::synopsys/admin/setup/.synopsys_galileo_gui.tcl. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_galileo_gui.tcl.

EXAMPLES

The following example deletes the Quit item from the File menu.

```
gui_delete_menu -menu "File->Quit"
```

SEE ALSO

gui_set_hotkey(2)
gui_report_hotkeys(2)
gui_create_menu(2)

gui_delete_toolbar(2)
gui_create_toolbar_item(2)
gui_delete_toolbar_item(2)
gui_default_window_type(3)
gui_custom_setup_files(3)

gui_delete_toolbar

Delete a toolbar with the specified name.

SYNTAX

string **gui_delete_toolbar** -name *ToolBarName*
[-window_type *WindowTypeName*]

ToolBarName *String*
WindowTypeName *String*

ARGUMENTS

-name *ToolBarName*

ToolBarName is the toolbar identifier for the toolbar to be deleted.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

DESCRIPTION

This command deletes a toolbar and all of its toolbar items.

EXAMPLES

Delete a toolbar called mytoolbar.

```
gui_delete_toolbar -name mytoolbar
```

SEE ALSO

gui_set_hotkey(2)
gui_report_hotkeys(2)
gui_create_menu(2)
gui_delete_menu(2)

gui_create_toolbar_item(2)
gui_delete_toolbar_item(2)
gui_get_toolbar_names(2)
gui_default_window_type(3)
gui_custom_setup_files(3)

gui_delete_toolbar_item

Remove a toolbar button specified by the menu name from the specified toolbar.

SYNTAX

string **gui_delete_toolbar_item** -toolbar *ToolBarName*
<-menu *MenuName*|-separator *SeparatorName*>
[-window_type *WindowTypeName*]

ToolBarName *String*
MenuName *String*
SeparatorName *String*
WindowTypeName *String*

ARGUMENTS

-toolbar *ToolBarName*

ToolBarName specifies the toolbar to be modified.

-menu *MenuName*

ItemName specifies the hierarchical menu name for some menu item, that this toolbar item is associated with. This option is mutually exclusive with the -separator option.

-separator *SeparatorName*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -item option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

DESCRIPTION

This command deletes a toolbar item specified by *MenuName* or *SeparatorName* from the specified toolbar. Returns the name of the deleted toolbar item if successful.

EXAMPLES

Delete the button bound to File->Quit from the toolbar mytoolbar.

```
gui_delete_toolbar_item -name mytoolbar -menu "File->Quit"
```

SEE ALSO

gui_edit_vmbucket_contents

Edit the collection contents of a Visual Mode Bucket

SYNTAX

string **gui_edit_vmbucket_contents** -vmname *mode_identifier*
-name *bucket_identifier*
[-add | -remove | -replace]
[-collection *handle*]

string *mode_identifier*
string *bucket_identifier*
string *handle*

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

-name *bucket_identifier*

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

-add

Add the collection to the collection already in the bucket

-remove

Remove the collection from the collection already in the bucket

-replace

Replace the collection already in the bucket

-collection *handle*

Tcl object collection to be colored by this visual mode bucket.

DESCRIPTION

The gui_edit_vmbucket_contents command modifies the collection stored in a visual mode bucket. The collection can either be appended to, removed, or replaced. The flags to control this are mutually exclusive.

EXAMPLES

Add the current selection to the collection in the bucket 0 of the SNAPSHOT visual mode:

```
shell> gui_edit_vmbucket_contents -vmname SNAPSHOT -name 0 -add -collection [get_selection]
```

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vm(2)
gui_get_vmbucket(2)
gui_list_vm(2)
gui_remove_vm(2)
gui_remove_vmbucket(2)
gui_set_vm(2)
gui_update_vm(2)

gui_error_browser

Show or hide the Error Browser Dialog

SYNTAX

string **gui_error_browser**
[-hide | -show | -toggle]

ARGUMENTS

-hide

Hides the Error Browser Dialog.

-show

Shows the Error Browser Dialog. If no option flag is provided, this is the default.

-toggle

Show the Error Browser Dialog if it is currently hidden, else hide it.

DESCRIPTION

The **gui_error_browser** command controls the visibility of the Error Browser Dialog. The Error Browser Dialog displays violations with physical shapes recorded by a checker, for example a DRC engine. This command is valid only when there is a design open. If the Error Browser Dialog is shown and it was not previously shown. If the Error Browser Dialog is shown and it was previously shown, it will show the error data last loaded.

EXAMPLES

The following example creates and shows the Error Browser Dialog:

```
gui_error_browser -show
```

SEE ALSO

gui_eval_cmd

Execute and (optionally) log a Tcl command.

SYNTAX

string **gui_eval_cmd** -cmd *command*
[-log | -no_log]
[-history | -no_history]
[-display| -no_display]
[-exec_callbacks | -no_exec_callbacks]

string *command*

ARGUMENTS

-cmd *command*

The command to execute and optionally log.

-log

Enables logging of the command. If neither -log nor -no_log is specified, -log is the default.

-no_log

Disables logging of the command.

-history

Enables putting the command into the command history. if neither -history nor -no_history is specified, the default is -history if logging is enabled, and -no_history if logging is disabled.

-no_history

Disables putting the command into the command history.

-display

Enables display of the command result. If neither -display nor -no_display is specified, -no_display is the default.

-no_display

Disables display of the command result.

-exec_callbacks

Enables running of shell execution callbacks for the command. If neither -exec_callbacks nor -no_exec_callbacks is specified, -no_exec_callbacks is the default.

-no_exec_callbacks

Disables running of shell execution callbacks for the command.

DESCRIPTION

Execute and (optionally) log a Tcl command.

The purpose of this command is to support logging of core commands run by Tcl code in qTcl dialogs. (It is just a wrapper around EkShellExecution::executeSync which exposes several of the executeSync boolean parameters.)

All options except -cmd are optional - the default behavior for the optional options is: -log -history -no_display -no_exec_callbacks.

For history, if neither -history nor -no_history are specified, the default is -history if logging is enabled, and -no_history if logging is disabled.

The command is hidden.

gui_eval_cmd will result in a "nested" command execution when run from the command line: the outermost command execution is the execution of gui_eval_cmd itself, and the nested command execution is for the -cmd command. A recursive call to EkShellExecution::executeSync will happen.

The result of the nested command is passed back as the result of gui_eval_cmd.

Some of the options, such as -exec_callbacks and -display, are included for completeness of the executeSync wrapper, and may not be very useful.

EXAMPLES

```
psyn_shell-t> gui_eval_cmd -cmd {echo abc}
abc
```

SEE ALSO

gui_log_cmd(2)

gui_eval_command

Executes and optionally logs a tool command language (Tcl) command.

SYNTAX

string **gui_eval_command**
-command *command*
[-echo]
[-history]
[-honor_preview | -preview]

Data Types

command string

ARGUMENTS

-command *command*

Specifies the Tcl command to execute and to record in the command replay log.

-echo

Echoes the command and displays the command result in the console log view. By default, the tool does not echo the command or display the result in the log view.

-history

Appends the command to the command history list in the console history view. By default, the tool does not append the command to the command history list.

-honor_preview

This option is mutually exclusive with the -preview option. Honors the Preview Command Only settting in the dialog. By default, the tool does not honor the Preview Command Only settting.

-preview

This option is mutually exclusive with the -honor_preview option. Runs the given command in preview mode, irregardless of the current preview mode set from a command dialog. When -preview is given, -echo is turned on since the previewed command cannot be seen in the xterm if -echo is turned off. As with all commands issued from command dialogs when in preview mode, if a script editor is present, then the previewed command is redirected to the scripte editor. Using this option does not set or clear the global preview mode in the application.

DESCRIPTION

This command executes a Tcl command and records it in the command replay log. Use the **-echo** option to echo the command and its result in the console log view Use the **-history** option to append the command to the command history list. Use the **-honor_preview** option to honor the Preview Command Only settting. Use the **-preview** option to preview the command only without executing it.

The result of a nested command is passed back as the result of **gui_eval_command**.

EXAMPLES

The following example evaluates the command "echo abc".

```
prompt> gui_eval_command -command {echo abc}
abc
```

The following example previews the command "echo abc".

```
prompt> gui_eval_command -command {echo abc} -preview
abc
```

gui_eval_task_command

Executes a command from a task assistant page

SYNTAX

string **gui_eval_task_command**
-command *command*
[-task taskName | -script]

Data Types

command string
command taskName

ARGUMENTS

-command *command*

Specifies the Tcl command to execute and to add to the favorites and most-recently-used (MRU) palettes. The executed command is logged in the command log.

-task *taskName*

If this option is present, then the given task name is used when the command is added to the favorites and MRU palettes. If not present, then the current task name is used.

-script

This option is mutually exclusive with the -task option. If this option is present, the command is not run but is appended in the script editor.

DESCRIPTION

This command executes the given Tcl command and records it in the command replay log. Use the **-script** option to append the command to the script editor only without executing it.

The result of a nested command is passed back as the result of **gui_eval_task_command**.

EXAMPLES

The following example evaluates the command "echo abc".

```
prompt> gui_eval_task_command -command {echo abc}
abc
```

The following example adds the command "echo abc" to the script editor.

```
prompt> gui_eval_task_command -command {echo abc} -script
abc
```

gui_execute_menu_item

Execute a menu item in the currently active window.

SYNTAX

status **gui_execute_menu_item**
{ -menu *menu_item_id* }

Data Types

menu_item_id string

ARGUMENTS

-menu *menu_item_id*

menu_item_id specifies the hierarchical name of the menu item to execute. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item in the File menu. These names are allowed to also specify the keyboard accelerator for the menu text which is specified with an embedded '&', but they are not required to do so.

DESCRIPTION

This command checks for the existence and enabled state of the given menu item in the currently active window. If it exists and is enabled, the menu item is executed.

The command returns and result value string from the executed menu item, if any.

EXAMPLES

The following example activates the main window named Toplevel.2, then executes the **Hierarchy Browser** menu item in the **View** menu in Tolevel.2.

shell> gui_set_active_window -window Toplevel.2
shell> gui_execute_menu_item -menu "View->Hierarchy Browser"

SEE ALSO

gui_create_menu(2)
gui_set_active_window(2)

gui_exist_pref_category

Check the existence of a preference category.

SYNTAX

bool **gui_exist_pref_category** -category *Category*

Category *String*

ARGUMENTS

-category *Category*

Category specifies the category.

DESCRIPTION

This command checks the existence of a preference category. Return "1" if the specified category exists, otherwise return "0".

SEE ALSO

gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_get_pref_value_type(2)
gui_remove_pref_key(2)
gui_get_pref_categories(2)
gui_get_pref_keys(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_exist_pref_key

Check the existence of a preference key.

SYNTAX

bool **gui_exist_pref_key** -key *Key*
[-category *Category*]

Key *String*
Category *String*

ARGUMENTS

-key *Key*

Key specifies the preference key of interest.

-category *Category*

Category specifies the category. Default category will be used if missing.

DESCRIPTION

This command checks the existence of a preference key given the key name and the preference category. Return "1" if the specified key exists, otherwise return "0".

SEE ALSO

gui_create_pref_category(2)
gui_create_pref_key(2)

gui_exist_pref_category(2)

gui_update_pref_file(2)

gui_exist_var

Check the existence of the typed tcl variable that is created with gui_create_var.

SYNTAX

bool **gui_exist_var** -name *VarName*

VarName *String*

ARGUMENTS

-name *VarName*

VarName specifies the variable name.

DESCRIPTION

This command checks the existence of the typed tcl variable with the specified name. Return "1" if the variable exists, otherwise return "0".

SEE ALSO

gui_create_var(2)
gui_set_var(2)
gui_get_var(2)
gui_remove_var(2)

gui_exist_window

Check for the existence of specified window or window type

SYNTAX

status **gui_exist_window**
{ -window *window_id* | -type *window_type* }
[-parent *window_id*]

Data Types

window_id string
window_type string

ARGUMENTS

-window *window_id*

Specifies the window id to test existence for.

This option is mutually exclusive with the *-type* option.

-type *window_type*

Specifies that the existence of a window of this window type is tested for.

If the *-parent* option is specified then the existence of a window of this window type is tested for in the specified toplevel window.

If the *-parent* option is **not** specified then the existence of a window of this window type is tested for in any toplevel window.

This option is mutually exclusive with the *-window* option.

-parent *window_id*

Specifies the toplevel window to check for existence in.

Note: This option is only relevant if the *-type* option is specified.

DESCRIPTION

This command checks the existence of the specified window, or window type across toplevel windows or within a specified toplevel window.

The command returns "1" or "0" for success or failure respectively.

EXAMPLES

The following example will create a toplevel window and a child layout view window, then check the existence of the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> set layout_exist [gui_exist_window $x]
shell> if { $layout_exist == 1} {echo "layout exist" }
```

gui_get_current_window(2)

gui_explore_logic_hierarchy

Creates, expands, colors, and removes enclosing module boundaries for cells in the logical hierarchy. This command is typically called by the tool from the Color by Hierarchy section of the Hierarchy Exploration panel.

SYNTAX

module_boundaries **gui_explore_logic_hierarchy**
[-threshold *threshold_ratio*]
[-create | -expand | -collapse | -remove | -update | -query]
[-color *color_id*]
[-force]
[*cells*]

Data Types

module_boundaries string
threshold_ratio real
color_id integer
cells collection

ARGUMENTS

-threshold *threshold_ratio*

Specifies the ratio to use when determining if a child hierarchical cell should have an enclosing module boundary created for it. Module boundaries are created if the size of the boundary relative to the total size is greater than *threshold_ratio*. For example, if the *threshold_ratio* is 0.03, logical hierarchies are ignored if they have a size smaller than 3 percent of total size.

By default, the ratio is specified by the *plan.explore.default_threshold* application option.

-create

Creates enclosing module boundaries for the specified logical hierarchical cells. Module boundaries are removed for the child cells of the specified logical hierarchical cells.

If the **-color** option isn't specified, a color will be automatically assigned.

-expand

Creates enclosing module boundaries for the child cells of the logical hierarchical cells (limited by a size threshold). If the parent cell already has a module boundary then, the module boundary for the parent will be removed. If module boundaries already exist on the child modules of the cell, the boundaries are re-created or removed as needed. For example, boundaries could be removed of the threshold changed.

The tool automatically assigns a color to the cells of each created module boundary.

-collapse

Removes the enclosing module boundaries for the currently selected module boundary and any sibling module boundaries, then creates a parent module boundary.

-remove

Removes the selected enclosing module boundary.

-update

Updates the shape of the enclosing module boundaries for the currently selected shape based on the current placement of their child cells.

If no cells are specified, all enclosing module boundaries are updated.

The application keeps track of the state of the created enclosing module boundaries, so updating update on module boundaries with no cell location changes will not normally modify the module boundary. To force an update, use the **-force** option.

The color of the cells within the module boundary will not be changed.

-query

Returns the instances for the existing enclosing module boundaries.

-color *color_id*

Specifies a color ID for the module boundary and its descendant. Valid *color_id* values are integer values from 0 to 63. If this option isn't specified, module boundaries and its descendant will be colored automatically. When creating the boundary, if *color_id* is 0, do not color the cells; Otherwise, color the objects with *color_id*.

-force

Forces update of enclosing module boundaries, even if the tool considers them up-to-date.

This option is not typically used, but can be added if you determine that an update is needed.

This option can only be used with the **-update** option.

DESCRIPTION

This command supports hierarchy exploration by creating, expanding, managing, and removing enclosing module boundaries for the physical child cells of logical hierarchical cells. This command is typically called by the tool from the Color by Hierarchy section of the Hierarchy Exploration panel.

The command returns the created or queried module boundaries.

The enclosing module boundary can be created for specific logical hierarchical cells (*create* mode) or for all the child modules of logical hierarchical cells (*expand* mode). When creating child boundaries, the actual cells which have boundaries created is controlled by a size threshold. Cells with a size below the threshold are skipped.

The created module boundary is shaped so its rectilinear boundary encloses the bounding boxes of all the child cells in the logical hierarchy. This provides visual feedback of the standard cell and macro placement for the logical hierarchy, even if the child cells are not visible.

The created module boundary and child cells are set to the same cell color, so the association between the module boundary and child cells can be seen at all zoom levels.

The created module boundaries can also be removed (*remove* mode) or updated (*update* mode).

Note: this command extends the functionality of the existing **explore_logic_hierarchy** command to support a more complex boundary (enclosing shape) and to support consistent module boundary and child cell coloring.

NOTE

This command does not require the gui to be open.

The command supports undo i.e. the undo command will restore the module boundaries and colors to their previous state.

EXAMPLES

The following example creates an enclosing module boundary for the ALU logical hierarchical cell using the auto color.

prompt> gui_explore_logic_hierarchy -create [get_cells ALU]

The following example creates enclosing module boundaries for the child cells of the top cell using the color which is auto assigned.

prompt> gui_explore_logic_hierarchy -expand

The following example removes the module boundary for the ALU logical hierarchical.

prompt> gui_explore_logic_hierarchy -remove [get_cells ALU]

The following example will remove the enclosing module boundaries for all cells.

prompt> gui_explore_logic_hierarchy -remove

The following example updates the module boundary for the ALU logical hierarchy.

prompt> gui_explore_logic_hierarchy -update [get_cells ALU]

The following example updates the enclosing module boundaries for all cells.

prompt> gui_explore_logic_hierarchy -update

SEE ALSO

explore_logic_hierarchy(2)
set_colors(2)

gui_export_utable

Export the UserTable to a value file.

SYNTAX

string **gui_export_utable**
-name *Table_Name*
[-file *File_Name* [-tsv_mode] [-ssv_mode]]
[-filter *Filter*]
[-tsv_mode]
[-ssv_mode]
[-add_col_type]
[-add_metadata]
[-overwrite]

Table_Name String
File_Name String

ARGUMENTS

-name *Table_Name*

The name of the user table to export to a CSV value file.

-file *File_Name*

The name of the file to write the table to, by default the name of the table is used with the '.csv' extension.

-filter *Filter*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

-tsv_mode

This flag changes the default delimiter from the comma char to the tab char.

-ssv_mode

This flag changes the default delimiter from the comma char to the semicolon char.

-add_col_type

This flag will add column type information to be added as a postfix to the header column names. This allows type information to be available if imported again by this tool at a later time.

-add_metadata

Add metadata to the top of the exported table. See the command gui_set_utable_meta for more information.

-overwrite

This flag will force the destination file to be overwritten.

DESCRIPTION

This command exports the contents of the given UserTable into a CSV value file. The first line contains all the column names and if the **-add_col_type** flag is given, it also appends column data type information to the column names.

EXAMPLES

The following example just exports the given UserTable to a file with the same name as the table plus a '.csv' extension.

shell> **gui_export_utable -name my_table**

The following example exports the UserTable 'my_table' to the filename 'results' and uses the Tab char as a delimiter. The resultant file will be called 'results.tsv'.

shell> **gui_export_utable -name my_table -file results -tsv_mode**

gui_filter_charts_model

Filter charts model

SYNTAX

status **gui_filter_charts_model**
-model *model_id*
-expr *string*

Data Types

model_id int

ARGUMENTS

-model *model_id*

Model to filter (previously created by **gui_create_charts_model** command).

-expr *string*

Filter expression which returns '1' for rows that should be kept in the model.

The expression can use tcl variable names that match the column name (as long as the column name is a legal tcl variable) name and can use some standard functions.

- column : get column value for row
- row : get row value for column
- cell : get cell value for row and column
- setColumn : set column value for row
- setRow : set row value for column
- setCell : set cell value for row and column
- header : get header value for column
- setHeader : set header value for column
- type : get type for column
- setType : set type for column
- map : map row number to range

- bucket : get bucket for column value
- norm : normalize column value
- rand : get random number
- rnorm : get normaized random number
- color : get color from name
- remap : map column value to range
- timeval : get time value from column with time format

DESCRIPTION

Filter data in an existing model.

EXAMPLES

TODO

SEE ALSO

gui_create_charts_plot(2)
gui_define_charts_proc(2)

gui_get_annotations

Return a collection of layout annotations

SYNTAX

string **gui_get_annotations**
[-window *window_name*]
[-group *group_id*]
[-within *region*]
[-intersect]
[-at *location*]
[-filter *filter*]
[-nocase]
[-regexp]

string *window_name*
string *group_name*
string *filter*
rectangle *region*
location *point*

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window. If not specified implies all windows.

-group *group_name*

Specifies the annotation group name. If not specified implies all groups.

-within *region*

Search for annotations contained within the specified rectangle.

-intersect

Use this option with the -within option. When -intersect is specified, all annotations that touch the search rectangle are also returned.

-at *location*

Search for annotations that are close to the specified point.

-filter *filter*

Only return annotations that satisfy the filter expression.

-nocase

Ignore case in the filter expression. Option requires -filter.

-regexp

Use regular expressions in the filter expression. Option requires -filter.

DESCRIPTION

Returns a collection of gui_annotation objects that satisfy the requirements. You can use get_attribute to query properties of the annotations. Also some attributes may be modified with set_attribute.

EXAMPLES

The following example retrieves all the annotations in the Layout.1 window.

```
shell> gui_get_annotations -window Layout.1
```

This example shows how to use the client_data attribute to find annotations with that setting.

```
shell> gui_get_annotations -filter client_data==MyData
```

This example shows how to find annotations that are within a specified rectangle

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}}
```

To also find the annotations that touch the search rectangle:

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}} -intersect
```

SEE ALSO

gui_add_annotation gui_remove_annotations

gui_get_attribute

Get the value of a GUI attribute for one or more objects.

SYNTAX

string **gui_get_attribute**
object_collection
attribute_name
[-default *default*]

string *object_collection*
string *attribute_name*
string *default*

ARGUMENTS

object_collection

A collection of one or more objects.

attribute_name

The name of a GUI attribute.

-default *default*

Default value for objects that do not support GUI attribute *attribute_name*.

DESCRIPTION

Queries the requested attribute value for each element of the object collection. The return value is a list of one or more attribute values (depending on the size of the object collection). If *default* is not specified and one of the objects in *object_collection* does not support attribute *attribute_name*, a Tcl error is raised. If *default* is specified that *default* is used for all objects that do not support attribute *attribute_name*. This command is hidden.

EXAMPLES

psyn_shell-t> **gui_get_attribute [find cell I_ALU] full_name**

I_ALU

psyn_shell-t> **gui_get_attribute [find cell U*7] full_name**
U7 U17 U27 U37

SEE ALSO

gui_set_attribute(2)

gui_get_bucket_option

Returns the value of a bucket option of a given visual or map mode.

SYNTAX

string **gui_get_bucket_option**
-map *map_name*
-bucket *bucket_name*
-option *option_name*
[-default]

Data Types

map_name	string
bucket_name	string
option_name	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-bucket *bucket_name*

Specifies the name of the bucket.

-option *option_name*

Specifies the name of the option to be set.

-default

Specifies that command has to return default option value.

DESCRIPTION

This command returns an option value that are available for the bucket in the specified visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. The command can return either current or default value.

EXAMPLES

The following example returns the value of 'visible' option of 'light blue' bucket of 'Highlight' visual mode:

prompt> **gui_get_bucket_option -map {Highlight} -bucket {light blue} -option {visible}**

SEE ALSO

gui_set_bucket_option(2)
gui_get_bucket_option_list(2)
gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_map_option(2)

gui_get_bucket_option_list

Lists the available options for buckets in the specified visual mode or map mode.

SYNTAX

string **gui_get_bucket_option_list**
-map *map_name*

Data Types

map_name string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

DESCRIPTION

This command displays a list of all options that are available for the buckets in the specified visual mode or map mode.

EXAMPLES

The following example displays a list of the available options for buckets in the global route congestion map:

prompt> **gui_get_bucket_option_list -map AREAPARTITION**

SEE ALSO

gui_get_bucket_option(2)
gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)

gui_set_bucket_option(2)
gui_set_map_option(2)

gui_get_category_nodes

Returns the specified category tree nodes as a collection.

SYNTAX

gui_get_category_nodes
[-tree *category_tree*]
category_nodes_list

Data Types

category_tree	string or category_tree collection
category_nodes_list	list

ARGUMENTS

-tree *category_tree*

The category tree in which the category node operation will happen; must be a category tree name or a category tree collection of size one; the most recently used category tree is used if the *-tree* option is omitted.

category_nodes_list

List of hierarchical (category node) name patterns and collections of category nodes to be returned. A category node name is a unique hierarchical name of a category node in a Tcl list format.

DESCRIPTION

Returns the specified category tree nodes as a collection.

You should use this command only if at least one category tree is available. The command acts on the category tree specified.

EXAMPLES

The following example shows how to get the ALL root category node as a collection.

```
shell> set my_clct [gui_get_category_nodes {ALL}]
```

The following example shows how to return (as a collection) the {Launch Clock: my_clock} category node that is a child of the {Pathgroup: my_clock} category node, which in turn is a child of the ALL root category node.

```
shell> set my_clct [gui_get_category_nodes \
? {{ALL {Pathgroup: my_clock} {Launch Clock: my_clock}}}]
```

SEE ALSO

gui_create_category_nodes(2)
gui_remove_category_nodes(2)

gui_get_category_trees

Returns the specified category trees (or all category trees by default) in a collection.

SYNTAX

category_tree_collection **gui_get_category_trees**
[*category_trees_list*]

Data Types

category_tree_collection collection (of category tree objects)
category_trees_list list (of category tree name patterns and collections)

ARGUMENTS

category_trees_list

A list of of category tree name patterns and category tree collections specifying the category trees to be returned in the result collection. If this option is omitted, then all existing category trees are returned in the result collection.

Each category tree name pattern must be either the exact name of an existing tree, or the pattern "*", which means "all category trees". More general forms of wild-card matching are not supported at this time.

DESCRIPTION

Returns the specified category trees (or all category trees by default) in a category tree collection. An empty string is returned if no matching category trees exist.

EXAMPLES

This example show the creation of a couple of category trees, and the results of several different runs of gui_get_category_trees:

```
shell> set path_clct [get_timing_paths ...]
_sel18
shell> set path_clct2 [get_timing_paths ...]
_sel19
shell> gui_create_category_tree -name tree0 -collections $path_clct
```

```
_sel20
shell> gui_create_category_tree -name tree1 -collections $path_clct2
_sel21
shell> get_attribute [gui_get_category_trees "tree1 tree0"] name
tree1 tree0
shell> get_attribute [gui_get_category_trees tree1] name
tree1
shell> get_attribute [gui_get_category_trees *] name
tree0 tree1
```

SEE ALSO

gui_create_category_tree(2)
gui_remove_category_trees(2)
get_attribute(2)

gui_get_cell_block_marks

Gets a list of the block mark string values on one or more cells.

SYNTAX

list **gui_get_cell_block_marks**
cells

Data Types

cells list

ARGUMENTS

cells

Lists one or more cell name patterns or cell collections.

DESCRIPTION

This command gets the block mark string values from one or more hierarchical or leaf-level cell instances.

EXAMPLES

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_get_cell_block_marks I_TOP/I_ALU
ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the **get_cells** command, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
prompt> gui_get_cell_block_marks [get_cells I_TOP/I_ALU]
ALU
```

The following example shows how using the **get_attribute** command to query the **block_mark** attribute is an alternative to using the **gui_get_cell_block_marks** command:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_get_cell_block_marks I_TOP/I_ALU
ALU
prompt> get_attribute -class cell I_TOP/I_ALU block_mark
ALU
```

SEE ALSO

gui_set_cell_block_marks(2)
gui_remove_cell_block_marks(2)

gui_get_charts_data

Get charts data

SYNTAX

value **gui_get_charts_data**
{ -global | -model *model_id* | -view *view_name* |
-plot *plot_name* | -annotation *annotation_name* }
[-object *object_id*]
[-column *column_name*]
[{ -header | -row *int* }]
-name *string*
[-data *string*]

Data Types

model_id int
view_name string
plot_name string
annotation_name string
object_id string
column_name int
value string

ARGUMENTS

-global

Get global data.

-model *model_id*

Model to get data from.

-view *view_name*

View to get data from.

-plot *plot_name*

Plot to get data from.

-annotation *annotation_name*

Annotation to get data from.

-object *object_id*

Plot object to get data from.

Only used by the *plot* option.

-column *column_name*

Column to get model data from.

Only used by the *model* option.

-header

get model data from header.

Only used by the *model* option.

-row *int*

Row to get model data from.

Only used by the *model* option.

-name *string*

Name of data to return.

The supported names depend on which object the data is extracted from:

For model the following names are supported:

value Get value of model horizontal header (using the *header* option) value or row value (using the *row* option). The column is specified using the *column* option.

num_rows Get number of rows in model.

num_columns Get number of columns in model.

hierarchical Is model hierarchical.

header Get model header names. If column is specified using the *column* option then only the header for that column is returned.

row Get model row values for the row specified using *row* option.

column Get model column values for the column specified using *column* option.

duplicates Get rows with duplicate values (same value in all columns).

column_index Get model column index from name specified in *data* option.

title Get the model title.

The following data names are queried on the specifed column (single value) or, if the column is not specified, then on all columns (list of values):

type Get model column type.

min or minimum Get model minimum column value.

max or maximum Get model maximum column value.

mean or avg or average Get model average column value.

monotonic Get if model column monotonic (increasing or descreasing)

increasing Get if model column increasing

num_unique Get number of unique model values in column.

unique_values Get unique model values in column.

unique_counts Get counts of each unique model value in column.

num_null Get number of null values in column.

median Get model median column value.

lower_median Get model lower median column value.

upper_median Get model upper median column value.

stddev or std_dev Get model standard deviation value.

outliers Get model outlier values.

For view the following names are supported:

plots return a list of all plots in the view.

annotations return a list of all annotations in the view.

selected_objects return a list of all selected objects in the view.

For plot the following names are supported:

model Model index.

view Parent view name.

annotations Get plot's annotation object ids.

objects Get plot's object ids.

selected_objects Get plot's selected object ids.

For annotation the following names are supported:

view Parent view name.

plot Parent plot name.

The following global data the following names are supported:

models Get model indices

views Get view names.

plot_types Get plot type names.

plots Get all plots names.

column_types Get all column type names.

column_type.names Get names of parameters for specified column type (in *data* option).

annotation_types Get all annotation type names.

symbol_names Get all symbol names.

procs Get all user defined procedure names.

You can also use the special name "?" which will return a list of the supported names for the specified object.

-data ***string***

Extra data needed to query some data values.

RETURNS

value

Returned value.

DESCRIPTION

Get data from model, view, plot type, plot objects or from global object.

If model is specified then the *column* and *header* or *row* should be specified.

EXAMPLES

The following example gets all the plots of a view.

shell> gui_get_charts_data -view $view -name plots

SEE ALSO

gui_set_charts_data(2)

gui_get_charts_property

Get charts property

SYNTAX

value **gui_get_charts_property**
{ -view *view_name* | -plot *plot_name* |
-annotation *annotation_id* }
[-object *object_id*]
-name *string*

Data Types

view_name string
plot_name string
annotation_id string
object_id string
value string

ARGUMENTS

-view *view_name*

View to get property from.

-plot *plot_name*

Plot to get property from.

-annotation *annotation_id*

Plot or view annotation to get property from.

-object *object_id*

Plot object to get property from.

The *plot* option must be specified as well.

-name *string*

Name of property to return.

The supported names depend on which object the property is extracted from but can be listed by using the special property name "?".

RETURNS

value

Returned value.

DESCRIPTION

Get property from view, plot, view annotation, plot annotation or plot objects.

EXAMPLES

The following example gets all the position of a annotation in a plot.

```
shell> gui_get_charts_property -plot $plot -annotation $annotation -name position
```

SEE ALSO

gui_set_charts_property(2)

gui_get_clock_tree

Returns clock tree fanin or fanout cone for given clock and start pin.

SYNTAX

status **gui_get_clock_tree**
-clocks *clocks*
-from *from_pins*
-trace_direction forward | backward | both

Data Types

clocks string or collection
from_pins string or collection

ARGUMENTS

-clocks *clocks*

Specifies the clocks on which the clock tree fanin or fanout cone is calculated.

-from *from_pins*

Specifies the start pins from which the fanin or fanout cone is traced.

-trace_direction forward | backward | both

Specifies the trace direction. The trace direction must be one of following values:

- forward: Trace forward through the clock tree (get fanout pins)
- backward: Trace backward through the clock tree (get fanin pins)
- both: Trace both forward and backward (get both fanout and fanin pins)

DESCRIPTION

Returns a collection of clock tree fanin or fanout pins for given clock and start pin.

EXAMPLES

The following example returns the fanout pins of clock CLK3, starting from selected pin.

```
prompt> gui_get_clock_tree \
  -clocks [get_clocks CLK3] -from [get_selection] -trace_direction forward
```

SEE ALSO

get_clocks(2)

gui_get_color_value

Get the RGB color value for given color index or name, else return all color information for the palette.

SYNTAX

string **gui_get_color_value** *[index]*
[-palette string]
[-color_name string]

ARGUMENTS

index

Use given color index number. An error message is posted if the given index is greater than the maximum index allowed for the current or given Palette. This argument is exclusive with option -color_name.

-palette

User given palette name, the default is 'highcontrast'. Valid values are: highcontrast, highlight, qt, style. An error message is printed if an invalid palette name is given.

-color_name

Use given color name. Must be valid for the current/given palette. If an invalid color name is given an error message is posted. This option is exclusive with the 'index' argument.

DESCRIPTION

Get the RGB color value string for the given color name or index value.

If no argument is given the command will return a TCL list of lists. One list for every color in the current/given palette. The list for each color contains the index number, the RGB color value and, if available, a color name.

EXAMPLES

shell> **gui_get_color_value 10**
#005000

```
shell> gui_get_color_value -color_name magenta
#ff00ff

shell> gui_get_color_value
{0 #000000 }
{1 #464646 }
{2 #00ff64 }
{3 #78bec8 }
{4 #ff00ff magenta}
{5 #00af96 }
{6 #0000be }
{7 #00ffff cyan}
{8 #b1f476 light_green}
{...}
```

gui_get_current_category_tree

Returns the "current category tree" (if any) in a collection of size 1.

SYNTAX

category_tree_collection **gui_get_current_category_tree**

Data Types

category_tree_collection collection (of one category tree object)

DESCRIPTION

Returns the "current category tree" (if any) in a collection of size 1. An empty string is returned if there are no existing category trees.

At any time, exactly one of the existing category trees has the status "current category tree". When a new category tree is created, it immediately becomes the current category tree. If the current category tree is removed, a different category tree will be chosen as the current category tree. If there are no existing category trees, then there is no current category tree.

EXAMPLES

Here are examples of getting and setting the current category tree:

```
shell> get_attribute [gui_get_category_trees *] name
_tree008 _tree009 _tree010 _tree011
shell> get_attribute [gui_get_current_category_tree] name
_tree009
shell> gui_set_current_category_tree _tree008
shell> get_attribute [gui_get_current_category_tree] name
_tree008
```

SEE ALSO

gui_get_current_task_page(2)
gui_set_current_task(2)
gui_get_task_list(2)

gui_get_current_task_item

Get the name of the current task item.

SYNTAX

string **gui_get_current_task_item**

DESCRIPTION

The gui_get_current_task_item command queries the name of the current task item.

SEE ALSO

gui_get_current_task(2)
gui_get_current_task_page(2)
gui_set_current_task(2)
gui_get_task_list(2)

gui_get_current_task_page

Get the name of the current task page.

SYNTAX

string **gui_get_current_task page**

DESCRIPTION

The gui_get_current_task_page command queries the name of the current task page.

SEE ALSO

gui_create_task(2)
gui_get_current_task(2)
gui_get_current_task_item(2)
gui_set_current_task(2)
gui_get_task_list(2)

gui_get_current_window

Retrieves the window ID of the active top-level or view window.

SYNTAX

string **gui_get_current_window**
[-toplevel | -view | -parent *parent_window_id*]
[-hier_name]
[-types *window_type_list*]
[-mru]

Data Types

parent_window_id string
window_type_list list

ARGUMENTS

-toplevel

Retrieves the active top-level window unless you also specify the **-types** option.

If you also specify the **-types** option, the **-toplevel** option retrieves the most recently active top-level window that has one of the specified window types.

The **-toplevel**, **-view**, and **-parent** options are all mutually exclusive.

-view

Retrieves the active view window in the active top-level window unless you also specify the **-types** option, the **-mru** option, or both.

if you also specify the **-types** option but not the **-mru** option, the **-view** option retrieves the most recently active view window with one of the specified window types in the active top-level window.

if you also specify the **-mru** option but not the **-types** option, the **-view** option retrieves the most recently active view window in any of the open top-level windows.

If you also specify both the **-types** option and the **-mru** option, the **-view** option retrieves the most recently active view window that has one of the specified window types and is in an open top-level window.

The **-view**, **-toplevel**, and **-parent** options are all mutually exclusive.

-parent *parent_window_id*

Retrieves the active view window in the specified top-level window unless you also specify the **-types** option.

If you also specify the **-types** option, the **-parent** option retrieves the most recently active view window that has any of the specified window types and is in the specified top-level window.

The **-parent**, **-toplevel**, and **-view** options are all mutually exclusive.

-hier_name

Returns the window ID in Qtcl format, which is similar to a full path name for the window, for use with the qtcl_* commands.

Note that a value returned in this format is not usable by gui_* commands.

-types *window_type_list*

Forces the tool to retrieve a window with one of the specified window types.

Use this option to restrict the search to certain types of windows. If you specify multiple types, they should be consistent (all toplevel window types or all view window types), but nonconsistency is not considered an error. The first type in the list determines whether the tool retrieves a top-level window or a view window when the **-toplevel** and **-view** options are not specified.

When you use the **-types** option, you should not use the **-toplevel** option or the **-view** option because the tool can determine from the list whether the window should be a top-level window or a view window. If you specify one of these options, any types that do not correspond to the option are silently ignored. For example, if you specify **-view**, then all top-level types are ignored.

-mru

Forces the tool to retrieve the most recently active view window from among all the open top-level and view windows. This option is effective only when you specify the **-view** option or when all the window types you specify with the **-types** option are view window types.

DESCRIPTION

This command retrieves the window ID of the active top-level or view window based on the options that you specify, or returns an empty string if no match is found.

A view window is a child window of a top-level window and is created with the **gui_create_window** command.

If you do not specify the **-toplevel**, **-view**, and **-parent** options, the tool uses the **-types** option to determine the window type. If you also do not specify the **-types** option, the tool uses the **-toplevel** option by default.

EXAMPLES

The following example retrieves the active top-level window:

```
prompt> gui_get_current_window -toplevel
```

The following example retrieves the active view window:

```
prompt> gui_get_current_window -view
```

The following example retrieves the most recently active layout view:

```
prompt> gui_get_current_window -types "Layout" -mru
```

The following example return $cons:

```
prompt> set top1 [gui_create_window -type LayoutWindow]
prompt> set top2 [gui_create_window -type LayoutWindow]
prompt> set cons [gui_create_window -type Layout -parent $top]
prompt> gui_get_current_window -parent $top
```

gui_create_window(2)

gui_get_display_view

Returns the display view type (abstract, design, frame, layout, or outline) used in the layout when cell-specific views are active. Views are set with the **gui_set_display_view** command.

SYNTAX

string **gui_get_display_view**
-cells *cell_list*

Data Types

cell_list list

ARGUMENTS

-cells *cell_list*

Specifies the physical cells for which to report the view.

DESCRIPTION

This command retrieves the cell-specific display view value. For this command, the view is set with the **gui_set_display_view** manpage for more detailed information.

EXAMPLES

The following example returns the view setting for cells A and B. The first command shows that cell A has no display view set. The second command shows that the display view type for cell is design.

```
prompt> gui_get_display_view -cells A
prompt> gui_get_display_view -cells B
design
```

SEE ALSO

gui_set_display_view(2)

gui_get_error_browser_option

Get Error Browser Dialog option values

SYNTAX

string **gui_get_error_browser_option**
-grouping
| -show_mode
| -view_mode
| -zoom_factor
| -hide_fixed
| -hide_ignored
| -advance_to_next_unfixed_error
| -dim
| -show_open_locator_nodes
| -show_tooltip
| -show_command_buttons
| -highlight_objects
| -auto_set_object_visible
| -auto_set_object_visible_type

ARGUMENTS

-grouping | -show_mode | -view_mode | -zoom_factor | -hide_fixed | -hide_ignored | -advance_to_next_unfixed_error | -dim | -show_open_locator_nodes | -show_tooltip -show_command_buttons | -highlight_objects | -auto_set_object_visible | -auto_set_object_visible_type

Mutually exclusive required option to specify the Error Browser option value to query.

DESCRIPTION

This command gets the value of the requested option setting for the Error Browser. One option value can be queried at a time.

The **-grouping** option returns *type* or *layer* which indicates whether errors are grouped by types or layers.

The **-show_mode** option returns *all*, *selected*, or *none* which indicates whether all errors, selected errors, are no errors are shown in layout views.

The **-view_mode** option returns *zoom*, *pan*, of *off* which indicates whether the layout view zooms to, pans to, or does not change to

the currently selected errors in the Error Browser.

The **-zoom_factor** option returns a float value between *0.1* and *10.0* and indicates the zoom factor used when the view_mode is zoom.

The **-hide_fixed** option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether fixed errors are hidden from display in the Error Browser and layout views.

The **-hide_ignored** option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether ignored errors are hidden from display in the Error Browser and layout views.

The **-advance_to_next_unfixed** option returns *true* to mean advance to next unfixed error when an error is fixed or *false* to mean advanced to next fixed/unfixed error.

The **-dim** option returns *true* to mean "dimmed" or *false* to mean "not dimmed" and indicates whether layout views are dimmed when errors are displayed.

The **-show_open_locator_nodes** returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether net nodes are highlighted along with the open locator flylines for selected open locator errors.

The **-show_tooltip** returns *true* to mean show tooltips or *false* to mean don't show tooltips in the error browser list and details panes.

The **-show_command_buttons** returns *true* to mean show the commannd buttons or *false* to mean don't show the command buttons in the error browser.

The **-highlight_objects** returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether associated design objects are highlighted in the layout view for selected errors.

The **-auto_set_object_visible** returns whether auto set layout/object visibility is turned on or not.

The **-auto_set_object_visible_type** returns whether auto set layout/object visibility turns on layers/objects incrementally (the default) or exclusively.

EXAMPLES

The following example gets the grouping option

```
gui_get_error_browser_option -grouping
```

The following example gets whether layout views are dimmed when errors are displayed

```
gui_get_error_browser_option -dim
```

SEE ALSO

gui_error_browser(2)
gui_set_error_browser_option(2)

gui_get_error_data

Creates a collection of physical DRC error data that are currently shown in the error browser.

SYNTAX

collection **gui_get_error_data**

DESCRIPTION

The **gui_get_error_data** command creates a collection of physical DRC error data that are currently shown in the error browser.

You can use the **get_drc_error_data** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **gui_get_error_data** result to a variable.

When issued from the command prompt, **gui_get_error_data** behaves as though **query_objects** had been called to display the objects in the collection.

EXAMPLES

The following example queries the physical DRC error data that are currently shown in the error browser. Although the output looks like a list, it is not. The output is just a display.

```
prompt> gui_get_drc_error_data
{"my_design_dppinassgn.err"}
```

SEE ALSO

gui_open_error_data(2)
gui_close_error_data(2)

gui_get_hierview_data

Get various state about the Hierarchy View and its sub-views. [Default return last used Hierarchy View name]

SYNTAX

string **gui_get_hierview_data**
[-view *View_Name*]
[-tree_agroup]
[-tree_filter]
[-map_area]
[-map_color]
[-childlist_name]
[-childlist_agroup]
[-childlist_filter]
[-sub_view]
[-columns]
[-values *Column_Name*]

View_Name String
Column_Name String

ARGUMENTS

-view *View_Name*

Use the given HierView window name (ex: Hier.1). Default is to get the most recent used HierView window name.

-tree_agroup

Get and return the current Hier Tree attribute group name.

-tree_filter

Get and return the current Hier Tree filter expression.

-map_area

Get and return the Hier Map Area attribute group name.

-map_color

Get and return the Hier Map Color attribute group name.

-childlist_name

Get and return the current ChildList sub-view name.

-childlist_agroup

Get and return the current ChildList attribute group name.

-childlist_filter

Get and return the current ChildList filter expression.

-sub_view

Get and return the current active sub-view type. The sub-view types are 'hier_tree', 'hier_map' and 'child_list'.

-columns

Get and return a list of all column name(s) of all selected table cells.

-values *Column_Name*

Get and return a list of all selected table cell value(s) in the given column name. **Note**: Any of the column value(s) in the row of the selected cell(s) can be retrieved.

DESCRIPTION

This command allows you to get various current Hierarchy View related view settings
and selected table cell data.

SEE ALSO

gui_set_hierview_data(2)

gui_get_highlight

Get a collection of highlighted objects.

SYNTAX

string **gui_get_highlight**

[-color *color_id* | -all_colors]
[-return_select_bus | -more_than]

string *color_id*
collection *clct*

ARGUMENTS

-color *color_id*

Specifies the color of objects to be returned. If neither -color nor -all_colors is used, the current color is assumed. The allowed colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

-all_colors

Specifies that all highlighted objects are to be returned.

-return_select_bus

Create a new selection bus in which to store the result instead of returning a collection of objects.

-more_than

Return 1 if more than the specified number of objects would be returned, otherwise 0.

DESCRIPTION

The gui_get_highlight command returns a collection of objects highlighted with the specified colors.

EXAMPLES

Get a collection of green highlighted objects.

```
shell> gui_get_highlight -color green
```

Get a collection of all highlighted objects.

```
shell> gui_get_highlight -all_colors
```

Query if any objects are highlighted

```
shell> gui_get_highlight -all_colors -more_than 0
```

SEE ALSO

gui_change_highlight(2)
gui_get_highlight_options(2)
gui_set_highlight_options(2)

gui_get_highlight_options

Query the options that control highlighting.

SYNTAX

string **gui_get_highlight_options**

[-current_color | -all_colors | -auto_cycle_color]

ARGUMENTS

-current_color

This option returns a string which is the current highlight color, or the default color for highlighting operations.

-all_colors

This option returns Tcl list of all of the colors which are allowed to be used for highlighting.

-auto_cycle_color

This option returns the current value of the auto cycle setting ("true" or "false").

DESCRIPTION

The gui_get_highlight_options command queries the settings which control highlighting. Exactly one option must be provided.

EXAMPLES

Get the current highlight color.

```
shell> gui_get_highlight_options -current_color
```

Get all highlight colors.

```
shell> gui_get_highlight_options -all_colors
```

SEE ALSO

gui_change_highlight(2)
gui_get_highlight(2)
gui_set_highlight_options(2)

gui_get_layer_widths

Returns a list of widths per layer for route editing.

SYNTAX

values **gui_get_layer_widths**
-layer *layer_name*
[{ -default | -current | -user }]

Data Types

layer_name string
values list

ARGUMENTS

-layer *layer_name*

Specifies the routing layer for which to query the widths.

-default

Returns the list of widths to use by default, if the user has not set up their own list of layers.

The default list consists of:

- layer minimum width
- layer default width
- any NDR widths for layer

-current

Returns the list of widths that is used by the editor. If the user specified a list then it will be returned, otherwise the default list will be returned.

-user

Returns the list of widths explicitly specified by the user. This may be an empty list if no values were specified by the user via **gui_set_layer_widths**.

DESCRIPTION

This command returns a list of discrete widths; these widths are used by the route editor.

By default the value returned by *-current* will be returned.

EXAMPLES

The following example returns the user defined widths for layer 'M1'.

prompt> **gui_get_layer_widths -layer M1 -user**

SEE ALSO

gui_set_layer_widths(2)

gui_get_map

Retrieves attributes for a specified map mode.

SYNTAX

string **gui_get_map**
-name *identifier*
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
[-icon_file]
[-update_cmd]
[-float]
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]

Data Types

identifier string

ARGUMENTS

-name *identifier*

Specifies the name of the map mode to be queried.

-buckets

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

-title

Returns the title string.

-help_topic

Returns the help topic string.

-infotip

Returns the InfoTip string.

-discrete

Returns a true or false value that indicates whether the buckets of this map mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this map mode was created, and cannot be changed.

-icon_file

Returns the gui menu icon file.

-update_cmd

Returns the Tcl command that is executed when the map mode is accessed. A typical use for this option is to update the state of the map mode if its contents are likely to change under certain circumstances.

-float

Returns a true or false value indicating whether the map mode buckets have a floating point range.

-top_exaggeration

Returns the top bucket exaggeration.

-mid_exaggeration

Returns the middle bucket exaggeration.

-bot_exaggeration

Returns the bottom bucket exaggeration.

DESCRIPTION

The **gui_get_map** command queries the option values of an existing map mode.

EXAMPLES

To retrieve names of the buckets in the map mode named "densityMap", use the following command:

prompt>**gui_get_map -name densityMap -buckets**

SEE ALSO

gui_get_mapbucket(2)

gui_get_map_list

Lists the current visual and map modes.

SYNTAX

string **gui_get_map_list**

ARGUMENTS

The **gui_get_map_list** command has no arguments.

DESCRIPTION

The **gui_get_map_list** command returns a list of existing visual and map modes.

EXAMPLES

The following example gets the names of all available visual and map modes:

```
prompt> gui_get_map_list
```

SEE ALSO

gui_set_map_option(2)
gui_set_vm(2)
gui_set_vmbucket(2)
gui_show_map(2)
gui_update_vm(2)

gui_get_map_option

Gets the value for an option in the specified visual mode or map mode.

SYNTAX

string **gui_get_map_option**
-map *map_name*
-option *option_name*
[-default]

Data Types

map_name string
option_name string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-option *option_name*

Specifies the name of the option to be set.

-default

Gets the option default value.

DESCRIPTION

This command gets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You can get set option specific value or its default value.

EXAMPLES

The following example gets the number of bins in the global route congestion map:

```
prompt> gui_get_map_option -map AREAPARTITION \
    -option num_bins -value 9
```

SEE ALSO

gui_get_bucket_option(2)
gui_get_bucket_option_list(2)
gui_get_map_list(2)
gui_set_map_option(2)
gui_get_map_option_list(2)
gui_set_bucket_option(2)

gui_get_map_option_list

Lists the available options for the specified visual mode or map mode.

SYNTAX

string **gui_get_map_option_list**
-map *map_name*

Data Types

map_name string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

DESCRIPTION

This command displays a list of all options that are available for the specified visual mode or map mode.

EXAMPLES

The following example displays a list of the available options for the global route congestion map:

prompt> **gui_get_map_option_list -map AREAPARTITION**

SEE ALSO

gui_get_bucket_option(2)
gui_get_bucket_option_list(2)
gui_get_map_list(2)
gui_get_map_option(2)

gui_set_bucket_option(2)
gui_set_map_option(2)

gui_get_mapbucket

Gets attributes for Map Mode Bucket

SYNTAX

string **gui_get_mapbucket**
-map *mode_identifier*
-name *bucket_identifier*
[-infotip]
[-color]
[-pattern]
[-exaggeration]
[-number]
[-maxval]
[-minval]
[-visible]
[-special]
[-title]
[-objcount]

Data Types

mode_identifier string
bucket_identifier string

ARGUMENTS

-map *mode_identifier*

Specifies the map mode to which the bucket is a member. The map mode must already exist.

-name *bucket_identifier*

Specifies the name of the map mode bucket to be queried. To see the list of buckets associated with a specific map mode use the gui_get_map command with the -buckets option.

-infotip

Return infotip string.

-color

Return bucket rendering color.

-pattern

Return bucket rendering fill pattern.

-exaggeration

Return bucket min pixel exaggeration value.

-number

Return bucket display number.

-maxval

Return bucket maximum value.

-minval

Return bucket minimum value.

-visible

Return visibility.

-special

Return whether bucket is special.

-title

Return bucket title.

-objcount

Return the number of objects in the bucket.

DESCRIPTION

The gui_get_mapbucket command queries an instance of a map mode bucket for the specified option values. The values are returned in a list of option-value pairs.

EXAMPLES

Query the current color for the bucket named "Bucket10" in the map mode "densityMap":

prompt> **gui_get_mapbucket -map densityMap -name Bucket10 -color**

Query the current color and pattern for the bucket named "Bucket10" in the map mode "densityMap":

prompt> **gui_get_mapbucket -map densityMap -name Bucket10 -color -pattern**

SEE ALSO

gui_get_map(2)

gui_get_menu_roots

Return a sorted list of all menu roots used by the application.

DESCRIPTION

This command returns a list of all the menu roots used by the application. The menu roots include menu roots used by toplevel menu bars and menu roots used by context menus. A menu root is used to group menu items that share the same menu root together. All items under each toplevel window's menu bar shares the same menu root; similarly, all items in a context menu (menu brought up with right mouse click in a window) shares the same context menu root.

SEE ALSO

gui_create_menu(2)

gui_get_mouse_tool_option

Get the value of a mouse tool option

SYNTAX

string **gui_get_mouse_tool_option** -tool *string*
-option *string*

string *string*
string *string*

ARGUMENTS

-tool *string*

Tool to get option for.

-option *string*

Option to get.

DESCRIPTION

This command returns value of a mouse tool option .

EXAMPLES

> gui_get_mouse_tool_option -tool SELECT -option InputMode
Smart

SEE ALSO

gui_mouse_tool(2)
gui_set_mouse_tool_option(2)

gui_get_performance_log_option

Gets the current option value controlling performance log behavior.

SYNTAX

string **gui_get_performance_log_option**

Data Types

ARGUMENTS

DESCRIPTION

This command is used to query the current setting for the performance log which is set by gui_set_performance_log_option.

EXAMPLES

The following example sets, then gets the current setting.

prompt> **gui_set_performance_log_option -commands {gui_zoom win_select_objects}**
prompt> **gui_get_performance_log_option**
commands: gui_zoom win_select_objects

SEE ALSO

gui_log_performance(2)
gui_set_performance_log_option(2)

gui_get_pref_categories

Return a list of the current preference categories.

SYNTAX

string **gui_get_pref_categories**

DESCRIPTION

This command returns a tcl list of the current preference categories.

SEE ALSO

gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_get_pref_value_type(2)
gui_remove_pref_key(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_get_pref_keys

Return a list of preference keys under the specified category.

SYNTAX

string **gui_get_pref_keys** -category *Category*

Category *String*

ARGUMENTS

-category *Category*

Category specifies the category to use.

DESCRIPTION

Return a list of preference keys under the specified category.

SEE ALSO

gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_get_pref_value_type(2)
gui_remove_pref_key(2)
gui_get_pref_categories(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_get_pref_value

Get the value of a preference key.

SYNTAX

string **gui_get_pref_value** -key *Key* [-category *Category*]

Key *String*
Category *String*

ARGUMENTS

-key *Key*

Key specifies the key to retrieve the value from.

-category *Category*

Category specifies the category to search for the key. If not specified, a default category will be used.

DESCRIPTION

This command retrieves the value of a preference key from the specified key name and category.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command **gui_get_pref_value** is then used to retrieve the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool -value false
set x [gui_get_pref_value -category my_category -key some_key]
```

SEE ALSO

gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value_type(2)
gui_remove_pref_key(2)
gui_get_pref_categories(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_get_pref_value_type

Get the data type of the value of a preference key.

SYNTAX

string **gui_get_pref_value_type** -key *Key* [-category *Category*]

Key *String*
Category *String*

ARGUMENTS

-key *Key*

Key specifies the key to retrieve the value type from.

-category *Category*

Category specifies the category to search for the key. If not specified, a default category will be used for searching the key.

DESCRIPTION

This command retrieves the data type of the value of a preference key from the specified key name and category.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200. The command **gui_get_pref_value_type** is then used to retrieve the data type of the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type integer -value 200
set x [gui_get_pref_value_type -category my_category -key some_key]
{comment: x should be equal to "integer" }
```

gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_get_presets

Gets list of preset name for object specified by category

SYNTAX

string **gui_get_presets**
  -category *category*
  [-system]
  [-shared]

Data Types

category string

ARGUMENTS

-category *category*

Specifies the name of the category that the presets be retrieved from.

-system

Return system presets. This option is mutually exclusive with the -shared option.

-shared

Return shared presets. This option is mutually exclusive with the -system option.

DESCRIPTION

This command retrieves the list of presets for a category.

EXAMPLES

The following example gets the system presets for the Layout.

prompt> **gui_get_presets -category Layout -system**

SEE ALSO

gui_set_preset(2)

gui_get_region

Returns the coordinates of the current region rectangle or rectilinear polygon.

SYNTAX

list **gui_get_region**

DESCRIPTION

This command returns the coordinates of the rectangle or rectilinear polygon that defines the current region in layout region mode.

Note that the preferred command for typical extension writing is usually **gui_set_layout_user_command** instead of **gui_get_region** because **gui_set_layout_user_command** has snapping, mouse up drag, cancel, and user prompt capabilities.

EXAMPLES

```
prompt> gui_get_region
{{-1743.945 18.357} {42.833 1523.657}}
```

SEE ALSO

gui_set_region(2)
gui_set_layout_user_command(2)

gui_get_setting

Gets a setting on the specified window.

SYNTAX

string **gui_get_setting**
  -window *WindowID*
  { -setting *Setting* | -list }

WindowID *String*
Setting *String*

ARGUMENTS

-window *WindowID*

WindowID specifies the window to get the setting

-setting *Setting*

Setting specifies the setting to get

-list

Specifies that the list of available settings needs to be returned

DESCRIPTION

Gets the list of available settings on the specified window. Windows are views or top level windows. The setting is a property of the window. The returned value is a string which has the type of the setting being read. Some windows might not have this function implemented.

EXAMPLES

shell> **gui_get_setting -window Layout.1 -setting showCell**
1

```
shell> gui_get_setting -window Layout.1 -setting viewLevel
2
```

SEE ALSO

gui_set_setting(2)

gui_get_task_list

Lists all the available task names.

SYNTAX

string **gui_get_task_list**

DESCRIPTION

The gui_get_task_list command queries the names of all available tasks.

DESCRIPTION

prompt> **gui_get_task_list** all {Block Implementation} {Design Planning}

SEE ALSO

gui_create_task(2)
gui_remove_task(2)
gui_set_task_list(2)
gui_set_current_task(2)
gui_get_current_task(2)

gui_get_task_page

Return the name of the task page for the given task item.

SYNTAX

string **gui_get_task_page**

SYNTAX

gui_get_task_page
-task *TaskName*
-item *ItemName*

TaskName *String*
ItemName *String*

ARGUMENTS

-task *TaskName*

TaskName specifies the name of the task.

-item *ItemName*

ItemName specifies the hierarchical name of the task item for which to get the page name",

DESCRIPTION

This command returns the name of the task page for the task item identified by the option values. This is useful when you want to create a new task item re-using a task page that is invoked by an existing task item.

EXAMPLES

To reuse the task page from the built-in task item "Pin Assignment->Pin Placement" in the task "Hierarchical Design" in your own task flow, you can do the following:

```
prompt> set pageName [gui_get_task_page -task "Hierarchical Design"
                -item "Pin Assignment->Pin Placement"]
prompt> gui_create_task_item -task myTask -name myItemName
                -page $pageName
```

SEE ALSO

gui_create_task_item(2)
gui_set_current_task(2)
gui_get_task_list(2)

gui_get_toolbar_names

Return a Tcl list of the names of all the toolbars that have been created with the **gui_create_toolbar** command.

SYNTAX

void **gui_get_toolbar_names**
[-window *WindowId*]

WindowId *String*

ARGUMENTS

-window *WindowId*

Return toolbars defined in this window. If omitted, return toolbars defined in the active window.

DESCRIPTION

Return a Tcl list of the names of all the toolbars that have been created with gui_create_toolbar command for the specified window.

SEE ALSO

gui_create_toolbar(2)
gui_create_toolbar_item(2)
gui_delete_toolbar(2)
gui_delete_toolbar_item(2)
gui_hide_toolbar(2)
gui_show_toolbar(2)

gui_get_utable

Get various state about User Table(s) [default: return list of all table names].

SYNTAX

string **gui_get_utable**
-name *Table_Name*
-has_name
-tag
-window *Window_name*
-values *Column_Name*
-columns

Table_Name String
Window_Name String
Column_Name String

ARGUMENTS

-name *Table_Name*

A table name argument used with other argument switches below.

-has_name

Check if given table name given by the '-name' argument switch exist and return '1', else return '0'.

-tag

Get the table MetaData tag string for given table argument.

-window *Window_Name*

A UserTable window name argument used with other arguments below. If used alone it will return the current table name of the given window name.

-values *Column_Name*

Get the selected table cell value(s) in the given column for the given window argument. **Note**: Any column value(s) in the row of the selected cell(s) can be retrieved.

-columns

Get the selected table column name(s) for the given window argument.

DESCRIPTION

This command allows you to get all current loaded UserTable names.
Other options allow you to get various other table state.

EXAMPLES

The following example check to see if the UserTable 'my_table' is currently loaded.

```
shell> if { [gui_get_utable -name my_table -has_name] } {
         echo "yes my_table is loaded"
       }
```

The following example looks for the 'full_name' column in the current active UserTable and prints all the selected values in that column.

```
shell> # Get the current active UserTable window:
     set win [gui_get_current_window -mru -type UserTable]
     # Get the table name in that window:
     set table [gui_get_utable -window $win]

     if { $table != {} } {
      # Get the selected column names in that table:
      set columns [gui_get_utable -window $win -columns]
      # If the column name 'full_name' is selected then list the values:
      if { [lsearch -exact $columns full_name] != -1} {
        set values [gui_get_utable -window $win -values full_name]
        foreach v $values {
          echo "value: $v"
        }
      }
     }
```

gui_write_utable(2)

gui_get_var

Get the value of a typed tcl variable that is created with gui_create_var.

SYNTAX

string **gui_get_var** -name *VarName*

VarName *String*

ARGUMENTS

-name *VarName*

VarName specifies the name of the typed tcl variable to retrieve the value of.

DESCRIPTION

This command retrieves the value of a typed tcl variable.

SEE ALSO

gui_create_var(2)
gui_set_var(2)
gui_remove_var(2)
gui_exist_var(2)

gui_get_vm

Retrieves attributes for a specified visual mode.

SYNTAX

string **gui_get_vm**
-name *identifier*
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
[-icon_file]
[-update_cmd]
[-netfilter]
[-float]
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]
[-show_only_pins_of_nets]
[-enable_bucket_delete]

Data Types

identifier string

ARGUMENTS

-name *identifier*

Specifies the name of the visual mode to be queried.

-buckets

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

-title

Returns the title string.

-help_topic

Returns the help topic string.

-infotip

Returns the InfoTip string.

-discrete

Returns a true or false value that indicates whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this visual mode was created, and cannot be changed.

-icon_file

Returns the gui menu icon file.

-update_cmd

Returns the Tcl command that is executed when the visual mode is accessed. A typical use for this option is to update the state of the visual mode if its contents are likely to change under certain circumstances.

-netfilter

Returns net connection filtering.

-float

Returns a true or false value indicating whether the visual mode buckets have a floating point range.

-top_exaggeration

Returns the top bucket exaggeration.

-mid_exaggeration

Returns the middle bucket exaggeration.

-bot_exaggeration

Returns the bottom bucket exaggeration.

-show_only_pins_of_nets

Returns a true or false value that indicates whether the layout shows only pins of net objects in buckets.

-enable_bucket_delete

Returns a true or false value indicating whether the visual mode buckets can be deleted from context menu.

DESCRIPTION

The **gui_set_vm** command queries the option values of an existing visual mode.

EXAMPLES

To retrieve names of the buckets in the visual mode named "mycoloring1", use the following command:

prompt>**gui_get_vm -name mycoloring1 -buckets**

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vmbucket(2)
gui_remove_vm(2)
gui_remove_vmbucket(2)
gui_set_vm(2)
gui_set_vmbucket(2)
gui_update_vm(2)

gui_get_vmbucket

Get attributes for Visual Mode Bucket

SYNTAX

string **gui_get_vmbucket** -vmname *mode_identifier*
-name *bucket_identifier*
[-infotip]
[-netfilter]
[-color]
[-pattern]
[-exaggeration]
[-number]
[-maxval]
[-minval]
[-visible]
[-title]
[-collection]
[-objcount]

string *mode_identifier*
string *bucket_identifier*

ARGUMENTS

-vmname *mode_idnetifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

-name *bucket_identifier*

Specifies the name of the visual mode bucket to be queried. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

-infotip

Return infotip string.

-netfilter *net_filter*

Return net connection filtering.

-color

Return bucket rendering color.

-pattern

Return bucket rendering fill pattern.

-exaggeration

Return bucket min pixel exaggeration value.

-number

Return bucket display number.

-maxval

Return bucket maximum value.

-minval

Return bucket minimum value.

-visible

Return visibility.

-title

Return bucket title.

-collection

Return object collection.

-objcount

Return the number of objects in the bucket.

DESCRIPTION

The gui_get_vmbucket command queries an instance of a visual mode bucket for the specified option values. The values are returned in a list of option-value pairs.

EXAMPLES

Query the current color for the bucket named "cat1" in the visual mode "foo":

shell> **gui_get_vmbucket -vmname foo -name cat1 -color**

Query the current color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> **gui_get_vmbucket -vmname foo -name cat1 -color -pattern**

SEE ALSO

gui_get_window_ids

Get a list of window ids

SYNTAX

ids **gui_get_window_ids**
[-parent *window_id*]
[-type *window_type*]

Data Types

window_id string
window_type string

ARGUMENTS

-parent *window_id*

Specifies the toplevel window id to get child view window ids from.

-type *window_type*

Specifies that the windows id returned should be restricted to those of the specified type.

Note: as a type can be only be associated with either a toplevel window or a child view window (not both) the type implies whether toplevel or child view window ids are returned.

If this option is not specified then either all toplevel window ids are returned (*-parent* option not specified) or all child view window ids of a specified toplevel window id are returned (*-parent* option specified).

RETURNS

ids

Returned list of window ids.

DESCRIPTION

This command gets a list of the ids of all toplevel windows, all toplevel windows of a specified type, all child view windows of a specified type, or all child view windows of a specified type in a specified toplevel window.

EXAMPLES

The following example will create a toplevel window and a child layout window. Then this command will be used to retrieve the ids of the existing windows.

```
shell> set top [gui_create_window -type TopLevel]
shell> set cons [gui_create_window -type Layout -parent $top]
shell> set ids [gui_get_window_ids]   # return list containing values of $top and value of $cons.
shell> set childs [gui_get_window_ids -parent $top]   # return value of $cons.
shell> set layout_instances [gui_get_window_ids -type Layout] # return value of $cons.
```

gui_get_window_pref_categories

Get list of preference categories for object specified by window

SYNTAX

categories **gui_get_window_pref_categories**
{ -window *window_id* | -window_type *window_type* }

Data Types

window_id string
window_type string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

RETURNS

categories

The returned preference categories.

DESCRIPTION

This command retrieves the list of preference categories for a window or window type.

EXAMPLES

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_categories -window TopLevel.1]
```

gui_get_window_pref_keys

Get list of preference categories for object specified by window

SYNTAX

categories **gui_get_window_pref_keys**
{ -window *window_id* | -window_type *window_type* }
[-category *category*]

Data Types

window_id string
window_type string
category string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

-category *category*

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

RETURNS

categories

The returned preference categories.

DESCRIPTION

This command retrieves the list of preference categories for a window or window type.

EXAMPLES

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_keys -window TopLevel.1]
```

gui_update_pref_file(2)

gui_get_window_pref_value

Get preference value for object specified by window or window type

SYNTAX

value **gui_get_window_pref_value**
{ -window *window_id* | -window_type *window_type* }
[-category *category*]
-key *key*

Data Types

window_id string
window_type string
category string
key string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference will be retrieved from. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference be retrieved from. This option is mutually exclusive with the -window option.

-category *category*

Specifies the category to search for the key. If not specified, a default category will be used.

-key *key*

Specifies the key to retrieve the value from.

RETURNS

value

The value of the key.

DESCRIPTION

This command retrieves the value of a preference key from the specified key name and category of the specified window or window type. If a preference is set on a window type, then all instances of that type will inherits the preference, so the value can be set on a type and retrieved from any instance of that type (or derived from that type).

EXAMPLES

The following example creates a preference for a window and then uses the **gui_get_window_pref_value** command to retrieve the value for the preference.

```
shell> gui_set_window_pref_key -window Console.1 -key test -value_type integer -value 201
shell> set x [gui_get_window_pref_value -window Console.1 -key test]
shell> if {$x == 201} { echo "success" }
```

gui_get_window_presets

Gets list of preset name for object specified by window_type

SYNTAX

string **gui_get_window_presets**
-window_type *window_type*
[-system]
[-shared]

Data Types

window_type string

ARGUMENTS

-window_type *window_type*

Specifies the name of the window type that the presets be retrieved from.

-system

Return system presets. This option is mutually exclusive with the -shared option.

-shared

Return shared presets. This option is mutually exclusive with the -system option.

DESCRIPTION

This command retrieves the list of presets for a window type. This command has been deprecated, please use gui_get_presets instead.

EXAMPLES

The following example gets the system presets for the Layout.

prompt> **gui_get_window_presets -window_type Layout -system**

SEE ALSO

gui_get_presets(2)
gui_set_preset(2)
gui_set_window_preset(2)

gui_get_window_types

Get a list of window types

SYNTAX

types **gui_get_window_types**
[-type *token*]

Data Types

token string

ARGUMENTS

-type *window_types*

Specifies whether to return toplevel windows ('toplevel') or child view windows ('child').

If toplevel window types are specified then the first type is guaranteed to be the default toplevel window type.

RETURNS

types

Returned list of window types.

DESCRIPTION

This command returns a list of existing window types. Instances of these types can be instantiated with the **gui_create_window** command. The returned list can be restricted to just toplevel windows or child view windows by specifying the *-type* option.

EXAMPLES

The following examples illustrate some usages of the command.

```
shell> gui_get_window_types
shell> gui_get_window_types -type toplevel
shell> gui_get_window_types -type child
```

SEE ALSO

gui_get_current_window(2)

gui_group_charts_plots

Group plots in charts view

SYNTAX

status **gui_group_charts_plots**
-view *view_name*
[-x1x2]
[-y1y2]
[-overlay]
[*plots*]

Data Types

view_name string
plot_id_list list

ARGUMENTS

-view *view_name*

Charts View to group.

-x1x2

This option specifies that two plots are connected such that they have a shared y axis range but two independent x axes ranges.

If the *-overlay* option is used then the two plots are overlaid and the X axis of the first plot is placed on the bottom and the X axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results horizontal stacking is recommended so the shared y axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-y1y2* option.

-y1y2

This option specifies that two plots are connected such that they have a shared x axis range but two independent y axes ranges.

If the *-overlay* option is used then the two plots are overlaid and the Y axis of the first plot is placed on the bottom and the Y axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results vertical stacking is recommended so the shared x axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-x1x2* option.

-overlay

This option specifies that the plots have shared x and/or y ranges and are drawn on top of each other so they can share a single key and title.

If the *-x1x2* or *-y1y2* option are specified then only the x or y axis range is shared (See descriptions of these options above).

If neither of the *-x1x2* or *-y1y2* options are specified then both the x and y axis ranges are shared. In this case two or more plots can be specified.

plots

List of plots to group.

For *x1x2* or *y1y2* options this must be two plots. For *-overlay* option, without the *x1x2* and *y1y2* options, this must be two or more plots.

DESCRIPTION

Group related plots in a view.

Grouped plots can share x or y axis ranges and can be overlaid.

Sharing x and/or y axis is useful when you want to compare data across two plots. Overlay is useful when you want to display multiple plot types with the same data e.g. a combined barchart and xy plot (line plot).

EXAMPLES

The following example groups two plots so they are overlaid and share a common x axes.

```
shell> gui_group_charts_plots -view $view -y1y2 -overlay -plots [list $plot1 $plot2]
```

SEE ALSO

gui_create_charts_plot(2)
gui_place_charts(2)

gui_hide_palette

Hides the specified palette.

SYNTAX

status **gui_hide_palette**
{ -name *palette_id* | -type *palette_type* | -all }
[-parent *window_id*]

Data Types

palette_id string
palette_type string
window_id string

ARGUMENTS

-name *palette_id*

Specifies the palette name id or title.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this name in all toplevel windows are hidden.

This option precludes the *-type* and *-all* options.

-type *palette_type*

Specifies the palette type id. Any matching palette of this type will be hidden.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this type in all toplevel windows are hidden.

This option precludes the *-name* and *-all* options.

-all

Hides all palettes.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes in all toplevel windows are hidden.

This option precludes the *-name* and *-type* options.

-parent *window_id*

Specifies the parent toplevel window to hide the palette type in.

Note: this option is only applicable if the *-type* option is specified.

DESCRIPTION

This command hides the specified palettes.

EXAMPLES

The following example hides all Layer palettes:

shell> gui_hide_palette -type Layout

SEE ALSO

gui_show_palette(2)

gui_hide_toolbar

Hides the specified toolbar or all the toolbars in the specified window or for a window type.

SYNTAX

void **gui_hide_toolbar**
-toolbar *tool_bar_name* | -all
[-window *window_id*]
[-window_type *window_type*]

Data Types

tool_bar_name string
window_id string
window_type string list

ARGUMENTS

-toolbar *tool_bar_name*

Specifies the toolbar you want to hide. The **-toolbar** option and the **-all** option are mutually exclusive.

-all

Hides all the toolbars in the specified window. The **-all** option and the **-toolbar** option are mutually exclusive.

-window *window_id*

Specifies the window in which you want to hide the specified toolbar or all toolbars. This option is mutually exclusive with the **-window_type** option. If both **-window** and **-window_type** options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

-window_type *window_type*

Specifies the window types in which you want to hide the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the **-window** option. If both **-window** and **-window_type** options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

DESCRIPTION

This command hides either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or in

all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by **gui_show_toolbar** will be saved and restored on next invocation of the tool if save and restore has not been disabled.

EXAMPLES

The following example hides the File toolbar in the active window:

```
prompt> gui_hide_toolbar -toolbar File
```

The following example hides all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_hide_toolbar -all -window LayoutWindow.1
```

The following example hides the File toolbar in all TimingWindow type windows:

```
prompt> gui_hide_toolbar -all -window_type TimingWindow
```

The following example hides all the toolbars in all window types:

```
prompt> gui_hide_toolbar -all -window_type [gui_get_window_types -type toplevel]
```

SEE ALSO

gui_get_window_types(2)

gui_highlight_nets_of_selected

Highlight the nets of the selected object in the current highlight color.

SYNTAX

status **gui_highlight_nets_of_selected**
[-flylines]

ARGUMENTS

-flylines

Specifies that the net should always be displayed on the layout using flylines, even if it is routed.

DESCRIPTION

The **gui_highlight_nets_of_selected** command highlights the nets of the objects currently selected in the GUI. Typically this is used in conjunction with the Layout view to view the highlighted nets, and is accessed via the Highlight menu item on the Layout Window. This command adds to any existing highlights and the highlighting will remain until cleared by the user or the objects referenced in the highlight are removed. If no objects are selected this command will not do anything.

The layout view renders the net using its routing if the net has routing, and if it does not the net is rendered using a flyline. However if the -flyline option is specified the layout will always render the highlighted net using the flylines between its pins.

EXAMPLES

Highlight the nets of the selected objects.

prompt> **gui_highlight_nets_of_selected**

SEE ALSO

gui_change_highlight(2)
change_selection(2)

gui_import_utable

Create a UserTable and import records from a value file or a report.

SYNTAX

string **gui_import_utable**
-file *File_Name* [-tsv_mode] [-ssv_mode]
[-name *Table_Name*]
[-tsv_mode]
[-ssv_mode]
[-fold]
[-report_type *Report_Type_Name*]
[-meta_obj *MetaObj_Name*]
[-replace]

Table_Name String
File_Name String
Report_Type_Name String
MetaObj_Name String

ARGUMENTS

-file *File_Name*

The name of the CSV value file from which to import and fill the user table with.

-name *Table_Name*

The name for the user table created. By default, the name takes the name of the file minus the extension.

-tsv_mode

This flag changes the default delimiter from the comma char to the tab char.

-ssv_mode

This flag changes the default delimiter from the comma char to the semicolon char.

-fold

This flag causes extra row data past the number of columns specified to fold into the last column. The default is to discard extra data.

-report_type

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

-meta_obj *MetaObj_Name*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

-replace

Optional flag that will replace the given table name, if it already exists, with the imported table data.

DESCRIPTION

This command creates a new UserTable in memory and imports the data from a CSV/TSV/SSV value file. The name of the table will take the base name of the file unless a name is provided.

The first line of the file is assumed to be a header line that defines the column names. In addition, column names can have postfixes that describe the data format of that column.

Supported column name postfixes are:

:string
:int
:double
:cell
:net
:port
:pin
:point
:endpoint
:file

EXAMPLES

The following example creates a new UserTable called 'data' and imports the values from the CSV file 'data.csv'.

shell> **gui_import_utable -file data.csv**

The following example creates a new UserTable, names it 'my_table' called 'data' and imports the values from the CSV file 'data.csv'. It also instructs the import to fold any extra data found in the row into the last column defined.

shell> **gui_import_utable -file data.csv -name my_table -fold**

gui_list_attrgroups

Lists attribute group information for a specified object type or all object types.

SYNTAX

status **gui_list_attrgroups**
-class *design_object*
-name *name*
[-all]
[-tcl]
[-full]
[-attr_list]

Data Types

design_object string
name string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be listed for the specified object type or for all object types.

-all

Lists the attribute groups for all object types. This option and the -class option are mutually exclusive.

-tcl

Lists the attribute group information in a tool command language (Tcl) format that is suitable for Tcl processing.

-full

Specifies the full Tcl output format, which reports all possible group information.

-attr_list

Lists attributes only.

DESCRIPTION

The **gui_list_attrgroups** command lists attribute group information for the specified object type or for all object types. Use the **-tcl** option to get results that are suitable for Tcl processing.

EXAMPLES

prompt> **gui_list_attrgroups -class Cell -tcl**
"Hierarchy" "Edit"

prompt> **gui_list_attrgroups -class Cell -name "Hierarchy" -tcl -attr_list**
{Name} {Hierarchical} {Owning Cell} {isPhysConstraint} {Hard Macro} ... {FullName}

prompt> **gui_list_attrgroups -all -tcl**
Cell { "Hierarchy" "Edit" } Net { "Timing" } Pin { "Timing" }

prompt> **gui_list_attrgroups -class Cell -tcl -attr_list**
{ "Hierarchy" { {Name} {Hierarchical} {Owning Cell} ...{FullName} } }
{ "Edit" { {Name} {isPhysConstraint} {Orientation} ... {FullName} } }

prompt> **gui_list_attrgroups -class Cell**
Cell, "Hierarchy", { {Name} {Hierarchical} {Owning Cell} {isPhysConstraint} ... } ;
Cell, "Edit", { {Name} {isPhysConstraint} {Orientation} {Location} ... } ;
The fields displayed above are in the following order:
Class, Group Name, Attributes list;

SEE ALSO

gui_delete_attrgroup(2)

gui_list_category_rules

Lists all category rules except built-in rules by default.

SYNTAX

list **gui_list_category_rules**
[-all | -names *rule_names_list*]
[-format script | tcl_list]

Data Types

rule_names_list list

ARGUMENTS

-all

Lists all category rules, including built-in rules.

This option and the **-names** option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

-names *rule_names_list*

Specifies the names of the category rules to be listed.

This option and the **-all** option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

-format script | tcl_list

Specifies the output format in which the category rules are listed. The default output format is **script**.

When the **script** format is used, the category rules are listed as a Tool Command Language (Tcl) script of **gui_create_category_rule** commands that you can replay. In this case, the rules are streamed to the output stream. You can redirect the output by using the **redirect** command, for example, if you want to capture the script output in a file to use again later. When the **script** format is used, the command result is an empty string.

If the **tcl_list** format is specified, the category rules are listed in an "array set compatible" Tcl list format. In this case, the command result is a Tcl list.

DESCRIPTION

This command lists category rules that have already been created by the **gui_create_category_rule** command during the current run of the tool.

When you run this command without specifying either the **-all** option or the **-names** option, the command lists all category rules except built-in rules. Specify the **-all** option to list all category rules, including the built-in rules. Specify the **-names** option to list individual rules by name.

EXAMPLES

The following example lists all category rules, including the built-in rules:

```
prompt> gui_list_category_rules -all
gui_create_category_rule  -name Pathgroups  -builtin \
  -category <path_group.full_name>
gui_create_category_rule  -name Session  -builtin \
  -category <session_name>
gui_create_category_rule  -name {Path Type}  -builtin \
  -category <path_type>
  ...
  ...
```

The following example lists all category rules except the built-in rules:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category <path_group.full_name>
rule2
prompt> gui_list_category_rules
gui_create_category_rule  -name rule1 \
  -category <session_name>
gui_create_category_rule  -name rule2 \
  -category <path_group.full_name>
```

The following example redirects the script output to a file that you can source during a subsequent run of the tool:

```
prompt> redirect -file /remote/dir1/rules.tcl {gui_list_category_rules}
prompt>
```

The following example uses the **-names** option to list only the rules named rule1 and rule3:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category <path_group.full_name>
rule2
prompt> gui_create_category_rule  -name rule3 -category <startpoint.full_name>
rule3
prompt> gui_list_category_rules -names {rule1 rule3}
gui_create_category_rule  -name rule1 \
  -category <session_name>
gui_create_category_rule  -name rule3 \
  -category <startpoint.full_name>
```

The following example uses the **tcl_list** output format to query the category specification of the rule named rule1:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
```

```
rule1
prompt> gui_create_category_rule  -name rule2 -category <path_group.full_name>
rule2
prompt> array set rules [gui_list_category_rules -format tcl_list]
Information: Defining new variable 'rules'. (CMD-041)
prompt> array set rule1_options $rules(rule1)
Information: Defining new variable 'rule1_options'. (CMD-041)
prompt> set rule1_cat_spec $rule1_options(category)
Information: Defining new variable 'rule1_cat_spec'. (CMD-041)
<session_name>
```

SEE ALSO

gui_create_category_rule(2)
gui_remove_category_rules(2)

gui_list_cell_block_marks

Lists the cell names and block mark values for cells that are marked in the design.

SYNTAX

list **gui_list_cell_block_marks**

ARGUMENTS

This command has no arguments

DESCRIPTION

This command lists the cell names and block mark values for all cells that are marked in the design. The listing is sorted by the full names of the marked cells.

EXAMPLES

The following example sets block marks on two hierarchical cell instances, and then lists the names of all the marked cells and their block marks:

```
prompt> gui_remove_cell_block_marks -all
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_set_cell_block_marks I_TOP/I_REG_FILE  REG_FILE
prompt> gui_list_cell_block_marks
I_TOP/I_ALU    ALU
I_TOP/I_REG_FILE    REG_FILE
```

SEE ALSO

gui_set_cell_block_marks(2)
gui_get_cell_block_marks(2)

gui_remove_cell_block_marks(2)

gui_list_vm

List Current Visual Modes

SYNTAX

string **gui_list_vm**

ARGUMENTS

DESCRIPTION

The gui_list_vm command will return a list of existing visual modes.

EXAMPLES

To get the names of all available visual modes, use the following command:

shell> **gui_list_vm**

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vm(2)
gui_set_vm(2)
gui_get_vmbucket(2)
gui_remove_vm(2)
gui_remove_vmbucket(2)
gui_set_vmbucket(2)
gui_update_vm(2)

gui_load_area_net_connection_vm

Loads data for the Net Connection in Area visual mode.

SYNTAX

status **gui_load_area_net_connection_vm**
-area {*llx lly urx ury*}
[-type {power ground clock signal tie_high tie_low}]
[-hier]

Data Types

llx float
lly float
urx float
ury float

ARGUMENTS

-area {*llx lly urx ury*}

Specifies the area to analyze for net connectivity.

-type {power ground clock signal tie_high tie_low}

Specifies one or more types of nets to show. Possible types are power, ground, clock, signal, tie_high, and tie_low. This option takes types as a list of strings.

-hier

Specifies that the analysis should include subhierarchies. If this option is not specified, the tool analyzes only nets in the current top-level design.

DESCRIPTION

The command generates visual mode of net connections in the specified area. Net connections are categorized as follows:

- local connection: Nets have all their pins within the specified area.
- global connection: nets have at least one pin outside of the specified area, and one pin inside of specified area.
- path-through connection: nets have all their pins outside of specified area.

Nets in the visual mode are displayed based on layout view setting of net.

EXAMPLES

The following example shows clock and signal types of net connections in the specified area.

```
prompt> gui_load_area_net_connection_vm -area \
  {550.710 1840.430 1247.100 2150.640} -type {clock signal}
```

SEE ALSO

None

gui_load_cell_density_mm

Loads the data for cell density map mode.

SYNTAX

status **gui_load_cell_density_mm**
[-area *area*]

Data Types

area list

ARGUMENTS

-area *area*

Analyzes area for cell density. If area is not given, the default area is whole design area.

DESCRIPTION

The command generates the map mode view of cell density in a given area. Each grid is colored based on the percentage of occupied area of cells in the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows cell density in the specified area.

```
prompt> gui_load_cell_density_mm -area \
{284.820 390.670 1202.790 954.120}
```

SEE ALSO

None

gui_load_cell_slack_vm

Loads the data for cell slack visual mode.

SYNTAX

status **gui_load_cell_slack_vm**
[-scenario *scenario*]
[-analysis *approach*]
[-num_bins *count*]
[-bin_range *range*]
[-lower_bound *value*]
[-lower_bound_strict]
[-upper_bound *value*]
[-upper_bound_strict]
[-cells *cell_list*]
[-color_scheme *scheme*]

Data Types

scenario string
approach string
count integer
range float
value float
cell_list list
scheme string

ARGUMENTS

-scenario *scenario*

Specifies the scenario for the visual mode. By default, current scenario is used.

-analysis setup | hold

Specifies the analysis approach for the visual mode. The alternatives are setup and hold. By default, the analysis approach is setup.

-num_bins *count*

Specifies the number of bins to create.

-bin_range *range*

Specifies the range of each bin to create when the number of bins is not specified.

-lower_bound *value*

Specifies the lower bound value for the bins. Values below this bound are placed in a separate bin.

-lower_bound_strict

Uses the lower bound as an exact minimum limit on the bound. Values below the lower bound are ignored.

-upper_bound *value*

Specifies the upper bound value for the bins. Values above this bound are placed in a separate bin.

-upper_bound_strict

Uses the upper bound as an exact maximum limit on the bound. Values above the upper bound are ignored.

-cells *cell_list*

Specifies the cells to be used in the visual mode. If this option is not specified, all the cells in the design are used by default.

-color_scheme temperature | gradient

Specifies the bucket coloring approach in the visual mode. The alternatives are temperature scale and gradient. By default, the color scheme is temperature scale.

DESCRIPTION

The command generates the visual mode view of cell slack. Each cell is colored based on the color of the bin it falls into.

EXAMPLES

The following example will place all the cells in the design into 8 bins.

```
prompt> gui_load_cell_slack_vm -num_bins 8 \
-lower_bound 0
```

The following example will place all the currently selected cells into 8 bins.

```
prompt> gui_load_cell_slack_vm -num_bins 8 \
-lower_bound 0 -cells [get_selection] -scenario [current_scenario]
```

SEE ALSO

None

gui_load_clock_trunk_planning

Starts a GUI clock trunk planning session.

SYNTAX

gui_load_clock_trunk_planning
[-clocks *clocks*]
[-include_generated]
[-self]
[-show_timing_flylines]

Data Types

clocks list

ARGUMENTS

-clocks *clocks*

Specifies the clocks to plan. By default, planning is performed for all clocks and all virtual clocks and generated clocks are skipped.

-include_generated

Includes generated clocks when get auto clocks. This option should not be used with the **-clocks** option.

-self

Ignore master clock portion for generated clock.

-show_timing_flylines

Generates data for timing flylines. This option requires a timing update.

DESCRIPTION

This command starts a clock trunk planning session for a given clock. To view the clock trunk in the layout window, open the GUI clock trunk planning flylines tool. The flylines tool identifies the clock trunk and displays the clock trunk annotations in the layout.

The clock trunk is identified as follows:

- The clock source pins are part of the clock trunk.

- If a certain pin is part of the clock trunk, then all pins on all paths from the clock source pin to that certain pin are implicitly part of the clock trunk
- All user-defined clock trunk endpoints are part of the clock trunk.
- All first-level block conns/ports are part of the clock trunk, unless there is already a user-defined clock trunk endpoint upstream (for example, somewhere on all paths from the clock root to here).
- For all pins in the clock trunk which have less than *fanout_limit* number of fanouts, the tool recursively adds fanout. However this is not done for clock-trunk leafs that are a user-defined clock trunk endpoint or a first-level block conn/port. (Note that nonleafs which fall into these categories are still expanded).
- The leaf pins of the resulting clock trunk are called clock trunk end points.

EXAMPLES

Start a planning session on all clocks which enter some block.

```
prompt> gui_load_clock_trunk_planning
```

Start a planning session for clock CLK.

```
prompt> gui_load_clock_trunk_planning -clock CLK
```

SEE ALSO

create_clock_buffer(2)
set_clock_trunk_endpoints(2)
synthesize_clock_trees(2)

gui_load_hierarchy_vm

Loads the data for hierarchy visual mode.

SYNTAX

status **gui_load_hierarchy_vm**
[-clear]
[-level *level*]
[-objects *object_list*]
[-hierarchical]

Data Types

level integer
object_list list

ARGUMENTS

-clear

Removes the coloring from all hierarchy levels.

-level *level*

Colors all the cells at a particular hierarchy level.

-objects *object_list*

Colors specific hierarchy objects. If objects are not provided, the tool colors cells in the entire design. if *plan.place.hierarchy_by_name* is *true*, the option accepts flat hier name bound objects.

-hierarchical

Specifies that subhierarchies are included in the analysis. If this option is not specified, the tool analyzes only cells in the current top-level design.

DESCRIPTION

This command loads the data for hierarchy visual mode. The hierarchy visual mode provides a high-level view of the placement quality of logic blocks and hierarchical cells in your physical design. This visual mode can be used to color all the cells on a particular hierarchy level or just the specified hierarchical cells.

EXAMPLES

The following example clears the hierarchy visual mode.

```
prompt> gui_load_hierarchy_vm -clear
```

The following example colors all the cells at hierarchical level 2.

```
prompt> gui_load_hierarchy_vm -level 2
```

The following example colors all the objects in the selection.

```
prompt> gui_load_hierarchy_vm -objects [get_selection]
```

SEE ALSO

None.

gui_load_imported_path_pins_vm

Loads the data for imported path pins visual mode.

SYNTAX

status **gui_load_imported_path_pins_vm**
[-timing_report *file_name*]
[-timing_text *report_text*]
[-draw_path *path_type*]
[-from *path_number*]
[-to *path_number*]
[-clear]

Data Types

file_name	string
report_text	string
path_type	string
path_number	integer

ARGUMENTS

-timing_report *file_name*

Generates the imported path pins visual mode from the timing report file. The file could be plain text or compressed(.gz).

-timing_text *report_text*

Generates imported path pins visual mode from the timing report text.

-draw_path *path_type*

Specifies the type to draw the path. The type value can be routes, flylines or both. The defult value is flylines. When specifies routes or both, the timing report should include input pins.

-from *path_number*

Generates imported path pins visual mode start from the specified path number.

-to *path_number*

Generates imported path pins visual mode ends with the specified path number.

-clear

Removes coloring from all pins and flylines.

DESCRIPTION

Loads the data for imported path pins visual mode. After importing timing path data from a timing report, the visual mode shows pins and the connectivity in one or more timing paths in Layout window. This visual mode colors the pins and flylines with a different color for each imported timing path.

EXAMPLES

The following example will load the timing report file "/remote/misc16/timing_report" to generate the imported path pins visual mode.

```
prompt> gui_load_imported_path_pins_vm \
  -timing_report "/remote/misc16/timing_report"
```

SEE ALSO

None

gui_load_path_analyzer_flylines

Loads the data for path analyzer flylines palette.

SYNTAX

status **gui_load_path_analyzer_flylines**

Data Types

None

ARGUMENTS

None

DESCRIPTION

The command generates the flylines data of path analyzer palette. Each timing path flyline is colored based on either its connection count in connection mode, or its timing effort in timing mode.

EXAMPLES

The following example reloads the timing path flylines data in the design.

prompt> **gui_load_path_analyzer_flylines**

SEE ALSO

None

gui_load_pin_density_mm

Loads the data for pin density map mode.

SYNTAX

status **gui_load_pin_density_mm**
[-area *area*]

Data Types

area list

ARGUMENTS

-area *area*

Area to be analyzed for pin density. By default, the command uses the entire design area.

DESCRIPTION

The command generates map mode view of pin density in a given area. The grids are colored based on the number of pins within the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows pin density in the specified area.

```
prompt> gui_load_pin_density_mm -area \
  {284.820 390.670 1202.790 954.120}
```

SEE ALSO

None

gui_load_power_density_mm

Loads the data for power density map mode.

SYNTAX

status **gui_load_power_density_mm**
[-area *{{x1 y1} {x2 y2}}*]
-scenario *scenario_name*

Data Types

x1 float
y1 float
x2 float
y2 float
scenario_name string

ARGUMENTS

-area *{{x1 y1} {x2 y2}}*

Limits the report scope to the specified area. This argument is optional. By default, the entire design area is used.

-scenario

Specifies the scenario to be reported. This option is required.

DESCRIPTION

This command generates the data for the power density map mode. The design layout area, or user specified area, is split into grids. The grids dimension is set in the mapmode panel. The power contribution for cells that intersect the grid is proportional to the area within each grid sector.

Multicorner-Multimode Support

This command performs its analysis for specified scenario. The **-scenario** argument is required.

EXAMPLES

The following example reloads the power density map mode data from the "default" scenario.

prompt> **gui_load_power_density_mm -scenario default**

The following example reloads the power density map mode data within the specified area from the "sc1.BC" scenario.

prompt> **gui_load_power_density_mm -scenario sc1.BC -area { {10.5 0.50} {300.0 129.80} }**

SEE ALSO

None.

gui_load_routing_guide_vm

Loads the data for routing guides by type visual mode.

SYNTAX

status **gui_load_routing_guide_vm**
-types *type_list*
[-hierarchical]

Data Types

type_list list

ARGUMENTS

-types *type_list*

Specifies the types of routing guide to load in the visual mode. This option is required. The supported types are:

access_preference
default
design_boundary_blockage
forbidden_preferred_grid_extension
max_patterns
metal_cut_allowed
pin_access
river_routing
single_row_via_ladder_pattern_must_join_allowed
standard_cell_region
switched_direction_only

-hierarchical

Searches for routing guides level-by-level relative to the current instance. if this option is not specified, the tool loads only routing guide in the current top-level design.

DESCRIPTION

The command generates the visual mode view of routing guide. Each routing guide is colored based on its type.

EXAMPLES

The following example will color routing guides which type is access_preference or metal_cut_allowed.

prompt> **gui_load_routing_guide_vm -types {access_preference metal_cut_allowed}**

SEE ALSO

None

gui_load_rp_group_net_connectivity_vm

Loads the data for the relative placement (RP) net connection visual mode.

SYNTAX

status **gui_load_rp_group_net_connectivity_vm**
-clct *rp_group_collection*
[-type {clock signal}]

Data Types

rp_group_collection collection

ARGUMENTS

-clct *rp_group_collection*

Specifies the collection of RP groups to load.

-type {clock signal}

Specifies the types of nets to show. Valid signal types are *clock* and *signal*. This option takes the types as a list of strings.

DESCRIPTION

This command generates visual mode of net connections of a specified RP group collection. Net connections are categorized as follows:

- local connection: Nets that only connect to cells inside the RP group collection.
- global connection: Nets that connect to the cells outside the given RP group collection.

  Nets in the visual mode are displayed based on the layout view setting of net.

EXAMPLES

The following example shows signal net connections for the RP group collection name test1.

```
prompt> gui_load_rp_group_net_connectivity_vm -type {signal} \
  -clct [get_rp_groups {test1}]
```

SEE ALSO

add_to_rp_group(2)
create_rp_group(2)
get_rp_groups(2)
remove_from_rp_group(2)
remove_rp_groups(2)

gui_load_rp_vm

Loads the data for relative placement (RP) group visual mode.

SYNTAX

status **gui_load_rp_vm**
[-color group | hierarchy]
[-num_colors *count*]
[-cell_only]

Data Types

count integer

ARGUMENTS

-color group | **hierarchy**

Specifies whether to color objects by relative placement group or relative placement hierarchy level.

-num_colors *count*

Specifies the number of colors to be used in the visual mode.

-cell_only

Colors cells inside the RP group only.

DESCRIPTION

This command loads the data for relative placement (RP) visual mode. Relative placement visual mode helps to examine the placement of the instances (cells and other RP groups) in each group. This visual mode displays a colored map of RP groups with a different color either for each group (by default) or for each relative placement hierarchy level.

EXAMPLES

The following example uses 11 colors to color the cells based on relative placement groups.

```
prompt> gui_load_rp_vm -color group \
-num_colors 11 -cell_only
```

SEE ALSO

None

gui_load_scan_chain_vm

Loads the data for scan chain visual mode.

SYNTAX

status **gui_load_scan_chain_vm**
-chains *scan_chain_names_list*

Data Types

scan_chain_names_list list

ARGUMENTS

-chains *scan_chain_names_list*

Loads the list of scan chains into the visual mode.

DESCRIPTION

Loads the data for scan chain visual mode. This visual mode can be used to examine the placement of scan cells in the design after a scan is inserted. This visual mode colors each scan chain with a different color.

Note that the cell count reported by this command includes all cell objects along the scan path.

EXAMPLES

The following example displays the scan chains 1, 2, and 3.

prompt> **gui_load_scan_chain_vm -chains {1 2 3}**

SEE ALSO

None

gui_load_voltage_area_vm

Loads the data for voltage area visual mode.

SYNTAX

status **gui_load_voltage_area_vm**

Data Types

ARGUMENTS

DESCRIPTION

The command generates the visual mode view of voltage areas. Each voltage area is colored based on its type.

EXAMPLES

The following example will place all the voltage areas in the design into different bins based on their types.

prompt> **gui_load_voltage_area_vm**

SEE ALSO

None.

gui_log_cmd

Log a Tcl command without executing it

SYNTAX

string **gui_log_cmd** -cmd *command*
  [-comment | -no_comment]
  [-suppress_newline | -no_suppress_newline]

string *command*

ARGUMENTS

-cmd *command*

The command to log.

-comment

Enables commenting out of the logged command. If neither -comment nor -no_comment is specified, -no_comment is the default.

-no_comment

Disables commenting out of the logged command.

-suppress_newline

The logged command will not include an added newline character. If neither -suppress_newline nor -no_suppress_newline is specified, -no_suppress_newline is the default.

-no_suppress_newline

The logged command will include an added newline character.

DESCRIPTION

Log a Tcl command without executing it.

The return value of the command is 1.

gui_log_cmd is a thin wrapper around EkShellExecution::log(), which in turn is a thin wrapper around cci_log_command.

The -comment, -no_comment, -suppress_newline, -no_suppress_newline options are there for completeness (cci_log_command

has comment and suppress_newline parms).

The command is hidden.

EXAMPLES

```
psyn_shell-t> gui_log_cmd -cmd {echo abc}
1
```

SEE ALSO

gui_eval_cmd(2)

gui_log_performance

Controls the start and stop of a performance data logging process and outputs into a file.

SYNTAX

string **gui_log_performance**
[-start *file_name*|-stop]
[-compress]
[-quiet]

Data Types

file_name string

ARGUMENTS

-start *file_name*

This option is mutually exclusive with -stop. The argument is the path name of the file to which the log is output. The option begins logging performance data. If the file already exists, the command overwrites the existing file.

-stop

This option is mutually exclusive with -start. This option stops logging performance data. After stopped, the log cannot be reopened for appending.

-compress

If given, the log is saved as a compressed file. This option must be combined with -start.

-quiet

If given, this option causes the command to ignore error conditions.

DESCRIPTION

This command controls the start and stop of a performance data logging process. The performance data is logged before and after executing the commands which are required. The data includes cpu, memory and time. After successfully start a log, the command returns the path name with extension .log or .log.gz if not given in *file_name*.

EXAMPLES

Start logging and save the log to a file without compressing.

prompt> **gui_log_performance -start ./test**
/an/absolute/path/.test.log

Start logging and save the log to a compressed file.

prompt> **gui_log_performance -start ./test -compress**
/an/absolute/path/.test.log.gz

Stop logging

prompt> **gui_log_performance -stop**

SEE ALSO

gui_measure_charts_text

Measure text size in view or plot

SYNTAX

value **gui_measure_charts_text**
{ -view *view_name* | -plot *plot_name* }
-name *string*
-text *string*
[-html]

Data Types

view_name string
plot_name string
value string

ARGUMENTS

-view *view_name*

View to get text size from.

-plot *plot_name*

Plot to get text size from.

-name *string*

Size value to return.

The supported names are width, height, ascent and descent.

width Return the text width in view or plot units

height Return the text height in view or plot units

ascent Return the text ascent in view or plot units

descent Return the text descent in view or plot units

-text *string*

Text to measure

-html

Specifies that the text is in HTML format.

RETURNS

value

Returned text size in view or plot units.

DESCRIPTION

Get the size of text displayed in view or plot for manual placement annotations.

EXAMPLES

The following example gets the width of the string "Abc" in a plot.

```
shell> gui_measure_charts_text -plot $plot -text "Abc" -name width
```

SEE ALSO

gui_get_charts_property(2)
gui_get_charts_data(2)

gui_merge_utable

Merge 2 (loaded) tables via the given join column(s).

SYNTAX

string **gui_merge_utable**
-name *Table_Name*
-merge_table *Table_Name*
-join_columns *Column_Names*
[-output_table *Table_Name*]
[-columns *Column_Names*]

Table_Name String
Column_Names List of Strings

ARGUMENTS

-name *Table_Name*

A primary table name to merge into unless an output table name is also given.

-merge_table *Table_Name*

The merge table name. This table must have the same 'join columns' as the primary table.

-join_columns *Column_Names*

The join columns can be one or more columns that provide a unique key that only matches one row at a time. This usually is a full object name like a net,port or cell name, but can also be a 'key set' like a full_name plus object_class.

-output_table *Table_Name*

An **optional** output table name where the resultant merged table is stored, default is the primary table.

-columns *Column_Names*

An **optional** merge column list of columns that specify the columns to merge from the merge table, default is all.

DESCRIPTION

This command allows you to merge two loaded tables with a common set of

(key/join) columns and produces a resultant merged table that can be saved under a new table name or by default, will be saved in the original primary table. Both tables have to be loaded in memory, see links for gui_import_utable and gui_open_utable below to read in tables.

EXAMPLES

The following example merges two tables (tableA & tableB) joining them via the common key columns (full_name & object_class) and then outputs the result into tableC. It also only merges the column 'power' from tableB with all of tableA, by default all columns in tableB would be merged.

```
shell> # Import tableA:
    gui_import_utable -file tableA.csv
    # Import tableB:
    gui_import_utable -file tableB.csv

    # Merge them into a new tableC
    gui_merge_utable -name tableA -merge tableB -output tableC \
        -join_columns {full_name object_class} -columns {power}

    # View merged tableC:
    gui_show_utable -name tableC
```

SEE ALSO

gui_get_utable(2)
gui_import_utable(2)

gui_open_utable(2)
gui_write_utable(2)

gui_mouse_tool

Operate mouse tools of a given view

SYNTAX

gui_mouse_tool
-window *window*
[-start *tool* |
-current |
-list |
-add_point *{x y}* |
-drag *{{x1 y1} {x2 y2}}* |
-delete_point |
-apply |
-reset |
-abort |
-cycle |
-cycle_back]

window *String*
tool *String*

ARGUMENTS

-window *window*

window specifies the window of which this command should operate the mouse tool.

-start *tool*

Starts the given mouse tool.

-current

Return the name of current active tool.

-list

Return the names of all available tools.

-add_point *{x y}*

Add an input point

-drag *{{x1 y1} {x2 y2}}*

Perform drag operation between two points.

-delete_point

Removes last input point

-apply

Performs tool action

-reset

Clears all pending input or ends the tool if no pending

-abort

Aborts mouse tool unconditionally

-cycle

Cycles through choices for a given operation

-cycle_back

Cycles back through choices for a given operation

DESCRIPTION

The **gui_mouse_tool** controls the mouse tool of a view that supports mouse actions log and replay capabilities. Not all views need to support all of the functionality provided by the interface of this command. User can use the command to script varios mouse action.

EXAMPLES

The following example has the layout view start the zoom in tool and perform a zoom to particular area.

```
> gui_mouse_tool -window Layout.1 -start ZOOM_IN_TOOL
> gui_mouse_tool -window Layout.1 -add_point {27.461 433.400}
> gui_mouse_tool -window Layout.1 -add_point {51.261 393.123}
> gui_mouse_tool -window Layout.1 -abort
```

SEE ALSO

gui_open_error_data

Opens an error data file in the error browser.

SYNTAX

gui_open_error_data
[-name *error_data_name*]
[-file_name *file_name*]
[*error_data*]

Data Types

error_data_name string
file_name string
error_data list

ARGUMENTS

-name *error_data_name*

Specifies the data name of the error data to open in the error browser. If other error data was already loaded into the error browser, the specified data is added to the existing data. This option is mutually exclusive with the **-file_name** and *error_data* options.

-file_name *file_name*

Specifies the name of the exported error file to open in the error browser. The name of the error data file to be opened and shown in the error browser. If other error data was already loaded into the error browser, the specified data is added to the existing data. This option is mutually exclusive with the **-name** and *error_data* options.

error_data

Specifies the data name or list of data names to open in the error browser. If the error data is already open, then a collection of the error data or the error data name can be used to show it in the error browser.

DESCRIPTION

The **gui_open_error_data** command displays the given error data in the GUI error browser. If the error browser is not already visible, it is first made visible.

If you specify a file name with the **-file_name** option, the command first opens an error data file with the given file name.

Note that if the command first opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The **gui_open_error_data** command opens an error data only when necessary. It does not increment the open_count if the error data is already open and in memory. If the **gui_open_error_data** command increments the open_count, then a subsequent call to **gui_close_error_data** for the same error data decrements the open_count. Otherwise, a subsequent call to **gui_close_error_data** simply removes the error_data from the error browser without decrementing the open_count.

EXAMPLES

The following example opens the physical DRC error data file that is named "my_design_dppinassgn.err" and shows it in the error browser.

```
prompt> gui_open_error_data -file_name my_design_dppinassgn.err]
```

The following example first opens the physical DRC error data file that is named "my_design_dppinassgn.err", then shows it in the error browser.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> gui_open_error_data $data
```

remove_drc_error_data(2)

gui_open_utable

Open the given UserTable file.

SYNTAX

string **gui_open_utable**
-file *File_Name*
[-name *Table_Name*]
[-read_only]

File_Name String
Table_Name String

ARGUMENTS

-file *File_Name*

The name of the file to open and copy the UserTable into memory.

-name *Table_Name*

The name of the user table located in the file. By default the name of the file minus the extension is used.

-read_only

This flag stops the table from being copied into memory and instead the table contents are streamed which can save a lot of system memory if the table is huge.

DESCRIPTION

This command opens the given UserTable file and copies the table contents into memory unless the **-read_only** flag is given which causes the contents to be streamed in as needed. This can save system memory if the table is huge.

EXAMPLES

The following example opens the UserTable file 'my_table.utable' and copies the

table 'my_table' into memory.

```
shell> gui_open_utable -file my_table.utable
```

The following example opens the given UserTable file but instead of copying it into memory it connects in read-only mode, steaming the contents as needed.

```
shell> gui_open_utable -file my_table.utable -read_only
```

SEE ALSO

gui_write_utable(2)

gui_overlay_layout

Add/Remove/Adjust a design overlay to a layout window

SYNTAX

gui_overlay_layout
-window *windowID*
-design *design*
-add
-remove
-brightness *value*

windowID *String*
design *String*
add *Boolean flag*
remove *Boolean flag*
brightness *Integer*

ARGUMENTS

-window *windowID*

windowID specifies the layout window to add the overlay

-design *design*

design specifies the design to overlay

-add

add the design as an overlay

-remove

remove the design as an overlay

-brightness *value*

adjust the brightness of the overlay design

DESCRIPTION

Use this command to add, remove, or adjust an overlay on a layout view. The design to overlay must already be an opened design. You cannot overlay the same design twice nor can you overlay a design on itself. The -add and -remove flags are mutually exclusive. The brightness of an overlay can be varied from 0 (not visible at all) and 100 (fully bright). The -remove flag is mutually exclusive with the -brightness flags.

EXAMPLES

shell> **gui_overlay_layout -window Layout.1 -design fill_view -add**
shell> **gui_overlay_layout -window Layout.1 -design fill_view -brightness Off**
shell> **gui_overlay_layout -window Layout.1 -design fill_view -brightness 33%**
shell> **gui_overlay_layout -window Layout.1 -design fill_view -remove**

gui_place_charts_plots

Place plots in charts view

SYNTAX

status **gui_place_charts_plots**
-view *view_name*
[-vertical]
[-horizontal]
[-rows *int*]
[-columns *int*]
[*plots*]

Data Types

view_name string
plot_id_list list

ARGUMENTS

-view *view_name*

Charts View to place plots in.

-vertical

Stack plots vertically.

-horizontal

Stack plots horizontally.

-rows *int*

Stack plots in grid using the specified number of rows.

-columns *int*

Stack plots in grid using the specified number of columns.

plots

List of plots to place. If not specified then all plots are placed

DESCRIPTION

Place plots in a view.

EXAMPLES

The following example stacks all plots horizontally.

```
shell> gui_place_charts_plots -view $view -horizontal
```

SEE ALSO

gui_create_charts_plot(2)
gui_group_charts(2)

gui_query_objects

Get the value of a query text for a collection of object.

SYNTAX

string **gui_query_objects**
object_collection

Data Types

string *object_collection*

ARGUMENTS

object_collection

Specifies the collection of objects to use to get the query text.

DESCRIPTION

The **object_collection** command returns and displays the query text. Same text will be shown in Query toolbar for a particular object query.

A **object_collection** is collection of objects for which the query text will be generated. The collection of objects might be returned as the result of another command such as the **get_cells** command.

For information about collections, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example displays query text for the all plan groups in the design.

```
prompt> gui_query_objects [get_plan_groups]
**********************************
```

```
Object summary:
plan_group : 5
**********

plan_group : RES_I109

plan_group : RES_I110

plan_group : RES_I111

plan_group : RES_I112

plan_group : RES_I113
```

The following example displays a query text for cell named RES_I112/nr02d0_B3_1.

```
prompt> gui_query_objects [get_cells RES_I112/nr02d0_B3_1]
**********

query_objects(2)

gui_read_timing_paths

Reads a persistent path data file containing a timing path collection from some design.

SYNTAX

string **gui_read_timing_paths**
-file *name*
[-report *type*]
[-blocks *insts*]
[-cells *clct*]
[-strict_validate]

Data Types

name string
type Values: summary, qor
insts list of block instances for a common block reference
clct collection of cell objects

ARGUMENTS

-file *name*

Specifies the name of the persistent path data file to be read.

-report *type*

Produces various summary reports on the contents of the path data file.

Note: When this option is used, it will print the report and return. No paths are loaded.

'summary': Produces a header of the contents of the file.
'qor': Produces a summary QOR report for the file.

-blocks *insts*

Given a list of block instances, read-only paths with points that are contained in these instances. The point names and objects are adjusted to the block scope shared by these instances. This allows loading a single block design and looking at paths that are in that block design. Note: This option is mutually exclusive with the **-cells** option.

-cells *clct*

Given a collection of cells in the current design, read-only paths with points that are contained in the given cell collection. Note: This option is mutually exclusive with the **-blocks** option.

-strict_validate

As the paths are read in and validated against the current design, exit on any error. Otherwise only messages are produced but paths are still created.

DESCRIPTION

The **gui_read_timing_paths** command reads a persistent path data file and re-creates the associated path collection. The persistent path data file written by **gui_write_timing_paths** contains all the information needed to re-create the timing paths.

EXAMPLES

The following examples read a timing path collection from a persistent path data file.

prompt> **set mypaths [gui_read_timing_paths -file "my.paths"]**

SEE ALSO

gui_write_timing_paths(2)

gui_remove_all_annotations

Removes specified group of annotations or all annotations from the specified layout window or from all windows.

SYNTAX

status **gui_remove_all_annotations**
[-window *window_name*]
[-group *group_name*]

Data Types

window_name string
group_name string

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-group *group_name*

Specifies the annotation group name.

DESCRIPTION

This command removes specified group of annotations from the specified layout window. If group name is omitted, it will remove all annotations groups. If window name is omitted, it will remove annotations from all windows. The command returns 1 if it is successful.

EXAMPLES

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \
  -type rect -text Test1 -color green -width 2 \
  -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_all_annotations -window Layout.1
```

1

SEE ALSO

gui_add_annotation(2)
gui_remove_annotations(2)

gui_remove_all_rulers

Removes rulers from the specified layout window or from all windows.

SYNTAX

status **gui_remove_all_rulers**
[-window *window_name*]

Data Types

window_name string

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

DESCRIPTION

This command removes rulers form specified layout window, or from all windows if the **-window** option is omitted, and returns 1 if it is successful.

EXAMPLES

prompt> **gui_remove_all_rulers -window Layout.1**
1

SEE ALSO

gui_remove_ruler(2)

gui_remove_annotations

Removes specified group of annotations from the specified layout window.

SYNTAX

status **gui_remove_annotations**
[-window *window_name*]
[-group *group_name*]
[*anno*]

Data Types

window_name string
group_name string
anno collection

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-group *group_name*

Specifies the annotation group name.

anno

Specifies a collection of annotations to remove. Get a collection of annotations with the gui_get_annotations command. This option cannot be specified with any other option.

DESCRIPTION

This command removes specified group of annotations from the specified layout window. If group name is omitted, global group name is used. If window name is omitted, global window name is used. The command returns 1 if it is successful.

EXAMPLES

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \
  -type rect -text Test1 -color green -width 2 \
  -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_annotations -window Layout.1
1
prompt> gui_remove_annotations [gui_get_annotations -filter client_data==MyData]
1
```

SEE ALSO

gui_add_annotation(2)
gui_remove_all_annotations(2)

gui_remove_category_nodes

Removes the offspring category nodes and any category node sub-trees rooted at the specified parent category nodes.

SYNTAX

gui_remove_category_nodes
[-tree *category_tree*]
-parent_categories *category_nodes_list*

Data Types

category_tree	string or category_tree collection
category_nodes_list	list

ARGUMENTS

-tree *category_tree*

The category tree in which the category node operation will happen; must be a category tree name or a category tree collection of size one; the most recently used category tree is used if the *-tree* option is omitted.

-parent_categories *category_nodes_list*

List of hierarchical (parent category node) name patterns and collections of parent category nodes under which one or more offspring category nodes will be removed. A parent category node name is a unique hierarchical name of a category node in a Tcl list format.

DESCRIPTION

Removes the offspring category nodes and any category node sub-trees rooted at the specified parent category nodes. All direct and indirect offspring category nodes of the specified parent category nodes are removed.

The command returns "1" if successful. Otherwise, an empty string is returned.

You should use this command only if at least one category tree is available. The command acts on the category tree specified.

EXAMPLES

In the following example, all category nodes that are direct or indirect children of the ALL root category node are removed. Only the ALL root category node remains.

```
shell> gui_remove_category_nodes -parent_categories {ALL}
1
```

In the following example, the offspring of the {Launch Clock: CLK1} category node is removed. This category node is a child of the {Pathgroup: CLK1} category node, which in turn is a child of the ALL root category node.

```
shell> gui_remove_category_nodes -parent_categories \
?   {{ALL {Pathgroup: CLK1} {Launch Clock: CLK1}}}
1
```

SEE ALSO

gui_create_category_nodes(2)
gui_get_category_nodes(2)

gui_remove_category_rules

Removes all category rules except built-in rules by default.

SYNTAX

string **gui_remove_category_rules**
[-all | -names *rule_names_list*]

Data Types

rule_names_list list

ARGUMENTS

-all

Removes all category rules, including built-in rules.

This option and the **-names** option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

-names *rule_names_list*

Specifies the names of the category rules to be removed.

This option and the **-all** option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

DESCRIPTION

This command removes category rules that have already been created by the **gui_create_category_rule** command during the current run of the tool.

When you use this command without specifying any options, it removes all category rules except built-in rules. Specify the **-all** option to remove all category rules, including the built-in rules. Specify the **-names** option to remove individual rules by name.

The command returns an empty string as its result.

EXAMPLES

The following example removes all category rules, including the built-in rules:

```
prompt> gui_remove_category_rules -all
```

The following example removes all category rules except the built-in rules:

```
prompt> gui_remove_category_rules
```

The following example removes the rules named Rule1 and Rule2:

```
prompt> gui_remove_category_rules -names {Rule1 Rule2}
```

The following example removes non-built-in rules at the top of a user-defined category rule creation script, which is being developed interactively. You can repeatedly change and refine this script by using a text editor, and you can source the script multiple times in a single run of the tool.

```
# first remove all existing user-defined non-built-in rules
gui_remove_category_rules
# now create the user-defined category rules
gui_create_category_rule ...
gui_create_category_rule ...
and so forth
```

SEE ALSO

gui_create_category_rule(2)
gui_list_category_rules(2)

gui_remove_category_trees

Removes the specified category trees (or all category trees by default).

SYNTAX

string **gui_remove_category_trees**
[*category_trees_list*]

Data Types

string	the string data type
category_trees_list	list (of category tree name patterns and collections)

ARGUMENTS

category_trees_list

A list of of category tree name patterns and category tree collections specifying the category trees to be removed. If this option is omitted, then all existing category trees are removed.

Each category tree name pattern must be either the exact name of an existing tree, or the pattern "*", which means "all category trees". More general forms of wild-card matching are not supported at this time.

DESCRIPTION

Removes the specified category trees (or all category trees by default). An empty string is returned.

EXAMPLES

This example show the creation of a couple of category trees, and the results of some different runs of gui_remove_category_trees:

```
shell> set path_clct [get_timing_paths ...]
_sel18
shell> set path_clct2 [get_timing_paths ...]
_sel19
shell> gui_create_category_tree -name tree0 -collections $path_clct
_sel20
```

```
shell> gui_create_category_tree -name tree1 -collections $path_clct2
_sel21
shell> gui_remove_category_trees tree1
shell> gui_remove_category_trees *
```

SEE ALSO

gui_create_category_tree(2)

gui_remove_cell_block_marks

Removes the block mark string values from one or more cells.

SYNTAX

status **gui_remove_cell_block_marks**
-all | *cells*

Data Types

cells list

ARGUMENTS

-all

Removes all block marks on all cells that are marked.

This option and the *cells* option are mutually exclusive, and one of them must be specified.

cells

Removes block marks from one or more cells specified in a list of cell name patterns or cell collections.

This option and the **-all** option are mutually exclusive, and one of them must be specified.

DESCRIPTION

This command removes the block mark string values from one or more hierarchical or leaf-level cell instances. If the **-all** option is specified, then all the block marks are removed from all the cell instances that are marked. If the *cells* option is specified, then block marks are removed only from the specified cell instances.

EXAMPLES

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then removes the block mark from that cell instance:

prompt> **gui_set_cell_block_marks I_TOP/I_ALU ALU**

```
prompt> gui_remove_cell_block_marks I_TOP/I_ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the **get_cells** command, and then removes the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
prompt> gui_remove_cell_block_marks [get_cells I_TOP/I_ALU]
```

The following example removes all the block marks from all the cell instances that are marked:

```
prompt> gui_remove_cell_block_marks -all
```

SEE ALSO

gui_remove_charts_annotation

Remove annotation object from view or plot

SYNTAX

status **gui_remove_charts_annotation**
{ -view *view_name* | -plot *chart_id* }
{ -id *string* | -all }

Data Types

view_name string
chart_id string

ARGUMENTS

-view *view_name*

View to remove annotations from.

-plot *chart_id*

Plot to remove annotations from.

-id *string*

Id of annotation to remove.

-all

Remove all remove annotations.

DESCRIPTION

Removes one or all annotations from a chart or a view.

EXAMPLES

The following example removes all annotations from a view.

```
shell> gui_remove_charts_annotation -view $view -all
```

SEE ALSO

gui_create_charts_arrow_annotation(2)
gui_create_charts_ellipse_annotation(2)
gui_create_charts_point_annotation(2)
gui_create_charts_polygon_annotation(2)
gui_create_charts_polyline_annotation(2)
gui_create_charts_rectangle_annotation(2)
gui_create_charts_text_annotation(2)

gui_remove_charts_model

Remove model from charts

SYNTAX

status **gui_remove_charts_model**
-model *model_id*

Data Types

model_id int

ARGUMENTS

-model *model_id*

Charts model to remove.

DESCRIPTION

Remove model data from charts.

Note: It is recommended that existing plots using the model should also be removed as they may lose access to some or all of the original data.

EXAMPLES

The following example removes a model.

shell> gui_remove_charts_model -model $model

SEE ALSO

gui_create_charts_model(2)

gui_remove_charts_plot

Remove one or all plots from a charts view

SYNTAX

status **gui_remove_charts_plot**
-view *view_name*
{ -plot *chart_id* | -all }

Data Types

view_name string
chart_id string

ARGUMENTS

-view *view_name*

View to remove chart from.

-plot *chart_id*

Chart to remove.

-all

Remove all changes.

DESCRIPTION

Removes one or all charts from a view.

EXAMPLES

The following example removes all charts from a view.

shell> gui_remove_charts_plot -view $view -all

SEE ALSO

gui_create_chart(2)

gui_remove_message_waivers

Removes message waivers created in the Message Browser or by using the **gui_create_message_waiver** command.

SYNTAX

status **gui_remove_message_waivers**
-name *waivers_name* | -all

Data Types

waivers_name string

ARGUMENTS

-name *waivers_name*

Specifies the name of the waivers to delete. This option is mutually exclusive with the **-all** option.

-all

Remove all waivers. This option is mutually exclusive with the **-name** option.

DESCRIPTION

The **gui_remove_message_waivers** command removes message waivers created in the Message Browser or by running the **gui_create_message_waiver** command.

EXAMPLES

The following example removes waiver 'mywaiver':

prompt> **gui_remove_message_waivers -name mywaiver**

SEE ALSO

gui_create_message_waiver(2)

gui_remove_pref_key

Remove a preference key.

SYNTAX

string **gui_remove_pref_key** -key *Key*
[-category *Category*]

Key *String*
Category *String*

ARGUMENTS

-key *Key*

Key specifies the key which will be used together with the specified category to uniquely identify the key to be removed.

-category *Category*

Category specifies the category that owns the specified key. If not specified, a default category will be used.

DESCRIPTION

This command removes the preference key specified by the key name.

SEE ALSO

gui_update_pref_file(2)

gui_remove_ruler

Removes the specified rulers.

SYNTAX

status **gui_remove_ruler**
[-window *window_name*]
-point *point* | -all

Data Types

window_name string
point point

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-point *point*

Specifies the coordinates of the point near the ruler to be removed, in following format:

{x y}

-all

Removes all rulers.

DESCRIPTION

This command removes rulers from the specified layout window, or from all windows if the **-window** option is omitted, and returns 1 if it is successful.

EXAMPLES

prompt> **gui_remove_ruler -window Layout.1 -point {400 400}**

```
1
prompt> gui_remove_ruler -window Layout.1 -all
1
```

SEE ALSO

gui_remove_all_rulers(2)

gui_remove_var

Remove the variable with the specified name.

SYNTAX

void **gui_remove_var** -name *VarName*

VarName *String*

ARGUMENTS

-name *VarName*

VarName specifies the name of the gui variable.

DESCRIPTION

This command removes the gui variable with the specified name. This variable is created with the *gui_create_var* command.

SEE ALSO

gui_create_var(2)
gui_set_var(2)
gui_get_var(2)
gui_exist_var(2)

gui_remove_vm

Remove Visual Mode

SYNTAX

string **gui_remove_vm** -name *identifier*

string *identfier*

ARGUMENTS

-name *identifier*

Specifies the name of the visual mode to be removed.

DESCRIPTION

Removes the specified visual mode and all the associated buckets.

EXAMPLES

To remove visual mode named "mycoloring1", use the following command:

shell> **gui_remove_vm -name mycoloring1**

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vm(2)
gui_get_vmbucket(2)
gui_list_vm(2)
gui_remove_vmbucket(2)
gui_set_vmbucket(2)

gui_update_vm(2)

gui_remove_vmbucket

Removes the specified bucket or all buckets from the specified visual mode

SYNTAX

string **gui_remove_vmbucket**
-vmname *mode_identifier*
[-name *bucket_identifier*]
[-all]

Data Types

mode_identifier string
bucket_identifier string

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode of which the bucket is a member. The visual mode must already exist.

-name *bucket_identifier*

Specifies the name of the bucket to be removed from the specified visual mode.

-all

Removes all buckets associated with the specified visual mode.

DESCRIPTION

Removes the specified bucket or all buckets from the specified visual mode.

EXAMPLES

To remove the visual mode bucket named red from the visual mode named vm1, enter the following command:

prompt> **gui_remove_vmbucket -vmname vm1 -name red**

To remove all the visual mode buckets from the visual mode named vm1, enter the following command:

prompt> **gui_remove_vmbucket -vmname vm1 -all**

SEE ALSO

gui_set_vmbucket(2)
gui_update_vm(2)

gui_report_errors

Output a textual report of errors.

SYNTAX

string **gui_report_errors**
  [-errors *Errors*]
  [-file *FileName*]
  [-include_hidden]

Errors *String*
FileName *String*

ARGUMENTS

-errors *Errors*

The **-errors** specifies the handle for a collection of errors to report on. This argument is optional. If omitted, a report is output for the errors currently loaded in the Error Browser error list.

-file *FileName*

FileName specifies the name of the file to write the report to. This argument is optional. If omitted, the report is output to stdout.

-include_hidden

-include_hidden specifies that errors that are currently hidden from the errors list due to filters or fixed errors being hidden should be included in the report. This option is ignored if errors are given with the *-errors* option.

DESCRIPTION

This command outputs a tabular textual representation of errors. If the -errors argument is omitted and an output file is specified, performs the same operation as the Error Browser option menu command to save to file.

EXAMPLES

The following example saves a textual report of current errors to a file named myErrors.txt:

```
gui_report_errors -file "myErrors.txt"
```

SEE ALSO

gui_error_browser(2)
gui_set_current_errors(2)

gui_report_hotkeys

Report on the current hotkey bindings

SYNTAX

string **gui_report_hotkeys**
[-window_type *WindowTypeName*]

WindowTypeName *String*

ARGUMENTS

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window that the hotkey should apply to. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

DESCRIPTION

This command prints a report on the current key bindings. The list of bindings printed in the report are sorted by hotkey.

EXAMPLES

The following example creates a menu item and add an additional hotkey to it.

```
gui> gui_report_hotkeys

****************************************
Report : hotkeys
Window : LayoutWindow
Version: V-2004.06-GALILEO-BETA1-1
Date   : Tue Aug 31 10:37:17 2004
****************************************

Hot Key    Type  Function
-----------------------------------------------------
```

```
Ctrl+O    Menu  File->Open Design...
Ctrl+S    Menu  File->Save Design

gui_report_map

Report information for a specified map mode.

SYNTAX

string **gui_report_map**
  -name identifier
  -report_type outputType

Data Types

identifier string

outputType string (Values: histogram, count)

ARGUMENTS

-name *identifier*

Specifies the name of the map mode to be queried.

-report_type outputType

Specifies the mode of report. Value of *outputType* can be **histogram** or **count**.

DESCRIPTION

The **gui_report_map** command queries the option values of an existing map mode name and a report mode. Histogram mode will print '**###**' as a graph bar for each bucket. Count mode will generate only count numbers of blocks in each bucket.

EXAMPLES

To generate a histogram data for the map mode named "cellDensityMap". Use the following command:

```
prompt>gui_report_map -name cellDensityMap -report_type histogram
****************************************
Report : map
Design : ORCA
```

```
Mode   : histogram
Version: P-2019.03-DEV

gui_report_performance

Generates a performance report.

SYNTAX

status **gui_report_performance**
[-type *report_type*]
[-file *file_name*]
[-compress *compress_method*]

Data Types

report_type string
file_name string
compress_method string

ARGUMENTS

-type *report_type*

Specifies the report type. If report type is omitted or the value of this option is simple, output a simple version report. If the value of this option is detail, output a detail version report which includes additional information of x11 performance, region searching, attribute querying and render time.

The supported values for this option are

simple
detail

-file *file_name*

Outputs the report as a file and specifies the file name. If file name is omitted, output the report to console.

-compress *compress_method*

Specifies the compress method. The supported values for this option are

none
gzip

DESCRIPTION

This command report the performance data of machine state, design information, GUI configurations and current GUI views state.

EXAMPLES

Generate a simple version report and output to console.

prompt> **gui_report_performance**

Generate a detail version report and output to a file.

prompt> **gui_report_performance -type detail -file file_name**

Generate a detail version report and output to a compressed file

prompt> **gui_report_performance -type detail -file file_name -compress gzip**

SEE ALSO

gui_report_proc_arg_type_names

Report on the available type_name attribute values.

SYNTAX

string **gui_report_proc_arg_type_names**

DESCRIPTION

This command prints a report on the available values for the type_name attribute for the **-define_args** argument to the **define_proc_attributes** command.

When a tcl proc has been defined using the **define_proc_attribute** command, a GUI form for the command will be auto-generated and shown from the application command search feature or using the command **gui_show_command_form**. The kinds of proc argument input fields used in the generated GUI form depend on the **type_name** attribute values provided for command options. The **type_name** attribute value for an option is given as a part of the **-define_args** argument. The **-define_args** option accepts a list of the following values, in this order:

* option name * option decription * option value type description * data_type * list of option attribute name-value pairs

Here is the usage for the **type_name** attribute within argument value for the **define_proc_attributes** command option **-define_args**:

```
define_proc_attributes <procedure name> \
  -define_args { \
    {<option name> <option description> <value type description> <data_type> \
      {[required | optional] {type_name <type_name_value>}} \
  } \
}
```

where <type_name_value> can be substituted with any of the type names reported by **gui_report_proc_arg_type_names**.

For the **type_name** attribute value to have effect on the input field used in a GUI form, the <data_type> value must be **string**, for a single value, or **list** for multiple values. The value **list** is not supported for all **type_name** values as shown in the report's **data_type** column.

The following is an example of a **define_proc_attribute** command invocation with options accepting a collection or names of nets:

```
define_proc_attributes myProc \
  -define_args { \
    {-net "select a net" "net name or a collection of a net" string \
        {optional {type_name net}}} \
    {-nets "select nets" "net names or a collection of nets" list   \
        {optional {type_name net}} \
  } \
}
```

In the above example, the **-net** option has **data_type** value **string** and **type_name** value **net**. This option accepts a single net as input. The **-nets** option has **data_type** value **list** and **type_name** value **net**. This option accepts multiple nets as input.

The report produced by this command lists the available **type_name** values. When one of these supported **type_name** values is used, the GUI form for the proc will use an input field that is appropriate for user input of that kind of value. For example, for a **net** type input, as shown in the example above, the form will use an object selector field which is configured to accept net input.

A proc argument with any combination of unspecified or unsupported **data_type** and **type_name** values is represented with a simple text input field in the generated GUI form.

Some **type_name** values use input editors that allow further configuration. For example, an editor for a file name can be configured to allow input of only existing files. Or an editor for a layer name can be configured to allow input of only certain types of layers.

Available configuration options are shown in the options column, then described in more detail at the end of the report output in a separate table keyed by associate type_name values. When providing optional configuration, list the configuration name-value pairs after the type_name value as a part of the the type_name attribute value. The following is an example of a "file" type_name attribute with multiple optional configuration settings:

```
define_proc_attributes myProc \
 -define_args { \
  {-file_option "Select an existing file name" "file name"  string \
   {required
    {type_name {file {subtype exist} \
                {operation "Save As"} \
                {filter {"Text files (*.txt)" "All files (*)"}} \
           } \
    } \
   } \
  } \
}
```

EXAMPLES

The following example outputs a report of available type_name attribute values.

```
gui> gui_report_proc_arg_type_names

corner              string, list  object type
cut_pattern         string      cut_pattern
directory           string      directory name  context, filter,
                                    operation, subtype
 ...

Configuration Options:

type_name   option     description
------------------------------------------------------------------------
layer       subtype    Layer type -- valid values: routing, contact,
                       cut, poly, poly_cont, user, system.  Multiple
                       values may be given in a tcl list.

directory,  context    A valid directory name for current directory
file                   context for the file dialog
            filter     File or directory name filter strings to
                       set for the file dialog.  Valid value is
                       a tcl list of filter strings, e.g. {"Text
                       files (*.txt)" "All files (*)"}
            operation  Operation name for file dialog titlebar
                       and button, e.g. "Save As"
            subtype    File type: valid values are: "existing"
                       (existing file only), "any" (any file)

gui_report_task

task.

SYNTAX

string **gui_report_task**
  -task | -item_root *TaskName | ItemRootName*
  [-file] *FileName*

TaskName *String*
ItemRootName *String*
FileName *String*

ARGUMENTS

-task *TaskName*

TaskName specifies the name of a task on which to report. This option is mutually exclusive with the -item_root option.

-item_root *ItemRootName*

ItemRootName specifies the name of a task item root name on which to report. This option is mutually exclusive with the -task option.

-file *FileName*

FileName optionally specfies the output file into which the report is written.

DESCRIPTION

This command outputs a textual report of the given task to the xterm console. If -file is given, then the report is also output to the given file. The report will have the following approximate format. The strings bracketed with the angle brackets will be replaced with the actual attribute value.

Attributes are omitted if they are not defined. Item are shown one to a line with the hierarchy structure indicated by indentations and bars. The leaf-leveltask item names are followed by the associated task page name:

Task: <task name>
 Default: <true | false>
 Items: <items>

SEE ALSO

gui_create_task(2)
gui_get_task_list(2)

gui_schematic_add_logic

Adds logic to a schematic

SYNTAX

string **gui_schematic_add_logic** [-window *<win>*]
[-new]
[-schematic *<schem>*]
objs

string *<win>*
string *<schem>*
string *objs*

ARGUMENTS

-window *<win>*

Top level window name to place new schematic (default: current window). This option is ignored unless -new is specified.

-new

Create new schematic.

-schematic *<schem>*

Schematic view to update (default: most recently active schematic).

objs

Objects to add to the schematic.

DESCRIPTION

This command adds logic into a Path Schematic view. The command either creates a new view containing the specified objects or updates an existing view. The command always returns the name of the schematic that was updated or created.

EXAMPLES

The following example creates a new path schematic containing all the cells in the current design:

```
gui_schematic_add_logic -new [get_cells *]
```

SEE ALSO

gui_get_current_window(2)
gui_schematic_remove_logic(2)

gui_schematic_remove_logic

Removes logic from a schematic

SYNTAX

string **gui_schematic_remove_logic** [-schematic *<schem>*]
objs

string *<schem>*
string *objs*

ARGUMENTS

-schematic *<schem>*

Schematic view to update (default: most recently active schematic).

objs

Objects to remove from the schematic.

DESCRIPTION

This command removes logic into a Path Schematic view. The command returns the name of the schematic that was updated

EXAMPLES

The following example removes the cell "U1" from the most recently active schematic view:

```
gui_schematic_remove_logic [get_cells U1]
```

SEE ALSO

gui_get_current_window(2)
gui_schematic_add_logic(2)

gui_scroll

Scroll a window's viewport.

SYNTAX

gui_scroll
-window *window*
[-selection | -clct *clct* | [-habs *absX* | -hrel *relX*] [-vabs *absY* | -vrel *relY*]]

window *String*
absX *Float*
relX *Float*
absY *Float*
relY *Float*

ARGUMENTS

-window *window*

window specifies the window to be scrolled.

-selection

Determine the bounding box for all selected objects present in the view, and scroll such that the center of that box is visible.

-clct *clct*

Determine the bounding box for the collection objects present in the view, and scroll such that the center of that box is visible.

-habs *absX*

Scroll such that the specified X model position is centered in the viewport.

-hrel *relX*

Scroll horizontally by the specified number of pages. A page is the width of the viewport. Negative values scroll left and positive values scroll right.

-vabs *absY*

Scroll such that the specified Y model position is centered in the viewport.

-vrel *relY*

Scroll vertically by the specified number of pages. A page is the height of the viewport. Negative values scroll up and positive values scroll down.

DESCRIPTION

The **gui_scroll** command adjusts the position of views that support zooming. The viewport can be adjusted in the X and/or Y direction. Absolute values are expressed in model coordinates. Relative values allow paging. For example, *-hrel 1.0* means page to the right by the width of the viewport.

EXAMPLES

Scroll such that model coordinates (287.0, 1422.0) are centered in the viewport.

```
gui_scroll -window Layout.1 -habs 287.0 -vabs 1422.0
```

Scroll to the right by one viewport width.

```
gui_scroll -window Layout.1 -hrel 1.0
```

SEE ALSO

gui_zoom(2)

gui_select_bounds_of_selected

Select the bounds of the selected objects.

SYNTAX

status **gui_select_bounds_of_selected**

DESCRIPTION

The **gui_select_bounds_of_selected** command selects the bounds related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Bounds that are already selected remain selected, while bound_shape, cell, pin, port objects will have their related bounds selected.

EXAMPLES

Select the bounds of the selected objects.

```
prompt> gui_select_bounds_of_selected
```

SEE ALSO

change_selection(2)
get_bounds(2)

gui_select_bundles_of_selected

Select the bundles of the selected objects.

SYNTAX

status **gui_select_bundles_of_selected**

DESCRIPTION

The **gui_select_bundles_of_selected** command selects the bundles related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the bundles associated with the nets of the selected net, routing_corridor, routing_corridor_shape, pin, port, terminal, shape, and via objects.

EXAMPLES

Select the bundles of the selected objects.

```
prompt> gui_select_bundles_of_selected
```

SEE ALSO

change_selection(2)
get_bundles(2)

gui_select_by_name

Select or highlight objects by name

SYNTAX

status **gui_select_by_name**
[{ -select | -highlight }]
-object_type *string*
[-pattern *string*]
[-filter *string*]
[{ -replace | -add | -remove }]
[-regexp]
[-nocase]
[-exact]
[-all]

ARGUMENTS

-select

Specifies that the matching objects are to be selected.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

-highlight

Specifies that the matching objects are to be highlighted.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

-object_type *string*

Specifies the type of objects to be selected.

The available types are dependant on the individual product. Please see your product's documentation for details.

-pattern *string*

Specifies the pattern to be used for a match.

By default matching is case-sensitive and uses wildcard patterns. If non case-sensitive matching is required use the *-nocase* option. If regular expression matching is required use the *-regexp* option. If no pattern matching is required use the *-exact* option.

-filter *string*

Specifies the expression to use when filtering the results.

-replace

Specifies that matching objects should replace the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

-add

Specifies that matching objects should be added to the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

-remove

Specifies that matching objects should be removed from the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

-regexp

Specifies the pattern matching should use regular expressions.

-nocase

Specifies the pattern matching should be case-insensitive.

-exact

Specifies that no pattern matching should be used so wildcards and regular expressions are ignored.

-all

Specifies that physical only objects be include in the search.

DESCRIPTION

This command allows objects of a specified type to be selected or highlighted.

It is used by the Select By Name Toolbar and Select By Name Dialog for correct log and replay of the resultant selection or highlight.

The command returns whether the search was successful or not.

EXAMPLES

The following example will add all nets matching the pattern 'A*' to the current selection.

```
shell> gui_select_by_name -select -object_type {Nets} -pattern {A*} -add
```

The following example will only highlight the Port '*Logic0*'.

```
shell> gui_select_by_name -highlight -object_type {Ports} -pattern {*Logic0*} -exact
```

SEE ALSO

change_selection(2)
gui_change_highlight(2)

gui_select_cells_of_selected

Select the cells of the selected objects.

SYNTAX

status **gui_select_cells_of_selected**

DESCRIPTION

The **gui_select_cells_of_selected** command selects the cells related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Cells that are already selected remain selected, while net, pin, shape, and via objects will have their related cells selected.

EXAMPLES

Select the cells of the selected objects.

```
prompt> gui_select_cells_of_selected
```

SEE ALSO

change_selection(2)
get_cells(2)

gui_select_connected_net_shapes

Selects the net shapes physically connected to the selected net shapes on the same nets.

SYNTAX

status **gui_select_connected_net_shapes**
[-hierarchical]
[-cross_net]

ARGUMENTS

-hierarchical

Traces connections across hierarchical module boundaries. For example, all net shapes of a connected feedthrough net are selected in one operation when this option is specified.

-cross_net

Traces physically connected shapes across different nets, except PG nets.

DESCRIPTION

The **gui_select_connected_net_shapes** command selects the physically connected net shapes of the currently selected net shapes. It is intended for interactive usage in the GUI for the application.

EXAMPLES

Select the objects of the selected net shapes.

prompt> **gui_select_connected_net_shapes**

SEE ALSO

change_selection(2)

get_shapes(2)

gui_select_connected_rdl_net_shapes

Selects the RDL net shapes physically connected to the selected RDL net shapes.

SYNTAX

status **gui_select_connected_rdl_net_shapes**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **gui_select_connected_rdl_net_shapes** command selects the physically connected RDL net shapes of the currently selected net shapes. It is intended for interactive usage in the GUI for the application.

RDL net shapes can have multiple paths from a driver to a bump. This command only selects the RDL net shapes on the same path as the currently selected net shapes.

EXAMPLES

Select the objects of the selected RDL net shapes.

```
prompt> gui_select_connected_rdl_net_shapes
```

SEE ALSO

change_selection(2)
get_shapes(2)

gui_select_connections_of_selected

Select the connections of the selected objects.

SYNTAX

status **gui_select_connections_of_selected**

DESCRIPTION

The **gui_select_connections_of_selected** command selects the connections related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Ports and Pins that are already selected remain selected, while cell, net, shape, via, terminal, bound, pin_guide, pin_blockage, and design objects will have their related connections selected.

EXAMPLES

Select the connections of the selected objects.

```
prompt> gui_select_connections_of_selected
```

gui_select_constraint_groups_of_selected

Select the constraint groups of the selected objects.

SYNTAX

status **gui_select_constraint_groups_of_selected**

DESCRIPTION

The **gui_select_constraint_groups_of_selected** command selects the constraint groups related to the currently selected nets, topology nodes, or topology edges. It is intended for interactive usage in the GUI for the application. Net, topology node, and topology edge objects will have their related constraint groups selected.

EXAMPLES

Select the constraint groups of the selected objects.

```
prompt> gui_select_constraint_groups_of_selected
```

gui_select_macros_of_selected

Select the macros of the selected objects.

SYNTAX

status **gui_select_macros_of_selected**

DESCRIPTION

The **gui_select_macros_of_selected** command selects the macros within the currently selected objects. It is intended for interactive usage in the GUI for the application. Macros that are already selected remain selected, while the macros within selected design or hierarchy boundaries are also selected.

EXAMPLES

Select the macros of the selected objects.

```
prompt> gui_select_macros_of_selected
```

SEE ALSO

change_selection(2)
get_cells(2)

gui_select_matching_types_of_selected

Select the matching types of the selected cells, pins, or terminals.

SYNTAX

status **gui_select_matching_types_of_selected**

DESCRIPTION

The **gui_select_matching_types_of_selected** command selects the matching types related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Matching types that are already selected remain selected, while pins, terminals and cells will have their related matching types selected.

EXAMPLES

Select the matching types of the selected objects.

```
prompt> gui_select_matching_types_of_selected
```

SEE ALSO

gui_select_mib_cells_of_selected

Selects the associated MIB cells of the selected macro cells.

SYNTAX

status **gui_select_mib_cells_of_selected**

DESCRIPTION

The **gui_select_mib_cells_of_selected** command selects the associated multiply instantiated block (MIB) cells of the currently selected macro cells.

It is intended for interactive usage in the GUI for the application.

If the command fails then the selection is not changed.

EXAMPLES

Select the MIB cells of the selected macro cells.

```
prompt> gui_select_mib_cells_of_selected
```

SEE ALSO

change_selection(2)
gui_select_mib_connections_of_selected(2)

gui_select_mib_connections_of_selected

Selects the associated MIB connections of the selected macro connections.

SYNTAX

status **gui_select_mib_connections_of_selected**

DESCRIPTION

The **gui_select_mib_connections_of_selected** command selects the associated multiply instantiated block (MIB) connections (pins) of the currently selected macro connections (macro pins).

It is intended for interactive usage in the GUI for the application.

If the command fails then the selection is not changed.

EXAMPLES

Select the MIB connections of the selected macro connections.

```
prompt> gui_select_mib_connections_of_selected
```

SEE ALSO

```

SEE ALSO

change_selection(2)
get_shapes(2)

gui_select_net_vias_of_selected

Select the vias of the nets of the selected objects.

SYNTAX

status **gui_select_net_vias_of_selected**

DESCRIPTION

The **gui_select_net_vias_of_selected** command selects the vias of the nets of the currently selected objects. It is intended for interactive usage in the GUI for the application. Vias that are already selected remain selected, while cell, pin, net, terminal, and port objects will have the vias of their nets selected.

EXAMPLES

Select the vias of the nets of the selected objects.

```
prompt> gui_select_net_vias_of_selected
```

SEE ALSO

change_selection(2)
get_vias(2)

gui_select_nets_of_selected

Select the nets of the selected objects.

SYNTAX

status **gui_select_nets_of_selected**
[-hierarchical]

ARGUMENTS

-hierarchical

If this option is specified then all hierarchical nets of the original logical net are selected.

DESCRIPTION

The **gui_select_nets_of_selected** command selects the nets related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Nets that are already selected remain selected, while cell, pin, shape, via, terminal, port, and bundle objects will have their related nets selected.

EXAMPLES

Select the nets of the selected objects.

gui_select_primary_power_supply_nets_of_selected

Select the primary power supply nets of the selected voltage areas, voltage area shapes, power domains.

SYNTAX

status **gui_select_primary_power_supply_nets_of_selected**

DESCRIPTION

The **gui_select_primary_power_supply_nets_of_selected** command selects the supply nets related to the currently selected voltage areas and power domains as primary power supply. It is intended for interactive usage in the GUI for the application. Voltage_areas, voltage area shapes, and power domains already selected will have their related primary power supply net selected.

EXAMPLES

Select the primary power supply nets of the selected objects.

```
prompt> gui_select_primary_power_supply_nets_of_selected
```

SEE ALSO

gui_select_routing_corridors_of_selected

Select the routing_corridors of the selected objects.

SYNTAX

status **gui_select_routing_corridors_of_selected**

DESCRIPTION

The **gui_select_routing_corridors_of_selected** command selects the routing_corridors related to the currently selected objects. It is intended for interactive usage in the GUI for the application. If there are selected net, super net, pin, port, bundle, terminal, shape, or via objects the nets associated with those objects are used to determine the associated routing corridor.

EXAMPLES

Select the routing_corridors of the selected objects.

```
prompt> gui_select_routing_corridors_of_selected
```

SEE ALSO

change_selection(2)
get_routing_corridors(2)

gui_select_rp_blockages_of_selected

Select the relative placement (RP) blockages of the selected objects.

SYNTAX

status **gui_select_rp_blockages_of_selected**

DESCRIPTION

The **gui_select_rp_blockages_of_selected** command selects the relative placement (RP) blockages related to the currently selected objects. It is intended for interactive usage in the GUI for the application. When rp_group is selected, this command returns its RP blockage if any.

EXAMPLES

Select the RP blockages of the selected objects.

```
prompt> gui_select_rp_blockages_of_selected
```

SEE ALSO

change_selection(2)
get_rp_blockages(2)

gui_select_rp_groups_of_selected

Select the relative placement (RP) groups of the selected objects.

SYNTAX

status **gui_select_rp_groups_of_selected**

DESCRIPTION

The **gui_select_rp_groups_of_selected** command selects the relative placement (RP) groups related to the currently selected objects. It is intended for interactive usage in the GUI for the application.

When an RP blockage or cell is selected, this command returns the rp group that host the rp blockage or cell; when rp group is selected, this command returns the RP group inside it if any.

EXAMPLES

Select the RP groups of the selected objects.

```
prompt> gui_select_rp_groups_of_selected
```

SEE ALSO

change_selection(2)

gui_select_site_arrays_of_selected

Select the site arrays of the selected objects.

SYNTAX

status **gui_select_site_arrays_of_selected**

DESCRIPTION

The **gui_select_site_arrays_of_selected** command selects the site arrays related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Site arrays that are already selected remain selected, while site rows, tracks will have their related site arrays selected.

EXAMPLES

Select the site arrays of the selected objects.

```
prompt> gui_select_site_arrays_of_selected
```

gui_select_site_rows_of_selected

Select the site rows of the selected objects.

SYNTAX

status **gui_select_site_rows_of_selected**

DESCRIPTION

The **gui_select_site_rows_of_selected** command selects the site rows related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Site rows that are already selected remain selected, while site arrays will have their related site rows selected.

EXAMPLES

Select the site rows of the selected objects.

```
prompt> gui_select_site_rows_of_selected
```

SEE ALSO

change_selection(2)
get_site_rows(2)
get_site_arrays(2)

gui_select_supernets_of_selected

Select the supernets of the selected objects.

SYNTAX

status **gui_select_supernets_of_selected**

DESCRIPTION

The **gui_select_supernets_of_selected** command selects the supernets related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Supernets that are already selected remain selected, while nets, pins, ports, shapes, vias, bundles, and routing corridors will have their related supernets selected.

EXAMPLES

Select the supernets of the selected objects.

```
prompt> gui_select_supernets_of_selected
```

SEE ALSO

change_selection(2)
get_supernets(2)

gui_select_terminals_of_selected

Select the terminals of the selected objects.

SYNTAX

status **gui_select_terminals_of_selected**

DESCRIPTION

The **gui_select_terminals_of_selected** command selects the terminals related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Terminals that are already selected remain selected, while port, net, and design objects will have their related terminals selected.

EXAMPLES

Select the terminals of the selected objects.

```
prompt> gui_select_terminals_of_selected
```

SEE ALSO

change_selection(2)
get_terminals(2)

gui_select_topology_edges_of_selected

Selects the topology edges of the selected objects.

SYNTAX

status **gui_select_topology_edges_of_selected**

DESCRIPTION

The **gui_select_topology_edges_of_selected** command selects the edges related to the currently selected objects, with whom the same nets are shared. It is intended for interactive usage in the GUI for the application. Cell, net, terminal, port, pin, topology node, and topology edge objects will have their related topology edges selected.

EXAMPLES

Select the topology edges of the selected objects.

```
prompt> gui_select_topology_edges_of_selected
```

SEE ALSO

change_selection(2)
get_topology_edges(2)

gui_select_topology_repeaters_of_selected(2)

gui_select_topology_nodes_of_selected

Selects the topology nodes of the selected objects.

SYNTAX

status **gui_select_topology_nodes_of_selected**

DESCRIPTION

The **gui_select_topology_nodes_of_selected** command selects the nodes related to the currently selected objects, with whom the same nets are shared. It is intended for interactive usage in the GUI for the application. Cell, net, terminal, port, pin, topology node, and topology edge objects will have their related topology nodes selected.

EXAMPLES

Select the topology nodes of the selected objects.

```
prompt> gui_select_topology_nodes_of_selected
```

SEE ALSO

change_selection(2)
get_topology_edges(2)
get_topology_nodes(2)
gui_select_topology_edges_of_selected(2)

gui_select_topology_plans_of_selected

Selects the topology plans of the selected objects.

SYNTAX

status **gui_select_topology_plans_of_selected**

DESCRIPTION

The **gui_select_topology_plans_of_selected** command selects the topology plans related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Topology node, edge, and repeater objects will have topology plans which own these objects selected.

If the objects are nets, supernets, or bundles, the command selects the topology plans that have one or more of those objects in their "objects" attribute collection.

EXAMPLES

Select the topology plans of the selected objects.

```
prompt> gui_select_topology_plans_of_selected
```

gui_select_topology_repeaters_of_selected

Selects the topology repeaters of the selected objects.

SYNTAX

status **gui_select_topology_repeaters_of_selected**

DESCRIPTION

The **gui_select_topology_repeaters_of_selected** command selects the repeaters related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Topology plan and topology edge objects will have their related topology repeaters selected.

EXAMPLES

Select the topology repeaters of the selected objects.

```
prompt> gui_select_topology_repeaters_of_selected
```

gui_select_vmbucket

Select the Contents of a Visual Mode Bucket

SYNTAX

string **gui_select_vmbucket** -vmname *mode_identifier*
-name *bucket_identifier*
[-replace | -add | -remove]

string *mode_identifier*
string *bucket_identifier*

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes, use the **gui_list_vm** command.

-name *bucket_identifier*

Specifies the name of the visual mode bucket.

-replace

Optional argument that indicates that the contents of the visual mode bucket will replace the selection list.

-add

Optional string that indicates that the contents of the visual mode bucket will be added to the selection list.

-remove

Optional string that indicates the contents of the visual mode bucket will be removed from the selection list.

DESCRIPTION

The **gui_select_vmbucket** command selects the contents of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The contents of the visual mode bucket can replace, be added to, or be removed from the selection list.

EXAMPLES

Select the 2nd bucket of SNAPSHOT visual mode.

```
shell> gui_select_vmbucket -vmname SNAPSHOT -name 1 -replace
```

SEE ALSO

gui_select_voltage_areas_of_selected

Select the voltage areas of the selected objects.

SYNTAX

status **gui_select_voltage_areas_of_selected**

DESCRIPTION

The **gui_select_voltage_areas_of_selected** command selects the voltage_areas related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Vias that are already selected remain selected, while voltage_area_shape objects will have their related voltage_areas selected.

EXAMPLES

Select the voltage_areas of the selected objects.

```
prompt> gui_select_voltage_areas_of_selected
```

SEE ALSO

change_selection(2)
get_voltage_areas(2)

gui_set_active_window

Make the specified window the active window

SYNTAX

status **gui_set_active_window**
-window *window_id*

Data Types

window_id string

ARGUMENTS

-window *window_id*

Specifies the window name id.

The matching window of this id will be made the active window.

Note: both toplevel windows and child windows of a particular toplevel window have a currently active window. If the window is a toplevel window then the currently active toplevel window is changed, of the window is a child window the currently active child window in the specified window's parent is changed.

DESCRIPTION

This command makes the specified window the active window.

EXAMPLES

The following example will make the toplevel window Toplevel.2 active.

shell> gui_set_active_window -window Toplevel.2

SEE ALSO

gui_close_window(2)
gui_exist_window(2)
gui_show_window(2)
gui_get_window_types(2)
gui_get_window_ids(2)
gui_create_window(2)
gui_get_current_window(2)

gui_set_attribute

Set the value of a GUI attribute for one or more objects.

SYNTAX

string **gui_set_attribute**
object_collection
attribute_name
attribute_value

string *object_collection*
string *attribute_name*
string *attribute_value*

ARGUMENTS

object_collection

A collection of one or more objects.

attribute_name

The name of a GUI attribute.

attribute_value

The value to be applied to the GUI attribute.

DESCRIPTION

Applies the given value to the GUI attribute for each element of the object collection. The return value is a list of one or more object names (depending on the size of the object collection) to which the attribute value has been applied. A Tcl error is raised if any error condition is encountered. This command is hidden.

EXAMPLES

psyn_shell-t> **gui_set_attribute [find cell U*7] some_attribute some_value**
/RISC_CORE/U7 /RISC_CORE/U17 /RISC_CORE/U27 /RISC_CORE/U37

SEE ALSO

gui_get_attribute(2)

gui_set_bucket_option

Sets the value for an option on a bucket in the specified visual mode or map mode.

SYNTAX

string **gui_set_bucket_option**
-map *map_name*
-bucket *bucket_name*
-option *option_name*
-value *value* | -default

Data Types

map_name string
bucket_name string
option_name string
value string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-bucket *bucket_name*

Specifies the name of the bucket.

-option *option_name*

Specifies the name of the option to be set.

-value *value*

Specifies the value for the option.

The **-value** option is mutually exclusive with the **-default** option. You must use one, but not both.

-default

Sets the option to its default value.

The **-default** option is mutually exclusive with the **-value** option. You must use one, but not both.

DESCRIPTION

This command sets the value for an option on a bucket in a visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. You must set the option to either a specific value or its default value. Use the **-value** option to set a specific value or use the **-default** option to set the option to its default value.

EXAMPLES

The following example sets the color of *bucket1* to yellow in the global route congestion map:

```
prompt> gui_set_bucket_option -map AREAPARTITION \
    -bucket bucket1 -option color -value yellow
```

SEE ALSO

gui_get_bucket_option(2)

gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_map_option(2)

gui_set_cell_block_marks

Sets a block mark on one or more cells.

SYNTAX

status **gui_set_cell_block_marks**
cells
block_mark

Data Types

cells list
block_mark string

ARGUMENTS

cells

Lists one or more cells to mark with a block mark, in a list of cell name patterns or cell collections.

block_mark

Specifies the block mark string value to be set for the listed cells.

DESCRIPTION

This command sets a block mark for one or more hierarchical or leaf-level cell instances. Typically, a short symbolic string name is used as the block mark. Ultimately, a block mark can appear in the GUI as the text label for a timing path category generated from a dynamic category rule. Such block marks should be kept short to avoid using up too much screen space in the GUI.

A common application involves marking certain interesting intellectual property (IP) blocks within a design. These block marks affect the calculation of the following timing path shell attributes, which are defined only when the GUI is running:

- **blocks** - An ordered block level path; includes start, through, and end blocks
- **through_blocks** - Includes through blocks, but not the start and end blocks
- **start_block** - The start block
- **end_block** - The end block
- **start_end_blocks** - A pair consisting of the start block and the end block, in that order

- **start_end_blocks_sorted** - A pair consisting of the start block and the end block, sorted alphabetically

These block marks also affect the calculation of the following cell shell attribute, which is defined only when the GUI is running:

- **block_mark** - String value of a cell instance's (explicit) block mark, or an empty string if there is no explicit block mark

In calculating the timing path shell attributes listed previously, a block is calculated for each timing point of a timing path. If the leaf cell instance on which a timing point resides is explicitly marked with a block mark, by using the **gui_set_cell_block_marks** command, the block for the timing point is the block mark for the leaf cell. If the leaf cell instance on which a timing point resides is not explicitly marked, the block for the timing point is the block mark on the first explicitly marked hierarchical cell located by traversing up the logical hierarchy from that leaf cell instance.

If no direct or indirect hierarchical parent cell is found to be explicitly marked, the block for the timing point has a default implicit string value of "_Top_". For a timing point that is a startpoint or endpoint of a timing path, where the startpoint or endpoint is an external design port, the block has a default implicit string value of "_Port_".

Note: Each timing point of a timing path always has a defined block, which can be an explicit block mark, "_Top_", or "_Port_".

The **through_blocks** attribute value can be an empty set of blocks, which is represented by the string value "_Empty_".

EXAMPLES

The following example sets the block mark to ALU for a hierarchical cell instance identified by a cell name:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
```

The following example sets the block mark to ALU for a hierarchical cell instance identified by a nested run of the **get_cells** command:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
```

The following example sets the block mark for a list of cell instances where the first item is identified by a cell name and the second item is identified by a nested run of the **get_cells** command:

```
prompt> gui_set_cell_block_marks [list I_ALU  [get_cells I_STACK_TOP/I1_STACK_MEM]] \
    my_mark
```

SEE ALSO

gui_get_cell_block_marks(2)
gui_remove_cell_block_marks(2)

gui_set_charts_data

Set charts data

SYNTAX

status **gui_set_charts_data**
{ -global | -model *model_id* | -view *view_name* |
-plot *plot_name* }
[-column *int*]
[{ -header | -row *int* }]
-name *string*
-value *string*

Data Types

model_id int
view_name string
plot_name string

ARGUMENTS

-global

Set global data.

-model *model_id*

Model to set data in.

-view *view_name*

View to set data in.

-plot *plot_name*

Plot to set data in.

-column *int*

Column to set model data in.

Only used by the *model* option.

-header

Set model header data.

Only used by the *model* option.

-row ***int***

Row to set model data in.

Only used by the *model* option.

-name ***string***

Name of data to set.

The supported names depend on which object the data is being set in:

For model the following names are supported:

value Set value of model horizontal header or row value.

column_type Set specific column type or all model column types. If the column is specified then this is the type for the specified column, if no column is specified this is a list of types for the model's columns. See **gui_create_charts_model** *column_type* for details of the syntax.

name Set model name.

For view the following names are supported:

fit fit plots in the view.

For plot no names are currently supported:

For global no names are currently supported:

-value ***string***

The value to set.

DESCRIPTION

Set data in model, view, plot or globally.

If model is specified then the *column* and *header* or *row* should be specified.

EXAMPLES

The following example sets the name of a model.

shell> gui_set_charts_data -model $model -name "Test Model"

SEE ALSO

gui_get_charts_data(2)

gui_set_charts_property

Set charts property

SYNTAX

status **gui_set_charts_property**
{ -view *view_name* | -plot *plot_name* |
-annotation *annotation_id* }
[-object *object_id*]
-name *string*
-value *string*

Data Types

view_name string
plot_name string
annotation_id string
object_id string

ARGUMENTS

-view *view_name*

View to set property in.

-plot *plot_name*

Plot to set property in.

-annotation *annotation_id*

Plot annotation to set property in.

-object *object_id*

Plot object to set property in.

The *plot* option must be specified as well.

-name *string*

Name of property to set.

The supported names depend on which object the data is being set in:

-value *string*

The value to set.

DESCRIPTION

Set property of view, plot or plot annotation.

EXAMPLES

The following example sets the line stroke color of a plot to red.

```
shell> gui_set_charts_property -plot $plot -name "stroke.color" -value red
```

SEE ALSO

gui_get_charts_property(2)

gui_set_current_category_tree

Sets the "current category tree" to the specified category tree

SYNTAX

gui_set_current_category_tree
category_tree

Data Types

category_tree name pattern or collection which resolves to exactly one category tree

ARGUMENTS

category_tree

A category tree name pattern or category tree collection which resolves to exactly one category tree.

DESCRIPTION

Sets the "current category tree" to the specified category tree. An empty string is returned.

The category tree name pattern (if specified) must be either the exact name of an existing tree, or (if there is only one existing category tree) the pattern "*", which means "all category trees" (or "the only category tree" in this case). More general forms of wild-card matching are not supported at this time.

At any time, exactly one of the existing category trees has the status "current category tree". When a new category tree is created, it immediately becomes the current category tree. If the current category tree is removed, a different category tree will be chosen as the current category tree. If there are no existing category trees, then there is no current category tree.

EXAMPLES

Here are examples of getting and setting the current category tree:

```
shell> get_attribute [gui_get_category_trees *] name
_tree008 _tree009 _tree010 _tree011
shell> get_attribute [gui_get_current_category_tree] name
_tree009
```

```
shell> gui_set_current_category_tree _tree008
shell> get_attribute [gui_get_current_category_tree] name
_tree008
```

SEE ALSO

gui_create_category_tree(2)
gui_remove_category_trees(2)
gui_get_category_trees(2)
gui_get_current_category_tree(2)
get_attribute(2)

gui_set_current_errors

Sets the current error data and the current error group in the Error Browser.

SYNTAX

string **gui_set_current_errors**
  [-data_name *ErrorDataName*]
  [-group *Group*]

ErrorDataName *String*
Group *String*

ARGUMENTS

-data_name *ErrorDataName*

ErrorDataName specifies the error data to make current. The error data name may be omitted. If omitted, makes all open error data current.

-group *Group*

Group specifies the group name, either a layer name or error type name, to make current. The group name may be omitted. If omitted, an entire error data file is made current.

DESCRIPTION

Sets the current error data and the current error group in the Error Browser. This is analogous to selecting error data and group in the Error Browser tree view. By default, there is are no current errors. The current errors determine the errors that are displayed in the error list and in the layout view by default.

If the error data option is omitted, selects the design, the parent of all open error data. The group option is valid only when there is a single error data specified, and raises an error if no error data was specified. The group string is interpreted as error type if error grouping has been set to **type**, else the group string is interpreted as layer. If the group option is omitted, all groups in the specified error data are made current.

EXAMPLES

The following example sets error grouping by error type, and sets the "Open Locator" type errors for LVS error data as the current

errors:

gui_set_error_browser_option -grouping type gui_set_current_errors -data_name LVS -group "Open Locator"

The following example sets the design as current, displaying all errors in all open error data in the error list and layout view.

gui_set_current_errors

SEE ALSO

gui_error_browser(2)
gui_set_selected_errors(2)

gui_set_current_task

Set current task to the given task.

SYNTAX

string **gui_set_current_task** -name *task_name*
-task *task_name*

string *task_name*

ARGUMENTS

-task *task_name*

Specifies the name of the task to make current.

DESCRIPTION

The gui_set_current_task command sets the current application task to the given task.

SEE ALSO

gui_create_task(2)
gui_remove_task(2)
gui_get_current_task(2)
gui_get_task_list(2)

gui_set_display_view

Sets the display view type (abstract, design, frame, layout, or outline) used in the layout when cell-specific views are active. Views are returned with the **gui_get_display_view** command.

SYNTAX

string **gui_set_display_view**
-cells *cell_list*
-view *view_name*

Data Types

cell_list list
view_name string

ARGUMENTS

-cells *cell_list*

Specifies the physical cells for which to set the view.

-view *view_name*

Specifies the view name. Accepted view names are abstract, design, frame, layout, outline, and the empty string {}.

DESCRIPTION

This command sets the display view type for the specified cell. The layout can display the contents of cells when the view level is set to a value greater than

1. Normally the displayed information is for the bound (or linked) view for the reference block. The layout also supports globally displaying an alternate view (for example the design view if the block is bound to abstracts) and a cell-specific view setting. Use this command to change the displayed view on a cell-by-cell basis.

If the specified view does not exist, then the layout will display the currently bound view.

This setting also controls the edit-in-place operation in the layout. The currently displayed view is always used.

EXAMPLES

The following example sets the design view for cell I_ORCA_TOP/I_BLENDER_4. When a block is bound to abstract views, you can display the design view for certain cells in order to fix DRC errors.

```
prompt> gui_set_display_view -cells I_ORCA_TOP/I_BLENDER_4 -view design
```

The following example resets the display view to the default by specifying an empty value.

```
prompt> gui_set_display_view -cells I_ORCA_TOP/I_BLENDER_4 -view {}
```

SEE ALSO

gui_get_display_view(2)

gui_set_error_browser_option

Sets options for the Error Browser dialog box.

SYNTAX

string **gui_set_error_browser_option**
[-grouping *Group*]
[-show_mode *ShowMode*]
[-view_mode *ViewMode*]
[-zoom_factor *ZoomFactor*]
[-hide_fixed *DoHide*]
[-hide_ignored *DoHide*]
[-advance_to_next_unfixed *DoNext*]
[-dim *DoDim*]
[-show_open_locator_nodes *DoShow*]
[-show_tooltip *DoShow*]
[-show_command_buttons *DoShow*]
[-highlight_objects *DoHighlight*]
[-auto_set_object_visible *SetVisible*]
[-auto_set_object_visible_type *SetVisibleType*]

Group *String*
ShowMode *String*
ViewMode *String*
ZoomFactor *float*
DoHide *Boolean*
DoNext *Boolean*
DoDim *Boolean*
DoShow *Boolean*
DoHighlight *Boolean*
SetVisible *Boolean*
SetVisibleType *String*

ARGUMENTS

-grouping *Group*

The **-grouping** option accepts argument values *type* or *layer* and sets whether errors are grouped by types or layers. This is similar to selecting or deselecting *Show by Layer* option in the Error Browser *Options* menu. By default, errors are grouped by type by default.

-show_mode *ShowMode*

The **-show_mode** option accepts argument values *all*, *selected*, or *none* and sets whether all errors, selected errors, are no

errors are shown in layout views. This is similar to making a selection from the *Show* field in the Error Browser. The default is that all errors are shown.

-view_mode *ViewMode*

The **-view_mode** option accepts argument values *zoom*, *pan*, or *off* and sets the layout view to zoom to, pan to, or not change to the currently selected errors in the Error Browser. This is similar to making a selection from the *Follow* field in the Error Browser. The default is to zoom to the selected error.

-zoom_factor *ZoomFactor*

The **-zoom_factor** option accepts float values between *0.1* and *10.0* and sets the zoom factor used when the view_mode is *zoom*. The zoom factor rounds to 1/10 precision. The default value is *1.0*.

-hide_fixed *DoHide*

The **-hide_fixed** option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether fixed errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Fixed Errors* option in the Error Browser *Options* menu. By default, fixed errors are shown.

-hide_ignored *DoHide*

The **-hide_ignored** option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether ignored errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Ignored Errors* option in the Error Browser *Options* menu. By default, ignored errors are shown.

-advance_to_next_unfixed *DoNext*

The **-advance_to_next_unfixed** option accepts Boolean values *1* or *true* to mean advance to next unfixed error when an error is fixed and *0* or *false* to advance to next fixed/unfixed error. This is similar to checking or unchecking the *Advance To Next Unfixed When Error is Fixed* option in the Error Browser. By default, unfixed errors are not advanced to.

-dim *DoDim*

The **-dim** option accepts Boolean values *1* or *true* to mean "dim" and *0* or *false* to mean "do not dim". The option governs whether layout views are dimmed when errors are displayed. This is similar to checking or unchecking the *Dim* option in the Error Browser. By default, layout views are not dimmed.

-show_open_locator_nodes *DoShow*

The **-show_open_locator_nodes** option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether net nodes are highlighted together with the open locator flylines for selected open locator errors. This is similar to selecting or deselecting the *Display Net Nodes for Selected Open Locators* option in the Error Browser *Options* menu. By default, the tool does not show the net node highlights.

-show_tooltip *DoShow*

The **-show_tooltip** option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether tool tips are shown on the error browser list view and details pane. By default, the tool shows the tool tips.

-show_command_buttons *DoShow*

The **-show_command_buttons** option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether the command buttons at the bottom of the error browser are shown. By default, the tool shows the command buttons.

-highlight_objects *DoHighlight*

The **-highlight_objects** option accepts Boolean values *1* or *true* to mean "highlight", and *0* or *false* to mean "do not highlight". This setting controls whether design objects associated with the selected error are highlighted in the layout view using design object highlighting. When the error object selection changes, the highlight is automatically removed from the associated design

objects. By default, the tool does not highlights associated design objects.

-auto_set_object_visible *SetVisible*

The **-auto_set_object_visible** option accepts Boolean values *1* or *true* to mean "turn on" and *0* or *false* to mean "do not turn on". The option governs whether relevant object visibility of layout view are turned on when errors are displayed. This is similar to checking or unchecking the *Auto Set Object Visible* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on for related error object display.

-auto_set_object_visible_type *SetVisibleType*

The **-auto_set_object_visible_type** option accepts argument values *incremental*, or *exclusive* to mean turn on layers/objects incrementally or exclusively when a different error is selected. This is similar to selecting the *Auto Set Object Visible Incremental/Exclusive* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on incrementally for related error object display.

DESCRIPTION

This command sets option setting for the Error Browser. Multiple option values can be set using one command.

EXAMPLES

The following example sets the grouping of errors by layers, to show all errors, and to pan to selected errors.

prompt> **gui_set_error_browser_option -grouping layer -show_mode all -view_mode pan**

The following example sets the option to dim layout views when errors are displayed and to hide fixed errors:

prompt> **gui_set_error_browser_option -dim true -hide_fixed true**

SEE ALSO

gui_error_browser(2)
gui_get_error_browser_option(2)

gui_set_error_data_filter

Set a filter on open error data.

SYNTAX

string **gui_set_error_data_filter**
  -show | -hide
  [-types *TypeList*]
  [-layers *LayerList*]
  [-objects *ObjectCollection*]
  [-typed_object_names *ObjectSpecification*]
  [-object_types *ObjectTypeSpecification*]

TypeList *String List*
LayerList *String List*
ObjectSpec *String List or collection*
ObjectCollection *collection*
ObjectTypeList *String List*

ARGUMENTS

-show | -hide

Mutually exclusive required option to specify whether the filtering should hide the records matching the filter criteria (-hide) or prune to the records matching the filter criteria (-show).

-types *TypeList*

Optional argument to specify a list of type names as filter criteria. An error record would match this criteria if its type attribute value matches any type name in the list.

-layers *LayerList*

Optional argument to specify a list of layer strings as filter criteria. An error record would match this criteria if its layer string matches any layer string in the list. The layer strings is the layer_names string attribute value for the error. It is is also displayed in the error browser.

-objects *ObjectCollection*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects,such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any object in the collection. Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects".

-typed_object_names *ObjectSpecification*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects, such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any objects in the specification. Specify objects with type-name, object-name-list pairs, for example

{ net { NetName1 NetName2 NetName3 {} } }.

Multilple such pairs may be listed to specify objects of multiple types as filter criteria, for example

{ { net { Net1 Net2 Net3 {} } } { pin { PinA PinB } } }.

Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects". A null object association can be specified using an empty string as the object name.

-object_types *ObjectTypeList*

Optional argument to specify a list of object type names as filter criteria. An error record would match this criteria if the type attribute value of any of its associated objects matches any type name in the list.

Specify object types with type-name, type-name-list pairs, for example

{ net_type { Signal Power } }.

Multilple such pairs may be listed to specify lists for multiple object types as filter criteria, for example

{ { net_type { Signal Power } } { route_type { Detail User } } }.

DESCRIPTION

Set the given filter on open error data. Filter state is set and is applied on currently open error data and subsequently opened error data until cleared. When a new filter is set, the new filter overrides any previously set filter. There is no accumulation of filters.

In order to show errors that have been hidden by a previously set filter, clear the filter with gui_clear_error_data_filter.

You can either filter out errors matching the filter specification (use -hide) or prune the current errors to errors matching the filter specification (use -show).

If multiple kinds of criteria are used in a filter, then an error must satisfy each kind of criteria to be a match. For example, if a filter with both an error type list (the -types option) AND an object type list (the -object_types option) is set, then for an error to be a match for the filter, its type must be one of the types set in the filter AND its associated object type must be one of the object types set in the filter.

EXAMPLES

The following example illustrates how to show only errors of type "Short":

gui_set_error_data_filter -show -types "Short"

The following example illustrates how to show only errors of type "Short" that are also associated with the "Signal" net type:

gui_set_error_data_filter -show -types "Short" -object_types {{net_type "Signal"}}

The following example illustrates how to hide errors associated with the "Global" route type:

```
gui_set_error_data_filter -hide -object_types {{route_type {Global}}}
```

The following example shows how to clear the error data filter:

```
gui_clear_error_data_filter
```

SEE ALSO

gui_error_browser(2)
gui_clear_error_data_filter(2)
gui_set_error_browser_option(2)

gui_set_error_status

Set the error status value of one or more error records.

SYNTAX

string **gui_set_error_status**
-errors *Errors*
-status *Status*

Errors *String*
Status *Status*

ARGUMENTS

-errors *Errors*

Errors specifies the handle for a collection of errors on which to set the fixed state.

-status *Status*

The **-status** argument specifies the status value. The supported status values are tool dependent. All tools with physical error data for the error browser support values "error" and "fixed". Some tools also support "ignored".

DESCRIPTION

This command sets the status of the given error objects to the given status value.

The status of an error is displayed in the Error Browser and an error can be hidden or shown based on its status value. The status is a part of the textual report written to a file by gui_report_errors.

SEE ALSO

gui_error_browser(2)
gui_set_error_browser_option(2)
gui_report_errors(2)

gui_set_flat_hierarchy_color

Sets colors on all leaf cells descended from top-level virtual hierarchical cells or the specified virtual hierarchy in the current design.

SYNTAX

gui_set_flat_hierarchy_color
[*virtual_hierarchy_cell*]
-color *color_Id* | -cycle_color
[*-separator _separator*]
[*-threshold _threshold*]

Data Types

virtual_hierarchy_cell string
color_Id integer
_separator string
_threshold integer

ARGUMENTS

virtual_hierarchy_cell

Specifies a virtual hierarchial cell in the design.

-color *color_Id*

Specifies a Milkyway color ID, which is used to set the color on all leaf cells descended from the virtual hierarchical cell.

-cycle_color

Automatically generates a different color for each virtual hierarchical cell and sets the color on all leaf cells descended from virtual hierarchical cells.

-separator _separator

Specifies the delimiter used to determine the hierarchical structure of the flat netlist. The default delimiter is a slash (/).

-threshold _threshold

If the total number of leaf cells under a hierarchy is less than the specified threshold value then color will not be applied to hierarchy.

DESCRIPTION

The **gui_set_flat_hierarchy_color** command sets the colors on the leaf cells descended from top-level virtual hierarchical cells or the specified virtual hierarchy cells in the current design. Theses colors are used to display the virtual hierarchial cells in some graphic windows,such as layout view.

When both *virtual_hierarchy_cell* and *-color* are specified, the command sets the color_id on all leaf cells descended from the specified virtual hierarchical cell. If a threshold is also specified and the total number of leaf cells is less than the threshold, then color is not applied to any of the leaf cells descended from the heirarchy.

When both *virtual_hierarchy_cell* and *cycle_color* are specified, the command generates a random color and sets the color on all leaf cells descended from the virtual hierarchical cell. If a threshold is also specified and the total number of leaf cells is less than the threshold, then color is not applied to any of the leaf cells descended from the heirarchy.

When *-color* is specified without *virtual_hierarchy_cell* , the command sets the color on all the leaf cells in current design.

When *cycle_color* is specified without *virtual_hierarchy_cell*, the command generates a different color for each top-level virtual hierarchical cell in the current design and sets the colors on all leaf cells descended from the virtual hierarchical cells.

EXAMPLES

The following example sets color ID 8 on all the leaf cells under the virtual hierarchy H1/H2 in the current design,

```
prompt> gui_set_flat_hierarchy_color H1/H2 -color 8
```

The following example generates a different color for the virtual hierarchy H1/H2 and sets the color on all the leaf cells under the virtual hierarchy H1/H2 in the current design,

```
prompt> gui_set_flat_hierarchy_color H1/H2 -color_cycle
```

The following example sets color Id 8 on all leaf cells in the current design

```
prompt> gui_set_flat_hierarchy_color -color 8
```

The following example generates the command generates a different color for each top-level virtual hierarchical cell in the current design, and sets the color on all leaf cells descended from that hierarchical cell.

```
prompt> gui_set_flat_hierarchy_color -color_cycle
```

SEE ALSO

gui_unset_flat_hierarchy_color(2)

gui_set_hierview_data

Set various state in the current or named Hierarchy View and its sub-views.

SYNTAX

string **gui_set_hierview_data**
[-view *View_Name*]
[-tree_agroup *Attr_Name*]
[-tree_filter *String*]
[-map_area *Attr_Name*]
[-map_color *Attr_Name*]
[-childlist_name *String*]
[-childlist_agroup *Attr_Name*]
[-childlist_filter *String*]

View_Name String
Attr_Name String

ARGUMENTS

-view *View_Name*

Use the given HierView window name (ex: Hier.1) for the following actions. Default is to get the most recent used HierView window name.

-tree_agroup *Attr_Name*

Set the current Hier Tree attribute group name.

-tree_filter *String*

Set the current Hier Tree filter expression.

-map_area *Attr_Name*

Set the Hier Map Area attribute group name.

-map_color *Attr_Name*

Set the Hier Map Color attribute group name.

-childlist_name *String*

Set the current ChildList sub-view name.

-childlist_agroup *Attr_Name*

Set the current ChildList attribute group name.

-childlist_filter ***String***

Set the current ChildList filter expression.

DESCRIPTION

This command allows you to set various current Hierarchy View related view settings.

SEE ALSO

gui_get_hierview_data(2)

gui_set_highlight_options

Change the options that control highlighting.

SYNTAX

string **gui_set_highlight_options**

[-current_color *color_id* | -next_color | -auto_cycle_color *enable*]

string *color_id*
bool *enable*

ARGUMENTS

-current_color *color_id*

Changes the current highlight color to the specified value. The current highlight color is used as a default when no color is specified for some operations.

-next_color

Changes the current highlight color to the next color in the set of available colors. This will wrap around so that it can be used to cycle through the color set. The provided colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

-auto_cycle_color *enable*

Specify if the current color should automatically be incremented after each gui_change_highlight -add operation. The color is not advanced if an explicit color is specified with the -color option of gui_change_highlight.

DESCRIPTION

The gui_set_highlight_options command can be used to modify highlighting behavior.

EXAMPLES

Set the current highlight color to blue.

```
shell> gui_set_highlight_options -current_color blue
```

Enable auto cycling.

```
shell> gui_set_highlight_options -auto_cycle_color true
```

Advance to the next color.

```
shell> gui_set_highlight_options -next_color
```

SEE ALSO

gui_change_highlight(2)
gui_get_highlight(2)
gui_get_highlight_options(2)

gui_set_hotkey

Sets a key binding to a Tcl command or a menu command in a GUI window.

SYNTAX

string **gui_set_hotkey**
  -hot_key *key_name*
  -tcl_cmd *command_name* | -menu *menu_name*
  [-replace]
  [-delete]
  [-replay_log_only]
  [-window_type *window_type_name* | -all_window_types]

key_name string
command_name string
menu_name string
window_type_name string

ARGUMENTS

-hot_key *key_name*

Specifies the key that you are associating with the specified command. The *key_name* is a string that contains the key name can also contain one or more modifiers. The valid modifier keys are **SHIFT**, **ALT**, and **CTRL**. You specify the modifier names by prepending them to the key name and connecting them with a plus sign (+).

If you bind an unmodified key and the shift-modified key is not bound, the binding works for both the shifted and nonshifted keys. If you set separate bindings for the shift-modified key and the unmodified key, the bindings are unique. Note that shift modifiers work only with letter keys and function keys.

Menus display the first key binding defined for a menu item. The key binding always appears in uppercase with its modifiers. For example, an unmodified accelerator for the letter "a" is shown as "A' and a shift-modified "a" (an uppercase A) is shown as "SHIFT+A."

-tcl_cmd *command_name*

Specifies the tool command language (Tcl) code that the tool executes when you press the key and its modifiers, if any.

The **-tcl_cmd** option and the **-menu** option are mutually exclusive.

-menu *menu_name*

Specifies the menu command that the tool invokes if you press the key and its modifiers, if any, when the menu command is enabled.

The *menu_name* is a string that specifies the hierarchy of the menu labels, with the labels connected by arrows formed from a

hyphen and a greater than sign (->). For example, "File->Exit" specifies the Exit command on the File menu. The *menu_name* can also include the mnemonic for the menu text, which is specified with an embedded ampersand (&), but they are not required to do so.

The **-menu** option and the **-tcl_cmd** option are mutually exclusive.

-replace

Replaces an existing key binding for the specified menu command or Tcl command with the specified key.

-delete

Removes the key binding from the specified menu command or Tcl command.

-replay_log_only

Limits logging of the Tcl command associated with the key to the command replay log file. The tool suppresses the command echo and result display to the xterm and console, and the command does not appear in the output log or the Tcl history log.

The tool ignores this option if you do not specify the **-tcl_cmd** option.

-window_type *window_type_name*

Specifies the type of top-level window that the key should apply to. (A top-level window is a window with a menu bar.) If you do not specify this option, the tool uses the application default window type.

The read-only variable **gui_default_window_type(3)** specifies the application default window type.

-all_window_types

Sets the key binding in every type of window for which it is applicable.

For menu command key bindings, the tool searches all of the top-level windows for the specified menu command and adds the key binding in any window where it exists. If the tool does not find any applicable windows, it issues a warning.

For Tcl command key bindings, the tool adds the binding in every type of top-level window.

DESCRIPTION

This command binds a given key to a function in the graphical user interface (GUI). The function might be available on a menu or specified by Tcl code. A menu command can have multiple key bindings. Key bindings can be specified for built-in or user-defined menu commands.

Key bindings for menu commands have several additional features that Tcl command key binding do not have. The function for a menu command key binding is invoked only when the menu command is enabled. This ensures that the function is invoked only when it is valid to invoke the function. In addition, the primary key bindings for menu commands appear with the menu text to make it easier for you to remember the bindings.

EXAMPLES

The following example creates a menu item and adds an additional key binding to it.

```
prompt> gui_create_menu -menu "&Test->Sub&Menu->Echo Hi" \
```

```
  -tcl_cmd "echo hi" -hot_key "Ctrl+5"
prompt> gui_set_hotkey -menu "Test->SubMenu->Echo Hi" \
  -hot_key "Ctrl+Y"
```

The following example creates a key binding, P, that invokes a Tcl command to print a query on the currently selected objects.

```
prompt> gui_set_hotkey -tcl_cmd {query_objects [get_selection]} \
  -key P
```

gui_set_layer_widths

Sets values in a list of widths per layer used for route editing.

SYNTAX

status **gui_set_layer_widths**
-layer *layer_name*
{ -clear | -values *layer_widths* }

Data Types

layer_name string
layer_widths list

ARGUMENTS

-layer *layer_name*

Specifies the routing layer for which to define the user widths.

-clear

Clears the list of user widths for the layer.

After the user widths are cleared, the *gui_get_layer_widths* command returns the default widths for the layer when the *-current* option is specified.

-values *layer_widths* }

Specifies a list of user widths to add to the current list of widths for the layer.

The list of layer widths is automatically sorted and uniquified.

If no user widths are currently defined, these values will be the only ones returned by *gui_get_layer_widths* when the *-current* option is specified.

DESCRIPTION

This command defines a list of discrete layer widths to be used for routing in the route editor.

EXAMPLES

The following example specifies the set of widths for the layer 'M1'.

prompt> **gui_set_layer_widths -layer M1 -values {0.1 0.2 0.4 0.8 1.6}**

SEE ALSO

gui_get_layer_widths(2)

gui_set_layout_layer_visibility

Set the visibility of layers in a layout window

SYNTAX

status **gui_set_layout_layer_visibility**
collection_of_layers
[-window *windowID*]
-toggle | -only

Data Types

string *windowID*

ARGUMENTS

collection_of_layers

The collection of layers or list of layer names provided in technology file.

-window *windowID*

This specifies the window to have its mode changed. If not specified then the currently active window will be used.

-toggle

Toggle the visibility of the specified layers. The option is mutually exclusive with -only.

-only

Turn off all layers and then turn on only the specified layers. The option is mutually exclusive with -toggle.

DESCRIPTION

This command is used to set visibility of layers in a layout view.

EXAMPLES

To turn on visibility of METAL2, METAL3 layers only:

```
shell-t> gui_set_layout_layer_visibility {METAL2 METAL3} -only -window Layout.1
1
```

To toggle visibility of layer METAL3:

```
shell-t> gui_set_layout_layer_visibility {METAL3} -toggle -window Layout.1
1
```

SEE ALSO

gui_set_setting(2)

gui_set_layout_user_command

Set user defined command for layout input.

SYNTAX

status **gui_set_layout_user_command**
-apply_cmd *TclCmd* | -clear
[-input_type *InputType*]
[-snap_type *SnapType*]
[-status_text *string*]
[-cancel_cmd *TclCmd*]

Data Types

TclCmd *string*
InputType *one of [rectangle | line | polygon | point]*
SnapType *one of [litho | site | midsite | wiretrack | midwiretrack | user]*

ARGUMENTS

-apply_cmd *TclCmd*

The user procedure to be called when input completed. The coordinates will be passed as an argument to this procedure. The options is mutually exclusive with -clear.

-clear

Cancel all pending input and return layout to default mouse mode. The options is mutually exclusive with -apply_cmd.

-input_type *InputType*

The desired input type: rectangle | line | polygon | point. Default is rectangle

-snap_type *SnapType*

The desired snap type: litho | site | midsite | wiretrack | midwiretrack | user Default is litho

-status_text *string*

The help string to be shown in layout window status bar.

-cancel_cmd *TclCmd*

The user procedure to be called when input is canceled.

DESCRIPTION

This command is used to facilitate creation of user defined tools to extend the layout view standard capabilities. The command sets layout view to given input mode and executes user callback procedure on input complete. The input points are passed as an argument to user callback.

EXAMPLES

Cut the object shape with user specified rectangle

```
proc my_cut_object_shape_proc { rect } {
  change_selection [cut_objects [get_selection] -bbox {$rect}]
}

gui_set_layout_user_command -apply_cmd {my_cut_object_shape_proc} -status_text "Drag the rectangle to cut selected objects"
1
```

SEE ALSO

change_selection(2)
get_selection(2)

gui_set_layout_visual_mode

Set the visual mode in a layout window

SYNTAX

string **gui_set_layout_visual_mode** [-mode *modeName*]
  [-window *windowID*]
  [-no_update]

string *modeName*
string *windowID*

ARGUMENTS

-mode *modeName*

This option specifies the name of the visual mode that should be shown. If not specified then it returns the view to its default coloring.

-window *windowID*

This specifies the window to have its mode changed. If not specified then the currently active window will be changed if it is a layout window, or it will chose a layout window if one exists.

-no_update

By default this command will also ask the visual mode to prompt for updating of its data. Specifying this option causes the command to switch to the new visual mode without updating its data.

DESCRIPTION

This command is used to change the current visual mode displayed in a layout view.

EXAMPLES

To set the layout view into snapshot visual mode:

shell-t> **gui_set_layout_visual_mode -mode snapshot**

Layout.1

To return the layout view to its default visual:

```
shell-t> gui_set_layout_visual_mode
Layout.1
```

SEE ALSO

gui_create_vm(2)

gui_set_map_option

Sets the value for an option in the specified visual mode or map mode.

SYNTAX

string **gui_set_map_option**
-map *map_name*
-option *option_name*
-value *value* | -default

Data Types

map_name string
option_name string
value string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-option *option_name*

Specifies the name of the option to be set.

-value *value*

Specifies the value for the option.

The **-value** option is mutually exclusive with the **-default** option. You must specify one, but not both.

-default

Sets the option to its default value.

The **-default** option is mutually exclusive with the **-value** option. You must specify one, but not both.

DESCRIPTION

This command sets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You must set the option to a specific value or its default value. Use the **-value** option to set a specific value or

the **-default** option to set the option to its default value.

EXAMPLES

The following example sets the number of bins to 9 in the global route congestion map:

```
prompt> gui_set_map_option -map AREAPARTITION \
    -option num_bins -value 9
```

SEE ALSO

gui_get_bucket_option(2)
gui_get_bucket_option_list(2)
gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_bucket_option(2)

gui_set_mouse_tool_option

Set an option on a mouse tool

SYNTAX

string **gui_set_mouse_tool_option** -tool *string*
-option *string*
-value *string*

string *string*
string *string*
string *string*

ARGUMENTS

-tool *string*

Tool to set option for.

-option *string*

Option to set.

-value *string*

New option value.

DESCRIPTION

This command sets a mouse tool option. Mouse tool options influence the operation of the mouse tool when that tool is active

EXAMPLES

> gui_set_mouse_tool_option -tool SELECT -option InputMode -value Rectangle

SEE ALSO

gui_mouse_tool(2)
gui_get_mouse_tool_option(2)

gui_set_performance_log_option

Configures performance log behavior of logging specific commands or all default commands

SYNTAX

status **gui_set_performance_log_option**
[-commands *command_names* | -log_all]
[-add | -remove]

Data Types

command_names list

ARGUMENTS

-commands *command_names*

This option is mutually exclusive -log_all. If -add or -remove are not given, the argument sets or refreshes the commands to be logged. If a logging process has not been started, this argument sets the specific commands to be logged for the upcoming logging process. If already been started, this argument refreshes the commands to be logged from now on.

If -add or -remove are given, the argument set the commands to be added to or removed from already existing commands list.

-add

This option is mutually exclusive with -remove and must be used with -commands. Use -add to add commands to the already existing commands list which is set by this command. If there is no existing commands list, this argument generates a commands list to be logged.

-remove

This option is mutually exclusive with -add and must be used with -commands. Use -remove to remove commands from the already existing commands list which is set by this command.

-log_all

This option is mutually exclusive with -commands. This option resets the commands to be logged as default.

DESCRIPTION

This command controls the performance log behavior of logging specific commands or all default commands. After execute option -commands, the default commands list is not effective until execute option -log_all. The commands to be logged can be reset as

default by option -log_all. This command can be used before and during a logging process and change the commands to be logged. After successfully execute this command, the logging behavior changes.

EXAMPLES

Configure log behavior which logs performance data before and after executing commands of gui_zoom and win_select_object.

prompt> **gui_set_performance_log_option -commands {gui_zoom win_select_objects}**

Add command gui_get_current_window to the already existing commands list.

prompt> **gui_set_performance_log_option -commands {gui_get_current_window} -add**

Remove command gui_get_current_window from the already existing commands list.

prompt> **gui_set_performance_log_option -commands {gui_get_current_window} -remove**

Reset the log behavior which logs performance data of all default commands.

prompt> **gui_set_performance_log_option -log_all**

SEE ALSO

gui_log_performance(2)
gui_get_performance_log_option(2)

gui_set_pref_value

Set the value of a preference key.

SYNTAX

string **gui_set_pref_value** -key *Key* -value *Value*
[-category *Category*]

Key *String*

Data Types

Category *String*

ARGUMENTS

-key *Key*

Key specifies the key to set the new value.

-value *Value*

Value specifies the new value of the key. The new value should be of the same data type, one of (integer,bool,double,color,string) as the data type of the value of the key.

-category *Category*

Category specifies the category that owns the specified key. If not specified, a default category will be used.

DESCRIPTION

This command set the value of a preference key. Returns the value of the preference key.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command **gui_set_pref_value** is then used to change the value of the preference key to true.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool -value false
gui_set_pref_value -category my_category -key some_key -value true
```

SEE ALSO

gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_set_preset

Sets the specified preset for object specified by category

SYNTAX

status **gui_set_preset**
-category *category*
[-system]
[-shared]
-default
-name *name*

Data Types

category string
name string

ARGUMENTS

-category *category*

Specifies the name of the category that the presets be applied to.

-system

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

-shared

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

-default

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

-preset *preset*

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

DESCRIPTION

This command applies the default or specified preset to a category.

EXAMPLES

The following example applies the system presets 'floorplan' to the Layout.

prompt> **gui_set_preset -category Layout -name floorplan -system**

SEE ALSO

gui_get_presets(2)

gui_set_region

Sets the coordinates of the current region rectangle or rectilinear polygon.

SYNTAX

status **gui_set_region**
shape

Data Types

shape list

ARGUMENTS

shape

Specifies the region coordinates.

For a rectangle, the values should be given in the following format:

{{x1 y1} {x2 y2}}

For a rectilinear polygon, the values should be given in the following format:

{{x1 y1} {x2 y2} ... {xN yN}}

DESCRIPTION

This command sets the region shape to be used in layout region mode and returns 1 if it is successful.

EXAMPLES

prompt> **gui_set_region {{-1743.945 18.357} {42.833 1523.657}}**
1

SEE ALSO

gui_get_region(2)

gui_set_select_menu_adds_to_selection

Controls the setting of the Select > Add to Selection menu item specifies whether Select > Related Object in the GUI replaces or adds to the current selection.

SYNTAX

gui_set_select_menu_adds_to_selection
-value true | false

ARGUMENTS

-value true | **false**

Specifies whether Select > Related Objects in the GUI replaces or adds to the current selection. Specify **-value true** to append to the current selection, **-value false** to replace the selection.

DESCRIPTION

This command controls the setting of the Select > Add to Selection menu item specifies whether Select > Related Object in the GUI replaces or adds to the current selection.

This command is logged when the Select > Add to Selection menu item is invoked.

EXAMPLES

The following example enables adding to the current selection.

prompt> **gui_set_select_menu_adds_to_selection true**

gui_set_selected_errors

Changes the selection in the Error Browser to add or replace errors.

SYNTAX

int **gui_set_selected_errors**
-add | -replace *errors*

Data Types

errors string

ARGUMENTS

-add *errors*

Adds the specified errors to the current selection. This option is mutually exclusive with the **-replace** option.

-replace *errors*

Replaces the specified errors in the current selection. This options is mutually exclusive with the **-add** option.

DESCRIPTION

Sets new selected errors or adds new selected errors in the Error Browser. Errors are identified as a collection of error objects. If the **-add** option is given, the command adds the given errors to the currently selected errors. If the **-replace** option is given, the command replaces the current selection with the given errors. The command fails if the given errors are not in the current set specified by the **gui_set_current_errors** command, or with a click in the Error Browser tree view. The command returns 1 if successful, 0 otherwise.

SEE ALSO

gui_clear_selected_errors(2)
gui_error_browser(2)
gui_set_current_errors(2)

gui_set_setting

Sets a setting on the specified window.

SYNTAX

gui_set_setting
-window *WindowID*
-setting *Setting*
-value *Value*

WindowID *String*
Setting *String*
Value *String* | *Bool* | *Int* | *Double*

ARGUMENTS

-window *WindowID*

WindowID specifies the window to set the setting

-setting *Setting*

Setting specifies the setting to set

-value *Value*

Value specifies the value of the setting

DESCRIPTION

Sets a setting on the specified window. Windows are views or top level windows. The setting is a property of the window and the value's type is specific to the given setting.

EXAMPLES

shell> **gui_set_setting -window Layout.1 -setting showCell -value true**

```
shell> gui_set_setting -window Layout.1 -setting viewLevel -value 1
```

SEE ALSO

gui_get_setting(2)

gui_set_task_list

Set the list of tasks that are visible in the task assistant, and set their order.

SYNTAX

gui_set_task_list
-tasks *TaskList*

TaskList *List*

DESCRIPTION

ARGUMENTS

-tasks *TaskList*

TaskList specifies the list of tasks that will be visible in the task assistant and their order. Tasks which are not included in the list will still exist but will not be shown in the selection combo box of the task assistant.

DESCRIPTION

The gui_set_task_list command sets the list of tasks that are visible and available in the task assistant and sets their order.

EXAMPLES

The following simple example sets the visible list of tasks to "Design Planning" followed by "Routing".

```
gui_set_task_list -tasks {{Design Planning} {Routing}}
```

SEE ALSO

gui_get_task_list(2)
gui_create_task(2)
gui_remove_task(2)

gui_set_timing_table_paths

Set timing paths into a specified timing table.

SYNTAX

status **gui_set_timing_table_paths**
[-command *ACmd*]
[-window *AWindow*]
[-new]
[-name *ATable*]

Data Types

ACmd string
AWindow string
ATable string

ARGUMENTS

-command *ACmd*

Specifies a tcl command that returns a collection of timing paths.

If no command is specified, the "Select Paths" dialog will appear, where the desired timing paths could be specified.

-window *AWindow*

Specifies a top level window id where the timing table is open.

If this option is not specified the most recently used top level window will be used.

-new

Creates a new timing table.

This option cannot be used with option -name at the same time.

-name *ATable*

Specifies an existing timing table by its window id.

This option cannot be used with option -new at the same time.

DESCRIPTION

The **gui_set_timing_table_paths** command sets a collection of timing paths into a specified timing table. The command allows to create new timing tables in a specified top level window, or setting a table with a collection of timing paths which are generated by a specified command.

EXAMPLES

The following example opens a new timing table in the most recently used top level window with fifteen timing paths.

```
shell> gui_set_timing_table_paths -new -command {get_timing_paths -max_paths 15}
```

This example shows how to update an existing timing table called TimingAnalysisDriver.3 with a command to show the selected timing paths.

```
shell> set my_paths [get_timing_paths -nworst 20 -delay_type max_rise]
shell> change_selection $my_paths
shell> gui_set_timing_table_paths -name TimingAnalysisDriver.3 -command { get_selection }
```

SEE ALSO

gui_get_window_ids(2)
get_timing_paths(2)

gui_set_utable_meta

Create a MetaData Object for use in creating a new UserTable.

SYNTAX

string **gui_set_utable_meta**
-name *MetaDataObj_Name*
[-remove]
[-title *Report_Title*]
[-comment *Report_Comment*]
[-tag *Report_Tag*]
[-menu *Root_Menu*]
[-col_name *Column_Name*]
[-col_type *Column_Type*]
[-read_only]
[-user_enums *Column_Type_Enums*]
[-user_list *Column_Type_List*]

MetaDataObj_Name String
Report_Title String
Report_Comment String
Report_Tag String
Root_Menu String
Column_Name String
Column_Type String
Column_Type_Enums List of Strings
Column_Type_List List of Strings

ARGUMENTS

-name *MetaDataObj_Name*

The name of the MetaData object.

-remove

Remove and free the given MetaData object.

-title *Report_Title*

Report title for a table.

-comment *Report_Comment*

Report comment for a table.

-tag *Report_Tag*

A tag string assigned to the table.

-menu *Root_Menu*

User Context Sensitive Menu Root name.

-col_name *Column_Name*

A column name that has the following column type.

-col_type *Column_Type*

A column type name.

-read_only

Mark the given column as read only which prevents editing data in that column.

-user_enums *Column_Type_Enums*

A list of single string values for a new user type defined by the -col_type argument.

-user_list *Column_Type_List*

A list of multi string values for a new user type defined by the -col_type argument. A table cell of this type can contain multiple unique values of this type separated by a comma.

DESCRIPTION

This command creates a new MetaData object that then can be used to add useful meta data to the creation of a new UserTable. A new UserTable is created via the gui_create_utable and the gui_import_utable commands. MetaData can be used to define certain column data/object types instead of using column name postfixes. Users can also define new data types that are made of a list of unique string values. A table cell can then be set to only allow single values (enums) of that new type or a comma separated list of values (lists) of that new data type. MetaData can also be exported via the gui_export_utable command along with the table data.

EXAMPLES

The following example creates a new MetaData object named myMetaObj which contains a report title and comment.

shell> **gui_set_utable_meta -name myMetaObj -title "My Report" -comment "This is a comment"**

The following example adds a definition of a new data type 'myData' assigned to the column 'myDataColumn'. This new data type has 4 values (valA valB valC and valD). Also optionally the user can add a help string after the value separated by a

colon ':' which is used to show tool tips.

```
shell> gui_set_utable_meta -name myMetaObj -col_name myDataColumn -col_type myData -user_enums {
  {valA: Help string for valA...}
  {valB: Help string for valB...}
  {valC: Help string for valC...}
  {valD: Help string for valD...}
}
```

The following example then imports a CSV file and adds the previously defined MetaData to that new table.

```
shell> gui_import_utable -file myTable.csv -meta_obj myMetaObj
```

SEE ALSO

gui_set_var

Set the value of a typed tcl variable which was created with the gui_create_var command.

SYNTAX

string **gui_set_var** -name *VarName* -value *Value*

VarName *String*

Data Types

ARGUMENTS

-name *VarName*

VarName specifies the typed tcl variable to set the new value.

-value *Value*

Value specifies the new value of the variable. The new value should be of the same data type, one of (integer,bool,double,color,string,point,size,rect) as the data type of the value of the variable.

DESCRIPTION

This command set the value of a typed tcl variable that has a name and a data type, one of (integer,bool,double,color,string,point,size,rect). Typed tcl variables are created with the gui_create_var command. Returns the current value of the variable.

EXAMPLES

The following example create a typed tcl variable *my_var_1* and then set it to a new value using the command gui_set_var.

```
gui_create_var -name my_var_1 -value_type integer 320
gui_set_var -name my_var_1 -value 360
```

SEE ALSO

gui_create_var(2)
gui_get_var(2)
gui_remove_var(2)
gui_exist_var(2)

gui_set_vm

Sets visual mode attributes.

SYNTAX

string **gui_set_vm**
-name *identifier*
[-update_cmd *update_command*]
[-title *label*]
[-help_topic *subject*]
[-infotip *infotip*]
[-buckets *buckets*]
[-icon *string*]
[-netfilter *string*]
[-float *bool*]
[-set_exaggerations]
[-top_exaggeration *float*]
[-mid_exaggeration *float*]
[-bot_exaggeration *float*]
[-show_only_pins_of_nets *bool*]
[-enable_bucket_delete *bool*]

Data Types

identifier string
update_command string
label string
subject string
infotip string
buckets string
net_filter string
icon_spec string

ARGUMENTS

-name *identifier*

Specifies the name of the visual mode to be modified. This name is used as the argument when the associated visual mode commands requires a visual mode name to be specified.

-update_cmd *update_command*

Specifies an optional Tcl command that is executed when the visual mode is accessed. A typical use for this command is to update the state of the visual mode if its contents are likely to change under certain circumstances.

-title *label*

Specifies an optional title. The title can include embedded spaces. Use this option to provide a label for the visual mode in the GUI.

If you do not specify the **-title** option, the default title is an empty string and the tool uses the **-name** option value to provide the label.

-help_topic *subject*

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

-infotip *infotip*

Specifies the infoTip string.

-buckets *buckets*

Specifies the rendering order of the buckets. The tool renders the specified buckets from left to right based on their order in the list. Buckets that are not included in the list are rendered before any of the buckets that are specified in the list.

-icon *string*

Specifies the icon file name. Use this option to provide an icon for GUI menus.

-netfilter *string*

Specifies the net connection filtering.

-float true | false

Specifies whether the bucket contents have a floating point range. By default, the value is false.

-set_exaggerations

Specifies the bucket exaggerations.

-top_exaggeration *float*

Specifies the exaggeration for the top bucket, the value should be greater than or equal to zero. By default, the value is 0.

-mid_exaggeration *float*

Specifies the exaggeration for the middle bucket, the value should be greater than or equal to -1. By default, the value is -1.

-bot_exaggeration *float*

Specifies the exaggeration for the bottom bucket, the value should be greater than or equal to zero. By default, the value is 0.

-show_only_pins_of_nets true | false

Indicates that layout only show pins of net objects in buckets.

-enable_bucket_delete true | false

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

DESCRIPTION

The **gui_set_vm** command modifies one or more attribute values of an existing visual mode.

EXAMPLES

The following example changes the title of a visual mode from "mycoloring1" to "test":

```
prompt> gui_set_vm -name mycoloring1 -title {test}
```

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vm(2)
gui_get_vmbucket(2)
gui_remove_vm(2)
gui_remove_vmbucket(2)
gui_set_vmbucket(2)
gui_update_vm(2)

gui_set_vmbucket

Set attributes for Visual Mode Bucket

SYNTAX

string **gui_set_vmbucket** -vmname *mode_identifier*
-name *bucket_identifier*
[-infotip *infotip*]
[-netfilter *net_filter*]
[-color *color*]
[-pattern *pattern*]
[-exaggeration double]
[-number int]
[-maxval double]
[-minval double]
[-visible *visibility*]
[-title *label*]
[-collection *handle*]
[-above *bucket_identifier* | -below *bucket_identifier* | -at *top*|*bottom*]

string *mode_identifier*
string *bucket_identifier*
string *infotip*
string *net_filter*
string *color*
string *pattern*
string *visibility*
string *label*
string *handle*
string *bucket_identifier*
string *bucket_identifier*
string *top*|*bottom*

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

-name *bucket_identifier*

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

-infotip *infotip*

String for infotip.

-netfilter *net_filter*

Specifies net connection filtering.

-color *color*

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

-pattern *pattern*

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

-exaggeration double

Specifies bucket min pixel exaggeration value >= 0.

-number int

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

-maxval double

Specifies bucket maximum value.

-minval double

Specifies bucket minimum value.

-visible *visibility*

Specifies visibility state of bucket contents. Valid values are TRUE and FALSE.

-title *label*

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

-collection *handle*

Tcl object collection to be colored by this visual mode bucket.

-above *bucket_identifier*

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

-below *bucket_identifier*

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

-at *top*|*bottom*

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

DESCRIPTION

The gui_set_vmbucket command modifies an instance of a visual mode bucket.

EXAMPLES

Change the color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> **gui_set_vmbucket -vmname foo -name cat1 -color #00FF00 -pattern FDiagPattern**

Color the objects in the current selection red by placing them in the bucket named "cat1" in the visual mode "foo" and setting its bucket color:

shell> **gui_set_vmbucket -vmname foo -name cat1 -collection [get_selection] -color red**

gui_set_window_pref_key

Create a preference key owned by a particular window or window type

SYNTAX

new_value **gui_set_window_pref_key**
{ -window *window_id* | -window_type *window_type* }
[-category *category*]
-key *key*
-value_type *value_type*
-value *value*

Data Types

window_id string
window_type string
category string
key string
value_type string
value string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference will be applied to. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference be applied to. This option is mutually exclusive with the -window option.

-category *category*

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

-key *key*

Specifies the name of the key to create.

-value_type *value_type*

Specifies the the data type of the value of the key. It must be one of [bool | integer | double | color | string].

-value *value*

Specifies the value of the key. The value should be set appropriately in accordance with its value type. The bool type accepts [true, false, 0, 1, on, off]. The color type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

RETURNS

new_value

The new value of the key.

DESCRIPTION

This command creates a preference key with the specified key name or sets the value of an existing pref key. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to a default category. Returns the value of the preference key.

EXAMPLES

The following example will create a window and set a preference on that window.

```
shell> set wnd [gui_create_window -type Console]
shell> gui_set_window_pref_key -window $wnd -category {caption} -key {title}
 -value_type string -value {Command Console}
```

gui_set_window_preset

Sets the specified preset for object specified by window_type

SYNTAX

status **gui_set_window_preset**
-window_type *window_type*
[-system]
[-shared]
-default
-preset *preset*

Data Types

window_type string
preset string

ARGUMENTS

-window_type *window_type*

Specifies the name of the window type that the presets be applied to.

-system

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

-shared

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

-default

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

-preset *preset*

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

DESCRIPTION

This command applies the default or specified preset to a window type. This command has been deprecated, please use

gui_set_preset instead.

EXAMPLES

The following example applies the system presets 'floorplan' to the Layout.

prompt> **gui_set_window_preset -window_type Layout -preset floorplan -system**

SEE ALSO

gui_set_preset(2)

gui_show_charts_create_plot_dialog

Show dialog to interactively create plot from model

SYNTAX

status **gui_show_charts_create_plot_dialog**
{ -clct *collection* | -model *model_id* }
[-view *view_name*]

Data Types

collection string
model_id int
view_name string

ARGUMENTS

-clct *collection*

Collection to create plot from.

-model *model_id*

Model to create plot from.

-view *view_name*

View to add plot to. If not specified a new view will be created.

DESCRIPTION

Shows a dialog which allows the user to interactively create a plot from a model.

EXAMPLES

The following example shows the dialog for a model.

shell> gui_show_charts_create_plot_dialog -model $model

SEE ALSO

gui_show_charts_load_model_dialog(2)

gui_show_charts_load_model_dialog

Show dialog to interactive load model from data file

SYNTAX

status **gui_show_charts_load_model_dialog**

Data Types

ARGUMENTS

DESCRIPTION

Shows a dialog which allows the user to interactively load a model from a data file.

EXAMPLES

The following example shows the dialog.

shell> gui_show_charts_load_model_dialog

SEE ALSO

gui_show_charts_create_plot_dialog(2)
gui_show_charts_view_model_dialog(2)

gui_show_charts_view_model_dialog

Show dialog with view of model or collection data

SYNTAX

status **gui_show_charts_view_model_dialog**
{ -clct *collection* | -model *model_id* }
[-columns *column_names*]

Data Types

collection string
model_id int
column_names string

ARGUMENTS

-clct *collection*

Collection to show.

-model *model_id*

Model to show.

-columns *column_names*

The names of the attributes to show columns for. If not specified all attributes are used.

DESCRIPTION

Shows a dialog which allows the user to view a model or collection.

EXAMPLES

The following example shows the dialog for a model.

shell> gui_show_charts_view_model_dialog -model $model

SEE ALSO

gui_show_charts_create_plot_dialog(2)
gui_show_charts_view_model_dialog(2)

gui_show_command_form

Generate and show a form dialog for a shell command.

SYNTAX

string **gui_show_command_form** -command *command*

string *command*

ARGUMENTS

-command *command*

The name of the shell command to show in the form.

DESCRIPTION

Create a form dialog for a shell command. The form contains fields to allow entry of option arguments.

The dialog provides the following operations for the command:

- execute the command
- append the command to a script
- show the man page for the command.

This command creates form dialogs for application defined commands. It will also create a form dialog for a public user defined tcl proc when its option value types have been defined using the **define_proc_attributes** command. The kinds of value input fields used in the form depends on the **type_name** attribute given for the option using the **-define_args** option. See man pages for **define_proc_attributes** and **gui_report_proc_arg_type_names** for more information.

This command is available only when the GUI is running.

EXAMPLES

The following example creates a form dialog for the command **gui_start**

```
shell> gui_show_command_form -command gui_start
1
```

The following is an example of a tcl proc definition followed by a **define_proc_attribute** command invocation to define its attributes. The proc is then shown in a form dialog with the **gui_show_command_form** command. The example proc accepts a net and routing layers as arguments.

```
shell> proc myProc {args} {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo $argname = $results($argname)
  }
}
shell> define_proc_attributes myProc \
  -info "echo argument values" \
  -define_args { \
    {-net "select a net" "net" string \
         {required {type_name net}}} \
    {-layers "select routing layers" "routing layers" list \
         {optional {type_name {layer {subtype routing}}}}} \
  }
shell> gui_show_command_form -command myProc
```

SEE ALSO

define_proc_attributes(2)
gui_report_proc_arg_type_names(2)
gui_start(2)
gui_stop(2)

gui_show_file_in_editor

Show the contents of a file in an external text editor.

SYNTAX

gui_show_file_in_editor
-filename *filename*
[-line *linenum*]

Data Types

filename *string*
linenum *integer*

ARGUMENTS

-filename *filename*

filename specifies the name of the file to be edited.

-line *linenum*

linenum specifies the line in the file to start editing at.

DESCRIPTION

The gui_show_file_in_editor command opens a text editor to edit the specified file. The editor is a separate task so doen not block the current application.

By default the file is edited using the text editor from the EDITOR environment variable in a xterm. If the EDITOR environment variable is not set then the 'vi' text editor is used.

Both the editor and terminal (xterm) are searched for on the users path. If either the editor or terminal can no be found the command will fail.

EXAMPLES

The following example shows the file "test.txt" starting at line 100.

```
shell> gui_show_file_in_editor -file test.txt -line 100
```

SEE ALSO

gui_show_url_in_browser(2)

gui_show_man_page

Show a man page in the man browser

SYNTAX

string **gui_show_man_page** *topic [-apropos] [-html]*

string *topic*

ARGUMENTS

topic

Man page topic to be shown.

-apropos

Use the apropos command so search for commands that are related to the given topic.

DESCRIPTION

This command will launch or raise the man page browser, and display the topic specified in it. If no topic is specified, then the HOME page for man page indexes will be shown.

If the specified topic does not exactly match a given man page, then additional searching will be done for commands. If the topic matches one or more commands, then an index page will be generated showing all of the commands which match the specified topic pattern. If the topic doesn't match any commands, then we will use the topic as the initial part of a command and add a * to it and do command matching. Any completions for the command will be shown on an index page that can then be used to select a man page for viewing.

If the -apropos option is specified, then the topic will be searched via the apropos command and the topics returned will be shown with thier brief help strings, and provide links the the man pages referenced.

If the -html option is specified, the tool will display assoicated html file for given topic if the html file exists.

EXAMPLES

To show the man page for the find command:

gui_show_man_page find

To show the man page for all commands containing the word cell:
gui_show_man_page *cell*

To show the man page for the get_attribute command using command completion:
gui_show_man_page get_attr

SEE ALSO

man(2)
apropos(2)

gui_show_map

Displays or hides the specified visual mode or map mode.

SYNTAX

string **gui_show_map**
-map *map_name*
-show true | false
[-window *window*]

Data Types

map_name string
window string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-show true | false

Displays the visual mode or map mode when set to **true**, or hides the visual mode or map mode when set to **false**.

-window *window*

Specifies the name of layout window in which to display or hide the visual mode or map mode.

DESCRIPTION

This command displays or hides the specified visual mode or map mode. If the **-window** option is not specified, the command uses the most recently active layout window.

EXAMPLES

The following example displays the highlight visual mode in the most recently active layout window:

```
prompt> gui_show_map -map Highlight \
    -show true
```

SEE ALSO

gui_get_map_list(2)

gui_show_palette

Shows the palette in the specified window state.

SYNTAX

status **gui_show_palette**
{ -name *palette_id* | -type *palette_type* }
[-parent *parent_name*]
[-show_state *window_state*]
[-dock_edge *dock_edge*]
[-size *{width height}*]

Data Types

palette_id string
palette_type string
parent_name string
window_state string
dock_edge string
width float
height float

ARGUMENTS

-name *palette_id*

Specifies the palette name id or title.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this name in all toplevel windows are shown.

This option precludes the **-type** option

-type *palette_type*

Specifies the palette type id. Any matching palette of this type will be shown.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this type in all toplevel windows are shown.

This option precludes the **-name** option

-parent *parent_name*

Specifies the parent toplevel window name.

-show_state *window_state*

Specifies the window state to show the palette.

Legal states are **maximized**, **minimized**, **normal**, or **docked**.

The default is **normal**.

-dock_edge *dock_edge*

Specifies the edge to dock the palette.

Legal dock edges are **left**, **top**, **right**, or **bottom**.

Note: this option is only valid if the state is set to **docked**.

The default is **right**.

-size *{width height}*

Specifies the width and height of the palette.

Note: this option is only valid if the state is set to **normal**.

DESCRIPTION

This command shows the specified palette in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

EXAMPLES

The following example shows the Layer palette docked on the left of the workspace.

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_palette -type Layout -parent $top]
shell> gui_show_palette -name $layout -show_state docked -dock_edge left
```

SEE ALSO

gui_hide_palette(2)

gui_show_task_assistant

Show the task assistant.

SYNTAX

gui_show_task_assistant
-task *TaskName*
-item *ItemName*

TaskName *String*
ItemName *String*

ARGUMENTS

-task *TaskName*

TaskName specifies the name of the task to show in the task assistant.

-item *ItemName*

ItemName specifies the name of the task item to show in the task assistant.

DESCRIPTION

The gui_show_task_assistant command opens the task assistant window and displays the page for given task and task item.

SEE ALSO

gui_create_task(2)
gui_set_current_task(2)
gui_get_current_task_item(2)
gui_get_current_task_page(2)

gui_show_timing_paths

Shows the details of a collection of timing paths in a timing path inspector.

SYNTAX

gui_show_timing_paths
-paths paths
[-new]

ARGUMENTS

-paths

Collection of timing pathss to be inspected.

-new

Creates a new timing path inspector window.

DESCRIPTION

The command shows the details of a collection of timing paths in a timing path inspector. Unless requested by the user, this command will use the most recently used timing path inspector window if it exists. Otherwise it will create a new timing path inspector window.

EXAMPLES

The following example inspects a collection of timing paths.

prompt> **gui_show_timing_paths -paths $paths**

SEE ALSO

change_selection(2)

gui_show_toolbar

Displays the specified toolbar or all the toolbars in the specified window or for a window type.

SYNTAX

void **gui_show_toolbar**
-toolbar *tool_bar_name* | -all
[-window *window_id*]
[-window_type *window_type*]

Data Types

tool_bar_name string
window_id string
window_type string list

ARGUMENTS

-toolbar *tool_bar_name*

Specifies the toolbar you want to display. The **-toolbar** option and the **-all** option are mutually exclusive.

-all

Displays all the toolbars in the specified window. The **-all** option and the **-toolbar** option are mutually exclusive.

-window *window_id*

Specifies the window in which you want to display the specified toolbar or all toolbars. This option is mutually exclusive with the **-window_type** option. If both **-window** and **-window_type** options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

-window_type *window_type*

Specifies the window types in which you want to display the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the **-window** option. If both **-window** and **-window_type** options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

DESCRIPTION

This command displays either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or

in all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by **gui_hide_toolbar** will be saved and restored on next invocation of the tool if save and restore has not been disabled.

EXAMPLES

The following example displays the File toolbar in the active window:

```
prompt> gui_show_toolbar -toolbar File
```

The following example displays all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_show_toolbar -all -window LayoutWindow.1
```

The following example displays the File toolbar in all TimingWindow type windows:

```
prompt> gui_show_toolbar -all -window_type TimingWindow
```

The following example display all the toolbars in all window types:

```
prompt> gui_show_toolbar -all -window_type [gui_get_window_types -type toplevel]
```

SEE ALSO

gui_create_toolbar(2)
gui_delete_toolbar(2)
gui_create_toolbar_item(2)
gui_delete_toolbar_item(2)
gui_hide_toolbar(2)
gui_get_toolbar_names(2)
gui_get_window_types(2)

gui_show_url_in_browser

Show the contents of a URL in an external web browser.

SYNTAX

gui_show_url_in_browser
-url *URL*

URL *String*

ARGUMENTS

-url *Url*

Url specifies the url to be displayed.

DESCRIPTION

The gui_show_url_in_browser command an external web browser to display the specified web page. The default web browser is defined by the application but is usually 'firefox' on UNIX platforms.

If the web browser supports external comminication (which 'firefox' does) then if no web browser is running the web browser is started. If the web browser is running then the URL is loaded in the browser usually as a new tab.

The default browser can be set using the 'gui_online_browser' variable but the set of valid browsers is usually restricted by the application so not all browsers may be supported. If a unsupported browser is specified the command will fail.

SEE ALSO

gui_online_browser(3)
gui_show_file_in_editor(2)

gui_show_utable

Show the current loaded user tables in a UserTable view.

SYNTAX

string **gui_show_utable**
[-name *Table_Name*]
[-view *View_Name*]
[-filter *Filter_Expr*]

[-distribution] [-columns *Column_List*]
[-report] [-columns *Column*]

[-import *CSV_Filename* [-tsv_mode] [-ssv_mode] [-report_type]]
[-meta_obj *MetaObj_Name*]
[-open *utable_Filename* [-read_only]]

[-top_window]

Table_Name String
Filter_Expr String
Column String
Column_List StringList
View_Name String
CSV_Filename String
MetaObj_Name String
utable_Filename String

ARGUMENTS

-name *Table_Name*

The name of the user table to show inside the view. If not given, the view will show the default help page. The user can then select a table via the table selector located at the top of the view.

-view *View_Name*

The name of an existing UserTable view to activate.

-filter *Filter_Expr*

Apply the given filter expression to the opened table view. **Note:** This option is exclusive with the **-import** option. To use this command and filter option you must first use **gui_import_utable**.

-distribution

Show table in distribution mode for the column given by the '-columns' option.

-report

Show table in report mode for the list of columns given by the '-columns' option.

-columns *Column_List*

Provides a list of one or more column names for the previous 2 options.

-import *CSV_Filename*

The name of a CSV (comma seperated values) file to import and create a UserTable from. A column configuration form is presented to allow the user to adjust the final produced UserTable.

-tsv_mode

This flag changes the default delimiter from the comma char to the tab char.

-ssv_mode

This flag changes the default delimiter from the comma char to the semicolon char.

-report_type

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

-meta_obj *MetaObj_Name*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

-open *utable_Filename*

The name of a UserTable native filename (.utable extension) to load into memory and present to the user. **Note**, this option is exclusive with the **-import** option.

-read_only

This flag can only be used with the **-open** option. It opens the file in a streaming read only manner, not copying all the data into memory which can save a lot of system memory if the file is huge.

-top_window

This flag will also open a new top level window to house the User Table view in.

DESCRIPTION

This command creates a new view (or reuse an existing view) to display and interact with your User Tables. For convenience, options are given for you to also import or open a new table from a file and display it.

User Tables provide a way for you to define and interact with your own tables of data. The data can persist on disk separate from the design database, and is completely under your control. User Tables can be generated from the attributes of a set of selected objects or they can come from external sources via an ASCII value file

in CSV/TSV/SSV format.

Interactively these tables can be viewed and support sorting, filtering, summary reporting, value distributions, editing, etc. as well as the ability to select/highlight objects in the design using the object names in columns identified as object type columns.

This command is available only when the GUI is running.

EXAMPLES

The following example just creates and opens a new UserTable view.

shell> **gui_show_utable**

The following example opens a new UserTable view and displays the contents of **my_table**.

shell> **gui_show_utable -name my_table**

The following example opens a new UserTable view and shows the import form used to configure the table being created from the values file **results.csv**. If no header line is supplied in the values file the configuration form will use default names that can be edited by the user before committing to table creation.

shell> **gui_show_utable -import results.csv**

The following example opens a new UserTable view and connects to the UserTable file **my_table.utable** in a read only streaming mode for display.

shell> **gui_show_utable -open my_table.utable -read_only**

gui_show_window

Show the window in the specified window state

SYNTAX

status **gui_show_window**
-window *window_id*
[-show_state *window_state*]
[{ -rect *rect* | -size *isize* }]

Data Types

window_id string
window_state string
rect {{x1 y1} {x2 y2}}
isize {width height}

ARGUMENTS

-window *window_id*

Specifies the toplevel window or view id to show.

-show_state *show_window_state*

Specifies the window state to show the toplevel window or view.

For a toplevel window we have one of:

normal - show at preferred size
maximized - show maximized (fill whole screen)
minimized - show iconized
hidden - hide but do not destroy

Note: The window manager may or may not fully honor the specified state. See your window manager documentation for more details.

For a view window we have one of:

normal - show at preferred size in view area and raise to top
maximized - show maximized in view area and raise to top
minimized - show iconized in view area
hidden - hide but do not destroy

Note: If displaying maximized then any existing view windows are also maximized. If displaying minimized or normal then any maximized windows are shown as normal.

The default is **SHOW_WINDOW_STATE_NORMAL**.

-rect ***rect***

Specifies the size and position of the window.

It is of this format "{{x1 y1} {x2 y2}}", where {x1 y1} specifies the top left location and {x2 y2} specifies the bottom right location of the window.

Note: This option precludes the use of the *-size* option.

-size ***isize***

Specifies the width and height of the window.

It is of this format "{width height}"

Note: This option precludes the use of the *-rect* option.

DESCRIPTION

This command shows the specified toplevel window or view in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

EXAMPLES

The following examples will create a layout window then use this command to illustrate the various options

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_window -type Layout -parent $top]
shell> gui_show_window -window $layout -show_state {maximized}
shell> gui_show_window -window $layout -show_state {normal}
```

SEE ALSO

gui_sort_charts_model

Sort charts model

SYNTAX

status **gui_sort_charts_model**
-model *model_id*
-column *column_name*
[-decreasing]

Data Types

model_id int
column_name string

ARGUMENTS

-model *model_id*

Model to sort.

-column *column_name*

Column name or number to sort.

-decreasing

Whether to sort descreasing instead of the default increasing.

DESCRIPTION

Sort column in charts model.

EXAMPLES

The following example sorts the second column of a model in decreasing order.

shell> gui_sort_charts_model -model $model -column 1 -decreasing

SEE ALSO

gui_create_charts_model(2)

gui_start

Starts the application GUI.

SYNTAX

string **gui_start**
[-file *script*]
[-no_windows]
[-offscreen 1|0]
[-- x_args ...]

string *script*

ARGUMENTS

-file "*script*"

The given script file is sourced before the GUI starts.

-no_windows

The GUI starts without showing the default window.

-offscreen

If the specified value is 1 then the GUI starts in offscreen mode.

If the specified value is 0 then the GUI starts in normal (X Display) mode.

-- x_args ...

X11-specific arguments to pass to the X connection.

DESCRIPTION

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. start_gui is an alias for gui_start.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful gui_start command has no effect.

EXAMPLES

The following example starts the application GUI.

shell> **gui_start**

SEE ALSO

gui_stop(2)
start_gui(2)
stop_gui(2)

gui_stop

Stops the application GUI.

SYNTAX

string **gui_stop**

ARGUMENTS

None.

DESCRIPTION

This command stops the application GUI and returns to the shell prompt. It is ignored if the application GUI has not been started or has been stopped. stop_gui is an alias for gui_stop.

EXAMPLES

The following example stops the application GUI and returns to the shell prompt.

shell> **gui_stop**

SEE ALSO

gui_start(2)
start_gui(2)
stop_gui(2)

gui_trim_dangling_wires

Trims dangling wire ends of selected wires or nets.

SYNTAX

status **gui_trim_dangling_wires**
[*object_list*]

Data Types

object_list collection

ARGUMENTS

object_list

Specifies a collection or selection set containing objects to trim. If this option is not specified, the global selection set is used.

DESCRIPTION

This command trims dangling ends of selected net shapes, net shapes of selected nets, selected route corridor shapes, or route corridor shapes of selected route corridors.

Only net shapes and route corridor shapes with connections at both ends will be trimmed. Unconnected shapes or shapes only connected at a single point will be ignored. You can manually delete these shapes if required.

Trimming of dangling net shapes on power and ground nets is limited to selected net shapes. Net shapes of selected power and ground nets will be ignored. This option allows you to do some minor repairs but reduces the chance that you will accidently try to repair the whole power mesh which could be slow and is better achieved using separate power planning commands.

This command honors the 'is_fixed' attribute. Any fixed net shapes or route corridor shapes are ignored unless 'Ignore fixed attribute' is set in the Edit Options dialog.

EXAMPLES

The following example trims dangling ends for all net shapes on the net N1.

prompt> **change_selection [get_nets N1]**

```
prompt> gui_trim_dangling_wires
```

This example uses an alternative syntax with a collection.

```
prompt> gui_trim_dangling_wires [get_nets N1]
```

SEE ALSO

change_selection(2)
get_edit_setting(2)
get_selection(2)
set_edit_setting(2)

gui_unset_flat_hierarchy_color

Removes colors set on leaf cells.

SYNTAX

gui_unset_flat_hierarchy_color
[*virtual_hierarchy_cell*]
[*-separator _separator*]

Data Types

virtual_hierarchy_cell string
_separator string

ARGUMENTS

virtual_hierarchy_cell

Specifies a virtual hierarchial cell in the design.

-separator _separator

Specifies the delimiter used in determining hierarchical structure of the flat netlist. The default delimiter option is a slash (/).

DESCRIPTION

The **gui_unset_flat_hierarchy_color** command removes the colors set on leaf cells. The uncolor cells are used to display the cells on some graphic windows, such as layout view.

If *virtual_hierarchy_cell* is specified, the command removes the colors set on all leaf cells descended from the virtual hierarchical cell in the current design and restores their original colors.

If *virtual_hierarchy_cell* is not specified, the command removes colors on all leaf cells in the current design.

EXAMPLES

The following example removes colors set on all the leaf cells in the current design,

prompt> **gui_unset_flat_hierarchy_color**

The following example removes colors set on all the leaf cells under the virtual hierarchy H1/H2 in the current design,

prompt> **gui_unset_flat_hierarchy_color H1/H2**

SEE ALSO

gui_set_flat_hierarchy_color(2)

gui_update_attrgroup

Updates a group of attributes for an object type.

SYNTAX

status **gui_update_attrgroup**
-class *design_object*
-name *name*
[-attr_list {{*attr_1*}...{*attr_n*}}]
[-add]
[-delete]
[-move up | down | top | bottom | after | before]
[-attr *attribute*]
[-anchor *attribute*]

Data Types

design_object string
name string
attr_1 string
attr_n string
attribute string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the non-editable name of the attribute group to update for the specified object type.

-attr_list {{*attr_1*}...{*attr_n*}}

Lists and orders the attributes to be included in the group.

-add

Adds the attribute specified by the **-attr** option to the end of attributes list, by default, or after the attribute specified by the **-anchor** option.

-delete

Removes the attributes specified by the **-attr** option from the attribute list. Note that the attribute still exists.

-move up | **down** | **top** | **bottom** | **after** | **before**

Moves the attribute specified by the **-attr** option in the specified direction. If you specify **before** or **after** to move the attribute relative to the position of a reference attribute, use the **-anchor** option to specify the reference attribute.

-attr ***attribute***

Specifies the attribute to be added, removed, or moved with the **-add**, **-delete**, or **-move** option.

-anchor ***attribute***

Specifies the reference attribute to be used with the **-add** or **-move** option.

DESCRIPTION

The **gui_update_attrgroup** command updates an attribute group for the specified object type. You can reset the entire attribute list by using the **-attr_list** option, or you can change the list by adding, removing, or moving with a single attribute.

The order of the attributes in an attribute group is important and is set by the **-attr_list** option when you create or update the group.

EXAMPLES

```
prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
  -attr_list { "TestAttr1" "TestAttr2" "TestAttr3" }

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
  -add -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
  -add -attr "TestAttr5" -anchor "TestAttr2"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
  -delete -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
  -move down -attr "TestAttr2"
```

SEE ALSO

gui_create_attrgroup(2)
gui_delete_attrgroup(2)
gui_list_attrgroups(2)

gui_update_pref_file

Save current application preferences to the user preference file.

SYNTAX

string **gui_update_pref_file** [-file *FilePathName*]

FilePathName *String*

ARGUMENTS

-file *FilePathName*

FilePathName specifies the full pathname of the user preference file to write the current preferences to. If this option is missing, the file to write to is controlled by the gui variables : pref_file_name and pref_file_path. These two variables are set with the gui_set_var command and their values retrieved with the gui_get_var command.

DESCRIPTION

This command updates the user preference file. Normally, application will automatically save user preferences to a default system preference file on exit, and retrieve the preferences from the default user preference file on application start. So, this command is rarely used, except internally.

gui_set_var(2)
gui_get_var(2)

gui_update_vm

Update Visual Mode

SYNTAX

string **gui_update_vm** -name *identifier*

string *identifier*

ARGUMENTS

-name *identifier*

Specifies the visual mode name whose associated tcl update command will be executed. The tcl update command is associated with the visual mode using the -update_cmd option to the gui_create_vm or gui_set_vm commands.

DESCRIPTION

Execute a visual mode's associated tcl update command.

EXAMPLES

To force the visual mode "vm1" to execute its associated update command, use the following:

shell> **gui_update_vm -name vm1**

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_get_vm(2)
gui_get_vmbucket(2)
gui_list_vm(2)
gui_remove_vm(2)

gui_remove_vmbucket(2)
gui_set_vmbucket(2)
gui_set_vm(2)

gui_update_vm_annotations

Updates visual mode annotations.

SYNTAX

string **gui_update_vm_annotations**
-clear
-center
-add *points*
-draw_net *style*
[-type *shape*]
[-text *message*]
[-color *color*]
[-pattern *pattern*]
[-line_style *line_style*]
[-width *width*]
[-info_tip *info_tip*]
[-query_text *query_text*]
[-query_command *query_command*]
object

Data Types

points list
style string
shape string
message string
color string
pattern string
line_style string
width integer
info_tip string
query_text string
query_command string
object string

ARGUMENTS

-clear

Removes all annotations from the specified object.

-center

Interprets all object locations as the centers of the objects rather than their origins.

-add *points*

Adds points for the annotation shape that you specify with the **-type** option. The points are specified by a tool command language (Tcl) list in which each element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.
- bbox_ul : the annotation is placed at the upper left of the

  bounding box of the object.
- bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

-draw_net *style*

Specifies how the nets are displayed in the layout view for this annotation if the specified objects are nets or physical buses.

This annotation overrides the current net display setting on the View Settings panel. The valid *style* values are

flyline
routing
routing_flyline

-type *shape*

Specifies the type of annotation. The valid *shape* values are

rect
line
arrow
polygon
polyline
text

-text *message*

Specifies a text string that you want to display.

-color *color*

Specifies the color. The default is the bucket color.

-pattern *pattern*

Specifies the fill pattern. The default is none.

-line_style *line_style>*

Specifies the line style. The default is none.

-width *width*

Specifies the line width. The default is 1.

-info_tip *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_text *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_command *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation
%x the x position clicked in design coordinates
%y the y position clicked in design coordinates

object

Specifies the object with which to associate the annotation.

DESCRIPTION

This command adds annotations to objects returned by the **gui_create_vm_objects** command.

Layout view visual modes are used to color objects in the layout view based on certain criteria. You can use the **gui_update_vm_annotations** command to display not only object coloring but some additional annotations for the objects in a visual mode bucket.

EXAMPLES

To create a bucket that displays cells and a line connecting those cells to the location (0,0), enter code like the following example:

```
prompt> set objs [gui_create_vm_objects $cells]
  foreach_in_collection o $objs {
    set c [get_attribute $o core_obj]
    gui_update_vm_annotations $o -type line -add [list {0 0} $c]
  }
prompt> gui_create_vmbucket -vmname $vm -name $bucket -color red -collection $objs
```

SEE ALSO

gui_create_vm(2)
gui_create_vmbucket(2)
gui_create_vm_objects(2)

gui_view_port_history

Does the gui_view_port_history operations.

SYNTAX

gui_view_port_history
[-window *window_name*]
[-next]
[-previous]
[-add *name*]
[-to *name*]
[-list_names]
[-rect *bounding box*]
[-delete_name]
[-isprevious]
[-isnext]
[-dialog]
[-tcl_list]
[-help_cmd]

ARGUMENTS

-window *fwindow_name*

Give the name of a window. this is required option except if you use *-dialog* option.

-next

Specify if you want to go to previous stored view port history. If you use *-next* option you can not use any other option except -*window* option: they are mutually exclusive.

-previous

Specify if you want to go to previous stored view port history. If you use *-previous* option you can not use any other option except -*window* option: they are mutually exclusive.

-add *name*

Current view port will be stored by this name. *-add* option can be combined with *-rect* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name.

If you use *-add* option you can not use any other option except *-window* and *-rect* option : they are mutually exclusive.

-to *name*

Give the name of a view port history already stored. If you use *-to* option you can not use any other option except -*window* option:

they are mutually exclusive.

-list_names

Specify if you want to see list of names of all the named view port history. If you use *-list_names* option you can not use any other option except *-window* option: they are mutually exclusive.

-delete_name *name*

The already stored view port history with this name will be deleted. If you use *-delete_name* option you can not use any other option except *-window* option: they are mutually exclusive.

-rect *boundingbox*

Adds give the bounding box (in design units) to unnamed view port history. The values should be given in following format. format: {{x1 y1} {x2 y2}} *-rect* option can be combined with *-add* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name. If you use *-add* option you can not use any other option except *-window* and *-add* option : they are mutually exclusive.

-isnext

return true returns true if there previous zoom history. If you use *-isnext* option you can not use any other option except *-window* option: they are mutually exclusive.

-isprevious

returns true if there next zoom history. If you use *-isprevious* option you can not use any other option except *-window* option: they are mutually exclusive.

-dialog

specify to invoke dialog for named view port history. If you use *-dialog* option you can not use any other option except *-help_cmd* option: they are mutually exclusive.

-tcl_list

return a tcl_list of named view port history If you use *-tcl_list* option you can not use any other option except *-window* option: they are mutually exclusive.

help_cmd *help_command*

Give a command which will be executed when help buttonis clicked in the dialog.

DESCRIPTION

This command store view port for the application. At least one option needs to be specified.

last 100 View ports will be stored in view port history, which can be accessed by specifying **-previous** and **-next** options.

When you use **-add** then the current view port will be stored by the given name in the to view port history.

when you use **-to** then the view port stored by this name will be shown and added to the view port history.

EXAMPLES

The following example zooms in to the given rectangle.

fpc_shell> **gui_view_port_history -rect {{-2232.321 -536.887} {141.286 2175.807}}**

The following example zooms to next .

fpc_shell> **gui_view_port_history -next**

The following example zooms to previous.

fpc_shell> **gui_view_port_history -previous**

The following example gives list of all the named zooms.

fpc_shell> **gui_view_port_history -list_names**

The following example puts the current zoom in to zoom history by given name.

fpc_shell> **gui_view_port_history -add xyz**

The following example zooms to already stored to zoom .

fpc_shell> **gui_view_port_history -to xyz**

The following example deletes an already stored to zoom.

fpc_shell> **gui_view_port_history -delete xyz**

gui_write_annotations

Saves annotations to a Tcl file.

SYNTAX

status **gui_write_annotations**
-file *filename*
[-append]
[-force]
[-compress *method*]
[*annotations*]

Data Types

filename string
method string
annotations collection

ARGUMENTS

-file *filename*

Specifies the name of the file in which the tool saves the annotation script.

-append

Append the annotation script to an existing file instead of creating a new one. The specified file must exist. This option cannot work with *-force*.

-force

Overwrite the specified file, if it exists, with the new one. This option cannot work with *-append*.

-compress *method*

Specifies the compression type to use when writing the file. By default, no compression is performed.

annotations

Specifies a collection of annotations to write. Get a collection of annotations with the gui_get_annotations command. If this option is not specified, then all the annotations with **global** window handle and **global** group type would be written by, annotations with specific window handle or group type are excluded.

DESCRIPTION

This command writes a collection of annotations to a Tcl script.

EXAMPLES

Write out all global annotations.

prompt> **gui_write_annotations -file my_annotations.tcl**

Write out all annotations in Layout.1.

prompt> **gui_write_annotations -file my_annotations.tcl** \
[gui_get_annotations -window Layout.1]

SEE ALSO

gui_add_annotation(2)
gui_get_annotations(2)
gui_remove_all_annotations(2)
gui_remove_annotations(2)

gui_write_category_script

Generates and writes out a categorization script.

SYNTAX

gui_write_category_script
-file *file_name*
[-overwrite]
[-tree *tree_id*]

Data Types

file_name sting
tree_id string

ARGUMENTS

-file *file_name*

File name of the output file to which to write the generated categorization script.

-overwrite

Allows an existing file to be overwritten. If you do not specify this option, an existing file cannot be overwritten, and an error message is generated.

-tree *tree_id*

String ID of the category tree in which the write category script operation occurs; the current category tree is used if the *-tree* option is omitted.

DESCRIPTION

This command generates and writes out a categorization Tcl script that captures the state of the specified category tree. The generated script includes needed commands, if any, to recreate any user-defined non-built-in category rules that the categorization scheme depends on. The generated script is suitable for replaying in a subsequent run of the tool by sourcing the script using the **source** command.

Before replaying the script it is recommended that a similar design and set of conditions (as existed when the categorization scheme was first created) are set up first. The command returns "1" if successful; otherwise, an empty string is returned.

You should run this command only if at least one category tree is available. The command acts on the category tree specified.

EXAMPLES

The following example shows how to generate a category replay script and write it to the category_script.tcl file:

```
shell> gui_write_category_script -file category_script.tcl
1
```

EXAMPLES

The following example shows the categorization script replaying what was previously saved using the **gui_write_category_script** command. The most recently used category tree is recreated.

```
shell> source category_script.tcl
1
```

SEE ALSO

gui_create_category(2)
gui_remove_category(2)

gui_write_charts_data

Write charts data

SYNTAX

status **gui_write_charts_data**
-view *view_name*
[-file *file_name*]

Data Types

view_name string
file_name string

ARGUMENTS

-view *view_name*

View to output data for.

-file *file_name*

Filename to output data to. If not specified then the the output is sent to the terminal.

DESCRIPTION

Write charts data as a tcl script to terminal or a file.

This command allows the user to save the state of the plots in the current view to a tcl command which can be source'd to reproduce the plot.

Details of the models loaded for the view's plots, the views annotations, the plots and the plots annotations are saved.

Only the view and plot properties that have changed from their default values are saved.

Note: Only the filename, tcl variable or collection name of the model data can be saved so these external dependencies, file data, contents of the tcl variable, or contents of the collection will need to be recreated before the script can be used.

EXAMPLES

The following example writes view data to the file "view_data.tcl".

```
shell> gui_write_charts_data -view Charts.1 -file "view_data.tcl"
```

SEE ALSO

gui_create_charts_model(2)

gui_write_charts_image

Save charts plot or view to image file

SYNTAX

status **gui_write_charts_image**
-view *view_name*
-plot *plot_name*
-file *string*

Data Types

view_name string
plot_name string

ARGUMENTS

-view *view_name*

Charts view to save (all charts).

-plot *plot_name*

Single charts plot in view to save.

-file *string*

Output filename.

The file suffix is used to determine type i.e. .png for PNG file or .svg for SVG file.

If the file suffix (converted to lower case) is not .png or .svg then PNG is used.

DESCRIPTION

Save charts plot or view to PNG or SVG image file.

EXAMPLES

The following example saves all charts in a view to a PNG file charts.png.

```
shell> gui_write_charts_image -view $view -file charts.png
```

SEE ALSO

gui_create_chart(2)

gui_write_hierarchy_colors

Writes current hierarchy Module Boundary status and colors to a file.

SYNTAX

status **gui_write_hierarchy_colors**
-file *file_name*

Data Types

file_name string

ARGUMENTS

-file *file_name*

Specifies the name of file to write.

DESCRIPTION

The **gui_write_hierarchy_colors** command writes current hierarchy Module Boundary status and colors to a file. Next time, you can source this file to restore hierarchy Module Boundary status and color.

EXAMPLES

The following examples writes current Module Boundary status and colors to a data file named color.tcl.

prompt> **gui_write_hierarchy_colors -file color.tcl**

SEE ALSO

gui_explore_logic_hierarchy(2)

gui_write_timing_paths

Writes a persistent path data file containing a timing path collection.

SYNTAX

status **gui_write_timing_paths**
-file *file_name*
[-overwrite]
[-tag *tag_name*]
[-comment *comment*]
paths

Data Types

file_name string
tag_name string
comment string
paths collection

ARGUMENTS

-file *file_name*

Specifies the name of the persistent path data file to write. By default, if the file already exists, the command exits without writing the file.

-overwrite

Specifies that file that already exists will be overwritten.

-tag *tag_name*

Specifies a tag name for the timing path.

-comment *comment*

Specifies a user comment for the timing path file.

paths

Specifies the collection of timing paths to write.

DESCRIPTION

The **gui_write_timing_paths** command writes a persistent path data file containing the given path collection. The persistent path data file contains all the information needed to re-create those timing paths using the **gui_read_timing_paths** command.

EXAMPLES

The following examples writes out a timing path collection to a persistent path data file named my.paths.

```
prompt> gui_write_timing_paths $paths -file "my.paths"
```

SEE ALSO

gui_read_timing_paths(2)

gui_write_utable

Write the UserTable to file in native UserTable format.

SYNTAX

string **gui_write_utable**
-name *Table_Name*
[-file *File_Name*]
[-filter *Filter*]
[-read_only]
[-overwrite]

Table_Name String
File_Name String

ARGUMENTS

-name *Table_Name*

The name of the user table to write out to a file.

-file *File_Name*

The name of the file to write the table to, by default the name of the table is used with the '.utable' extension.

-filter *Filter*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

-read_only

This flag closes the table that has been written out and then re-opens it in read-only (streaming) mode which can save a lot of system memory if the table is huge.

-overwrite

This flag will force the destination file to be overwritten.

DESCRIPTION

This command writes the given table name to a file in the native user table format, preserving all meta data (filter, sort order and column information). The UserTable file can then be later re-opened to copy the information back into memory or opened in a read-only (streaming) mode using the command **gui_open_utable**.

EXAMPLES

The following example writes out the given table to a file name equal to the table name plus the extension '.utable'.

```
shell> gui_write_utable -name my_table
```

The following example writes out the given table (overwrites the file if necessary) and then closes the table in memory and re-opens it in read-only (streaming) mode.

```
shell> gui_write_utable -name my_table -read_only -overwrite
```

SEE ALSO

gui_append_utable(2)
gui_change_selection_utable(2)
gui_close_utable(2)
gui_create_utable(2)
gui_export_utable(2)
gui_import_utable(2)
gui_open_utable(2)
gui_show_utable(2)

gui_write_window_image

Saves an image of a view window or toplevel window in the specified image file

SYNTAX

status **gui_write_window_image**
-file *filename*
[-format *image_format*]
[-window *window_name*]
[-size *window_size*]

Data Types

filename string
image_format string
window_name string
window_size {width height}

ARGUMENTS

-file *filename*

Specifies the name of the file in which the tool saves the window image.

If you include a file name extension, it determines the image format unless you also specify the *-format* option.

-format *png* | *xpm* | *jpg* | *bmp*

Specifies the image format to be used in the file. The default value is png.

Note that if the format that you specify with the *-format* option is different from the format specified by the file name extension, the *-format* value takes precedence and the tool appends an additional extension to the file name.

-window *window_name*

Specifies the name of the window for which you want to save an image in the specified image file.

You can view a list of the window names for all the open toplevel and view windows by using the *gui_get_window_ids* command.

By default, the tool saves an image of the most recently active view window.

-size *window_size*

The size of the image to be generated. If not specified then the full window size is used.

DESCRIPTION

The **gui_write_window_image** takes a snapshot of a specified toplevel window or child view window in a specified image format and writes the result to a specified file.

EXAMPLES

The following example writes a snapshot of the TopLevel.1 window to a image file "snapshot.png".

```
shell> gui_write_window_image -window TopLevel.1 -file snapshot.png
```

The following example writes a snapshot of the Layout.1 view to a image file "layout.png" of size 800 pixels by 600 pixels.

```
shell> gui_write_window_image -window Layout.1 -file layout.png -size {800 600}
```

SEE ALSO

gui_get_window_ids(2)
gui_get_current_window(2)

gui_zoom

Change the viewport of a view

SYNTAX

gui_zoom
-window *window*
[-fit | -exact]
[-full]
[-selection]
[-rect *{{lx ly} {ux uy}}*]
[-factor *factor*]
[-at_point *{x y}*]
[-clct *clcf*]
[-zoom_in_mode]
[-zoom_out_mode]
[-select_mode]

window *String*
rect *String*
factor *Float*

ARGUMENTS

-window *window*

window specifies the window of which this command should change the viewport.

-full

Zoom such that all objects are visible.

-factor *factor*

Keep the center of the viewport and zoom by factor *factor*. A *factor*" > 1 causes a zoom-in, a *factor*" < 1 causes a zoom-out. The argument must be greater than zero.

-at_point *{x y}*

Can only be specified with -factor argument. If supplied, zoom is performed at specified point instead of viewport center. The option is not supported by all window types.

-fit

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to not over zoom. Will zoom a reasonable

distance away from the rectangle or objects being zoomed. The definition of "reasonable" is window dependent. This argument is mutually exclusive with -exact.

-exact

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to zoom exactly to the arguments. This argument is mutually exclusive with -fit.

-selection

Zoom such that all selected objects that are represented in the window are visible and if possible are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

-rect *{{lx ly} {ux uy}}*

Zoom such that the window shows the rectangle *rect* in its viewport. What coordinates are assumed for *rect* are dependent on the window. If neither -fit or -exact is supplied, -exact is assumed.

-clct *clct*

Zoom such that all objects in *clct* that are represented in the window are visible and if possible, are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

-zoom_in_mode

Put the window in zoom-in mode.

-zoom_out_mode

Put the window in zoom-out mode.

-select_mode

Put the window in selection mode.

DESCRIPTION

The **gui_zoom** controls the viewport of a view that supports zooming. Not all views need to support all of the functionality provided by the interface of this command.

EXAMPLES

The following example has the layout view show the entire design and then zooms in by a factor of 2, i.e. only a quarter of the area of the design is still visible:

```
gui_zoom -window Layout.1 -full
gui_zoom -window Layout.1 -factor 2
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}}
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}} -fit
gui_zoom -window Layout.1 -selection -exact
```

SEE ALSO

gui_zoom_all_layouts_to_current_view

Rescales all layout views to the current view.

SYNTAX

gui_zoom_all_layouts_to_current_view

ARGUMENTS

None.

DESCRIPTION

The command sets the zoom factor of all layout views to the zoom factor of current layout view.

EXAMPLES

prompt> **gui_zoom_all_layouts_to_current_view**

SEE ALSO

gui_zoom(2)

gui_zoom_to_selected_errors

Layout window zoom to errors selected in the error browser.

SYNTAX

string **gui_zoom_to_selected_errors**

DESCRIPTION

If you have selected the errors in the error browser, you can execute this command to have layout zoom to the selected errors.

EXAMPLES

If you select errors, then perform layout zooming operations, the following command will force layout to zoom to selected errors:
gui_zoom_to_selected_errors

SEE ALSO

gui_error_browser(2)
gui_set_current_errors(2)
gui_set_selected_errors(2)
gui_set_error_browser_option(2)

help

Displays quick help for one or more commands.

SYNTAX

string **help**
  [-verbose]
  [-groups]
  [*pattern*]

Data Types

pattern string

ARGUMENTS

-verbose

Displays the command options; for example *command_name* **-help**.

-groups

Displays a list of command groups only.

pattern

Displays commands matching the specified pattern.

DESCRIPTION

The **help** command is used to get quick help for one or more commands or procedures. This is not the same as the **man** command that displays reference manual pages for a command. There are many levels of help.

By typing the **help** command, a brief informational message is printed followed by the available command groups.

List all of the commands in a group by typing the group name as the argument to **help**. Each command is followed by a one-line description of the command.

To get a one-line help description for a single command, type **help** followed by the command name. You can specify a wildcard pattern for the name; for example, all commands containing the string "alias". Use the **-verbose** option to get syntax help for one or more commands. Use the **-groups** option to show only the command groups in the application. This option cannot be combined with any other option.

EXAMPLES

The following example lists the commands by command group:

```
prompt> help
Specify a command name or wild card pattern to get help on individual
commands. Use the '-verbose' option to get detailed option help for a
command. Commands also provide help when the '-help' option is passed to
the command.'

You can also specify a command group to get the commands available in
that group. Available groups are:

 Procedures:          Miscellaneous procedures
 Help:                Help commands
 Builtins:            Generic Tcl commands
...
```

The following example displays the list of procedures in the Procedures group:

```
prompt> help procedures
 ls             # List files
 sh             # Execute a shell command
```

The following example uses a wildcard character to display a one-line description of all commands beginning with *a*:

```
prompt> help a*
 alias          # Create a command which expands to words.
 append           # Builtin
 array          # Builtin
```

This example displays option information for the **source** command:

```
prompt> help -verbose source
 source           # Read a file and execute it as a script
  [-echo]           (Echo all commands)
  [-verbose]        (Display intermediate results)
  file_name         (Script file to read)
```

SEE ALSO

man(2)
sh_help_shows_group_overview(3)

help_app_options

Displays the help information for application options.

SYNTAX

help_app_options
[-verbose]
[-scope *scope*]
[-category *category*]
[*patterns*]

Data Types

scope string
category string
patterns string

ARGUMENTS

-verbose

Displays the detailed information on the application options. This is an optional option. If this option is not specified, the information displayed is just the option name and the help string.

-scope *scope*

Specifies the scope of the application options for which the help string is to be displayed. This is an optional option. If this option is not specified, the help string for application options from both the global scope and design scope will be displayed.

-category *category*

Specifies the category of application options for which the help string is to be displayed. The help string for all the application options belonging to the specified category will be displayed.

patterns

Specifies a pattern for the option names. A pattern can include the wildcard characters asterisk (*) and question mark (?). "*" will match zero or more of any character, and "?" will match any single character. If this option is specified, the command displays the help string for only those application option names that match the specified pattern. If not specified, includes all the options.

DESCRIPTION

This command displays the help information for the application options whose names match the specified pattern.

The default behavior is to display the names of all the categories of registered application options.

EXAMPLES

The following example shows the default behavior

```
prompt> help_app_options
Categories of the registered application options are:
  abstract
  budget
  calc
  clock_opt
  constraint
  \...
  upf
  verilog
```

The following example displays the help string of all application options belonging to category 'verilog'.

```
prompt> help_app_options -category verilog
verilog.default_user_label          # Default user label to create the design in
verilog.enable_vpp                  # Enable Verilog pre-processor
verilog.keep_unconnected_cells      # Keep unconnected cells
verilog.keep_unconnected_nets       # Keep unconnected nets
```

The following example displays the help string for application options that are global scoped, belong to category 'shell' and match the pattern '*product*'

```
prompt> help_app_options -scope global -category shell *product*
shell.product_abbreviation          # Specifies the abbreviated string
for the product for this application.
shell.product_build_date            # Specifies the build date of this
application.
shell.product_name                  # Specifies the name for the product
for this application.
shell.product_version               # Specifies the version of this
application.
```

The following example displays a detailed information for the application option 'route.detail.max_antenna_pin_count'

```
prompt> help_app_options route.detail.max_antenna_pin_count -verbose
name                    route.detail.max_antenna_pin_count
value_type              integer
default_value           -1
help                    fix antenna on nets with number of
                        pins less than given value
status                  basic
minimum_value           -1
maximum_value           1000000
allowed_values          --
app_var_name            --
is_obsolete             false
is_global_only          false
```

```
    is_read_only                false
    is_persistent               true
    is_subscripted              false
```

SEE ALSO

set_app_options(2)

help_attributes

Display help for attributes and object types

SYNTAX

string **help_attributes** [-verbose]
[-application]
[-user]
[*class_name*]
[*attr_pattern*]

string *class_name*
string *attr_pattern*

ARGUMENTS

-verbose

Display attribute properties.

-application

Only display application defined attributes.

-user

Only display user defined attributes.

class_name

Object class to retrieve help for.

attr_pattern

Show attributes matching pattern.

DESCRIPTION

The **help_attributes** command is used to get quick help for the set of available attributes. When this command is run with no arguments a brief informational message is printed followed by the available object classes.

EXAMPLES

```
prompt> help
cci_test> help_attributes
Specify an object type and an optional wild card pattern to get information
on the available attributes defined for the specified object type. Use the
-verbose option to get detailed information on the attributes

The available object types are:

 cell      net      pin
 ...
```

SEE ALSO

get_attribute(2)
help(2)
get_defined_attributes(2)

history

Displays or modifies the commands recorded in the history list.

SYNTAX

string **history**
  [-h]
  [-r]
  [*argument_list*]

Data Types

argument_list list

ARGUMENTS

-h

Displays the history list without the leading numbers. You can use this for creating scripts from existing history. You can then source the script with the **source** command. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

-r

Reverses the order of output so that most recent history entries display first rather than the oldest entries first. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

argument_list

Additional arguments to **history** (see DESCRIPTION).

DESCRIPTION

The **history** command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." The most commonly used forms of the command are described below. You can combine each with either the **-h** or **-r** option, but not both.

- With no arguments, the **history** command returns a formatted string (intended for you to read) giving the event number and contents for each of the events in the history list.
- If a single, integer argument *count* is specified, only the most recent *count* events are returned. Note that this option is a

nonstandard extension to Tcl.

- Initially, 20 events are retained in the history list. You can change the length of the history list using the following:

  history keep *count*

Tcl supports many additional forms of the **history** command. See the "Advanced Tcl History" section below.

EXAMPLES

The following examples show the basic forms of the **history** command. The first is an example of how to limit the number of events shown using a single numeric argument:

```
prompt> history 3
   7  set base_name "my_file"
   8  set fname [format "%s.db" $base_name]
   9  history 3
```

Using the **-r** option creates the history listing in reverse order:

```
prompt> history -r 3
   9  history -r 3
   8  set fname [format "%s.db" $base_name]
   7  set base_name "my_file"
```

Using the **-h** option removes the leading numbers from each history line:

```
prompt> history -h 3
set base_name "my_file"
set fname [format "%s.db" $base_name]
history -h 3
```

Advanced Tcl History

The **history** command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." When specifying an event to the **history** command, the following forms may be used:

- A number, which if positive, refers to the event with that number (all events are numbered starting at 1). If the number is negative, it selects an event relative to the current event; for example, **-1** refers to the previous event, **-2** to the one before that, and so on. Event **0** refers to the current event.
- A string selects the most recent event that matches the string. An event is considered to match the string either if the string is the same as the first characters of the event, or if the string matches the event in the sense of the **string match** command.

The **history** command can take any of the following forms:

history

Same as **history info**, described below.

history add *command [exec]*

Adds the *command* argument to the history list as a new event. If **exec** is specified (or abbreviated), the command is also executed and its result is returned. If **exec** is not specified, an empty string is returned.

history change *newValue [event_number]*

Replaces the value recorded for an event with *newValue*. The *event_number* specifies the event to replace, and defaults to the *current* event (not event **-1**). This command is intended for use in commands that implement new forms of history substitution and want to replace the current event (that invokes the substitution) with the command created through substitution. The return value is an empty string.

history clear

Erases the history list. The current keep limit is retained. The history event numbers are reset.

history event *[event_number]*

Returns the value of the event given by *event_number*. The default value of *event_number* is **-1**.

history info *[count]*

Returns a formatted string, giving the event number and contents for each of the events in the history list except the current event. If *count* is specified, then only the most recent *count* events are returned.

history keep *[count]*

Changes the size of the history list to *count* events. Initially, 20 events are retained in the history list. If *count* is not specified, the current keep limit is returned.

history nextid

Returns the number of the next event to be recorded in the history list. Use this for printing the event number in command-line prompts.

history redo *[event_number]*

Reruns the command indicated by *event* and returns its result. The default value of *event_number* is **-1**. This command results in history revision. See the following section for details.

History Revision

Pre-8.0 Tcl had a complex history revision mechanism. The current mechanism is more limited, and the **substitute** and **words** history operations have been removed. The **clear** operation was added.

The **redo** history option results in much simpler "history revision." When this option is invoked, the most recent event is modified to eliminate the history command and replace it with the result of the history command. If you want to redo an event without modifying the history, use the **event** operation to retrieve an event, and use the **add** operation to add it to history and execute it.

identify_channels

Identifies channels between specified objects. The supported objects are cells, site rows, placement blockages, routing blockages, and wires.

SYNTAX

status **identify_channels**
[-output_filename *file_name*]
[-horizontal_threshold *horizontal_threshold*]
[-vertical_threshold *vertical_threshold*]J
[-cross_area]
[-cross_area_width *cross_area_width*]
[-cross_area_height *cross_area_height*]
[*collection_of_objects*]

Data Types

file_name string
horizontal_threshold double
vertical_threshold double
cross_area_width double
cross_area_height double
collection_of_objects collection

ARGUMENTS

-output_filename *file_name*

Specifies the file name in which to write out the identified channels. By default, the command writes the channel information to "channels.txt".

-horizontal_threshold *horizontal_threshold*

Specifies the threshold value for horizontal channels. Channels taller than *horizontal_threshold* are not reported. If you specify **-horizontal_threshold** without specifying **-vertical_threshold**, only horizontal channels are reported.

-vertical_threshold *vertical_threshold*

Specifies the threshold value for vertical channels. Channels wider than *vertical_threshold* are not reported. If you specify **-vertical_threshold** without specifying **-horizontal_threshold**, only vertical channels are reported.

-cross_area

Identify cross area channels. Cross area channels have both a height and a width.

-cross_area_width *cross_area_width*

Specifies the width threshold value for cross area channels. Cross area channels with a width smaller than *cross_area_width* are not reported.

-cross_area_height *cross_area_height*

Specifies the height threshold value for cross area channels. Cross area channels with a height smaller than *cross_area_height* are not reported.

collection_of_objects

Specifies a collection of objects. The supported objects are cells, site rows, placement blockage, routing blockage, and wires.

DESCRIPTION

This command identifies channels between specified objects and writes the channel coordinates to channels.txt. The **-horizontal_threshold** and **-vertical_threshold** options specify an upper limit to the height and width of the channels; channels outside the limit are not reported.

The output format written to channels.txt of channel is

direction (xlo ylo) (xhi yhi)

For example,

vertical (1339.255 367.195) (1392.445 489.325)

EXAMPLES

The following example writes out a channel file named channels.txt for channels between cells SD_RFIFO_RAM and SD_WFIFO_RAM, site row unit_row_2, placement_blockage PB1, routing blockage RB1, and wires PATH_14_653.

```
prompt> set objects [get_cells "SD_RFIFO_RAM SD_WFIFO_RAM"]
prompt> append_to_collection objects [get_site_rows "unit_row_2"]
prompt> append_to_collection objects [get_placement_blockages "PB1"]
prompt> append_to_collection objects [get_routing_blockages "RB1"]
prompt> append_to_collection objects [get_shapes "PATH_14_653"]
prompt> identify_channels $objects
```

The following example writes out a channel file named channelObjects.txt and displays the file for channels between selected objects.

```
prompt> identify_channels [get_selection] -output_filename channelObjects.txt
prompt> sh cat channelObjects.txt
horizontal (1.6 1392.07) (352.165 1408.07)
horizontal (442.7 1408.07) (793.265 1424.07)
vertical (352.165 1424.07) (442.7 1616.515)
vertical (352.165 1648.515) (442.7 1856.96)
```

The following example writes out horizontal channels with a height less than 10 microns and vertical channels with a width less than 5 microns.

```
prompt> identify_channels [get_selection] -horizontal_threshold 10 -vertical_threshold 5
```

SEE ALSO

compile_pg(2)
create_pg_strap(2)

identify_multibit

Identifies multibit banking opportunities and writes out a register or mv_cell banking script.

SYNTAX

status **identify_multibit**
-register | -mv_cell
-output_file *file_name* | -apply
[-input_map_file *file_name*]
[-slack_threshold *slack_value*]
[-exclude_instance *exclude_cells*]
[-exclude_library_cells *library_cells*]
[-no_dft_opt]
[-cells *list_of_cells*]

Data Types

file_name string
slack_value float
exclude_cells list or collection
library_cells list or collection
list_of_cells list or collection

ARGUMENTS

-register

This option allows the user to identify groups of registers that can be replaced by multibit registers. You must specify either the **-register** or **-mv_cell** option.

-mv_cell

This option allows the user to identify groups of level_shifters or isolation cells that can be replaced by multibit level_shifter or isolation cell. You must specify either the **-register** or **-mv_cell** option.

-output_file *file_name*

Specifies the name of the output file that contains the generated banking commands. The output file contains a series of **create_multibit** commands. The output file can be sourced back into the tool to replace single-bit cells with multi-bit cells. You must specify either the **-output_file** or **-apply** option.

-apply

If this option is specified, tool modifies the netlist by replacing identified groups of single bit cells with multibit cells instead of

generating the output script file. You must specify either the **-output_file** or **-apply**.

-input_map_file *file_name*

Specifies the name of the input map file that contains functional group information and mapping information about which multibit register bank replaces which single-bit registers for each functional group.

If you do not specify this option, the command identifies the single-bit registers that can be replaced by available multibit registers in the libraries based on the functional information of the library cells; the tool then uses that information to control mapping.

This option can be used only when you are using the **-register** option. The format for the input map file is described in the FILE FORMATS section of this man page.

-exclude_instance *exclude_cells*

Specifies the list of instances to be ignored for grouping.

-exclude_library_cells *library_cells*

Specifies the list of library cells whose instances are ignored for grouping.

-slack_threshold *slack_value*

Specifies the slack value for a register to be considered for banking. Registers having slack value below this number is ignored for banking. By default tool consider all registers for banking. This option can be used only when you are using the **-register** option.

-no_dft_opt

This option disables the call to the **optimize_dft** command. If this option is not used, the netlist may get modified.

-cells *list_of_cells*

Specifies the list of single-bit cells, multibit cells or both to be considered for grouping.

DESCRIPTION

The **identify_multibit** command identifies groups of single-bit registers or mv_cells that can be replaced by multibit registers or mv_cells and then either modifies the netlist accordingly or generates a banking script file which can then be sourced back into the tool to replace single-bit cells with multibit cells. For high banking ratio consideration, **optimize_dft** is employed at the beginning by default, which may modify the netlist.

FILE FORMATS

Format for specifying -input_map_file

You can specify the input map file sequence as shown:

reg_group_name {*list_of_reference_of_single_bit_flops* }
bits { *number_of_instances ref_multibit_flop* } { ... }
bits { *number_of_instances ref_multibit_flop* } { ... }

Where *reg_group_name* specifies the name of the register group, *list_of_reference_of_single_bit_flops* specifies the list of references of single-bit registers. **bits** specifies the number of single-bit registers in a group to be replaced, *number_of_instance* specifies the number of multibit registers to be used, and *ref_multibit_flop* specifies the reference multibit library cell to be used.

For example:

```
reg_group_1 {REGX1 REGX2 REGX4}
2 {1 MREG2}
3 {1 MREG2}
4 {1 MREG4}
5 {1 MREG4}
6 {1 MREG2} {1 MREG4}
reg_group_2 {REGNX1 REGNX2 REGNX4}
2 {1 MREG2N}
3 {1 MREG2N}
4 {1 MREG4N}
5 {1 MREG4N}
6 {1 MREG2N} {1 MREG4N}
```

reg_group_1 {REGX1 REGX2 REGX4} means that single-bit registers whose reference is either REGX1, REGX2, or REGX4 can be grouped together. **4 {1 MREG4}** specifies that a group of four single-bit registers can be replaced by one cell whose reference is MREG4. Similarly, **6 {1 MREG2} {1 MREG4}** means a group of six single-bit registers can be replaced using one instances of MREG2 and one instance of MREG4.

You can include a comment using the # character in the input map file. Lines beginning with the # character to the end of the line is treated as a comment.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **identify_multibit** command to generate the banking script.

```
prompt> identify_multibit -register -input_map_file ./input.map -output_file ./create_bank.out
1
```

SEE ALSO

create_multibit(2)
split_multibit(2)

index_collection

Given a collection and an index into it, if the index is in range, create a new collection containing only the single object at the index in the base collection. The base collection remains unchanged.

Optionally, a second index can be passed which creates a new collection with the objects between the two indices in the base collection. Makes an implicit assumption that index<=index2

SYNTAX

collection **index_collection**
collection1
index
[index2]

Data Types

collection1 collection
index index
index2 index

ARGUMENTS

collection1

Specifies the collection to be searched.

index

Specifies the index into the collection.

The index is either a simple integer to specify the offset from the start of the collection or the string "end" optionally followed by a negative integer to specify the offset from the end of the collection.

For the start offset case the value must range from 0 to **sizeof_collection** - 1. For the end offset case the negative integer (if specified) must range from 0 to -(**sizeof_collection** - 1).

index2

Specifies an optional second index into the collection.

Specifies a second index to create a collection of a range of objects from the base collection, defined by the two indices [index, index2] (boundaries inclusive)

DESCRIPTION

You can use the **index_collection** command to extract a single object from a collection. The result is a new collection containing only that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index.

The range of indices is from 0 to one less than the size of the collection. If the specified index is outside that range, an error message is generated.

Commands that create a collection of objects do not impose a specific order on the collection, but they do generate the objects in the same, predictable order each time. Applications that support the sorting of collections allow you to impose a specific order on a collection.

You can use the empty string for the *collection1* argument. However, by definition, any index into the empty collection is invalid. Therefore, using the **index_collection** command with the empty collection always generates the empty collection as a result and generates an error message.

Note that not all collections can be indexed.

EXAMPLES

The following examples from PrimeTime use the **index_collection** command to extract the first, second, last and penultimate object of a collection.

```
pt_shell> set c1 [get_cells {u1 u2 u3}]
{"u1", "u2", "u3"}
pt_shell> query_objects [index_collection $c1 0]
{"u1"}
pt_shell> query_objects [index_collection $c1 1]
{"u2"}
pt_shell> query_objects [index_collection $c1 0 1]
{"u1", "u2"}
pt_shell> query_objects [index_collection $c1 end]
{"u3"}
pt_shell> query_objects [index_collection $c1 end-1]
{"u2"}
pt_shell> query_objects [index_collection $c1 end-1 end]
{"u2", "u3"}
```

infer_supply_from_pg_net

Infer supply net connections to leaf PG pins in power intent based on their existing net connections in the PG netlist.

SYNTAX

status **infer_supply_from_pg_net**
[-create_supply_port]
[-verbose]

ARGUMENTS

-create_supply_port

If specified, supply net connection translation into the power intent may entail creation of supply ports in certain specific cases such as when there are domain dependent supply nets or when connecting across scopes.

-verbose

Prints the details for the inference information for each pin.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

commit_upf(2)

infer_switching_activity

Infers the switching activity on the drivers of special control input pins in the current design.

SYNTAX

int **infer_switching_activity**
[-objects *object_list*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-sci_based *type*]
[-apply]
[-verbose]
[-quiet]
[-output *file_name*]

Data Types

object_list list
mode_list list
corner_list list
scenario_list list
type string
file_name string

ARGUMENTS

-objects *object_list*

List of objects (pins, ports, nets, cells) for which to report the activity influencing essential points. For a net, the tool considers any essential point in its fanin. For pins or ports, the tool considers any essential point in the fanin; if the pin or port happens to be an essential point, it reports and applies activity for the pin/port itself. For cells, the tool considers any essential point that is in the fanin of its input pins.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes occurs.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering occurs on corners.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then the considers only those scenarios that contain the modes and corners specified through **-modes** and **-corners** options. The command output is generated separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options is specified, the command reports the current scenario in the design.

-sci_based ***type***

Specifies whether to report or apply activity on any essential point based on the number of special control inputs it influences. The **type** specified can take one of the following three values: **sci**, **non_sci**, and **all**. If type is **sci**, the activity for any essential point is reported and applied based on the number of SCIs (Special Control Inputs) in its fanout. If there is no SCI in the fanout of an essential point, the tool does not report for the point. For the **non_sci** type, the default activity value is reported and applied on all essential points that do not have any SCIs in their fanout. If the type is **all**, the tool reports and applies all the essential points. If this option is not specified, the default behavior corresponds to **all**.

-apply

Applies the proposed switching activity annotation on the drivers of the special control input pins. The activity type for points where activity has been applied is **inferred**.

-verbose

Reports detailed information for each special control input in the fanout of an object.

-quiet

Suppresses the output report of the command. If either **-apply** or **-output** option has been specified, activity will still be applied/written out to a file accordingly.

-output ***file_name***

Creates a file with **set_switching_activity** commands that can be used to apply the activity on all or specified essential points.

DESCRIPTION

This command infers the switching activity on the drivers of the Special Control Input pins (SCIs) in the design. These pins can be clock pins, set pins, reset pins, scan enables, isolation cell control pins, power switch control pins, and so on. The switching activity includes toggle rate and static probability on the drivers of these pins.

The **-objects** option can be used to filter the essential points for reporting and applying the activity. To filter for scenarios, the **-modes**, **-corners**, and **-scenarios** options can be used. To determine whether to report and apply activity for essential points with zero or nonzero SCI count, the **-sci_based** option can be used. If the **-sci_based** option is not specified, all essential points are considered for reporting and applying. Use the **-apply** option to apply the inferred switching activity values on the drivers of the pins. For a detailed report, the **-verbose** option can be used. The **-quiet** option can be used to suppress the output report. The **-output** option creates a file with **set_switching_activity** commands that can be used to annotate the inferred activity later.

EXAMPLES

The following example shows the report generated by the **infer_switching_activity** command.

```
prompt> infer_switching_activity
Information: Activity for scenario scenario1 was cached, no propagation required. (POW-005)

initialize_floorplan

Creates an initial floorplan with a die boundary, core, site array (or rows), and wire tracks. Support is provided for a die boundary that is coincident with the core, or a rectilinear core with rectangular die boundary.

SYNTAX

int **initialize_floorplan**
[-control_type core | die]
[-shape R | L | T | U]
[-side_length {side_a side_b [side_c side_d side_e side_f]}]
[-side_ratio {side_a side_b [side_c side_d side_e side_f]}]
[-core_utilization *ratio*]
[-keep_boundary]
[-boundary { {*x y*} {*x y*} {*x y*} {*x y*} ... }]
[-orientation N | W | S | E]
[-coincident_boundary true | false]
[-core_offset { *value* | *vertical_value horizontal_value* | *side_1 ... side_N*}]
[-row_core_ratio *ratio*]
[-flip_first_row true | false]
[-keep_pg_route]
[-keep_detail_route]
[-keep_placement {io macro block std_cell physical_only all}]
[-keep_objects *object_name_or_collection*]
[-keep_object_types {placement_blockage routing_blockage move_bound}]
[-keep_all]
[-honor_pad_limit]
[-site_def *site_def_name*]
[-use_site_row]
[-origin_offset {*x*, *y*}]
[-row_pattern {*row_pattern_name*}]

Data Types

ratio	float
x	float
y	float
value	float
vertical_value	float
horizontal_value	float
*side_**	float
object_name_or_collection	string or collection
site_def_name	string
row_pattern_name	string

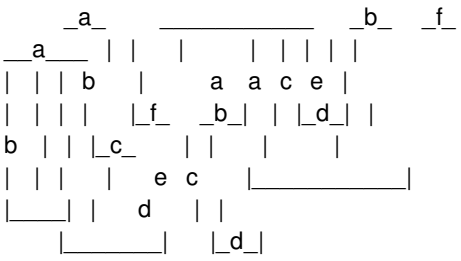
ARGUMENTS

-control_type core | die

Specifies whether the side_length and side_ratio options apply to the core or the die boundary. If set to die, then the dimensions will be applied to the die boundary and the core_offset values will be subtracted from the dimensions to determine the core boundary. If set to core (default), the dimensions will be applied to the core boundary and the core_offset values will be added to the dimensions to determine the final die boundary. By default, the control type is core.

-shape R | L | T | U

Specifies the shape to be used by the command. If the control_type is die, this option applies to the die boundary shape. The argument to this option specifies a template shape used to determine the cell boundary and core shape of the rectilinear block. The following diagram shows the definition of the edges and the orientation of the R-, L-, T-, and U- rectilinear blocks. By default, the core shape is R (rectangular).



-side_length { *side_a side_b side_c side_d side_e side_f*}

Specifies the side lengths for the edges of the floorplan. If the control_type is die, the side lengths apply to the die boundary. Each dimension in the list represents the length of the edge. If you provide more values than required to describe the specified shape, the extra values are ignored. If you do not provide all of the values required to describe the specified shape, the tool issues an error message. There are only two dimensions for **-shape R**: width and height. This option is mutually exclusive with the **-side_ratio** option.

-side_ratio { *side_a side_b side_c side_d side_e side_f*}

Specifies the relative proportion of the floorplan edges in relation to each other. If the control_type is die, the side rations apply to the boundary side settings. Each dimension in the list represents the relative proportion of the dimension of the edge to the sum of all the dimensions listed. For example, if the list of dimensions of an L-shaped block is {1 2 1 1}, the tool calculates the dimension of side a, c, or d (where the value is 1) as 20% (1/1+2+1+1) of the sum of the dimensions listed. The dimension of side b is 40% of the summation, and so on.

-core_utilization *ratio*

Specifies the utilization of the core area. The utilization is the total area of the core occupied by all standard cells and macro cells divided by the total core area. You can specify a value between 0 and 1. The cell area includes all standard and macro cells. For example, a core utilization of 0.8 specifies that 80 percent of the core area is used for cell placement at this stage. The tool might later add more cell area, the remaining area is available for routing. By default, the core utilization is 0.7.

-keep_boundary

Uses the existing die boundary. If this option is specified and the core-based constraints result in a core that is too large to fit in the existing die boundary, the command issues an error message. Default is not specified.

-boundary { {*x y*} {*x y*} {*x y*} {*x y*} ... }

Specifies the shape to be used by the command. If the control_type is core, then the boundary defines the core area and the

core_offsets should be added to create the die boundary. If control_type is die, then the core_offset is subtracted from the die boundary to create the core boundary.

-orientation N | W | S | E

Specifies one of four possible orientations for the specified rectilinear shape. The tool repositions the block to the specified orientation by rotating it in a clockwise direction. For **-shape R**, the orientation is always N.

-coincident_boundary true | false

Specifies whether the die boundary follows the shape of the core. If true, the die boundary assumes the same shape as the core and requires a **-core_offset** setting with the same number of sides as the core. If false, the die boundary is rectangular and the **-core_offset** option requires only four values. When the die boundary is rectangular it is created with **-core_offset** values such that the offset value is honored to the closest core edge on a per side basis. In this case, the bounding box of the die boundary is the minimum size that meets all four **-core_offset** values. By default, this option is true.

-core_offset { *value* | *vertical_value horizontal_value* | *side_1 ... side_N*}

Specifies the distance between the side of the core and the side of the die boundary. If only one value is specified, the value is used for all sides. If two values are specified, the first value is applied to all vertical edges and then second value is applied to all horizontal edges. Side numbers are based on the standard rectilinear numbering and do not correlate to the side_a, side_b, and so on. numbering scheme used to define the size of each edge. By default, the core offset equals to the minimum I/O cell height. If there are no I/O cells, the core offset is 0.

-row_core_ratio *ratio*

Specifies the amount of channel area between cell rows in the core area to reserve for routing. The *ratio* is a number between 0 and 1.0. A smaller row-to-core ratio creates more space for routing channels. A value of 1.0 creates no routing channel space. By default, the ratio is 1.0. Note that this ratio should be equal to or greater than the core utilization value.

-flip_first_row true | false

Specifies whether the command flips the first row at the bottom of the core area for horizontally placed cell rows, or flips the leftmost row for vertically placed cell rows. By default, this option is true.

-keep_pg_route

Specifies that the command keeps the PG routes and does not delete them. By default, the command delete all existing routes.

-keep_detail_route

Specifies that the command keeps all the routes except PG routes and does not delete them. By default, the command delete all existing routes.

-keep_placement {io macro block std_cell physical_only all}

Specifies that the command keeps the placement of specified object types. The valid value for this options are: *io, macro, block, std_cell, physical_only, all*.

io means objects with design type "*flip_chip_driver, flip_chip_pad, corner, pad, pad_spacer*";

macro means objects with design type "*macro, analog, abstract*";

block means objects with design type "*module, black_box*";

physical_only means objects with design type "*physical_only, fill*";

std_cell means objects with design type "*lib_cell, cover, diode, end_cap, well_tap, filler*";

all means all objects with design type list above.

-keep_objects *object_name_or_collection*

Specifies the objects to be kept. Currently supported objects are cells and nets. Specify the objects either by using an object access command, such as **get_cells** or **get_nets**, or by specifying object name patterns in a Tcl list.

-keep_object_types {placement_blockage routing_blockage move_bound}

Specifies the object type to be kept. Currently supported object types are placement_blockage, routing_blockage and move_bound.

-keep_all

Specifies this option to keep macro, std_cell, IO, physical_only, block, blockage, detail_route and pg_route.

-honor_pad_limit

Adjusts the core and die size to honor pad-limited designs. If this option is not specified, the core area is created based on the default core utilization ratio 0.7.

The option can be used only for rectangular floorplans, not for L, T, or U shapes.

The assumption for the command option is that the pad-type cells ()I/O pads or flip chip drivers) will be placed around the design boundary.

-site_def *site_def_name*

Specifies the site def to be used in floorplan when there are multiple site defs in the technology file. The default is to use default site def. If there is no default site def, the command uses the site def with the smallest site width.

-use_site_row

By default, the **initialize_floorplan** command creates siteArray objects. This option forces the command to create siteRow rather than siteArray.

-origin_offset {x y}

Specifies the location of the lower-left corner of the die boundary bbox with respect to the origin of the block.

-row_pattern {*row_pattern_name*}

Specifies the name of row_pattern to be used for floorplan when there are row patterns specification in the physical rule section of technology file.

DESCRIPTION

Creates a floorplan with a boundary, core, site array (or rows), and wire tracks. Before executing this command, you must open a physical design by using the **open_block** command, or create a design with the **read_verilog** or **read_verilog_outline** commands.

EXAMPLES

The following example creates a rectangular core and die boundary with a core utilization of 80% and a core offset of 1000 um for each side.

```
prompt> initialize_floorplan -core_utilization 0.8 \
    -core_offset {1000 1000 1000 1000}
```

The following example creates a rectangular die boundary and a T-shaped rectilinear core with the specified side dimensions for the core and a core_offset of 100 um for each side.

```
prompt> initialize_floorplan -control_type core -shape T \
        -side_length {1000 750 1500 750 1750 750} \
        -coincident_boundary false \
        -core_offset {100}
```

The following example creates a T-shaped rectilinear core and die boundary with the specified side dimensions for the core and a core offset of 100 um for each side.

```
prompt> initialize_floorplan -shape T \
        -side_length {1000 750 2500 500 3000 500} \
        -core_offset {100 100 100 100 100 100 100 100}
```

The following example creates a T-shaped rectilinear core and die boundary with the specified side ratios for the core and a core offset of 10 um for each side and a core utilization of 80%.

```
prompt> initialize_floorplan -core_utilization 0.8 \
        -shape T \
        -side_ratio {2 1 3 1 3 1} \
        -core_offset {100 100 100 100 100 100 100 100}
```

insert_buffer

Adds buffer cells on the nets that are connected to the specified pins.

SYNTAX

collection **insert_buffer**
[-new_net_names *new_net_names*]
[-new_cell_names *new_cell_names*]
[-inverter_pair]
[-no_of_cells *number*]
object_list
[-lib_cell *buffer_lib_cell* | *buffer_lib_cell*]

Data Types

new_net_names list
new_cell_names list
number integer
buffer_lib_cell collection
object_list list

ARGUMENTS

-new_net_names *new_net_names*

Specifies the names of the new nets to add. You must specify one net name per buffer when adding buffers, and two net names per inverter pair when adding inverter pairs. If the specified net name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the net name.

Optionally, if you specify only the common base name, the tool generates new net names by adding unique numeric suffixes to the common base name. The specified names can be any valid net names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance. By default, the command uses the base name eco_net.

-new_cell_names *new_cell_names*

Specifies the names of the new cells to be added. You must specify one cell name per buffer when adding buffers, and two cell names per inverter pair when adding inverter pairs. If the specified cell name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the cell name.

Optionally, if you specify only the common base name, the tool generates new cell names by adding unique numeric suffixes to the common base name. These names can be any valid cell names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance.

By default, the command uses *eco_cell* as the common base name.

-inverter_pair

Adds inverter pairs instead of buffer cells. If you specify this option, you must supply a library cell that has an inverting output. You can use this option when the specified library cell or buffer has both inverting and noninverting outputs.

-no_of_cells ***number***

Specifies the number of buffer cells or inverter pairs to be inserted per net. The inserted repeaters are connected back-to-back in series. By default, the command inserts a single buffer cell or inverter pair per net.

object_list

Specifies a list of nets, pins, or ports that must be buffered. The new buffer cells or inverter pairs are placed close to the specified pins or ports if their cells are placed.

If you specify a net, the tool connects the buffers or inverter pairs such that a new buffer cell is the new load of the original net.

If you specify pins, the tool groups all of the specified pins based on the nets to which they are connected. When the grouped pins are load pins, the tool adds the buffers so that the new buffer cells can drive them. When the grouped pins are driver pins, the tool connects the new buffer cells so that they become the load of the specified driver pin.

-lib_cell ***buffer_lib_cell***

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. This is a required option.

If the library cell has both inverting and noninverting outputs, that is, it can act both as buffer and inverter, the **-inverter_pair** option controls which output is used. If the library cell has multiple outputs, the command uses the first noninverting or inverting output.

buffer_lib_cell

This positional option is exactly equivalent to **-lib_cell**. And it is mutual exclusive with **-lib_cell**.

DESCRIPTION

This command adds buffers or inverter pairs at one or more specified pins or ports. A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

Like all other netlist editing commands, the command arguments to **insert_buffer** must be valid for the command to run successfully. If the command succeeds, the result is a collection of the newly-added cells. If the command fails, the command returns an empty collection or an empty string and does not change the netlist.

By default, each newly-created cell has a name beginning with the eco_cell string and ending with a unique numeric suffix. Each newly-created net has a name beginning with the eco_net string and ending with a unique numeric suffix. To override the automatic name generation by the tool, use the **-new_net_names** and **-new_cell_names** options.

You can mimic buffer addition by using other commands, such as **create_cell**, **create_net**, **disconnect_net**, and **connect_net**. The **insert_buffer** command provides a more efficient and safe way to add buffers.

This command support editing a verilog module in the module aspect, through **edit_module**.

This command honors design.eco_freeze_silicon_mode. When this app option is true, attribute is_fs_eco_add of buffers added will be true.

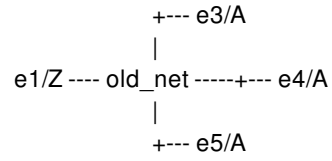
This command is exactly equivalent to **add_buffer**.

The **insert_buffer** command uses the following basic rules to check its arguments for validity:

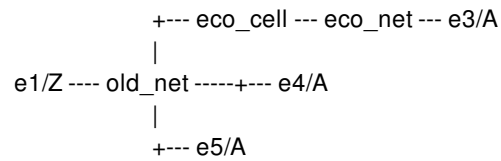
- The pin or port must be in scope; that is, at or below the current instance.
  For a description of special scoping rules, see the "Buffering Inside Boundary Pins" section.
- The pin or port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The net cannot be either a PG net or a tie net.
- The specified library cell cannot be sequential.
- The specified library cell must be a buffer, as previously defined.
- The *number* argument of the **-no_of_cells** option must be a positive, nonzero integer.
- The library cell must have an inverting output, when you use the **-inverter_pair** option.
  The command uses the first inverting output and adds two cells so that it preserves the logic of the path.

Adding and Connecting the New Buffer

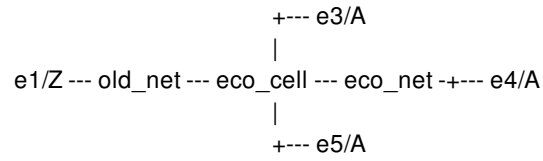
The following figure shows an example network that is used to describe the rules used by the **insert_buffer** command to connect the new buffer or inverter pair:



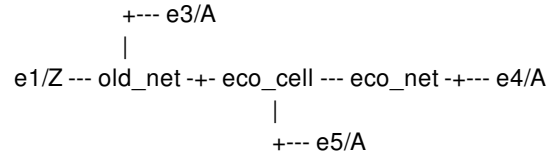
If the specified pin is a load, the load is first disconnected from its old net and then connected to the new net, as shown in the following figure:



If the specified pin is a driver, all loads on that net are disconnected from the old net and are connected to the new net, as shown in the following figure:



If you specify a list of load pins on the same net, these load pins are grouped and the new net drives them, as shown in the following figure:



Note that the tool cannot buffer a net driven by multiple drivers.

Buffering Inside Boundary Pins

When you use this command to add a buffer at a pin on the boundary of a hierarchical block, the command adds the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To add the buffer inside the hierarchical block, set the scope to that block by using the **current_instance** command, and then run the **insert_buffer** command. The tool adds the buffer within the block to which the **current_instance** is set.

Don't touch support for nets

When app option *eco.add_buffer.honor_dont_touch* is set to true, nets with dont_touch attribute are skipped.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a library cell that is not a buffer. The command fails and generates an error message.

```
prompt> insert_buffer e1/Z -lib_cell class/AN2P
Information: Buffering net old_net. (HFS-701)
Error: library cell 'AN2P' is not a buffer or an inverter. (ECOUI-010)
```

The following example specifies a buffer for the library cell:

```
prompt> insert_buffer e1/Z -lib_cell class/B1I
{eco_cell}
```

The following example specifies an inverter for the library cell. The command succeeds and creates the new cells named *eco_cell* and *eco_cell_1*. The new nets are named *eco_net* and *eco_net_1*. The **report_cells** command displays the connections for cell e3.

```
prompt> insert_buffer e3/A -lib_cell class/IV -inverter_pair
{eco_cell eco_cell_1}

prompt> report_cells -connections e3
****************************************
Report : cell
        -connections
****************************************

Connections for cell 'e3':
  Reference:        B1I
  Library:          class

  Input Pins        Net
  ----------------  ------------
  A                 eco_net

  Output Pins       Net
  ----------------  ------------

insert_dft

Inserts DFT structures in the current design

SYNTAX

status **insert_dft**

ARGUMENTS

This command has no arguments.

DESCRIPTION

insert_dft performs DFT structures insertion and routing. To insert scan compressor IP, clock controller or wrapper cells, use the applicable DFT configuration commands for that DFT logic type before running insert_dft.

EXAMPLES

prompt> insert_dft

insert_via_ladders

Inserts via ladders on pins with via ladder constraints.

SYNTAX

status **insert_via_ladders**
[-allow_drcs true | false]
[-allow_patching true | false]
[-allow_samenet_intersection true | false]
[-auto_stagger true | false]
[-bias_top_layer_to_samenet_connection true | false]
[-clean true | false]
[-connect_within_metal true | false]
[-connect_within_metal_for_via_ladder *mode*]
[-ignore_min_max_layer_constraints true | false]
[-ignore_rippable_shapes true | false]
[-ignore_routing_shape_drcs true | false]
[-ndr_mode full | top_layer_only | none]
[-ndr_on_top_layer_only true | false]
[-nets {*collection_of_nets*}]
[-pattern_must_join_over_pin_layer *number_of_levels*]
[-relax_line_end_via_enclosure_rule true | false]
[-relax_pin_layer_metal_spacing_rules true | false]
[-remove_routing_shapes_below_net_via_ladder_top_layer true | false]
[-shift_vias_on_transition_layers true | false]
[-strictly_honor_cut_table true | false]
[-top_layer_to_samenet_min_nonzero_distance *distance*]
[-user_debug true | false]
[-verbose true | false]

Data Types

mode string
{*collection_of_nets*} collection
number_of_levels int
distance float

ARGUMENTS

-allow_drcs true | false

Specifies whether via ladders are allowed to create DRC violations with routing shapes.

By default, this option is **false** and via ladders are inserted only if this can be done without creating any DRC violations.

If **true**, via ladder insertion tries to avoid creating DRC violations, but might create DRC violations with routing shapes if a clean solution cannot be found. Created DRC violations are tracked and reported by the command.

The recommended setting for this option is **false**. The via ladders that are created when this option is **true** might be structured to avoid DRC violations with routing shapes. Those routing shapes are often later ripped up and rerouted during detail routing. This option can therefore introduce a via ladder topology that is suboptimal and selected to avoid DRC violations with wires that might not be present after detail routing.

The recommended setting for optimal via ladder topology are **-allow_drcs false** and **-ignore_rippable_shapes true**, which is identical to **-ignore_routing_shape_drcs true**.

-allow_patching true | **false**

Specifies whether via ladder shapes can be patched to honor the minimum length rules specified in the technology file. The minimum length rules are specified by the **minLength** attribute in the Layer sections and The applicable minimum length on a layer is the maximum of these two values.

Generalized patching of other DRC types is not supported during via ladder insertion. However, the **upperMetalMinLengthTbl** attribute can sometimes be used to cover for other rule types.

The default is **false**.

-allow_samenet_intersection true | **false**

Specifies whether via ladder shapes on a net are allowed to intersect preroute shapes on the same net.

By default, this option is **false** and a via ladder is inserted on a pin but preroute shapes on the same net will be treated as blockages to be avoided. If the option is set to **true** a via ladder is allowed to touch other shapes on the same net as long as the result is DRC clean.

This option alone does NOT encourage connections to same net shapes. See the documentation for the **-bias_top_layer_to_samenet_connection** companion option.

-auto_stagger true | **false**

Specifies whether via ladder insertion is free to stagger by any amount on any layer to achieve a successful insertion.

The option only impacts attempts to insert via ladder template types that have no user-defined staggering values. If a template has user-defined values, the tool will honor those.

For example, auto stagger is only active for via ladder templates defined in the tech file with an empty or zeroed maxNumStaggerTracksTbl, or for Tcl-defined templates with empty or zeroed max_num_stagger_tracks_table. Staggering for other templates would occur normally, regardless of the option setting.

When auto stagger is active for an insertion attempt, the tool will analyze the track configurations and layout around the pin to determine if staggering should be enabled on a level of the via ladder and by how much. This relieves the need for a user to specify any staggering values in the template.

By default, this option is **false**.

-bias_top_layer_to_samenet_connection true | **false**

Specifies whether via ladder insertion should prefer to create a top level of a via ladder that intersects existing same net preroutes.

This option only has an impact when the **-allow_samenet_intersection** option is true and the top layer of a via ladder consists of 1 row.

If preconditions are met and this option is true, the tool always strongly prefers to create a via ladder top row so that it overlaps any existing samenet geometry on the top layer.

By default, this option is **false**.

-clean true | **false**

Specifies whether all existing via ladders in the design should be removed before proceeding with via ladder insertion.

By default, this option is **false** and existing via ladders are not removed. Insertion of a new via ladder is attempted only on pins that do not already have a via ladder.

-connect_within_metal true | **false**

Specifies whether via ladder shapes must be within pin shapes and their extensions on the pin layer.

This option controls both "is_via_ladder" and "is_pattern_must_join" shapes.

By default, this option is **false**.

-connect_within_metal_for_via_ladder ***mode***

Specifies whether via ladder shapes must be within pin shapes and their extensions on the pin layer.

This option controls only "is_via_ladder" shapes and overrides the setting of the **-connect_within_metal** option.

The default is **same_as_global**. The other two settings are **true** or **false**.

-ignore_min_max_layer_constraints true | **false**

Specifies whether minimum and maximum layer constraints are ignored during via ladder insertion.

By default, this option is **false**.

If **true**, minimum and maximum layer constraints will be ignored during via ladder insertion. Any "Min-max layer" DRC will not prevent successful insertion of a via ladder.

If **false** (default), a via ladder will not be inserted if minimum or maximum layer constraints would be violated.

-ignore_rippable_shapes true | **false**

Specifies whether detail routing shapes are ignored during via ladder insertion DRC checking.

By default, this option is **false**.

If **true**, via ladder insertion ignores any detail routing shape that the detail router would be allowed to reroute. DRCs are not checked against detail routing shapes during via ladder insertion.

-ignore_routing_shape_drcs true | **false**

This is a convenience option equivalent to using both **-allow_drcs false** and **-ignore_rippable_shapes true**, which are the recommended option settings for ideal via ladder topology.

By default, this option is **false**.

If **true**, any conflicting setting of the **-allow_drcs** and **-ignore_rippable_shapes** are ignored.

-ndr_mode full | **top_layer_only** | **none**

Controls how via ladders on nets with nondefault routing rules are created with default width wires.

If **full** (default), all layers of the via ladder will honor the NDR.

If **top_layer_only**, only the top layer of the via ladder will honor the NDR. All lower layers will use default width wires.

If **none**, the NDR is ignored and all layers of the via ladder will use default width wires.

This option replaces and overrides the **-ndr_on_top_layer_only** option. That legacy option will be obsoleted in a future release.

-ndr_on_top_layer_only true | false

Controls whether via ladders on nets with nondefault routing rules are created with default width wires.

By default, this option is **false** and the command honors the nondefault routing rules on all layers.

If **true**, the command honors the nondefault routing rules only on the top layer and uses default width wires on the lower layers.

-nets {*collection_of_nets*}

Specifies the nets on which to insert via ladders. A via ladder is inserted on pins with via ladder constraints only when the pin is also on one of the specified nets.

If you do not specify this option, via ladders are inserted on any pin with a via ladder constraint.

-pattern_must_join_over_pin_layer *number_of_levels*

Specifies number of levels of pattern-must-join structure. The default value is 1, and the maximum is 2.

- If the value set to 1, a single-level pattern-must-join structure is inserted.
- If the value set to 2, a single via is added on top of the original single-level pattern-must-join structure. The via on the second level has the **is_pattern_must_join** attribute and the router connects to it through its upper via enclosure.

-relax_line_end_via_enclosure_rule true | false

Specifies whether the command ignores the "End extension for via enclosure" rule during via ladder insertion.

By default, this option is **false**.

-relax_pin_layer_metal_spacing_rules true | false

Specifies whether the command can ignore some metal spacing rules on the pin layer during via ladder insertion whenever the involved via ladder shape is fully contained within the pin. This includes the "Diff net spacing," "End to end forbidden spacing," and "End to end space keepout" DRC types.

By default, this option is **false**.

-remove_routing_shapes_below_net_via_ladder_top_layer true | false

Specifies whether to remove all routing shapes below the maximum instantiated via ladder top layer on all nets with via ladders.

By default, this option is **false**.

If **true**, after inserting a via ladder on a net, the tool removes all routing shapes below the top layer of all inserted via ladders on that net.

-shift_vias_on_transition_layers true | false

Specifies whether via ladder cuts on transition layers can be shifted off the routing tracks for improved DRC compliance.

By default, this option is **false** and via ladder cuts are always centered at the intersection of routing tracks between adjacent layers.

If **true**, via ladder cuts can be shifted off track on transition layers for improved DRC compliance.

-strictly_honor_cut_table true | false

Specifies whether via ladder insertion must strictly honor the cuts specified in the via rule definition.

By default, this option is **false** and via ladder insertion usually honors the cuts specified in the via rule definition, but can choose

other cuts if they improve compliance with the fat via rules.

If **true**, via ladder insertion strictly honors the cut names specified in the via rule definition.

-top_layer_to_samenet_min_nonzero_distance ***distance***

This option only has an impact when the **-allow_samenet_intersection** option is true and bias_top_layer_to_samenet_connection is true.

See the documentation for the **-bias_top_layer_to_samenet_connection** option.

If a legal directly-overlapping top layer connection is not possible and a **-top_layer_to_samenet_min_nonzero_distance** value is specified, the tool tries to create a top layer row at least this distance from any samenet layout on the top layer. If this distance is not supplied or is 0, a row may be created any legal distance from samenet layout when a direct connection is impossible.

The distance is specified in user units.

If distance is supplied and a legal solution cannot be found, the tool tries to create any legal via ladder that satisfies all other constraints. I.e. the tool would create a via ladder as if the **-bias_top_layer_to_samenet_connection** option is false.

The default is **0**.

-user_debug true | **false**

Specifies whether to print additional information about via ladder insertion failures.

By default, this option is **false**.

If **true**, the command outputs information about track restrictions and flagged DRC types when via ladder insertion fails on a pin. This information can help you understand why via ladder insertion failed.

-verbose true | **false**

Species whether the command prints the success or failure status of each attempted via ladder insertion.

By default, this option is **false**.

DESCRIPTION

The **insert_via_ladders** command inserts via ladders on pins with via ladder constraints.

Via ladder rules are specified in a ViaRule section of the technology file or by using the **create_via_rule** command.

Via ladder constraints are assigned to pins by using the **set_via_ladder_constraints** or **set_via_ladder_rules** command.

EXAMPLES

The following example inserts a via ladder on any pin with a via ladder constraint. Non-fixed detail routing shapes are ignored. Patching is allowed. Extra information is printed for any via ladder insertion failure.

```
prompt> insert_via_ladders -ignore_routing_shape_drcs true \
  -allow_patching true -user_debug true
```

The following example removes all via ladders in the design and tries to create new via ladders.

```
prompt> insert_via_ladders -clean true -ignore_routing_shape_drcs true \
  -allow_patching true -user_debug true
```

The following example allows "is_via_ladder" shapes to extend beyond the pins, while confining "is_pattern_must_join" shapes within the pins.

```
prompt> insert_via_ladders -connect_within_metal true \
  -connect_within_metal_for_via_ladder false
```

is_false

Tests the value of a specified variable, and returns 1 if the value is 0 or the case-insensitive string **false**; returns 0 if the value is 1 or the case-insensitive string **true**.

SYNTAX

status **is_false**
value

Data Types

value string

ARGUMENTS

value

Specifies the name of the variable whose value is to be tested.

DESCRIPTION

This command tests the value of a specified variable, and returns 1 if the value is either 0 or the case-insensitive string **false**. The command returns 0 if the value is either 1 or the case-insensitive string **true**. Any value other than 1, 0, **true**, or **false** generates a Tcl error message.

The **is_false** command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings **true** or **false**. When such variables are set to **true** or **false**, they cannot be tested in the negative in an **if** statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x FALSE
if { !$x } {
  set y TRUE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, **is_false** allows you to test both conditions safely.

EXAMPLES

The following example shows the use of the **is_false** command:

```
prompt> set x TRUE
TRUE

prompt> if { ![is_false $x] } {
?       set y TRUE
?     }
TRUE

prompt>
```

SEE ALSO

expr(2)

is_true(2)

is_true

Tests the value of a specified variable, and returns 1 if the value is 1 or the case-insensitive string **true**; returns 0 if the value is 0 or the case-insensitive string **false**.

SYNTAX

status **is_true**
value

Data Types

value string

ARGUMENTS

value

Specifies the name of the variable whose value is to be tested.

DESCRIPTION

This command tests the value of a specified variable, and returns 1 if the value is either 1 or the case-insensitive string **true**. The command returns 0 if the value is either 0 or the case-insensitive string **false**. Any value other than 1, 0, **true**, or **false** generates a Tcl error message.

The **is_true** command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings **true** or **false**. When such variables are set to **true** or **false**, they cannot be tested in the negative in an **if** statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x TRUE
if { !$x } {
  set y FALSE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, **is_true** allows you to test both conditions safely.

EXAMPLES

The following example shows the use of the **is_true** command:

```
prompt> set x FALSE
FALSE

prompt> if { ![is_true $x] } {
?       set y FALSE
?     }

FALSE

prompt>
```

is_false(2)

legalize_placement

Executes detailed placement on the current design.

SYNTAX

status **legalize_placement**
[-cells *list_of_cells*]
[-moveable_distance *distance*]
[-boundary { {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }]
[-incremental]
[-post_route]

Data Types

list_of_cells list or collection
distance float

ARGUMENTS

-cells *list_of_cells*

Specifies the cells to be legalized. You must set app-option 'place.legalize.legalize_only_selected_cells' to true or use command 'place_eco_cells -cells -legalize_only' before legalize_placement -cells. Without specifying the **-moveable_distance** option, only those cells will be legalized and all other cells not in the list will remain unchanged, no matter they are legal or not.

Example: To legalize all BUF* cells in the design

prompt> **set_app_option -name place.legalize.legalize_only_selected_cells -value true** prompt> **legalize_placement -cells [get_cells BUF*]** or prompt> **place_eco_cells -cells -legalize_only** prompt> **legalize_placement -cells [get_cells BUF*]**

Example: To legalize individual cells in the design

prompt> **set_app_option -name place.legalize.legalize_only_selected_cells -value true** prompt> **legalize_placement -cells "cellA cellB cellC"** or prompt> **place_eco_cells -cells -legalize_only** prompt> **legalize_placement -cells "cellA cellB cellC"**

-moveable_distance *distance*

By default, the value of moveable_distance is 0.0. That means only the specified cells will be legalized. When user specifies a moveable_distance value, other cells around that target cell will become moveable during legalization.

The size of moveable rectangle region based on the given distance will be {{llx - moveable_distance lly - moveable_distance} {urx + moveable_distance ury + moveable_distance}}. All the cells inside that rectangle region will be legalized and moveable while other cells not in the region will remain unchanged during legalization.

The moveable_distance value should be equal or larger than 0.0, and it can be used only with -cells option.

Example: To legalize all BUF* cells in the design, and include other cells around each BUF* cells within the specific distance

prompt> **legalize_placement -cells [get_cells BUF*] -moveable_distance 100**

To customize the moveable_distance value per cell instead of a global moveable_distance value, like high density area or critical timing area, user can create an user-defined attribute, and specify different moveable_distance value per cell. For example:

prompt> **define_user_attribute -type float -classes cell -name moveable_distance**

prompt> **set_attribute -name moveable_distance -value 1 [get_cells A]**

prompt> **set_attribute -name moveable_distance -value 100 [get_cells B]**

prompt> **set_attribute -name moveable_distance -value 10000 [get_cells C]**

prompt> **legalize_placement -cells "A B C" -moveable_distance 500**

So cell A will use 1 as its region value, cell B will use 100 as its region value and cell C will use 1000 as its region value. For other cells, they will use 500 as the region value.

The moveable distance will be considered during legalization only if user also specifies the **-cells** option.

-boundary { {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }

Instead of specifying a collection of cells, user can use the **-boundary** option to specify a region of cells to legalize without knowing the cell name. The boundary syntax is {{llx lly} {urx ury}} or {{x1 y1} {x2 y2} ...}. All cells inside the specific region will be included and legalized while other cells will remain unchanged. Note that -boundary option includes cells based on cell's bbox, not based on cell's boundary bbox. In certain situations, cell's bbox may be bigger than cell's boundary bbox, so please make sure the -boundary region if it is very close to cells, user should check the cell's bbox values and adjust -boundary if needed.

Users may start the GUI to identify the area, get the coordinate information, and run legalization with the **-boundary** option to only legalize that specific area they have interest while other area will remain same. This option is similar to using the **-cells** option without the **-moveable_distance** option, but users don't have to know the all cell names.

The **-boundary** option should be exclusive with the **-cells** or **-moveable_distance** option.

Example: To legalize all cells inside the boundary without knowing their names

prompt> **legalize_placement -boundary {{100 100} {1500 1500}}**

-incremental

By using the **-incremental** option, **legalize_placement** first tries to find all illegal cells. The API used is same as for the **check_legality** command. Once it finds illegal cells, the **legalize_placement** command only legalizes those illegal cells while other legal cells will remain the same without any change. This is good idea when you don't know which cells are illegal, or you don't want to modify an existing design for those legal cells. The tradeoff is that when legalizer tries to fix those illegal cells, as legal cells will remain at the same location and cannot be moved, it may cause legalizer to move illegal cells to other available locations and cause larger displacement. You can use the **-cells** and **-moveable_distance** options to allow the legalizer to move some cells around those illegal cells to resolve larger displacement if this is needed.

The **-incremental** option should be exclusive with **-boundary** option.

-post_route

Specifies that post-route mode should be used. Legalizer will try to remain original orientation as possible.

DESCRIPTION

The **legalize_placement** command performs placement on the current design after coarse placement has already been performed.

When you run this command, the design should contain a floorplan with a site array specified and all cells and blockages in the design should have an initial location.

Multicorner-Multimode Support This command uses information from all active scenarios.

EXAMPLES

The following example runs the **legalize_placement** command:

```
prompt> legalize_placement
```

SEE ALSO

create_placement(2)

legalize_rp_groups

Executes detailed placement of relative placement groups in a design.

SYNTAX

status **legalize_rp_groups**
[*rp_groups*]
[-legalize_over_rp]

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups for which you want to do detailed placement. If you do not specify this option, the command performs detailed placement on all relative placement groups of current block.

-legalize_over_rp

Controls the detailed placement of the specified relative placement groups. When this option is set, the cells of the specified relative placement groups can be legalized over the cells of unspecified relative placement groups.

-prototype

Enables faster legalization of the RP groups. If you specify this option then RP groups will be legalized much faster compared to when this option is not used. Specifying **-prototype** option disables few advanced rules resulting in faster search of legal location for cells.

DESCRIPTION

The **legalize_rp_groups** command performs placement legalization of relative placement groups in the current block, where coarse placement has already been performed. It is necessary to specify a site array for the floorplan. The legalization of relative placement groups of child blocks can not be done by this command.

Note: After you ran this command, the specified relative placement groups might overlap other unfixed cells. Therefore, you might need to run the **legalize_placement** command. If you do not need to perform detailed placement on the specified relative placement groups again, those relative placement groups can be fixed before you run the **legalize_placement** command. You can unfix them after running the **legalize_placement** command if necessary.

EXAMPLES

The following examples show how to use the **legalize_rp_groups** command.

prompt> **legalize_rp_groups rp_group**

prompt> **legalize_rp_groups rp_group -legalize_over_rp**

prompt> **legalize_rp_groups -prototype**

link_block

Resolves block references.

SYNTAX

status **link_block**
[-force]
[-rebind | -incremental]
[-verbose]
[*block_name*]

Data Types

block_name string

ARGUMENTS

-force

Forces the block to relink, even if the block is already linked. If this option is not specified, the command does not link a block if it is already linked.

-rebind

Rebind all references using the current ref_lib list, view switch list and label switch list. The **-rebind** option is mutually exclusive with the **-incremental** option.

-incremental

Update only unresolved references. The **-incremental** option is mutually exclusive with the **-rebind** option.

-verbose

Writes out additional debugging messages.

block

Specifies the name of the block to be linked. If you do not specify this option, the command links the current block.

DESCRIPTION

This command performs a name-based resolution of block references for the specified *block_name* or for the current block.

References are resolved using other modules within this block, top modules of other physical hierarchy blocks, and leaf cells within lib cell libraries.

Libraries specified in the ref_lib list are then searched in order for references to physical hierarchy blocks and lib cells. The ref_lib list uses the *search_path* variable to locate libraries. The ref_lib list is usually set when the library is created with the **create_lib** command, but can be updated with the **set_ref_libs** command.

Physical hierarchy blocks can have multiple block views. The command determines the initial block view to use to resolve a reference based on the view switch list for the current block. If none of the selected views of a block exist, the reference is left unbound. Once bound to a particular view, a cell remains bound to that view unless rebound with **link_block -rebind**, **change_view**, or **change_abstract**. Use the **set_view_switch_list** command to set the view switch list for the session, a library, or a block.

Physical hierarchy blocks can also have multiple user labels. The reference resolves by default to the user label of the top-level block when label switch list is absent. For example, if the top-level block is created with the "netlist" label or unnamed ("") label, then all physical hierarchy block references are resolved using the respective label. If labels are absent, it will remain linked in its previous state. Note that lib-cell references unlike hierarchcical blocks, are only available and resolved under the default label. Once bound to a particular label, a cell remains bound to that label unless rebound with **link_block -rebind**. Use the **set_label_switch_list** command to set the label switch list for the session, a library, or a block.

Physical hierarchy blocks in a reference library can be linked using that library's ref_lib list by setting the *use_hier_ref_libs* attribute on that library to "true".

Unresolved References

If the linker fails to resolve one or more references, it creates an unbound leaf cell for each unresolved reference. To fix the problem, first determine and correct the source of the problem, then relink the block using the **link_block** command with the **-force** option. Failures are typically caused by missing libraries or blocks, an incorrectly specified ref_lib list, an incorrectly specified view switch list, label switch list or an incomplete *search_path* variable.

If you can resolve the references by changing the ref_lib list, view switch list, label switch list or *search_path* variable, you must relink the block with **link_block -rebind -force**.

You can limit the detailed reporting for unresolved references by setting the *link.reference_limit* app option. After this limit has been reached, the command reports only a summary of the number of additional unresolved references. Change *link.reference_limit* app option with the **set_app_options** command. Information on **link_block** app options can be found in the *link_options* manual page.

Link Errors

Mismatched port references to a lib cell or to a module in the same block cause the **link_block** command to fail. To correct the problem, you must remove the block, correct the Verilog netlist, and reread the design.

Circular or recursive module references cause the **link_block** command to fail. To correct the problem, you must remove the block, correct the Verilog netlist, and reread the design.

Auto Link

Many commands automatically link the current block before executing. These automatic links are always incremental, and might not fully rebind block references when the reference library list, view switch list or label switch list is changed. To force a full relink and rebinding of the block, use the **link_block -force -rebind** command.

EXAMPLES

In the following example, block TOP in library blockLib is linked to the physical hierarchy blocks MID and BOT, and the lib cell library

leafCellLib.

```
prompt> link_block TOP
Using libraries: designLib leafCellLib
Linking design TOP
Linking design BOT
Linking design MID
Information: units loaded from library 'leafCellLib' (LNK-040)
Design 'TOP' was successfully linked.
1
```

The following example shows the linking and relinking of views and labels.
The following commands set and get global view switch list.

```
prompt> set_view_switch_list {design abstract frame outline}
prompt> get_view_switch_list
design abstract frame outline
```

Similarly, the following commands set and get the global label switch list.

```
prompt> set_label_switch_list {label3 label2 label4 label1}
prompt> get_label_switch_list
label link map: { * {label3 label2 label4 label1 } }
```

Initial linking of views and labels is shown below :

```
prompt> current_design TOP
{leafCellLib:TOP.design}

prompt> link_block
Warning: Block 'leafCellLib:TOP.design' is already linked. (LNK-067)
0
prompt> get_blocks MID -hierarchical
{leafCellLib:MID.design}
```

The following command relinks and blocks are rebound to abstract view and label2 label.

```
prompt> set_view_switch_list {abstract frame design}
prompt> set_label_switch_list {label2 label3 label4 label1}
prompt> link_block -rebind
prompt> get_blocks MID -hierarchical
{leafCellLib:MID/label2.abstract}
```

The following command fails to rebind as the specified labels of block MID are absent.
The binding of block MID remains unchanged.

```
prompt> set_label_switch_list {label4 label1}
prompt> link_block -rebind
prompt> get_blocks MID -hierarchical
{leafCellLib:MID/label2.abstract}
```

For more info, see man page of these commands.

list_attributes

Lists currently defined attributes.

SYNTAX

string **list_attributes**
[-application]
[-class *class_name*]
[-nosplit]

class_name string

ARGUMENTS

-application

Lists application attributes as well as user-defined attributes.

-class *class_name*

Limit the listing to attributes of a single class.

To determine the valid classes, use the **get_defined_attributes -return_classes** command.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the output. Most of the information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **list_attributes** command displays an alphabetically sorted list of currently defined attributes. There are two categories of tool attributes: application-defined and user-defined. By default, **list_attributes** lists all user-defined attributes.

To add the application attributes to the listing, use the **-application** option. Note that there are many application attributes. It is often useful to limit the listing to a specific object class by using the **-class** option.

EXAMPLES

The following example lists the attributes defined with the **define_user_attribute** command.

```
prompt> list_attributes

list_blocks

List blocks in one or more libraries.

SYNTAX

int **list_blocks** [-ref_libs] [-lib_cells] [*libraries*]

list *libraries*

ARGUMENTS

-ref_libs

List blocks from libraries in the current blocks's (or current library's) ref_lib list.

-lib_cells

Also list lib_cells within lib_cell libraries.

libraries

List blocks only from the given list of libraries.

-refresh

Refresh library catalog to bring in additional blocks added by another process.

DESCRIPTION

The **list_blocks** command lists the blocks from the specified libraries. By default, blocks from all libraries are listed. If a list of libraries are given, then only blocks from those libraries are listed. With the -ref_libs option, blocks are listed from the libraries in the order of the ref_libs for the current block. By default lib cells from lib cell libraries are not list. Lib cells can be listed with the -lib_cells option.

Each library is listed with its name and path. The current library is tagged "current". Libraries containing technology sections are tagged "tech". Lib cell libraries are tagged "lib_cell".

Each block in a library is listed with the block name and the block view type (abstract blackbox design frame outline timing). Each block has a count of the number of blocks containing instances that currently bound to this block.

Open blocks are marked with a "+", modified blocks are marked with a "*". Designs are tagged with their modification date or last saved date. The current block is tagged "current". Lib cell blocks are tagged "lib_cell".

Designs selected to resolve references by the **link_block** command are marked with a ">". This depends on the current block, the view switch list, and the current library's ref_lib list. See the **link_block** command for more information on linking blocks.

Many of these values can be accessed with the **get_attribute** command, see the **get_attribute** and **list_attributes** commands for more information on attributes.

EXAMPLES

This example lists the current blocks in libraries.

```
prompt> list_blocks
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>  1 BOT.design Jul-23-09:29
  -   1 BOT.frame  Jul-23-10:14
Lib legacy.nlib /user/joe/mylibs/legacy.nlib tech
  -   1 BOT.design Aug-31-2011
  -   1 MID.design Sep-14-2011
  +   0 TOP.design Oct-03-2011
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>  1 MID.design Jul-23-09:29
  *>  0 TOP.design Jul-23-09:29 current
7
```

This example lists the libraries in the current block's ref_lib list.

```
prompt> list_blocks -ref_libs
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>  1 MID.design Jul-23-09:29
  *>  0 TOP.design Jul-23-09:29 current
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>  1 BOT.design Jul-23-09:29
  -   1 BOT.frame  Jul-23-10:14
4
```

This example also lists the lib cell library.

```
prompt> list_blocks -ref_libs -lib_cells
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>  1 MID.design Jul-23-09:29
  *>  0 TOP.design Jul-23-09:29 current
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>  1 BOT.design Jul-23-09:29
  -   1 BOT.frame  Jul-23-10:14
Lib techlib /project/exportLibs/techlib.nlib lib_cell tech
  -   0 INV.design Jun-27-2011 lib_cell
  +   0 INV.frame  Jun-27-2011 lib_cell
  +>  3 INV.timing Jun-27-2011 lib_cell
  -   0 ND2.design Jun-27-2011 lib_cell
  +   0 ND2.frame  Jun-27-2011 lib_cell
  +>  3 ND2.timing Jun-27-2011 lib_cell
        ...
  -   0 MUX8.design Jun-27-2011 lib_cell
  +   0 MUX8.frame  Jun-27-2011 lib_cell
  +>  1 MUX8.timing Jun-27-2011 lib_cell
```

```
2254
```

This example lists blocks in the specified library.

```
prompt> list_blocks legacy.nlib
Lib legacy.nlib /user/joe/mylibs/legacy.nlib tech
  -  1 BOT.design Aug-31-2011
  -  1 MID.design Sep-14-2011
  +  0 TOP.design Oct-03-2011
3
```

list_commands

Prints list of all the commands.

SYNTAX

status **list_commands**
[pattern]
[-status {*command_status*}]
[-options]
[-bg]

Data Types

pattern string
command_status string

ARGUMENTS

pattern

Specifies to print the commands matching this pattern only.

-status {*command_status*}

Specifies to print the commands of this status only.

Status can be one of normal, obsolete, deprecated, retired or all. Default value is all.

-options

Specifies to print the list of command options of the commands also.

-bg

Specifies to print the list of command supported within redirect -bg.

DESCRIPTION

The **list_commands** command will print names of all the commands and their attributes such as status (normal/deprecated/obsolete) and read-only/undoable by default.

When a pattern is specified after **list_commands**, only commands matching the pattern will be printed. Further the list of commands

can be filtered using *-status* option.

When *-options* is specified it will print the command options of the commands with their status (normal/deprecated).

EXAMPLES

The following example lists all the commands.

```
prompt> list_commands

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name             Attributes
------------             ----------
add_attachment           N
add_buffer               N, U
add_buffer_on_route      N, U
 ...
```

The following example lists all the commands with their command options and options attributes.

```
prompt> list_commands -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name          Attributes    Command Options    Options Attributes
------------          ----------    ---------------    ------------------
add_attachment        N             -file_name         N
                                    -object            N
                                    name               N

add_buffer            N, U          -inverter_pair     N
                                    -lib_cell          N
                                    -new_cell_names    N
                                    ...
 ...
```

The following example lists all the commands which match the pattern 'fi' with their command options and options attributes.

```
prompt> list_commands fi -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name          Attributes    Command Options    Options Attributes
------------          ----------    ---------------    ------------------
find_objects          N, R          -direction         N
```

```
                          -exact          N
                          -leaf_only      N
                          ...

   fix_signal_em      N          -nets          N
    ...
```

The following example lists all the commands which match the pattern 'map' and have status 'normal' with their command options and options attributes.

```
prompt> list_commands map -status normal -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name             Attributes    Command Options    Options Attributes
------------             ----------    ---------------    ------------------
map_freeze_silicon        N, U         -eco_cell          N
                                       -map_file          N
                                       -spare_cell        N
                                       ...

map_isolation_cell        N           -domain            N
                                       -lib_cells         N
                                       ...

map_level_shifter_cell    N           -domain            N
                                       -lib_cells         N
                                       ...
 ...
```

The following example lists all the commands supported within redirect -bg.

```
prompt> list_commands -bg

Commands allowed in redirect -bg are:
- all_clocks
- all_connected
 ...
```

list_licenses

Displays a list of licenses currently checked out by the user.

SYNTAX

status **list_licenses**

ARGUMENTS

The **list_licenses** command has no arguments.

DESCRIPTION

The **list_licenses** command lists the licenses you currently have checked out. If more than one copy of a license key is checked out, the number of keys checked out is shown in parentheses following the license name.

EXAMPLES

The following example shows the output from **list_licenses**:

```
prompt> list_licenses
Licenses in use:
        Fusion-Compiler-BE (2)
        Fusion-Compiler-AG (2)
1
```

SEE ALSO

check_license(2)
get_licenses(2)
remove_licenses(2)

list_test_models

Lists the designs in memory that have CTL test models attached to them.

SYNTAX

status **list_test_models**

ARGUMENTS

The **list_test_models** command has no arguments.

DESCRIPTION

This command displays the designs in memory that have CTL test models attached to them. Designs that do not have CTL test model information are not listed. All designs in memory are analyzed, even if they are not a part of the current design or its hierarchy.

EXAMPLES

The following example lists the designs that have CTL test model information:

```
prompt> list_test_models
  des_unit                  /remote/my_dir/des_unit_xtol/db/des_unit.db
  des_unit_SCCOMP_COMPRESSOR     /remote/my_dir/des_unit_xtol/ \
                        des_unit_SCCOMP_COMPRESSOR.db
  des_unit_SCCOMP_DECOMPRESSOR   /remote/my_dir/des_unit_xtol/ \
                        des_unit_SCCOMP_DECOMPRESSOR.db
```

list_test_modes

Displays all of the test modes that are defined for the current design.

SYNTAX

status **list_test_modes**

ARGUMENTS

The **list_test_modes** command has no arguments.

DESCRIPTION

The **list_test_modes** command displays all of the modes defined for the current design. The **define_test_mode** command is used to define a mode of operation for a design.

If a design does not have any test modes defined, it displays the message "Design has no test modes."

EXAMPLES

The following is an example of the test modes report:

```
prompt> list_test_modes
Test Modes
==========

    Name: ScanCompression_mode
    Type: InternalTest
    Focus:
    Core des_unit_U_decompressor in decompress mode
    Core des_unit_U_compressor in compress mode

    Name: Internal_scan
    Type: InternalTest
    Focus:
```

```
        Name: Mission_mode
        Type: Normal
    1
```

lminus

Removes one or more named elements from a list and returns a new list.

SYNTAX

list **lminus**
[-exact]
original_list
elements

Data Types

original_list list
elements list

ARGUMENTS

-exact

Specifies that the exact pattern is to be matched. By default, **lminus** uses the default match mode of **lsearch**, the **-glob** mode.

original_list

Specifies the list to copy and modify.

elements

Specifies a list of elements to remove from *original_list*.

DESCRIPTION

The **lminus** command removes elements from a list by using the element itself, rather than the index of the element in the list (as in **lreplace**). The **lminus** command uses the **lsearch** and **lreplace** commands to find the elements and replace them with nothing.

If none of the elements are found, a copy of *original_list* is returned.

The **lminus** command is often used in the translation of Design Compiler scripts that use the subtraction operator (-) to remove elements from a list.

EXAMPLES

The following example shows the use of the **lminus** command. Notice that no error message is issued if a specified element is not in the list.

```
prompt> set l1 {a b c}
a b c

prompt> set l2 [lminus $l1 {a b d}]
c

prompt> set l3 [lminus $l1 d]
a b c
```

The following example illustrates the use of **lminus** with the **-exact** option:

```
prompt> set l1 {a a[1] a* b[1] b c}
a a[1] a* b[1] b c

prompt> set l2 [lminus $l1 a*]
{b[1]} b c

prompt> set l3 [lminus -exact $l1 a*]
a {a[1]} {b[1]} b c

prompt> set l4 [lminus -exact $l1 {a[1] b[1]} ]
a a* b c
```

SEE ALSO

lsearch(2)

load_block_constraints

Loads constraints for child and/or top blocks.

SYNTAX

status **load_block_constraints**
-type PRECHECK | DEF | UPF | SDC | BUDGET | CLKNET | CTS_CONSTRAINT | BTM | FLOORPLAN | SCANDEF
-all_blocks | -blocks *block_designs*
[-host_options *host_option_name*]
[-work_dir *directory_name*]

Data Types

block_designs list
host_option_name string
directory_name string

ARGUMENTS

-type PRECHECK | DEF | UPF | SDC | BUDGET | CLKNET | CTS_CONSTRAINT | BTM | FLOORPLAN | SCANDEF

Specifies the type(s) of constraints to load or check. Valid values are: PRECHECK, DEF, UPF, SDC, BUDGET, CLKNET, CTS_CONSTRAINT, BTM, FLOORPLAN, SCANDEF. The values are case-insensitive.

The types, except *PRECHECK*, correspond to the keywords used in the constraint mapping file set through **set_constraint_mapping_file** command.

When type *PRECHECK* is specified, the tool prints information about the physical hierarchy tree of the design. If any other type is specified together with type *PRECHECK*, the information in the constraint mapping file related to the specified type is also reported.

When the command is issued without type *PRECHECK*, the tool loads the constraint of the specified types to the specified blocks according to information in the constraint mapping file.

You can specify *-type* multiple times with one **load_block_constraints** command.

-all_blocks

Loads constraints for all the child blocks in the current design and the current design itself, if the specified constraint types for the block are available in the constraint mapping file.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and runs the blocks in a bottom-up order.

This option is mutually exclusive with *-blocks*. One and only one of them should be specified.

-blocks *block_designs*

Specifies the list of child block designs to load constraints to.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and runs the blocks in a bottom-up order.

This option is mutually exclusive with *-all_blocks*. One and only one of them should be specified.

-host_options *host_option_name*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

-work_dir *directory_name*

Writes all generated scripts and log files to the specified directory.

By default, the work directory is *./work_dir*. If there are host option settings for distributed processing, the work_dir setting from the host option is used. This option takes precedence over the default and the host option setting.

DESCRIPTION

This command loads constraints for child blocks as well as for top level.

The tool gets the constraint files from the constraint mapping file. See the man page for **set_constraint_mapping_file** for details of how to set up the constraint mapping file.

DEF constraints are loaded through command **read_def**.

UPF constraints are loaded through command **load_upf** and only when UPF constraints has not been loaded previously for a given block. After **load_upf** is run, **commit_upf** is performed.

SDC constraints are loaded through command **source**. Operations **remove_modes -all** and **remove_corners -all** are performed before loading the SDC constraints for a block.

BTM stands for *blackbox timing model*. BTM constraints are loaded using command **source**.

FLOORPLAN, CLKNET and BUDGET constraints are loaded through command **source**.

CTS_CONSTRAINT constraints are loaded through command **source**. Then **synthesize_clock_trunks** is performed on the block.

Only blocks whose specified constraint types that are available in the constraint mapping file are run. If the abstract view exists for a block, the same type of abstract would be re-created after loading the constraints for that block.

If a block started as an outline view, command **expand_outline** is first performed on the block. Then constraints are loaded for the block and the abstract view is created. Any necessary **change_abstract** commands are added for any parent block where it is needed.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and run the blocks in a bottom-up order.

EXAMPLES

The following example UPF and SDC for all the child blocks as well as the top level are loaded.

```
prompt> set_constraint_mapping_file ./split/mapfile
prompt> load_block_constraints -all_blocks -type SDC -type UPF
```

The following example shows that FLOORPLAN constraints are loaded to all the child blocks as well as the top level.

```
prompt> set_constraint_mapping_file ./floorplan/mapfile
prompt> load_block_constraints -all_blocks -type FLOORPLAN
```

The following example CTS constraints are loaded to the block BOT and **synthesize_clock_trunks** is performed on BLK_A.

```
prompt> load_block_constraints -blocks BLK_A -type cts_constraint
```

The following example prints information about the design's physical hierarchy.

```
prompt> load_block_constraints -type precheck
```

SEE ALSO

commit_blackbox_timing(2)
report_constraint_mapping_file(2)
set_constraint_mapping_file(2)
write_floorplan(2)

load_busplans

Loads XML data and re-creates busplans.

SYNTAX

status **load_busplans**
-xml_file *filename*
[-only_create]
[-replace_existing]
[-verbose]
[-ignore_mib_compliance]
[-buses *patterns*]

Data Types

filename string
patterns string (patterns)

ARGUMENTS

-xml_file *filename*

Specifies the name of the XML data file to read. The XML file should have the same format as written by the *write_busplans -xml_file filename* command.

-only_create

Creates only the start and end parts of the busplans in the data file. No virtual registers or pins will be re-inserted into the busplans.

-replace_existing

Remove the existing busplan, specified by the **-buses patterns** argument, before re-creating it. Matching is done only based on busplan name; no other checking is done. If not specified, busplans that already exist are skipped.

-verbose

Prints more detail about each busplan as it is being re-created. Messages include errors detected during the process. Otherwise, the command prints only a summary at the end.

-ignore_mib_compliance

Do not try to re-create busplans in the order required for MIB compliance. As well, if any required MIB parent busplans are not in the explicit list of busplans to re-create, do NOT add them to the list automatically.

By default, MIB parent busplans will be created first, even if they appear later in the XML file, or are not in the explicit list of

busplans to re-create.

-buses *patterns*

Specifies the names of busplans to re-create, if found inside the XML data file. Pattern matching is done based on the Tcl "string match" algorithm. Multiple patterns can be included in one Tcl list such as: -buses {busABC* busDEF* bus3}.

DESCRIPTION

Loads and re-creates busplans from an XML data file, such as one previously written by *write_busplans -xml_file filename*.

EXAMPLES

The following example loads a busplan from the XML-formatted file named busplan.xml

prompt> **load_busplans -xml_file busplan.xml**

SEE ALSO

create_busplans(2)
get_busplans(2)
modify_busplan(2)
report_busplans(2)
write_busplans(2)

load_metal_pattern_density

Reads the metal density information of hard macro, including layer, bounding box and metal density value.

SYNTAX

int **load_metal_pattern_density**

Data Types

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **load_metal_pattern_density** command reads the metal density information for hard macros. The information includes layer, bounding box and metal density value. Using the command in the GUI, you can configure the visual metal pattern density map.

EXAMPLES

The following example loads the metal density information for the macro.

```
prompt> load_metal_pattern_density
1
```

SEE ALSO

load_of

Gets the capacitance of a library cell pin.

SYNTAX

float **load_of**
lib_pin

Data Types

lib_pin collection

ARGUMENTS

lib_pin

Specifies the name of the library cell pin, or a collection that contains the library cell pin, for which to get the capacitance. But the tool wrill only return the capacitance for first lib pin in the collection.

DESCRIPTION

The **load_of** command returns the capacitance of the first given library cell pin.

load_upf

Reads in a script in Unified Power Format (UPF) format.

SYNTAX

status **load_upf**
[-scope *instance_name*]
[-noecho]
[-strict_check true | false]
[-supplemental *supf_file_name*]
file_name

Data Types

instance_name string
file_name string

ARGUMENTS

-scope *instance_name*

Specifies the scope where the UPF commands contained in the *file_name* file are to be executed.

If you do not use this option, the command uses the current scope.

-noecho

If specified, commands in the UPF file are not echoed to the output.

-strict_check true | false

Specifies whether to perform strict name matching during execution of the UPF commands. Use this option only in the golden UPF mode.

Set this option to **true** when you load the golden UPF file into the synthesis tool for the very first time, when object names in the UPF commands are expected to match object names in the design exactly.

Set this option to **false** when you reapply the golden UPF file any time after the tool has operated on the design, when object names in the file are not expected to match object names in the design due to optimization, grouping, and wildcard name expansion. In this case, the tool identifies objects using rule-based matching and name map file, if any.

In front-end mode, the default setting is **true**; if you do not use the **-strict_check** option in the golden UPF mode, the tool uses strict name checking.

In back-end mode, the default setting is **false**; if you do not use the **-strict_check** option in the golden UPF mode, the tool uses non-strict name checking.

-supplemental *supf_file_name*

Specifies the name of the supplemental UPF file to be read. This option is supported only in the golden UPF mode.

When loading a UPF file with this option, any UPF that is not explicitly preceded by "set derived_upf false" is designated as "set derived_upf true". Supplemental UPF content is always loaded with the **-strict_check true** setting.

file_name

Specifies the name of the file that contains the UPF script to be read.

DESCRIPTION

The **load_upf** command sets the scope to the specified instance and executes the set of UPF commands in the specified file. When the command completes, it restores the current scope to what it was before. The commands are executed in the same way as the Tcl **source** command.

The tool automatically identifies the UPF constraint type based on the setting of the Synopsys-specific **derived_upf** variable, which is set on the design UPF by the Synopsys implementation tools when they update the UPF constraints, such as by adding **connect_supply_net** constraints. When the **derived_upf** variable is **true**, the constraints loaded by the **load_upf** command are considered supplemental constraints. When this variable is **false**, the constraints loaded by the **load_upf** command are considered golden constraints.

The following example shows a UPF file that has been modified by the tool:

```
## Constraints below are generated by icc2. Please do not modify.
set derived_upf true
if ($derived_upf) {
  connect_supply_net VDD_VSS.power -ports {
    u0_0/U41/VDD \
    u0_0/U24/VDD u0_0/U4/VDD \
    u0_1/U321/VDD }
}
set derived_upf false
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example loads the UPF script file named top.upf.

```
prompt> load_upf top.upf
1
```

SEE ALSO

source(2)
mv.upf.enable_golden_upf(3)
read_name_map(2)

log_trace

Control creation of a replay log of traced commands.

SYNTAX

string **log_trace** [-start file_name|-stop|-pause|-resume] [-log log_string] [-quiet]

string *file_name*
string *log_string*

ARGUMENTS

-start *file-Name*

This option is mutually exclusive with -stop, -pause, and -resume. The argument is the pathname of the file to which the replay trace log is output. The option opens a file for output and begins logging command execution strings and application variable changes. Note that if the file already exists, the command overwrites the existing file. There can only be a single replay trace log output at any time.

-stop

This option is mutually exclusive with -start, -pause, and -resume. This option stops replay trace log output and closes the log file. Once stopped, the replay log cannot be repopened for appending.

-pause

This option is mutually exclusive with -start, -stop, and -resume. This option pauses replay trace log output. Execution of all commands and application variable settings are ignored and omitted from the log until output is resumed with -resume.

Note that pausing replay log output may render the resulting log unable to replay or incapable of replicating tool results.

-resume

This option is mutually exclusive with -start, -stop, and -pause. This option resumes replay trace log output.

-log *log_string*

This option outputs the given log_string, verbatim, to the replay trace log. The option may be used to explicitly log a command invocation or a comment. If the string is a comment, it must start with the Tcl comment character '#'.

-quiet

If given, this option causes the command to ignore error conditions such as an attempt to pause the trace log output before it is started. The command will exit quietly when it encounters an error condition.

DESCRIPTION

The **log_trace** command performs operations related to creating a flat replay log of traced command execution and application variable changes. All options are optional. Upon successful completion, the command returns the pathname of the trace log file, if any, or an error message if the command fails.

Trace log output contains a comment header with the tool name and version, and the date and time when trace log output was started.

The resulting replay log is not 100% guaranteed to be able to replay or to reproduce tool results. One reason is that the tool execution environment may be different. If any operations are performed during log creation that would further compromise the ability to replay the resulting log or to replicate tool results, a warning message is appended to the log. Such operations including pausing log output.

Invoking the **log_trace** with no options will report the current status of logging: on, paused, or off, followed by the currently open log file name, if any.

EXAMPLES

The following example shows reporting of the log status before starting trace logging.

```
prompt> log_trace
off
```

The following example starts trace log creation.

```
prompt> log_trace -start ./tracelog.tcl
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

The following example pauses, then resumes log creation.

```
prompt> log_trace -pause
/an/absolute/path/.tracelog.tcl
prompt> log_trace
paused: /an/absolute/path/.tracelog.tcl
prompt> log_trace -resume
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

SEE ALSO

set_trace_option(2)
get_trace_option(2)
annotate_trace(2)

ls

Lists the contents of a directory.

SYNTAX

string **ls** [*filename ...*]

string *filename*

ARGUMENTS

filename

Provides the name of a directory or filename, or a pattern which matches files or directories.

DESCRIPTION

If no argument is specified, the contents of the current directory are listed. For each *filename* matching a directory, **ls** lists the contents of that directory. If *filename* matches a file name, the file name is listed.

EXAMPLES

shell> **ls *.db *.pt**

test1.pt c1.db c3.db c5.db

test2.pt c2.db c4.db c6.db

SEE ALSO

cd(2)
pwd(2)

magnet_placement

Performs magnet placement on current design.

SYNTAX

status **magnet_placement**
[-move_fixed]
[-mark_fixed]
[-move_legalize_only]
[-mark_legalize_only]
[-stop_by_sequential_cells]
[-stop_on_sequential_cells]
[-exclude_buffers]
[-avoid_soft_blockage]
[-only_report_magnet_cells]
[-get_collection]
[-logical_levels *level*]
[-multiple_long_port_mode auto | nearby]
[-cells *object_list*]
[-stop_points *object_list*]
[-hierarchy_mode default | block | all]
magnet_objects

Data Types

level integer
object_list collection
magnet_objects collection

ARGUMENTS

-move_fixed

Specifies that the cell marked as fixed can be moved. By default, the fixed cells and the cells behind them won't be pulled.

-mark_fixed

Specifies that the cells are to be marked fixed after running the **magnet_placement** command. By default, no cell is marked as fixed after the command. This option is mutually exclusive with **-mark_legalize_only**.

-move_legalize_only

Specifies that a cell marked as legalize_only can be moved. By default, legalize_only cells cannot be moved.

-mark_legalize_only

Specifies that the cells are to be marked as legalize_only after running the **magnet_placement** command. By default, no cell is marked as legalize_only after the command. This option is mutually exclusive with **-mark_fixed**.

-stop_by_sequential_cells

Stops pulling cells when a sequential cell is encountered during level traversal. The sequential cell is not pulled itself. This option is mutually exclusive with **-cells**, **-stop_on_sequential_cells** and **-stop_points**.

By default, cells in logical level 1 only are considered for pulling. Logical level can be changed using **-logical_level** command option.

-stop_on_sequential_cells

Stops pulling cells when a sequential cell is encountered during level traversal. The sequential cell is pulled itself. This option is mutually exclusive with **-cells**, **-stop_by_sequential_cells** and **-stop_points**.

By default, cells in logical level 1 only are considered for pulling. Logical level can be changed using **-logical_level** command option.

-logical_levels *level*

Specifies the number of logical levels to pull. By default, *level* is 1 and only the first-level cells are pulled. This option is mutually exclusive with **-cells**.

-cells *object_list*

Pulls only the cells in the specified object list. You specify only cell objects in the object list. This option is mutually exclusive with **-logical_levels** and **-stop_by_sequential_cells**.

The cells that you specify should form an intact datapath with magnet object. For example, if magnet object connects to cell_a, and cell_a connects to cell_b, you should specify both cell_a and cell_b. These cells do not have to be a timing path.

-exclude_buffers

Ignores buffers and inverters when calculating the level. Buffers and inverters are pulled like normal cells but are skipped over for level determination. By default, buffers and inverters are considered as one level of logic.

-avoid_soft_blockage

Avoids placing cells in soft placement blockages. By default, hard placement blockage are honored and cells might be placed within soft blockages.

-only_report_magnet_cells

Only report the magnet cells to be pulled while no cells are pulled. This option is mutually exclusive with **-get_collection**.

-get_collection

Return the pulled cells as a collection while pulling them. Use this option with any other options except **-only_report_magnet_cells** to easily get the collection of pulled cells while pulling them within single command.

-stop_points *object_list*

Pulls only the cells that are on the paths between the magnet objects and the given stoppoint objects. The stoppoint objects can be lists of any pin, port, or cell objects.

This option is mutually exclusive with **-logical_levels**, **-exclude_buffers**, **-stop_by_sequential_cells**, and **-cells**.

-multiple_long_port_mode auto | nearby

Specifies how cells are pulled for multiple or long ports. The command supports two modes: auto and nearby.

When 'nearby' set for long port, command pulls placed cells to the nearest location on the port and unplaced cells nearby the port center. When 'nearby' set for multiple port, the command pulls placed cells to one of the nearest port terminals and unplaced cells nearby any one of terminals.

When 'auto' set for a long port, the command places cells evenly near the port. When 'auto' set for a multiple port, command places cells evenly nearby each port terminal.

By default, multiple ports and long port not supported without setting this option.

-hierarchy_mode default | **block** | **all**

Specifies how the command traces cells in the hierarchy in hierarchy placing mode. When this option is specified, all cell instances within each hierarchical block that are connected to the magnet object are pulled toward it. All hierarchies specified by using the **-cells** option are placed one by one.

This option must be used together with the **-cells** option, which by default accepts only flat cell instances as input. When this option is specified, the **-cells** option accepts only hierarchical cell instances as input.

The valid modes are:

- default: The tool traces through only buffers and inverters when traversing from the magnet object to the cells within the specified hierarchical block. This is the default setting.
- block: The tool does not trace through any cell when traversing from the magnet object to the cells within the hierarchical block. The tool pulls the cells of the specified hierarchical block toward the magnet object only if they are directly connected to the magnet object. This is the most restrictive setting.
- all: The tool traces through all combinational cells when traversing from the magnet object to the cells within the specified hierarchical block. However, it does not trace through sequential cells. This is the least restrictive setting.

magnet_objects

Specifies the magnet objects. A magnet object should be a fixed object, for example, a fixed macro cell, a fixed standard cell, a pin of a fixed macro cell, or an I/O pin. Objects like vias and blockages are not allowed to be magnets.

DESCRIPTION

The command defines a set of objects as magnets and pulls the neighboring cells up to a specified logical level closer to the magnet.

It is considered a best practice to run this command before coarse placement, so that sufficient areas are available for magnet placement operation.

A large macro with many placeable standard cell neighbors can be used to ensure that the standard cells are placed close to the macro, resulting in better timing and congestion.

If a net has a fanouts number larger than 1000, the command ignores the net because pulling such a large high-fanout net might cause runtime and congestion issues.

The effect of magnet placement is not preserved from one invocation to another. For example, consider a design where cells A and B are made magnets and there are cells that are connected to both of them through possibly multiple levels. Running **magnet_placement A** and then **magnet_placement B** could result in a different result from running **magnet_placement [get_cells "A B"]** together.

If **magnet_placement** is invoked after **create_placement**, cell overlap issues might occur since there could be standard cells already placed. You can run **legalize_placement** to remove the overlaps.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs magnet placement on the *INST_1* cell:

```
prompt> magnet_placement [get_cells "INST_1"]
```

The following example performs magnet placement and marks the moved cells as fixed afterwards:

```
prompt> magnet_placement -mark_fixed [get_cells "INST_2"]
```

The following example pulls two levels of cells to *INST_2*.

```
prompt> magnet_placement -logical_levels 2 \
  [get_cells "INST_2"]
```

The following example pulls the specified cells to INST_3.

```
prompt> magnet_placement INST_3 -cells {Cel_1 Cel_2 Cel_3}
```

man

Displays reference manual pages.

SYNTAX

string **man**
topic

Data Types

topic string

ARGUMENTS

topic

Specifies the subject to display. Available topics include commands, variables, and error messages

DESCRIPTION

The **man** command displays the online manual page for a command, variable, or error message. You can write man pages for your own Tcl procedures and access them with the **man** command by setting the **sh_user_man_path** variable to an appropriate value. See the man page for the **sh_user_man_path** variable for details.

EXAMPLES

The following command displays the man page for the **echo** command:

prompt> **man echo**

The following command displays the man page for the error message CMD-025:

prompt> **man CMD-025**

SEE ALSO

help(2)
sh_user_man_path(3)

map_freeze_silicon

Manually maps cells to the specified spare cells.

SYNTAX

status **map_freeze_silicon**
-eco_cell *eco_cell_names*
-spare_cell *spare_cell_names*
[-filler_map_strategy pack_left | pack_right | pack_top | pack_bottom | closest]
| -map_file *map_file_name*
[-lib_cells_for_filler_recovery *psc_filler_lib_cells*]

Data Types

eco_cell_names	list of cells
spare_cell_names	list of cells
map_file_name	string
psc_filler_lib_cells	list of library cells

ARGUMENTS

-eco_cell *eco_cell_names*

Specifies one or multiple cells to be mapped. The specified cells should already exist in the design, whose attribute "is_fs_eco_add" are true and "eco_change_status" are one of create_cell, change_link, add_buffer, add_buffer_on_route, size_cell, eco_placed. If multiple cells are specified and one of them is with error, none of them will be mapped.

This option is mutually exclusive with the **-map_file** option and is used together with the *-spare_cell* option.

-spare_cell *spare_cell_names*

Specifies one or multiple spare cells used for mapping. For programmable spare cell (PSC) mapping, user can specify one or multiple adjacent PSC fillers. But for non-PSC mapping, user can only specify one spare cell. These cells should already exist in the design and they should be spare cells.

This option is mutually exclusive with the **-map_file** option and is used together with the *-eco_cell* option.

-filler_map_strategy pack_left | pack_right | pack_top | pack_bottom | closest

Specifies the location of the ECO cell inside the specified programmable spare cell (PSC) filler. It can only be used when the spare cell is a PSC filler. Default strategy is "pack_left" or "pack_bottom", which means ECO cells will be put one by one from left or bottom of the specified PSC filler. "pack_right" or "pack_top" means ECO cells will be put one by one from right or top of the specified PSC filler. "closest" means a ECO cell will be put at the closest valid location inside the specified PSC filler. "closest" strategy is designed for ECO cells which are already put near expected locations. In this strategy, attribute is_placed of ECO cells must be true.

This option is mutually exclusive with the **-map_file** option and can only be used together with the *-eco_cell* and *-spare_cell* option. When **-map_file** is used, strategy can be specified inside the map file.

-map_file ***map_file_name***

Specifies the name of the map file.

The following is the format of a map file:

```
# Comment should starts by "#". "#" must be the first character of the comment line
# Each line specify a pair of ECO cell and spare cell, separating by a space
eco_cell_1 spare_cell_1
eco_cell_2 spare_cell_2
 ...       ...
# format is same for programmable spare cell (PSC) filler or non-PSC spare
# cell, tool will detect them automatically.
eco_cell_3 psc_filler_3
 ...       ...
# To specify filler_map_strategy, just put it after spare cell (must be a
# PSC filler), separating by a space; If not specified, default is also
# "pack_left" or "pack_bottom"
eco_cell_4 psc_filler_4 pack_top
# To map multi ECO cells to same PSC filler, put them in a {}
# If multiple cells are specified and one of them is with error, none of
# them will be mapped.
{eco_cell_5_1 eco_cell_5_2} psc_filler_5
# It allows that specify multiple PSC fillers in the same mapping pair. But
# these PSC fillers must be adjacent and have the same PSC type. Then they
# can be merged together for mapping large ECO cell or multiple ECO cells.
eco_cell_6 {psc_filler_6_1 psc_filler_6_2}
{eco_cell_7_1 eco_cell_7_2} {psc_filler_7_1 psc_filler_7_2}
```

Error lines will not be mapped, while other lines in the map file still will be mapped. Same ECO cell / PSC filler cannot be specified two times in a map file, otherwise both lines in which they appear will not be executed.

-lib_cells_for_filler_recovery

Specifies the programmable spare cell (PSC) filler lib cells to fill the rest of the specified PSC filler as spare cell, after mapping. When the PSC filler as spare cell is larger than the ECO cell, the rest of it will be filled by newly created PSC fillers of same PSC type. If this option is specified, only lib cells specified will be used for such filling. Otherwise, all available PSC lib cells in the reference libraries will be used.

DESCRIPTION

This command maps the freeze silicon added ECO cell to the specified spare cell, to use the silicon of the spare cell as the ECO cell. The location, orientation, and PG connection of the spare cell will be inherited by the ECO cell. Then the original spare cell itself will be deleted from database. After mapping, an ECO routing command can be used to complete the routing.

In this command, ECO cell must be mapped to spare cell of a compatible lib cell, which means either:

1. ECO cell and spare cell are of same reference lib cell. In this scenario, user can specify only one ECO cell and one spare cell in the mapping pair.

2. Spare cell is programmable spare cell (PSC) filler, whose PSC type is same as the PSC type of the ECO cell or meets PSC mapping rule. In this scenario, user can specify one or multiple PSC fillers with the same PSC type of ECO cells (or meeting PSC

mapping rule) in the mapping pair.
This command will detect these 2 types of mapping automatically.

This command support specify multiple ECO cells or spare PSC fillers. However, this should only be used when it is necessary:

1. Have to specify multiple ECO cells to be mapped by splitting PSC fillers.

2. Have to specify multiple PSC fillers and merge them to map ECO cells. Otherwise, e.g., if you want to map eco_cell1 to psc_filler1 and eco_cell2 to psc_filler2, explicitly specify them in separate **map_freeze_silicon** commands or separate lines in the map file. Otherwise the mapping result might be different than your expectation.

You can specify the ECO cell and spare cell either by using the **-eco_cell** and **-spare_cell** options, or by using a map file.

If PSC filler is larger than the ECO cell, the rest of it will be filled by fillers of same PSC type.

Behavior of this command is same whether the **design.eco_freeze_silicon_mode** application option is true or false.

EXAMPLES

The following example uses **map_freeze_silicon**.

```
prompt> map_freeze_silicon -eco_cell h1_1/U3 -spare_cell spare_buf_0
```

The following example uses **map_freeze_silicon** and specifies a map file.

```
prompt> map_freeze_silicon -map_file map_file
```

The following example uses **map_freeze_silicon** and specifies a programmable spare cell (PSC) filler.

```
prompt> map_freeze_silicon -eco_cell {h1/U3 h2/U4} \
  -spare_cell filler16 -filler_map_strategy pack_right \
  -lib_cells_for_filler_recovery {FILL1 FILL2}
```

SEE ALSO

place_freeze_silicon(2)

map_isolation_cell

Specifies how to map or remap the isolation and enable level-shifter cells belonging to the specified isolation strategy.

SYNTAX

status **map_isolation_cell**
isolation_strategy
-domain *power_domain*
-lib_cells *lib_cells*

Data Types

isolation_strategy	string
power_domain	string
lib_cells	list

ARGUMENTS

isolation_strategy

Specifies the UPF isolation strategy name. The name of the isolation strategy must be unique within the specified power domain.

-domain *power_domain*

Specifies the name of the power domain name to which this isolation strategy belongs.

-lib_cells *lib_cells*

Specifies a list of the target library cells to be used for the isolation mapping.

DESCRIPTION

This command defines how the **compile** command performs the mapping of an isolation cell. All isolation cells that match the strategy will be mapped or remapped to one of the cells specified with the **-lib_cells** option with the highest priority. If no mapped lib cell cannot be used, the tool will select available cell from all libraries. Resizing is done if required; Mapped lib cells have higher priority than library cells.

You can also specify enable level-shifter cells using the **-lib_cell** option. If the isolation cells are later changed to enable level-shifter cells in the technology library, the cells can only be mapped to the one of the enable level-shifter cells specified with this command.

EXAMPLES

In the following example, the isolation cells belonging to the strategy named isolation_1 will be mapped to the LIB_HICLAMP0X2 or LIB_HICLAMP0X4 library cells with the highest priority:

```
prompt> map_isolation_cell isolation_1 -domain PD1 \
 -lib_cells {LIB_HICLAMP0X2 LIB_HICLAMP0X4}
```

SEE ALSO

set_isolation(2)
set_isolation_control(2)

map_level_shifter_cell

Specifies that the level-shifter cells belonging to the specified strategy can only be mapped to a subset of the library cells.

SYNTAX

status **map_level_shifter_cell**
level_shifter_strategy
-domain *power_domain*
-lib_cells *lib_cells*

Data Types

level_shifter_strategy	string
power_domain	string
lib_cells	list

ARGUMENTS

level_shifter_strategy

Specifies the UPF level-shifter strategy name. The level-shifter strategy name must be unique within the specified power domain.

-domain *power_domain*

Specifies the power domain name to which this level-shifter strategy belongs.

-lib_cells *lib_cells*

Specifies a list of library cells that can be used to map to the level-shifter cells.

DESCRIPTION

This command defines how the **compile** command maps the level-shifter cells. All level-shifter cells belonging to the specified strategy are mapped to one of the library cells specified in the **-lib_cells** list with the highest priority. If no library cell is available from the mapped list, the tool will select available cells from all libraries. Resizing is done if required; Mapped lib cells have higher priority than library cells.

If a valid solution cannot be reached using any library cell, no level-shifter cells are inserted. For example, if the level shifters specified in the **-lib_cells** option cannot be used to shift between the required voltage levels, and no other library cell can be used neither, the tool does not insert any level-shifter cell.

For mapping the enable level-shifter cells, use the **map_isolation_cell** command.

EXAMPLES

In the following example the level-shifter cells belonging to the strategy named VL_1 will be mapped to the LIB_LSHIX2 or LIB_LSHIX4 library cells with the highest priority:

```
prompt> map_level_shifter_cell LVL_1 -domain PD1 \
 -lib_cells {LIB_LSHIX2 LIB_LSHIX4}
```

SEE ALSO

map_isolation_cell(2)
set_level_shifter(2)

map_power_switch

Defines which power switch library cells to use for the mapping of the given UPF power switch.

SYNTAX

status **map_power_switch**
switch_name
-domain *domain_name*
-lib_cells *list*

Data Types

switch_name string
domain_name string
list list

ARGUMENTS

switch_name

Specifies the name of the power switch to be mapped using the specified library cells. This is a required option.

-domain *domain_name*

Specifies the power domain where this power switch was created. This is a required option.

-lib_cells *list*

Specifies a list of target library cells to use for the power switch cell mapping. This is a required option.

DESCRIPTION

This command is used to explicitly specify which library power switch cells are mapped for the corresponding UPF power switch.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the switch_1A power switch in the power domain named myPowerDomain with the lib2A/switch2A library cell:

```
prompt> map_power_switch switch_1A \
        -domain myPowerDomain -lib_cells lib2A/switch2A
1
```

SEE ALSO

create_power_switch(2)
get_lib_cells(2)

map_retention_cell

Defines how to map the unmapped sequential cells to retention cells for the specified UPF retention strategy of the power domain.

SYNTAX

status **map_retention_cell**
retention_strategy
-domain *power_domain*
[-lib_cells *lib_cells*]
[-lib_cell_type *lib_cell_type*]
[-elements *objects*]
[-lib_model_name *name* {-port *port_name net_ref*}*]

Data Types

retention_strategy string
power_domain string
lib_cells list
lib_cell_type string
objects list
port_name string
net_ref string

ARGUMENTS

retention_strategy

Specifies the UPF retention strategy name. The retention strategy name should be unique within the specified power domain.

-domain *power_domain*

Specifies the power domain name that this UPF retention strategy will be applied to.

-lib_cells *lib_cells*

Specifies a list of target library lib cells to be used for the retention mapping.

-lib_cell_type *lib_cell_type*

Specifies the retention type to be used for the retention mapping.

-elements *objects*

Specifies that retention mapping only applies to the sequential cells within the specified objects. The objects can be a list of hierarchical cells, leaf cells, or seqgen output signal nets.

-lib_model_name ***name*** **{-port** ***port_name net_ref*****}***

Specifies the retention library cell or behavioral model and associated port connectivity for verification tools.

DESCRIPTION

This command defines how the retention cells are mapped and implemented. In front-end mode, the tool ignores **-elements** and applies this mapping directive to all sequential cells to which the specified retention strategy applies. Also, **-elements** does not get written out in UPF' file.

In back-end mode, the tool ignores **-elements** and applies this mapping directive to all mapped registers to which the specified retention strategy applies. Also, **-elements** does not get written out in UPF' file.

The retention cell specified using the **-lib_model_name** option is not used during implementation. The **-lib_model_name** option is not written out in the UPF' file post compile.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the sequential cells under the *retention_1* retention strategy to the *CLK_LOW* retention type:

```
prompt> map_retention_cell retention_1 \
    -domain PD1 -lib_cell_type CLK_LOW
```

The following example maps the sequential cells under the retention_2 retention strategy to the RSDFCD1HVT and RSDFCD2HVT retention library cells. The **-lib_model_name** option specifies the retention library cell, port name, and net reference used by the verification tools.

```
prompt> map_retention_cell retention_2 \
    -domain PDM -lib_cells { RSDFCD1HVT RSDFCD2HVT } \
    -lib_model_name RSDFCDHVT { -port CP UPF_GENERIC_CLOCK \
                    -port D ~UPF_GENERIC_DATA \
                    -port VDD sn1 \
                    -port TVDD retention_ref.power }
```

SEE ALSO

set_retention(2)
set_retention_control(2)

mark_clock_trees

Marks clock attributes on clock objects.

SYNTAX

status **mark_clock_trees**
[-clocks *clock_list*]
[-clear]
[-synthesized | -dont_touch | -routing_rules]
[-clock_cell_spacing]
[-fix_sinks]
[-freeze_routing]

Data Types

clock_list collection

ARGUMENTS

-clocks *clock_list*

Marks only the clock trees specified in *clock_list*. By default, the command marks for all currently defined clocks in all active modes.

-clear

Removes the attributes on clock objects. If no option other than **-clear** is specified, then tool will remove clock synthesized attributes on clock objects. If the **-dont_touch** option is specified, the tool will remove the dont_touch atrribute on clock objects. Similarly, if any other options are specified together with this option, the tool will clear attributes or settings that the other options are supposed to set on the clock objects.

-synthesized

Marks clock synthesized attributes on clock objects, including cells and nets in the clock trees. On clock nets the net_type attribute updated as clock. The dont_touch attribute for CTS reason is also marked on clock nets. On clock network cells physical_status attribute set as application fixed. On sinks cts_size_in_place attribute set to true. This option cannot be used together with **-dont_touch** and **-routing_rules**.

-dont_touch

Sets dont_touch attribute on clock objects, including cells and nets in the clock trees. This option cannot be used together with **-synthesized** and **-routing_rules**.

-routing_rules

Propagates the non-default routing rules according to the settings of clock routing rules by **set_clock_routing_rules** command.

This option cannot be used together with **-synthesized** and **-dont_touch**.

-clock_cell_spacing

Propagates the clock cell spacing to the clock cells according to the rules specified by **set_clock_cell_spacing** command.

-fix_sinks

Marks clock sink as fixed placement in order to avoid subsequent commands sizing or moving them.

-freeze_routing

Marks synthesized net as locked and dont_touch in order to avoid routing of net by subsequent commands. This option cannot be used together with **-routing_rules**.

DESCRIPTION

This command marks clock attributes on clock objects to prevent the subsequent optimization programs to modify the built clock trees. Since the **synthesize_clock_trees** command automatically marks attributes on clock objects, the motivation of this command is for the third party tools. Default behavior of mark_clock_trees is "synthesized" mode.

EXAMPLES

The following example assumes a clock tree clk1 synthesized by a third party tool. After **mark_clock_trees**, this clock tree can then be recognized by the optimization programs.

```
prompt> mark_clock_trees
```

In the following example, default behavior of clear option is shown. It will only clear settings done by "synthesized" mode.

```
prompt> mark_clock_trees -clear
```

SEE ALSO

synthesize_clock_trees(2)
set_clock_cell_spacing(2)

mem

Retrieves the total memory allocated by the current process.

SYNTAX

int **get_mem**

DESCRIPTION

The *get_mem* command returns the size of memory currently allocated by the current process for the purposes of storing design netlist, design annotations, and constraints information as well as computed timing information. The value printed represents the amount in kilobytes (kB).

Note that the value reported would not match values obtained by the user through Unix process tracking commands, such as *top*. This is the case because the *get_mem* command does not track memory used to load the executable and maintain process stack space. Also, it does not differentiate between resident and swapped memory.

```
prompt> get_mem
8092
```

SEE ALSO

get_cputime(2)

merge_abstract

Merges changes made to the current design's abstract view into the full design view.

SYNTAX

status **merge_abstract**
[-blocks *block_designs*]
[-all_blocks]
[-host_options *host_option_name*]
[-force]

Data Types

block_designs list *host_option_name* string

ARGUMENTS

-blocks *block_designs*

Specifies the list of child block designs on which to perform merge. This option is mutually exclusive with *-all_blocks*. If the *-blocks* or *-all_blocks* options are not specified, the command merges the current design.

-all_blocks

Merges abstracts for all the child block instances in the current design. This option is mutually exclusive with *-blocks*. If the *-blocks* or *-all_blocks* options are not specified, the command merges the current design.

-host_options *host_option_name*

Specifies the name of the host option to use for distributed processing. When *-blocks* or *-all_blocks* is specified, the tool might need to perform merge for more than one block. Some of the blocks can run at the same time, depending on the hierarchy nesting.

-force

Merges changes to the abstract view for the current design into the full design view, regardless of the current state of the views.

DESCRIPTION

This command updates the full netlist design view for the current design with any changes made to the abstract view.

Use the **merge_abstract** command to keep the design view representation up-to-date. After running **merge_abstract**, you can

immediately run the **create_abstract** command to generate a new abstract view from the up-to-date design view, or you can perform other operations before creating a new abstract view.

This command merges any changes to the abstract view into the design view. Possible changes include: netlist modification, boundary shape change, cell location change, newly created or deleted objects, objects pushed down from higher level of physical hierarchy, and so on.

By default, abstracts created with **create_abstract** can be edited. That is, you can open the abstract in edit mode and make changes. Changes can be merged back into the full netlist design by using the **merge_abstract** command.

Design Flow for Editable Abstracts

When you create an editable abstract (the default), it is assumed that you will eventually run **merge_abstract** after editing the abstract. The **merge_abstract** command requires that the full netlist design remain unchanged between the time that the abstract is created with the **create_abstract** command and the abstract is merged with the **merge_abstract** command.

Because the netlist should not be changed, the **create_abstract** command marks the full netlist as read-only until after running the **merge_abstract** command. After you run **merge_abstract**, the open blocks that depend on the abstract are automatically upgraded to "edit" mode.

EXAMPLES

The following example opens the design view of CHIPTOP and merges the changes to the abstract view back to the design view of design CHIPTOP.

```
prompt> open_block CHIPTOP.design
prompt> merge_abstract
```

SEE ALSO

change_abstract(2)
create_abstract(2)
get_abstract_type(2)
remove_abstract(2)
report_abstracts(2)

merge_clock_gates

Merges ICG cells in clock trees.

SYNTAX

status **merge_clock_gates**
[-clocks *clock_list*]

Data Types

clock_list list

ARGUMENTS

-clocks *clock_list*

Merges ICG cells only in the clock trees specified in *clock_list*. By default, the command merges ICG cells for all currently defined clocks in all active modes.

DESCRIPTION

This command merges ICG cells in each clock tree without affecting the logic of the design. The merged ICG cells have the same type and their enable pins have the same logic.

EXAMPLES

The following example merges ICG cells in the specified clock tree.

prompt> **merge_clock_gates -clocks clk1**

SEE ALSO

merge_objects

Merges shapes of the specified objects.

SYNTAX

status **merge_objects**
[*object_list*]
[-attributes *attribute_list*]
[-connections]

Data Types

object_list string or collection
attribute_list list of attribute names

ARGUMENTS

object_list

Specifies a collection or selection set containing objects to merge. If this option is not specified, the global selection set is used.

-attributes *attribute_list*

Specifies additional list of attributes which need to match in order to merge two shapes. By default merge happens when **object_class**, **layer**, **shape_use** and **owner** attributes match.

Note: The additional attribute are being compared by the string values.

-connections

If specified collection or selection set contains shapes and vias, lookup for the first level connections to merge with.

DESCRIPTION

This command merges specified object shapes; all fixed objects are skipped. The following objects are supported: move bound shapes, voltage area shapes, corridor shapes, net shapes, and pin shapes.

Snapping is not performed as it is assumed that the shapes are already correct.

Note that only interconnected net shapes that belong to the same net, are on the same metal layer, and have the same width and end type can be merged. Nonrectilinear ending segments of a path are not merged.

The command returns a collection of the merged objects if the specified *object_list* is a collection of objects. Otherwise the command modifies objects in specified selection set and returns status.

EXAMPLES

The example merges two shapes to a single shape.

```
prompt> merge_objects
```

The alternative syntax uses collection to specify objects.

```
prompt> merge_objects [get_selection]
```

SEE ALSO

change_selection(2)
create_shape(2)
get_selection(2)
get_shapes(2)
split_objects(2)

merge_pg_mesh

Merges overlapped wires of PG nets after the PG mesh is created.

SYNTAX

status **merge_pg_mesh**
[-nets *netname_list*]
[-types *type_list*]
[-layers *layer_list*]
[-shapes *shape_list*]
[-undo]

Data Types

netname_list list
type_list list
layer_list list
shape_list list

ARGUMENTS

-nets *net_list*

Specifies a list of PG nets on which to merge wires. By default, all PG nets are processed.

-types *type_list*

Specifies a list of PG object types. The PG types should include one or more of the following keywords: **stripe**, **ring**, **macro_pin_connect**, **lib_cell_pin_connect**, **follow_pin**, **core_wire**, and **user_route**. These types are for PG stripes, PG rings, macro pin connections, standard cell pin connections, follow pins wires, core wires and user route wires. By default, all of these types are considered for wire merging.

-layers *layer_list*

Specifies metal layer names for the PG objects. *layer_list* is a list containing layer names. By default, objects on all metal layers are considered for wire merging.

-shapes *shape_list*

Specifies a list of PG shapes for which to merge wires. By default, only top-level wires of PG nets will be merged.

-undo

Restores merged shapes to their original objects that merged by most recent **merge_pg_mesh** command. Only one level of undo is supported. The **merge_pg_mesh -undo** command clears the undo command stack.

DESCRIPTION

This command performs PG wire merging after the PG mesh is created for the whole design. The command is use to reduce PG wire objects without changing wire shape geometry. The command only merge rectangle shapes. If the two overlapped shapes cannot form a new rectangle, they won't be merged. The **merge_pg_mesh** command only merges wire shapes on top-level. After **merge_pg_mesh**, one level undo is supported for user to recover original shapes.

EXAMPLES

The following example performs PG wire merging on all PG nets. after PG mesh is created.

```
prompt> merge_pg_mesh
```

The following example performs PG wire merging with some constraints. Only wire shapes with those attribute are process.

```
prompt> merge_pg_mesh \
   -nets {VDD VSS} \
   -types {stripe lib_cell_pin_connect} \
   -layers M5
```

merge_stream

Merges multiple GDSII or OASIS stream files to a single stream file.

SYNTAX

status **merge_stream**
[-format *output_format*]
[-rename_cell *cell_renaming_file*]
[-merge_cell_shapes]
[-rename_conflicting_cell]
[-merge_conflict_suffix *suffix_string*]
[-compress_gds]
[-oasis_compression_level *level*]
[-cell_log_file *cell_log_file*]
[-units *value*]
[-top_cell *cell_name*]
[-verbose]
-merge_files *file_names*
output_file

Data Types

output_format string
cell_renaming_file string
suffix_string string
level integer
cell_log_file string
value double
cell_name string
file_names list of strings
output_file string

ARGUMENTS

-format *output_format*

Specifies the output file format, either **gds** for GDSII or **oasis** for OASIS. The default is **gds**.

-rename_cell *cell_renaming_file*

Specifies the file that contains the mapping from original cell names to new cell names. For the renaming file format, see the DESCRIPTION section. The renaming works for both leaf-level library cells and macros. By default, the merging process keeps the original cell names.

-merge_cell_shapes

Specifies that the shapes from identically named cells in different source files are to be merged into a single cell in the output file. The first source file must contain all the cells' structure definitions. If one cell's structure definition is not included in the first source file, it will not be merged into the output file. By default, while reading the source files, the command overwrites any previous cell of the same name, without performing any merging or renaming of the conflicting cells.

-rename_conflicting_cell

Specifies that identically named cells in different source files are to be renamed to avoid conflict. The first cell read in keeps its original name. Any subsequent cells with the same name are renamed by appending a string and then written to the output file as separate cells. The default strings appended are _R, _R1, _R2, and so on. By default, while reading the source files, the command overwrites any previous cell of the same name, without performing any merging or renaming of the conflicting cells.

-merge_conflict_suffix *suffix_string*

Specifies the suffix string used with the **-rename_conflicting_cell** option. The string can be up to 10 characters and may contain letters, numerals, dollar signs ($), and underscore characters. The default suffix is "_R".

-compress_gds

Writes out the GDSII file in gzip compressed format. By default, the output GDSII file is written as uncompressed plain text.

-oasis_compression_level *level*

Writes out the OASIS file in compressed format using the specified compression level, an integer between 1 and 9. By default, the output OASIS file is not compressed. This option has an effect only if the **-format** option is set to **oasis**.

-cell_log_file *cell_log_file*

Specifies the name of a cell log file. The command writes out the names of the processed cells into this file.

-units *value*

Specifies the database unit size for the output stream file. The default is 1e-09 (nanometer units).

-top_cell *cell_name*

The top cell considered in the merge flow. The command merges only the specified cell and the cells in its hierarchy. All other cells are omitted from the output file. By default, the command writes out all cells in the input files.

-verbose

Generates detailed system messages during stream merging.

-merge_files *file_names*

Specifies the names of the input stream files to be merged. You can specify both GDSII and OASIS files as input.

output_file

Specifies the name of the output file generated by merging the input files.

DESCRIPTION

This command merges multiple GDSII/OASIS stream files into a single stream file in GDSII or OASIS format. You must specify at least the name of the stream files to be merged and the name of the new file generated by the merging process.

You can optionally specify the handling of identically named cells in different input files. By default, the last cell read in overwrites any earlier cells of the same name. Instead, you can merge the data in these cells (**-merge_cell_shapes**), or you can rename the

cells to avoid conflict.

To rename cells, you can have a string automatically appended to each cell name (**-rename_conflicting_cell**). Alternatively, you can specify the new cell names explicitly in a file (**-rename_cell** *filename*), with each line in the file specifying the name mapping for a cell in the following format:

OldCellName NewCellName

For example, to rename the cell TOP to NEWTOP, enter the following line in the renaming file:

TOP NEWTOP

EXAMPLES

The following example merges the colored macro named top.gds with the IP hard macros named HM1.gds and HM2.oasis:

```
prompt> merge_stream -format gds -units 1e-09 \
  -merge_files {top.gds HM1.gds HM2.oasis} my_merge.gds
```

merge_topology_plans

SYNTAX

merge_topology_plans
[-repeaters]
[-supernets]
[-verbose]

[*topology plans*]

Data Types

topology plans collection or list of names of topology plans to estimate

merge_topology_plans.

ARGUMENTS

-repeaters

Only attempt to associate std cell register arrays with topology repeaters.

If neither *-repeaters* or *-supernets* is specified, both actions are attempted.

-supernets

Only attempt to create new supernet exceptions for topology plans with std cell repeaters in the netlist for which supernet exceptions have not been created. Do not attempt to associate repeaters.

If neither *-repeaters* or *-supernets* is specified, both actions are attempted.

-verbose

Print additional information at the end of processing each topology plan as to actions taken for that topology plan.

DESCRIPTION

This command can be used to process topology plans after various actions that would invalidate them for further processing. For example, adding new std cell registers to the netlist that is associated to a topology plan, without adding new supernet exceptions, or associating those registers to topology repeaters.

The supernet exception creation operation scans the netlist from the terminals associated with the end(s) of a topology plan to the terminals associated with the start of that plan and records any register cell encountered. If any such cells do not have a corresponding supernet exception, one is created for that cell.

The repeater association operation scans the netlist from the terminals associated with the end(s) of a topology plan to the terminals associated with the start of that plan and records any register cell encountered. If any such cells are not associated with a topology repeater, and a valid un-associated topology repeater exists in the plan, the std cells are associated with the topology repeater.

By default (no arguments) both operations are performed: supernet exception creation, followed by repeater association. All specified topology plans are first processed for supernet creation, and then all specified topology plans are processed for repeater association.

KNOWN LIMITATIONS

Currently, new topology repeaters are not created, only existing topology repeaters are assigned std cells.

modify_busplan

Modify various elements of a busplan.

SYNTAX

int **modify_busplan**
[-add_guide]
[-add_register]
[-move_element *element*]
[-balance_registers]
[-remove_elements *elements*]
[-reconnect_elements *elements*]
[-change_rule *rule*]
[-after *element*]
[-before *element*]
[-location *coord*]
[-name *element_name*]
[-rename *new_name*]
[-load_launch_capture_budget]
[*busplan*]

Data Types

element	bus_element
elements	bus_elements
rule	bus_rule
coord	coordinate
element_name	string
new_name	string
busplan	busplan_name

ARGUMENTS

-add_guide

Adds a guide element to the bus plan.

-add_register

Adds a virtual register to the bus plan.

-move_element *element*

Changes the location of *element*. You must specify the *-location* option together with this option.

-balance_registers

Adds a minimal number of registers such that each branch of the busplan has the same number of registers. This only applies to busplans that have branches.

-remove_elements *elements*

Removes the specified elements from the busplan. It is an error to try to remove a start or end element of a busplan.

-reconnect_elements *elements*

Removes and reconnects the path tree starting from *elements* to a new position in busplan. This is likely to change the topology of the bus plan. You must specify the *-after* option together with this option.

-change_rule *rule*

Specifies the net estimation rule to use.

-after *element*

Specifies the position in the bus to connect a newly created element with the *-add_guide* or *-add_register* options, or reconnect an existing element with the *-reconnect_elements* option.

-before *element*

Specifies the position in the bus to connect a newly created element with the *-add_guide* or *-add_register* option.

-location *coord*

Specifies the physical location for a newly created element with the *-add_guide* or *-add_register* options, or specifies a location for *-move_element*. This option is required when you specify *-move_element*.

-name *element_name*

Specifies the name for the newly created element. If not specified, a default name is created.

-rename *new_name*

Specifies a new name for the busplan.

-load_launch_capture_budget

Specifies to load the launch and/or capture budget from the current SDC constraints. This only works for top level ports on the busplan. The launch budget is gotten from the **set_input_delay** values on the starting elements of the busplan. The capture budget is gotten from the **set_output_delay** values on the ending elements of the busplan.

busplan

Specifies the busplan to be modified. This is required.

DESCRIPTION

This command changes the specified busplan. These changes include structural changes as well as placement changes.

You must specify one of the following options to indicate the change required: *-add_guide*, *-add_register*, *-move_element*, *-remove_elements*, *-reconnect_elements*, or *-change_rule*.

Depending on the change required, other options then are required. See above for more details.

EXAMPLES

The following example creates a bus plan, then adds a virtual route pin to the bus plan.

```
prompt> create_busplans -name bus1 -from B1/OUT1[*] -start_end_cells {B1 B2 B3 B4}
prompt> report_busplans bus1
