ARGUMENTS

-to *to_list*

Reports only the paths that connect to the named pins, ports, cells, or clocks. If you do not specify this option, the command reports the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the command reports the path with the worst slack within each path group if **-group** is not present. If **-group** is given, the command reports the path with the worst slack within the group specified by **-group**.

-rise_to *rise_to_list*

Reports only the paths with a rising edge at the endpoint that connect to the named pins, ports, cells, or clocks. If a clock object is specified, this option selects endpoints clocked by the named clock, if the capturing edge is the rising edge of the clock at the clock source. The command considers logical inversions along the clock path.

-fall_to *fall_to_list*

Reports only the paths with a falling edge at the endpoint that connect to the named pins, ports, cells, or clocks. If a clock object is specified, this option selects endpoints clocked by the named clock, if the capturing edge is the falling edge of the clock at the clock source. The command considers logical inversions along the clock path.

-from *from_list*

Reports only the paths that originate from the named pins, ports, cells, or clocks. If you do not specify this option, the command reports the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the command reports the path with the worst slack within each path group if **-group** is not present. If **-group** is given, the command

reports the path with the worst slack within the group specified by **-group**.

-rise_from ***rise_from_list***

Reports only the paths with a rising edge from the named pins, ports, cells, or clocks. If a clock object is specified, this option selects startpoints clocked by the named clock, if the paths are launched by the rising edge of the clock at the clock source. The command considers logical inversions along the clock path.

-fall_from ***fall_from_list***

Reports only the paths with a falling edge from the named pins, ports, cells, or clocks. If a clock object is specified, this option selects startpoints clocked by the named clock, if the paths are launched by the falling edge of the clock at the clock source. The command considers logical inversions along the clock path.

-through ***through_list***

Reports only paths that pass through the named pins, ports, cells, or nets. If you specify only one **-through** option, the tool reports only the paths that travel through one or more of the objects in the list. You can specify **-through** multiple times with one **report_timing** command. See the DESCRIPTION section for more information.

-rise_through ***rise_through_list***

Reports only paths that pass through the named pins, ports, cells, or nets and have a rising transition at those objects. If you specify only one **-through** option, the tool reports only the paths that travel through one or more of the objects in the list. You can specify **-rise_through** multiple times with one **report_timing** command. See the DESCRIPTION section for more information.

-fall_through ***fall_through_list***

Reports only paths that pass through the named pins, ports, cells, or nets and have a falling transition at those objects. If you specify only one **-through** option, the tool reports only the paths that travel through one or more of the objects in the list. You can specify **-fall_through** multiple times with one **report_timing** command. See the DESCRIPTION section for more information.

-exclude ***exclude_list***

Prevents the reporting of data paths that contain the specified pins, ports, nets, and cell instances. Reporting excludes all data paths from, through, or to the named pins, ports, nets, and cell instances. If a cell instance is specified, all pins of the cell are excluded. The **-exclude** option

o Takes precedence over the **-from**, **-through**, and **-to** options.

o Is exclusive with the **-rise_exclude** and **-fall_exclude** options.

o Does not apply to borrowing path from the **-trace_latch_borrow** option or clock path from the **-path full_clock** or **full_clock_expanded** option.

o Does not apply to clock pins.

Note that this option is intended for use in conjunction with **-from**, **-through** and **-to** options and can lead to long runtime when used on its own, i.e. without other such topological options.

-rise_exclude ***rise_exclude_list***

Same as the **-exclude** option, but applies only to paths rising at the named pins, ports, nets, and cell instances.

-fall_exclude ***fall_exclude_list***

Same as the **-exclude** option, but applies only to paths falling at the named pins, ports, nets, and cell instances.

-path_type short | **full** | **full_clock** | **full_clock_expanded** | **only** | **end** | **end_detailed**

Specifies how to display the timing path. By default, the full path is displayed. If **full_clock** is specified, the report is similar to the one generated by **full** but includes the full clock paths for propagated clocks. If **full_clock_expanded** is specified, the report is

similar to the one generated by **full_clock** but incudes full clock paths from the primary clock to the related generated clock source. If you specify **short**, only startpoints and endpoints are displayed. If you specify **only**, only the path is displayed without the accompanying required-time and slack calculation. If you specify **end**, the report has a column format that shows one line for each path, showing only the endpoint name, delay, required-time, slack, and scenario name. If you specify **end_detailed**, the report is similar to the one generated by **end**, but with additional columns showing the pathgroup name and the number of logic levels.

-delay_type min | min_rise | min_fall | max | max_rise | max_fall

Specifies the path type at the endpoint. The default is **max**.

-report_by design | mode | corner | scenario | group

Specifies the grouping criteria for reporting paths. The default is **design**. It is an error to give both the **-report_by** and **-sort_by** options.

-sort_by group | slack

Specifies the sorting criteria for reporting paths, group or slack. It is an error to give both the **-report_by** and **-sort_by** options. This option is deprecated in favor of the **-report_by** option.

-nworst *paths_per_endpoint*

Specifies the number of paths to report per endpoint. The default value is 1.

-max_paths *max_path_count*

Specifies the number of paths to report. The default value is 1. Depending of the value of the **-report_by** option, the max_paths value is applied to each path group, scenario, mode, or corner, or to the entire design.

-slack_lesser_than *lower_slack_limit*

Reports only those paths with a slack less than **lower_slack_limit**. When you specify this option, there might be an insufficient number of paths to satisfy the **-max_paths** and **-nworst** options. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not have a defined slack.

-pba_mode none | path | exhaustive

Controls path-based analysis with the following modes:

- **none** (the default) - Path-based analysis is not applied.
- **path** - Path-based analysis is applied to paths after they have been gathered.
- **exhaustive** - An exhaustive path-based analysis path search algorithm is applied to determine the worst path-based analysis path set in the design. If you use **exhaustive**, you cannot use the **-start_end_pair** option.

-start_end_pair

Reports paths for each pair of startpoint and endpoint based on connectivity. This option can lead to long runtime and can lead to generating a huge number of paths depending on the design. By default, this option searches only for paths that are violating. This default can be changed by having an explicit -slack_lesser_than option. The options that do not work with this option are -nworst, -max_paths, -report_by. Unlike other options of the report_timing command, this option causes the paths reported to no longer be sorted based on slack. Instead, paths are arranged based on the endpoint with those sharing the same endpoint appearing next to one another. The maximum number of paths reported is limited to 2000000.

-significant_digits *digits*

Specifies the number of significant digits (digits to the right of the decimal point) to report. Allowed values are from 0 through 13. The default is 2. Using this option overrides the value set by the **shell.common.report_default_significant_digits** application option.

-nosplit

Writes out wide report lines, even if the line length is greater than 80 columns. Use this option to simplify post-processing of the output files or when comparing the output files with the UNIX **diff** command. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-modes *mode_list*

Specifies the modes for which to generate the timing report. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option will be included in the report. If this option is not given, the report will include scenarios of all modes. If none of the **-modes**, **-corners**, or **-scenarios** options are given, the report will include every active scenario of the design. It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to generate the timing report. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option will be included in the report. If this option is not given, the command reports every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to generate the timing report. Each of the specified scenarios is included in the report. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the report will include every scenario of the design.

-groups *group_list*

Specify the list of path group names for reporting paths. Default is all path groups. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not belong to any path group.

-nets

Print nets.

-physical

Print pin XY locations.

-attributes

Print attributes of each pin.

-input_pins

Print data for input pins.

-transition_time

Print transition time of each pin.

-capacitance

Print capacitance of each load pin.

-process

Print process number and process label (if any) of each leaf pin.

-voltage

Print voltage of each leaf pin.

-temperature

Print temperature of each leaf pin.

-derate

Print timing derates of each leaf pin.

-crosstalk_delta

Print SI delta-delays of each load pin. This option is effective only if SI analysis is enabled.

-variation

Reports parametric on-chip variation (POCV) information by expanding column "Incr" to columns "Mean", "Sensit", "Corner" and "Value", and expanding column "Path" to columns "Mean", "Sensit" and "Value". This option works only when POCV analysis is enabled.

-exception *exception_type*

Prints user-specified timing exceptions, namely false paths, multicycle paths, and minimum and maximum delays, that are satisfied per timing path being reported. Only "dominant" exception type is acceptable, which is to report the dominant exception constraint used for the reported path.

Note: The additional analysis required per path with the -exceptions option is not trivial. Therefore, using a report_timing command with the -exceptions option is expected to execute slower than the exact same command without this option. The -exceptions option does not work with -path_type short/end/end_detailed option and forces the -input_pins option.

-skip_transparency_window

Skip printing the detailed transparency window.

-include_hierarchical_pins

Print the hierarchical pins.

timing_path_list

Specifies the collection of timing paths to report. This option is mutually exclusive with options that control the selection of paths to report and is only compatible with options which control the formatting of the report.

DESCRIPTION

The **report_timing** command generates a report that contains timing information for the current design. By default, the **report_timing** command reports the single worst setup path for each of the scenarios specified by the **-modes**, **-corners**, or **-scenarios** options. If none of these options are specified, the command will report the single worst path over all scenarios of the design.

Command options let you specify the number of paths reported, the types of paths reported, and the amount of detail included in the report. You can restrict the scope of paths reported by startpoints, endpoints, and intermediate points by using the **-from**, **-to**, and **-through** options. To restrict the report by slack or clock group, use the **-slack_lesser_than** and **-group** options.

If the **time.report_unconstrained_paths** application option is set to **true**, the command will search for unconstrained paths to endpoints for which constrained paths cannot be found. Searching for unconstrained paths can cause significantly longer runtimes.

The report actually consists of a series of sub-reports, each containing up to **max_paths** paths, sorted by slack. The value of the **-report_by** option controls the contents of each sub-report as follows:

design \(em There will be a single sub-report for the entire design, containing the worst paths across all pathgroups of all scenarios. This is the default.

group \(em There will be a sub-report (with up to **max_paths** paths) for each pathgroup of each specified scenario. (This is equivalent to the old default **-sort_by group** option.)

scenario \(em There will be a sub-report for each scenario, containing the worst paths across all pathgroups. (This is equivalent to the old **-sort_by slack** option.)

mode \(em There will be a sub-report for each mode, containing the worst paths across all pathgroups of all scenarios of that mode.

corner \(em There will be a sub-report for each corner, containing the worst paths across all pathgroups of all scenarios of that corner.

The command can also report on a collection of timing paths which were retrieved using the **get_timing_paths** command.

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example uses multiple **-through** options in a single command to specify paths that traverse multiple points in the design. The command reports paths beginning at A1, passing through B1, then through C1, and ending at D1:

```
prompt> report_timing -from A1 -through B1 -through C1 -to D1
```

The following example allows multiple possible paths by specifying multiple objects within one **-through** option. The path can pass through any of the objects. The command specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
prompt> report_timing -from A1 -through {B1 B2} -through {C1 C2} -to D1
```

The following example uses the **-report_by design** option to report the single worst path over the entire design:

```
prompt> report_timing -report_by design -scenarios [all_scenarios] -max_paths 1
```

The following example shows how a pre-existing collection of paths can be printed:

```
prompt> set paths [get_timing_paths -report_by corner -corner c23 -max_paths 100]
prompt> report_timing $paths
```

If you specify the **-pba_mode exhaustive** option, path-based analysis is used during the path search, and the worst recalculated paths meeting your criteria are returned. This option requires that a path search be performed to ensure that the paths being returned truly are the worst paths. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing improvement from path-based analysis increases, the runtime for the path search increases. Large **-nworst** values can significantly increase the time needed for the search.

To see the worst path in the design with path-based analysis applied:

```
prompt> report_timing -pba_mode exhaustive
```

To report all endpoints in the design which fail after considering path-based analysis:

```
prompt> report_timing -pba_mode exhaustive -slack_lesser_than 0 -max_paths 1000
```

time.report_unconstrained_paths(3)

report_timing_derate

Reports derate factors annotated on the current design.

SYNTAX

int **report_timing_derate**
[-corners *corner_list*]
[-include_inherited]
[-aocvm_guardband]
[-pocvm_guardband]
[-pocvm_coefficient_scale_factor]
[-pocvm_subtract_sigma_factor_from_nominal]
[-increment]
[-significant_digits *digits*]
[-nosplit]
[*object_list*]

Data Types

corner_list list
digits int
object_list list

ARGUMENTS

-corners *corner_list*

Reports timing derates for all the corners specified in *corner_list*. The default is to only report the current corner.

-include_inherited

Indicates that the derate factors reported on each object should also include what object they inherit their value from in the design.

-aocvm_guardband

Indicates that only the AOCVM guard band derate factors should be reported.

-pocvm_guardband

Indicates that only the POCVM guardband derate factors should be reported.

-pocvm_coefficient_scale_factor

Indicates that only the POCVM coefficient scale factors should be reported.

-pocvm_subtract_sigma_factor_from_nominal

Indicates that only the POCVM subtract sigma factors should be reported.

-increment

Indicates that only incremental derate factors should be reported. The option -increment and -aocvm_guardband/-pocvm_guardband are mutually exclusive.

-significant_digits *digits*

Specifies the number of digits after the decimal point to be displayed for values in the report. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option. Use this option if you want to override the default.

-nosplit

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing scripts to extract information from the report output.

object_list

Specifies a list of cells, lib_cells in the current design.

DESCRIPTION

Reports the derate factors either on the design or specific instances (cells or library cells) contained in the design. If this command is successful a Boolean of true or 1 is returned; otherwise, it returns a false or 0.

If this command is called with no arguments, every object where a timing derate value has been applied it listed. The inheritance information is not displayed.

If this command is called with the *-include_inherited* Boolean argument, the derate report for each instance also contains the name of the object from which the derate value is inherited. Examples of this would be a leaf cell inheriting cell derate factors set on the hierarchical cell to which it belongs, or a leaf cell inheriting a derate factor set on the library cell of which it is an instantiation.

Because net derating factors are global, they are displayed only under the top hierarchical design (the current_design). With the support of dynamic derates, the report shows 2 separate lines for static and dynamic net derates.

If the command is called with the *object_list* option specified, derate reports are only issued for the instances specified in the object list.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

In the following example derate factors have only been set globally (on the design), therefore only global derate factors are reported.

prompt> **set_timing_derate -data -early 0.92**

```
prompt> set_timing_derate -data  -late  1.14
prompt> set_timing_derate -clock -early 0.75
prompt> set_timing_derate -clock -late  1.26
prompt> report_timing_derate

report_topological_constraints

Generates a report of the topological pin feedthrough constraint information.

SYNTAX

status **report_topological_constraints**
topological_constraints | -all

topological_constraints collection

ARGUMENTS

topological_constraints

Specifies a list of topological pin feedthrough constraints from the design that are to be reported. Each topological pin feedthrough constraint name in the *topological_constraints* must exist in the design.

You must specify the *topological_constraints* or **-all**. The *topological_constraints* and **-all** options are mutually exclusive.

-all

Reports all the topological pin feedthrough constraints in the design. The *topological_constraints* and **-all** options are mutually exclusive.

DESCRIPTION

This command displays information about the topological pin feedthrough constraints in the current design.

EXAMPLE

The following example reports the topological pin feedthrough constraint TPF_CONSTRAINT_0

```
prompt> report_topological_constraints TPF_CONSTRAINT_0
TPF Constraint     Description
-------------------------------------------------------------------------------
TPF_CONSTRAINT_0   Owner Type          blk_net
                   Owner Name          pad[15]
                   Start Type          blk_inst
```

```
                Start Name          DFTC_4
                End Type            blk_inst
                End Name            sdram_DQ_iopad_14
                Start Sides         --
                End Sides           --
                Start Offset        --
                End Offset          --

get_topological_constraints(2)
remove_topological_constraints(2)

report_topology_plans

Reports topology plans in the current block.

SYNTAX

int **report_topology_plans**
[-verbose]
[-nosplit]
[-significant_digits *digits*]
[*topology_plan_list*]

Data Types

digits int
topology_plan_list collection

ARGUMENTS

-verbose

Displays verbose topology plan information.

-nosplit

Retains long lines and does not split lines if column overflows.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point to report. Allowed values are 0-13. The default is determined by the **shell.report_default_significant_digits** application option, whose default is 2. Use this option to override the default.

topology_plan_list

Specifies a list of topology plans to report. The list can contain topology plan names, patterns, or collections. A collection can be specified by using the **get_topology_plans** command.

DESCRIPTION

The **report_topology_plans** command generates a report about the topology plans in the design. The report includes the topology plan name and a description of the topology plan. If **-verbose** is specified, the report also includes additional attributes and a list of constraint groups the topology plan is a member of.

If *topology_plan_list* is specified, those topology plans are reported. If it is not specified, then all topology plans in the design are reported.

EXAMPLES

The following example reports information for the topology_plan named "plan0".

```
prompt> report_topology_plans plan0
Topology Plan     Description
-------------------------------------------------------------------------------
plan0           comment: Plan for decoder sys 3
                stats: 2 nodes, 1 edges, 2 repeaters

report_trace

Produce a report of performance profile metrics collected for traced commands.

SYNTAX

report_trace [-start|-stop|resume]
[-profile profile_type]
[-command command_name]
[-cumulative count]
[-top count]
[-quiet]

string *profile_type*
string *command_name*
int *count*

ARGUMENTS

-start

This option is mutually exclusive with -stop, -resume, -profile, -top, -cumulative, -command. The option starts the collection of performance profile statics for each traced command invocation. If metric collection had previously been stopped with -stop, then previously collected data are deleted before collection starts.

-stop

This option is mutually exclusive with -start,-resume, -profile, -top, -cumulative, -command. The option stops the collection of performance profile statics for traced command invocations.

-resume

This option is mutually exclusive with -start, -stop, -profile, -top, -cumulative, -command. The option resume the collection of performance profile statics for traced command invocations. Previous gathered statics remain and newly collected metrics are added to pre-existing data. This option may be used after -stop to resume data collection without deleting previously collected data.

-profile *profile_type*

This option is mutually exclusive with -start, -stop, and -resume. This option selects the profile metrics that are included in the report. Allowed valuesA valid value is a list of permitted values {memory, cpu, time, count}, or the value all to select all metrics. If -profile is given, then the report output contains performance profile data of given types only. If the option is omitted, then it defaults to all.

-cumulative *count*

This optional option is mutually exclusive with -start, -stop, -resume, and -command. This option limits the number of commands reported for the top resource consumer accumulated over all invocations. However, all commands that share the same usage metric as the minimum consumer included in the count will be shown. If the option is omitted, the report output contains the top 10 consumers.

-top *count*

This optional option is mutually exclusive with -start, -stop, -resume and -command. This option limits the number of commands reported for the top resource consumer per single invocation. However, all commands that share the same usage metric as the minimum consumer included in the count will be shown. If the option is omitted, the report output contains the top 10 consumers.

-command *command_name*

This option is mutually exclusive with -start, -stop, -resume, -top and -cumulative. This option causes a performance profile report to be displayed for the given command. Cumulative and top single invocation metrics are shown. If the command was not invoked, then a message with this information is displayed instead of a report.

-quiet

If given, this option causes the command to ignore error conditions such as an attempt to start profile gathering when it has already been started or reporting on a non-existent command. The command will exit quietly when it encounters an error condition.

DESCRIPTION

The **report_trace** command collects performance profile metrics on all traced command invocations since the last -start. Stopping the gathering is not necessary to produce a report. When performance profile collection is started with report_trace -start, each traced command will be measured for the available performance metrics: memory, CPU, wallclock time, and call count. The accumulated profile data can be reported at any time by calling this command

Stopping the metric gathering with -stop freezes the gathered metrics until the next -start. When gathering is restarted, all previously gathered metrics are deleted. Alternatively, metric collection may be restarted without deleting previously collected data using -resume.

The **report_trace** with no options will report the top 10 consumers in both cumulative and single call metrics for all profile types collected thus far.

EXAMPLES

The following example starts the collection of performance profile metrics.

```
prompt> report_trace -start
on
```

The following example produces a report of top 10 commands with most usage for all profile types for both cumulative and individual call consumption. 10 is the default number reported for -top and -cumulative when these options are omitted.

```
prompt> report_trace
on
```

The following example produces a report of cumulative and the single most expensive invocation for each profile type for the command update_timing.

```
prompt> report_trace -command update_timing
on
```

The following example produces a report of top 20 consumers for cumulative and single invocation collected thus far.

```
prompt> report_trace -top 20 -cumulative 20
on
```

The following example produces a report of top 5 cumulative consumption of memory.

```
prompt> report_trace -profile memory -cumulative 5
on
```

The following example produces a report of top 15 commands with most invocations.

```
prompt> report_trace -profile count -cumulative 15
on
```

The following example produces a report of top 10 commands with most cpu and wallclock time usage for both cumulative and individual call consumption. 10 is the default number reported for -top and -cumulative when these options are omitted.

```
prompt> report_trace -profile {cpu time}
on
```

report_track_constraints

The command outputs a report describing the track constraints set for the current block.

SYNTAX

int **report_track_constraints**

DESCRIPTION

The report_track_constraints command takes no arguments. It displays information on the track constraints defined in the current block. Labels that exceed the defined column width in the report are automatically condensed as seen in the below example with the label "thisIsAReallyLongLabelString" being reported as "thisIsAReallyLon...".

EXAMPLES

The following commands set and remove track constraints and then show the resulting track constraint report.

```
prompt> set_track_constraint -block [current_block] -layer M1 \
  -label A -grid 1 -offset 1 -mask mask_one -origin block
prompt> set_track_constraint -block [current_block] -layer M2 \
  -label B -grid 1 -offset {0 0.5} -mask {mask_one mask_two} -origin block
prompt> set_track_constraint -block [current_block] -layer M2 \
  -label C -grid 4.5 -offset 1 -mask mask_one -origin block \
  -track_direction vertical
prompt> set_track_constraint -block [current_block] -layer M3 \
  -label thisIsAReallyLongLabelString -grid 1 -offset {0 0.1 0.9} \
  -mask mask_two -origin block -track_direction horizontal
prompt> remove_track_constraint -block [current_block] -layer M1 \
  -mask {mask_one mask_two}
prompt> remove_track_constraint -block [current_block] -layer M2 \
  -mask mask_one -track_direction vertical
prompt> report_track_constraints
Track Constraint Report
   Layer: M1
   Label          Constraint            Origin   Grid  Offset

   Layer: M2
   Label          Constraint            Origin   Grid  Offset
   B            {Horizontal, mask_one}   block    1    {0 0.5}
```

```
B           {Vertical, mask_one}     block    1    {0 0.5}
B           {Vertical, mask_two}     block    1    {0 0.5}

Layer: M3
Label       Constraint               Origin   Grid  Offset
thisIsAReallyLon... {Vertical, mask_one}     block    1    {0 0.1 0.9}

Layer: M4
Label       Constraint               Origin   Grid  Offset

Layer: M5
Label       Constraint               Origin   Grid  Offset

Layer: M6
Label       Constraint               Origin   Grid  Offset

Layer: M7
Label       Constraint               Origin   Grid  Offset
```

SEE ALSO

remove_track_constraint(2)

report_tracks

Reports the routing tracks for a specified layer or for all layers.

SYNTAX

int **report_tracks**
[-nosplit]
[-significant_digits *digits*]
[-layer *layer*]
[-dir X | Y]

Data Types

digits int
layer string

ARGUMENTS

-nosplit

Does not split lines if column overflows.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.commmon.report_default_significant_digits** application option, whose default is 2. Use this option if you want to override the default.

-layer *layer*

Specifies the routing layer to use the routing tracks. You can use layer name, layer number, or a collection containing one layer object.

The default is to report the routing tracks on all layers.

-dir X | Y

Specifies the direction how routing tracks are placed. The valid values are **X** and **Y**; specify either. The default is to report routing tracks in both direction.

DESCRIPTION

This command reports a group of routing tracks for the routing layer.

EXAMPLES

The following example reports routing tracks on the floorplan.

```
prompt> report_tracks
Layer        Direction    Start       Tracks   Pitch       Attr
-----------------------------------------------------------------------

m2             Y       233.720      2861     0.560     default
m2             X       233.720      2649     0.560     default
m3             X       233.720      2649     0.560     default
m3             Y       233.720      2861     0.560     default
m2             Y       233.720      2861     0.560     default
m4             Y       233.720      2861     0.560     default
m4             X       233.720      2649     0.560     default
m3             X       233.720      2649     0.560     default
m5             X       233.720      2649     0.560     default
m5             Y       233.720      2861     0.560     default
m4             Y       233.720      2861     0.560     default
m6             Y       233.720      2861     0.560     default
m6             X       232.600      1327     1.120     default
m5             X       232.600      1327     1.120     non-reserved, width=0.5

report_transformed_registers

Reports register transformations during compile

SYNTAX

status **report_transformed_registers**
[-nosplit]
[-constants]
[-unloaded]
[-shiftReg]
[-multibit]
[-merged]
[-inverted]
[-replicated]
[-summary]

Data Types

ARGUMENTS

-nosplit

Does not split lines if the column overflow.

-constants

Reports constant regsiters in the design. The report will list constant registers that are optimized as well as constant register that are not removed due to user constraints.

-unloaded

Reports unloaded regsiters in the design. The report will list unloaded registers that are optimized as well as unloaded register that are not removed due to user constraints.

-shiftReg

Reports shift registers inferred by the tool.

-multibit

Reports multibit registers inferred by the tool.

-merged

Report registers that are optimized away by transferring loads to a logically equivalent register.

-inverted

Reports phase inverted registers. The report only includes register whose final state is phase inverted compared to its original state.

-replicated

Report registers that are duplicated to meeting optimization objective.

-summary

Gives total count of each individual transformations.

DESCRIPTION

This command reports the registers undergoing transformations during compile. If no option is specified then all the transformations are reported by default. Any of the above options can be independently specified to report that specific optimization.

EXAMPLES

prompt> **report_transformed_registers -constants**

prompt> **report_transformed_registers**

SEE ALSO

report_constant_registers(2)
report_unloaded_registers(2)

report_transitive_fanin

Reports logic in the transitive fanin of specified sinks.

SYNTAX

status **report_transitive_fanin**
-to *sink_list*
[-nosplit]

Data Types

sink_list list

ARGUMENTS

-to *sink_list*

Specifies a list of sink pins, ports, or nets in the design. The transitive fanin of each sink in the *sink_list* is reported. If a net is specified, the effect is the same as listing all driver pins on the net. This argument is required.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanin** command produces a report showing the transitive fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the transitive fanin of a sink if there is a path through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells). It is independent on timing graph.

Use the **report_transitive_fanout** command to see the fanout of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanin within the current instance. The report stops at the boundaries of the current instance, and paths outside the current instance are not reported. The report shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the transitive fanin of two internal pins in the design:

```
prompt> report_transitive_fanin -to {u5/A u5/B}

****************************************
Report : transitive_fanin
 ...

****************************************

The fanin network of sink u5/A is as follows:

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
u2/Z            u5/A            (net arc)   same

Load Pin        Driver Pin      Type      Sense
-------------------------------------------------------------
u2/A            u2/Z            IVA       opposite

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
b               u2/A            (net arc)   opposite

The fanin network of sink u5/B is as follows:

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
c               u5/B            (net arc)   same
```

SEE ALSO

current_design(2)
current_instance(2)
report_clock(2)
report_timing(2)
report_transitive_fanout(2)

report_transitive_fanout

Reports logic in the transitive fanout of specified sources.

SYNTAX

status **report_transitive_fanout**
-from *source_list*
[-nosplit]

Data Types

source_list list

ARGUMENTS

-from *source_list*

Specifies a list of source pins, ports, and nets in the design. The transitive fanout of each source in the *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanout** command produces a report showing the transitive fanout of specified source pins or ports in the design. A pin is considered to be in the transitive fanout of a source if there is a path through combinational logic from the source to that pin. The fanout report stops at the inputs to registers (sequential cells). The source pins or ports are specified with **-from** *source_list*. It is independent on timing graph.

Use the **report_transitive_fanin** command to see the fanin of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanout within the current instance. The report stops at the boundaries of the current instance, and does not report paths outside the current instance. The report also shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the transitive fanout of two internal pins in the design:

```
prompt> report_transitive_fanout -from {ffa/Q ffb/Q}

****************************************
Report : transitive_fanout
 ...

****************************************

The fanout network of source ffa/Q is as follows:

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
ffa/Q           QA/A            (net arc)  same

Load Pin        Driver Pin      Type      Sense
-------------------------------------------------------------
QA/A            QA/Z            IV        opposite

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
QA/Z            QA              (net arc)  opposite

The fanout network of source ffb/Q is as follows:

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
ffb/Q           QB/A            (net arc)  same

Load Pin        Driver Pin      Type      Sense
-------------------------------------------------------------
QB/A            QB/Z            IV        opposite

Driver Pin      Load Pin        Type      Sense
-------------------------------------------------------------
QB/Z            QB              (net arc)  opposite
```

report_unbound

Reports unbound cell, via, via array, site row, site array, shape, track, layer, pin_guide, pin_blockage, routing_guide, routing_corridor_shape and via_def object types.

SYNTAX

int **report_unbound**
[-hierarchical]
[-cell]
[-via]
[-site_row]
[-site_array]
[-shape]
[-track]
[-layer]
[-pin_guide]
[-pin_blockage]
[-routing_guide]
[-routing_corridor_shape]
[-via_def]
[-verbose]

Data Types

No data types.

ARGUMENTS

-hierarchical

Reports unbound objects within the physical hierarchy.

-cell

Reports unbound cell instance objects. Specify **-hierarchical** to consider cell instances within the physical hierarchy. Specify **-verbose** to report cell instances with missing references.

-via

Reports unbound via and via array objects. Specify **-hierarchical** to report via and via arrays within the physical hierarchy. Specify **-verbose** to report via and via arrays with missing references.

-site_row

Reports unbound site row objects. Specify **-hierarchical** to report unbound site rows within the physical hierarchy. Specify **-**

verbose to report site rows with missing site definitions.

-site_array

Report unbound site array objects. Specify **-hierarchical** to report unbound site arrays within the physical hierarchy. Specify **-verbose** to report site arrays with missing site definitions.

-shape

Reports unbound layer along with shape object name in the command output.

-track

Reports unbound layer along with track object name in the command output.

-layer

Reports unbound layer for layer object.

-pin_guide

Reports unbound layer along with pin guide object name in the command output.

-pin_blockage

Reports unbound layer along with pin blockage object name in the command output.

-routing_guide

Reports unbound layer along with routing guide object name. If type of routing guide is access_preference then it will also be mentioned in the command output.

-routing_corridor_shape

Reports unbound layer along with routing corridor shape object name. Reports min_layer_name and max_layer_name in command output if layers are unbound.

-via_def

Reports unbound layer along with via_def object name. Reports upper, lower and cut layers for via_def object if they are unbound.

-verbose

Reports cell instances with missing references. If only this option is specified, the command reports cell instance objects with missing references. Specify **-verbose** and **-hierarchical** to report unbound cell instances within the physical hierarchy.

DESCRIPTION

This command displays information for unbound objects in the design. The object types considered are cell, via, via matrix, site row, site array, shape, track, layer, pin_guide, pin_blockage, routing_guide, routing_corridor_shape and via_def.

With **-verbose** option, for cell, via, via matrix, site row, site array objects, the command reports each unbound object and its reference name. for other supporting objects it reports the unbound layer with object name. With **-hierarchical** option, for cell, via, via matrix, site row, site array objects, the command reports objects inside physical hierarchy as well.

If none of the options are specified then for **-cell**, **-via**, **-site_row** and **-site_array**, the tool prints out all missing references of all these object types considered and the count of unbound objects per reference. For shape, track, layer, pin_guide, pin_blockage,

routing_guide, routing_corridor_shape and via_def tool prints out all the unbound layers with object name.

EXAMPLES

The following example reports unbound objects for cell, via, site row, site array, shape, track, layer, pin_guide, pin_blockage, routing_guide, routing_corridor_shape and via_def object types.

```

remove_objects(2)
remove_site_defs(2)
remove_via_defs(2)

report_units

Reports the currently specified input and output units.

SYNTAX

string **report_user_units**
[-nosplit]

ARGUMENTS

-nosplit

Retains long lines in the output, even if the lines are longer than 80 columns. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing scripts to extract information from the report output.

DESCRIPTION

The **report_user_units** command displays the currently specified input and output units.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example reports the user units for the current design.

```
prompt> report_user_units

****************************************
Report : user_units
 ...

****************************************
```

```
Input Units (set to default)
-------------------------------------------------
time                : 1.00ns
resistance          : 1.00kOhm
capacitance         : 1.00pF
voltage             : 1.00V
current             : 1.00mA
power               : 1.00mW

Output Units (set to default)
-------------------------------------------------
time                : 1.00ns
resistance          : 1.00kOhm
capacitance         : 1.00pF
voltage             : 1.00V
current             : 1.00mA
power               : 1.00mW
```

SEE ALSO

get_user_units(2)
set_user_units(2)

report_unloaded_registers

Reports registers that were removed because their values were not used.

SYNTAX

string **report_unloaded_registers**

DESCRIPTION

Displays a list of registers that were removed from the design by the **compile** command because their values were unused. Unloaded register removal is controlled by the **compile.seqmap.remove_unread_registers** application option.

EXAMPLES

The following example shows a summary report:

```
shell> report_unloaded_registers
****************************************
Report : unloaded_registers
 ...

****************************************

Register
--------------------------------------------------------------------------------
bot/z0_reg
bot/z1_reg
bot/z2_reg
bot/c1_reg
1
```

SEE ALSO

compile_fusion(2)
compile.seqmap.remove_unloaded_registers(3)

report_user_units

Reports the currently specified input and output units.

SYNTAX

string **report_user_units**
  [-nosplit]

ARGUMENTS

-nosplit

Retains long lines in the output, even if the lines are longer than 80 columns. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing scripts to extract information from the report output.

DESCRIPTION

The **report_user_units** command displays the currently specified input and output units.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example reports the user units for the current design.

```
prompt> report_user_units

****************************************
Report : user_units
 ...

****************************************
```

```
Input Units (set to default)
-------------------------------------------------
time                : 1.00ns
resistance          : 1.00kOhm
capacitance         : 1.00pF
voltage             : 1.00V
current             : 1.00mA
power               : 1.00mW

Output Units (set to default)
-------------------------------------------------
time                : 1.00ns
resistance          : 1.00kOhm
capacitance         : 1.00pF
voltage             : 1.00V
current             : 1.00mA
power               : 1.00mW
```

SEE ALSO

get_user_units(2)
set_user_units(2)

report_utilization

Report utilization of the current block.

SYNTAX

float **report_utilization**
[-of_objects *objects*]
[-config *config*]
[-scope *config_scope*]
[-region *region_spec*]
[-grid_size *distance*]
[-verbose]

Data Types

objects	collection
config	string
distance	float
region_spec	list

ARGUMENTS

-of_objects *objects*

A homogeneous collection consisting of objects for which the utilization needs to be reported. In this case, each object in the list is a name, pattern or collection. The supported objects are

- **block**

  The block on which utilization is to be reported. Only one block is allowed with this option. If multiple blocks are specified, then utilization is reported only for the first block.

- **voltage_area**

  The utilization for the voltage area will be reported. If multiple voltage areas are specified, then the collective utilization of all voltage areas will be reported.

- **site_array**

  The utilization for the site-array will be reported. If multiple site arrays are specified, then the collective utilization of all site arrays will be reported.

- **bound**

  The utilization for the move-bound will be reported. If multiple move bounds are specified, then the collective utilization of all move bounds will be reported. Only move bounds are supported with this option.

-config *config*

Name (or collection) of the utilization configuration, created using *create_utilization_configuration*, to be used for reporting. If the input is a collection, then the first configuration in the collection will be used for reporting. In the absence of this option user defined default configuration would be used if any exists.

-scope *scope*

The values it can take are 'lib', 'tech' and 'block'. Restricts the search for a configuration to a particular scope. By default, the order of search is block, lib and then tech i.e. the configuration is first searched in the current block, then the current library and finally the tech associated with the current library.

-region

Specifies the region for which to report utilization. Specify a rectangle, polygon, or collection of geometric objects.

To specify a rectangle, use the following syntax to specify the lower-left and upper-right corners of the rectangle:

{{*llx lly*} {*urx ury*}}

To specify a polygon, use the following syntax to specify the coordinates of the polygon:

{{*x y*} {*x y*} {*x y*} {*x y*}...}

By default, the utilization of the current block is reported.

This option is mutually exclusive with the **-of_objects** option.

-grid_size *distance*

Specifies the grid size of each subregion. In addition to the entire block or a user-specified region, the command divides the given area (either entire chip or a user specified region if you specify the -region option) into a set of sub-regions and reports the corresponding utilization of the subregion to provide a better understanding of the evenness of the cell distribution. The grid_size is the size of each subregion. The minimum grid size is 3 times the height of the placement site_def. The unit for grid size is in microns. This option is mutually exclusive with the **-of_objects** option.

-verbose

Prints additional information in the report for utilization based on block boundary and for utilization based on site-rows of the block.

DESCRIPTION

The utilization calculation involves the computation of available area (Capacity) and the utilized area (Demand), and is calculated as :

Utilization = Demand / Capacity,

where,

Demand: Sum total of area occupied by the objects

Capacity: Total available area.

This command can be used to report the utilization of the current block. By default, with no options specified, the command reports utilization of the current block with respect to site-rows, and excluding the following:

- hard-macros

- soft-macros
- macro-keepouts
- io cells
- hard blockages

The utilization configurations created using the command "*create_utilization_configuration*" can be used to control the way utilization is calculated.

Capacity calculation:

For the utilization of a block, if a configuration is specified, then the capacity area calculation depends upon the value of "-capacity" option in the configuration.

For the utilization of other objects specified through '-of_objects', the capacity area calculation is essentially the effective boundary of the object. For voltage-area the total capacity is the effective region occupied by the constituent voltage-area shapes. For move-bounds the total capacity is the effective region occupied by the constituent move-bound regions. For site-arrays, the total capacity is the effecitve shape of the site-array based on the stacking order.

If the utilization configuration has the '-exclude' option set, then the effective regions of the objects corresponding to the exclusion types are deducted from the capacity region.

Demand calculation:

The default demand is the sum of the areas of all the cells in the block. All the cells, belonging to the container (block, voltage-area, move-bound or site-array) will be considered for demand calculation regardless of whether or not they overlap with the capacity region.

If two cells, to be considered as demand, overlap and either of them are not fixed then the demand of these two cells is the sum of areas of the individual cells. If they are fixed, then the demand will be the union of individual areas.

The hierarchical physical blocks will be handled as follows:

- If the physical block is of view type DESIGN then the demand
computation will be hierarchical and will follow the same rules for the
physical block contents as the top block

- If the physical block is of view type FRAME or OUTLINE
then the demand computation will not be hierarchical and the bounding box
of the physical block will be considered as demand

For the utilization of a block, with respect to its boundary, the '-verbose' option will report information about the number of cells outside or partially overlapping with the block-boundary and their aggregate area. For the utilization of a block, with respect to its site-rows, the '-verbose' option will report information about the independent utilization of all the site-definitions.

On success, the command returns as a string, the computed utilization upto 4 significant digits.

EXAMPLES

The following example reports utilization of the current block using the default configuration.

```
prompt> report_utilization

report_vclp_options

This command is used to report the VCLP related option settings.

SYNTAX

status **report_vclp_options**

DESCRIPTION

The **report_vclp_options** command is used to report the VCLP related option settings. This command can be used to check if the settings are correct or need to be changed.

SEE ALSO

check_vclp_design(2)

report_versions

Displays information about release versions supported for saving and committing libraries.

SYNTAX

status **report_versions**

DESCRIPTION

The **report_versions** command displays information about the release versions supported by save_lib -as -version in an implementation tool and commit_workspace -version in the library manager.

Compatibility in the report means the tools listed are natively on this schema revision. They can read all the data in the current schema, and create the database in the same schema too.

Forward compatibility means the tools listed can read the database in newer schema revision in a way that, any object which is specific to the newer schema revision is ignored, while all the already supported objects are read by the tools. Please refer to **Includes support for** section in the same report for details of the new schema objects attached to the specific schema revision.

EXAMPLE

The following command reports the currently supported versions:

```
prompt> report_versions

J-2014.06
  ICC2 schema revision: 1.0
  Compatibility:
     - ICV J-2014.06-SP1

J-2014.06-SP1
  ICC2 schema revision: 1.001
  Includes Support for:
     - Analog Constraints
     - Dynamic Power
     - finFet Grid
     - net min/max routing layers
     - viaDef attributes

1
```

SEE ALSO

save_lib(2)
commit_workspace(2)

report_via_defs

Generates a report of via_defs in a specified block or tech.

SYNTAX

string **report_via_defs**
[-design *design*]
[-library *library*]
[-tech *tech*]
[-verbose]
[-significant_digits *digits*]
[-nosplit]
[*via_def_list*]

Data Types

design collection
library collection
tech collection
digits integer
via_def_list collection

ARGUMENTS

-design *design*

Specifies the block for finding via_defs. If neither a design nor tech is specified, the current block is used.

-library *library*

Specifies the tech for finding via_defs. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used.

-tech *tech*

Specifies the tech for finding via_defs. If neither a design nor tech is specified, the current block is used.

-verbose

Specifies whether the report contains additional columns of data, reporting more complete information about the given via_defs.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option, whose default value is 2. Set this application option to override the default.

-nosplit

Most of the via_def information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing software to extract information from the report output.

via_def_list

Specifies a list of via_defs in the given block or tech to be reported. The default is to report all via_defs in the given container.

DESCRIPTION

The command displays information about the via_defs in the block or tech specified. Attributes such as the cut and metal layers of the via_def are displayed.

EXAMPLES

The following example reports all via_defs in the current block.

```
prompt> report_via_defs

****************************************
Report : report_via_defs
Design : top
 ...

****************************************
Via_def              Type    Lower  Cuts   Upper  Is_default
--------------------------------------------------------------------------
FATVIA12_1_2          custom  M1     VIA1   M2     --
FATVIA12_2_1          custom  M1     VIA1   M2     --
VIA12_r90             custom  M1     VIA1   M2     --

report_via_ladder_candidates

Reports via ladder candidates set by the **set_via_ladder_candidate** command.

SYNTAX

status **report_via_ladder_candidates**
list_of_lib_pins

Data Types

list_of_lib_pins pin names or collection

ARGUMENTS

list_of_lib_pins

Specifies list of library-pins for which via ladder candidates will be reported.

DESCRIPTION

This command reports existing via ladder candidates on the specified library-pins. This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

The following example reports all via ladder candidates for the library-pin.

```
prompt> report_via_ladder_candidates [get_lib_pin tcbn90ghvt/AN2HVTD0/A1]
Lib Pin              Via Ladder Candidates
--------------------------------------------------------------------------------
tcbn90ghvt/AN2HVTD0/A1  VL1 VL2 VL3
1
```

SEE ALSO

reset_via_ladder_candidates(2)
set_via_ladder_constraints(2)
remove_via_ladder_constraints(2)
report_via_ladder_constraints(2)

report_via_ladder_constraints

Reports via ladder constraints set by the **set_via_ladder_constraints** command.

SYNTAX

status **report_via_ladder_constraints**
[-pins *pins*]
[-all]
[-nosplit]

Data Types

pins pin names or collection

ARGUMENTS

-pins *pins*

Specifies pins for which via ladder constraints will be reported. Pins must have block context and should belong to current block.

-all

Enables reporting of consolidated list of via ladders in prioritized order for the pins specified using the **-pins** option. The consolidated list comprises the following via ladders in descending order of priority:

- **the tool specified via ladder constraint**: via ladders auto inferred by the tool.
- **the user specified via ladder constraint**: via ladders set using **set_via_ladder_constraints**.
- **the user specified via ladder rules**: via ladders set using **set_via_ladder_rules**.
- **electro-migration via ladder candidates**: subset of via ladders set using **set_via_ladder_candidate**. Only the electro-migration type via ladders are union merged to the consolidated list if the library-pin has the **is_em_via_ladder_required** attribute specified as true. If any via ladder has both **for_electro_migration** and **for_high_performance** attribute set to true it would appear after all **for_electro_migration** via ladders that has **for_high_performance** attribute set to false.
- **pattern must join via ladder**: a representative via ladder with generated name is appended to the consolidated list if the library-pin has the **pattern_must_join** attribute specified as true. The generated via ladder name has the format **VL_auto_<n>_*** where n is the count of top-layer pin shapes for the pattern must join port.

  If you specify this option, you must also specify the **-pins** option.

-nosplit

Does not split lines if column overflows.

DESCRIPTION

This command reports existing via ladder constraints. If pins are specified with "-pins" option, then constraints are reported for only those pins. Otherwise, all existing constraints are reported. For every pin specified with "-pins" option, for which via ladder constraints were not set, warning is printed.

This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

The following example reports all via ladder constraints from the block.

```
prompt> report_via_ladder_constraints
Pin             Via ladders
--------------------------------------------------------------------------------
u1/i1           VL1,VL3
u1/i2           VL4,VL6,VL8
1
```

The following example reports via ladder constraints for specified pins only.

```
prompt> report_via_ladder_constraints -pins "u1/i1"
Pin             Via ladders
--------------------------------------------------------------------------------
u1/i1           VL1,VL3
1
```

The following example reports consolidated list of via ladder for specified pin that has both **is_em_via_ladder_required** and **pattern_must_join** attributes set as true on its library-pin. In this example VL_EM_1, VL_EM_2 and VL_EM_PERF_1 are all electro-migration type via ladder candidates and VL_EM_PERF_1 is also the only performance type via ladder candidate. The generated name of pattern must join via ladder is VL_auto_2_* where 2 is the top-layer pin shape count of the pattern must join port.

```
prompt> report_via_ladder_constraints -all -pins "u1/i1"
Pin             Via ladders
--------------------------------------------------------------------------------
u1/i1           VL1,VL3,VL_EM_1,VL_EM_2,VL_EM_PERF_1,VL_auto_2_*
1
```

report_via_ladder_rules

Reports via ladder rules set by the **set_via_ladder_rules** command.

SYNTAX

status **report_via_ladder_rules**
[-nosplit]

ARGUMENTS

-nosplit

Does not split lines if column overflows.

DESCRIPTION

This command reports existing via ladder rules.

This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

The following example reports all via ladder constraints from the block.

```
prompt> report_via_ladder_rules
****************************************
Report : report_via_ladder_rules
Design : r4000
Version: K-2015.06-SP3-BETA
Date   : Mon Sep  7 04:48:12 2015

SEE ALSO

set_via_ladder_rules(2)
remove_via_ladder_rules(2)

report_via_ladders

Generates a report of via ladders in the current design.

SYNTAX

string **report_via_ladders**
[-verbose]
[-nosplit]
[-significant_digits *digits*]
[*via_ladder_list*]

Data Types

digits integer
via_ladder_list collection

ARGUMENTS

-verbose

Specifies whether the report contains additional columns of data, reporting more complete information about the given via ladders.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option, whose default is 2. Use this application option if you want to override the default. Fixed-precision floating-point arithmetics is used for delay calculation; therefore, the actual precision might depend on the platform. For example, on SVR4 UNIX see FLT_DIG in limits.h. The upper bound on a meaningful value of the argument to **-significant_digits** is then FLT_DIG - ceil(log10(fabs(*any_reported_value*))).

-nosplit

Most of the via ladder information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing software to extract information from the report output.

via_ladder_list

Specifies a list of via ladders in the given block to be reported. The default is to report all via ladders in the given container.

DESCRIPTION

The command displays information about the via ladders in the block specified. Attributes such as the via_rule_name and name of the via ladder are displayed.

EXAMPLES

The following example reports a via_ladder named "VIA_LADDER_0" in the current design.

prompt> **report_via_ladders VIA_LADDER_0**

```
Via_ladder    Via_rule     EM      PMJ     HP
-------------------------------------------------------------------------------
VIA_LADDER_0  rule_1       false   true    false
```

report_via_mapping

Report the via-mapping options used for redundant via insertion.

SYNTAX

status **report_via_mapping**
[-nosplit]
[-from {*via_pattern*}]
[-to {*via_pattern*}]

Data Types

via_pattern string

ARGUMENTS

-nosplit

Does not split lines if column overflows.

-from {*via_pattern*}

Specifies the via-pattern corresponding to the vias to be replaced during redundant via insertion.

Any via-mapping whose "to be replaced" via matches with this pattern will be reported.

A via-pattern has two parts: viaDefName and site_spec mxn. viaDefName is via definition name. mxn specifies the number of contacts in the horizontal (m) and vertical (n) directions.

-to {*via_pattern*}

Specifies the via-pattern corresponding to the vias to be inserted during redundant via insertion.

Any via-mapping option whose "replacement" via matches with this pattern will be reported.

DESCRIPTION

The **report_via_mapping** command reports the existing via-mapping options from the current block. By default, all the via-mappings defined in the current block will be reported.

EXAMPLES

The following example reports the via-mapping options for the replacement of via with via-def 'VIA12':

```
prompt> report_via_mapping  -from {VIA12 1x1}
```

The following example reports the via-mapping options where, the replacement via is a double via with via-def 'VIA12':

```
prompt> report_via_mapping -to {VIA12 1x2}
```

The following example reports the via-mapping options for via replacement from vias with via-def 'VIA12' to a double via with via-def 'VIA12':

```
prompt> report_via_mapping -from {VIA12 1x1} -to {VIA12 1x2}
```

SEE ALSO

remove_via_mappings(2)
add_via_mapping(2)

report_via_matrixes

Generates a report of via_matrixes in the current design.

SYNTAX

string **report_via_matrixes**
[-verbose]
[-nosplit]
[-significant_digits *digits*]
[*via_matrix_list*]

Data Types

digits integer
via_matrix_list collection

ARGUMENTS

-verbose

Specifies whether the report contains additional columns of data, reporting more complete information about the given via_matrixes.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option, whose default is 2. Use this application option if you want to override the default. Fixed-precision floating-point arithmetics is used for delay calculation; therefore, the actual precision might depend on the platform. For example, on SVR4 UNIX see FLT_DIG in limits.h. The upper bound on a meaningful value of the argument to **-significant_digits** is then FLT_DIG - ceil(log10(fabs(*any_reported_value*))).

-nosplit

Most of the via_matrix information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing software to extract information from the report output.

via_matrix_list

Specifies a list of via_matrixes in the given block or tech to be reported. The default is to report all via_matrixes in the given container.

DESCRIPTION

The command displays information about the via_matrixes in the block or tech specified. Attributes such as the via_def and name of the via_matrix are displayed.

Note: The results of 'Lower Mask Constraint', 'Cut Mask Constraint' and 'Top Mask Constraint' are only reported for 1000 base vias.

EXAMPLES

The following example reports a via matrix named VIA_MATRIX_0 in the current block.

```
prompt> report_via_matrixes VIA_MATRIX_0

Via_matrix    Via_def   Origin
--------------------------------------------------------------------------------
VIA_MATRIX_0  VIA12     {1000 200}
```

The following example displays verbose information for the via matrix named VIA_MATRIX_0.

```
prompt> report_via_matrix -verbose VIA_MATRIX_0
Via_matrix    Via_def   Origin          Description
--------------------------------------------------------------------------------
VIA_MATRIX_0  VIA12     {1000 200}      Orientation:  R90
                                        Base Pitch:   {10 10}
                                        Base Size:    {20 30}
                                        Pitch:        {10 10}
                                        Size:         {20 30}
                                        Shape Use:    detail_route
                                        Net:          Clk
                                        Lower Mask Pattern:
                                                arbitrary
                                        Lower Mask Constraint:
                                                {{0 0 no_mask}
                                                 {0 1 mask_one}
                                                 {1 1 mask_two}}
                                        Cut Mask Pattern:
                                                uniform
                                        Cut Mask Constraint:
                                                {{0 0 no_mask}}
                                        Top Mask Pattern:
                                                arbitrary
                                        Top Mask Constraint:
                                                {{0 0 no_mask}
                                                 {0 1 mask_one}
                                                 {1 1 mask_two}}
                                        Base Pattern: 10 01
                                        Via Pattern   1111
```

report_via_regions

Generates a report of via_regions in a specified frame block.

SYNTAX

string **report_via_regions**
[-design *design*]
[-verbose]
[-significant_digits *digits*]
[-nosplit]
[*via_region_list*]

Data Types

design collection
digits integer
via_region_list collection

ARGUMENTS

-design *design*

Specifies the block for finding via_regions. If no design is specified, the current block is used.

-verbose

Specifies whether the report contains additional columns of data, reporting more complete information about the given via_regions.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option, whose default value is 2. Use this application option to override the default.

-nosplit

Most of the via_def information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing software to extract information from the report output.

via_region_list

Specifies a list of via_regions in the given block to be reported. The default is to report all via_regions in the given container.

DESCRIPTION

The command displays information about the via_regions in the block specified. Attributes such as the owner, via_def and type are displayed.

EXAMPLES

The following example reports all via_regions in the current block.

```
prompt> report_via_regions

****************************************
Report : Report via regions
 ...

****************************************
ViaRegion       Owner      ViaDef    Type    Rect Rotate
--------------------------------------------------------------------------------
Reset/VR_0      Reset      VIA12     User    Yes  --

MemData[31]/VR_0  MemData[31] CONT1     User    Yes  --

MemData[31]/VR_1  MemData[31] FATVIA23  User    Yes  Yes

MemData[31]/VR_2  MemData[31] CONT1     User    Yes  --
```

The following example displays a verbose via_region report.

```
prompt> report_via_regions -verbose
report_via_regions -verbose
****************************************
Report : Report via regions
 ...

****************************************
ViaRegion       Owner      ViaDef    Type    Rect Rotate  BBox
-------------------------------------------------------------------------------
Reset/VR_0      Reset      VIA12     User    Yes  --     {104.9 133.42} {105 133.56}

MemData[31]/VR_0  MemData[31] CONT1     User    Yes  --     {113.53 133.42} {113.67 133.56}

MemData[31]/VR_1  MemData[31] FATVIA23  User    Yes  Yes    {113.53 133.42} {113.6 133.5}

MemData[31]/VR_2  MemData[31] CONT1     User    Yes  --     {113.53 133.42} {113.6 133.5}
```

SEE ALSO

get_via_regions(2)
create_via_region(2)
shell.common.report_default_significant_digits(3)

report_via_rules

Generates a report of via rules in a specified block or tech.

SYNTAX

string **report_via_rules**
[-design *design*]
[-library *library*]
[-tech *tech*]
[-verbose]
[-nosplit]
[-all]
[*via_rule_list*]

Data Types

design collection *library* collection *tech* collection *via_rule_list* string or collection

ARGUMENTS

-design *design*

Specifies the block for finding via rules. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

-library *library*

Specifies the library for finding via rules. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

-tech *tech*

Specifies the tech for finding via rules. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

-verbose

Outputs the various set properties names and their values for each of the via rules along with default information. Name of the properties displayed is same as used in the technology file.

-nosplit

Prevents line splitting if the column overflows. Most information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

-all

Displays all via rules in the specified scope. You must specify either **-all** or *via_rule_list*.

via_rule_list

Displays information only on the specified objects in *via_rule_list*. The argument contains either a collection of via rules or a pattern that matches the via_rule names in the specified scope. You must specify either **-all** or *via_rule_list*.

DESCRIPTION

This command displays information about via rules in the block or technology file. By default, the command displays the via rules in both block and tech scope. If the search is to be limited to either block or tech scope, the same can be specified as an option. By default, the command produces a brief report containing via_rule's name and if they are a via ladder. You must specify either **-all** or *via_rule_list*.

EXAMPLES

The following example outputs the report for all via rule objects.

```
prompt> report_via_rules -all
****************************************
Report : report_via_rules
Version:
Date   :
****************************************
Name             Via ladder
------------------------------------------
VR1              No
VL1              Yes
1
```

The following example outputs the verbose report for the via rule named VL1.

```
prompt> report_via_rules VL1 -verbose
****************************************
Report : report_via_rules
Version: L-2016.03-SP5-1-BETA
Date   : Sun Oct 23 23:27:33 2016
****************************************
Name   Via ladder Property name        Value
-----------------------------------------------------
VL1    Yes       cutLayerNameTblSize   2
                 cutLayerNameTbl       VIA1, VIA2
                 cutNameTbl            cut1, cut2
                 numCutRowsTbl         2, 2
                 numCutsPerRowTbl      2, 2
1
```

report_virtual_pads

Reports existing virtual pads.

SYNTAX

status **report_virtual_pads**

ARGUMENTS

This command has no arguments

DESCRIPTION

This command reports all existing virtual pads.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example reports all existing virtual pads.

prompt> **report_virtual_pads**

SEE ALSO

analyze_power_plan(2)
read_virtual_pad_file(2)
remove_virtual_pads(2)
set_virtual_pad(2)
write_virtual_pad_file(2)

report_voltage_area_rules

Reports voltage area rules in the design.

SYNTAX

status **report_voltage_area_rules**
  [-nosplit]
  [*voltage_area_rules*]

Data Types

voltage_area_rules collection

ARGUMENTS

-nosplit

Does not split lines if column overflows.

voltage_area_rules

Specifies the voltage area rules to report. This can be a collection handle of voltage area rules or names of patterns. You can use the **get_voltage_area_rules** command to specify objects. If not specified, the tool reports all voltage area rules in the design.

DESCRIPTION

This command reports the details of the specified voltage area rules. Details include the rule name, whether or not pass through and physical feedthrough are allowed, and a list of voltage areas constrained by the rule.

EXAMPLES

The following example reports the voltage area rule named "RULE1" in the design.

prompt> **report_voltage_area_rules RULE1**

The following example reports all voltage area rules in the design.

prompt> **report_voltage_area_rules**

SEE ALSO

create_voltage_area_rule(2)
get_voltage_area_rules(2)
remove_voltage_area_rules(2)

report_voltage_areas

Reports the voltage areas in the design.

SYNTAX

status **report_voltage_areas**
[-design design]
[-hierarchical]
[-verbose]
[-nosplit]
[-significant_digits *digits*]
[*voltage_area_list*]

Data Types

digits int
voltage_area_list list

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-hierarchical

Show hierrachical voltage_area info.

-verbose

Displays verbose voltage area information.

-nosplit

Does not split lines if column overflows.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the **shell.common.report_default_significant_digits** application option, whose default is 2. Use this option if you want to override the default.

voltage_area_list

Specifies a list of voltage areas to report. The list may contain voltage area names, patterns, or collections. A collection may be specified by using the **get_voltage_areas** command. This argument is mutually exclusive with the **-all** option. You must specify

one, but not both.

DESCRIPTION

This command reports the user-specified voltage area constraints in the design, as specified by the **create_voltage_area** command. If you use the **-all** option, all voltage areas in the design, created by the **create_voltage_area** command are reported.

The report includes voltage area name, target utilization rate, the power domain associated with this voltage area, the voltage area shapes, guardbands, the voltage boundary coordinates, and the relative stacking order.

EXAMPLES

The following example reports the voltage area *cntrl/d1*:

```
prompt> report_voltage_areas cntrl/d1 -verbose

Voltage_area       Description
-------------------------------------------------------------------------------
cntrl/d1          not_fixed with 5 shapes target_utilization 0.5
                  power_domain: cntrl/d1
                  VOLTAGE_AREA_SHAPE_1
                  guard_band:       (1.00, 2.00)
                  boundary:         (0.00, 0.00)
                                    (0.00, 60.00)
                                    (60.00, 60.00)
                                    (60.00, 0.00)
                  stacking_order:   1

                  VOLTAGE_AREA_SHAPE_2
                  guard_band:       (1.00, 1.00)
                  boundary:         (0.00, 0.00)
                                    (0.00, 70.00)
                                    (70.00, 70.00)
                                    (70.00, 0.00)
                  stacking_order:   2

                  VOLTAGE_AREA_SHAPE_3
                  guard_band:       (2.00, 2.00)
                  boundary:         (0.00, 0.00)
                                    (0.00, 80.00)
                                    (80.00, 80.00)
                                    (80.00, 0.00)
                  stacking_order:   3

                  VOLTAGE_AREA_SHAPE_4

report_wrapper_configuration

Reports the wrapper configuration of the current design.

SYNTAX

status **report_wrapper_configuration**

ARGUMENTS

The **report_wrapper_configuration** command has no arguments.

DESCRIPTION

This command reports the wrapper configuration applied by the **set_wrapper_configuration** command.

EXAMPLES

The following example shows a wrapper configuration report.

```
prompt> set_wrapper_configuration -reuse_threshold 5
1
prompt> report_wrapper_configuration
****************************************
Report : Wrapper Specification
Design : top
Version: P-2019.03
Date   : Thu Feb  7 08:03:48 2019
****************************************

----------------------------------------
TEST MODE: all_dft
VIEW    : Specification
----------------------------------------
Wrapper Configuration
=====================
Reuse Threshold:                5
```

```
Hier Wrapping:                    Enable
Add Wrapper Cells To Power Domain:    Enable
Mix Cells:                        False
Mix With Scan Cells:              True
Use System Clock For Dedicated Wrapper Cells: Enable
Depth Threshold:                  Unspecified
Chain count:                      Unspecified
Gate Cells:                       none
```

SEE ALSO

set_wrapper_configuration(2)

reset_app_options

Resets application options to the unset status on the specified block.

SYNTAX

integer **reset_app_options**
[-block *block*]
[-user_default]
[-unknown]
names

OLD SYNTAX

integer **reset_app_options**
[-design *design*]
[-global]
names

Data Types

block block name or collection
names list

ARGUMENTS

-block *block*

The name of the block on which the option values will be reset. This is an optional option and cannot be specified with the *-user_default* option. If this option is not specified and the application option being reset it design scoped, then the value on the current block with be reset.

-user_default

Indicates that the user-default for the specified option will be reset. This option cannot be specified with the *-block* option.

-unknown

Indicates that the value for the unknown option in the specified block will be reset. If the block is not specified, the value of the current block's unknown app option will be reset.

names

Specifies a list of option names. An option name can include the wildcard characters asterisk (*) and question mark (?). "*" will match zero or more of any character, and "?" will match any single character. Note that if any of the names specified with no wild cards is invalid, this command will fail with no effect.

-design *design*

The name of the design on which the option values will be reset. This option cannot be specified with the *-global* option, and either *-design* or *-global* must be specified. This option is deprecated, use *-block* option instead.

-global

Indicates that the specified option values will be reset in the global scope. This option cannot be specified with the *-design* option. This option is deprecated.

DESCRIPTION

This command resets the values of the specified application options to unset status, on the specified block, or in the global scope, depending on the scope of the application option.

Each design will store only the options explicitly set on it. Any option values which are unset on the design will be obtained from the user-default or system-default (if user-default does not exist).

For application options that are of type "list of {name value} pairs", the subscript mechanism can be used to remove specific keys from the option value.

For backward compatibility the older syntax of the command will still be supported, but the options are made hidden. The option '-design', is made hidden.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following example unsets the value of the *time.enable_preset_clear_arcs* option on the current block.

```
prompt> reset_app_options -block [current_block] {time.enable_preset_clear_arcs}
1
```

The following example unsets the value of the *shell.tmp_dir_path* option and the *time.enable_preset_clear_arcs* option, in the global scope.

```
prompt> reset_app_options {shell.tmp_dir_path time.enable_preset_clear_arcs}
1
```

The following example unsets the user default value of the *gui.enable_custom_setup_files*

```
prompt> reset_app_options -user_default {gui.enable_custom_setup_files}
1
```

The following example removes the key 'M4' from the current block's value of *test.layer_name_number_pair_list* option.

```
prompt> get_app_option_value -name test.layer_name_number_pair_list
```

```
M1 31 M2 32 M3 33 M4 34
prompt> reset_app_options -name test.layer_name_number_pair_list(M4)
1
prompt> get_app_option_value -name test.layer_name_number_pair_list
M1 31 M2 32 M3 33
```

help_app_options(2)

reset_cell_mode

Resets cell modes for cell instances.

SYNTAX

status **reset_cell_mode**
[*cell_list*]

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a list of instances for which the specified cell modes are to be made inactive. If not specified, reset cell modes for all cell instances in the design with cell mode settings.

DESCRIPTION

Removes the active mode for specified cell instances or for all instances in the design.

If this cell is a moded-ETM cell created with the library manager ETM flow, calling the **reset_cell_mode** command disables all modes of the cell, and all moded generated clocks and moded case values are removed.

If this is a cell with modes defined in the logic library source file, calling the **reset_cell_mode** command makes all modes of the cell active at once.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following command resets cell mode information for the RAM instance named Uram1.

prompt> **reset_cell_mode Uram1**

SEE ALSO

set_cell_mode(2)
report_cell_mode(2)

reset_checkpoints

Reset the logging of the checkpoint system and clears the stored state of previous checkpoints.

SYNTAX

integer **reset_checkpoints**
[-from *checkpoint_name*]

Data Types

checkpoint_name string

ARGUMENTS

-from *checkpoint_name*

Reset the checkpoint information from the gvien checkpoint name. This is an optional option.

DESCRIPTION

This command does either a full or partial reset of previously captured checkpoint history. By default, it resets all history, with the following effects:

- The ./checkpoint/checkpoint_history.rpt file will show no checkpoints
- The get_checkpoint_data -list_names command will show no checkpoints
- The ./checkpoint directory gets fully reset. If there is an existing ./checkpoint directory, it is backed up to a timestamped directory in the run directory called ./checkpoint_YYYY_MM_DD_hh:mm:ss, and a new ./checkpoint directory is created. Initially, this new checkpoint directory will have no contents except an unpopulated checkpoint_history.rpt file.

If the reset_checkpoints -from option is used, the checkpoint history is reset starting from the specified checkpoint. For example, if checkpoints A, B, C, D had been run, and reset_checkpoints -from C is called, then the history of only C and D are removed, but A and B remain:

- The ./checkpoint/checkpoint_history.rpt file will show history prior to the specified checkpoint, but none from that checkpoint
- The get_checkpoint_data -list_names command will show only the checkpoints prior to the -from checkpoint
- The get_checkpoint_data -name <checkpoint_name> command can be called only for those checkpoints prior to the -from checkpoint

- The ./checkpoint directory does not get fully reset. No backup is made. The only change to that directory is in the contents of the checkpoint_history.rpt file. Any other outputs in that directory generated by checkpoint reports will remain, even for those checkpoints that were reset. The user must manually clean-up those files if they wish to do so, as the checkpoint system has no knowledge of which files were written for which checkpoint.

Resetting the checkpoint system does not reset any report or action definitions or associations. All of those settings remain intact. Only the history of executed checkpoints is affected.

A typical application of using reset_checkpoints is when a user wants to restart a run through the flow scripts in the same directory where they previously ran. Or, when a user copies a previous run directory to a new directory to modify for a new experiment. If the new run does not pick up where the previous run left off, it is sensible to reset or partially reset the checkpoint history.

Resetting checkpoints is not the same as disabling the checkpoint system. Any checkpoint history is cleared, but the system is still active, and new eval_checkpoint commands encountered in the flow scripts can still trigger their associated actions and reports.

EXAMPLES

In this example, a user wishes to restart a run from the beginning of the flow in a previously existing run directory that used the checkpoint system. To avoid a duplicated checkpoint history, they start off by resetting the checkpoints:

```
prompt> reset_checkpoints
```

In this example, a user previously ran through place_opt, clock_opt, route, and route_opt flow steps, but later found problems in the setup requiring a rerun from the clock_opt step. Their first checkpoint name in that step was called clock_opt_route_clock, so they reset the checkpoints from that checkpoint name at the start of their rerun, to avoid duplicating the checkpoints from clock_opt onward:

```
prompt> reset_checkpoints -from clock_opt_route_clock
```

reset_clock_gate_latency

Resets all clock-latency values previously applied to registers and clock-gating cells.

SYNTAX

status **reset_clock_gate_latency**

ARGUMENTS

The **reset_clock_gate_latency** command has no arguments.

DESCRIPTION

This command resets all clock-latency values previously applied to registers and clock-gating cells from all clocks that are currently defined. Only the latencies set using the **set_clock_gate_latency** command will be removed. This command will not remove latencies that were set by other sources, such as **set_clock_latency** command.

Note that this command does not remove the clock gate latency settings that were specified by the **set_clock_gate_latency** command. For this, use the **set_clock_gate_latency -reset** command.

To report the clock gate latency settings that were specified by the **set_clock_gate_latency** command, use the **report_clock_gate_latency** command.

Multicorner-Multimode Support

This command is scenario dependent and will affect the current scenario only. You must use this command on each scenario that already has a clock-gate latency setting to remove the specified configuration.

EXAMPLES

The following command removes clock-latency values from all clocks currently defined:

prompt> **reset_clock_gate_latency**

SEE ALSO

apply_clock_gate_latency(2)
compile.clockgate.physically_aware(3)
remove_clock_latency(2)
report_clock_gate_latency(2)
set_clock_gate_latency(2)
set_clock_latency(2)

reset_design

Removes all user-specified objects and attributes from the current design, except those defined by using the **set_attribute** command.

SYNTAX

status **reset_design**

ARGUMENTS

The **reset_design** command has no arguments.

DESCRIPTION

The **reset_design** command removes all user-specified modes, corner, scenarios, clocks, path groups, and constraints of the current design. Attributes defined by using the **set_attribute** command will not be removed. This command returns zero if there is no current design.

WARNING: Executing **reset_design** has wide-ranging consequences. This command removes all user-specified attributes on the design, with a result that is often equivalent to starting the design process from the beginning. If you want to reset only a few attributes, consider using the **remove_attributes** command. Alternatively, you might be able to remove selected attributes by using the commands that set them. See the appropriate man page to determine whether a specific **set_*** command has the **-default** option.

Note that when the **reset_design** command removes user-specified objects such as clocks, collections that contain those objects are implicitly deleted. For more information about collections, see the collections man page.

Multicorner-Multimode Support

This command works on all scenarios.

EXAMPLES

The following example resets the current design:

```
prompt> reset_design
```

```
1
```

The following example illustrates how the **reset_design** command can implicitly delete collections:

```
prompt> set a [get_clocks]
{clk}
prompt> query_objects $a
{clk}
prompt> reset_design
1
prompt> query_objects $a
Error: No such collection '_sel126' (SEL-001)
```

reset_dft_configuration

Resets the DFT configuration for the current design specified by the **set_dft_configuration** command.

SYNTAX

status **reset_dft_configuration**

ARGUMENTS

The **reset_dft_configuration** command has no arguments.

DESCRIPTION

The **reset_dft_configuration** command resets the DFT configuration for the current design.

EXAMPLES

In the following example, the command resets the current design to the default configuration:

```
prompt> reset_dft_configuration
```

SEE ALSO

insert_dft(2)
report_dft_configuration(2)
set_dft_configuration(2)

reset_dft_drc_configuration

Resets the DFT DRC configuration to the default behavior.

SYNTAX

status **reset_dft_drc_configuration**

ARGUMENTS

The **reset_dft_drc_configuration** command has no arguments.

DESCRIPTION

The **reset_dft_drc_configuration** command resets any modifications to the DFT DRC configuration that were applied by the **reset_dft_drc_configuration** command.

SEE ALSO

report_dft_drc_configuration(2)
set_dft_drc_configuration(2)

reset_dft_insertion_configuration

Resets the DFT insertion configuration for the current design.

SYNTAX

status **reset_dft_insertion_configuration**

ARGUMENTS

The **reset_dft_insertion_configuration** command has no arguments.

DESCRIPTION

This command resets the existing insertion configuration to its defaults.

Use the **report_dft_insertion_configuration** command to display the current DFT insertion configuration of the design.

EXAMPLES

The following example shows how to reset the DFT insertion configuration:

```
prompt> reset_dft_insertion_configuration
```

SEE ALSO

compile(2)
insert_dft(2)
report_dft_insertion_configuration(2)
set_dft_insertion_configuration(2)

reset_disable_tie_insert

Remove the pins which are set by set_disable_tie_insert.

SYNTAX

status **reset_disable_tie_insert**
[-objects *object_name_or_collection*]
[-all]

Data Types

object_name_or_collection collection

ARGUMENTS

-objects *object_name_or_collection*

Specifies the objects for exclusion during tie cell insertion. Currently supported object types are pins and ports.If you dont specify this option then all option need to be used.

-all

Remove all the pins which are marked by set_disable_tie_insert.

DESCRIPTION

Remove the pins which are set by set_disable_tie_insert.

EXAMPLES

prompt>set_disable_tie_insert -object h1/reg_2_/SE

prompt>report_disable_tie_insert

Report:Disabled tie ports and pins

```
h1/reg_2_/SE

prompt>reset_disable_tie_insert -object h1/reg_2_/SE

prompt>report_disable_tie_insert

Report:Disabled tie ports and pins

-------------------------------------

EXAMPLE2

prompt>set_disable_tie_insert -objects [get_pins {h1/reg_2_/SE h1/reg_2_/SI}]

prompt>report_disable_tie_insert -all

Report:Disabled tie ports and pins

---------------------------------

h1/reg_2_/SE

h1/reg_2_/SI

prompt>reset_disable_tie_insert -all

prompt>report_disable_tie_insert

Report:Disabled tie ports and pins

-------------------------------------
```

SEE ALSO

add_tie_cells(2)
set_disable_tie_insert(2)
report_disable_tie_insert(2)

reset_multi_input_switching_coefficient

Resets user-specified multi-input switching (MIS) coefficients.

SYNTAX

int **reset_multi_input_switching_coefficient**
-all
object_list

Data Types

object_list list

ARGUMENTS

-all

Resets all the library cells specified for multi-input switching analysis. You cannot use this option together with the *object_list* option.

object_list

Specifies a list of library cells to be reset. You cannot use this option together with the **-all** option.

DESCRIPTION

This command resets the user-specified base coefficients for multi-input switching (MIS) analysis. If you reset the coefficient of a library cell, then the tool does not perform multi-input switching analysis on that library cell.

EXAMPLES

The following example resets the base coefficients of library cell AND2 in the library MY_LIB:

prompt> **reset_multi_input_switching_coefficient [get_lib_cells MY_LIB/AND2]**

SEE ALSO

set_multi_input_switching_coefficient(2)
report_multi_input_switching_coefficient(2)
enable_multi_input_switching_analysis(3)
enable_multi_input_switching_timing_window_filter(3)

reset_multi_vth_constraint

Disable percentage vth flow, reset low vth percentage limit and cost type to default values

SYNTAX

reset_multi_vth_constraint

DESCRIPTION

This command disables percentage vth flow and resets percentage vth constraints to default values, including low vth percentage limit and cost type. Default value of low vth percentage limit is 100.0. Default cost type is cell_count. These settings are persistent across shell sessions.

EXAMPLES

prompt> **reset_multi_vth_constraint**
Percentage vth flow : disabled
Percentage vth limit : 100.000 (%)
Percentage vth cost : cell_count

SEE ALSO

set_multi_vth_constraint(2)
report_multi_vth_constraint(2)
report_threshold_voltage_group(2)
set_vth_threshold_controls(2)

reset_parasitics_derate

Resets parasitic derating factors that influence extraction for DR/GR/CTO/RDE.

SYNTAX

string **set_parasitics_derate**
[-corners *corners*]
[-min | -max]

Data Types

corners list

ARGUMENTS

-corners *corners*

Specifies the list of corners for which to apply the extraction options. Reseting derating factors will be applied to all corners without -corners.

-min

Specifies derating factor for min analysis.

-max

Specifies derating factor for max analysis.

DESCRIPTION

This command resets derating factors to default derating factors used during RC extraction. The derating options will be associated with default constraint corner, or each list of constraint corners.

The default derating factor value is 1.0, which means no derating. This command supports 0 and positive derating factor value.

Multicorner-Multimode Support

EXAMPLES

```
prompt> report_parasitics_derate

Global factors:
---------------

Corner: default
* max
  Cap factor(Data,Clock)         : {1.1, 1.3}

reset_path

Resets specified paths to single-cycle behavior.

SYNTAX

```
Boolean reset_paths
  [-setup] [-hold]
  [-rise] [-fall]
  [-from from_list
    | -rise_from rise_from_list
    | -fall_from fall_from_list]
  [-through through_list]*
  [-rise_through rise_through_list]*
  [-fall_through fall_through_list]*
  [-to to_list
    | -rise_to rise_to_list
    | -fall_to fall_to_list]
  [-all]

list from_list
list rise_from_list
list fall_from_list
list through_list
list rise_through_list
list fall_through_list
list to_list
list rise_to_list
list fall_to_list
```

ARGUMENTS

-setup

Indicates that only setup (maximum delay) evaluation is to be reset to its default, single-cycle behavior. If neither **-setup** nor **-hold** is specified, both setup and hold checking are reset to single-cycle.

-hold

Indicates that only hold (minimum delay) evaluation is to be reset to its default, single-cycle behavior. If neither **-setup** nor **-hold** is specified, both setup and hold checking are reset to single-cycle.

-rise

Indicates that only rising path delays are to be reset to single-cycle behavior. If neither **-rise** nor **-fall** is specified, both rising and

falling delays are reset to single-cycle.

-fall

Indicates that only falling path delays are to be reset to single-cycle behavior. If neither **-rise** nor **-fall** is specified, both rising and falling delays are reset to single-cycle.

-from ***from_list***

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from ***rise_from_list***

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from ***fall_from_list***

Same as the **-from** option, except that the path must fall from the objects specified.If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through ***through_list***

Specifies a list of pins, ports, and nets through which the paths must pass that are to be reset. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-rise_through ***rise_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-rise_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-fall_through ***fall_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-fall_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-to ***to_list***

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints

clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-all

This option removes all the timing exceptions (set_false_path, set_multicycle_path, set_max_delay, set_min_delay) in this mode. This option cannot be specified with any other from/to/through or rise/fall/setup/hold option.

DESCRIPTION

The command restores designated timing paths in the current design the default single-cycle behavior. Use **reset_paths** to undo the effect of **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay**. Attributes set by these commands are removed by **reset_paths**.

Note that a general **reset_paths** command removes the effect of matching general or specific point-to-point exception commands, as long as there is a matching object in the path specification of the original exception-setting commands. For example, the following command

reset_paths -from {CLK}

resets more specific matching exceptions for the object CLK, such as

set_false_path -from {CLK} -to {d/Z}
set_false_path -from {CLK} -to {g/Z}

If you do not specify either **-setup** or **-hold**, the default behavior is restored to both. The default is a setup relation of one cycle and a hold relation of zero cycles, so that hold is checked one active edge before the setup data at the destination register.

Setup and hold information is different for rising and falling transitions. In most cases, these are reset together. Use the **-rise** or **-fall** options to reset only one or the other. To disable setup or hold calculations for paths, use **set_false_path**.

The general and specific constraint options (for example, **-through** and **-rise_through** or **-fall_through**) are treated as different qualifiers. That is, if you issue **reset_paths -fall_through**, only those constraints are removed that were set with the **-fall_through** option; any that were set with the **-through** option are not removed. The same applies to the general and specific **-to** and **-from** options. For an example, see the EXAMPLES section.

You can use multiple **-through**, **-rise_through**, and **fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

-from A1 -through B1 -through C1 -to D1

If more than one object is specified within one **-through**, **-rise_through**, or **fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

-from A1 -through {B1 B2} -through {C1 C2} -to D1

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following command resets the timing relation between ff1/CP and ff2/D to the default single-cycle behavior.

prompt> **reset_paths -from { ff1/CP } -to { ff2/D }**

The following command resets only the rising delay to single cycle for all paths ending at latch2d.

prompt> **reset_paths -rise -to latch2d**

The following example first sets a specific and a general point-to-point exception, then removes the exceptions.

prompt> **set_multicycle_path 2 -from A -to Z**
prompt> **set_max_delay 15 -to Z**
prompt> **reset_paths -to Z**

In following example, the **reset_paths** command removes only the max_delay constraints, because **-to** and **-rise_to** are treated as different qualifiers and do not match.

prompt> **set_multicycle_path 2 -from A -to Z**
prompt> **set_max_delay 15 -rise_to Z**
prompt> **reset_paths -rise_to Z**

reset_paths

Resets specified paths to single-cycle behavior.

SYNTAX

Boolean **reset_paths**
[-setup] [-hold]
[-rise] [-fall]
[-from *from_list*
| -rise_from *rise_from_list*
| -fall_from *fall_from_list*]
[-through *through_list*]*
[-rise_through *rise_through_list*]*
[-fall_through *fall_through_list*]*
[-to *to_list*
| -rise_to *rise_to_list*
| -fall_to *fall_to_list*]
[-all]

list *from_list*
list *rise_from_list*
list *fall_from_list*
list *through_list*
list *rise_through_list*
list *fall_through_list*
list *to_list*
list *rise_to_list*
list *fall_to_list*

ARGUMENTS

-setup

Indicates that only setup (maximum delay) evaluation is to be reset to its default, single-cycle behavior. If neither **-setup** nor **-hold** is specified, both setup and hold checking are reset to single-cycle.

-hold

Indicates that only hold (minimum delay) evaluation is to be reset to its default, single-cycle behavior. If neither **-setup** nor **-hold** is specified, both setup and hold checking are reset to single-cycle.

-rise

Indicates that only rising path delays are to be reset to single-cycle behavior. If neither **-rise** nor **-fall** is specified, both rising and

falling delays are reset to single-cycle.

-fall

Indicates that only falling path delays are to be reset to single-cycle behavior. If neither **-rise** nor **-fall** is specified, both rising and falling delays are reset to single-cycle.

-from ***from_list***

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from ***rise_from_list***

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from ***fall_from_list***

Same as the **-from** option, except that the path must fall from the objects specified.If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through ***through_list***

Specifies a list of pins, ports, and nets through which the paths must pass that are to be reset. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-rise_through ***rise_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-rise_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-fall_through ***fall_through_list***

This option is similar to the **-through** option, but applies only to paths with a rising transition at the through points. You can specify **-fall_through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-to ***to_list***

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints

clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-all

This option removes all the timing exceptions (set_false_path, set_multicycle_path, set_max_delay, set_min_delay) in this mode. This option cannot be specified with any other from/to/through or rise/fall/setup/hold option.

DESCRIPTION

The command restores designated timing paths in the current design the default single-cycle behavior. Use **reset_paths** to undo the effect of **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay**. Attributes set by these commands are removed by **reset_paths**.

Note that a general **reset_paths** command removes the effect of matching general or specific point-to-point exception commands, as long as there is a matching object in the path specification of the original exception-setting commands. For example, the following command

reset_paths -from {CLK}

resets more specific matching exceptions for the object CLK, such as

set_false_path -from {CLK} -to {d/Z}
set_false_path -from {CLK} -to {g/Z}

If you do not specify either **-setup** or **-hold**, the default behavior is restored to both. The default is a setup relation of one cycle and a hold relation of zero cycles, so that hold is checked one active edge before the setup data at the destination register.

Setup and hold information is different for rising and falling transitions. In most cases, these are reset together. Use the **-rise** or **-fall** options to reset only one or the other. To disable setup or hold calculations for paths, use **set_false_path**.

The general and specific constraint options (for example, **-through** and **-rise_through** or **-fall_through**) are treated as different qualifiers. That is, if you issue **reset_paths -fall_through**, only those constraints are removed that were set with the **-fall_through** option; any that were set with the **-through** option are not removed. The same applies to the general and specific **-to** and **-from** options. For an example, see the EXAMPLES section.

You can use multiple **-through**, **-rise_through**, and **fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

-from A1 -through B1 -through C1 -to D1

If more than one object is specified within one **-through**, **-rise_through**, or **fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

-from A1 -through {B1 B2} -through {C1 C2} -to D1

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following command resets the timing relation between ff1/CP and ff2/D to the default single-cycle behavior.

prompt> **reset_paths -from { ff1/CP } -to { ff2/D }**

The following command resets only the rising delay to single cycle for all paths ending at latch2d.

prompt> **reset_paths -rise -to latch2d**

The following example first sets a specific and a general point-to-point exception, then removes the exceptions.

prompt> **set_multicycle_path 2 -from A -to Z**
prompt> **set_max_delay 15 -to Z**
prompt> **reset_paths -to Z**

In following example, the **reset_paths** command removes only the max_delay constraints, because **-to** and **-rise_to** are treated as different qualifiers and do not match.

prompt> **set_multicycle_path 2 -from A -to Z**
prompt> **set_max_delay 15 -rise_to Z**
prompt> **reset_paths -rise_to Z**

reset_pipeline_scan_data_configuration

Resets the pipeline scan data configuration specified by the **set_pipeline_scan_data_configuration** command.

SYNTAX

status **reset_pipeline_scan_data_configuration**

ARGUMENTS

The **reset_pipeline_scan_data_configuration** command has no arguments.

DESCRIPTION

This command resets the pipeline scan data configuration for the current design.

EXAMPLES

The following example resets the pipeline scan data configuration of the current design to the default:

prompt> **reset_pipeline_scan_data_configuration**

SEE ALSO

set_pipeline_scan_data_configuration(2)

reset_placement

Unplace all cells in the core area

SYNTAX

collection **reset_placement**
[-spread_cells]

-spread_cells

Specifies that the cells should be spread out to the right of the block.

DESCRIPTION

Unplace cells in the core area. The command does not unplace fixed & dont_touch cells. I

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example unplaces all cells

prompt> **reset_placement**

SEE ALSO

create_placement(2)

reset_placement_ir_drop_target

Reset placer IR drop targets

SYNTAX

string **reset_placement_ir_drop_target** *voltage_area*
type

list *voltage_area*
string *type*

ARGUMENTS

voltage_area

Specifies the voltage area for settings the IR drop targets

type

Specifies the type of IR drop target setting, either low or high

DESCRIPTION

This command resets the IR aware placement settings.

EXAMPLES

The followin example sets for the voltage area DEFAULT_VA the low voltage drop target to 3.0% of the effective supply voltage and the high voltage drop target to 5.0% of the effective supply voltage. Then the high target is reset.

```
prompt> set_placement_ir_drop_target DEFAULT_VA low 3.0 -irdrop
prompt> set_placement_ir_drop_target DEFAULT_VA high 5.0 -irdrop
prompt> get_placement_ir_drop_target DEFAULT_VA
{ { DEFAULT_VA low 3.000000 -irdrop } { DEFAULT_VA high 5.000000 -irdrop } }
prompt> reset_placement_ir_drop_target DEFAULT_VA high
prompt> get_placement_ir_drop_target DEFAULT_VA
{ { DEFAULT_VA low 3.000000 -irdrop } }
```

reset_power_budget

Resets power budget set on the design, or on the hierarchical instances in the design.

SYNTAX

status **reset_power_budget**
[-scenarios *scenario_list*]
[-cell*cell_list*]

Data Types

scenario_list list
cell_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the budget values are to be reset. If no scenario is specified, the current_scenario is used.

-cell*cell_list*

Specifies the list of cells on which the power budget values are reset.

DESCRIPTION

Invoke this command with no arguments to reset all budget. This includes both budget values set globally on the design and those set on specific instances in the current design. If the command is called with a list of cells, only the power budget values on the specified cells are reset. Note that power budget value set specifically on a cell is not overwritten by a set or reset command on its parent hierarchical cell. To reset the power budget values set specifically on the child cells, include them in the cell list with the -cell option.

Multicorner-Multimode Support

EXAMPLES

The following command resets both power budget values set globally and those set on specific instances in the design for the

scenario SC1.

```
prompt> reset_power_budget -scenario SC1
```

The following example resets the power budget set on cell H1 for the current scenario.

```
prompt> reset_power_budget -cell [get_cell H1]
```

The following command resets the power budget values set on all cells matching "*"

```
prompt> reset_power_budget -cell [get_cells *]
```

Assuming that the hierarchical cell H1 contains a cell H2, then the following command resets the budget set on H2.

```
prompt> reset_power_budget -cell [get_cells H1/H2]
```

SEE ALSO

set_power_budget(2)

report_power(2)

reset_power_clock_scaling

Resets the clock frequency scaling data for power analysis.

SYNTAX

status **reset_power_clock_scaling**
[-scenarios *scenario_list*]
[-all]
[*clock_list*]

Data Types

scenario_list list
clock_list list

ARGUMENTS

-scenarios *scenario_list*

Specify the list of scenarios for which the scaling data will be reset. If not specified, the current scenario is used.

clock_list

Specify a list of clocks in the design for which the scaling data is to be reset. If this option is not used then the global ratio value for the scenario is reset. If this option is used then the clock specific value for the scenario will be reset.

-all

A boolean option to clear the entire scaling data present for all the scenarios.

DESCRIPTION

The command resets the scaling data already present for the design. If '-all' option is used, then the entire scaling data is removed. The '-scenarios' option determines which scenario specifc data is to be reset. If the option is not used, the current scenario is the scenario taken for reset operation. The 'clock_list' option will reset the clock specific data for the scenario(s) specified or the current scenario if '-scenarios' option is not used. If the option is not used, then the global ratio value will be reset for the applicable scenario(s). The command returns 1 on success and 0 on failure.

EXAMPLES

The following examples describe the behavior of the cmd.

The following example resets the clk1 data present for the current scenario.

```
prompt> reset_power_clock_scaling clk1
```

The following example resets the clk1 data for the scenario scn1 having mode scn1.mode.

```
prompt> reset_power_clock_scaling [get_clocks -mode scn1.mode clk1]
```

The following example resets the global ratio values for the scenarios 'default' and 'scn1'

```
prompt> reset_power_clock_scaling -scenarios {default scn1}
```

The following example resets the clk1 and clk2 data for the scenario scn1 having mode scn1.mode, and global ratio value for the scenario 'default'.Here the current scenario is scn1.

```
prompt> reset_power_clock_scaling -scenarios {scn1 default} {clk1 clk2}
```

SEE ALSO

get_power_clock_scaling(2)
set_power_clock_scaling(2)

reset_power_derate

Resets the power derating factors for either the current design, a list of cells, library cells or all cells in a power group in the current design.

SYNTAX

status **reset_power_derate**
[-scenarios *scenario_list*]
[-groups *group_names*]
[*object_list*]

Data Types

scenario_list list
group_names list
object_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is to be reset. If no scenario is specified the current_scenario is used.

-group *group_names*

Specifies the power group for which the derate factor is to be reset. The derate factors are reset for each cell object in the power group. Note groups and object_list are mutually exclusive option.

object_list

Specifies the list of cells or library cells on which the power derating factors are reset. Note groups and object_list are mutually exclusive option.

DESCRIPTION

Invoke this command with no arguments to reset all derate (to the default of 1.0). This includes both derating factors set globally on the design and those set on specific instances in the current design. If the command is called with a list of objects, only the power derating factors on the specified objects are reset. After a reset_power_derate command is applied to an object, the power derating factors of all power components, including leakage, internal and switching power are reset.

Note that power derating factors set specifically on an object are not overwritten by a set or reset command on its parent hierarchical cell. To reset the power derating factors set specifically on the child cells, include them in the object list of the command.

The -group options allows to reset the derate factors of cells only in the specified group.

Heterogeneous collections of objects can be combined and passed to this command.

This command does not impact the power budget applied using set_power_budget.

Multicorner-Multimode Support

EXAMPLES

The following command resets both power derating factors set globally and those set on specific instances in the design for the scenario SCN1.

```
prompt> reset_power_derate -scenario SCN1
```

The following example resets the power derating factors set on cell U1 for the current scenario.

```
prompt> reset_power_derate [get_cell U1]
```

The following command resets the power derating factors set on all cells matching "*"

```
prompt> reset_power_derate [get_cells *]
```

The following example resets the power derating factors set on all instances of library cell IV in the library MY_LIB.

```
prompt> reset_power_derate [get_lib_cells MY_LIB/IV]
```

Assuming that the hierarchical cell H1 contains a cell U1, then the following command resets the derate factors set on U1. As a result, U1 inherits the derate factors that are set on H1.

```
prompt> reset_power_derate [get_cells H1/U1]
```

SEE ALSO

set_power_derate(2)

report_power_derate(2)

reset_power_group

Resets user specified power group on cells and libcells.

SYNTAX

status **reset_power_group**
object_list
-name *group_name*
-all

Data Types

object_list list
group_name string

ARGUMENTS

-name *group_name*

Specifies the user power group name that needs to be removed on all the cells and libcells present in the design having that power group name.

object_list

Specifies list of cells and/or libcells whose user specified power groups needs to be removed.

-all

Resets user specified power group of all the cells and libcells in the design.

DESCRIPTION

The command resets user specified power group(s). One and only one option among '-name', 'object_list' or '-all' can be specified.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example resets power group 'macro1' from all libcells and cells having that power group name.

```
prompt> reset_power_group -name macro1
```

SEE ALSO

get_power_group(2)
set_power_group(2)
report_power_groups(2)
get_power_group_objects(2)
report_power(2)
power.report_user_power_groups(3)

reset_pvt

Resets all user specified process, voltage, temperature, and derate settings set on one or more corners of the design.

SYNTAX

int **reset_pvt**
[-corners *corner_list*]

list *corner_list*

ARGUMENTS

-corners *corner_list*

Specifies a list of corners to be processed. If this option is not given, the current corner will be processed.

DESCRIPTION

This command will reset all process label, process number, voltage, temperature, and timing derate settings for the given corner(s). Voltages set on UPF supply nets and supply ports will also be reset. All timing derates will be reset to 1.0. After this command is executed, the corner(s) will have the same settings that a newly-created corner would have, based on the main library default PVT values.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

SEE ALSO

set_process_label(2)
set_process_number(2)
set_process_voltage(2)
set_process_temperature(2)
set_timing_derate(2)

reset_scan_configuration

Resets the scan configuration for the current design.

SYNTAX

status **reset_scan_configuration**

ARGUMENTS

The **reset_scan_configuration** command has no arguments.

DESCRIPTION

The **reset_scan_configuration** command resets the current scan configuration from the design.

EXAMPLES

The following example shows how to reset the scan configuration:

```
prompt> reset_scan_configuration
```

SEE ALSO

report_scan_configuration(2)
set_scan_configuration(2)

reset_supply_net_probability

Resets switching probability on selected supply nets in the current design.

SYNTAX

status **reset_supply_net_probability**
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
object_list

Data Types

scenario_list	list
mode_list	list
corner_list	list
object_list	list

ARGUMENTS

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Probability is reset separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, probability is reset for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

DESCRIPTION

Use this command to reset the switching activity of design supply nets. The activity of a supply net is used to scale leakage power and dynamic power of the cells connected to the supply net. The scaling of leakage power is governed by app option *power.scale_leakage_power_at_power_off* (by default true), the scaling of dynamic power by app option

power.scale_dynamic_power_at_power_off (by default false). The scaling factor for a cells is the lowest static_probability of all its supply nets.

The supply nets that are being reset can be specified explicitly as a list of objects.

If a combination of a mode and corner is specified that does not represent a valid scenario, those are ignored.

Multicorner-Multimode Support

EXAMPLES

The following **reset_supply_net_probablity** command reset the static_probablity on a supply net

```
prompt> set_supply_net_probability -static_probability 0.9 [get_supply_net VDD]
```

SEE ALSO

set_supply_net_probability(2)
get_supply_net_probiblity(2)
power.scale_leakage_power_at_power_off(3)
power.scale_dynamic_power_at_power_off(3)

reset_switching_activity

Resets switching activity information on nets, pins, ports and cells in the current design.

SYNTAX

status **reset_switching_activity**
[-state_condition *state_condition*]
[-path_sources *path_sources*]
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
[*object_list*]

Data Types

state_condition	string
path_sources	list
scenario_list	list
mode_list	list
corner_list	list
object_list	list

ARGUMENTS

-state_condition *state_condition*

Specifies the state condition to reset state-dependent activities. State dependent activities can be reset when the object is already annotated with state-dependent activities. The state condition specified with this argument must match to a state condition already annotated for this object. Use -state_condition default to specify the default state condition.

-path_sources *path_sources*

Specifies the path sources to reset path-dependent activities. This can be used when the object is already annotated with path-dependent activities. The path sources specified with this argument must be the same as those annotated for this object.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Activity is reset separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, activity is reset for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

object_list

Specifies a list of nets, pins or ports in the current design for which the values of static probability, rise toggle rate, fall toggle rate and type of activity are reset.

DESCRIPTION

Use this command to reset switching activity of nets, ports, pins and cells in the design. The values reset include rise toggle rate, fall toggle rate, static probability and the type of activity.

The design objects whose switching activities are reset can be specified as a list of objects. If no such list is provided, activities of all objects in the design which had been annotated with the **set_switching_activity** command will be reset.

If an instance is specified in the object list, then the state-dependent path_dependent activity information will be removed from the instance.

Multicorner-Multimode Support

EXAMPLES

The following example depicts the command resetting the values of rise toggle rate, fall toggle rate, static probability and type of activity on the pin 'InstDecode/InstReg_reg_23_/SI'. Initially the pin had the following activity:

(mode = default, corner = default, probability = 0.9, rise_toggle_rate = 0.4, fall_toggle_rate = 0.6, type = annotated)

After reset, it will have the following activity.

(mode = default, corner = default, probability = 0.8, rise_toggle_rate = 0.116667, fall_toggle_rate = 0.116667, type = default)

Such default activity would be derived from the values as specified by the user in the app options 'power_default_static_probability', 'power_default_toggle_rate' and 'power_default_toggle_rate_reference_clock'.

```
prompt> reset_switching_activity {InstDecode/InstReg_reg_23_/SI}
```

SEE ALSO

reset_test_mode

Resets the test mode for the current design.

SYNTAX

status **reset_test_mode**

ARGUMENTS

The **reset_test_mode** command has no arguments.

DESCRIPTION

The **reset_test_mode** command resets the current test mode of the current design to the default test mode.

EXAMPLES

The following example resets the current test mode:

```
prompt> reset_test_mode
Current test mode is reset to default
1
```

SEE ALSO

current_test_mode(2)
define_test_mode(2)

reset_testability_configuration

Resets the testability configuration for the current design.

SYNTAX

status **reset_testability_configuration**

ARGUMENTS

The **reset_testability_configuration** command has no arguments.

DESCRIPTION

The **reset_testability_configuration** command resets the testability configuration for the current design.

SEE ALSO

report_testability_configuration(2)
set_testability_configuration(2)

reset_timing_derate

Resets user specified derate factors set either on a design or on a specified list of objects (cells, library cells, or nets).

SYNTAX

int **reset_timing_derate**
[-hierarchical_net_delay]
[-scalar] [-variation]
[-aocvm_guardband]
[-pocvm_guardband]
[-pocvm_coefficient_scale_factor]
[-pocvm_subtract_sigma_factor_from_nominal]
[-increment]
[-corners *corner_list*]
object_list

list *object_list*
list *corner_list*

ARGUMENTS

-hierarchical_net_delay

Resets net delay derating (as well as cell delay derating) previously set by the **set_timing_derate** command for the hierarchical cells specified in the *object_list*. Without the **-hierarchical_net_delay** option, the **reset_timing_derate ... [get_cells ...]** command resets only the cell delay (not net delay) derating in the hierarchical cells.

-scalar

Indicates that only derate factors for deterministic delays should be reset. This option is currently ignored.

-variation

Indicates that only derate factors for statistical delays should be reset. This option is currently ignored.

-aocvm_guardband

Indicates that only AOCVM guardband derate factors should be reset.

-pocvm_guardband

Indicates that only POCVM guardband derate factors should be reset.

-pocvm_coefficient_scale_factor

Indicates that only POCVM coefficient scale factors should be reset.

-pocvm_subtract_sigma_factor_from_nominal

Indicates that only POCVM subtract sigma factors should be reset.

-increment

Indicates that only incremental derate factors for the specifed delays should be reset.

-corners *corner_list*

Specifies the corner(s) where the derate values will be reset. If this option is not given, the current corner will be used.

object_list

Specifies a list of designs, cells, library cells or nets which will be reset.

DESCRIPTION

Call this command with no arguments to reset all derate factors set on the design (to the default value, 1.0). This will include both derate factors set globally on the design and those set on specific instances in the design. Call this command with a list of objects to reset a specific set of objects.

The *object_list* option may be used to reset derate factors on specific objects (cells or library cells) in the design. All derate factors are reset on each instance. If *object_list* contains a design, then only global derate factors are reset and instance specific derate factors are not reset.

Heterogeneous collections of objects may be combined and passed to this command.

If neither *-scalar* nor *-variation* options are specified, then both deterministic and variation derates are reset.

The incremental derate factors are reset when no options are specified or when -increment option is specified.

If *object_list* contains any hierarchical cells then all cells within that hierarchical cell and also all cells of all lower hierarchies will have their inherited derate factors updated accordingly. Note that derate factors set specifically on an object will not be overwritten by a set/reset command on its parent hierarchical cell.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

The following command resets both incremental and non-incremental derate factors set globally on the design and those set on specific instances in the design.

prompt> **reset_timing_derate**

The following command resets the derate factors set globally on the design MY_DESIGN only.

prompt> **reset_timing_derate [get_designs MY_DESIGN]**

The following example resets the derate factors set on cell U1.

prompt> **reset_timing_derate [get_cells U1]**

The following command resets the derate factors set on all cells matching "*".

prompt> **reset_timing_derate [add_to_collection [get_cells *]]**

The following example resets the derate factors set on all instances of library cell IV in the library MY_LIB.

prompt> **reset_timing_derate [get_lib_cells MY_LIB/IV]**

Assuming that the hierarchical cell H1 contains a cell U1, then the following command resets the derate factors set on U1 and as a result U1 inherits the derate factors that are set on H1.

prompt> **reset_timing_derate [get_cells H1/U1]**

Assuming that the hierarchical cell H1 also contains a hierarchical cell H2, then the following command resets the derate factors set on H2 and as a result H2 and all of its cells inherit the derate factors that are set on H1.

prompt> **reset_timing_derate [get_cells H1/H2]**

Following example reset only incremental derates on cell top/H1/u12.

prompt> **reset_timing_derate -increment [get_cells top/H1/u12]**

The following command resets the cell **and net** delay derating previously set on hierarchical cell H1/H2. As a result, cell H2 and all of its lower-level cells inherit the cell **and net** delay derating set on their parent (or grandparent) cell, H1.

prompt> **reset_timing_derate -hierarchical_net_delay [get_cells H1/H2]**

SEE ALSO

set_timing_derate(2)
report_timing_derate(2)

reset_upf

Removes all UPF constraints and UPF data-dependent constraints from the current design. The entire design is restored back to default single voltage UPF condition.

SYNTAX

status **reset_upf**

ARGUMENTS

The **reset_upf** command has no arguments.

DESCRIPTION

The **reset_upf** command is used to clean up all UPF constraints in the current design. This command returns a 1 if successful and returns a 0 otherwise.

The **reset_upf** command also removes UPF data-dependent constraints, which include the following commands:

set_voltage
set_related_supply_net

After **reset_upf** is executed and new UPF constraints are reloaded using the **load_upf** command, run the above commands again with respect to the new UPF constraints.

Warning: Executing **reset_upf** has extremely wide-ranging consequences. This command removes all UPF constraints in the current design, with a result that is often equivalent to starting the UPF flow. This command removes UPF constraints without touching the netlist. The command does not check if the netlist has been processed by prior UPF constraints. All commands that might change the netlist after the **load_upf** command will not be backed out by the **reset_upf** command. Remember to verify that the UPF constraints are consistent.

EXAMPLES

The following example shows a typical use of the *reset_upf* command:

```
prompt> load_upf upf_file1
prompt> reset_upf
```

```
prompt> load_upf upf_file2
1
```

The following example shows one of the risks of using the **reset_upf** command. After running the **reset_upf** command, the power domain is removed along with the relationship of the power domain with its related voltage area. So even after reloading the UPF file, you cannot get related power domain information on those voltage areas. In this case, remove the related voltage areas and recreate them with the power domain.

```
prompt> get_voltage_area VA1
VA1
prompt> get_power_domain VA1
VA1
prompt> reset_upf
prompt> load_upf upf_file
prompt> report_voltage_areas VA1
```

SEE ALSO

load_upf(2)
save_upf(2)

reset_via_ladder_candidates

Resets all via ladder candidates for the specified library-pin.

SYNTAX

status **reset_via_ladder_candidates**
lib_pin

Data Types

lib_pin pin name or collection

ARGUMENTS

lib_pin

Specifies the library-pin for which via ladder candidate will be reset.

DESCRIPTION

This command clears all via ladder candidates for the specified library pin. This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

The following example resets via ladder candidates for specified pins.

```
prompt> reset_via_ladder_candidates [get_lib_pin tcbn90ghvt/AN2HVTD0/A1]
1
```

SEE ALSO

set_via_ladder_candidate(2)

set_via_ladder_constraints(2)

remove_via_ladder_constraints(2)
report_via_ladder_constraints(2)

reset_wrapper_configuration

Resets the wrapper configuration for the current design.

SYNTAX

status **reset_wrapper_configuration**
[-test_mode *mode_name*]

Data Types

mode_name string

ARGUMENTS

-test_mode *mode_name*

Specifies the test mode to which the **reset_wrapper_configuration** command applies. The default is **all**, which resets the global wrapper configuration, but keeps any mode-specific configurations.

DESCRIPTION

This command resets the wrapper configuration to the following values:

```
Wrapper Configuration
====================
Reuse Threshold:                  0
Hier Wrapping:                    Disable
Add Wrapper Cells To Power Domain:    Disable
Mix Cells:                        False
Mix With Scan Cells:              False
Use System Clock For Dedicated Wrapper Cells: Enable
Depth Threshold:                  Unspecified
Chain count:                      Unspecified
Gate Cells:                       none
```

reshape_objects

Cuts from the boundary or adds to the boundary of one or more geometric objects.

SYNTAX

string **reshape_objects**
-add *rectangle*
-cut *rectangle*
-cut_by_locked
[-ignore_end_cap]
[-gap *distance*]
[-gap_min_spacing]
[-keep_inside]
[-via_cut_pattern]
[-force]
[-simple]
[*object_list*]

Data Types

rectangle	rectangle string
object_list	collection or selection
distance	float

ARGUMENTS

object_list

Collection or selection set containing objects to reshape. If this option is not specified, global selection set is used.

-add *rectangle*

Specifies the rectangle to append to the object boundaries.

-cut *rectangle*

Specifies the rectangle to cut from the object boundaries.

-cut_by_locked

Cuts object boundary by another locked object. It implicitly works on the specified objects. The objects must either be resizable or support a rectilinear boundary depending on the final result of the cut.

-ignore_end_cap

Treats the wire as if it has no cap extension.

-gap *distance*

Specifies an extra gap spacing by which to cut. This option is mutually exclusive with the **-gap_min_spacing**. By default, the gap spacing is 0 if neither **-gap_min_spacing** nor **-gap** distance are specified.

-gap_min_spacing

Specifies a gap spacing as the minimum spacing rule. This option is mutually exclusive with the **-gap distance** option. By default, the gap spacing is 0 if neither **-gap_min_spacing** nor **-gap** distance are specified.

-keep_inside

Controls whether the tool removes the parts of the object outside the rectangle and keeps the inside parts. This option works only with the **-cut** option.

-via_cut_pattern

Updates via cut pattern of multi cut via. This option works with both the **-add** and the **-cut** options. By default, multi cut vias can only be trimmed. Note that the term "cut" refers to via metal pieces on the middle layer.

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

DESCRIPTION

This command cuts from or adds to the boundary of a set of objects by using an explicit rectangle or the boundary of fixed objects.

When multiple specified objects are to be cut, each object is treated independently and the result is the cumulative result of all cuts.

Note that cutting takes place only if the rectangle, or fixed object boundary by which to cut, overlaps with the boundary of the object being cut.

Snapping is done automatically by using global snap settings.

The command returns a collection of the reshaped objects if the input *object_list* is a collection of objects. Otherwise, this command reshapes objects in the specified selection set and returns status.

EXAMPLES

The following example cuts the boundary of the selected objects by a bounding box defined by the points {0 0} {100 100}.

```
prompt> reshape_objects -cut {{0 0} {100 100}}
```

The following example cuts the boundary of three the non-fixed selected objects by one fixed selected objects:

```
prompt> sizeof_collection [get_selection] "is_fixed==false"]
3
```

```
prompt> sizeof_collection [get_selection] "is_fixed==true"]
1
prompt> reshape_objects -cut_by_locked
```

The alternative syntax uses collection to specify objects.

```
prompt> reshape_objects [get_selection] -cut_by_locked
```

SEE ALSO

resize_objects

Resizes one or more objects. Resizes the width and height of move bounds, keepouts, and obstruction objects.

SYNTAX

status **resize_objects**
{ -bbox *bounding_box* |
-delta *offset* |
-scale *scale_factor* |
-width *object_width* |
-height *object_height* |
-utilization *util_factor* |
-aspect *aspect* |
-area *area* }
[-force]
[-simple]
[-quiet]
[*object_list*]

Data Types

bounding_box rectangle
offset rectangle
scale_factor point
object_width real
object_height real
util_factor real
aspect real
area real
object_list collection

ARGUMENTS

object_list

Collection or selection set containing objects to reshape. If this option is not specified, global selection set is used.

-bbox *bounding_box*

Specifies the new bounding box of the object.

The **-bbox** option cannot be used with any of the following options: **-delta**, **-scale**, **-width**, **-height**, **-utilization**, **-aspect** and **-area**.

-delta *offset*

Specifies the offset of the current bounding box of the object.

The *offset* argument should be of the following formats: {{x1 y1} {x2 y2}}.

The **-delta** option cannot be used with any of the following options: **-bbox**, **-scale**, **-width**, **-height**, **-utilization**, **-aspect** and **-area**.

-scale ***scale_factor***

Specifies an x-axis and y-axis scale factor. All objects will be resized by this factor.

The **-scale** option cannot be used with any of the following options: **-bbox**, **-delta**, **-width**, **-height**, **-utilization**, **-aspect** and **-area**.

The scale factor must be positive and non-zero.

-width ***object_width***

Specifies the width for a given object (or collection of objects).

All objects are resized so that their bounding box has this width and lower-left corner or center does not change. For pins located on the edge of a block, the width is a dimension parallel to the edge.

The **-width** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-utilization**, **-aspect** and **-area**.

The **-width** and **-height** options can be used together.

-height ***object_height***

Specifies the height for the given object (or collection of objects).

All objects are resized so that their bounding box has this width and lower-left corner or center does not change. For pins located on the edge of a block, the height is a dimension orthogonal to the edge.

The **-height** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-utilization**, **-aspect** and **-area**.

The **-width** and **-height** options can be used together.

-utilization ***util_factor***

Specifies the required utilization for the object. The object changes size based on *util_factor* value, but keeps the lower-left corner (center for pins and vias) fixed and retains the original aspect ratio.

The **-utilization** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-width**, **-height**, **-aspect** and **-area**.

The utilization factor must be positive and non-zero.

Note: this option is usable only for soft macros and movebounds.

-aspect ***aspect***

Specifies the required aspect for the object. The object changes size based on the *aspect* value, but keeps the lower-left corner (center for pins and vias) fixed and retains the original area.

The **-aspect** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-width**, **-height**, **-utilization** and **-area**.

-area ***area***

Specifies the required area for the object.

The **-area** option cannot be used with any of the following options: **-bbox**, **-delta**, **-scale**, **-width**, **-height**, **-utilization** and **-aspect**.

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be

accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

-quiet

Suppress all warning messages.

DESCRIPTION

This command resizes a list of objects to either an explicit bounding box, a delta from the current bounding box, an x and y scale, an explicit width and height, a size that gives a required utilization given a constant aspect ratio, or a size that gives a specified aspect ratio given a constant area.

Only resizable objects can be used with this command.

Notes

Locked objects are not moved unless you use the **-ignore_locked** option.

Snapping is done automatically using global snap settings. This command can be used to adjust the width and height of objects specified in the object list. You can use it to adjust the width and height of a single object or apply it to multiple objects that are individually resized and respaced in a linearly.

EXAMPLES

The following example resizes all selected objects so that they have an aspect ratio of 2.5.

prompt> **resize_objects [get_selection] -aspect 2.5**

The following example resizes all specified objects so that their lower-left corner is at the point {0 0} and they are 100 units wide and 100 units high.

prompt> **resize_objects [get_selection] -bbox {{0 0} {100 100}}**

SEE ALSO

change_selection(2)
get_selection(2)
get_snap_setting(2)
set_snap_setting(2)

snap_objects(2)

resize_polygons

Adjusts the edges of a geometric region and returns the result as a geo_mask.

SYNTAX

collection **resize_polygons**
[-objects *object_list*]
[*pos_object_list*]
-size { *d* | *lr tb* | *l b r t* }

Data Types

object_list collection
pos_object_list collection
d float
lr float
tb float
l float
b float
r float
t float

ARGUMENTS

-objects *object_list*

Specifies the objects to be used to define the geometric region to be resized. Objects may be a heterogenous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

The specified region must not be empty, i.e. must have positive area. It is an error to attempt to resize an empty region.

pos_object_list

Specifies the objects to be used to define the geometric region to be resized. This positional option is provided for compatibility with other tools.

-size { *d* | *lr tb* | *l b r t* }

Specifies the distance to expand the edges. If one value is provided, the left, bottom, right, and top edges are each expanded by that distance. If two values are provided, the left and right edges are each expanded by the first distance, and the top and bottom

edges are each expanded by the second distance. If four values are provided, the left, bottom, right, and top edges are expanded by the respective distances.

You may specify negative distance values, in which case the respective edges will be shrunk by the absolute value. Zero value distances will result in no change.

This is a required option.

DESCRIPTION

This command expands or shrinks the boundaries of the region specified by *objects*, and returns a collection that contains the result as geo_mask object.

EXAMPLES

The following example returns a geo_mask with a region that is a shape padded by 5 units of distance.

prompt> **resize_polygons -objects [get_shapes RECT_0] -size {5}**

The following example returns a geo_mask with a region composed of the shapes on a layer, with each contiguous polygon expanded by a margin of 15 units of distance on its right-hand side.

prompt> **resize_polygons -objects [get_layers M1] -size {0 0 15 0}**

resolve_pg_nets

Resolves power and ground connections based on power domains.

SYNTAX

status **resolve_pg_nets**
[-check_only]
[-design *design*]
[-verbose]

ARGUMENTS

-check_only

Specifies the check_only mode. Under this mode, the **resolve_pg_nets** command prints out intended PG connection changes without applying the changes.

-design *design*

Specifies the design in which to resolve the power and ground nets. If no design is specified, the power and ground nets are resolved in the current design.

-verbose

Prints the details of the changes to the power and ground connections.

DESCRIPTION

This command resolves the conflicts between power and ground network with power domains. In MV mode, UPF must be committed before running the **resolve_pg_nets** command. In non MV mode, the default power domain is used to resolve PG connections.

EXAMPLES

The following example uses the **resolve_pg_nets** command to resolve PG connection based on power domains.

prompt> **resolve_pg_nets -verbose**

The following example uses the **resolve_pg_nets** command to check PG connection against power domains without making any changes.

```
prompt> resolve_pg_nets -check_only
```

SEE ALSO

commit_upf(2)
connect_pg_net(2)

revert_blocks

Reverts one or more blocks of a sparse library to its version in the base library, removes the on-disk data of the design in the directory of the sparse library.

SYNTAX

return_val **revert_blocks**
blocks

Data Types

return_val The number of blocks reverted, 0 if none
blocks The single block name in
[libName:]blockName[/labelName][.viewName] format or
a collection of blocks

ARGUMENTS

blocks

A block name with optional library, label, and view specifications, or a collection of blocks. If the library specification is not present, the **current_lib** is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then *design view* is used. If the option is not given, the **current_block** is used. The blocks if opened must be removed/purged from the memory using **close_block** command before reverting them.

RETURN VALUE

Returns the number of blocks reverted, 0 if none. If an illegal name (with a slash) is given for the block, a TCL error is raised. If any specified block belongs to a non-sparse library, a TCL error is raised. If any specified block is open, a TCL error is raised.

DESCRIPTION

This command reverts a block and removes all of on-disk contents in the sparse library, retaining just the entry in the sparse library's catalog as remote. After it is executed the disk contents of the block are removed. Note that this command works only if the block is not loaded in memory.

EXAMPLES

This example reverts the block Top from catalog of the sparse library and removes it from disk.

```
prompt> revert_blocks Top
Information: Reverted design 'sparse_lib:Top.design' and removed it from disk. (NDMUI-365)
1
prompt> get_attribute [get_blocks -all Top] is_remote
true
```

revert_cell_sizing

Reverts unacceptable ECO changes. This command is only for reverting ECO changes made by using the size_cell command that cause cell spacing rule violations.

SYNTAX

status **revert_cell_sizing**
-cells *cell_objects*
[-include_adjacent_sized_cells]
[-adjacent_cell_distance *distance*]

Data Types

cell_objects	string
distance	float

ARGUMENTS

-cells *cell_objects*

Specifies the cell objects on which the ECO changes are reverted. The cell objects can be a name string or collection.

-include_adjacent_sized_cells

Reverts adjacent sized cells, along with given sized cells, to avoid potential spacing rules violation. Adjacent cells are the cells on the same row that are close to the given cell. The search for adjacent cells is a recursive process, which means the tool reverts the adjacent sized cells of adjacent sized cells of the given sized cells until there is no adjacent sized cells.

-adjacent_cell_distance

Specifies the distance threshold for selecting the adjacent sized cells. The units are microns. The value cannot be negative. This option can only be used with the -include_adjacent_sized_cells option.

If the option is not used, the default value of the distance threshold between two cells is zero and the adjacent cells selected are the cells on the same row that abuts the given cell. If the option is used, adjacent cells selected are the cells on the same row that are within a distance that is less than or equal to the distance threshold.

DESCRIPTION

This command reverts unacceptable ECO changes on the specified objects. It rolls back the latest sizing changes applied on the objects.

The type of ECO changes supported by this command are those performed by the size_cell command.

When reverting the changes made by the size_cell command, the reference of cell is changed back to the original reference, before it was sized. Besides, the cell location and orientation of the cell are also reverted.

EXAMPLES

The following example reverts ECO changes by specifying the object name:

```
prompt> revert_cell_sizing cell_name
```

The following example reverts ECO changes by specifying a collection:

```
prompt> revert_cell_sizing [get_cells cell_name]
```

The following example reverts adjacent sized cells:

```
prompt> revert_cell_sizing [get_cells $revert_cells] \
    -include_adjacent_sized_cells
```

The following example reverts adjacent sized cells within a specified distance threshold:

```
prompt> revert_cell_sizing [get_cells $revert_cells] \
  -include_adjacent_sized_cells -adjacent_cell_distance 0.5
```

SEE ALSO

size_cell(2)

revert_eco_changes

Reverts unacceptable ECO changes. This command is for reverting ECO changes made by using size_cell, add_buffer and add_buffer_on_route.

SYNTAX

status **revert_eco_changes**
-cells *cell_objects*

Data Types

cell_objects collection

ARGUMENTS

-cells *cell_objects*

Specifies the cell objects on which the ECO changes are reverted. The cell objects can be a name string or collection.

DESCRIPTION

This command reverts unacceptable ECO changes on the specified objects.

The type of ECO changes supported by this command are those performed by the size_cell, add_buffer and add_buffer_on_route commands.

For newly added buffers, we can simply remove the buffers and recover the original connections. For inverters, we can identify inverter pairs and remove them at the same time to make sure the logic unchanged. For sized cell, the reference of cell is changed back to the original reference before it was sized. Besides, the cell location and orientation of the cell are also reverted.

EXAMPLES

The following example reverts ECO changes by specifying a collection:

prompt> **revert_eco_changes** -cells [get_cells $revert_cells]

SEE ALSO

size_cell(2)
add_buffer(2)
add_buffer_on_route(2)

rotate_objects

Rotates the specified objects.

SYNTAX

status **rotate_objects**
-orient *orient*
-angle *angle*
[-anchor center | ll | lr | ul | ur]
[-pivot {*x y*}]
[-group]
[-force]
[-simple]
[*object_list*]

Data Types

orient string
angle string
x float
y float
object_list collection or selection

ARGUMENTS

object_list

Collection or selection set that contains objects to rotate. If this option is not specified, global selection set is used.

-orient *orient*

Specifies the cell orientation.

The valid values are:

N, **W**, **S**, **E**,
FN, **FS**, **FE**, **FW**,
NW, **NE**, **EN**, **ES**,
SE, **SW**, **WN**, **WS**

-angle *angle*

Specifies the rotation angle of the objects.

The valid values are:

0, **90**, **180**, **270**,
CW90, **CW180**, **CW270**, **CCW90**, **CCW180**, **CCW270**
FLIPX, **FLIPY**

The rotation value definitions are:

CW90 is 90 degrees clockwise
CW180 and **CCW180** are 180 degrees
CW270 is 270 degrees clockwise
CCW90 is 90 degrees counterclockwise
CCW270 is 270 degrees counterclockwise
FLIPX is the reflection about the x-axis
FLIPY is the reflection about the y-axis

The following values are synonymous:

0, **R0**
CW90, **90**
CW180, **180**
CW270, **270**,
CCW90, **R90**
CCW180, **R180**
CCW270, **R270**,
FLIPX, **MY**
FLIPY, **MX**

-anchor center | ll | lr | ul | ur

Specifies anchor point for rotation.

The anchor values are:

center is center
ll is lower left
lr is lower right
ul is upper left
ur is upper right

The option cannot be specified together with the **-pivot** or **-group** option.

-pivot {*x y*}

Specifies the rotation pivot point.

The option cannot be specified together with the **-anchor** or **-group** option.

-group

Specifies the center point of a group as an anchor for rotation.

The option cannot be specified together with the **-anchor** or **-pivot** option.

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

DESCRIPTION

This command rotates one or more specified objects by given angle skipping all fixed objects. It can also set selected cell orientation to given value.

Snapping is done automatically using the global snap settings.

EXAMPLES

The following example rotates all selected objects by 90 degrees.

```
prompt> rotate_objects -angle 90
```

The alternative syntax uses a collection to specify objects.

```
prompt> rotate_objects [get_selection] -angle 90
```

snap_objects(2)

route_3d_rdl

Routes 3DIC flip-chip nets.

SYNTAX

status **route_3d_rdl**
-layer *layer*
[-nets *collection_of_nets* | -nets_in_file *nets_file*]
[-objects *collection_of_objects*]
[-skip_detail_route true | false]
[-reuse_existing_global_route true | false]
[-coordinates *bbox_list*]

Data Types

layer collection
collection_of_nets collection
nets_file string
collection_of_objects collection
bbox_list list

ARGUMENTS

-layer *layer*

Specifies the target layer for 3DIC RDL routing by the names from the technology file.

-nets *collection_of_nets*

Specifies the flip-chip nets to route.

-nets_in_file *nets_file*

Specifies the name of the file that contains the list of RDL nets to route.

-nets has higher priority than **-nets_in_file**.

-objects *collection_of_objects*

Specifies the RDL nets (see **-nets**) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option **flip_chip.route.routing_style** is **spanning_tree**, the whole nets of the cells or pins are regarded as involved.

If neither **-nets**, **-nets_in_file**, nor **-objects** option is specified, all flip-chip nets are routed.

-skip_detail_route *true* | *false*

Controls whether the command runs detail routing. If this option is true, the command skips detail routing and runs only global routing. By default, the option is false and the command runs both global routing and detail routing.

Only one of **-skip_detail_route** and **-reuse_existing_global_route** can be true.

-reuse_existing_global_route ***true*** | ***false***

Controls whether the command runs global routing. If this option is true, the command skips global routing and runs only detail routing by reusing the existing global route information. The default is false and the command deletes all existing global routes from the design before routing starts.

Only one of **-skip_detail_route** and **-reuse_existing_global_route** can be true.

-coordinates ***bbox_list***

Specifies the regions of routing for speeding up the routing process. If any input regions overlapped, then they are merged into a larger region. All the pins for each target net should be in the same routing region, and there needs to be enough space for routing inside the regions.

DESCRIPTION

This command routes 3DIC RDL nets using the RDL router. In addition, it can rip up and reroute wires.

A valid 3DIC RDL net is a net that connects a TSV to another TSV, a TSV to a bump cell, or a bump cell to another bump cell.

RDL routing is a special application where a shape-based router routes nets on specified layers. It meets the following requirements:

- Provides a routing tool to route, rip-up, and reroute automatically.
- Optimizes routing patterns to eliminate jogs and shorten wire length.
- Checks DRCs and opens for routed wires.
- Routes flip-chip nets on specified layers.

The suggested flow for RDL routing is as follows:

1. Define NDR rules by running the **create_routing_rule** command and then associate the rules to the flip-chip nets by the **set_routing_rule** command.
2. Set the RDL routing specific options by running the **set_app_options** command.

   Please specify flip_chip.route.point_to_point_connection_file_name and set flip_chip.route.design_tyle to 3dic_interposer for a high-bandwidth memory (HBM) design.
3. Create RDL I/O pad to bump assignments with the **create_matching_type** and **add_to_matching_type** commands if needed.
4. Perform RDL routing by running the **route_3d_rdl** command.
5. Manually route the open nets, if there are any, by using the **remove_routes**, **push_rdl_routes** and **route_3d_rdl** commands.
6. After all RDL nets are routed, improve the routing pattern by running the **optimize_rdl_routes** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example routes the flip-chip nets specified in the RDLNetFile.

```
prompt> route_3d_rdl -nets_in_file RDLNetFile -layer BM3
```

The following example routes all RDL nets.

```
prompt> route_3d_rdl -layer BM3
```

The following example places vias and routes in a HBM design.

```
prompt> create_interposer_routeplan
prompt> set_app_option -list {flip_chip.route.design_style 3d_interposer}
prompt> set_app_option -list {flip_chip.route.point_to_point_connection_file_name p2pfile.txt}
prompt> route_3d_rdl -layer BM3
```

remove_routes(2)
create_interposer_routeplan(2)

route_auto

Performs global routing, track assignment, and detail routing in one step.

SYNTAX

status **route_auto**
[-max_detail_route_iterations *num*]
[-reuse_existing_global_route true | false]
[-route_nondefault_nets_first true | false]
[-stop_after_track_assignment true | false]
[-save_after_global_route true | false]
[-save_after_track_assignment true | false]
[-save_after_detail_route true | false]
[-save_cell_prefix *name*]

Data Types

num integer
name string

ARGUMENTS

-max_detail_route_iterations *num*

Specifies the maximum number of detail routing iterations. You can specify an integer between 1 and 1000.

By default, the maximum number of iterations for the detail routing command (40) is used.

-reuse_existing_global_route true | false

Enables or disables incremental global routing.

By default (false), the global router ignores all existing global routes from the design for initial routing.

If this option is set to true, the global router considers and reuses existing global routes.

-route_nondefault_nets_first true | false

Specifies whether to route the nets with nondefault routing rules before the nets that use the default routing rule.

When **false** (the default), nets with nondefault routing rules are not routed before the nets without nondefault routing rules.

When **true**, the tool performs global routing and track assignment first on nets with nondefault routing rules, and then on nets that use the default routing rule.

-stop_after_track_assignment true | false

Controls whether the command runs detail routing.

By default (false), the command runs global routing, track assignment, and detail routing.

If this option is true, the command skips detail routing and runs only global routing and track assignment.

-save_after_global_route true | **false**

Controls whether the design is saved after global routing.

The default value is false.

-save_after_track_assignment true | **false**

Controls whether the design is saved after track assignment.

The default value is false.

-save_after_detail_route true | **false**

Controls whether the design is saved after detail routing.

The default value is false.

-save_cell_prefix ***name***

Specifies the prefix to use when saving the design. For example, if you specify "foo" as the prefix, the name of the design saved after global routing is foo_icGRt.

The default prefix is auto.

DESCRIPTION

The **route_auto** command runs global routing, track assignment, and detail routing in one step. This command runs faster than using the basic commands because it does not access the disk between the different stages. The results are comparable to the basic flow (it might not be identical because the shapes could be ordered differently when the design is saved to disk).

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command runs automatic routing using the **-save_after_global_route**, **-save_after_detail_route**, **-save_cell_prefix**, and **-max_detail_route_iterations** options:

```
prompt> route_auto \
   -save_after_global_route true \
   -save_after_detail_route true \
   -save_cell_prefix auto \
   -max_detail_route_iterations 15
```

SEE ALSO

route_global(2)
route_track(2)
route_detail(2)

route_busplans

Determines busplan topologies by using global routes.

SYNTAX

int **route_busplans**
[-force]
[-incremental]
[-quick [-reduce_virtual_pins]]
[-spread [-no_plan_busplans] [-skip_wns_check] [-reduce_virtual_pins]]
[*buses*]

Data Types

buses list of busplans

ARGUMENTS

-force

Normally the command includes a check that the horizontal and vertical layers are properly assigned to each bus by its associated busplan rule. Use this option to bypass this check to allow the router to run even if layers are not properly assigned. In this case, the router is free to use all layers to route. This option cannot be used with the **-quick** or **-reduce_virtual_pins** option. This option cannot be used with the **-spread** or **-no_plan_busplans** or **-skip_wns_check** options.

-incremental

This option specifies that all the planned buses that are not specified in the command are to have their busplans sent to router as a constraint. These planned buses are not going to be changed, but the influence of their busplans will be seen by router when routing the specified buses. A bus is considered to be planned if it has a valid net_estimation_rule and timing is met. In the busplan GUI, a planned busplan would be in green and not have any suggested registers in the layout window. This option cannot be used with the **-quick** option or **-reduce_virtual_pins** option. This option cannot be used with the **-spread** or **-no_plan_busplans** or **-skip_wns_check** options.

-quick

This option is labeled "Auto-plan" in the busplan GUI. It uses a modified greedy algorithm to quickly find a shortest path (where possible) for the specified busplans. If successful in planning a bus, virtual or real registers are spread, and if slack is negative, subsequently packed. This command is allowed to remove virtual pins not marked "fixed". Virtual pins marked "fixed" are considered as mandatory waypoints and will split a plan into 2 or more segments, each of which is planned individually. Where possible, each planned segment is rectilinear. This option cannot be used with the **-force** or **-incremental** options. This option cannot be used with the **-spread** or **-no_plan_busplans** or **-skip_wns_check** options.

Branching busplans (those with more than one endpoint per startpoint) are split into multiple separate paths and planned individually using this algorithm.

-reduce_virtual_pins

This option adds an intermediate reduction step to the **-quick** (Auto-plan) algorithm to try to create less virtual pins in the final plan. Note that the reduced paths produced by this option may not always be rectilinear. This option is for backward compatibility with previous auto-plan releases, and might be deprecated in the future. This cannot be used with the **-force** or **-incremental** options.

-spread

This option is labeled "Spread Plans" in the GUI. It uses a greedy, priority-based algorithm to allocate a portion of every channel to a particular busplan, where possible and no over-allocation exists. The list of busplans passed to this option is first adjusted to remove any branching busplans, or non-rectilinear busplans or busplans not meeting timing (attribute *timing_valid* is false, or attribute *worst_slack* is not at least slightly positive) or any busplans with a fixed element. If a busplan is too wide for a required channel, it is placed in the center of that channel. If a channel is over-subscribed, busplans will be placed on top of each other.

If a busplan is not rectilinear, an attempt to route/plan it using the **-quick** option (auto-plan) is first attempted, and if it still not rectilinear, it is discarded from the list of busplans to spread, unless the **-no_plan_busplans** option is specified.

The only busplans that are considered for channel spreading purposes are those passed in to one execution of this command - no context is saved between successive invocations. In general, all applicable busplans should be passed in at once, rather than one at a time. Passing in one busplan at a time will result in a much larger number of overlaps.

-no_plan_busplans

When used together with the *-spread* option, will not attempt to auto-plan busplans that are not rectilinear - instead, it will just skip them completely. This option can only be used together with *-spread*.

-skip_wns_check

When used together with the *-spread* option, will attempt to spread busplans that are rectilinear and having valid timing, but which may have negative slack. This option can only be used together with *-spread*.

buses

Specifies the busplans to route/plan. The buses must be created with the **create_busplans** command.

Application Options

This command is affected by the following application options, all of which are used ONLY by the **-quick** option. See the appropriate man page for details. **plan.busplan.channels_include_hm plan.busplan.channels_include_placement_blockage**

None of these options are used when the **-quick** option is not specified.

DESCRIPTION

This command determines the topology of busplans that are previously defined with the **create_busplans** command. The topology is determined by the global router (without **-quick**) or a greedy algorithm (with **-quick**).

EXAMPLES

The following example creates a busplan named bus1 and determines the topology for the busplan using global router.

```
prompt> set_net_estimation_rule fast_rule -parameter ns_per_mm -value 0.5
prompt> create_busplans -name bus1 -rule fast_rule -from B1/OUT1[*]
prompt> route_busplans bus1
```

This example re-plans the previous busplan using the Auto-plan option, first with virtual pin reduction, then with virtual pin reduction.

```
prompt> route_busplans -quick bus1
prompt> route_busplans -quick -reduce_virtual_pins bus1
```

plan.busplan.channels_include_placement_blockage(3)

route_clock_straps

Performs routing on a group of clock nets that have clock straps. You should use this command before clock routing to route pins to clock meshes or other predefined physical clock structures.

SYNTAX

status **route_clock_straps**
-nets *nets*
[-topology comb|fishbone|sub_strap]
[-fishbone_fanout *fanout*]
[-fishbone_span *distance*]
[-fishbone_sub_span *distance*]
[-fishbone_layers *layer_names*]
[-sub_strap_layers *layer_names*]
[-sub_strap_max_delay *delay*]
[-stop_after_global_route true | false]
[-max_detail_route_iterations *num*]

Data Types

nets collection
fanout integer
distance integer
delay float
layer_names list
num integer

ARGUMENTS

-nets *nets*

Specifies the nets to be routed.

-topology comb|fishbone|sub_strap

Specifies the routing topology used to route each net. With comb routing, each pin is routed to a net shape with shape_use stripe, without sharing the connection with other pins, unless the nearest stripe is further away than the so-called comb distance. In case, there is no stripe shape within the comb distance, the connection would be similar to route_group behavior(includes steiner routing), in which case it may connect to non-stripe object as well create jogs for connection. By default, the comb distance is 2 time cell row height. The max comb distance that can be set is 10. However, larger the comb distance, longer is the routing runtime. Fishbone routing (the default) allows multiple load pins to share a so-called finger to connect to the nearest stripe; comb routing is used to connect the pins to the fingers. Each finger is a single straight shape that is routed orthogonally to the stripe. Driver pins get their own finger, which is not shared with other pins. In case of sub_strap routing, the sub-straps are created on same direction metal layer under pre-routes of type stripe. This leads to better routability as well as allows denser packing of the

pins under a substrap.

-fishbone_fanout ***fanout***

Specifies the target number of loads that get connected to a finger. A finger can connect to fewer loads if that is better for wirelength, it should not connect to more loads than the target fanout. The default value is 20.

-fishbone_span ***distance***

Specifies the maximum distance between any two loads connected to the finger, measured in the direction orthogonal to the direction of the finger. The actual span of a finger can be below the target if that is better for wirelength. By default a target span equal to 20 gcells distance is automatically derived.

-fishbone_sub_span ***distance***

Specifies the maximum distance between any two loads connected to the sub-finger, measured in the direction orthogonal to the direction of the sub-finger. The actual span of a sub-finger can be below the target if that is better for wirelength. The default value is 0, which means that no sub-fingers are created.

-fishbone_layers ***layer_names***

Specifies the routing layers that can be used for routing the fishbone fingers and sub-fingers. This option can only be used to reduce the allowed layer range, it cannot be used to extend the allowed routing layers for a net. By default, only the routing layers adjacent to the layer of the clock strap will be used.

-sub_strap_layers ***layer_names***

Specifies the routing layers that can be used for substraps. In case of multiple layers, layer parallel to the pre-route and closest to it will be picked for sub-strap creation. In case this option is not specified, the pre-route -2 layer is picked up for sub-strap creation.

-sub_strap_max_delay ***delay***

The delay from pre-route to sub-strap to the pins has to be contained to limit skew across sub-straps. In addition, this avoid overloading of Via Tower of sub-strap. Rough delay calculation would be done based on RC estimation of sub-strap and its allocated loads. This delay would be limited to 2 ps by default or a user specified value as the option specified.

-stop_after_global_route true | false

Controls whether the router stops after global routing or continues all the way to detail routing. By default, comb routing continues all the way to detail routing.

-max_detail_route_iterations ***num***

Specifies the maximum number of detail routing iterations for comb routing. You can specify an integer between 1 and 1000. By default, the maximum number of iterations is 40, the same number as for the detail routing command.

DESCRIPTION

The **route_clock_straps** command completes the routing of clock nets with clock straps, by routing the pins to clock straps with shape_use stripe. It supports two routing styles: the comb routing style and the fishbone routing style.

The **route_clock_straps** command honors the routing rule and the allowed routing layers defined on a net, including the settings defined with the **set_clock_routing_rules** command. The **-fishbone_layers** option can be used to explicitly define the layers that can be used for routing the fishbone fingers. It can only be used to reduce the set of allowed routing layers for a net. If more than one layer is available for routing a finger, the **route_clock_straps** command prefers the routing layers that are nearest to the clock strap that the finger connects to.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example uses fishbone routing to route pins to a clock mesh using a fishbone topology.

prompt> **route_clock_straps -nets [get_nets clk1_mesh]**

SEE ALSO

create_clock_straps(2)

route_custom

Performs custom routing with the Custom Router.

SYNTAX

status **route_custom**
  [-nets *nets*]
  [-keep_session true | false]

Data Types

nets collection

ARGUMENTS

-nets *nets*

Specifies the collection of nets to route. If no nets are specified, the command routes the entire design.

-keep_session true | false

Specifies whether or not the custom router view of the data is retained after the command completes. Specify *true* only if you expect to perform additional custom route commands immediately after the current command. The default is false.

DESCRIPTION

The **route_custom** command runs custom routing for a set of specified nets.

EXAMPLES

The following command routes the Data[0] net in the design using the Custom Router.

prompt> **route_custom -nets Data[0]**

SEE ALSO

route_detail

Performs detail routing on the block.

SYNTAX

status **route_detail**
[-max_number_iterations *count*]
[-coordinates *list_of_rectangles*
[-incremental true | false]
[-initial_drc_from_input true | false]
[-start_iteration *int*]

Data Types

count integer
list_of_rectangles list
int integer

ARGUMENTS

-max_number_iterations *count*

Specifies the maximum number of routing iterations. The detail router terminates after the maximum number of iterations or when it detects a lack of progress, whichever occurs first.

The range is from 1 to 1000. The default value is 40.

Limiting the number of routing iterations can provide faster results; however, it might cause the detail router to terminate before the design rule violations are resolved.

To disable automatic termination of detail routing (and force the router to complete the maximum number of iterations), set the **route.detail.force_max_number_iterations** application option to **true**.

-coordinates *list_of_rectangle*

Specifies the routing area in user units. You can specify multiple rectangular routing areas.

You must use the following syntax to specify the rectangles:

{ {{*llx1 lly1*} {*urx1 ury1*}} ...}"

If you do not specify this option, the entire chip is routed.

-incremental true | **false**

Controls whether the router uses incremental mode.

By default (**false**), the router does not use incremental mode.

When **true**, the router uses incremental mode and starts starts from the last iteration from the previous detail routing run on the block. To explicitly specify the starting iteration, use the **-start_iteration** option.

-initial_drc_from_input true | **false**

Controls whether the router uses the DRC information stored in the block.

By default, the command performs design rule checking on the entire block and then resolves the violations.

When **true**, the command skips design rule checking and uses the violations stored in the block as the starting point. Use this option very carefully; set it to **true** only if you are absolutely sure that the DRC information in the block are up-to-date.

-start_iteration ***int***

Specifies the start iteration for detail routing.

The router performs detail route iterations from the specified iteration up to the maximum iteration specified by the **-max_number_iterations** option.

The range is from 0 to 1000. The default is 0.

DESCRIPTION

This command performs detail routing on a block. You run this command after running the **route_track** command.

The behavior of this command is influenced by the route.detail and route.common application options.

Following is the treatment of shapes as fixed/unfixed within detail route.

Object NDM attribute value Router ---------- Net physical_status locked fixed wire/via user_route true fixed wire/via physical_status fixed/locked fixed wire/via physical_status firm fixed wire/via physical_status application_fixed not-fixed wire/via shape_use detail_route not-fixed wire/via shape_use shield_route not-fixed wire/via shape_use area_fill/active_fill not-fixed wire/via shape_use lib_cell_pin_connect not-fixed for detail route.

Object app option value Router ---------- Layer route.common.freeze_layer_by_layer_name layer-names fixed

When shape_use of a wire/via is lib_cell_pin_connect, check_routes treats the shape as not-fixed with the following exception:

- a net is frozen or a routing layer is frozen, AND - user runs check_routes with option check_from_frozen shapes and routing shape is on power/ground net. If the above conditions are satisfied, the shape is treated as fixed.

Route shapes with attributes not listed above will be treated as not-fixed.

Man page of shape_attributes describes supported values of "physical_status" for routing shapes. The settable attributes among them can be modified with command set_attribute or remove_attribute.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs detail routing:

```
prompt> route_detail
```

The following command performs detail routing with a maximum of 3 iterations:

```
prompt> route_detail -max_number_iterations 3
```

The following command performs detail routing in the rectangle areas {0 0 50.0 60.2} and {100.0 100.0 120.2 110.2}:

```
prompt> route_detail \
  -coordinates { {{0 0} {50.0 60.2}} {{100.0 100.0} {120.2 110.2}} }
```

The following command performs incremental detail routing:

```
prompt> route_detail -incremental true
```

The following command uses the DRC information stored in the block and starts with iteration 1:

```
prompt> route_detail -initial_drc_from_input true \
  -start_iteration 1
```

SEE ALSO

route_auto(2)
route_global(2)
route_track(2)
route.common_options(3)
route.detail_options(3)

route_eco

Performs ECO routing on the design. This command should be used after signal routing has been completed. It should not be used to route nets before signal routing. Instead the group route command (**route_group**) should be used.

SYNTAX

status **route_eco**
[-max_detail_route_iterations *count*]
[-nets *list*]
[-cells *list*]
[-open_net_driven true | false]
[-max_reported_nets *limit*]
[-reroute modified_nets_only | modified_nets_first_then_others | any_nets]
[-reuse_existing_global_route true | false]
[-utilize_dangling_wires true | false]

Data Types

count integer
limit integer
list list

ARGUMENTS

-max_detail_route_iterations *count*

Specifies the maximum number of detail routing iterations. You can specify an integer between 1 and 1000.

By default, the maximum number of iterations for the detail routing command (40) is used.

-nets *list*

Specifies the nets on which to perform ECO routing. The command first connects the open nets in this list, and then fixes design rule violations within the bounding box of these nets.

By default, this command works on all nets in the design.

-cells *list*

Specifies the cells of the nets on which to perform ECO routing. The command fixes design rule violations within the bounding box of these cells.

By default, this command works on all cells in the design.

-open_net_driven true | false

Controls whether ECO route fixes DRC violations for the whole design (default) or only in the neighborhood (bounding box) of the open nets.

By default (false), ECO route connects the open nets in the design and fixes design rule violations for the entire design.

When true, ECO route connects the open nets in the design and fixes DRC violations only in the neighborhood of the open nets.

This option is ignored if the **-nets** option is specified.

-max_reported_nets ***limit***

Sets a limit on the number of changed nets to be reported at the end of the execution of this command. You can specify an integer between -1 and INT_MAX. When -1 is specified, the router will report all the nets that are changed.

By default, the limit is 100.

-reroute modified_nets_only | **modified_nets_first_then_others** | **any_nets**

Controls which nets are rerouted.

The definition for each mode is

* **any_nets** (default) The router reroutes any nets freely to fix the DRC violations. * **modified_nets_only** The router freezes all the fully connected nets and tries to finish the routing by modifying only the nets with open ECO changes. This can be very restrictive and can cause the router to fail to fix the violations. It is only suitable for very minor ECO changes. * **modified_nets_first_then_others** The router first freezes all the fully connected nets and tries to finish the routing by modifying only the nets with open ECO changes. If there are violations remaining, the router tries to reroute those fully connected nets to resolve the violations. This reduces the layout changes for minor ECO operations but is not suitable for major ECO changes.

-reuse_existing_global_route true | **false**

Enables or disables incremental global routing.

By default (false), the global router ignores all existing global routes from the design for initial routing.

If this option is set to true, the global router considers and reuses existing global routes.

-utilize_dangling_wires true | **false**

Controls whether the router tries to reuse the dangling routes as much as possible to fix the opens.

The default value is true.

DESCRIPTION

The **route_eco** command performs ECO routing. It first connects the open nets and then fixes the DRC violations. The options control which nets are connected and on which areas of the chip the DRCs are fixed.

This command should be used after signal routing has been completed. The group route command (**route_group**) should be used to route nets before signal routing.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs ECO routing using the **-nets**, **-utilize_dangling_wires**, and **-reroute** options.

```
prompt> route_eco -nets {n1 n2 n3} -utilize_dangling_wires true \
   -reroute modified_nets_first_then_others
```

route_detail(2)
route.common(3)
route.detail(3)

route_fishbone

Performs fishbone style routing on a group of clock nets. Fishbone routing may not be shortest but reduces via count and clock skew.

SYNTAX

status **route_fishbone**
-nets *nets*
[-stop_after_global_route true | false]

Data Types

nets collection of nets

ARGUMENTS

-nets *nets*

Specifies the clock nets to be routed.

-stop_after_global_route true | false

Controls whether the router stops after global routing or continues all the way to detail routing. By default, the value is false and the router continues all the way to detail routing.

DESCRIPTION

The *route_fishbone* command completes the routing of clock nets with fishbone routing style. Fishbone routing is a structured routing topology where the net driver feeds a central fishbone trunk that spans the cluster of net loads being driven.

Several fishbone fingers can extend from the central trunk. The net loads connect directly to the fishbone fingers by way of comb routes, typically one comb route for each net load. The frequency of these fingers is controlled by the cts.routing.fishbone_max_tie_distance app option, which specifies a maximum distance from a net load to its nearest fishbone finger.

Optionally, you can use an additional level of fishbone routing, called sub-fingers. The sub-fingers connect to the fingers, and then the comb routes can instead connect the net loads to the sub-fingers. This can reduce wire length, especially in the case that a large fishbone_max_tie_distance is used. The behavior of sub-fingers is controlled by the cts.routing.fishbone_max_sub_tie_distance app option. The trunk, finger and sub-finger are defined as preroutes, using the shape_use==stripe attribute. After the route_fishbone command completes, the comb routes to pins are detail or global routed (depending on option "-stop_after_global_route"). The comb routes connecting the net loads would have shape_use==global_route or

shape_use==detail_route.

Fishbone trunks can optionally be biased toward power or ground nets to act as a shield on one side of the trunk, to improve signal integrity on the fishbone trunks. Biasing is enabled separately for horizontal and vertical trunks by setting a spacing rule between the trunk and the power or ground net using the cts.routing.fishbone_horizon- tal_bias_spacing and/or cts.routing.fishbone_vertical_bias_spacing app options.

When biasing is enabled, two additional controls are available. The cts.routing.fishbone_bias_threshold app option specifies a minimum trunk length before biasing is attempted. The cts.routing.fish- bone_bias_window app option specifies a maximum displacement from the preferred trunk location to the biased trunk location, above which biasing is not attempted.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example uses fishbone routing to route clock net using a fishbone topology.

prompt> **route_fishbone -nets [get_nets clk1]**

route_global

Performs global routing on the design.

SYNTAX

status **route_global**
[-effort_level minimum | low | medium | high | ultra]
[-congestion_map_only true | false]
[-routing_utilization_only true | false]
[-reuse_existing_global_route true | false]
[-floorplan true | false]
[-virtual_flat all_routing | top_and_interface_routing_only]
[-host_options *host_option_name*]

Data Types

host_option_name string

ARGUMENTS

-effort_level minimum | **low** | **medium** | **high** | **ultra**

Specifies the effort level used to perform global routing. By default, the effort level is **medium**.

-congestion_map_only true | **false**

Creates the congestion map without creating global route segments (glinks). By default, this option is false and the command generates glinks. If design has existing glinks, the command will not remove them if this option is true and the new congestion map could potentially be out of sync comparing with the existing glinks.

-routing_utilization_only true | **false**

Creates the wire utilization maps without creating global route segments (glinks). Three wire utilization maps are output to indicate the track occupation by preroute, preroute plus clock nets, and all objects respectively. Extra memory consumption is needed to calculate and store wire utilization maps. By default, this option is false and the command generates glinks. If design has existing glinks, the command will not remove them if this option is true and the new wire utilization maps could potentially be out of sync comparing with the existing glinks.

-reuse_existing_global_route true | **false**

Specifies whether to reuse existing global routes. If this option is true, the global router considers and reuses existing global routes. By default, the option is false and the global router ignores all existing global routes for initial routing.

-floorplan true | **false**

Specifies whether to perform fast, lower effort global routing. If this option is true, the global router uses less effort to avoid

blockages on blocked pins and makes other simplifying assumptions to complete global routing quickly. Designs can be unlegalized in floorplan mode. Floorplan mode also disables timing or crosstalk-driven routing. The resulting congestion map shows the location of congestion hot spots in the floorplan. Absolute congestion statistics might differ from the non-floorplan mode global routing, especially if the design is not clean. Floorplan mode is intended to be used only in floorplan analysis or design planning to give a quick picture of floorplan routing problems as a guide for placement improvements. You should not run track assignment or detail routing based on floorplan mode global routing. By default, this option is false and the router routes the design with higher effort to reduce congestion.

-virtual_flat all_routing | top_and_interface_routing_only

Routes the design using a virtual flat approach while honoring all feedthrough or pin constraints and maintaining the physical hierarchy. In this mode, global router routes the top-level design and routes all the child-level blocks. This can be useful if the design has physical blocks and you want to route the whole design, including all child-level blocks.

When you specify **-virtual_flat all_routing**, the router routes all nets in both the top-level design and child-level blocks. When you specify **-virtual_flat top_and_interface_routing_only**, the router routes nets in top-level design and only the nets that connect to child-level blocks. Interface and feedthrough nets are routed crossing the block boundaries, and the resultant routes are stored in top-level and the corresponding child-level blocks.

After virtual flat global routing, you can place pins based on the global routing results with the **place_pins -use_existing_routing** command.

This option can only used together with **-floorplan true**.

-host_options *host_option_name*

Specifies that options set with the **set_host_options** command should be used for distributed processing. Note that this option can only be used together with the **-virtual_flat** option.

DESCRIPTION

The **route_global** command maps general pathways through the design for each unrouted signal or clock net. The global router uses a three-dimensional array of global routing cells to model the demand and capacity of global routing. The average height of the standard cells is used to create the height and width of each global routing cell. During global routing, the tool assigns nets to the global routing cells through which they pass. For each global routing cell, routing capacity is calculated according to the blockages, pins, and routing tracks inside the cell. Although global routing does not assign the nets to the actual wire tracks, it notes the number of nets assigned to each global routing cell. The tool calculates the demand for wire tracks in each global routing cell and reports the overflows, which are the number of wire tracks still needed after the tool assigns nets to the available wire tracks in a global routing cell. The tool might reduce overflows by detouring nets around congested areas and increasing the wire length. When a wire is prerouted, the tool checks whether it is completely connected. If the net is completely connected, the tool treats the net as a blockage. If the net is partially connected, the tool connects all parts of the net.

Note that the global router treats power and ground nets as blockages, and treats prerouted meshes and trunks as a single connection. Make sure that you examine the routing to determine whether the nets are connected properly.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs global routing using high effort:

```
prompt> route_global -effort_level high
```

SEE ALSO

route_auto(2)

route_group

Performs routing on a group of nets in the design using router. You should use this command before signal routing to route critical nets such as clock nets or timing-critical nets. Do not use this command to connect nets after signal routing (use the **route_eco** command instead).

SYNTAX

status **route_group**
[-max_detail_route_iterations *num*]
[-nets *nets* [-from_file *filename*] | -all_clock_nets]
[-stop_after_global_route true | false]
[-reuse_existing_global_route true | false]
[-utilize_dangling_wires true | false]
[-floorplan true | false]
[-global_planning true | false]
[-route_nondefault_nets_first true | false]

Data Types

num integer
nets collection
filename string

ARGUMENTS

-max_detail_route_iterations *num*

Specifies the maximum number of detail routing iterations. You can specify an integer between 1 and 1000. By default, the maximum number of iterations is 40, the same number as for the detail routing command.

-nets *nets*

Specifies the nets to be routed. You must specify the nets on which to run this command by specifying at least one of the following options: **-nets**, **-all_clock_nets**, or **-from_file**. The **-nets** and **-all_clock_nets** options are mutually exclusive; you can specify only one. You can specify the **-from_file** option and the **-nets** option.

-from_file *filename*

Routes the nets specified by name in the file named *filename*. If the file does not exist or does not contain any valid nets, the tool generates an error message that indicates the source of the problem.

You must specify the nets on which to run this command by specifying at least one of the following options: **-nets**, **-all_clock_nets**, or **-from_file**. You can specify the **-from_file** option and the **-nets** option. However, the **-from_file** option cannot be used with the **-all_clock_nets** option.

-all_clock_nets

Routes all clock nets. You must specify the nets on which to run this command by specifying at least one of the following options: **-nets**, **-all_clock_nets**, or **-from_file**. If you specify the **-all_clock_nets** option, you cannot specify the **-nets** or **-from_file** option. Zroute's timing driven mode are turned off temporarily when running route_group -all_clock_nets.

-stop_after_global_route true | false

Controls whether the router stops after global routing or continues all the way to detail routing. By default, the value is false and the router continues all the way to detail routing. In this mode, we don't perform via ladder insertion. Please use refresh_via_ladders to update via ladders prior than route_group.

-reuse_existing_global_route true | false

Controls whether the tool performs incremental global routing. If you specify **-reuse_existing_global_route true**, the global router considers and reuses the existing global routes. By default, this option is false and the global router ignores all existing global routes from the design for initial routing.

-utilize_dangling_wires true | false

Controls whether the router tries to reuse the dangling routes as much as possible. By default, this option is true.

-floorplan true | false

Specifies the routing quality used for global routing.

If you specify **-floorplan true**, the global router uses less effort to avoid the blockages on blocked pins when routing the design and makes other simplifying assumptions to complete global routing quickly. Designs can be unlegalized in floorplan mode. Floorplan mode also disables timing and crosstalk-driven routing. The resulting congestion map shows the location of congestion hot spots in the floorplan. Absolute congestion statistics might differ from the normal global router, especially if the design is not clean. Floorplan mode should be used only in floorplan analysis or design planning. Its purpose is to give a quick picture of floorplan routing problems as a guide for placement improvements. You should not run track assignment or detail routing based on floorplan mode global routing. If you omit the **-stop_after_global_route true** option when you specify **-floorplan true**, the router sets **-stop_after_global_route true** and issues an error message indicating that floorplan mode global routing should not be used for detail routing.

By default, this option is false and the router routes the design in normal mode using higher effort to reduce congestion.

-global_planning true | false

Controls whether the global router routes the design in a virtual flat way while honoring all the feedthrough or pin constraints with physical hierarchy awareness. In this mode, global router connects to pins inside child blocks when routing a net. This is useful when you want to route the top-level net while considering the objects inside the child blocks. The router honors routing blockages, route guide, hardmacros and pre-route inside the child blocks.

If this option is used together with the **-stop_after_global_route true** option, the router outputs global route results and skips wire track assignment and detail routing. In addition, when the net is connected to a child block, the router creates pins for the child block ports that connected to this net. The pins have the same shape, layer, and location as the pins inside child block that connect to the same top-level net. After global routing, you can use the **place_pins -use_existing_routing** command to create feedthroughs and place pins based on this global route result. This method will only create feedthroughs and pins on the blocks instantiated in the next level below, not at all levels of hierarchy.

-route_nondefault_nets_first true | false

Specifies whether to route the nets with nondefault routing rules before the nets that use the default routing rule.

When **false** (the default), nets with nondefault routing rules are not routed before the nets without nondefault routing rules.

When **true**, the tool performs global routing and track assignment first on nets with nondefault routing rules, and then on nets that use the default routing rule.

DESCRIPTION

The **route_group** command routes a specified group of nets. You should use this command before signal routing to route critical nets such as clock nets or timing-critical nets. After signal routing, do not use this command to connect nets; use the **route_eco** command instead.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs routing for all clock nets using the **-max_detail_route_iterations** and **-utilize_dangling_wires** options.

```
prompt> route_group -all_clock_nets \
  -max_detail_route_iterations 6 \
  -utilize_dangling_wires true
```

SEE ALSO

route_detail(2)
route_global(2)
route_track(2)
route_eco(2)

route_opt

Optimize the current routed design.

SYNTAX

route_opt

DESCRIPTION

This command optimizes the current routed design for timing, electrical DRC violations, area, and power. It performs legalization and ECO routing on the optimized design. By default, power optimization, concurrent clock and data optimization, and crosstalk reduction are not performed by this command. Use application options in the "SEE ALSO" section to enable them.

SEE ALSO

route_auto(2)
route_opt.eco_route.mode(3)
route_opt.flow.enable_ccd(3)
route_opt.flow.enable_power(3)

route_rdl_differential

Routes RDL nets and matches the route length or the pattern for each net.

SYNTAX

status **route_rdl_differential**
-layers *layer_list*
[-nets *collection_of_nets* | -nets_in_file *nets_file*]
[-objects *collection_of_objects*]
[-mode length | parallel]
[-allow_push_neighbor_nets true | false]

Data Types

layer_list collection
collection_of_nets collection
nets_file string
collection_of_objects collection

ARGUMENTS

-layers *layer_list*

Specifies the target layers for RDL differential routing from the technology file. The number of layers is limited to no more than 2 and the layers must be adjacent to each other. The command considers the first layer in the list as the primary layer.

-nets *collection_of_nets*

Specifies the RDL nets on which to perform differential routing. The number of nets must be 16 or fewer.

-nets_in_file *nets_file*

Specifies the name of the file that contains the list of RDL nets on which to perform differential routing. The number of nets must be 16 or fewer.

-nets has higher priority than **-nets_in_file**.

-objects *collection_of_objects*

Specifies the RDL nets (see **-nets**) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option **flip_chip.route.routing_style** is **spanning_tree**, the whole nets of the cells or pins are regarded as involved.

-mode length | parallel

Specifies the mode of differential routing. In length mode, the router routes the RDL nets and matches the route length. In parallel

mode, the router routes the RDL nets in parallel in the middle part and routes separately to each pins. Thus, in this mode, the routing pattern will match in the middle part of the routing.

The default value is length.

-allow_push_neighbor_nets true | false

Specifies if the router can push away the neighbors of the target nets in order to achieve better length matching quality. The default value is false.

This option applies to length matching mode only.

DESCRIPTION

This command routes the specified nets on the redistribution layers and matches the route lengths. After running this command, do not use the **route_rdl_flip_chip**, **push_rdl_routes**, or **optimize_rdl_routes** command to further process the group of nets.

RDL nets are nets in flip-chip designs which are routed on the redistribution layer. In a flip-chip design, RDL nets connect a bump cell to driver I/O cells.

The suggested flow for RDL differential routing is as follows:

1. Run the **route_rdl_differential** command on the group of target nets to perform RDL differential routing.
2. Check the report generated by **route_rdl_differential** and adjust the route length or pattern manually if needed.
3. Perform RDL routing on other nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example routes the RDL nets specified in the RDLNetFile and matches the RDL route length.

```
prompt> route_rdl_differential -nets_in_file RDLNetFile -layers M9
```

The following example perform the differential routing parallel mode.

```
  .in +0.25in
prompt> route_rdl_differential -nets {NetA NetB} -mode parallel -layers M9
```

SEE ALSO

route_rdl_flip_chip(2)

route_rdl_flip_chip

Routes flip-chip nets.

SYNTAX

status **route_rdl_flip_chip**
-layers *layer_list*
[-nets *collection_of_nets* | -nets_in_file *nets_file*]
[-objects *collection_of_objects*]
[-skip_detail_route true | false]
[-reuse_existing_global_route true | false]
[-coordinates *bbox_list*]

Data Types

layer_list collection
collection_of_nets collection
nets_file string
collection_of_objects collection
bbox_list list

ARGUMENTS

-layers *layer_list*

Specifies the target layers for flip-chip routing by the names from the technology file. Currently, the number of layers is limited to 2, and the layers must be adjacent to each other. The command treats the first layer as the primary layer.

-nets *collection_of_nets*

Specifies the flip-chip nets to route.

-nets_in_file *nets_file*

Specifies the name of the file that contains the list of flip-chip nets to route.

-nets has higher priority than **-nets_in_file**.

-objects *collection_of_objects*

Specifies the RDL nets (see **-nets**) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option **flip_chip.route.routing_style** is **spanning_tree**, the whole nets of the cells or pins are regarded as involved.

If neither **-nets**, **-nets_in_file**, nor **-objects** option is specified, all flip-chip nets are routed.

-skip_detail_route ***true*** | ***false***

Controls whether the command runs detail routing. If this option is true, the command skips detail routing and runs only global routing. By default, the option is false and the command runs both global routing and detail routing.

Only one of **-skip_detail_route** and **-reuse_existing_global_route** can be true.

-reuse_existing_global_route ***true*** | ***false***

Controls whether the command runs global routing. If this option is true, the command skips global routing and runs only detail routing by reusing the existing global route information. The default is false and the command deletes all existing global routes from the design before routing starts.

Only one of **-skip_detail_route** and **-reuse_existing_global_route** can be true.

-coordinates ***bbox_list***

Specifies the regions of routing for speeding up the routing process. The regions are applied to all RDL layers. If any input regions overlapped, then they are merged into a larger region. All the pins for each target net should be in the same routing region, and there needs to be enough space for routing inside the regions.

DESCRIPTION

This command routes flip-chip nets using the flip-chip router. In addition, it can rip up and reroute wires.

A flip-chip net is a net that connects a flip-chip driver I/O cell to a bump cell, which is also called a flip-chip pad.

Flip-chip routing is a special application where a shape-based router routes nets on specified layers. It meets the following requirements:

- Provides a routing tool to route, rip-up, and reroute automatically.
- Optimizes routing patterns to eliminate jogs and shorten wire length.
- Checks DRCs and opens for routed wires.
- Routes flip-chip nets on specified layers.

The suggested flow for flip-chip routing is as follows:

1. Define NDR rules by running the **create_routing_rule** command and then associate the rules to the flip-chip nets by the **set_routing_rule** command.
2. Set the flip-chip routing specific options by running the **set_app_options** command.
3. Create flip-chip I/O pad to bump assignments with the **create_matching_type** and **add_to_matching_type** commands if needed.
4. Perform flip-chip routing by running the **route_rdl_flip_chip** command.
5. Manually route the open nets, if there are any, by using the **remove_routes**, **push_rdl_routes** and **route_rdl_flip_chip** commands.
6. After all flip-chip nets are routed, improve the routing pattern by running the **optimize_rdl_routes** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example routes the flip-chip nets specified in the RDLNetFile.

```
prompt> route_rdl_flip_chip -nets_in_file RDLNetFile -layers M9
```

The following example routes all flip-chip nets.

```
prompt> route_rdl_flip_chip -layers M9
```

create_matching_type(2)
optimize_rdl_routes(2)
push_rdl_routes(2)
remove_routes(2)

route_track

Performs track assignment on the design.

SYNTAX

status **route_track**

ARGUMENTS

This command has no arguments.

DESCRIPTION

This command performs track assignment on a global routed design. Run this command after running **route_global** and before running **route_detail** to assign wires to the routing tracks defined in the technology file. Track assignment operates on the entire design at once; whereas the detail router routes a small area at a time. Track assignment can make long routes straight and reduce the number of vias. After track assignment finishes, all nets are routed, but there are many violations, particularly where the routing connects to pins. The detail router fixes the violations.

The behavior of this command is influenced by options **route.track** and **route.common** set by the **set_app_options** command.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs track assignment.

```
prompt> route_track
```

route_eco(2)

run_block_compile_pg

Runs distributed power and ground (PG) creation for the top-level and block-level designs. This command creates power and ground within the blocks for the block-level designs.

SYNTAX

status **run_block_compile_pg**
[-skip_top]
[-host_options *host_options_name*]

Data Types

host_options_name string

ARGUMENTS

-skip_top

Do not create PG network in top-level design.

-host_options *host_options_name*

Uses the specified host option for distributed processing. If this option is not specified, the PG network is created sequentially, beginning with the top-level design and followed by each reference block.

DESCRIPTION

This command runs distributed PG creation for the top-level and block-level designs.

Before running this command, you must define the full-design PG constraints, including PG via master rules, PG patterns, PG strategies, and PG strategy via rules. A separate **compile_pg** script, which contains any application options and **compile_pg** commands, is also required. You must run the **characterize_block_pg** command first to characterize the PG constraints for each block, as well as the top-level design. The top-level PG is created based on the currently defined PG constraints and the specified **compile_pg** command script while for each block the PG is created based on the characterized PG constraints and the **compile_pg** command script. The *pg_mapfile* PG mapping file is created from the characterization. The mapping file must be set with the **set_constraint_mapping_file** command, before using the **run_block_compile_pg** command for distributed PG creation.

Not all PG related commands are supported. Currently **check_pg_missing_vias**, **check_pg_connectivity**, and **check_pg_drc** are not supported for distributed PG creation.

EXAMPLES

The following example runs PG characterization, sets the mapping file, and starts distributed PG creation for up to the first-level of physical hierarchy.

```
prompt> set_host_options -name my_hosts -submit_command "sh"
prompt> set_editability -value false -from_level 2
prompt> characterize_block_pg -compile_pg_script compile_pg.tcl
prompt> set_constraint_mapping_file ./pgroute_output/pg_mapfile
prompt> run_block_compile_pg -host_options my_hosts
```

The following example runs PG characterization, sets the mapping file, and starts distributed PG creation for all levels of physical hierarchy.

```
prompt> set_host_options -name my_hosts -submit_command "sh"
prompt> characterize_block_pg -compile_pg_script compile_pg.tcl
prompt> set_constraint_mapping_file ./pgroute_output/pg_mapfile
prompt> run_block_compile_pg -host_options my_hosts
```

The following example runs PG characterization, sets the mapping file, and starts distributed PG creation for up to the second level of physical hierarchy.

```
prompt> set_host_options -name my_hosts -submit_command "sh"
prompt> set_editability -value false -from_level 3
prompt> characterize_block_pg -compile_pg_script compile_pg.tcl
prompt> set_constraint_mapping_file ./pgroute_output/pg_mapfile
prompt> run_block_compile_pg -host_options my_hosts
```

The following example runs PG characterization, sets the mapping file, and starts distributed PG creation for all levels of physical hierarchy excluding the AUINPUT block.

```
prompt> set_host_options -name my_hosts -submit_command "sh"
prompt> set_editability -value false -blocks AUINPUT
prompt> characterize_block_pg -compile_pg_script compile_pg.tcl
prompt> set_constraint_mapping_file ./pgroute_output/pg_mapfile
prompt> run_block_compile_pg -host_options my_hosts
```

SEE ALSO

compile_pg(2)
set_constraint_mapping_file(2)
set_editability(2)
set_host_options(2)

run_block_script

Runs the specified Tcl script on a set of blocks.

SYNTAX

status **run_block_script**
-script *script_name*
-cells *collection_of_cells*
-blocks *list_of_blocks*
-run_order bottom_up | top_down
[-host_options *host_option_name*]
[-var_list *list_of_variable_value_pairs*]
[-reuse_processes]
[-work_dir *directory*]
[-force]
[-name *job_name*]

Data Types

script_name	string
collection_of_cells	collection of cells
list_of_blocks	list of block names
host_option_name	name of a host option
list_of_variable_value_pairs	list of variables and their values
directory	working directory
job_name	string

ARGUMENTS

-script *script_name*

Specifies the script to run for each specified block.

-cells *collection_of_cells*

Specifies the cells to run. Each cell specified in the list must be a block. If you specify cells with the same master (if they are Multiply Instantiated Blocks), then only one will be run. The **-blocks** option is mutually exclusive with the **-cells** option.

-blocks *list_of_blocks*

Specifies the names of the blocks to run. The **-blocks** option is mutually exclusive with the **-cells** option.

-run_order bottom_up | top_down

Specifies the order to run the blocks. Valid values are *top_down* or *bottom_up*. The default is *bottom_up*.

In a multilevel physical hierarchy design, blocks have to run in a certain order. Jobs for any pair of blocks with ancestor/descendant relation cannot be run in parallel, which means the blocks need to run in either top-down order or bottom-up order. Use this option to control which order to use.

With top-down order, a block cannot start to run until all the jobs for the blocks that this block is instantiated in finishes. With bottom-up order, a block cannot start to run until all its child blocks finishes.

-host_options *host_option_name*

Specifies the name of the host option to use for distributed processing. Host options are created using the **set_host_options** command. Before using this option, you should test the *host_option_name* argument with the **check_host_options** command.

-var_list *list_of_variable_value_pairs*

Specifies the Tcl variables and settings to pass to the block runs. For example, to set variable a to 1 and variable b to 2 and pass the settings to the block runs, use one of the following formats for the option arguments:

{{a} {1} {b} {2}}
"a 1 b 2"

To pass variable c with value $c, use one of the following formats for the option arguments:

[list [list c] [list $c]]
"c $c"

-reuse_processes

Specifies that more than one block can be run in the same process. By default, each block is run in a separate process during a parallel run. That is because it ensures that each block run is independent of other blocks. However sometime there is a high cost to launching new processes. In those cases, you can use this option to enable running more than one block in the same process. However in this case, you need to take care that the input script is clean. See description section for an example of an issue that could arise.

-work_dir *directory*

Specifies a directory in which to write data and log files from the run. By default, the tool uses the ./work_dir directory. If you also specify the **-host_options** option, the **-work_dir** directory must be a network disk that is accessible to all clients.

-force

Forces the command to run, even if some blocks might be dirty. The distributed run proceeds and any unsaved modifications are lost. By default, the command issues an error message if any block is modified but not saved, and gives you a chance to save the changes.

-name *job_name*

Gives a prefix name to the job to run, rather than the system default prefix name. This allows for jobs to be labeled with a name meaningful to the task.

DESCRIPTION

This command executes a Tcl script on a specified collection of blocks. The command sets five Tcl variables while running the blocks: *block_refname*, *block_refname_no_label*, *block_libfilename*, *top_libname*, and *work_dir*. You can use these variables in the Tcl script specified by the **-script** option. *block_refname* is the reference name of the block being processed including the block label. *block_refname_no_label* is the reference name of the block being processed without the block label. *block_libfilename* is the full path name of the library of the block being processed. *top_libname* is the name of the library for the top-level design which contains the blocks being processed. *work_dir* is a subdirectory named *block_refname* in the directory specified by the **-work_dir**

option.

If the **-host_options** option is specified, the blocks are run in parallel, otherwise they are run one-by-one. Before using this option, you should check the host options with the **check_host_options** command. Note that the **run_block_script** command with the **-host_options** option closes all reference libraries, so all reference libs must be clean for the command to work properly. You should save all reference libraries with the **save_lib -all** command, but do not close the reference libs.

If you use the **-reuse_processes** option, or if you run sequentially, then you need to be careful when creating the block script. In particular, you must create the script to run in an order-independent fashion to generate consistent results. One common issue is setting a variable for a specific block A, but not clearing the variable after block A completes. The script might appear to work, but if another block is run after block A on the same process, the new block inherits the special variable setting. This might cause a problem or an unwanted side effect. Note that if you set a variable in the block script and run serially, the master process inherits the variable setting.

APP OPTIONS

The following app options can be used to control the behavior of run_block_script: plan.distributed_run.block_priority(3) plan.distributed_run.priority_dependencies(3) plan.distributed_run.priority_size(3) plan.distributed_run.reuse_rbs_workers(3)

EXAMPLES

The following example block script and command illustrate the basic use of the **run_block_script** command.

```
# Block script run.tcl
open_lib $block_libfilename
open_block $block_refname
echo "run" $block_refname
close_block $block_refname
close_lib $block_libfilename

prompt> set_host_option -name myhost -submit_command "bsub"
prompt> run_block_script -script run.tcl -cells {cell1 cell2} -host_options myhost
Distributed run start.
Worker_msg: block block1 log : <path to log for block1>
Worker_msg: block block2 log : <path to log for block2>

run_monitor_gui

Starts the Synopsys Distributed Processing Monitor GUI program.

SYNTAX

pid **run_monitor_gui**
[-kill]
[-nolaunch]

Data Types

pid process id of started program, 0 on failure.

ARGUMENTS

-kill

Terminates (kills) any existing monitor instances before launching.

-nolaunch

Prevents the command from starting a new distributed process manager window. Use the **-nolaunch** and **-kill** options together to close all running instances of the Distributed Processing Monitor GUI, without starting a new instance.

DESCRIPTION

This command launches one instance of the Synopsys Distributed Processing Monitor GUI program, up to a maximum of two instances. The Monitor GUI can be used to watch the progress of all distributed tasks, such as the **run_block_script** or **create_abstract**, if the host options are set to use distributed processing with the **set_host_options** command. The distributed workers periodically send updates to the Monitor GUI to show the currently running command, RAM and CPU usage. Not all commands update the Monitor GUI in this way. The command returns the process id for the dpmanager task that was created.

If there are any other Monitor GUI tasks still running when the current session ends, they are also terminated before the session exits.

There is a limit of two running instances at the same time. The IC Compiler II shell tracks the number of running instances and enforces this limit. If there are existing Monitor GUI instances from another Synopsys product that are using the CDPL Distributed Library, or a previous session, they can also connect to the current session to act as a monitor. In this case, even though the shell will launch two instances, one or both of the instances might not connect to the current session and display worker progress. If the instance cannot connect, close the existing Monitor GUI instances or use the other sessions instead.

The Monitor GUI can also be started independent of a session by running **dpmanager -n** as a UNIX/Linux command from the

cdpl/bin directory of the distribution image.

EXAMPLES

The following example starts a new instance of the Monitor GUI if less than two instances already running. The command returns the process number for the dpmanager task started by **run_monitor_gui**.

```
prompt> run_monitor_gui
15123
```

The following example start a new instance of the Monitor GUI, but first terminates all running Monitor GUI instances launched from this session. The command returns the process number for the dpmanager task started by **run_monitor_gui**.

```
prompt> run_monitor_gui -kill
15254
```

The following example terminates all running Monitor GUI instances launched from this session.

```
prompt> run_monitor_gui -kill -nolaunch
```

run_test_point_analysis

Runs SpyGlass DFT testability analysis.

SYNTAX

status **run_test_point_analysis**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **run_test_point_analysis** command performs SpyGlass DFT analysis to determine the test points to be inserted by the **testability** DFT client.

Testability analysis is configured by the **set_testability_configuration** command. For details, see that man page.

This command is supported only in the gate-level flow.

Before running this command, the SPYGLASS_HOME environmental variable (not Tcl application variable) must be set so the tool can find the **spyglass** binary. You can check this as follows:

```
prompt> echo $env(SPYGLASS_HOME)
/global/apps/spyglass_2016.06-SP2
```

When you run this command, it reports information about the SpyGlass DFT analysis as it runs, such as coverage values and number of test points found.

The following testability targets do not require you to run testability analysis (although doing so is harmless):

- The **core_wrapper** target
- The **user** target

EXAMPLES

The following example configures and runs test point analysis:

```
# enable and configure testability analysis
set_dft_configuration -testability enable
set_testability_configuration -target {random_resistant}
set_testability_configuration -target {untestable_logic}

# perform pre-DFT DRC
create_test_protocol

# perform testability analysis
run_test_point_analysis
```

SEE ALSO

set_dft_configuration(2)

run_vclp_cmd

Used to execute a command in VCLP from inside ICC2/Fusion Compiler shell.

SYNTAX

status **run_vclp_cmd "command name"**

DESCRIPTION

The **run_vclp_cmd** command is used to execute a command in VCLP from ICC2/FC Shell. The command to be run in VCLP must be specified inside double quotes.

Example: run_vclp_cmd "report_lp"

SEE ALSO

check_mv_design(2)

saif_map

Controls the name-mapping database for pins, ports, cells and nets through its various options.

SYNTAX

status **saif_map**
[-start]
[-stop]
[-reset]
[-report]
[-get_saif_names *object_list*]
[-write_map *file_name* [-type ptpx | primepower [-saif_file *file_name* [-strip_path *source_name*]] [-essential]]]
[-read_map *file_name*]
[-set_name *object_list*]
[-add_name *object_list*]
[-inverted]
[-remove_name *object_list*]
[-get_object_names *saif_name_list*]
[-change_name *{saif_name changed_name}*]

Data Types

object_list	collection
file_name	string
source_name	string
saif_name_list	string list
saif_name changed_name	string pair

ARGUMENTS

-start

Starts the internal name-mapping mechanism. The name transformations are stored and are tracked, only after the command is run with this option. Reading and writing operations can also be performed if the command has been run with this option.

-stop

Stops the internal name-mapping mechanism. The name transformations stored are deleted. To begin tracking of the name transformations, the **saif_map** command has to be restarted. After the command has been run with this option, no **saif_map** feature works, unless the **saif_map** is restarted.

-reset

Deletes the manual SAIF name mapping from the database.

-report

Reports any manual SAIF name mapping you set.

-get_saif_names *object_list*

Reports the SAIF names corresponding to the specified objects. An *object_list* must be provided when this option is specified.

-write_map *file_name* -type ptpx | primepower -saif_file *file_name* -strip_path *source_name* -essential

Writes the name-mapping information into the file specified by *file_name*. The **-type ptpx** or **-type primepower** writes the name-mapping information in PrimeTime PX file format. When the optional **-saif_file** option is given with PrimeTime PX file format, only mappings for the names that occur in the specified SAIF file are written out. If no **-saif_file** option is given, PrimeTime PX mappings for all objects which have changed from original netlist (the netlist when **saif_map -start** was executed) are written out. The **-strip_path** option can be specified only with **-saif_file**. **-strip_path** specifies the name of the instance of the current design as it appears in SAIF. It is equivalent to the **-strip_path** option of the **read_saif** command. The **-essential** option writes only the essential points in the PrimeTime PX mapping file. Option **-essential** and **-saif_file** are mutually exclusive. Also option **-essential** can only be specified with **-type ptpx** or **-type primepower**.

-read_map *file_name*

Reads the name-mapping information from the file specified by **file_name**. The name-mapping information read from this file is written over the existing name-mapping information stored internally.

-set_name *object_list*

Sets the given SAIF name for specified objects in the name-mapping database, replacing any existing mapping for the objects. If a pin or a port is specified, the mapping is applied to the net connected to the pin/port. The **-inverted** option can be specified along with this option, to indicate that the SAIF name maps to a logically inverted object. An *object_list* must be provided when this option is specified.

-add_name *object_list*

Adds the given SAIF name for specified objects in the name-mapping database. The **-inverted** option can be specified along with this option, to indicate that the SAIF name maps to a logically inverted object. An *object_list* must be provided when this option is specified.

-inverted

Specifies that the name to be set maps to a logically inverted object. This option is valid only with the **-set_name** and **-add_name** options. For example, you can use the **-inverted** option when specifying that the object A_reg/QN maps to the SAIF name A, but its logical value is inverted.

-remove_name *object_list*

Removes the given SAIF name for specified objects in the name-mapping database. An *object_list* must be provided when this option is specified.

-get_object_names *saif_name_list*

Returns the objects to which the specified SAIF names map in the name-mapping database.

-change_name {*saif_name changed_name*}

Interprets the *saif_name* as the *changed_name* while parsing the SAIF file.

DESCRIPTION

The **saif_map** command controls the name transformations' tracking, storage, writing and reading. The objects that are tracked through this command are - pins, ports, nets, and cells. This command provides several options for reporting, querying, and modifying the SAIF name-mapping database information. To use any saif_map option, you need to have first specified **saif_map -start**, or **saif_map -read_map**, which starts the name mapping mechanism. You can write the name-mapping database information to a file by using the **-write_map** option. You can read the information back into the design by using the **-read_map** option. Using the **-set_name**, **-add_name**, and **-remove_name** options, you can manually set your name mappings for specific objects. Note that if the object specified is a pin or a port, the mapping is applied on the net connected to the pin or port. The **-inverted** option can be specified along with the **-set_name** and **-add_name** options, to indicate that the object corresponding to the specified name is logically inverted. You can change the way a particular SAIF name is interpreted while parsing the SAIF file by using the **-change_name** option. Note that both the *saif_name* and the *changed_name* need to be valid hierarchical names for the interpretation to be successful. To report the manual name mappings, you can use the **-report** option, which generates a report in the Tcl command format. The **-reset** option clears any user-specified manual name mappings. The **-get_saif_names** and **-get_object_names** options can be used to see the mappings for certain objects and SAIF names, respectively. The output of the **-get_saif_names** option consists of the *object_type*, the *object_name*, a list of SAIF names which can be empty, and optionally, a list of inverted SAIF names, as shown as follows:

{{*object_type object_name*} {saif_names {*saif_names*}}
  {inverted_saif_names {*inverted_saif_names*}}}

The return value of the -get_object_names option is a Tcl list with an element for each specified SAIF name. The format is:

{*saif_name* {objects {*objects*}} {inverted_objects {*inverted_objects*}}}

Each object or inverted object is formatted as {object_type object_name}.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example starts the name transformation tracking.

```
prompt> saif_map -start
```

The following example stops the name transformation tracking, and deletes the internally stored name-mapping information.

```
prompt> saif_map -stop
```

The following example writes the name-mapping information using the default hierarchy separator in the test1.map file.

```
prompt> saif_map -write_map test1.map
```

The following example writes the name-mapping information in PrimeTime PX command format in the test1.ptpx file. Only name mappings for names that occur in SAIF file test.saif are written. This results in a SAIF-file specific SAIF map.

```
prompt> saif_map -write_map test1.ptpx -type ptpx -saif_file test.saif
```

The following example writes the name-mapping information in PrimePower command format in the test1.primepower file. Only name mappings for names that occur in SAIF file test.saif are written. This results in a SAIF-file specific SAIF map.

```
prompt> saif_map -write_map test1.primepower -type primepower -saif_file test.saif
```

The following example reads the name-mapping information from the test1.map file.

```
prompt> saif_map -read_map test1.map
```

The following example sets the SAIF name A/B/C for the pin InstDecode/U15/AN.

```
prompt> saif_map -set_name A/B/C [get_pins InstDecode/U15/AN]
```

The following example adds the SAIF name A/B/C for the pin InstDecode/U15/AN to the name-mapping database, also indicating that the pin is logically inverted.

```
prompt> saif_map -add_name A/B/C -inverted [get_cells InstDecode/U15/AN]
```

The following example removes the SAIF name A/B for the cell InstDecode/U15.

```
prompt> saif_map -remove_name A/B [get_cells InstDecode/U15]
```

In the following example, the SAIF name mydesign is changed to InstDecode. When a SAIF file containing mydesign is read after this, mydesign is interpreted as InstDecode and annotation is performed accordingly.

```
prompt> saif_map -change_name {mydesign InstDecode}
```

The following example reports the manual name mappings that you specified. Note that the **-set_name** and **-add_name** functions, performed on the pin InstDecode/U15/AN, is applied to its connected net InstDecode/n3, as shown in the report.

```
prompt> saif_map -change_name {abc xyz}
prompt> saif_map -set_name x [get_pin InstDecode/U15/AN]
prompt> saif_map -add_name y [get_pin InstDecode/U15/AN]
prompt> saif_map -report
##########################
# USER SAIF-NAME MAPPING #
##########################
saif_map -change_name {abc xyz}
saif_map -set_name x [get_net InstDecode/n3]
saif_map -set_name y [get_net InstDecode/n3]
```

The following example resets the manual, user-specified SAIF name-mappings.

```
prompt> saif_map -reset
```

The following example returns the SAIF names corresponding to the pin InstDecode/U15/AN.

```
prompt> saif_map -change_name {x c}
prompt> saif_map -set_name a/b/c [get_pins InstDecode/U15/AN] -inverted
prompt> saif_map -add_name c/d/e [get_pins InstDecode/U15/AN]
prompt> saif_map -get_saif_names [get_pins InstDecode/U15/AN]
{{pin InstDecode/U15/AN} {saif_names {c/d/e x/d/e}} {inverted_saif_names a/b/c}}
```

The following example returns the object to which the SAIF name mydesign/bar/blah maps.

```
prompt> saif_map -change_name {mydesign/bar InstDecode/U15}
```

```
prompt> saif_map -set_name InstDecode/U15/blah [get_pin InstDecode/U15/AN]
prompt> get_nets -of_objects [get_pin InstDecode/U15/AN]
InstDecode/n3
prompt> saif_map -get_object_names mydesign/bar/blah
{mydesign/bar/blah {objects {{net InstDecode/n3}}}}
```

SEE ALSO

read_saif(2)

save_block

Saves a block to its current location or as a new block.

SYNTAX

status **save_block**
[-as *block_name*]
[-label *label_name*]
[-force]
[-hierarchical]
[-verbose]
[-compress]
[-blocks *blocks*]
[*block*]

Data Types

block_name string
label_name string
blocks collection
block string

ARGUMENTS

-as *block_name*

Specifies the destination block name with optional library and view specifications. The format for *block_name* is:

[libName:]blockName[/labelName][.viewName]

If no library is specified, **current_lib** is used. If no block name is specified, **current_block** is used. If no view name is specified, the design view is used. If no label name is specified, the default label "" is used. Note that **save_block block_name -as block_name** is equivalent to **save_block block_name**. It is an error to save to a sub-block referenced by the top block. The source and destination label must be different when used with the **-hierarchical** option; otherwise, it is an error.

By default, a new block of the specified block_name is created and saved to disk. This behavior can be changed by setting the "design.morph_on_save_as" application option to true. In this case, the source block and all of its views are renamed into the specified block_name and then saved, instead of making a copy of the source block and saving the copy to disk. The following conditions must be met: 1) the destination and source block are in the same library, and 2) no other blocks in memory reference the source block or any of its views.

-label *label_name*

Specifies the user label to be used when saving the block(s) using this command. This command is the safe way to save a block

(or a physical hierarchy rooted at a top block when combined with the **-hierarchical** option) to a new user label. This is generally used for stages of flow progression, with user label names like "placed", "clocked", and "routed" being typical. The user label names are entirely at the discretion of the user. Specifying an empty user label name causes the block(s) to be saved to the default, which is to have no user label.

As with the **-as** option above, this option is modified by use of the "design.morph_on_save_as" application option, in the same way.

This option is exclusive with the **-as** option.

-force

Overwrites the destination block when the destination is open and modified but not yet saved. This option is used with the **-as** option.

-hierarchical

Saves the entire physical hierarchy of the specified block. When used with the **-as** option and a specific label name, it saves each non library cell reference block and all its views into the specified label. The command follows the hierarchy into the reference blocks and save the subblocks referenced by its instances, stopping when it reaches the leaf-level library cell references. Each labeled block is created in-place in the library of the original block, and each of its non library cell instances are updated such that their references point to the new labeled block.

-verbose

Prints out additional debugging and informational messages.

-compress

Saves design in compressed format. This can be used along with -hierarchical to save the entire physical hierarchy in compressed format. Once a block has been saved with "-compress", the "is_compressed" attribute on the block is set to true. All future save_block on this block will be in compressed format even if the "-compress" option isn't specified. If the "is_compressed" attribute is later set to false, future save_block on this block will be in uncompressed format.

-blocks *blocks*

specifies the source block collection which are to saved. This option is exclusive with options **-as** and **block**. When this option is specified, the blocks corresponding to the collection are saved.

block

Specifies the source block name with optional library and view specifications. The format is as follows:

[libName:]blockName[/labelName][.viewName]

If the library specification is not present, the **current_lib** is used. If the label specification is not present, the default label "" is used. If the view specification is not present, then *design* view is used. If the option is not given, the **current_block** is used.

DESCRIPTION

This command saves the specified (or current) block. When the **-as** option is used, a copy of the block is saved to the specified block destination. The destination block can be in a different library. It can also be with a different block name, or with the same block name by different label name. With option **-blocks**, a collection of blocks can be saved. The command returns 1 if the block is saved and 0 if not. If an illegal name (with a slash) is given for the block, a Tcl error is raised.

Note that the command fails if the block is opened in read-only mode and the **-as** option is not used. The command fails if the **-as** option is used but the destination block exists, but is open for read-only access, or if the destination block has been modified, but not

saved, and the **-force** option is not also used.

When no view is explicitly specified for both source and destination then all available views of source block are saved into destination block.

A given source block view can't be saved into a different destination block view, like a design view can't be saved to a frame view. An error is issued while trying to do such operation.

EXAMPLES

This example saves the block Top and all its views as Top2, meaning that it becomes Top2. Note that Top no longer exists in memory, but remains unchanged on disk.

```
prompt> save_block -as Top2 Top
1
```

This example saves the current block and its particular view.

```
prompt> save_block
1
```

This example saves the block Mid and all its views, which is not the current block:

```
prompt> save_block Mid
1
```

This example does a hierarchical save of Top and all its views, which includes Mid and Bot:

```
prompt> save_block -hierarchical Top
1
```

This example saves the entire physical hierarchy of "Top" into a set of "placed" labeled blocks. This will create a labeled block from "top" and below in their respective libraries, stopping at the library cell level, for each of Top, Mid, and Bot:

```
prompt> save_block Top.design -hierarchical -as Top/placed -verbose
Information: Saving 'Top_lib:Top.design' to 'Top_lib:Top/placed.design'
Information: Saving 'Top_lib:Mid.design' to 'Top_lib:Mid/placed.design'
Information: Saving 'Top_lib:Bot.design' to
"Top_lib:Bot/placed.design"
1
```

This example saves the entire physical hierarchy starting from Mid and all its views into a set of "placed2" label blocks. This will create a labeled block from "Mid" and below, for each of Mid, and Bot:

```
prompt> save_block Mid -hierarchical -as Mid/placed2 -verbose
Information: Saving 'Top_lib:Mid.design' to 'Top_lib:Mid/placed2.design'
Information: Saving 'Top_lib:Bot.design' to
"Top_lib:Bot/placed2.design"
1
```

This example saves just the Top and all its views into a "placed3" labeled block. Note that only the "Top" block is saved as a copy. New label are not created for the lower-level blocks, and "Top/placed" still references "Mid" and "Bot" blocks.

```
prompt> save_block Top -as Top/placed3 -verbose
Information: Saving 'Top_lib:Top.design' to 'Top_lib:Top/placed3.design'
Information: Saving 'Top_lib:Top.frame' to 'Top_lib:Top/placed3.frame'
```

save_drc_error_data

Saves an external DRC error data object to disk.

SYNTAX

status **save_drc_error_data**
drc_error_data
[-as *file_name*]

Data Types

drc_error_data collection
file_name string

ARGUMENTS

drc_error_data

Specifies the collection of external physical DRC error data objects to save.

-as *file_name*

Specifies a new file name for the external error data file.

If you do not specify this option, the error data file is saved with its original name.

DESCRIPTION

The **save_drc_error_data** command saves the specified external DRC error data object to disk.

This command does not save error data objects that are attached to a block. To save an error data object that is attached to a block, save the block with the **save_block** command. To save the attached error data object to a file, use the **write_drc_error_data** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example opens the external error data file named my_design_dppinassgn.err, removes fixed errors, and then saves and closes the file.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{my_design_dppinassgn.err}
prompt> remove_drc_errors -error_data $data \
  [get_drc_errors -error_data $data -filter {status==fixed}]
prompt> save_drc_error_data $data
1
prompt> close_drc_error_data $data
1
```

remove_drc_error_data(2)
save_block(2)
write_drc_error_data(2)

save_ems_database

Saves opened EMS databases to disk.

SYNTAX

status **save_ems_database**
[-as *filename* | -all | *ems_databases*]
[-overwrite]

Data Types

filename string
ems_databases collection

ARGUMENTS

-as *filename*

Saves the current EMS database to disk with the specified name. The *filename* argument must end with ".ems". If there is no current EMS database, then tool will issue an error message. If a file with name "filename" already exists, the command will issue an error message. Use the **-overwrite** option to overwrite an existing file.

-all

Writes all opened EMS databases to disk. If a file already exists on disk with the same name as the EMS database, the command issues an error message. Include the **-overwrite** option to overwrite existing files.

ems_databases

Specifies a collection of EMS databases to write. Use the **get_ems_databases** to create a collection of all EMS databases. If the database files already exist on disk, the command issues an error message. Use the **-overwrite** option to overwrite the files.

-overwrite

Overwrites an existing EMS database file on disk. By default, the command issues an error message if a file with the same name already exists on disk.

DESCRIPTION

The **save_ems_database** command writes the current EMS databases in memory to disk. When no filename is specified, this command writes out the current EMS database. If there is no current EMS database, the command issues a warning message. When you specify a filename, this command writes out the current EMS database to the specified file. The **save_ems_database -all**

command writes out all open EMS databases. **save_ems_database {db1.ems db2.ems}** writes out the EMS databases specified in the collection. The **-all**, **-as** and *ems_databases* options are mutually exclusive.

EXAMPLES

The following examples shows the error message your receive if you run the **save_ems_database** command and there are no open EMS databases.

```
prompt> get_current_ems_database
prompt> save_ems_database
Warning: No current EMS database present. (EMS-036)
```

The following example writes out the current EMS database.

```
save_ems_database with current database
prompt> get_current_ems_database
{test.ems}
prompt> save_ems_database
```

The following example overwrites the test.ems file with the current EMS database.

```
save_ems_database using -as option
prompt> save_ems_database -as test.ems
Error: File 'test.ems' already exists. Use -overwrite flag to force
  writing of messages database. (EMS-002)
prompt> save_ems_database -as test.ems -overwrite
```

The following example writes out all open EMS databases.

```
prompt> get_ems_databases
{test.ems abc.ems}
prompt> save_ems_database -all
```

The following example writes out all open EMS databases; the database names are specified with the **get_ems_databases** command.

```
prompt> get_ems_databases
{test.ems abc.ems}
prompt> save_ems_database [get_ems_databases]
```

SEE ALSO

get_ems_databases(2)
open_ems_database(2)
set_current_ems_database(2)

save_lib

Saves a library and its changed blocks to disk.

SYNTAX

status **save_lib**
[-as *library_name* [-version *release_version*]]
[-all]
[-compress]
[*library*]

Data Types

library_name string
release_version string
library collection

ARGUMENTS

-as *library_name*

Specifies the name of the saved library.

If you do not specify this option, the library is saved with the same name.

This option is mutually exclusive with the **-all** option; you can specify only one of these options.

-version *release_version*

Specifies the version of the saved library.

To see the valid version strings, use the **report_versions** command.

This option is valid only with the **-as** option.

-all

Saves all open libraries that have changed blocks. Note that in an implementation tool, the command saves only design libraries and not reference libraries that contain library cells.

This option is mutually exclusive with the **-as** option and *library* argument; you can specify only one of these arguments.

-compress

Saves libraries in compressed format. This option is applicable to design libraries only. lib-cell libraries cannot be compressed. Once a library has been saved with "-compress", the "is_compressed" attribute on the library is set to true. All future save_lib or save_block on this library or its blocks will be in compressed format, even if the "-compress" option isn't specified. If the

"is_compressed" attribute is set to false, future save_lib on this library will be in uncompressed format.

library

Specifies the library to save. This can be either the library name or a collection that contains a single library.

If you do not specify this option, the command saves the current library.

This argument is mutually exclusive with the **-all** option; you can specify only one of these arguments.

DESCRIPTION

This command saves the library data to disk. Library data includes the design catalog, library attributes, technology data, and parasitic data. The command also saves all blocks in the library that have been modified but not saved.

In an implementation tool, the command saves only design libraries in edit mode. It does not save read-only libraries or reference libraries that contain library cells.

If the command successfully saves one or more libraries, it returns 1. Otherwise, it returns 0. If you try to save a library with an illegal name, such as a name that contains a slash, the command raises a Tcl error.

EXAMPLES

This example saves the contents of the MyDesign design library.

```
prompt> save_lib MyDesign
1
```

This example saves the contents of the Top library to a library named Top.1.0 using the database schema revision for version J-2014.06.

```
prompt> save_lib Top -as Top.1.0 -version J-2014.06
Saving library 'Top' as 'Top.1.0' in version 'J-2014.06'
1
```

save_upf

Writes out the UPF commands in the specified file.

SYNTAX

collection **save_upf**
[-full_chip | -for_empty_blackbox]
[-format supplemental]
[-force_reference | -force_no_reference]
[-include | -exclude]
[-nosplit]
file_name

Data Types

file_name string

ARGUMENTS

-format supplemental

Specifies the format of output file. Specifying *supplemental* means that the output file contains only the UPF constraints generated by the tool(s). This option and value work only in the golden UPF mode.

For the golden UPF flow, when the application option **mv.upf.enable_golden_upf** is set to true, default is set to *supplemental* since only the supplemental format is supported. So specifying **-format** is not really necessary.

-full_chip

Save full_chip UPF from top-only design links with blocks. The linked blocks can be abstract view (recommended) or design view.

-for_empty_blackbox

Save UPF for empty black_box created from this design. This option cannot be combined with **-format**.

-force_reference

Specifies lib_cells to output for **connect_supply_net** or **set_related_supply_net** if exists. This option cannot be combined with **-full_chip**, **-for_empty_blackbox**.

-force_no_reference

Specifies lib_cells to not output for **connect_supply_net** or **set_related_supply_net** if exists. This option cannot be combined with **-full_chip**, **-for_empty_blackbox**.

-include

Types of cell instance to include in **connect_supply_net** or **set_related_supply_net**. This option cannot be combined with **-exclude**, **-full_chip**, **-for_empty_blackbox**.

-exclude

Types of cell instance to exclude in **connect_supply_net** or **set_related_supply_net**. This option cannot be combined with **-include**, **-full_chip**, **-for_empty_blackbox**.

-nosplit

Specifies the UPF file to be output in none split mode, the commands will be output in a line instead of multiple lines. By default, user UPF will preserve the line width as specified in input UPF file, derived UPF will be output as the values defined by app option mv.upf.save_upf_line_width and mv.upf.save_upf_line_indent.

It is exclusive with option *-full_chip*.

file_name

Specifies the name of the file to which UPF commands are to be written out.

DESCRIPTION

This command writes out the UPF file that is currently part of the design to the specified file. This UPF file is what you have loaded by using the **load_upf** command or the command line, with the changes made to the file during optimization, and the UPF commands specified at the command prompt in that session.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of the **save_upf** command:

```
prompt> save_upf design.upf
```

The user section in the UPF file will preserve the line width as specified in input UPF file, the derived section in the file will be output with the default value of line width, and the continuing lines for a command in multiple lines will be indented with the default value of line indent.

Following are an example for command option *-nosplit* and app options

mv.upf.save_upf_line_width and *mv.upf.save_upf_line_indent*, they will impact the UPF file as below.

prompt> **save_upf -nosplit design.upf**

The commands both in user and derived section will be printed in a line instead of multiple lines.

Following are another example for line width and line indent.

```
prompt> set_app_options -name mv.upf.save_upf_line_width -value 60
prompt> set_app_options -name mv.upf.save_upf_line_indent -value 2
prompt> save_upf design.upf
```

The commands both in user and derived section will be printed in multiple lines if the command reaches max line width 60, and continuing command lines will be indented with 2 empty spaces.

SEE ALSO

mv.upf.save_upf_line_width(3)
mv.upf.save_upf_line_indent(3)

send_status

Sends the specified message from the distributed processing machine to the calling process.

SYNTAX

status **send_status**
-status *message_string*

Data Types

message_string string

ARGUMENTS

-status *msg_string*

Specifies the string to send to the main process.

DESCRIPTION

This command is used only by a distributed processing worker to send a text string to the main process. Distributed processing is initiated by using the **run_block_script** command. You can add this command to the distributed processing script to send status, runtime, or any other messages to the main calling process.

EXAMPLES

The following example sends a message from the distributed processing worker to the main process. The test.tcl distributed processing script contains the following command:

```
send_status -status "Processing block $block_refname"
```

The script is called by the **run_block_script** command as follows and produces the output shown.

```
prompt> set_host_options -name myLSFtest -submit_command "bsub"
1
prompt> run_block_script -script test.tcl -host_options myLSFtest -ref_blocks { A B }
...
Processing block A
```

```
Processing block B
1
```

SEE ALSO

run_block_script(2)
set_host_options(2)

set_analyze_rtl_logic_level_threshold

Specifies the logic level threshold value to be used by report_logic_levels command. Also used to remove the previously set value.

SYNTAX

status **set_analyze_rtl_logic_level_threshold**
[-group <group_name>]
[-reset]
[threshold]

Data Types

group_name string
threshold integer

ARGUMENTS

-group *group_name*

Specifies a name for the path group for which threshold value is being set or reset. The group name should be one of the group names reported by report_path_group command. When this option is not used, the threshold setting is applied at global level.

-reset

Specifies that the previously specified threshold value be reset. If -group option is specified, then reset applies only to the specified path group. If -group option is not specified, then the threshold value is reset for all path groups and global level.

threshold

Specifies the threshold integer value to be used by report_logic_levels command.

DESCRIPTION

This command is used to specifiy the threshold value to be used by report_logic_levels command. The value can be specified at each path group level or at global level. When threshold is specified both at global level and path group level, path group threshold setting is used for the paths belonging to that path group.

Not using this command will result in tool computing the threshold automatically based on the required time for the path and the delay of average size NAND2 cell in the target library.

When threshold is specified both at global level and path group level and reset is applied on path group level, global threshold setting is used for paths belonging to that path group.

When threshold is specified only at path group level and reset is applied on that path group level, in absence of global threshold, tool computed threshold is used for paths belonging to that path group.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the logic level threshold to 10 at global level.

```
prompt> set_analyze_rtl_logic_level_threshold  10
```

The following example sets the logic level threshold to 5 only for the paths in the path group CLOCK while setting 6 for all other paths.

```
prompt> set_analyze_rtl_logic_level_threshold 6
prompt> set_analyze_rtl_logic_level_threshold -group CLOCK 5
```

The following example re-sets the logic level threshold for path group CLOCK.

```
prompt> set_analyze_rtl_logic_level_threshold -group CLOCK -reset
```

The following example re-sets the logic level threshold for all paths (all path groups).

```
prompt> set_analyze_rtl_logic_level_threshold -reset
```

SEE ALSO

report_logic_levels(2)
report_path_group(2)

set_annotated_check

Sets the setup, hold, recovery, or removal timing check value between two pins.

SYNTAX

status **set_annotated_check**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
check_value
-from *from_pins*
-to *to_pins*
-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low | -width | -period
[-rise | -fall]
[-clock rise | fall]
[-increment]
[-override_increment]

Data Types

check_value float
from_pins list
to_pins list

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the annotated value. Each of the specified scenarios is annotated separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command applies to the current scenario only.

check_value

Specifies the timing check value between pins on the same cell, which can be positive or negative. You must express the *check_value* argument in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, the *check_value* argument must be expressed in nanoseconds.

-from *from_pins*

Specifies the leaf-cell clock pins that are the startpoints of the timing arcs for which checks are to be annotated.

-to *to_pins*

Specifies the leaf-cell data pins that are the endpoints of the timing arcs for which checks are to be annotated.

-setup | **-hold** | **-recovery** | **-removal** | **-nochange_high** | **-nochange_low** | **-width** | **-period**

Specifies the type of the timing check. There must be a corresponding timing arc between the from and to pins.

- The **-setup** option specifies that data must be stable for the amount of time specified by *check_value* before the closing clock edge.
- The **-hold** option specifies that data must be stable for the amount of time specified by *check_value* after the closing clock edge.
- The **-recovery** option specifies that an asynchronous set or clear inactive edge cannot occur within the amount of time specified by *check_value* before the closing clock edge. This is essentially a setup requirement on an asynchronous pin, but only the inactive transition is considered.
- The **-removal** option specifies that an asynchronous set or clear inactive edge cannot occur until the amount of time specified by *check_value* after the closing clock edge. This is essentially a hold requirement on an asynchronous pin, but only the inactive transition is considered.
- The **-nochange_high** option provides a timing check that specifies that the data must not rise within the amount of time specified by *check_value* before the clock becomes active and must not fall until the amount of time specified by *check_value* after the clock becomes inactive.
- The **-nochange_low** option provides a timing check that specifies that the data must not fall within the amount of time specified by *check_value* before the clock becomes active and must not rise until the amount of time specified by *check_value* after the clock becomes inactive.
- The **-width** option specifies a minimum pulse width constraint for a clock pin. The timing check is defined on the -from pin, so the related pin (-to) should be the same.
- The **-period** option specifies the minimum period constraint for a clock pin. The timing check is defined on the **-from** pin, so the related pin (**-to**) should either be the same or it can be omitted.

-rise | **-fall**

Specifies whether the check is for the data rise or fall transition. If you do not specify either **-rise** or **-fall**, both values are set.

The **-rise** option specifies a rise data transition that corresponds to the check before the activating clock edge. A rise data transition corresponds to the check after the deactivating clock edge. A rise clock transition indicates that the clock is active-high.

The **-fall** option specifies a fall data transition that corresponds to the check after the deactivating clock edge. A fall data transition corresponds to the check before the activating clock edge. A fall clock transition indicates that the clock is active-low.

-clock rise | **fall**

Specifies whether the check is for clock rising or falling. By default, checks for both clock rise and fall are set.

-increment

Adds the specified check value to the existing default check value. Without this option, the check value replaces the default check value. If you use the **set_annotated_check** command multiple times with the **-increment** option, the last **-increment** setting is

used and earlier ones are ignored. If you use a **set_annotated_check** command without the **-increment** option, that check value is used, and any **-increment** setting is ignored.

-override_increment

Overwrite incremental values instead of adding them to the already existing ones. Applies only for annotating incremental values.

DESCRIPTION

This command annotates a timing check between two or more pins on a cell or a net in the current design. This might be appropriate after place and route for technologies where the timing check value varies for different instances and the library timing check values do not provide sufficient accuracy.

If the design is not already linked, the **set_annotated_check** command links it automatically.

The command can be used for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To list annotated timing check values, use the **report_annotated_check** command. To remove annotated timing check values from a design, use the **remove_annotated_check** or **reset_design** command. To see the effect of **set_annotated_check** for a specific instance, use the **report_timing** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example annotates a setup time of 2.1 units between the CP clock pin and the D data pin of the u1/ff12 cell instance:

```
prompt> set_annotated_check -setup 2.1 \
  -from u1/ff12/CP -to u1/ff12/D
```

The following example annotates a nochange check between data low and clock low. The nochange margin before the clock is 1.3 units and the nochange margin after the clock is 2.4 units.

```
prompt> set_annotated_check -nochange_low 1.3 \
  -clock fall -fall -from u1/CP -to u1/EN

prompt> set_annotated_check -nochange_low 2.4 \
  -clock fall -rise -from u1/CP -to u1/EN
```

SEE ALSO

current_design(2)
link(2)
remove_annotated_check(2)

report_annotated_check(2)
report_timing(2)
reset_design(2)

set_annotated_delay

Sets the net or cell delay value between two pins.

SYNTAX

status **set_annotated_delay**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
-net | -cell
[-rise | -fall]
[-min]
[-max]
[-increment]
delay_value
-from *from_pins*
-to *to_pins*

Data Types

delay_value	float
from_pins	list
to_pins	list

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the annotated value. Each of the specified scenarios is annotated separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command applies to the current scenario only.

-net | -cell

Specifies whether the delay annotated is a net or cell delay. You must specify one of the options, but not both.

-rise | **-fall**

Specifies whether the delay is for data rise or fall transition. If you do not specify **-rise** or **-fall**, both values are set.

-min

Specifies that the delay is to be used for minimum delay analysis.

-max

Specifies that the delay is to be used for maximum delay analysis. By default, the delay is used for maximum and minimum delay analysis.

-increment

Increments the delay value to the current delay of the specified timing arc.

delay_value

Specifies the delay value between pins on the same cell or net. The *delay_value* must be expressed in units consistent with the logic library used during optimization. For example, if the logic library specifies delay values in nanoseconds, *delay_value* must be expressed in nanoseconds.

-from ***from_pins***

Specifies a list of leaf-cell pins or top-level ports that are the startpoints of the timing arcs for which delays are to be annotated.

-to ***to_pins***

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs for which delays are to be annotated.

DESCRIPTION

This command annotates cell or net delays in the design.

Cell delays exist between pins of the same leaf cell. With the **-cell** option, pins in *from_pins* must be cell input or inout pins, and pins in *to_pins* must be cell output or inout pins.

Net delays exist between leaf-cell pins or top-level ports connected by a net. With the **-net** option, pins in *from_pins* must be cell output or inout pins or top-level input ports, and pins in *to_pins* must be cell input or inout pins or top-level output ports.

To verify the accuracy of the back-annotation done by the **set_annotated_delay** command, run the **update_timing** command.

The specified delay value overrides the internally-estimated cell and net delay value. If the specified pins are not in the same cell or on the same net, when the timing is updated, the tool issues an error message and *delay_value* is discarded for those pins.

You can use **set_annotated_delay** for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To remove the annotated cell or net delay values from a design, use the **remove_annotated_delay** or **reset_design** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example annotates a cell delay of 20 units between input pin A of cell instance U1/U2/U3 and output pin Z of the same cell instance.

```
prompt> set_annotated_delay -cell 20 \
    -from U1/U2/U3/A -to U1/U2/U3/Z
```

The following example annotates a rise net delay of 1.4 units between output pin *U1/Z* and input pin *U2/A*.

```
prompt> set_annotated_delay -net -rise 1.4 \
    -from U1/Z -to U2/A
```

SEE ALSO

remove_annotated_delay(2)
report_timing(2)
reset_design(2)

set_annotated_power

Sets cell power dissipation values. Overrides calculated values.

SYNTAX

status **set_annotated_power**
-scenarios *scenario_list*
-supply_net *supply_net*
-leakage *power_value*
-internal *power_value*
cell_list

Data Types

power_value float
scenario_list list
cell_list list

ARGUMENTS

-scenarios

Specifies the set of scenarios for which the annotated values apply. The default is the current_scenario value.

-supply_net

Specifies the supply net from which the specified power is drawn. You can annotate power for multiple supply nets by multiple invocations of the command.

-leakage

Specifies the leakage power value in user power units. The -leakage option can be used together with the -internal option.

-internal

Specifies the internal (dynamic) power value in user power units. The -internal option can used together with the -leakage option.

cell_list

Specifies the cells for which the power values apply. The command can be used to annotate black-box cells, physical block instances or leaf cells.

DESCRIPTION

This command annotates leakage and/or internal power values on cells. The annotated power overrides calculated power values. If a leakage value is annotated, **all** calculated leakage values for the specified scenarios are discarded. Likewise, if an internal power value is annotated **all** calculated internal power values for the scenarios are discarded.

The cells to be annotated should be either black-box cells, physical block instances or leaf cells.

If no scenario is specified, the values are applied for the current scenario only. If no supply net is specified, for leaf cells the primary supply net for the domain of the cell is used. For hierarchical cells, no supply net will be infered when no *-supply_net* option was specified.

The power is accounted in the power_group of the cell. If the cell has no power group (e.g. for physical blocks), implicit power_group **annotated** is used.

Multicorner-Multimode Support

EXAMPLES

The following example annotates a cell leakage power of 13.2 user units on cell instance U1/U2/U3 for the current scenario and the primary supply net of the cell's domain. The annotated leakage power is accounted in the power_group of the cell. All calculated leakage power of the cell in the current scenario is discarded.

```
prompt> set_annotated_power -leakage 13.2 \
        U1/U2/U3
```

The following example annotates a cell leakage power of 13.2 user units and an internal power of 125.6 user units on cell instance U1/U2/U3 for scenario *func.wc* and supply net *VDDB*. All calculated leakage power and internal power of the cell in scenario *func.wc*. is discarded. The annotated leakage power is accounted in the power_group of the cell.

```
prompt> set_annotated_power -leakage 13.2 \
        -internal 125.6 -scenarios func.wc \
        -supply_net VDDB U1/U2/U3
```

The following example annotates a cell leakage power of 13.2 user units and an internal power of 125.6 user units on cell instance U1/U2/U3 for scenario *func.wc* and supply net *VDD*. For supply net *VDDB* it annotates an internal power of 30.4 in scenario *func.wc*. All calculated leakage power and internal power of the cell in scenario *func.wc*. is discarded. The annotated leakage power is accounted in the power_group of the cell.

```
prompt> set_annotated_power -leakage 13.2 \
        -internal 125.6 -scenarios func.wc \
        -supply_net VDD U1/U2/U3
prompt> set_annotated_power \
        -internal 30.4 -scenarios func.wc \
        -supply_net VDDB U1/U2/U3
```

SEE ALSO

remove_annotated_power(2)
report_annotated_power(2)

set_annotated_transition

Sets the transition time at a given pin.

SYNTAX

status **set_annotated_transition**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-rise | -fall]
[-min]
[-max]
transition
port_pin_list

Data Types

transition	float
port_pin_list	list

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to apply the annotated value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the annotated value. Each of the specified scenarios is annotated separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command applies to the current scenario only.

-rise | **-fall**

Specifies whether the transition time is for a data rise or data fall transition. If you do not specify **-rise** or **-fall**, both values are set.

-min

Specifies that the transition is to be used for minimum delay analysis. By default, the transition value is used for maximum and minimum delay analysis. If a transition value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different transition values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

-max

Specifies that the transition is to be used for maximum delay analysis. By default, the transition value is used for maximum and minimum delay analysis. If a transition value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different transition values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

transition

Specifies the transition value at the pins supplied with the *port_pin_list* argument. The transition value must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies transition values in nanoseconds, the transition values must be expressed in nanoseconds.

port_pin_list

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs for which delays are to be annotated.

DESCRIPTION

This command sets the transition time at a given pin.

To remove the annotated transition values from a design, use the **remove_annotated_transition** or **reset_design** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example annotates a transition time of 20 units at input pin *A* of cell instance U1/U2/U3:

```
prompt> set_annotated_transition 20  U1/U2/U3/A
```

The following example annotates a rise transition of 1.4 units at the input pin U5/A:

```
prompt> set_annotated_transition -rise 1.4 U5/A
```

The following example annotates a rise transition of 12.3 units for minimum delay analysis at U5/A:

```
prompt> set_annotated_transition -rise -min 12.3 U5/A
```

set_aocvm_coefficient

Sets advanced on-chip variation (OCV) random coefficients on cells and library cells for use during an advanced OCV analysis.

SYNTAX

status **set_aocvm_coefficient**
rnd_coeff
object_list

Data Types

rnd_coeff float
object_list list

ARGUMENTS

rnd_coeff

Specifies the random coefficient applied to the objects in the *object_list*. The *rnd_coeff* setting must be a floating-point value greater than zero.

object_list

Specifies a list of library cells or leaf cells on which the coefficient is set.

DESCRIPTION

This command sets random coefficients on library cells or leaf cells for advanced on-chip variation (OCV) analysis. These are user-specified depth adjustment factors (default of 1.0) that you can apply at the library cell or cell instance level. These coefficients are not required for an advanced OCV analysis. However, their application may increase the accuracy of the analysis.

If different coefficients have been annotated on a library cell and an instance of that cell, the coefficient annotated on the cell instance takes precedence.

Random coefficients are used to calculate cell path depths. The default increment of path depth for any cell is 1.0. The path depth increment for a cell, if defined, is *rnd_coeff*.

To display the advanced OCV coefficients that have been set, use the **report_ocvm** command.

To remove advanced OCV coefficients from a cell, use the **remove_ocvm -coefficient** command.

Multicorner-Multimode Support

EXAMPLES

The following example sets an advanced OCV random coefficient on a library cell named *lib/bufA*:

```
prompt> set_aocvm_coefficient 1.2 [get_lib_cells lib/bufA]
```

SEE ALSO

read_ocvm(2)
remove_ocvm(2)
report_ocvm(2)

set_app_options

Sets application options to the specified value on the specified block.

SYNTAX

list **set_app_options**
[-block *block*]
[-as_user_default]
[-category *category*]
[-name *name*]
[-value *value*]
[-list *name_value_list*]

Data Types

block	block name or collection
category	string
name	string
value	string
name_value_list	list

ARGUMENTS

-block *block*

The name of the block on which to set the option values.

If this option is not specified, the option value is set on the current block, if the option is a block-scoped application option.

This option cannot be specified with the **-as_user_default** option.

-as_user_default

Sets the specified value as the user default for the application option.

Note that the user default setting applies only to the current session and is not saved.

This option cannot be specified with the **-block** option.

-category *category*

Specifies one or two levels of the category of the application options to follow, either with the **-name** or **-list** option. When setting multiple application options that belong to the same category, this option enables you to provide the category one time, instead of multiple times with the option name.

If this option is not specified, you must specify the complete application option name.

-name ***name***

Specifies the name of the application option to modify.

The **-name** and **-value** options go together and are mutually exclusive with the **-list** option. You must specify either the **-name** and **-value** options or specify the **-list** option.

-value ***value***

Specifies the value of the application option specified in the **-name** option.

The **-name** and **-value** options go together and are mutually exclusive with the **-list** option. You must specify either the **-name** and **-value** options or specify the **-list** option.

-list ***name_value_list***

Specifies a list of option name and value pairs to set. The list must have an even number of tokens to be valid. If any of the key value pairs is invalid, this command fails with no effect.

The **-name** and **-value** options go together and are mutually exclusive with the **-list** option. You must specify either the **-name** and **-value** options or specify the **-list** option.

DESCRIPTION

This command sets the values of the specified application options.

There are two types of application options:

- Global application options, which apply everywhere within the current session

  Global application option settings are not stored and are not carried over from one session to the next. To retain these option settings, you must set them in your setup file.

- Block-level application options, which apply only to the blocks on which they are set

  Block-level application option settings are saved with the block in the design library and are persistent across tool sessions except when they are set by the **set_app_options -as_user_default** command. In this case, the application options are treated like global application options and are not persistent across tool sessions.

To determine whether an application option is global or block-scoped, use the **report_app_options** command.

For application options that are of type "list of {name value} pairs", the command supports pointed modifications through the subscript mechanism. For subscripts to be recognized, the application options must be enabled for subscript modification and access.

Many application options have a value that must be expressed in units of time, voltage, and so on. In this case, the value must include a multiplier character (such as 'p', 'n', or 'k') and/or a units specifier character (such as 'F', 'V', or 's'). The units specifier character must use the correct case. For example, uppercase 'V' for volts and lowercase 's' for seconds. If the units character does not specify the correct type of unit, the command fails with no effect. Note that the user input units currently in effect are **not** used by this command.

The command returns the name-value pair of the application option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following example sets the value of the **time.enable_preset_clear_arcs** application option to **true** on the current block.

```
prompt> set_app_options -name time.enable_preset_clear_arcs -value true
time.enable_preset_clear_arcs true
```

The following example sets the value of the **shell.tmp_dir_path** application option to "/tmp" and the **time.enable_preset_clear_arcs** application option to **true**.

```
prompt> set_app_options \
  -list {shell.tmp_dir_path "/tmp" time.enable_preset_clear_arcs true}
shell.tmp_dir_path /tmp time.enable_preset_clear_arcs true
```

The following example sets the **time.high_fanout_net_pin_capacitance** application option, which requires a capacitance value, to 1.5 picofarads.

```
prompt> set_app_options \
  -name time.high_fanout_net_pin_capacitance -value 1.5p
time.high_fanout_net_pin_capacitance 1.5pF
```

The following example also sets the **time.high_fanout_net_pin_capacitance** application option to 1.5 picofarads.

```
prompt> set_app_options \
  -name time.high_fanout_net_pin_capacitance -value 1.5pF
time.high_fanout_net_pin_capacitance 1.5pF
```

The following example issues an error message because no units or multiplier characters are specified.

```
prompt> set_app_options \
  -name time.high_fanout_net_pin_capacitance -value 1.5
Error: Application option 'time.high_fanout_net_pin_capacitance' must
be specified with a capacitance unit. (UIM-009)
Error: Problem in set_app_options
  Use error_info for more info. (CMD-013
```

The following example issues an error message because the units character is incorrect. Capacitance is represented by an uppercase 'F'.

```
prompt> set_app_options \
  -name time.high_fanout_net_pin_capacitance -value 1.5pf
Error: Invalid value '1.5pf' specified for option
 'time.high_fanout_net_pin_capacitance'
      Use error_info for more info. (CMD-013)
```

The following example issues an error message because the wrong units as specified.

```
prompt> set_app_options \
  -name time.high_fanout_net_pin_capacitance -value 1.5mV
Error: Invalid value '1.5mV' specified for option
 'time.high_fanout_net_pin_capacitance'
       Use error_info for more info. (CMD-013)
```

The following example adds a value for the M1 key of the **test.layer_name_number_pair_list** application option.

```
prompt> set_app_options \
  -name test.layer_name_number_pair_list(M1) -value 31
```

```
test.layer_name_number_pair_list {M1 31}
```

The following example adds a value for the M2 key of the **test.layer_name_number_pair_list** application option.

```
prompt> set_app_options \
  -name test.layer_name_number_pair_list(M2) -value 32
test.layer_name_number_pair_list {M1 31 M2 32}
```

The following example modifies the value of the M1 key of the **test.layer_name_number_pair_list** application option.

```
prompt> set_app_options \
  -name test.layer_name_number_pair_list(M1) -value 33
test.layer_name_number_pair_list {M1 33 M2 32}
```

The following example uses the **-category** option to modify multiple application options of the same category.

```
prompt> set_app_options -category signoff.create_metal_fill \
  -list {flat true run_dir /tmp}
signoff.create_metal_fill.flat true signoff.create_metal_fill.run_dir /tmp
```

SEE ALSO

get_app_option_value(2)
get_app_options(2)
help_app_options(2)
report_app_options(2)
reset_app_options(2)

set_app_var

Sets the value of an application variable.

SYNTAX

string **set_app_var**
-default
var
value

Data Types

var string
value string

ARGUMENTS

-default

Resets the variable to its default value.

var

Specifies the application variable to set.

value

Specifies the value to which the variable is to be set.

DESCRIPTION

The **set_app_var** command sets the specified application variable. This command sets the variable to its default value or to a new value you specify.

This command returns the new value of the variable if setting the variable was successful. If the application variable could not be set, then an error is returned indicating the reason for the failure.

Reasons for failure include:

- The specified variable name is not an application variable, unless the application variable **sh_allow_tcl_with_set_app_var** is set to true See the **sh_allow_tcl_with_set_app_var** man page for details.

- The specified application variable is read only.
- The value specified is not a legal value for this application variable

EXAMPLES

The following example attempts to set a read-only application variable:

```
prompt> set_app_var synopsys_root /tmp
Error: can't set "synopsys_root": variable is read-only
    Use error_info for more info. (CMD-013)
```

In this example, the application variable name is entered incorrectly, which generates an error message:

```
prompt> set_app_var sh_enabel_page_mode 1
Error: "sh_enabel_page_mode" is not an application variable
    Use error_info for more info. (CMD-013)
```

This example shows the variable name entered correctly:

```
prompt> set_app_var sh_enable_page_mode 1
1
```

This example resets the variable to its default value:

```
prompt> set_app_var sh_enable_page_mode -default
0
```

SEE ALSO

get_app_var(2)
report_app_var(2)
write_app_var(2)

set_attribute

Sets attribute values to the specified value on the specified list of objects.

SYNTAX

collection **set_attribute**
[-class *class_name*]
[-quiet]
-objects *object_list*
-name *attribute_name*
-value *attribute_value*
pos_object_list
pos_attribute_name
pos_attribute_value

class_name string
object_list list
attribute_name string
attribute_value string
pos_object_list list
pos_attribute_name string
pos_attribute_value string

ARGUMENTS

-class *class_name*

Specifies the first class object type name used for implicit search of objects. This can be used when objects are specified as string and its object type is not among the predefined types in the search order set by app option *shell.common.implicit_find_mode*.

-quiet

Turns off the warning message that would otherwise be issued if the attribute or objects are not found.

-objects *object_list*

Specifies a list of objects on which the attribute value is to be set. Each element in the list is a collection of objects. This option is mutually exclusive with *pos_object_list*. Either one (and only one) of *-objects* or *pos_object_list* must be specified.

-name *attribute_name*

Specifies the name of the attribute to be set. This option is mutually exclusive with *pos_attribute_name*. Either one (and only one) of *-name* or *pos_attribute_name* must be specified.

-value *attribute_value*

Specifies the value of the attribute. This option is mutually exclusive with *pos_attribute_value*. Either one (and only one) of *-value* or *pos_attribute_value* must be specified.

pos_object_list

Specifies a list of objects on which the attribute value is to be set. Each element in the list is a collection of objects. This positional option is provided for compatibility with other tools.

pos_attribute_name

Specifies the name of the attribute to be set. This positional option is provided for compatibility with other tools.

pos_attribute_value

Specifies the value of the attribute. This positional option is provided for compatibility with other tools.

DESCRIPTION

This command sets the attribute values on the specified objects. This command returns a collection of objects that have the specified attribute value set.

The *object_list* can be specified as strings in which case objects will be implicitly searched based on object type search order as specified by app option *shell.common.implicit_find_mode*. If none of the predefined object type matches specified input string then the command will fail. If the object type is known then user can use *-class* to provide that input.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the attributes. However, for attributes such as **max_leakage_power**, which are scenario dependent, this command uses information from the current scenario only.

EXAMPLES

The following example defines an integer cell attribute named X, and then sets this attribute to 30 on all cells in this level of the hierarchy:

```
prompt> define_user_attribute -type int -classes cell -name X
1
prompt> set_attribute -objects [get_cells *] -name X -value 30
{"U1"}
```

The following example sets the value of *is_fixed* attribute for voltage area VA1 by specifying VA1 as string and using *-class* option since voltage area is not among predefined object types for implicit find search order.

```
prompt> set_attribute -objects VA1 -name is_fixed -value true -class voltage_area
{VA1}
```

The following example sets the value of *orientation* attribute for cell U1234 by specifying U1234 as string.

```
prompt> set_attribute -objects U1234 -name orientation -value R180
{U1234}
```

SEE ALSO

define_user_attribute(2)
get_attribute(2)
get_defined_attributes(2)
list_attributes(2)
remove_attributes(2)
report_attributes(2)
shell.common.implicit_find_mode(3)

set_auto_disable_drc_nets

Disables DRC for specified nets.

SYNTAX

status **set_auto_disable_drc_nets**
[-none]
[-all]
[-constant true | false]
[-scan true | false]
[-on_clock_network true | false]
[-dft_signal signal_list]

ARGUMENTS

-none

Enables DRC for all nets in the current design, including nets connected to clocks.

-all

Disables DRC on all applicable nets in the current design. It is equivalent to setting **-on_clock_network true**, **-constant true**, and **-scan true**.

-constant true | **false**

Disables or enables DRC on constant nets in the current design. When set to **true**, it automatically disables DRC on constant nets. When set to **false**, it enables DRC on constant nets.

-scan true | **false**

Disables or enables DRC on scan enable and scan clock nets in the current design. When set to **true**, it automatically disables DRC on scan enable and scan clock nets. When **false**, it enables DRC on scan enable and scan clock nets.

-scan true | **false**

Disables or enables DRC on scan enable and scan clock nets in the current design. When set to **true**, it automatically disables DRC on scan enable and scan clock nets. When **false**, it enables DRC on scan enable and scan clock nets.

-dft_signal { type1 type2 ... }

Disables DRC only for the specified scan signal types when **-scan true**. If not specified then DRC is disabled for all supported types when **-scan true** is set. The supported types are:

- **ScanEnable**
- **TestMode**

- **wrp_shift**
- **input_wrp_shift**
- **output_wrp_shift**
- **LOSPipelineEnable**
- **ScanClock**

-on_clock_network true | **false**

Disables or enables DRC on clock networks in the current design. When set to **true**, DRC is disabled on clock networks.

DESCRIPTION

This command disables design rule checking (DRC) for specified nets in the current design. The command options are additive each time a new **set_auto_disable_drc_nets** command is executed.

To disable DRC for clock networks, use the **-on_clock_network true** option.

To prevent constant nets from having DRC disabled, use the **-constant false** or **-none** options.

DRC disabled nets are those nets that are free from the max_capacitance, max_fanout, and max_transition design rule constraints. They are useful for reducing DRC violations caused by clock trees, because these nets usually have high max_capacitance and max_fanout violations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables DRC on nets connected to clocks and constant nets in the current design:

prompt> **set_auto_disable_drc_nets -on_clock_network true -constant true**

The following example disables DRC on only the constant nets in the current design:

prompt> **set_auto_disable_drc_nets -constant true**

The following example re-enables DRC for all relevant nets, including those on clock nets, in the current design:

prompt> **set_auto_disable_drc_nets -none**

The following example disables DRC only for ScanEnable and TestMode scan signal nets:

prompt> **set_auto_disable_drc_nets -scan true -dft_signal { ScanEnable TestMode }**

set_auto_floorplan_constraints

Sets constraints for implicit floorplan initialization.

SYNTAX

status **set_auto_floorplan_constraints**
[-control_type core | die]
[-core_utilization *utilization*]
[-shape R | L | T | U]
[-orientation N | W | S | E]
[-side_ratio {side_a side_b [side_c side_d side_e side_f]}]
[-side_length {side_a side_b [side_c side_d side_e side_f]}]
[-core_offset { *value* | *vertical_value horizontal_value* | *side_1 ... side_N*}]
[-row_core_ratio *row_core_ratio*]
[-coincident_boundary]
[-boundary *boundary*]
[-flip_first_row]
[-reset]
[-pin_snap]
[-honor_pad_limit]
[-tile *tile_name*]
[-site_def *site_def_name*]
[-use_site_array]
[-use_site_row]

Data Types

utilization float
row_core_ratio float
boundary vector of coordinates
tile_name string
site_def_name string

ARGUMENTS

-control_type core | die

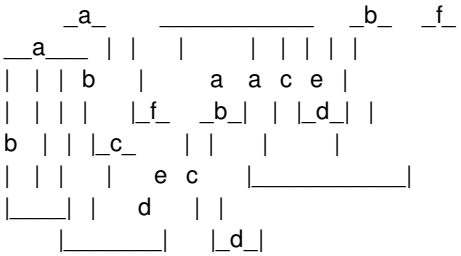
Specifies whether the side_length and side_ratio options apply to the core or the die boundary. If set to die, then the dimensions (side_length and side_ratio) are applied to the die boundary and the core_offset values are subtracted from the dimensions to determine the core boundary. If set to core (default), the dimensions are applied to the core boundary and the core_offset values are added to the dimensions to determine the final die boundary. By default, the control_type is core.

-core_utilization *utilization*

Specifies the utilization of the core area. The utilization is the total area of the core occupied by all standard cells and macro cells divided by the total core area. You can specify a value between 0 and 1. The cell area includes all standard and macro cells. For example, a core utilization of 0.8 specifies that 80 percent of the core area is used for cell placement at this stage. Later, the tool might add more cell area, with the remaining area available for routing. By default, the core utilization is 0.7.

-shape R | L | T | U

Specifies the shape used by the command. If the control_type is die, then the shape applies to the die boundary shape settings. Specifies a template shape used to determine the cell boundary and core shape of the rectilinear block. The following diagram shows the definition of the edges and the orientation of the R-, L-, T-, and U- rectilinear blocks. By default, the core shape is R (rectangular).



-orientation N | W | S | E

Specifies one of four possible orientations for the specified rectilinear shape. The orientations are North (N), West (W), South (S), and East (E). The tool repositions the block to the specified orientation by rotating it in a clockwise direction. For **-shape R**, the orientation is always N.

-side_ratio { *side_a side_b side_c side_d side_e side_f*}

Specifies the side ratio used by the command. If the control_type is die, then it applies the side_ratio to the die boundary side settings. Each dimension in the list represents the relative proportion of the dimension of the edge to the sum of all the dimensions listed. For example, if the list of dimensions of an L-shaped block is {1 2 1 1}, the tool calculates the dimension of side a, c, or d (where the value is 1) as 20% (1/(1+2+1+1)) of the sum of the dimensions listed, and the dimension of side b is 40% of the summation.

-side_length { *side_a side_b side_c side_d side_e side_f*}

Specifies the side length used by the command. If the control_type is die, then it applies to the die boundary side settings. Each dimension in the side_length list represents the length of the edge. If you provide more values than required to describe the specified shape, the extra values are ignored. If you do not provide all of the values required to describe the specified shape, the tool issues an error message. There are only two dimensions for **-shape Rect**: width and height. This option is mutually exclusive with the **-side_ratio** option.

-core_offset { *value* | *vertical_value horizontal_value* | *side_1 ... side_N*}

Specifies the distance between the side of the core and the side of the die boundary. If only one value is specified, the value is used for all sides. If two values are specified, the first value is applied to all vertical edges and the second value is applied to all horizontal edges. Side numbers are based on the standard rectilinear numbering and do not correlate to the numbering scheme used to define the size of each edge (side_a, side_b, etc). By default, the core offset is equal to the minimum I/O cell height. If there are no I/O cells, the core offset is 0.

-row_core_ratio *row_core_ratio*

Specifies the amount of channel area between cell rows in the core area to reserve for routing. The *ratio* is a number between 0 and 1.0. A smaller row-to-core ratio creates more space for routing channels. A value of 1.0 creates no routing channel space. By default, the ratio is 1.0. Note that this ratio should be greater than or equal to the core utilization value.

-coincident_boundary

Uses the existing die boundary. If this option is specified and the core-based constraints result in a core that is too large to fit in

the existing die boundary, the command issues an error message. No default is specified.

-boundary *boundary*

Specifies the shape to be used by the command. If the control_type is core, then the boundary defines the core area and the core_offsets should be added to create the die. If control_type is die, then the core_offset should be subtracted from the die boundary to create the core area. The format is { {x1 y1} {x2 y2} {x3 y3} {x4 y4} }.

-flip_first_row

Specifies whether the command flips the first row at the bottom of the core area for horizontally-placed cell rows, or flips the leftmost row for vertically-placed cell rows. By default, the tool flips the first row at the bottom of the core area.

-reset

Reset all the constraints to their defaults.

-pin_snap

Specifies the snapping of terminal centers to the center of wire tracks. The **-pin_snap** option snaps the center of terminals to the center of the closest wire track for existing pins. Note that this option does not snap power terminals, ground terminals, or terminals with I/O constraints. By default, the setting is off.

-honor_pad_limit

Adjusts the core and die size to honor pad-limited designs. If this option is not specified, the core area is created based on the default core utilization ratio 0.7.

-tile *tile_name*

Specifies the tile name to be used in floorplanning when there are multiple tiles in the technology file.

-site_def *site_def_name*

Specifies the site def to be used in floorplanning when there are multiple site defs in the technology file. The default is to use default site def. If there is no default site def, the command uses the site def with the smallest site width.

-use_site_array

Specifies that the tool creates site arrays.

-use_site_row

Specifies that the tool creates site rows.

DESCRIPTION

Specifies the constraints used to create a floorplan with a boundary, core, site array (or rows), and wire tracks. Before executing this command, you must open a physical design by using the **open_block** command, or create a design with the **read_verilog** or **read_verilog_outline** commands.

EXAMPLES

The following example sets the constraint of utilization to be 0.8.

```
prompt> set_auto_floorplan_constraints -utilization 0.8
1
```

The following example sets the preferred core shape to be a rectangle (R).

```
prompt> set_auto_floorplan_constraints -shape R
1
```

The following example sets the preferred core length to create the floorplan.

```
prompt> set_auto_floorplan_constraints -side_length {200 200}
1
```

report_io_rings(2)

set_base_lib

Updates the base library location on a sparse library.

SYNTAX

set_base_lib
[-library *library_name*]
-base_lib *base_library_path*

Data Types

library_name string
base_library_path string

ARGUMENTS

-library *library_name*

The sparse library to update the base library path. If no library is specified, the *current_lib* is used. Note that the given library must be a sparse library. Using this command on a non-sparse library will cause an error. Use the *is_sparse* attribute on a library to verify if it is a sparse library.

-base_lib *base_library_path*

A base library path to set on this library. Base library path can be simple, relative, or absolute. A simple library path will be resolved with the first library found on the *search_path*. A note of caution: only design-type libraries can be used as base library, and relying on *search_path* to resolve to a specific library, when there are multiple matches on the *search_path*, the order in the *search_path* decides the library used as base. Note that the base library itself can also be a sparse library, and this command triggers an auto re-synchronizing of the sparse base library with the base libraries.

DESCRIPTION

The **set_base_lib** command modifies the base library location stored on a sparse library. It is useful for keeping the sparse library's reference base library up to date, after the base library has been moved or renamed. All blocks of the sparse library must be closed when this command is used. The library catalog of the updated base library is read, and merged into the sparse library. This merging does not change the local blocks already saved in the sparse library, even if their base library counterparts have been modified, or even deleted. If there are new blocks in the base library, the block entries are appended to the sparse library's catalog.

The sparse library's ref_lib list will also be reset with that of the base library.

The base library and its location can be retrieved with the *base_lib* and *base_lib_path* attribute on the library.

EXAMPLES

The following example sets the base library on the sparse library top_sparse_lib.

```
prompt> set_base_lib -library top_sparse_lib -base_lib /home/user/top_lib
Information: Rebasing Sparse View library 'top_sparse_lib' to base
library '/home/user/top_lib'. (NDM-103)
prompt> get_attribute [get_libs top_sparse_lib] base_lib
{top_lib}
prompt> get_attribute [get_libs top_sparse_lib] base_lib_path
/home/user/top_lib/lib.ndm
```

set_blackbox_clock_port

Specifies the clock ports for black box timing.

SYNTAX

status **set_blackbox_clock_port**
ports

Data Types

ports collection

ARGUMENTS

ports

Specifies the port objects that are clock ports as part of the black box timing information for the current block.

DESCRIPTION

This command specifies the ports that are clock ports of the current block, either clock input ports or clock output ports.

The information is part of the black box timing information. The **commit_blackbox_timing** command uses this information to create and save black box timing data for the current block.

EXAMPLES

The following example specifies port *Clk* as the clock port and specifies the clock network delay from this port.

```
prompt> set_blackbox_clock_port Clk
prompt> create_blackbox_clock_network_delay -value 0.5 [get_ports Clk]
```

SEE ALSO

create_blackbox_clock_network_delay(2)
create_blackbox_constraint(2)
create_blackbox_delay(2)
commit_blackbox_timing(2)

set_blackbox_port_drive

Specifies the driver of ports in black box timing.

SYNTAX

status **set_blackbox_port_drive**
-type *drive_type_name*
[-input_transition_rise *rise_transition_time*]
[-input_transition_fall *fall_transition_time*]
ports

Data Types

drive_type_name string
rise_transition_time float
fall_transition_time float

ARGUMENTS

-type *drive_type_name*

Specifies the drive type for the ports. The *drive_type_name* is the name created by using the *create_blackbox_drive_type drive_type_name* to define the output drive type.

-input_transition_rise *transition_time*

Specifies the rise transition time at the input pin of the driver cell for the given ports. By default, the input rise transition time of the drive type is used.

-input_transition_fall *transition_time*

Specifies the fall transition time at the input pin of the driver cell for the given ports. By default, the input fall transition time of the drive type is used.

ports

Specifies the port objects for which to apply the driver description.

DESCRIPTION

This command defines the driver of a specified set of output or inout ports as part of the black box timing information for the current block.

EXAMPLES

The following example defines the driver at output port *DataOut* as a cell whose reference library cell is *BUF8* in reference library *stdreflib1* with 0.03ns rise and fall transition time at the input pin.

```
prompt> create_blackbox_drive_type -lib_cell [get_lib_cells stdreflib1/BUF8] \
    -input_transition_rise 0.01 -input_transition_fall 0.01 driveType1
prompt> set_blackbox_port_drive -type driveType1 -input_transition_rise 0.03 \
    -input_transition_fall 0.03 [get_ports DataOut]
```

SEE ALSO

create_blackbox_drive_type(2)
create_blackbox_load_type(2)
commit_blackbox_timing(2)
set_blackbox_port_load(2)

set_blackbox_port_load

Sets the load for the specified ports in black box timing.

SYNTAX

status **set_blackbox_port_load**
-value *capacitance_value* | -type *load_type_name*
[-factor *number*]
ports

Data Types

capacitance_value float
load_type_name string
number integer

ARGUMENTS

-value *capacitance_value*

Specifies the load capacitance for the ports. This option is mutually exclusive with the **-type** option.

-type *load_type_name*

Specifies the load type for the ports. The *load_type_name* is the name created with the **create_blackbox_load_type load_type_name** command to define the output load type. This option is mutually exclusive with the **-value** option.

-factor *number*

Specifies the multiplication factor for the load type at the specified ports. You must specify the **-type** option together with the **-factor** option.

ports

Specifies the port objects for which to apply the load description.

DESCRIPTION

This command defines the load of a specified set of input or inout ports as part of the black box timing information for the current block.

EXAMPLES

The following example defines the load at input port *DataIn* as five *BUF8* cells in reference library *stdreflib1*.

```
prompt> create_blackbox_load_type -lib_cell [get_lib_cells stdreflib1/BUF8] loadType1
prompt> set_blackbox_port_load -type loadType1 -factor 5 [get_ports DataIn]
```

The following example defines the load at input port *DataIn* as 0.5pF.

```
prompt> set_blackbox_port_load -value 0.5 [get_ports DataIn]
```

set_block_boundary

Sets the boundary for block.

SYNTAX

int **set_block_boundary**
-cell *block_instance_name*
[-boundary *polyrect*]
[-origin {*x y*}]
[-orientation *orientation*]

Data Types

block_instance_name string
polyrect list
x float
y float
orientation orientation in DEF syntax

ARGUMENTS

-cell *block_instance_name*

Specifies the block instance name.

-boundary *polyrect*

Specifies *polyrect* region as the block instance boundary in current design. The *polyrect* is described as a list of location coordinates.

-origin {*x y*}

Specifies the origin point of the specified block instance. If this option is not specified, the command automatically derives the origin co-ordinates based on the orientation of the block instance. For example: Block instance which has R0 orientation will have the lower-left point of the block instance boundary bounding box as it's origin, block instance with MX orientation will have upper-left point of the block instance boundary bounding box as it's origin and so on.

-orientation orientation

Specifies the orientation of the block instance.

DESCRIPTION

Generate the specified boundary for the block instance.

EXAMPLES

The following example sets the block instance boundary.

```
prompt> set_block_boundary -cell uSUB2 -boundary {{50 50} {300 50} {300 200} {150 200} {150 300} {50 300}}
```

SEE ALSO

explore_logic_hierarchy(2)
block_attributes(3)

set_block_grid_references

Creates a block grid for a block design reference.

SYNTAX

status **set_block_grid_references**
[-designs *design_list*]
[-grid *grid*]
[-snap_point {*x y*}]
[-adjust_snap_point_of_cell *block_instance*]
[-reset]

Data Types

design_list collection
grid block_grid_object
x float
y float
block_instance block_cell_object

ARGUMENTS

-designs *design_list*

Specifies the block reference designs which to setup with block grid information. One block reference design can only be associated with one block grid.

-grid *grid*

Specifies the block grid to associate with the block reference designs. One block grid can be associated with multiple block reference designs.

-snap_point {*x y*}

Specifies the block grid snap point of the block reference designs. A snap point in a block reference design is the point on the block that should be on the associated block grid. By default, the snap point is the origin of the block.

The **shape_blocks** command can move the snap point away from the origin of the block, depending on the needs of block placement. You can use this command and option to change the snap point. The user- specified snap point of a block reference design is fixed.

The **shape_blocks** command honors and does not move the snap point on the block reference if it is fixed. If you did not specify the snap point, it is not fixed. Use **set_block_grid_references -reset** to unfix the snap point and reset it to the origin of the block.

-adjust_snap_point_of_cell *block_instance*

Specifies the block cell instance on which to adjust the snap point. The tool uses the given block cell instance and its current location and orientation to adjust the snap point of the block reference design. The snap point is moved to a location on the block reference design, such that the given block cell instance is on the associated block grid. If there are other cell instances of the same reference design, you can use **snap_cells_to_block_grid** to move those cells on grid with the new snap point location.

-reset

Removes the association between the block grid and the block reference design. Also moves the snap point of the reference design to its origin and unfixes it.

DESCRIPTION

This command sets or resets the association between block reference designs and block grids. The command also sets up or resets snap point information of a block reference design.

EXAMPLES

The following example associates block grid gr1 with block reference BLK1, then changes the associated grid to gr2 and set the snap point of BLK1 to {0 10}.

```
prompt> set_block_grid_references -designs BLK1 -grid gr1
prompt> set_block_grid_references -designs BLK1 -grid gr2 -snap_point {0 10}
```

The following example associates block grid gr1 with block reference BLK2, then set the snap point of BLK2 to {0 10}.

```
prompt> set_block_grid_references -designs BLK2 -grid gr1
prompt> set_block_grid_references -designs BLK2 -snap_point {0 10}
```

set_block_pin_constraints

Sets pin constraints on the pins of block cells.

SYNTAX

int **set_block_pin_constraints**
[-allowed_layers *metal_layers*]
[-corner_keepout_num_tracks *tracks*]
[-corner_keepout_distance *distance*]
[-pin_spacing *spacing*]
[-pin_spacing_distance *distance*]
[-sides *side_numbers*]
[-exclude_sides *exclude_sides_numbers*]
[-allow_feedthroughs true | false]
[-stacking_allowed any | none | with_pg_pins_only | with_signal_pins_only]
[-cells *cell_collection*]
[-width *pin_width*]
[-length *pin_length*]
[-self]
[-hard_constraints layer | spacing | location | length | off]

Data Types

metal_layers list
tracks integer
distance real
spacing real
side_numbers list of integers
exclude_sides_numbers list of integers
cell_collection list
pin_width real or list of layer-real pairs
pin_length real or list of layer-real pairs

ARGUMENTS

-allowed_layers *metal_layers*

Specifies the set of metal layers allowed for pin placement. The argument is a list of metal layers.

By default, the metal layers from Min-routing layer to the maximum metal layer (specified earlier during floorplan) are allowed for pin placement. If the maximum metal layer has not been specified, the maximum available metal layer specified in the technology file is used as the default. If the maximum layer specified is beyond the maximum metal layer for the current design, then the maximum metal layer for the current design is used.

-corner_keepout_num_tracks *tracks*

Specifies the distance in wire tracks from the corners of blocks where pin placement should begin.

If neither the **-corner_keepout_num_tracks** nor the **-corner_keepout_distance** option is specified, the default distance is five wire tracks. The value for *tracks* must be zero or a positive integer. This option is mutually exclusive with option "-corner_keepout_distance". Setting this option will invalidate "-corner_keepout_distance" option.

-corner_keepout_distance *corner_keepout_distance*

Specifies the distance in microns from the corners of blocks where pin placement should begin. The distance has to be 0 or a positive integer. By default, the default distance is five wire tracks. This option is mutually exclusive with the **-corner_keepout_num_tracks** option. Setting this option will invalidate **-corner_keepout_num_tracks** option.

-pin_spacing *int*

Specifies the minimum number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks. The default pin-to-pin spacing is one wire track. The spacing number must be zero or a positive integer.

-pin_spacing_distance *spacing_distance*

Specifies the minimum distance between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks.

-sides *side_numbers*

Specifies the block sides on which the pin must be placed.

A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the leftmost vertical edge is the starting edge (side number 1). If there are multiple leftmost edges, then the edge 1 is the lowest leftmost edge. You cannot specify a value of 0 for this option.

Side number is counted as observed inside the corresponding reference block itself. You can reset the side number to default value by specifying the **-sides** option with an empty string. For example, to reset the side number, enter

-sides {}

This option is mutually exclusive with the **-exclude_sides** option.

-exclude_sides *exclude_side_numbers*

Specifies the block edges on which pins cannot be placed. The *exclude_side_numbers* argument is a list of positive integers. A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the leftmost vertical edge is the starting edge (side number 1). If there are multiple leftmost edges, then the edge 1 is the lowest leftmost edge.

For example, to exclude sides 2, 4, and 6, enter

-exclude_sides {2 4 6}

You can reset the excluded side number to default value by specifying the **-exclude_sides** option with an empty string. For example, to reset the excluded sides, enter

-exclude_sides {}

This option is mutually exclusive with **-sides** option.

-allow_feedthroughs *true* | *false*

Specifies whether feedthrough ports can be created in pin placement flow. By default, this option is *false* and new feedthroughs cannot be created. When feedthroughs are allowed, global routing creates feedthrough routing on blocks as needed. Each top-

level net for which a feedthrough port is created is split into a set of new top-level nets and child-level nets, if feedthrough nets are created for the child nets. Directions are assigned for the newly created feedthrough ports. Because new ports are created in the block cell, the netlist is modified as well.

-stacking_allowed any | none | with_pg_pins_only | with_signal_pins_only

Specifies how signal pins can stack with other pins during pin placement. This option takes one of the four allowed values:

- **any**
  Signal pins can stack with other signal pins on different layers. Signal pins can also stack with power or ground straps, power or ground pins on different layers as well. This is the default value.
- **none**
  Signal pins cannot stack with other signal pins on different layers. Signal pins cannot stack with power or ground traps, power or ground pins on different layers neither.
- **with_pg_pins_only**
  Signal pins cannot stack with other signal pins on different layers. But signal pins can stack with power or ground straps, power or ground pins on different layers.
- **with_signal_pins_only**
  Signal pins can stack with other signal pins on different layers. But signal pins cannot stack with power or ground straps, power or ground pins on different layers.

-cells *cell_collection*

If this option is specified, the constraints are only applied to pins on those blocks in the *cell_collection*. By default, the constraints are applied to pins on all blocks.

-width *pin_width*

Specifies the width of the pin. The width is perpendicular to the layer's preferred routing direction. The syntax can be a single real number to indicate the width is applied to all allowed layers (referred to as common pin width). Or alternatively, the width can be specified as a list of layer-real pairs as the following (referred to as per layer pin width):

-width {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its width should be 0.2 and if on M4 or M5, 0.3. On other layers, use the default width defined by the tech file.

If user first sets the pin width to be common pin width (or per layer pin width), then in a second **set_block_pin_constraints** sets the pin width to be per layer width (or common pin width), then the width specified in the second command will override the first.

However, if user first sets the pin width to be per layer, then in a second command sets the pin width again to be per layer but with different layers or different values, then the combined per layer pin width will be the final constraints. For example, the following example:

```
set_block_pin_constraints -cells mid1 -width 0.3
set_block_pin_constraints -cells mid1 -width {{M2 0.3} {M3 0.3}}
```

The first common pin width constraint will be overridden by the second per layer pin width. The pin width should be 0.3 on layer M2 or M3, but default width on all other layers.

And for the following example:

```
set_block_pin_constraints -cells mid1 -width {{M3 0.4} {M4 0.4}}
set_block_pin_constraints -cells mid1 -width {{M2 0.3} {M3 0.3}}
```

The pin width should be 0.3 on layer M2 or M3, 0.4 on layer M4, and default width on all other layers.

-length *pin_length*

Specifies the length of the pin. The length is in parallel to the layer's preferred routing direction. The syntax can be a single real number to indicate the length is applied to all allowed layers (referred to as common pin length). Or alternatively, the length can be specified as a list of layer-real pairs as the following (referred to as per layer pin length):

-length {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its length should be 0.2 and if on M4 or M5, 0.3. On unspecified layers, the pin length is derived from the pin width. Refer to the manpage of **place_pins** for details.

-self

Applies constraints only to the top-level design. By default, the constraints are applied to block cells inside current top design.

-hard_constraints off | spacing | location | layer | length

Specifies hard constraint types. The supported hard constraint types are spacing, location, layer, or length. If none of the constraints should be hard, user can use the keyword off.

When one particular type of constraint is specified as hard, **place_pins** honors it without any design rule checks, even if honoring it means one or more design rule violations.

If spacing is specified as hard, then the minimum spacing between applicable pins is at least the value specified by the associated spacing constraints.

If location is specified as hard, then the applicable pin is placed at the exact side and offset specified by the associated pin constraints. If the location constraint is specified as coordinates by **set_individual_pin_constraints** instead, the coordinates are snapped to the edge unless option **-off_edge** is presented, then during **place_pins** the pin is placed at the snapped edge and offset (option **-off_edge** is not presented) or the specified coordinates (option **-off_edge** is presented).

If layer is specified as hard, then the applicable pin is placed at the layer specified by the associated layer constraints.

If length is hard, then the applicable pin's length is exactly the value specified by the associated length constraints.

If two constraints conflict and only one of those two constraints is specified as a hard constraint, the other constraint is ignored. For example, you can specify a layer constraint and a side constraint on a pin. When the layer's preferred direction is horizontal and the side is horizontal edge, if the layer constraint set to hard constraint, **place_pins** places pins on the horizontal layer and vertical edge as there is no legal horizontal wiretrack on horizontal edge.

You can specify more than one hard constraint type.

By default, this option is off.

DESCRIPTION

This command sets pin placement constraints on blocks. The constraints are honored during pin placement and are saved in the design database.

The **set_block_pin_constraints** command is additive. The constraint values set by previous **set_block_pin_constraints** commands are retained unless they are explicitly overridden by subsequent calls

The **set_editability** command can enable or disable the **set_block_pin_constraints** command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the **set_editability** command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

Following example sets the allowed block pin layers to METAL2 and METAL3, and allows feedthroughs on all the blocks in the design.

```
prompt> set_block_pin_constraints -allowed_layers [get_layers METAL2 METAL3] \
  -allow_feedthroughs true
```

set_block_to_top_map

Specifies the relationship between the top-level mode, corner, and clock objects to objects inside of instances of lower level designs.

SYNTAX

int **set_block_to_top_map**
-block *cell* | -path *cell_name* |
-auto_clock connected | local | all
[-mode {*block_mode top_mode*}]
[-corner {*block_corner top_corner*}]
[-clock {*top_mode block_clock top_clock*}]
[-inverted_clock {*top_mode block_clock top_clock*}]
[-unused_clock {*top_mode block_clock*}]
[-ignore_waveform]
[-report_only]

Data Types

cell string
cell_name string
block_mode string
top_mode string
block_corner string
top_corner string
block_clock string
top_clock string

ARGUMENTS

-block *cell*

Specifies a cell in the current design in which to map objects. The cell must be an instance of a separate design in the hierarchy. That is, the cell must not be a leaf cell or simply a logic hierarchy. You must specify one of the **-block**, **-path** or **-auto_clock** options.

-path *cell_name*

Specifies the name of a cell in which to map objects. The cell must be an instance of a separate design in the hierarchy. That is, the cell must not be a leaf cell or simply a logic hierarchy. It is not necessary that the cell currently be in memory, however, the cell name, block modes, block corners, and block clocks will not be checked for errors. If the cell name or block object is not eventually read into memory, the setting associated with **-path** will not be used. You must specify either **-path**, **-block** or **-auto_clock**. You should use **-block** instead of **-path** for cells in memory so that error checking is performed.

-auto_clock connected | local | all

Automatically derives any clock associations between top-level clocks and block-level clocks. Clocks are mapped for all blocks and modes. You can use this option to avoid specifying multiple **-clock** options. In order for **-auto_clock** to work properly, you must first use the **-mode** option to define any mode mappings where the block and top mode names do not match. The command traces the clocks and determines where top-level clocks cross into the blocks to build the list of associations. The **-auto_clock** function will not change clock associations that were set with the **-clock**, **-unused_clock**, or with previous **set_block_to_top map -auto_clock** commands.

You can select one of three rules for auto-clock mapping:

- **connected** - If you select the "connected" rule, block-level clocks will be associated with top-level clocks under the following conditions: If a block clock has its source at a block port (a boundary clock), it can be associated to a top-level clock that propagates to that port. If a block clock has its source on an internal pin sources (a local clock), the top-level clock source must be declared at the same pin.
- **local** - If you select the "local" rule, connected clocks will be mapped. In addition, if a block clock has its source on an internal pin sources (a local clock) and has no associated top-level clock, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock.
- **all** - If you select the "all" rule, clocks will be mapped as in the "local" rule. In addition, if a block clock has its source at a block port (a boundary clock) and no top-level clock propagates to that port, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock. The top-level boundary clock will allow timing analysis to be done, but it is not necessarily correct for signoff. You should consider removing or replacing this clock before signoff.

Note that if two block-level clocks are declared at the same boundary port, the "all" rule cannot resolve both of them. This is because it will not automatically declare two conflicting clocks in the top-level block. You must manually declare two top-level clocks, with the appropriate waveforms. After the top clocks exist, **-auto_clock** mapping can associate them with the block clocks.

-mode

Specifies the mapping between mode constraints in a block and mode constraints at the top level. For example, you can associate constraints from block mode "A" with top mode "B". You can specify multiple **-mode** options in the same **set_block_to_top_map** command, and specify all mode mappings in one command. If you don't specify a mapping for a block mode, the command assumes that the block mode and the top mode have the same name.

-corner

Specifies a mapping between corner constraints in a block and corner constraints at the top level. For example, you can associate constraints from block corner "A" with top corner "B". You can specify multiple **-corner** options in one **set_block_to_top_map** command to specify all corner mappings for a block at one time. If you don't specify a mapping for a block corner, it will be assumed that the block corner and the top corner have the same name.

-clock

Specifies a mapping between clock objects in a block and clock objects at the top level. For example, you can associate constraints from block clock "CLK" with top clock "SYS_CLK". You can specify multiple **-clock** options with one **set_block_to_top_map** command to specify all clock mappings for a block at one time. When specifying a clock mapping, you must also state the mode associated with the top-level clock. This helps disambiguate between top-level clocks that have the same name in different modes. You can use the **-auto_clock** option to have the tool to generate clock mappings automatically.

-inverted_clock

Inverts the waveform of the clock in the block from the waveform at the top level. Use this option when there is an inverter between the top-level clock source and the block boundary.

-unused_clock

Specifies that a clock defined at the block level should be ignored and should not to be used to constrain the top-level design. You can specify multiple **-unused_clock** options with one **set_block_to_top_map** command to specify all unused clocks for a block at once. When specifying an unused clock mapping you must also specify the top-level mode in which the clock will be

unused.

-ignore_waveform

By default, you cannot associate a block-level clock with a top-level clock unless the clock waveforms match exactly. The **-ignore_waveform** option causes the **-clock** and **-auto_clock** options to allow associations, even though the clock waveforms don't match.

-report_only

If you use the option along with **-auto_clock**, then the tool prints out all the automatic clock mappings that it is able to derive. However, only the association is printed; the association is not changed in the database. This allows you to preview the mapping results before committing to them.

DESCRIPTION

Specifies the relationship between top-level mode, corner, and clock objects to objects inside of instances of lower level designs. These associations are used by commands such as **write_io_constraints**.

For example, you can specify that top-level mode "mission" is associated with block-level mode "func". When you want to create budgets for the various blocks at the top level, the top level will be timed in "mission" mode. But when constraints are written for the block, they will be written for "func" mode. It is possible that many top-level modes might be associated with the same block level mode. Or, some block modes might not be used for top-level timing.

Mappings for corners and clocks can also be provided. You can also specify that some block-level clocks are not to be considered for top-level timing.

It can be tedious to provide a block-to-top mapping for all objects. By default, mode and corners are automatically associated if they have the same name. For clocks, you can use the **-auto_clock** option to let the tool derive clock mappings for you. Manual specification of clock mappings might be needed in case of ambiguity or error.

Block-to-top mappings can be written out using the **write_script** command, so they can be easily reapplied to new netlists. You can view the current mappings by using the **report_block_to_top_map** command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example sets mode, corner, and clock mappings for block core/CPU. Block mode "func" is used along with top-mode bscan. The other modes and corners are mapped based on matching names. The clock CLK inside of the block has different top-level associations for each top-level mode. For top-level mode "func", the clock "CLK2" inside of the block is not used:

```
prompt> set_block_to_top_map -block core/CPU -mode {test bscan} \
    -clock {func CLK SYS_CLK} -clock {test CLK TCLK} \
    -clock {bscan CLK TCLK} -unused_clock {func CLK2}
```

The following automatically associates block and top clocks which are connected in your design:

```
prompt> set_block_to_top_map -auto_clock connected
```

The following automatically associates block and top clocks which are connected in your design, and creates new top-level clocks where connections cannot be found.

```
prompt> set_block_to_top_map -auto_clock all
```

write_script(2)

set_boundary_budget_constraints

Creates or modifies constraints for block boundaries of budgeted blocks.

SYNTAX

int **set_boundary_budget_constraints**
-name *boundary_name*
[-driving_cell *lib_cell_name*]
[-library *lib_name*]
[-pin *pin_name*]
[-from_pin *from_pin_name*]
[-input_transition_rise *rtrans*]
[-input_transition_fall *ftrans*]
[-fanin_capacitance *capacitance*]
[-load_capacitance *capacitance*]
[-max_transition *transition*]
[-corner *corner_name* | -default]
[-auto]

Data Types

boundary_name string
lib_cell_name string
lib_name string
pin_name string
from_pin_name string
rtrans float
ftrans float
capacitance float
transition float
corner_name string

ARGUMENTS

-name *boundary_name*

Specifies the name of the boundary being defined. You can use this name along with the **-early_boundary** and **-late_boundary** options of the **set_pin_budget_constraints** command to associate constraints with a particular budgeted pin.

-driving_cell *lib_cell_name*

Specifies the name of a driving cell to drive a budgeted input pin. This option creates a **set_driving_cell** constraint in your final budget.

-library *lib_name*

Specifies the library of your driving cell. If you don't specify the library, your driving cell will be automatically selected from your reference libraries.

-pin ***pin_name***

Specifies the output pin on the driving cell to use. By default, the first output of the driving cell is used.

-from_pin ***from_pin_name***

Specifies which input pin of your driving cell is used when evaluating the drive and delay of the output pin. By default, the pin resulting in the worst drive is used.

-input_transition_rise ***rtrans***

Specifies the rising transition to be used at the input pin of your driving cell. By default, zero transition is used.

-input_transition_fall ***ftrans***

Specifies the falling transition to be used at the input pin of your driving cell. By default, zero transition is used.

-fanin_capacitance ***capacitance***

Specifies the **set_load** value to apply to input pins in your budget. This option must be accompanied either by **-corner** or **-default**.

-load_capacitance ***capacitance***

Specifies the **set_load** value to apply to output pins in your budget. This option must be accompanied either by **-corner** or **-default**.

-max_transition ***transition***

Specifies the **max_transition** value to apply to boundary pins in your budget. This option must be accompanied either by **-corner** or **-default**.

-corner ***corner_name*** | **-default**

Specifies that values given for the **-fanin_capacitance** and **-load_capacitance** options should be applied in the process corner with the given name.

-default

Specify that values given for the **-fanin_capacitance** and **-load_capacitance** options should be applied in process corners do not have specific values given with the **-corner** option. If no specific **-corner** value and no **-default** value is given, zero is used.

-auto

This option is set by the tool when a boundary constraint was automatically derived. If a new automatic constraint is calculated in the future, the current automatic constraint will be deleted. User boundary constraints are never deleted by the tool.

DESCRIPTION

Creates or modifies constraints for block boundaries of budgeted blocks. Use this command to create a "budget boundary" definition that specifies how to apply driving cell and loads to pins of budgeted blocks. You can call **set_boundary_budget_constraints** multiple times with the same boundary name to modify or augment your boundary definition. The boundary definition can be associated with specific budgeted pins by using the **-early_boundary** and **-late_boundary** options of the **set_pin_budget_constraints** command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following declares a driving cell that should is applied to the input pins of "block1". An additional 0.1 of capacitance is also applied to the input:

```
prompt> set_boundary_budget_constraints -name DCbuf8 -driving_cell bufX8
prompt> set_boundary_budget_constraints -name DCbuf8 -default -fanin_capacitance 0.1
prompt> set_pin_budget_constraints -late_boundary DCbuf8 -input block1/*
```

The following sets output loads for all budgeted pins. The value is different for different corners.

```
prompt> set_boundary_budget_constraints -name OUTload -default \
  -load_capacitance 0.1
prompt> set_boundary_budget_constraints -name OUTload -corner c1 \
  -load_capacitance 0.15
prompt> set_boundary_budget_constraints -name OUTload -corner c2 \
  -load_capacitance 0.05
prompt> set_pin_budget_constraints -late_boundary OUTload -output -all
```

write_budgets(2)

set_boundary_cell

Sets the boundary-cell configuration for the specified ports.

SYNTAX

status **set_boundary_cell**
[-class wrapper]

[-type type]
[-ports port_list]
[-shift_clk *bcell_shift_clk*]
[-instance *hier_cell_list*]
[-exclude *cell_list*]
[-reuse_threshold *threshold_value*]

Data Types

port_list list
type string
hier_cell_list list
cell_list list

ARGUMENTS

-class wrapper

Specifies the name of the class for which the configuration applies. The only valid value is **wrapper**, which is the default.

-type type

Specifies the cell type to be used for the boundary cell in DFT insertion. There is no default value for this option. If this option is not specified, the tool uses the **WC_D1** type for the specified ports.
The following values are valid for *type*: **WC_D1** | **WC_S1** | **none**

-ports port_list

Specifies the list of ports for which the configuration applies. There is no default value for this option. You must specify the **-ports**option.

-shift_clk *bcell_shift_clk*

Specifies the shift clock to be used for the boundary cell.

This option is applicable only with the **-class core_wrapper** and either of the **-type WC_D1** or **-type WC_D1_S** options.

The value of this option must be a port or an internal pin. The specified port or pin is connected to the shift clock pin of the dedicated boundary cell.

The timing information of the specified clock is obtained from DRC.

There is no default value for this option.

-instance *hier_cell_list*

This option is applicable only when the **-class** option is set to **wrapper**.

This option specifies a list of hierarchical cells. If a port is connected to a register inside one of these hierarchical cells, the tool adds the specified type of boundary cell to the port.

The valid types of boundary cells supported with this option are **none** or **WC_D1**.

If the type of the boundary cell is chosen as **none**, no wrapper cell is added to the port.

If the type of the boundary cell is chosen as **WC_D1**, a dedicated wrapper cell is added to the port.

This option is mutually exclusive with the **-port** option.

There is no default value for this option.

-exclude *cell_list*

Applies only when the class option is set to **wrapper**.

This option specifies the list of I/O register cells to be excluded for the specified port.

To specify a list of cells to be excluded from all the ports, do not specify the port names with the command.

There is no default value for this option.

-reuse_threshold *threshold_value*

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells for the specified ports.

This option is applicable only when the **-class** option is set to **wrapper**.

When the number of I/O registers detected for the specified ports exceeds the specified threshold value, a dedicated wrapper cell is added to the ports.

The default value of this option is -1; that is, the reuse threshold value specified with wrapper configuration is applicable to the specified ports.

If the value of the option is set to 0, all I/O registers associated with the specified ports are reused as shared wrapper cells.

DESCRIPTION

This command sets the boundary-cell configuration for the specified ports.

EXAMPLES

```
prompt> set_boundary_cell -ports { i_din[0] o_dout[0] } -type WC_D1
```

Data Types

boundary_cell_prefix string
boundary_cell_separator string
lib_cell_name string

orientation	orientation in DEF syntax
distance	float
width	float

ARGUMENTS

-left_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the beginning of each cell row.

-right_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the end of each cell row.

-bottom_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the bottom object boundaries. In a double-back design, adjacent rows are flipped; the bottom boundary cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the top of object boundaries. In a double-back design, adjacent rows are flipped; the top boundary cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-left outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-bottom_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-right outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-left outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-top_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-right outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-bottom_right_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-top_left_inside_corner_cells ***lib_cell_name***

Specifies the library cell to be placed at the top-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-top_right_inside_corner_cells ***lib_cell_name***

Specifies the library cell to be placed at the top-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-mirror_left_outside_corner_cell

Places left outside corner cells in a mirrored orientation.

-mirror_right_outside_corner_cell

Places right outside corner cells in a mirrored orientation.

-mirror_left_inside_corner_cell

Places left inside corner cells in a mirrored orientation.

-mirror_right_inside_corner_cell

Places right inside corner cells in a mirrored orientation.

-mirror_left_boundary_cell

Places left boundary cells in a mirrored orientation.

-mirror_right_boundary_cell

Places right boundary cells in a mirrored orientation.

-mirror_left_inside_horizontal_abutment_cell

Places left inside horizontal abutment cells in a mirrored orientation.

-mirror_right_inside_horizontal_abutment_cell

Places right inside horizontal abutment cells in a mirrored orientation.

-tap_distance ***distance***

Specifies the distance in microns between tap cells.

-top_tap_cell ***lib_cell_name***

Specifies the tap cell to be placed at the top boundary. The tool inserts this tap cell at the specified interval on top boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the top tap cell is used on unflipped top boundary rows and on flipped bottom boundary rows. This option must be used with the **-tap_distance** option.

-bottom_tap_cell ***lib_cell_name***

Specifies the tap cell to be placed at the bottom boundary. The tool inserts this tap cell at the specified interval on bottom boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the bottom tap cell is used on unflipped bottom boundary rows and on flipped top boundary rows. This option must be used with the **-tap_distance** option.

-prefix ***boundary_cell_prefix***

Specifies the prefix for the created boundary cells. By default, no prefix is added. When you use this option, the command uses

the following naming convention for created boundary cells:

boundarycell!*prefix*!*library_cell_name*!*number*

By default, no prefix is added and the command uses the following naming convention:

boundarycell!*library_cell_name*!*number*

-separator *boundary_cell_separator*

Specifies the separator character that is used when composing the instance name of the boundary cell. The boundary cell instance name consists of a prefix, the library reference cell name and an incrementing number. For example, the instance name "boundarycell!MY_CELL!25" has the boundary cell prefix, the MY_CELL library reference cell name, the incrementing number 25, and the boundary cell separator !. This naming convention allows you to do pattern matching selection of the boundary cells.

By default, the separator character is an exclamation mark (!) and the command uses the following naming convention for created boundary cells:

boundarycell![*prefix*!]*library_cell_name*!*number*

-insert_into_blocks

Performs boundary cell insertion in the subblocks. By default, the tool performs boundary cell insertion only in the top-level block.

-at_va_boundary

Places horizontal boundary cells on both sides of the voltage area boundaries. When you use this option, rows are treated as cut by voltage area boundaries. Therefore, boundary cells are placed on both sides of a voltage area boundary. By default, voltage area boundaries are ignored during boundary cell insertion.

-no_1x

Prevents the tool from placing boundary cells on a row when the row length equals two times the corner cell width plus one unit tile width. Note that if the row length equals two times the corner cell width, the tool inserts boundary cells on that row.

This option can be used only when the **-top_right_outside_corner_cell**, **-bottom_right_outside_corner_cell**, **-top_left_outside_corner_cell** and **-bottom_left_outside_corner_cell** options are all specified.

-min_row_width *width*

Skips rows with a row width that is smaller than the specified width value.

-min_horizontal_jog *distance*

Specify the minimum horizontal jog distance required for boundary cell placement. If the minimum length is not met, placement blockages will be added by **compile_boundary_cells -add_placement_blockage** to either eliminate the jog or lengthen the jog to meet the minimum length in boundary cell placement.

-min_vertical_jog *distance*

Specify the minimum vertical jog distance required for boundary cell placement. If the minimum length is not met, placement blockages will be added by **compile_boundary_cells -add_placement_blockage** to either eliminate the jog or lengthen the jog to meet the minimum length in boundary cell placement.

-min_horizontal_separation *width*

Specify the minimum horizontal separation required for boundary cell placement. A horizontal separation width is the vertical channel width. If the minimum separation is not met, placement blockages will be added by **compile_boundary_cells -add_placement_blockage** to eliminate the offending standard cell area.

-min_vertical_separation *width*

Specify the minimum vertical separation required for boundary cell placement. A vertical separation width is the horizontal channel width. If the minimum separation is not met, placement blockages will be added by **compile_boundary_cells -add_placement_blockage** to eliminate the offending standard cell area.

-add_metal_cut_allowed

Adds metal cut allowed underneath the standard cell placeable area. Metal cut allowed and forbidden preferred grid extension routing guides are created. Metal cut allowed routing guides cover the area taken up by all the placable site rows reduced by the vertical and horizontal shrink factor. The vertical shrink factor is expressed as a percentage of the smallest site row height and the default is 50%. It can be set using the chipfinishing.metal_cut_allowed_vertical_shrink_factor app option. The horizontal shrink factor is expressed as a percentage of the smallest site row width. It can be set using the chipfinishing.metal_cut_allowed_horizontal_shrink_factor app option. Finally, forbidden preferred grid extension routing guides are created to cover the remaining area up to the boundary.

-do_not_swap_top_and_bottom_inside_corner_cell

Prevents swapping of the top and bottom inside-corner cells for flipped rows.

By default, if a top inside-corner cell is on a flipped row, the tool uses a bottom inside-corner cell instead. If a bottom inside-corner cell is on a flipped row, the tool uses a top inside-corner cell instead.

DESCRIPTION

This command sets the boundary cell insertion and checking rules for the current design. You can run this command multiple times to set the boundary cell rules incrementally.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the boundary cell rules for the left and right edges.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \
  -right_boundary_cell myLib/CellRight
```

SEE ALSO

remove_boundary_cell_rules(2)
report_boundary_cell_rules(2)
compile_boundary_cells(2)
check_boundary_cells(2)
compile_targeted_boundary_cells(2)
check_targeted_boundary_cells(2)

set_boundary_optimization

Sets the boundary_optimization restriction on specified pins, cells or modules, thus allowing/restricting optimization across hierarchical boundaries.

SYNTAX

int **set_boundary_optimization**
object_list all | none | auto
[-constant_propagation true | false]
[-unloaded_propagation true | false]
[-equal_opposite_propagation true | false]
[-phase_inversion true | false]

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of pins, cells or modules where to enable/disable boundary optimization. Cell or reference names in object_list must be from the current design. If more than one object is specified, they must be enclosed in quotation marks ("") or braces ({}).

all | **auto** | **none**

Specifies the value of the boundary optimization restriction. All: refers to all Boundary optimization types are true constant_propagation - true unloaded_propagation - true equal_opposite_propagation - true phase_inversion - true

auto: refers to phase_inversion and equal_opposite_propagation false and rest true constant_propagation - true unloaded_propagation - true equal_opposite_propagation - false phase_inversion - false

none: refers to all Boundary optimization types are false constant_propagation - false unloaded_propagation - false equal_opposite_propagation - false phase_inversion - false

-constant_propagation true | **false**

Specifies the value of constant propagation restriction on the specified objects. If true (default), constant propagation is allowed.

-unloaded_propagation true | **false**

Specifies the value of unloaded propagation restriction on the specified objects. If true (default), unloaded propagation is allowed.

-equal_opposite_propagation true | **false**

Specifies the value of equal opposite propagation restriction on the specified objects. If true, equal opposite propagation is allowed. The default value is same as the value of the boundary optimization restriction.

-phase_inversion true | false

Specifies the value of phase inversion restriction on the specified objects. If true, phase inversion is allowed. The default value is same as the value of the boundary optimization restriction.

DESCRIPTION

This command sets the boundary_optimization restrictions on object_list. The restriction allows/restricts the pins, cells or modules to be optimized across hierarchical boundaries. The **compile_fusion** command generally performs four kinds of cross boundary optimizations - constant propagation, unloaded propagation, equal opposite propagation and phase inversion. The specific optimizations can be allowed or restricted on the specified objects by using the corresponding optimization options.

Note: Boundary optimization settings over objects follows below specified priority. pin > cell > module. It implies that change in the settings of cell will not affect the settings of pin (if already restricted with boundary optimization settings) because it has higher priority.

Calling boundary_optimization with the value "auto" does not disable constant propagation and unloaded propagation across hierarchical boundaries of the specified object. To disable those propagations also, -constant_propagation false -unloaded_propagation false needs to be used with the command.Calling set_boundary_optimization with the value "all" will enable all BO types while calling set_boundary_optimization with the value "none" will disable all BO types

Occasionally, cells use an input signal only in its complemented form. In this case, it is best to invert the signal and its ports. The set_boundary_optimization command considers these optimizations (phase inversion). When this occurs, port names are changed.

Note that the **compile.optimization.constant_and_unloaded_propagation_with_no_boundary_optimization** application option does not have any effect on this command.

It is to imply that all | none | auto values are mutually exclusive with individual options i.e. -constant_propagation , -unloaded_propataion, -equal_opposite_propagation, -phase_inversion. Demostration is given in example

This command puts a list of read only attributes on the specified objects. The attributes are boundary_optimization, constant_propagation, unloaded_propagation, equal_opposite_propagation and phase_inversion. Note that, boundary_optimization attribute is an umbrella attribute. If any of the other 4 attribute is false, boundary_optimization is set to false. If all other 4 attributes are true, boundary_optimization is set to true.

To remove this restriction, use the remove_boundary_optimization command.

To report existing restrictions, use the report_boundary_optimization command.

EXAMPLES

The following example shows how to ignore hierarchical boundaries during optimization for cells named U0 and U1 and how to preserve them for a cell named U2 and U3 where U2 still allows constant and unloaded propagation.

```
prompt> set_boundary_optimization [get_cells -regexp U0|U1] all

prompt> set_boundary_optimization [get_cells U2] auto

prompt> set_boundary_optimization [get_cells U3] none
```

The following example shows how to disable only phase inversion optimization on pin U4/out whereas all other optimizations are allowed.

```
prompt> set_boundary_optimization [get_pins U4/out] -phase_inversion false
```

The following example shows how to disable equal-opposite propagation and phase inversion optimization on module named mid1 whereas all other optimizations are allowed.

```
prompt> set_boundary_optimization [get_modules mid1] auto
```

The following example shows how it errors out when all | auto | none are set along with individual options. Both the option setting are mutual exclusive and should not be used together.

```
prompt> set_boundary_optimization [get_modules mid1] auto -constant_propagation false
```

The following example shows how set_boundary_optimization setting should be done for global as well as individual options

```
prompt> set_boundary_optimization [get_modules mid1] auto
prompt> set_boundary_optimization [get_modules mid1] -constant_propagation false
```

set_budget_margins

Define timing margins to be used in budgets

SYNTAX

int **set_budget_margins**
[-launch *delay*]
[-capture *delay*]
[-setup]
[-hold]
[-prects]
[-postcts]
[-target]
[-actual]
[-clock *budget_clock_spec*]
[-from_clock *budget_clock_spec*]
[-to_clock *budget_clock_spec*]
[-corner *corner_name* | -default]

Data Types

delay float
budget_clock_spec string
corner_name string

ARGUMENTS

-launch *delay*

Specify a margin to be added to the launching block part of a budgeted path. The margin will be added value of the **set_clock_uncertainty** statement in the output SDC of the **write_budgets** command. If **-capture** is also specified for the same path, the effective margin for the whole path will be the sum of the two margins.

-capture *delay*

Specify a margin to be added to the capturing block part of a budgeted path. The margin will be added value of the **set_clock_uncertainty** statement in the output SDC of the **write_budgets** command. If **-launch** is also specified for the same path, the effective margin for the whole path will be the sum of the two margins.

-setup

Only apply the margin to setup paths. By default, the margin is applied to both setup and hold paths.

-hold

Only apply the margin to hold paths. By default, the margin is applied to both setup and hold paths.

-prects

Only apply the margin to parts of the path that are in the "prects" budget mode. The budget mode of the path is determined by the **-adjust_latency** option of the **set_budget_options** command. Some blocks may be in the prects mode while others are in postcts modes. By default, the margin is applied in all modes.

-postcts

Only apply the margin to parts of the path that are in one of the postcts budget modes. The budget mode of the path is determined by the **-adjust_latency** option of the **set_budget_options** command. Both "target" and "actual" modes are considered to be postcts. Some blocks may be in the prects mode while others are in postcts modes. By default, the margin is applied in all modes.

-target

Only apply the margin to parts of the path that are in the "target" budget mode. The budget mode of the path is determined by the **-adjust_latency** option of the **set_budget_options** command. The "target" budget mode is one of the possible postcts modes. Some blocks may be in the prects mode while others are in postcts modes. By default, the margin is applied in all modes.

-actual

Only apply the margin to parts of the path that are in the "actual" budget mode. The budget mode of the path is determined by the **-adjust_latency** option of the **set_budget_options** command. The "actual" budget mode is one of the possible postcts modes. Some blocks may be in the prects mode while others are in postcts modes. By default, the margin is applied in all modes.

-clock *budget_clock_spec*

Apply the margin to budgeted paths that start from or end at the clocks or part of clocks given in the *budget_clock_spec*. See the "Budget clock specs" section below for details on how to select specific clocks.

-from_clock *budget_clock_spec*

Apply the margin to budgeted paths that start from the clocks or part of clocks given in the *budget_clock_spec*. See the "Budget clock specs" below section for details on how to select specific clocks. This option must be used along with **-to_clock**.

-to_clock *budget_clock_spec*

Apply the margin to budgeted paths that end at the clocks or part of clocks given in the *budget_clock_spec*. See the "Budget clock specs" below section for details on how to select specific clocks. This option must be used along with **-from_clock**.

-corner *corner_name*

Specifies that values given for the other options should be applied in the process corner with the specified name.

-default

Specifies that values given for the other options should be applied in process corners do not have specific values given with the **-corner** option.

DESCRIPTION

Margins specified by this command are added to the clock uncertainty of budgeted paths in the SDC output of the **write_budgets** command. Use **-launch** to specify the margins to be applied at the start of the path. Use **-capture** to specify the margins to be applied at the end of the path. If both are specified, the effective margin for the whole path will be the sum of the two margins.

Various options can be used to limit the circumstances where the margins are applied. Use **-setup** or **-hold** to specify that the margin

should be applied on setup or hold paths.

The **-prects**, **-postcts**, **-target**, or **-actual** options work in conjuction with the **-adjust_latency** option of the **set_budget_options** command. For example, if you use the **-prects** option in **set_budget_margins**, then the given margin will be applied to any block that has "-adjust_latency prects" set by the **set_budget_options** command. If you use the **-postcts** command, the given margin will be applied to any block that has "-adjust_latency target" or "-adjust_latency actual" set by the **set_budget_options** command.

In the case of conflicts between margin constraints, more specific constraints will override more general constraints.

Budget margins are also used by the **compute_budget_constraints** command during automatic budget optimization. Please see the man page for the app option **plan.budget.time_with_margins** for details on how to control this feature.

You can use the **report_budgets -html_dir** command to dump out statistics about your budgets. Margins from this command will be reflected in the "path summaries" in the html report.

This command returns 1 on success, 0 otherwise.

Budget clock specs

When specifying clocks for various budgeting options, you can provide extra information to limit the parameter to a specific subtree of the clock or edge of a clock. For example, you can set a parameter for the subtree of CLK1 which is inside of BLOCK1. And you can set a different parameter for the subtree of CLK1 which is inside of BLOCK2. In general, every time a clock tree passes into or out of a block, this will define a new part to the tree that you can control.

The syntax for specifying a budget_clock_spec is as follows. To specify all parts of a clock (in all blocks), use the clock name:

CLK1

To specify all clocks in all blocks, use "*":

*****

To specify the part of a clock in a selected block, append ":" and the name of the block instance:

CLK1:my_block

To specify all clocks in a selected block, use "*" followed by ":" and the name of the block instance:

***:my_block**

To specify the part of a clock that crosses into or out of a block at a particular block pin, use the clock name, followed by ":" and the name of the block pin. For example, use the following to specify the top-level portion of CLK1 that originates at the clock output of my_block:

CLK1:my_block/CLKOUT

To specify a particular edge of a clock, use a second ":" followed by the word "rise" or "fall". This can be used in combination with any of the specifications above that name a particular clock. For example:

CLK1::rise
CLK1:my_block:fall
CLK1:my_block/CLKOUT:rise

Sometimes it is convenient to specify constraints for a master clock and all of the generated clocks downstream from the master clock. This is refereed to this as a constraint "clock group". To specify a clock group, follow the name of the master clock by a plus (+) character. The specify clock must a be regular clock, not a generated clock. The downstream generated clocks will be implicitly included in the group. Here are the legal usages of clock groups:

CLK1+
CLK1+::rise
CLK1+::fall

If this command is called multiple times for the same clock, the more specific parameter is applied. For example, if you set a parameter for "CLK:my_block" and you set a parameter for "CLK", the parameter for "CLK:my_block" will be used inside my_block and the parameter for "CLK" will be used everywhere else. More general parameters will not overwrite more specific ones.

EXAMPLES

Apply a margin on paths launched from the rising edge clock CLK1 in block B1. Apply only for setup paths and only if the launch block has "-adjust_latency prects" set in the set_budget_options command.

```
prompt> set_budget_margin -prects -setup -launch 0.2 -clock CLK:B1:rise
```

Apply margins on all hold paths between block B2 and block B3. Only apply if the block has "-adjust_latency target" or "-adjust_latency actual" set in the set_budget_options command. A margin of 0.2 will be set in the launch block (B2) and a margin of 0.1 will be set in the capture block (B3).

```
prompt> set_budget_margin -postcts -hold -launch 0.2 -capture 0.1 \
        -from_clock *:B2 -to_clock *:B3
```

plan.budget.time_with_margins(3)

set_budget_options

Specifies general options to be used during creation of timing budgets.

SYNTAX

int **set_budget_options**
[-reset]
[-add_blocks]
[-remove_blocks]
[-adjust_latency prects | target | actual]
[-launch_hold_fix true | false]
[-capture_hold_fix true | false]
[-feed_hold_fix true | false]
[-launch_fixed_delay true | false]
[-capture_fixed_delay true | false]
[-feed_fixed_delay true | false]
[-min_segment_percent percent]

[-top_level]
[-all]
[*instances*]

Data Types

instances collection
percent float

ARGUMENTS

-reset

Removes all previously specified budget constraints from the current design. This includes constraints and options from **set_budget_options**, **set_pin_budget_constraints**, **set_latency_budget_constraints**, **set_boundary_budget_constraints**, and **compute_budget_constraints**.

-add_blocks

Specifies that budgeting commands should create a budget for the specified block instances. This option must be accompanied by a list of instance path names to add.

-remove_blocks

Specifies that blocks previous added by the *-add_blocks* option should no longer be considered for budgeting. This option must be accompanied by a list of instance path names to remove or the *-all* option.

-adjust_latency prects | target | actual

This option controls how clock alignment is handled at the boundary of budgeted blocks. At the time your block budgets are written (in the **write_budgets** command), it is possible that the clocks of your designs are not yet balanced. For example, you may have run clock tree synthesis in one of your blocks and not another. Or perhaps, you have run clock tree synthesis in each of your blocks, but have not yet balanced the blocks with each other.

By setting *-adjust_latency* for your blocks, you can create block budgets that offset the current clock imbalances between the blocks and the top level. Constraints will be created that assume all of your clocks will eventually be optimized to have budget values similar those set manually by the *-early_latency* and *-late_latency* options of the **set_latency_budget_constraints** command -- or set automatically by the **compute_budget_constraints** command.

It is important to choose the correct adjust_option for *-adjust_latency*. The correct choice will depend on the state of your design in the design flow. The choices are outlined below. If -adjust_latency has never been specified for a block, the "prects" style of adjustment will be used, which is most appropriate for early in the design flow. It is OK to use a "prects" budget throughout the entire design flow, but this early budget will not be adapted to changes in your clocks that occur during CTS.

You should specify the blocks to apply this option to by specifying an instance list or using the *-all* option.

Refer to the **write_budgets** man page for more examples of the recommended use of the *-adjust_latency* option.

prects

When your block's I/O constraints are generated, the latency of the virtual clocks that define the block's I/O timing will be adjusted to match the current clock latencies in your block. The internal clock latency of the block will not be adjusted. For example, if the block currently has small clock latency and the budget latency target is large, the virtual clocks at the block's boundary will be adjusted to have short latencies that are similar to those inside of the block. You can use the *-latency* option of the **report_budget** to see the adjustment being applied. You should use "prects" latency adjustment when your block is using ideal (not propagated) clocks.

target

The internal latency of your block will be adjusted to match the target top-level budget constraint, as set by **set_latency_budget_constraints** or **compute_budget_constraints**. This adjustment will be accomplished by resetting the source latency on the clocks entering your block. For example, if the block currently has small clock latency and the budget latency target is large, the source latency on the clocks entering your block will be increased. You can use the *-latency* option of the **report_budget** to see the adjustment being applied. You should use "target" latency adjustment when your block has propagated clocks.

actual

The internal latency of your block will be adjusted to match the actual propagated top-level latency. This adjustment will be accomplished by propagating latency on your top-level clock until it reaches the block boundary. The resulting latency will be directly applied as the source latency for your block clock. Since the budgeted top-level latencies are ignored during this adjustment, you should only use "actual" adjustment after your top-level clocks have been balanced to the desired values.

Note that your datapath budgets will still use budget latency targets to determine the budgeted path length. You should use **compute_budget_constraints -latency_targets actual balance_latency false** to readjust your budget latency targets before you call **write_budgets**.

-launch_hold_fix true | false

This option affects the operation of the **write_budgets** command when outputting hold constraints. When set to false, the **write_budgets** command will create constraints that avoid the insertion of hold buffers on the output of selected blocks. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is true.

-capture_hold_fix true | false

This option affects the operation of the **write_budgets** command when outputting hold constraints. When set to false, the

write_budgets command will create constraints that avoid the insertion of hold buffers on the input of selected blocks. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is true.

-feed_hold_fix true | false

This option affects the operation of the **write_budgets** command when outputting hold constraints. When set to false, the **write_budgets** command will create constraints that avoid the insertion of hold buffers on the part of paths that feed through selected blocks. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is false.

-launch_fixed_delay true | false

This option affects the operation of the **compute_budget_constraints** command. By default, the budgeting algorithm assigns slack to all blocks along a top level path. If the top-level path has negative slack, then each block is assigned part of that negative slack to fix. By setting this option to true, you are telling the budgeter that the output of the selected block is "fixed". The budgeter will treat this part of the path as it would treat a hard macro. The budgeter will not assign negative slack to this part of the path, because it will assume that the block will not be optimized. Likewise, the budgeter will assign only a very small fraction of any positive slack to this part of the path. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is false.

-capture_fixed_delay true | false

This option affects the operation of the **compute_budget_constraints** command. By default, the budgeting algorithm assigns slack to all blocks along a top level path. If the top-level path has negative slack, then each block is assigned part of that negative slack to fix. By setting this option to true, you are telling the budgeter that the input of the selected block is "fixed". The budgeter will treat this part of the path as it would treat a hard macro. The budgeter will not assign negative slack to this part of the path, because it will assume that the block will not be optimized. Likewise, the budgeter will assign only a very small fraction of any positive slack to this part of the path. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is false.

-feed_fixed_delay true | false

This option affects the operation of the **compute_budget_constraints** command. By default, the budgeting algorithm assigns slack to all blocks along a top level path. If the top-level path has negative slack, then each block is assigned part of that negative slack to fix. By setting this option to true, you are telling the budgeter that parts of the path that feed through the selected block are "fixed". The budgeter will treat this part of the path as it would treat a hard macro. The budgeter will not assign negative slack to this part of the path, because it will assume that the block will not be optimized. Likewise, the budgeter will assign only a very small fraction of any positive slack to this part of the path. You should specify the blocks to apply this option to by specifying an instance list, *-top_level*, or the *-all* option. The default value is false.

-min_segment_percent percent

This option affects the operation of the **compute_budget_constraints** command. When it is used, the budgeting computation tries to assign at least the indicated percentage of the clock cycle to all the budget segments in a path if possible. The percent number given should be less or equal to 0.5. If the percent number 0 is given, it has the effect of removing any previously set *min_segment_percent* constraints. This is a low priority constraint that will be taken into account only if higher priority constraints can also be satisfied. Higher priority constraints include zero-slack budgeting, fixed delay budgets and user-specified budgets. This option cannot be used together with the options **-top_level** or with a list of instances.

-top_level

Specify that the given option should be applied to the top level of your design, not the blocks.

-all

Use with other options of this command to operate on all blocks and the top_level of your design. The blocks that are used are the same ones that were previously added with the *-add_blocks* option.

instances

Specify a list of instance names for blocks of your design. Use with other options of this command to operate only on specific blocks of your design. The instances specified must be added previously by using the *-add_blocks* option.

DESCRIPTION

Specifies general options to be used during creation of timing budgets. To get a summary of the options you have set, use "**report_budget -blocks**". To set specific budget parameters, use the **set_pin_budget_constraints**, **set_segment_budget_constraints**, **set_latency_budget_constraints**, and **set_boundary_budget_constraints** commands.

Use the **write_budgets** command to generate SDC that can be applied to lower level blocks. The **compute_budget_constraints** can be used to set key budget parameters automatically. The **report_budget** command will generate useful information about the current budget calculation, allocation, and whether that budget is currently being met. Use "**write_script -include budget**" to save a Tcl script that includes your current settings from this command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example declares three blocks in the current design which will be budgeted:

```
prompt> set_budget_options -add_blocks { core/CPU core/MMU exif }
```

The following example removes one block from the list of blocks to be budgeted:

```
prompt> set_budget_options -remove_blocks exif
```

The following example marks core/CPU to have fixed timing. The **compute_budget_constraints** command will treat this block as if it were a hard macro.

```
prompt> set_budget_options -launch_fixed_delay true \
  -capture_fixed_delay true -feed_fixed_delay true core/CPU
```

The following example marks core/CPU as having complete clock trees. When the budget is written by the **write_budgets** command, clock latencies at the block boundary will be adjusted accordingly. Also, the skew margin for the block will no longer be reserved.

```
prompt> set_budget_options -adjust_latency target core/CPU
```

Refer to the **write_budgets** man page for more examples of using the *-adjust_latency* option.

set_budget_shell_latencies

Creates special latencies for clocks that are generated in a budget shell or pass through a budget shell.

SYNTAX

int **set_budget_shell_latencies**
-block *block_module_name*
[-clock *clock_name*]
[-block_mode *block_mode_name*]
[-block_output *block_port_name*]
[-corner *corner_name*]
[-rise]
[-fall]
[-early]
[-late]
delay_value

Data Types

block_module_name string
clock_name string
block_mode_name string
block_port_name string
corner_name string
delay_value float

ARGUMENTS

-block *block_module_name*

Specifies the name of the budget shell block. This is the name of the module, not the instance of the module.

-clock *clock_name*

Applies the latency only for the specified top-level clock. By default, the latency is applied to all clocks.

-block_mode *block_mode_name*

Applies the latency only for clocks that are associated with the given operating mode of the block. By default, the latency is applied to clocks for all modes.

-block_output *block_port_name*

Applies the latency only for clocks leaving the block at the given output port. By default, the latency is applied to clocks leaving the block at any port.

-corner *corner_name*

Applies the latency only for the given process corner. By default, all corners are used.

-rise

Applies the latency only for the rising edge of the clock at the block output. By default, both rise and fall are used.

-fall

Applies the latency only for the falling edge of the clock at the block output. By default, both rise and fall are used.

-early

Applies the delay only for the best case latency. By default, both early and late are used.

-late

Applies the delay only for the worst case latency. By default, both early and late are used.

delay_value

Specifies the value set for the latency.

DESCRIPTION

This command creates budget shell latencies. Budget shells are created by the **-shell_subblocks** option of the **write_budgets** command. If the subblock in question has internal clocks of one of the following types, it is necessary to specify the latency of that clock.

- "Feedthrough clock": If a budget shell block has a top-level clock feeding through it, the **set_budget_shell_latencies** command specifies the part of the clock latency that is inside of the block.
- "Clock source in the block": If a budget shell block has a clock whose source is in the block, the **set_budget_shell_latencies** command specifies the part of the clock latency that is inside of the block.
- "Generated clock in the block": If a budget shell block has a generated clock source in the block and the master clock is outside of the block, the **set_budget_shell_latencies** command specifies the latency between the point where the master clock enters the block and the generated clock leaves the block.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example sets the shell latency for any clocks that leave the block at port "clock_out".

```
prompt> set_budget_shell_latencies -block BLOCK -block_output clock_out
2.0
```

set_bundle_pin_constraints

Sets pin constraints on net bundles defined with the **create_bundle** and **create_bundles_from_patterns** commands.

SYNTAX

status **set_bundle_pin_constraints**
[-bundles *bundles*]
[-cells *cells*]
[-self]
[-keep_pins_together true | false]
[-range {*start end*}]
[-bundle_order ordered | increasing | decreasing | equal-distance]
[-allow_feedthroughs true | false]
[-allowed_layers *layers*]
[-pin_spacing *spacing*]
[-pin_spacing_distance *distance*]
[-sides *side_numbers*]
[-width *width*]
[-length *length*]

Data Types

bundles collection of net bundles
cells collection cells
start integer
end integer
layers collection of layers
spacing float
distance float
side_numbers collection of integers
width real or list of layer-real pairs
length real or list of layer-real pairs

ARGUMENTS

-bundles *bundles*

Limits the constraints to the specified net bundles. The bundles must be in the top-level of the current design. If not specified, the command applies the constraints to all net bundles.

-cells *cell_collection*

Limits the constraints to the specified cells. For example, you can combine the **-cells** and **-allowed_layers** options to restrict the pins to only specified layers for the specified cell. You can combine the **-cells** and **-self** options. The cells must be in the top-level

of the current design. If both the **-cells** and **-self** options are unspecified, the constraints apply to all block cells.

-self

Applies the constraints to the top-level block. You can combine the **-cells** and **-self** options. If both the **-cells** and **-self** options are unspecified, the constraints apply to all block cells.

-keep_pins_together true | false

Specify whether bundle pins are kept together. When this option is true, all bundle pins on the same block are placed on the same layer (hard constraint) and no other pins should be placed between the bundle pins (soft constraint). In certain cases, the command might violate the soft constraint and insert other pins between the bundle pins. The default value is false.

-bundle_order ordered | increasing | decreasing | equal-distance

Specifies the relative placement order of the pins connected to the bundle nets. Note that the order refers to the net order in the bundle, not the pins on the block. The bundle order is measured as seen at the current top design. Pin placement considers this option only when option **-keep_pins_together** is set to true. If two or more bundles connecting the same collection of MIB pins but with conflict orders, only one of them can be honored.

- ordered: Pins are ordered according to the net order in the bundle. For vertical block sides, bundle pins can be placed either from bottom to top or from top to bottom. For horizontal sides, bundle pins can be placed either from left to right or from right to left. The orders on each edges are chosen such that for the bundle nets connect the bundle pins from one edge to another edge, there is no net crossing, i.e. river turn style.

  In the following example, bundle pin constraint is specified as *ordered* so that the nets connecting two bundle pins are of the river turn style, i.e. no crossing.

  ```
  prompt> set_bundle_pin_constraints -allowed_layers {M3}\
    -bundles bundle1 -bundle_order ordered -keep_pins_together true
  ```

- increasing: Pins are ordered according to the increasing net order in the bundle. For vertical block sides, bundle pins are placed from bottom to top. For horizontal block sides, bundle pins are placed from left to right.

  In the following example, bundle pin constraint is specified on a rectangular block so that bundle pins are placed on side 2 (horizontal edge) of block. Pins are placed from left to right (Least significant bit is the leftmost; Most significant bit is the right most on side2).

  ```
  prompt> set_bundle_pin_constraints -bundles bundle1 -sides 2 \
    -bundle_order increasing -keep_pins_together true
  ```

- decreasing: Pins are ordered according to the decreasing net order in the bundle. For vertical block sides, bundle pins are placed from top to bottom. For horizontal block sides, bundle pins are placed from right to left.

  In the following example, bundle pin constraint is specified on a rectangular block so that bundle pins are placed on side 2 (horizontal edge) of block. Pins are placed from right to left (Most significant bit is the leftmost; Least significant bit is the rightmost).

  ```
  prompt> set_bundle_pin_constraints -bundles bundle1 -sides 2 \
    -bundle_order decreasing -keep_pins_together true
  ```

- equal-distance: Pins are ordered as with **-bundle_order ordered**, but the pin ordering for two edges is chosen to create the same Manhattan distance between each corresponding pair of pins.

  In the following example, bundle pin constraint is specified as *equal-distance* so that the Manhattan distacnes of each bits of the bundle are the same for bundle *bundle1*.

  ```
  prompt> set_bundle_pin_constraints -allowed_layers {M3}\
    -bundles bundle1 -bundle_order equal-distance -keep_pins_together true
  ```

  Note that when setting bundle pin constraints on pins of multiple instantiated blocks (MIB), as the orientation of MIBs can be

different, the tool chooses one of the MIBs randomly to honor the constraints. Therefore the bundle constraints could be not honored for the other MIBs.

When option **-keep_pins_together** is set to true but option **-bundle_order** is not specified, the tool will choose from either **increasing** or **decreasing** based on alignment, abutment and wire length cost. The bundle order might also be decided by already placed or fixed bundle pins on this bundle due to alignment or abutment.

-allow_feedthroughs true | **false**

Specifies whether feedthrough ports can be created in pin placement flow. When feedthroughs are allowed, the global router creates feedthrough routing on a block cell as needed for the selected nets. Each top-level net for which a feedthrough port is created is split into a set of new top-level nets and child-level nets, if feedthrough nets are created for the child nets. Directions are assigned for the newly created feedthrough ports. Because new ports are created in the block cell, the netlist is modified as well.

By default, the feedthrough is not allowed for bundle nets.

-allowed_layers ***metal_layers***

Specifies the set of metal layers allowed for pin placement. The argument is a list of metal layer names as returned by the **get_layers** command.

By default, the metal layers from M2 to the maximum metal layer (specified earlier during floorplan flow) are allowed for pin placement. If the maximum metal layer has not been specified, the maximum available metal layer specified in the technology file is used as the default. If the maximum layer specified is beyond the maximum metal layer for the current design, then the maximum layer in the technology file is used.

-pin_spacing ***spacing_number***

Specifies the minimum number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks. The default pin-to-pin spacing is one wire track. The spacing number must be 0 or a positive integer.

-pin_spacing_distance ***spacing_distance***

Specifies the minimum distance between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks.

-sides ***side_numbers***

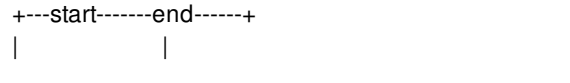
Specifies one or more block sides on which the pin must be placed.

The side numbers are a list of positive integers that start from 1. The left edge of a rectangular shape, or the lower left-most vertical edge of a rectilinear shape, is side number 1. The side numbers increment as you proceed clockwise around the shape. You cannot specify a value of 0 for this option.

-range {*start end*}

Specifies the range of positions on a side within which the bundle pins must be placed. The positive *start* and *end* values refer to the distances as measured to the starting point of the edge in microns (or the default unit). The negative *start* and *end* values refer to the distances as measured to the ending point of the edge in microns (or the default unit). Postive *start* is the position that is closest to the edge's starting point, and postive *end* is the position that is farthest to the edge's starting point. Vice versa for negative *start* and *end* positions. The starting point of an edge is the vertex of the edge where the edge begins as you proceed clockwise around the block's boundary from the lowest vertex of the leftmost edge. If there are more than one leftmost edges, then from the lowest one.

The following simple drawing shows an example of how postive *start* and *end* are measured on a rectangular block on each of the sides.



```
 |                start
end                  |
 |                 |
 |                end
start                |
 |                 |
 +------end-----start-----+
```

The following simple drawing shows an example of how negative *start* and *end* are measured on a rectangular block on each of the sides.

```
 +---end-------start------+
 |                 |
 |                end
start                |
 |                 |
 |                start
end                  |
 |                 |
 +------start-----end-----+
```

-width *pin_width*

Specifies the width of the pin. The width is perpendicular to the layer's preferred routing direction. The syntax can be a single real number to indicate the width is applied to all allowed layers (referred to as common pin width). Or alternatively, the width can be specified as a list of layer-real pairs as the following (referred to as per layer pin width):

-width {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its width should be 0.2 and if on M4 or M5, 0.3. On other layers, use the default width defined by the tech file.

If you first set the pin width to be common pin width, then set the pin width to be per layer width with a second **set_bundle_pin_constraints** command, then the width specified in the second command will override the first. Likewise, if you first set the pin width to be per-layer width, then set the pin width to be a common pin width with a second **set_bundle_pin_constraints** command, then the width specified in the second command will override the first.

However, if you first set the pin width to be per layer, then in a second command sets the pin width again to be per layer but with different layers or different values, then the combined per layer pin width will be the final constraints. For example, consider the following example:

```
set_bundle_pin_constraints -bundles {bundle1} -width 0.3
set_bundle_pin_constraints -bundles {bundle1} -width {{M2 0.3} {M3 0.3}}
```

The first common pin width constraint will be overridden by the second per layer pin width. The pin width should be 0.3 on layer M2 or M3, but default width on all other layers.

And for the following example:

```
set_bundle_pin_constraints -bundles {bundle1} -width {{M3 0.4} {M4 0.4}}
set_bundle_pin_constraints -bundles {bundle1} -width {{M2 0.3} {M3 0.3}}
```

The pin width should be 0.3 on layer M2 or M3, 0.4 on layer M4, and default width on all other layers.

-length *pin_length*

Specifies the length of the pin. The length is in parallel to the layer's preferred routing direction. The syntax can be a single real number to indicate the length is applied to all allowed layers (referred to as common pin length). Or alternatively, the length can be specified as a list of layer-real pairs as the following (referred to as per layer pin length):

-length {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its length should be 0.2 and if on M4 or M5, 0.3. On unspecified layers, the pin length is derived from the pin width. Refer to the manpage of **place_pins** for details.

DESCRIPTION

This command constrains the placement of net bundles on a physical design block. The constraints are honored by the **place_pins** command. The constraints specify the block side, pin ordering, and other pin placement details.

The **set_bundle_pin_constraints** command is additive. The constraint values set in previous calls are retained, unless they are explicitly overridden by subsequent calls.

Constraints can apply to certain cell instances only. The cell specified with the *-cells* option must be a physical block and must not be a library cell or logical block. The constraint can apply to the top-level block of the current design by specifying the **-self** option.

The constraints can apply to either a specific bundle or to all bundles. Also, the constraints can apply to a specific block cell or to all block cells. There are four possible combinations of bundle and block constraints, ordered from general to specific.

The **set_editability** command can enable or disable the **set_bundle_pin_constraints** command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the **set_editability** command.

- Global constraints: Constraints apply to all bundles and all block instances.
- Specific bundle constraints: Constraints apply to a specific bundle and all block instances.
- Specific block constraints: Constraints apply to all bundles and a specific block instance. Note that this can apply to the top-level block when you specify the *-self* option.
- Bundle and block pair constraints: Constraints apply to a specific bundle and a specific block instance. Note that this can apply to the top-level block when you specify the *-self* option.

Note that bundle and block pair constraints override the other three types; block constraints override bundle and global constraints, and so on.

Unless otherwise mentioned, all types of constraints can be applied in each of these situations.

The command can only be used to set constraints on bundles and cells in the top-level design, not within the blocks. To set constraints within a block, use the **current_design** command to make the block the current design and apply the constraint.

The **set_editability** command can enable or disable the **set_bundle_pin_constraints** command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the **set_editability** command.

This command returns 1 on success, 0 otherwise.

Please note, starting from 2019.12 release, a new command **create_pin_constraint** is introduced that can also creates the bundle pin constraints (as well as individual pin constraints) and has similar command line options. The major difference is that **create_pin_constraint** returns a collection of constraints it created, which under certain scenarios might be desired.

EXAMPLES

The following example sets the allowed pin layers to METAL2 and METAL3 for bundle BUNDLE_0. This creates a specific bundle constraint.

```
prompt> set_bundle_pin_constraints \
  -allowed_layers [get_layers METAL2 METAL3] \
  -bundles [get_bundles BUNDLE_0]
```

The following example enforces ordering on all bundle pins of cell BLOCK1. This creates a specific block constraint.

```
prompt> set_bundle_pin_constraints -bundle_order ordered \
  -cells [get_cells BLOCK0] -keep_pins_together true
```

The following example enforces ordering and minimum pin spacing for bundle BUNDLE_0. This creates a specific bundle constraint.

```
prompt> set_bundle_pin_constraints -bundle_order ordered \
  -pin_spacing 2 -bundles [get_bundles BUNDLE_0] -keep_pins_together true
```

set_busplan_constraints

Sets constraints on pipeline register counts for buses during bus planning.

SYNTAX

int **set_busplan_constraints**
-from *buses*
[-to *buses*]
[-to_value *constraint_value*]
[-type *constraint_type*]
[-remove]

Data Types

buses	collection of buses
constraint_value	integer
constraint_type	string

ARGUMENTS

-from *buses*

Specifies the buses on which to set or remove constraints.

-to *buses*

Specifies the buses on which the constraint is to created to. This option is mutually exclusive with *-to_value* and *-remove*.

-to_value *constraint_value*

Specifies the value of the constraint for constraints that accept a specific value. This option is mutually exclusive with *-to* and *-remove*.

-type *constraint_type*

Specifies the type of constraint to apply. There are 5 valid constraints: *less*, *less_or_equal*, *greater*, *greater_or_equal*, and *equal*. These constraints can also be represented by the following symbols: <, <=, >, >=, and =. These constraints can be applied between 2 buses using *-from* and *-to* or can be applied on a single bus using *-from* and *-to_value*.

-remove

Removes any constraints on the *-from* bus. This option is mutually exclusive with *-to* and *-to_value*.

DESCRIPTION

This command defines constraints between buses by restricting the number of registers allowed on each bus. There are 5 valid constraints: *less*, *less_or_equal*, *greater*, *greater_or_equal*, and *equal*. These constraints can also be represented by the following symbols: <, <=, >, >=, =.

Constraints can be applied between 2 buses using *-from* and *-to* or can be applied on a single bus using *-from* and *-to_value*. Constraints can be removed using *-from* and *-remove*.

EXAMPLES

The following example creates a constraint that requires bus1 and bus2 have the same number of pipeline registers. Note that this example assumes bus1 and bus2 are created previously with the *create_busplans* command.

```
prompt> set_busplan_constraints -from bus1 -to bus2 -type =
1
```

The following example creates a constraint that requires bus1 have less than 5 pipeline registers.

```
prompt> set_busplan_constraints -from bus1 -to_value 5 -type <
1
```

set_case_analysis

Specifies that a port or pin is at a constant logic value 1 or 0, or is considered with a rising or falling transition.

SYNTAX

string **set_case_analysis** *value*
port_or_pin_list

string *0* | *1* | *rising* | *falling*
list *port_or_pin_list*

ARGUMENTS

value

Specifies a constant logic value or a transition to assign to the given pin or port. The valid constant values are **0**, **1**, **zero**, and **one**. The valid transition values are **rising**, **falling**, **rise**, and **fall**.

port_or_pin_list

Lists ports or pins to which the case analysis is assigned. In the case of pins, constant propagation is executed forward only. No backward constant propagation is performed.

DESCRIPTION

Case analysis is a way of specifying a given mode for the design without altering the netlist structure. You can specify for the current timing analysis session, that some signals are at a constant value (**1** or **0**), or that only one type of transition (**rising** or **falling**) is considered.

Pins of a design may be driven by logic values from the design, but if case analysis is used to set a value on such pins, the values set by case analysis will dominate. If the case values are subsequently removed, the value driving the pin from the design will be propagated.

When case analysis is specified as a constant value, this value is propagated through the network as long as the constant value is a controlling value for the traversed logic. For example, if you specify that one of the inputs of a NAND gate is a constant value **0**, it is propagated to the NAND output, which is now considered at a logic constant **1**. This propagated constant value is then propagated to all cells driven by this signal.

In the event that the case analysis value is a transition, the given pin or port is considered only for timing analysis with the specified transition. The other transition is disabled. The case analysis information is used by all analysis commands.

Case analysis is used in addition to the mode commands to fully specify the mode of a design. For example, a design that

instantiates models with a TESTMODE, is specified so that the TESTMODE is disabled during the timing analysis session by using the **set_mode** command. In addition, if a TESTMODE signal exists on the design, it is specified to a constant logic value, so that all test logic controlled by the TESTMODE signal is disabled.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example shows that the port *IN1* is at a constant logic value of **0**.

```
prompt> set_case_analysis 0 IN1
```

The following example shows that the pins *U1/U2/A* and *U1/U3/CI* are considered only for a *rising* transition. The *falling* transition on these pins is disabled.

```
prompt> set_case_analysis rising {U1/U2/A U1/U3/CI}
```

The following example specifies how to disable the TESTMODE of a design for which instances are models having a TESTMODE mode. The design also has a *TEST_PORT* port set to a constant logic value **0**.

```
prompt> remove_mode TESTMODE U1/U2
prompt> set_case_analysis 0 TEST_PORT
```

SEE ALSO

remove_case_analysis(2)
report_case_analysis(2)
disable_case_analysis(3)
set_mode(2)

set_cell_hierarchy_type

Change the hierarchy type of a hierarchical instance and optionally add a boundary, if specified.

SYNTAX

collection **set_cell_hierarchy_type**
-type *hierarchy_type*
[-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]
cell

Data Types

hierarchy_type string
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection
cell A single hierarchical cell

ARGUMENTS

-type *hierarchy_type*

New hierarchy_type for the cell. Valid values are normal or boundary. This option is required.

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary of the cell. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogenous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This is an optional option.

cell

Specifies the hierarchical cell whose hierarchy_type is to be changed. It can be specified as the cell name or a collection containing one cell object.

This option is required.

DESCRIPTION

This command takes the name of a hierarchical (not leaf) cell or a collection containing a single cell and changes the hierarchy_type to the specified type. If the optional boundary argument is given it is used to set the boundary, if the type is changing to boundary or to create the initial boundary for the new hierBoundary object, if the type is boundary.

The command will fail if the given path doesnt exist, or is a lib-cell (non-hierarchical cell).

EXAMPLES

The following example creates a hierBoundary out of the cell found at path a/b/c with a rectangular boundary from (0, 0) through (1000, 1000).

prompt> **set_cell_hierarchy_type -type boundary -boundary {{0 0} {1000 1000}} a/b/c**

The following command will turn the cell a/b/c, into a logical hierarchical cell

prompt> set_cell_hierarchy_type -type normal a/b/c

SEE ALSO

get_cells(2)
commit_block(2)
uncommit_block(2)

set_cell_location

Specifies the physical location for leaf cells.

SYNTAX

status **set_cell_location**
[-design *design*]
-coordinates *location*
[-z_offset *value*
[-ignore_fixed]
[-orientation *orient*]
[-fixed]
cell_list

Data Types

location	point
value	int
orient	string
cell_list	collection

ARGUMENTS

-coordinates *point*

Specifies the lower-left coordinates of the boundary of the specified cells. The numbers are in microns relative to the chip origin.

-z_offset *value*

Specifies the stack_order/z-offset of the physical cell in a 3DIC design

-ignore_fixed

Sets the location for cells even if they have fixed placement status.

-fixed

Sets the **physical_status** attribute on the specified cells to fixed to prevent the tool from moving these cells.

-orientation *orient*

Specifies the new orientation.

Valid values are

- **R0**: Nominal orientation (north)

- **R90**: 90-degree counterclockwise rotation (west)
- **R180**: 180-degree rotation (south)
- **R270**: 270-degree counterclockwise rotation (east)
- **MY**: reflection in the y-axis (flipped north)
- **MX**: 180-degree rotation followed by reflection in the y-axis (flipped south)
- **MYR90**: 90-degree counterclockwise rotation followed by reflection in the y-axis (flipped east)
- **MXR90**: 270-degree counterclockwise rotation followed by reflection in the y-axis (flipped west)

cell_list

Specifies the affected leaf cells. Typically, this command uses a single leaf cell as the argument.

DESCRIPTION

The **set_cell_location** command sets the physical location for the specified leaf cells. The specified location is used as the lower-left corner of the boundary of the cell.

This command can also set the orientation for the specified cells and change their **physical_status** attribute to **fixed**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the location of the lower-left corner of the cell named INST_1 to (100 100):

```
prompt> set_cell_location -coordinates { 100 100 } INST_1
```

SEE ALSO

set_attribute(2)
move_objects(2)

set_cell_mode

Specifies the active cell mode for cell instances

SYNTAX

Boolean **set_cell_mode**
mode_list
cell_list
list *mode_list*
list *cell_list*
[-quiet]

ARGUMENTS

mode_list

Specifies a list of modes, each of which is to be made the active mode for its mode group.

cell_list

Specifies a list of instances for which the specified cell modes are to be made active. This option is required.

-quiet

Suppresses warning and error messages if objects do not have the mode specified. Syntax error messages are not suppressed.

DESCRIPTION

Selects the active mode for a mode group or for several mode groups and disables modes in the same group as the selected active mode. For moded-ETM the mode group **etm** must have one mode enabled to work correctly. The next timing update will give a warning if that is not the case, and report_cell_mode -missing will display mode-ETM cells that lack any set_cell_mode settings.

The moded-ETM is created by the library manager ETM flow.

It is possible for cell mode groups are defined in the .lib library source. Cell like this have slightly different rules from moded-ETMs where the mode group **etm** is added by the Library Manager. For .lib mode groups if no set_cell_mode is given all the modes are enabled. For moded-ETMs where no set_cell_mode is given all arcs are disabled.

Each library cell that is not an moded-ETM can have a set of cell mode groups. Each of these cell mode groups can have two or more cell modes. Each of these cell modes can be mapped to a set of timing arcs of the library cell. When a cell mode is made active for a given instance of the library cell, the cell mode is enabled and all of its timing arcs are enabled for that cell. All other cell

modes are automatically disabled. The timing arcs of the disabled cell modes are then automatically disabled. In the special case of an arc having multiple cell modes mapped to it, the arc will be enabled if any of the modes are enabled.

Note that the cell "modes" managed by this command have nothing to do with "modes" created on a design with the **create_mode** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following command selects the READ cell mode as the active mode for the RAM instance Uram1.

prompt> **set_cell_mode READ Uram1**

SEE ALSO

reset_cell_mode(2)
report_cell_mode(2)

set_cell_site

Sets the specified site definition on the cells that match the site definition's size.

SYNTAX

status **set_cell_site**
-site_def *site_name*
[-library *lib_name*]
[-cells *cell_list*]
[-height_type single | multiple]

Data Types

lib_name string
cell_list list
site_name string

ARGUMENTS

-library *lib_name*

Specifies the reference library that contains the library cells. The specified library must be a complete in-memory reference library. It cannot be a pure logic library, such as a library read by the **read_db** command.

If you do not specify this option, the command uses the current library.

-cells *cell_list*

Specifies the cells for which to set the site definition. The specified cells must exist in the reference library.

If you do not specify this option, the command uses all cells in the reference library.

-site_def *site_name*

Specifies the site definition to set on the matching cells. The specified site definition must be defined in the library's technology data.

-height_type single | multiple

Specifies how to match the cell height with the site definition height.

Valid values are

- **multiple** (the default)

  The cell height can be an integer multiple of the site definition height.

- **single**

  The cell height must be the same as the site definition height.

DESCRIPTION

The **set_cell_site** command sets the specified site definition on the design and frame views of the standard cells that match its size. By default, the command applies to all standard cells in the reference library. To restrict the set of cells, use the **-cells** option. The command ignores cells whose **design_type** attribute is **macro**, **black_box**, **module**, **pad**, **pad_spacer**, **flip_chip_driver**, or **corner_pad**.

A cell matches the site definition's size if

- The cell's width is an integer multiple of the site definition's width.
- The cell's height is either an integer multiple of the site definition's height or the same as the site definition's height, depending on the value of the **-height_type** option.

If the cell size does not match the site definition size, the command issues a warning and does not apply the site definition.

EXAMPLES

The following example sets the site definition to unit for the standard cells in the current library whose height is an integer multiple of the site definition's height.

```
prompt> set_cell_site -site_def unit
1
```

The following example sets the site definition to unit for all standard cells named AO* in the lib1 reference library whose height is the same as the site definition's height.

```
prompt> set_cell_site -site_def unit \
  -library lib1 -cells [get_attribute [get_lib_cells lib1/AO*] name] \
  -height_type single
```

SEE ALSO

current_lib(2)

get_attribute(2)
get_site_defs(2)

set_cell_vt_type

This sets the VT type of a library cell that is used to determine which filler is inserted when the create_vtcell_fillers command is issued.

SYNTAX

status **set_cell_vt_type**
-lib_cells *lib_cells*
-vt_type *vt_type*
[-silent]

Data Types

lib_cells	collection
vt_type	string

ARGUMENTS

-lib_cells *lib_cells*

Specifies the library cells that will be marked with the given VT type.

-vt_type *vt_type*

Specifies the VT type to mark the library cells with. The string default is keyworded to be the default VT type.

-silent

When this option is specified the command prints minimal information about the current VT settings.

DESCRIPTION

This sets the VT type of a library cell that is used to determine which filler is inserted when the create_vtcell_fillers command is issued.

EXAMPLES

The following example shows how specify the invx1 cell to be the default VT type and all cells that end with _vtA to have a VT type of

vtA.

```
prompt> set_cell_vt_type -lib_cells "*/*_vtA"  -vt_type vtA
prompt> set_cell_vt_type -lib_cells "mylib/invx1"  -vt_type default
```

SEE ALSO

set_vt_filler_rule(2)
create_vtcell_fillers(2)
create_stdcell_fillers(2)

set_checkpoint_options

Configure the check pointing system.

SYNTAX

integer **set_checkpoint_options**
[-active *boolean*]
[-runtime_units *runtime_units*]

Data Types

boolean string

ARGUMENTS

-active *boolean*

Enable or disable the checkpointing system. The valid values can be 'true' or 'false'.

-runtime_units *runtime_units*

Sets the units for reporting of runtimes of various checkpoint commands. The valid values can be 'seconds' and 'hours'. By default, the runtime is reported in Hours.

DESCRIPTION

The command configures behaviors of the checkpoint system. The -active option controls whether the checkpoint system is enabled or not. It takes a value of either true or false, defaulting to true.

When the checkpoint system is active:

- eval_checkpoint commands in the flow scripts execute their enwrapped Tcl command/s, and execute all actions or reports associated to that checkpoint
- The ./checkpoint.config.tcl file is sourced during tool startup. This happens after the home init and local init files (like .synopsys_icc2.setup) are sourced, and also after any Tcl commands specified with the -x command line option are executed.
- The ./checkpoint directory is created as soon as any checkpoint related command is encountered (except set_checkpoint_options -active false), or if a ./checkpoint.config.tcl file is found and sourced.
- Checkpoint history of any newly encountered checkpoints is recorded and can be reported with get_checkpoint_data -name,

or by looking at the ./checkpoint/checkpoint_summary.rpt file

Note that when the checkpoint system is active, no actions or reports will be run unless the user first defines and associates them. In terms of impact on the user's flow trajectory and QoR, the active checkpoint system does nothing until such reports and actions are defined and associated. It does still track checkpoint execution history.

When the checkpoint system is inactive:

- eval_checkpoint commands in the flow scripts execute their enwrapped Tcl command/s. Effectively, the Tcl statements enwrapped by the eval_checkpoint command are executed as though they were not wrapped in eval_checkpoint.
- No actions or reports associated with eval_checkpoint are executed
- The ./checkpoint directory will not be created. Note that if a ./checkpoint.config.tcl file exists in the run directory and gets sourced before disabling the checkpoint system, then the ./checkpoint directory will be created.

EXAMPLES

The following example disables the checkpoint system.

```
prompt> set_checkpoint_options -active false
```

The following example sets runtime to be captured in units of 'seconds':

```
prompt> set_checkpoint_options -runtime_units seconds
```

set_clock_balance_points

Specifies exceptions to apply while balancing clock trees at the specified pins, ports, and clocks.

SYNTAX

string **set_clock_balance_points**
[-rise]
[-fall]
[-early]
[-late]
[-consider_for_balancing true | false]
[-offset *offset delay applied at clock sink pins*]
[-delay *delay_value*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-clock *clock_list*]
-balance_points *port_pin_list*

Data Types

delay_value float
corner_list list
clock_list list
port_pin_list list

ARGUMENTS

-rise

Specifies that the exception is for the rising edge of the clock at the specified pin or port. If neither **-rise** or **-fall** are specified, then both are assumed to have been applied.

-fall

Specifies that the exception is for the falling edge of the clock at the specified pin or port. If neither **-rise** or **-fall** are specified then both are assumed to have been applied.

-early

Applies the exception for early/shortest path calculations. If neither **-early** or **-late** are specified, then both are assumed to have been applied.

-late

Applies the exception for late/longest path calculations. If neither **-early** or **-late** are specified, then both are assumed to have been applied.

-consider_for_balancing true | false

Specifies whether this constraint excludes a pin or port from balancing. If this option is not provided, then it is assumed that this constraint is for explicitly balancing a point.

When this option is set to true, it becomes a balance-point exception, which is a scenario specific constraint and accepts both **-corner** and **-scenario** options.

When this option is set to false, it becomes an ignore-point exception, which is a mode specific constraint and does not accept either **-corner** or **-scenario** options.

-offset ***offset delay applied at clock sink pins***

Specifies the offset delay which can be applied at clock sink nodes only. This option can not be specified with option **-consider_for_balancing false**.

-delay ***delay_value***

Specifies the delay seen at the pin or port. If this option is specified, **-consider_for_balancing** is assumed to be **true**. It is an error to use **-consider_for_balancing false** and **-delay** together.

-modes ***mode_list***

Specifies the scenarios to which the balance delay value is applied. If this option is given, all scenarios of the specified modes will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners ***corner_list***

Specifies the scenarios to which the balance delay value is applied. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios ***scenario_list***

Specifies the scenarios to which the balance delay value is applied. The **-modes** or **-corners** option must not be specified with this option.

-clock ***clock_list***

Specifies a list of clock objects for which to apply the constraint. For clock tree synthesis, generated clocks are a part of the master clock network. Therefore, only non-generated clocks can be specified.

-balance_points ***port_pin_list***

Specifies a list of ports and pins on which to apply the balance point.

DESCRIPTION

This command adds constraints that are used during clock tree synthesis for either excluding or explicitly balancing ports/pins with a specific delay value. A port/pin can only be an exclude point or a balancing point. It cannot be both a balance point for early-rise and an exclude point for late-fall.

Use the **-consider_for_balancing true** option to set balancing constraints on any port or pin on the clock network. If the constraints

are applied to jump pins, then they will be ignored during clock network updates and synthesis. Jump pins are register clock pins that appear in the source latency networks of a generated clock. Constraints for setting exclude pins can be applied on any pin/port on the clock network. Balance point can also be set on hierarchical pins. If hierarchical balance point is connected to a dangling/black box then during **synthesize_clock_trees**, a guide buffer is inserted next to the hierarchical pin and constraint is moved to the input pin of the guide buffer.

Objects marked with only **-consider_for_balancing true** and no **-delay value** option will assume a delay value of zero. If the object and the clock are the same, a new constraint command will overwrite or be combined with a previous constraint. The command issues a warning message if a previous constraint is overwritten. When no early/late values are specified, the corresponding late/early values are copied. The early values cannot be greater than the late values, if such a constraint is given the tool issues a warning and makes the late value equal to the early value.

Balance delay is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different delay values for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is specified, the command applies to all of the specified scenarios.

Use the **report_clock_balance_points** command to list the currently specified balance points. **remove_clock_balance_points** command can be used to remove these constraints.

Multicorner-Multimode Support : By default, if **-consider_for_balancing true** is used then this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

If **-consider_for_balancing false** is used then, this command by default is mode specific , and it is applied to all scenarios of a mode . The **-mode** option can be used to apply ignore points exceptions in other modes.

EXAMPLES

The following example sets a balance point at **gck/CP** for rise and early for clock **clk1** with a delay value of 2.0 for the current scenario.

```
prompt> set_clock_balance_points -rise -early -delay 2.0 \
  -clock clk1 -balance_points gck/CP
```

The following example overwrites the previously specified balancing constraint. The command issues a warning message when it overwrites an existing balancing constraint.

```
prompt> set_clock_balance_points -rise -early -delay 2.0 \
  -clock clk1 -balance_points gck/CP
Warning: Object 'gck/CP' had a previously specified constraint set on it for
clock 'clk1', which will be overwritten. (UIC-044)
```

The following example sets an ignore point at **mux/A** for rise and early for clock **clk1**

```
prompt> set_clock_balance_points -consider_for_balancing false \
  -clock clk1 -balance_points mux/A
```

report_clock_balance_points(2)

set_clock_cell_spacing

Defines spacing rules for the cells in the clock tree.

SYNTAX

status **set_clock_cell_spacing**
[-clocks *clock_list*]
[-lib_cells *libcell_name_list*]
[-x_spacing *x_offset*]
[-y_spacing *y_offset*]

Data Types

clock_list collection
libcell_name_list list
x_offset float
y_offset float

ARGUMENTS

-clocks *clock_list*

Specifies the clock trees for which the cell spacing settings will be applied.

-lib_cells *libcell_name_list*

Specifies a list of library cell names, so that if an instance on the clock tree is of that library cell type, it is affected by specified x,y offset.

-x_spacing *x_offset*

Specifies an offset (spacing) in x_direction. The units are microns.

-y_spacing *y_offset*

Specifies an offset (spacing) in y_direction. The units are microns.

DESCRIPTION

This command addresses a need to apply the placement based design rule (the cell to cell spacing rule) to avoid EM problem on the P/G rails by the cells which are contained in clock networks. The leaf cells (Registers, RAM) of the clock networks will be ignored from this rule. The cells which are not contained in the clock networks will be ignored from this rule. This rule will be applied to the

clock buffers/inverters, the clock gating cells only.

If **-lib_cells** switch is not specified, the rule will be applied to all appropriate cells on the clock network. If **-clocks** option is used then it will apply cell spacing settings for specified clock networks.

With default behavior correct spacing between 2 cells on the clock tree is the maximum of the offsets in each direction. This could be changed to the sum of the offsets in each direction by setting app_option cts.placement.cell_spacing_rule_style to cumulative.

Please note that this command does not directly apply the rules to the relevant instances, it serves only as directive. To apply the rules specified by this command, you need to run the **synthesize_clock_trees** command.

EXAMPLES

The following example specifies clock cell spacing rule for all clock buffers that are of the cell type BUFFD2BWP

```
prompt> set_clock_cell_spacing \
  -x_spacing 0.9 -y_spacing 0.4 -lib_cells mylib/BUFFD2BWP
```

The following example specifies cell spacing rule for all clock cells on the clock tree

```
prompt> set_clock_cell_spacing \
  -x_spacing 0.9 -y_spacing 0.0
```

The following example specifies cell spacing rule for the cells of clk1 clock tree

```
prompt> set_clock_cell_spacing -clocks clk1 \
  -x_spacing 0.9 -y_spacing 0.0
```

report_clock_cell_spacings(2)
cts.placement.cell_spacing_rule_style(3)

set_clock_exclusivity

Specifies a cell for which all the clocks that traverse from input pins to the output pin will be mutually exclusive.

SYNTAX

int **set_clock_exclusivity**
-output output_pin
[-type mux | user_defined]
[-inputs *input_pin_list*]*

ARGUMENTS

-output output_pin

This option specifies a single output pin as the exclusivity point. Depending on the -type option, all or some of the clocks going out of this pin are considered mutually exclusive.

-type mux | user_defined

Specifies the type of clock exclusivity setting, either mux or user_defined. Use the mux setting to set the clock exclusivity for a multiplexer (MUX) cell. Use the user_defined setting for a non-MUX cell.

Use the mux setting only with the -output option, not the -inputs option. The specified output pin must belong to a MUX. All clocks at different data signal inputs of the MUX (inputs that are not MUX select pins) are considered mutually exclusive clocks beyond the output. This behavior is similar to setting the time.enable_auto_mux_clock_exclusivity app option to true.

You can use the user_defined setting for both MUX or non-MUX cells. Use this option with the -inputs and -output options; the specified input and output pins must belong to the same cell in the design. All clocks at the specified inputs are considered mutually exclusive clocks beyond the output.

-inputs input_pin_list

Use this option together with the -type user_defined option. The clocks coming through these input pins are exclusive at the output pin specified by the -output option.

DESCRIPTION

IC designs often contain MUXes in the clock network to select between multiple exclusive clocks. If the MUX select lines are known not to dynamically change, the clocks going through the input pins of the MUX are in fact exclusive.

In this case, to properly constrain a MUXed clock, we can specify the output pin of cell by using set_clock_exclusivity command. The

timing paths that are launched from a clock that goes through one input pin and captured by a clock that goes through another input pin are consid- ered false timing paths. Furthermore, crosstalk interactions between the two clocks coming from different inputs of the exclusive cell are ignored. Please note that if there is a generated clock defined after the exclusivity point, the exclusivity states will be lost. This is similar to the existing behavior of the generated clocks. When a gener- ated clock is created at a pin, all other clocks arriving at that pin are blocked unless they also have generated clock versions created at that pin.

Please note that this feature is not currently supported in extract_model, characterize_context and write_eco_design commands.

To undo the set_clock_exclusivity command, use the remove_clock_exclusivity command.

To report the exclusivities defined in a design, use the report_clock command with the -exclusivity option.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example defines a mux cell output as point of exclusivity.

prompt> **set_clock_exclusivity -type mux -output MUX02/Z**

The following example defines an AND gate as a point of exlusivity.

prompt> **set_clock_exclusivity -type user_defined -output iAND02/Z -inputs {iAND02/A iAND02/B}**

SEE ALSO

remove_clock_exclusivity(2)
report_clock(2)
set_disable_auto_mux_clock_exclusivity(2)
time.enable_auto_mux_clock_exclusivity(3)

set_clock_gate_latency

Specifies clock network latency values to be used for clock-gating cells, as a function of clock domain, clock-gating stage, and transitive fanout.

SYNTAX

status **set_clock_gate_latency**
[-clock *clock_list*]
[-stage *cg_stage*]
[-fanout_latency *cg_fanout_list*]
[-reset]

Data Types

clock_list list
cg_stage integer
cg_fanout_list string

ARGUMENTS

-clock *clock_list*

Specifies that the latency must be applied with respect to the specified clocks. If the **-clock** option is not specified, the latency is applied with respect to all clock domains to which the clock-gating cell belongs. This option cannot be used with the **-reset** option.

-stage *cg_stage*

Specifies the clock-gating stage to which the clock latency data from the fanout range is applied. Registers are considered to be stage 0. Clock gates driving only registers directly or across buffers, inverters, or hierarchical transitions are stage 1. Clock gates, that are stage N, drive at least one clock gate which is stage N-1, directly or across buffers, inverters or hierarchical transitions. The value of N is the maximum possible that can be assigned to a stage. Clock gates whose stage cannot be determined (for example, unloaded clock gates) are assumed to be stage 1, but no value of latency will be applied to an unloaded clock gate.

If this option is used, it must be used with the **-fanout_latency** option. This option cannot be used with **-reset** option.

-fanout_latency *cg_fanout_list*

Specifies the list of latency tuples. When the clock-gating stage is zero (0), the values of each latency tuple are absolute. If the stage is not zero, the values of the latency tuple are relative values. The relative values are calculated with respect to the minimum latency value of the gated cells in the direct fanout of the stage\(aqs clock gate.

Each latency tuple consists of a transitive fanout range and clock latency values. For example, {{1-5 0.9} {6-20 0.5} {21-inf 0.3}}, which consists of a list with 3 latency tuples: a fanout of 1 to 5 has a latency value of 0.9; a fanout of 21 or larger has a latency value of 0.3. If you want the same latency value for the entire fanout range, specify it as {{1-inf 0.9}}. Note that \(dqinf\(dq means

infinity.

If this option is used, it must be used with the **-stage** option. This option cannot be used with the **-reset** option.

The transitive fanout of a clock-gating cell is the set of all clock pins of registers, clock pins of macro cells, and primary output ports which are driven directly or across intermediate objects (such as buffers, inverters, hierarchical transitions, and other clock gates).

-reset

Clears all the current clock gate latency settings that were specified by the **set_clock_gate_latency** command. This option cannot be used with **-clock**, **-stage** or **-fanout_latency** options.

DESCRIPTION

The **set_clock_gate_latency** command allows you to specify clock network latency values for clock-gating cells and registers, as a function of clock domain, clock-gating stage, and transitive fanout. Latency values are calculated and annotated on the clock pins of clock-gating cells and registers during the execution of the **compile** command, or by using the **apply_clock_gate_latency** command. Latency annotation is only supported for flip-flops and clock gates. The tool does not annotate macro cell pins.

When performing annotation on clock pins of clock gate cells, the latency values specified using the **-fanout_latency** option are interpreted as the time required for the clock signal to propagate from the clock-gate cell to the registers or clock gates in its fanout. The clock latency annotated on the clock pin of the gate cell is the clock network latency annotated on its fanout minus the respective relative latency value specified using the **-fanout_latency** option. When performing annotation on registers clock pins, the latency value specified is used as the absolute clock network latency.

Use the **set_clock_gate_latency** command to specify the latency for registers by specifying the command for stage 0. By definition, stage 0 has no fanout, so use the following syntax:

```
prompt> set_clock_gate_latency -stage 0 -fanout_latency \
    {{ 1-inf] value }}
```

When clock latency settings are provided for stage 0, the specified values are annotated on the clock pin of each register, regardless if the register is gated or not. The value that is specified for the given latency tuple is absolute. This means that the specified value is directly annotated on the clock pin of the cell and can be positive or negative

When clock latency settings are provided for nonzero stages, the calculated values are annotated on the clock pin of each clock gate as specified by the command. The annotated value is the annotated latency of on the fanout minus the relative latency specified. The relative latency value must be nonnegative values. If different latency values are detected among the fanout of a clock gate, the lowest latency value is used to compute the relative latency to annotate on the clock gate.

For example, applying the following setting results in registers with an absolute latency value of 1.5. Stage 1 clock gates whose transitive fanout count is lower or equal than 20 get an absolute value of 1.0 (computed as 1.5 - 0.5), and stage 1 clock gates whose transitive fanout count is greater than 20 get an absolute value of 0.8 (computed as 1.5 - 0.7):

```
prompt> set_clock_gate_latency -stage 0 -fanout_latency \
    {{ 1-inf 1.5 }}

prompt> set_clock_gate_latency -stage 1 -fanout_latency \
    {{ 1-20 0.5 } { 21-inf 0.7 }}
```

The tool only annotates the absolute latency value on the clock pin of a cell (clock gate or register) whose stage is N and whose clock domain is **clk**, if the command with the **-stage** N option for that clock domain was explicitly used.

If **set_clock_gate_latency** is used more than one time with the same stage and clock options, the tool overrides the values with the last command given.

The tool can overwrite values that were annotated using optimizations that were enabled by the application option **compile.clockgate.physically_aware**.

When **set_clock_latency** and **set_clock_gate_latency** have different specifications, other rules apply. The following example illustrates the order of precedence:

1) **set_clock_latency -clock clk 0.1 [all_registers -clock_pins]**

2) **set_clock_gate_latency -clock clk -stage 0 -fanout_latency {{1-inf 0.2}}**

3) **set_clock_latency 0.3 [all_registers -clock_pins]**

4) **set_clock_gate_latency -stage 0 -fanout_latency {{1-inf 0.4}}**

5) **set_clock_latency 0.5 [get_clocks]**

The precedence is listed from highest to lowest, regardless of the order in which they are used. All the previous commands can be used independently, in any combination, and in any order. Keep in mind they follow the same precedence as described. If both commands are used with the same specifications, the **set_clock_latency** command prevails over the **set_clock_gate_latency** command.

If you specify fanout ranges in the *cg_fanout_list* and you do not cover all values from 1 to *infinity*, this results in an error. If you specify overlapping ranges in the *cg_fanout_list*, this also results in an error.

If an inconsistent clock latency annotation is detected when running the **apply_clock_gate_latency** or **compile** command, the tool reports a warning message.

If you use the **-reset** option, all the clock gate latency settings that were specified with the **set_clock_gate_latency** command are deleted. Note that this does not remove the annotated latencies that were set during the execution of compile or **apply_clock_gate_latency** command.

To remove annotated latencies that were specified using the **set_clock_gate_latency** command, use the **reset_clock_gate_latency** command.

To report the clock gate latency settings that were specified by the **set_clock_gate_latency** command, use the **report_clock_gate_latency** command.

Multicorner-Multimode Support

This command is scenario dependent and only affects the current scenario. Absolute latency values are calculated with respect to the same scenario.

The actual clock latency annotation is performed during the execution of the compile or **apply_clock_gate_latency** commands, for all the scenarios for which a clock latency value is available.

Latency computation and annotation depends on clock marking which in turn depends on some user constraints like **set_case_analysis** on the clock logic. To guarantee that all clock gates are constrained properly for all clocks, make sure multiple scenarios that cover complementary cases are defined.

Using the **-reset** option deletes all the clock gate latency settings for the current scenario only.

EXAMPLES

The following example specifies the clock latency values for the complete fanout range of clock-gating cells for stages 1, 2, and 3. This latency data applies to the clock-gating cells whose clock pins belong to **clk1**.

```
prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 1 \
```

```
        -fanout_latency {{1-30 2.1} {31-100 1.7} {101-inf 1.1}}

    prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 2 \
        -fanout_latency {{1-5 0.9} {6-20 0.5} {21-inf 0.3}}

    prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 3 \
        -fanout_latency {{1-10 0.28} {11-inf 0.11}}
```

The following example shows how to specify and annotate different clock gate latency values for different multicorner-multimode scenarios.

```
    prompt> current_scenario sc1
    prompt> set_clock_gate_latency -stage 1 \
        -fanout_latency {{1-inf 0.11}}

    prompt> current_scenario sc2
    prompt> set_clock_gate_latency -stage 1 \
        -fanout_latency {{1-inf 0.15}}

    prompt> compile
```

The following example shows how to delete the current clock gate latency settings from the current scenario.

```
    prompt> current_scenario sc1
    prompt> set_clock_gate_latency -reset
```

set_clock_gate_routing_rule

Specify a non-default or default routing rule to be applied to the output nets of leaf level tool inserted clock gates during compile.

SYNTAX

status **set_clock_gate_routing_rule**
  [-rule *rule*
    | -default_rule
    | -no_rule
    | -clear]
  [-min_routing_layer *layer*]
  [-max_routing_layer *layer*]
  [-min_layer_mode *mode*]
  [-max_layer_mode *mode*]
  [-min_layer_mode_soft_cost *cost*]
  [-max_layer_mode_soft_cost *cost*]

Data Types

rule	string or collection
layer	list or collection
mode	string
cost	string

ARGUMENTS

-rule *rule*

Specifies the name of the non-default routing rule to be assigned to the leaf level tool inserted clock gate\(qas output nets.

The -rule, -default_rule, -no_rule, and -clear options are mutually exclusive; you can specify only one.

-default_rule

Specifies that the default routing rule should be assigned to the leaf level tool inserted clock gate\(qas output nets.

The -rule, -default_rule, -no_rule, and -clear options are mutually exclusive; you can specify only one.

-no_rule

Specifies no routing rule. This allows the tool to automatically assign a non-default rule or the default rule to the nets.

The -rule, -default_rule, -no_rule, and -clear options are mutually exclusive; you can specify only one.

-clear

Removes the current clock gate routing rule setting, if any. This option will make that no clock gate routing rule setting will be applied during compile. This option is mutually exclusive with all other options.

-min_routing_layer ***layer***

Specifies the minimum routing layer for the nets. Only one layer can be specified.

-max_routing_layer ***layer***

Specifies the maximum routing layer for the nets. Only one layer can be specified.

-min_layer_mode ***mode***

Specifies the minimum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

-max_layer_mode ***mode***

Specifies the maximum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

-min_layer_mode_soft_cost ***cost***

Specifies the minimum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

-max_layer_mode_soft_cost ***cost***

Specifies the maximum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

DESCRIPTION

This command specify a non-default or default routing rule to be applied to the output nets of leaf level tool inserted clock gates during compile. This command also specify minimum and maximum routing layer, mode, and cost constrains to the output nets of leaf level tool inserted clock gates during compile.

Each call to this command will overwrite any previous calls.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a non-default rule named *cg_ndr* to be set during compile.

```
prompt> set_clock_gate_routing_rule -rule cg_ndr
```

This example clears any settings for this command.

```
prompt> set_clock_gate_routing_rule -clear
```

set_clock_gate_style

Sets the types of integrated clock-gating library cells to be used for clock gating insertion.

SYNTAX

status **set_clock_gate_style**
[-test_point before | after | none]
[-observation_output]
[-target *target_list*]
[-objects *object_list*]

Data Types

target_list list
object_list list

ARGUMENTS

-test_point before | after | none

Specifies whether the test control inside the clock gating circuitry is implemented before the latch or after the latch or not at all. If the option is not used, test point *before* is selected by default.

-observation_output

Specifies whether the selected clock gate must have an observability logic output pin. By default selected clock gates don't have this pin.

-target *target_list*

Specifies the target sequential elements to be clock gated by the selected integrated clock-gating library cell type. Valid target values are *pos_edge_flip_flop* and *neg_edge_flip_flop*. If more than one target is included, they must be enclosed in quotes or braces ({}). If the option is not used, both targets *pos_edge_flip_flop* and *neg_edge_flip_flop* are selected by default.

-objects *object_list*

Specifies that the clock gate style should be applied over the given list of design objects. Valid objects are hierarchical instances, power domains and designs. If the option is not used, the clock gate style is set for the top design.

DESCRIPTION

This command specifies the characteristics of integrated clock-gating (ICG) library cells to be used for clock gating insertion.

To be selected for clock gating insertion, an ICG library cell must have the **clock_gating_integrated_cell** attribute set to one of these values:

- latch_posedge
- latch_posedge_precontrol
- latch_posedge_postcontrol
- latch_posedge_precontrol_obs
- latch_posedge_postcontrol_obs
- latch_negedge
- latch_negedge_precontrol
- latch_negedge_postcontrol
- latch_negedge_precontrol_obs
- latch_negedge_postcontrol_obs

In the preceding attribute values the presence of **precontrol** or **postcontrol** substrings means that the test-control logic is located before or after the latch, respectively. This corresponds to the use of **-test_point** option with arguments *before* or *after*, respectively.

The presence of the **obs** substring in the attribute value means that the ICG has observability output pin, and this can be selected by using **-observation_output** option.

Use the **-target** option to specify the type sequential element the current instance of the command applies. This means that the ICG library cell being selected is intended to gate this type of register. Supported targets are:

- Positive-edge triggered flip-flops (use the *pos_edge_flip_flop* argument)
- Negative-edge triggered flip-flops (use the *neg_edge_flip_flop* argument)

Use the **-objects** option to specify different styles for different blocks in the circuit. The clock gate style applies to all cells hierarchically under the specified object, unless a lower-level object has set a different clock gate style. Valid arguments for this option are hierarchical instances, power domains and designs.

The clock gate style is always attached to a netlist object, irrespective of whether the **-objects** option is used or not. When not used, the specified style is attached to the top design. Therefore the execution of the command requires that the design is already loaded in memory, otherwise it errors out. The clock gate style is persistent in the database.

In addition to the **clock_gating_integrated_cell** attribute, **valid_purposes** attribute must be also set on the ICG library cell and its value must contain **cts** purpose. This can be used as a mechanism to allow/disallow the use of specific ICG library cells. To add/remove the **cts** attribute purpose to/from a given ICG library cell, use the **set_lib_cell_purpose** command.

If **set_clock_gate_style** command is not executed at all or the specification for one target is missing, clock gating insertion uses these default values:

- Test control point before the latch.
- No observation logic output pin.

In other words, the tool selects an ICG library cell with attribute value **latch_posedge_precontrol** for positive-edge triggered flip-flops and **latch_negedge_precontrol** for negative-edge triggered flip-flops.

If no latch_negedge_precontrol library cell is available but a latch_posedge_precontrol library cell is available and vice-versa, then the tool uses the ICG library cell that is available. Additional inverters are inferred at the clock input pin of the clock gating cell and between the clock output pin of the clock-gating cell and the clock input pin of the register for functional equivalence.

To check the availability of ICG library cells for a block in the design, use the **check_clock_gate_library_cell_availability** command.

The specified clock gate style is only applicable to the newly instantiated clock gates. The type of cell used for preexisting clock gates, either user-instantiated or inserted by the tool in a previous command, is not modified to fit the current style.

The clock gates are inserted as instances of flat ICG cells, without any hierarchical wrapper around. Discrete clock gates are not supported for insertion, so the technology library must contain ICG cells for the insertion to occur.

The ICG cell circuitry must be latch-based, latch-free clock gating is not supported. The presence of a latch in the clock gating circuitry prevents a leading clock edge by maintaining the value of the clock signal after the trailing edge. For example, for positive-edge triggered flip-flops, the clock signal is forced and kept to logic 0 after the negative edge, preventing a rising edge that loads new data into the register.

Hierarchical instances that have an explicit clock gate style set are not automatically ungrouped. If the ungrouping is explicitly requested by using the **ungroup** command, the clock gate style is lost.

EXAMPLES

The following example specifies that flip-flops with any activation edge have to be clock gated by using ICGs with the test-control circuitry implemented before the latch and without observability output pin. Therefore an ICG with its **clock_gating_integrated_cell** attribute set to **latch_posedge_precontrol** is selected for positive-edge triggered flip-flops, and one with **latch_negedge_precontrol** is selected for negative-edge triggered flip-flops:

```
prompt> set_clock_gate_style -test_point before
The following clock gating style is applied to: top-level (design)
Target: pos_edge_flip_flop neg_edge_flip_flop
Test control position: before
Observation output: false
1
```

The following example specifies that positive-edge triggered flip-flops have to be clock gated by using ICGs with the test-control circuitry implemented after the latch and with observability output pin, while negative-edge triggered flip-flops have to be clock gated by using ICGs without test-control circuitry nor observability output pin. Therefore an ICG with its **clock_gating_integrated_cell** attribute set to **latch_posedge_postcontrol_obs** is selected for positive-edge triggered flip-flops, and one with **latch_negedge** is selected for negative-edge triggered flip-flops:

```
prompt> set_clock_gate_style -test_point after \
  -observation_output \
  -target pos_edge_flip_flop
The following clock gating style is applied to: top-level (design)
Target: pos_edge_flip_flop
Test control position: after
Observation output: true
1

prompt> set_clock_gate_style -test_point none \
  -target neg_edge_flip_flop
The following clock gating style is applied to: top-level (design)
Target: neg_edge_flip_flop
Test control position: none
Observation output: false
1
```

The following example specifies that flip-flops with any activation edge have to be clock gated by using ICGs with the test-control circuitry implemented before the latch. Clock gates must have observability output pin in the whole design, except for hierarchical cells m1/b1 and m2, as well as power domain PD1. So under these specifics objects the selected ICGs have the **clock_gating_integrated_cell** attribute set to either **latch_posedge_precontrol** or **latch_negedge_precontrol**, while for the rest of the circuit the selected ICGs have the attribute set to either **latch_posedge_precontrol_obs** or **latch_negedge_precontrol_obs**.

```
prompt> set_clock_gate_style -test_point before \
  -observation_output
The following clock gating style is applied to: top-level (design)
Target: pos_edge_flip_flop neg_edge_flip_flop
Test control position: before
Observation output: true
1

prompt> set_clock_gate_style -test_point before \
  -objects [get_cells {m1/b1 m2}]
The following clock gating style is applied to: m1/b1 (hier inst) m2 (hier inst)
Target: pos_edge_flip_flop neg_edge_flip_flop
Test control position: before
Observation output: false
1

prompt> set_clock_gate_style -test_point before \
  -objects [get_power_domains PD1]
The following clock gating style is applied to: PD1 (power domain)
Target: pos_edge_flip_flop neg_edge_flip_flop
Test control position: before
Observation output: false
1
```

set_clock_gate_transformations

Sets transformation restrictions on specified clock gates instances during compile.

SYNTAX

status **set_clock_gate_transformations**
object_list true | false
[-split_fanout true | false]
[-ungate_fanout true | false]
[-collapse_levels true | false]
[-merge_equivalents true | false]
[-reset]

Data Types

object_list list

ARGUMENTS

object_list

Specifies the target clock gate instances to apply the transformation restrictions. This option is required unless *-reset* is specified.

true | **false**

Specifies the default for any transformation that it's not explicitly specified by the current command call. This option is required unless *-reset* is specified.

-split_fanout true | **false**

Specifies whether clock gating can move part of a clock gate's fanout to another clone of that clock gate.

-ungate_fanout true | **false**

Specifies whether clock gating can ungate a clock gate's fanout during optimization.

-collapse_levels true | **false**

Specifies whether clock gating can collapse or modify the enable signal of the clock gates during optimization.

-merge_equivalents true | **false**

Specifies whether clock gating can merge equivalent clock gates.

-reset

Removes the previous restrictions set by **set_clock_gate_transformations** on all clock gates. This option cannot be used in

combination with any other option.

DESCRIPTION

Sets restrictions for the *split_fanout*, *ungate_fanout*, *collapse_levels*, and *merge_equivalents* transformations during compile on the specified clock gate instances in *object_list*.

Restricting the *split_fanout* transformation prevents moving part of the clock gate's fanout to another clone of the clock gate. This means that if the clock gate does not honor the maximum fanout, its fanout is not redistributed in other copies of the clock gate. Or, if the clock gate can be collapsed with another upstream clock gate and it also has a side fanout, it cannot be collapsed because that would involve splitting the side fanout.

The *split_fanout* restriction also restricts Physically Aware Clock Gating splitting.

Restricting the *ungate_fanout* transformation prevents the ungating of the clock gate's fanout when trying to honor the minimum bitwidth set by **set_clock_gating_options**. If the clock gate has a constant enable signal or if all its fanout has been removed, the clock gate can still be removed because it is redundant and there is no enable signal transferred to the clock gate's fanout.

Removal of redundant clock gates can be prevented via set_dont_touch or set_size_only. Applying these constraints can also prevent other optimizations.

Restricting the *collapse_levels* transformation prevents the collapse of the clock gate with another upstream or downstream clock gate. This also means that the clock gate's enable function is not modified.

Restricting the *merge_equivalents* transformation prevents the merging of a clock gate with another equivalent clock gate. This restriction does not apply for collapsing with an upstream or downstream clock gates.

A clock gate that have any of the transformation's restriction is selected as the preferred survivor clock gate for the merging and collapsing transformations.

For the merge, collapse, and split transformation, any restriction is inherited by the resulting clock gates.

The restrictions applying to a clock gate can be reported with **report_clock_gating -gating_elements**.

EXAMPLES

The following example restrict the clock gate clock_gate_0 to not be split, but allowing all other transformations.

```
prompt> set_clock_gate_transformations -split_fanout false {clock_gate_0} true
```

The following example allows the clock gate clock_gate_1 to be merged with an equivalent clock gate and ungate its fanout, but restricting all other transformations.

```
prompt> set_clock_gate_transformations -merge_equivalents true -ungate_fanout true {clock_gate_1} false
```

The following example restricts all transformation for all clock gates on the design.

```
prompt> set_clock_gate_transformations [get_clock_gates] false
```

The following example shows how the transformation restrictions are reported in **report_clock_gating -gating_elements**.

```
prompt> set_clock_gate_transformations {clock_gate_2} false
prompt> report_clock_gating -gating_elements
```

```

SEE ALSO

report_clock_gating(2)
set_clock_gating_options(2)

set_clock_gating_check

Specifies the value of setup and hold time for clock gating checks.

SYNTAX

string **set_clock_gating_check**
[-setup *setup_value*]
[-hold *hold_value*]
[-rise | -fall]
[-high | -low]
[*object_list*]

float *setup_value*
float *hold_value*
list *object_list*

ARGUMENTS

-setup *setup_value*

Specifies the clock gating setup time. The default is 0.0.

-hold *hold_value*

Specifies the clock gating hold time. The default is 0.0.

-rise

Indicates that only rising delays are to be constrained. By default, if neither **-rise** nor **-fall** are specified, both rising and falling delays are constrained.

-fall

Indicates that only falling delays are to be constrained. By default, if neither **-rise** nor **-fall** are specified, both rising and falling delays are constrained.

-high

Indicate that the check is to be performed on the high level of the clock. By default, the tool determines whether to use the high or low level of the clock using information from the cell's logic. That is, for AND and NAND gates the tool performs the check on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX, OR-AND) the tool cannot determine which to use, and does not perform checks unless you specify either **-high** or **-low**. If the user-specified value differs from that derived by the tool, the user-specified value takes precedence. Unlike setup or hold time, this option sets the attribute only on the specified pin or cell and does not affect the transitive fanout pin or cell. If you specify **-high** or **-low** you must also specify *object_list*; in that case, *object_list* must not contain a clock or a port.

-low

Indicates that the check is to be performed on the low level of the clock. By default, the tool determines whether to use the high or low clock level using information from the cell's logic. That is, for AND and NAND gates the tool performs the check on the high level; for OR and NOR gates, on the low edge. For some complex cells (for example, MUX, OR-AND) the tool cannot determine which to use, and does not perform checks unless you specify either **-high** or **-low**. If the user-specified value differs from that derived by the tool, the user-specified value takes precedence. Unlike setup or hold time, this option sets the attribute only on the specified pin or cell and does not affect the transitive fanout pin or cell. If you specify **-high** or **-low** you must also specify *object_list*; in that case, *object_list* must not contain a clock or a port.

object_list

Specifies a list of objects in the current design for which the clock gating check is to be applied. The objects can be clocks, ports, pins, or cells. If a cell is specified, all input pins of that cell are affected. If a pin, cell, or port is specified, all gates in the transitive fanout are affected. If a clock is specified, the clock gating check is applied to all gating gates driven by that clock. If you specify **-high** or **-low** you must also specify *object_list*; in that case, *object_list* must not contain a clock or a port. By default, if *object_list* is not specified, the clock gating check is applied to the current design.

DESCRIPTION

The **set_clock_gating_check** command specifies a setup or hold time clock gating check to be used for clocks, pins, or cells. The gating check is performed on pins that gate a clock signal.

The clock gating setup check is used to ensure the controlling data signals are stable before the clock is active. This check is performed on combinational gates through which the clock signals are propagated. The arrival time of the leading edge of the clock pin is checked against both levels of any data signals gating the clock. A clock gating setup failure can cause either a glitch at the leading edge of the clock pulse, or a clipped clock pulse.

The clock gating hold check is used to ensure that the controlling data signals are stable while the clock is active. The arrival time of the trailing edge of the clock pin is checked against both levels of any data signal gating the clipped clock pulse.

The options **-high** and **-low** are intended to specify clock gating checks that the tool cannot determine. These options apply only to the pins specified and not to the cells or pins in the transitive fanout. Conversely, setup and hold values for clock gating checks apply to the cells and pins in the transitive fanout. If you need to use the **-setup** or **-hold** options and also the **-high** or **-low** options, issue two separate **set_clock_gating_check** commands to avoid confusion as to what is propagated and what is not propagated.

Use the **remove_clock_gating_check** command to remove information set by **set_clock_gating_check**. The **reset_design** command removes all attributes from the design, including those set by **set_clock_gating_check**.

Use the **report_clock_gating_check** command to report the information for the clock gating check.

When a cell object is given to **set_clock_gating_check** command it is the same as setting it on all the pins of that cell. The precedence for setup and hold values is: enable pin, clock pin, library cell value, clock value, design value.

The **set_clock_gating_check** command does not in fact create a clock-gating check. The correct conditions for a clock-gating check to occur need to already exist on the specified objects.

The **set_clock_gating_check** may be used to modify the properties of an inferred or library-specified clock-gating check.

The command need only be used when either a non-zero setup or hold time check is required or a high or low pulse check is desired.

Solvnet article 015769 "How Are Clock Gating Checks Inferred?" describes clock-gating checks in detail.

Multicorner-Multimode Support

This command works only on the mode associated with the current scenario.

EXAMPLES

The following example specifies a setup time of 0.2 and a hold time of 0.4 for all gates in the clock network of clock CK1.

```
prompt> set_clock_gating_check -setup 0.2 -hold 0.4 [get_clocks CK1]
```

The following example specifies a setup time of 0.5 on the gate and1.

```
prompt> set_clock_gating_check -setup 0.5 [get_cells and1]
```

set_clock_gating_objects

Controls the clock gating for specified objects in the current design and overrides the default behavior for clock gating in **compile**. Objects can be a register, hierarchical cell, power domain, or module.

SYNTAX

status **set_clock_gating_objects**
[-exclude *object_list*]
[-force *object_list*]
[-include *object_list*]
[-clear *object_list*]
[-enable_source *signal_type*]
[-reset]

Data Types

object_list list
signal_type none, enable_pin_only, feedback_loop_only, both, prefer_enable_pin, prefer_feedback_loop

ARGUMENTS

-exclude *object_list*

Specifies a list of objects in the current design to be excluded from clock gating. An object can only appear in one object_list for the following options: **-force**, **-exclude**, **-include** and **-clear**.

-force *object_list*

Specifies a list of objects in the current design to be forcibly gated during clock gate insertion. An object can only appear in one object_list for the following options: **-force**, **-exclude**, **-include** and **-clear**.

-include *object_list*

Specifies a list of objects in the current design for which clock gating should be done as specified by the **set_clock_gate_style** and **set_clock_gating_options** commands. This is the default for all objects in the design. An object can only appear in one object_list for the following options: **-force**, **-exclude**, **-include** and **-clear**.

-clear *object_list*

Specifies a list of objects in the current design for which the inclusion or exclusion criteria for clock gating should be removed. An object can only appear in one object_list for the following options: **-force**, **-exclude**, **-include** and **-clear**.

-enable_source *signal_type*

Specifies the signal source from which the enable logic will be obtained. This option applies to all objects specified for the **-force** and/or **-include** option of the same command instance. When the enable_source option is used the **-clear**, **-exclude**, and **-reset**

option must not be used.

-reset

Removes the criteria previously set by the **set_clock_gating_objects** command. This option cannot be used in combination with any other option.

DESCRIPTION

This command specifies the objects on which clock gating is to be either forced, enabled, or disabled, overriding all conditions necessary for automatic clock gating by the **compile** command.

Use the **-exclude** option to specify that regular clock gating must NOT gate the specified objects.

Use the **-force** option to specify that regular clock gating must gate the specified objects. If the object does not belong to a bank that fulfills the minimum bitwidth requirement, the forced object is gated with an always-enabled clock gate. Note that the tool-inserted always-enabled clock gates are not required to meet the minimum bitwidth. The **-force** option takes precedence over the minimum bitwidth requirement.

Use the **-enable_source** option to control for each register whether to use either only the synch-enable connection (*enable_pin_only*), or only the feedback loop (*feedback_loop_only*), or both feedback loop and synch-enable (default, *both*), or neither synch-enable nor feedback loop (*none*), or feedback loop only if no non-constant synch-enable connection (*prefer_enable_pin*), or synch-enable only if no feedback loop (*prefer_feedack_loop*). The meaning of the signal types is detailed below:

- **-enable_source none** means that no enable condition is derived from any feature of the specified registers. The registers will either not be gated, or if -force is used for them, be gated by an always enable clock gate. The use of **-enable_source none** together with **-include** is an error.
- **-enable_source enable_pin_only** means that only the synchronous enable connection, if any, will be used for computing the enable function for clock gating the specified registers. Note that in case of non-constant synchronous set / synchronous clear signals, the clock will be enabled whenever these are active.
- **-enable_source feedback_loop_only** means that only an enable condition derived from the feedback loop around the register, if any, will be used for computing the enable function for clock gating the specified registers. Note that in case of non-constant synchronous set / synchronous clear signals, the clock will be enabled whenever these are active.
- **-enable_source both** means that any enable condition derived from both the feedback loop, if any, and the synchronous enable connection, if any, of the specified registers will be used for clock gating. Note that in case of non-constant synchronous set / synchronous clear signals, the clock will be enabled whenever these are active. This is the default behavior for all registers.
- **-enable_source prefer_enable_pin** means that, if the specified registers have both a synchronous enable connection and a feedback loop, only the enable condition derived from the enable connection will be used for gating. The feedback loop will only be used, if there is no non-constant enable connection. Note that in case of non-constant synchronous set / synchronous clear signals, the clock will be enabled whenever these are active.
- **-enable_source prefer_feedback_loop** means that, if the specified registers have both a synchronous enable connection and a feedback loop, only the enable condition derived from the feedback loop will be used for gating. The enable connection will only be used, if there is no feedback loop from which an enable condition could be derived. Note that in case of non-constant synchronous set / synchronous clear signals, the clock will be enabled whenever these are active.

Use the **-include** option to specify that regular clock gating criteria should be used on the specified objects.

Use the **-clear** option to remove a previously specified criteria on the specified objects.

For modules and power domains, the criteria is applied to the instances associated with each of the specified objects at the moment the command is executed. Future instances of modules or power domains will not have this criteria.

For an instance referenced by more than one object in one call of the command, the criteria is applied in the following order, overwriting any previously set criteria:

- Set to modules.
- Set to power domains.
- Set to instances.

You must run the **set_clock_gating_objects** command before running the **compile** command. The specifications persist during the subsequent executions of **compile**.

EXAMPLES

The following example excludes the register bank A_reg in the current design, from clock gating:

```
prompt> set_clock_gating_objects -exclude A_reg[*]
```

The following example removes the directive to include and exclude clock gating for the registers the ADDER:

```
prompt> set_clock_gating_objects \
        -clear {ADDER/out1_reg[*] ADDER/out2_reg[*]}
```

The following example excludes every register present in ADDER, except for the out1_reg bank, which is clock gated according to the specified style.

```
prompt> set_clock_gating_objects \
        -exclude ADDER \
        -include ADDER/out1_reg[*]
```

The following example removes the directive to include or exclude clock gating for all objects:

```
prompt> set_clock_gating_objects -reset
```

The following example excludes the module mid and includes mid_A, an instance of mid:

```
prompt> set_clock_gating_objects -exclude mid -include mid_A
```

The following example forces the registers inside the mid_A hierarchy to be gated with always enable clock gates.

```
prompt> set_clock_gating_objects -force {mid_A} -enable_source none
```

The following example specify that the registers inside the mid_A hierarchy should be gated using just the synch enable pin signal. It also forces the tool to insert a clock gate before the register mid_A/out_reg[1] using just the synch enable pin signal or an always enable signal.

```
prompt> set_clock_gating_objects -include {mid_A} -force {mid_A/out_reg[1]} -enable_source enable_pin_only
```

SEE ALSO

compile(2)

set_clock_gate_style(2)
set_clock_gating_options(2)

set_clock_gating_options

Set the structural options for clock gate insertion and configuration in the compile flow.

SYNTAX

status **set_clock_gating_options**
[-minimum_bitwidth *bit_count*]
[-max_fanout *reg_count*]
[-objects *object_list*]

Data Types

bit_count integer
reg_count integer
object_list list

ARGUMENTS

-minimum_bitwidth *bit_count*

Specifies the minimum accumulated bitwidth (See CLOCK GATE FANOUT) that a clock gate can gate. It is an integer value, greater than or equal to one. This setting is optional, and if not set it defaults to 3.

-max_fanout *reg_count*

Specifies the maximum register count (See CLOCK GATE FANOUT) that a clock gate can gate. It is an integer value, greater than or equal to one. This setting is optional, and if not set the fanout of a clock gate is unlimited.

-objects *object_list*

Specifies that the clock gating options are applied to the specified list of design objects. Valid objects are hierarchical instances, power domains and designs. If this option is not used, the clock-gating options are set for the entire design.

DESCRIPTION

This command sets the structural options for clock gate insertion and configuration in the compile flow.

CLOCK GATE FANOUT (BITWIDTH/COUNT)

The clock gate fanout is counted in two ways:

- Accumulated bitwidth, which is the sum of the bitwidths of each register,

either latches or flip-flops, whose clock pin is driven by a clock gate directly or across buffers, inverters or hierarchical transitions.

- Register count, which refers to the number of latches or flip-flops whose clock pin is driven by a clock gate, either directly or across buffers, inverters or hierarchical transitions.

Note that for honoring the minimum bitwidth, only the accumulated bitwidths of the gated flip-flops or latches will be counted. As for the maximum fanout, all pins, either connected directly or through buffers, inverters or hierarchical transitions, will be counted as part of the fanout, including:

- Any pin of a clock gate.
- Any non-clock pin of a flip-flop or a latch.
- Primary outputs.
- Any pin of a combinational cell.
- Any pin of a sequential cell that is neither a flip-flop nor a latch.

MIN AND MAX VALUES

In order to ensure that the tool can create clock-gating banks for single and multibit registers, the minimum bitwidth value is required to be less than or equal to the maximum fanout value.

Value of parameter -minimum_bitwidth is checked several times during the compile flow, by identifying clock gates whose accumulated bitwidth is under the minimum bitwidth requirement. Clock gates driving a small bank will be removed and its fanout ungated unless:

- The clock gate has a constraint that prevents its removal, such as dont_touch or size_only.
- The clock gate is driving two or more clock gates.
- The clock gate is gating an object that cannot be ungated, such as a primary output, a non-clock pin of a flip-flop or latch, etc.

Value of parameter -max_fanout is checked after multibit packing, by identifying clock gates whose fanout exceeds the maximum fanout requirement. The registers that are part of a large clock-gating bank are split into banks using as many clock gates as needed to honor both the minimum bitwidth and max fanout. Using the least amount of clock gates possible, each of them having aproximately the same register fanout. The splitting process does not trigger any ungating of registers.

Note that the tool cannot ensure that both the minimum bitwidth and maximum fanout will be honored after splitting a large clock gating bank if the minimum bitwidth is greater than half of the maximum fanout. In this case, the command issues a WARNING message stating that some clock gates might not honor the max_fanout setting.

If large bank splitting cannot honor the maximum fanout, the tool will evenly distribute the excess of registers among all the clock gates derived from the splitting.

Please note that some of the physical optimizations could lead to small changes in the register fanout of a clock gate, causing the tool to fail to honor the minimum bitwidth or the maximum fanout at the end of compile.

EXAMPLES

The following examples specify the clock-gating options described below:

```
prompt> set_clock_gating_options -max_fanout 3
The following clock gating options are applied to: top-level (design)
Minimum bitwidth: 3
Maximum fanout: 3
```

```
1

prompt> set_clock_gating_options -minimum_bitwidth 6 \
                        -max_fanout 8 \
The following clock gating options are applied to: top-level (design)
Minimum bitwidth: 6
Maximum fanout: 8
1

prompt> set_clock_gating_options -minimum_bitwidth 4 \
                        -max_fanout 6 \
                        -objects [get_cells] \
The following clock gating options are applied to: b1 (hier inst)
Minimum bitwidth: 4
Maximum fanout: 6
1
```

SEE ALSO

compile(2)
report_clock_gating(2)
set_clock_gate_style(2)

set_clock_groups

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during the timing analysis.

SYNTAX

Boolean **set_clock_groups**
[-physically_exclusive | -logically_exclusive | -asynchronous]
[-allow_paths]
[-name *name*]
[-group *clock_list*]*

list *clock_list*

ARGUMENTS

Note: Options marked with asterisks (*) in the SYNTAX can be used more than once in the same command.

-physically_exclusive

Specifies that the clock groups are physically exclusive with each other. Physically exclusive clocks cannot co-exist in the design physically. An example of this is multiple clocks that are defined on the same source pin. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-logically_exclusive

Logically exclusive clocks do not have any functional paths between them, but may have coupling interactions with each other. An example of logically-exclusive clocks is multiple clocks, which are selected by a MUX but can still interact through coupling upstream of the MUX cell. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-asynchronous

Specifies that the clock groups are asynchronous to each other. Two clocks are asynchronous with respect to each other if they have no phase relationship at all. Signal integrity analysis uses an infinite arrival window on the aggressor unless all the arrival windows on the victim net and the aggressor net are defined by synchronous clocks. The **-physically_exclusive**, **-logically_exclusive** and **-asynchronous** options are mutually exclusive; you must choose only one.

-allow_paths

Enable the timing analysis between specified asynchronous clock groups. The default behavior is to suppress timing paths between asynchronous clocks. The *-allow_paths* option must be used with *-asynchronous* option.

-name *name*

Specifies a name for the clock grouping to be created. Each command should specify a unique name, which identifies the

exclusive or asynchronous relationship among specified clock groups, and this name is used later on to easily remove the clock grouping defined here. By default, the command creates a unique name.

-group *clock_list*

Specifies a list of clocks. You can use the **-group** option more than once in a single command execution. Each **-group** iteration specifies a group of clocks, which are exclusive or asynchronous with the clocks in all other groups. If only one group is specified, it means that the clocks in that group are exclusive or asynchronous with all other clocks in the design. Thus, a default other group is created for this single group. Whenever a new clock is created, it is automatically included in the default exclusive or asynchronous group. Substitute the list you want for *clock_list*.

-comment *comment_string*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during the timing analysis. This is similar to using the set_false_path command. In addition, these relationships also imply the type of crosstalk analysis which should be performed between the clocks. A clock cannot be present in multiple groups during one **set_clock_groups** command execution, but can be included in multiple groups by executing multiple **set_clock_groups** commands. Clock relationships are only implied across the specified clock groups; no relationship is implied across clocks within a group.

For all three relationships, timing paths between the clocks are suppressed. The relationships differ in how crosstalk is handled. If clocks are asynchronous, the clocks are assumed to have an infinite window relationship with each other. If clocks are physically exclusive, only one clock can act as an aggressor or victim during crosstalk analysis; interactions between the clocks will not be explored. If clocks are logically exclusive, the crosstalk computation will be computed normally (synchronously if the clocks are synchronous) even though the timing paths between the clocks are not reported.

Multiple relationship types can exist between two clocks. When this happens, the relationships obey the following precedence:

** physically exclusive (highest)*
** asynchronous*
** logically exclusive (lowest)*

These precedence rules reflect the real physical behavior of the resulting circuit. For example, if two clocks are asynchronous but they are never simultaneously present, then no crosstalk should be computed.

Note that the traditional set_false_path exception between clocks will not result in infinite window crosstalk computation between two clocks. If multiple clocks are asynchronous with each other, the asynchronous relationship should be specified with set_clock_groups. Failure to specify this relationship for asynchronous clocks could result in an optimistic analysis!

A special -allow_paths modifier can be used with the -asynchronous option. When used, the clocks are assumed to have an infinite window relationship for crosstalk purposes, but timing paths between the clocks will be treated normally. When using this option, paths between the clock domains can be manually disabled using the set_false_path command.

When a clock pair is defined such that it has false paths (using either physically or logically exclusive or asynchronous) but subsequently modified to have -asynchronous -allow_paths, then this is an error and the first definition holds. In the reverse situation, also the redefinition to false paths from -allow-paths between the clock pairs would also be an error. Please refer message UITE-457 and UITE-458.

You should not also set a false path if you have already specified two clocks as exclusive or asynchronous. An error message is issued if you attempt to set a false path between two clocks which are already exclusive or asynchronous. If a false path was previously set between two clocks when an exclusive or asynchronous relationship is applied, the false path is overwritten by the

set_clock_groups command. Other exceptions are unaffected.

A clock relationship on a master clock will not automatically propagate to any generated clocks. If the relationship should also apply to generated clocks, they should be explicitly included in the set_clock_groups command.

To undo the **set_clock_groups** command, use the **remove_clock_groups** command. To report the clock groups defined in a design, use the **report_clock** command with the **-groups** option.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example defines two asynchronous clock domains.

```
prompt> set_clock_groups -asynchronous -name g1 -group CLK33 -group CLK50
```

The following example defines a clock named *TESTCLK* to be asynchronous with all other clocks in the design:

```
prompt> set_clock_groups -asynchronous -group TESTCLK
```

The following example shows how to simultaneously analyze multiple clocks per register without manually specifying false paths. Assume two pairs of mutually-exclusive clocks that are multiplexed:

CLK1 and *CLK2*
CLK3 and *CLK4*.

If each pair of clocks is selected by a different signal, you must execute two **set_clock_groups** commands to specify two independent exclusivity relationships, one for each MUX selection signal:

```
prompt> set_clock_groups -physically_exclusive -group CLK1 -group CLK2
prompt> set_clock_groups -physically_exclusive -group CLK3 -group CLK4
```

If each pair of clocks is selected by a single MUX selection signal, you would execute only one **set_clock_groups** command to simultaneously analyze all four clocks.

```
prompt> set_clock_groups -physically_exclusive -group {CLK1 CLK3} -group {CLK2 CLK4}
```

In this case, we are not implying any type of relationship between CLK1-CLK3 or CLK2-CLK4. For example, f CLK1 and CLK3 were also asynchronous with each other, we would need to specify an additional relationship between them.

set_clock_jitter

Sets the duty-cycle jitter and/or the cycle clock jitter.

SYNTAX

status **set_clock_jitter**
-clock *clock_list*
[-cycle *cycle_to_cycle_jitter*]
[-duty_cycle *duty_cycle_jitter*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]

Data Types

clock_list list
cycle_to_cycle_jitter float
duty_cycle_jitter float

ARGUMENTS

-clock *clock_list*

Specifies a list of clock on which to set the clock jitter.

-cycle *cycle_to_cycle_jitter*

Specifies the cycle-to-cycle jitter on the clock.

-duty_cycle *duty_cycle_jitter*

Specifies the duty-cycle jitter on the clock.

-modes *mode_list*

Specifies the scenarios to which the path margin delay value is applied. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners *corner_list*

Specifies the scenarios to which the path margin delay value is applied. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios *scenario_list*

Specifies the scenarios to which the path margin delay value is applied. The **-modes** or **-corners** option must not be given with this option.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

DESCRIPTION

This command specifies the cycle-to-cycle jitter and the duty-cycle jitter on a primary master clock(a clock that is not a generated clock itself), or a generated clock that is defined with the **-multiply_by** option.

Cycle-to-cycle jitter models the variation between the edges that are in-phase. In other words, it models the variation between the edges that are multiple clock cycles apart.

Duty-cycle jitter models the variation between the edges that are out-of-phase. In other words, they are 0.5, 1.5, 2.5, and so on, cycles apart.

Duty-cycle jitter and cycle-to-cycle jitter are realized between the launch clock and the capture clock that are both generated from the same master clock. To figure out the right clock jitter value between the launch clock and capture clock, we trace the launch edge and the capture edge to corresponding edges of the master clock. There are three cases to consider:

1. If the corresponding edges of the master clock are multiple cycles apart. cycle-to-cycle jitter is realized.
2. If they are not and integral number of cycles apart. duty-cycle jitter is realized.
3. If they are traced back to the same edge of the master clock. no clock jitter is realized.

In crosstalk analysis, clock jitter does not change the arrival windows used in overlap analysis. However, in level-sensitive latch designs, latches can start borrowing in the presence of clock jitter, leading to changes in delta delays for logic nets in the fanout of affected latches.

Please note that the generated clocks defined with the **-multiply_by** option do not inherit the clock jitter from their master clocks.

To remove the clock jitters set by the **set_clock_jitter** command, use the **remove_clock_jitter** command.

To view clock jitter information, use the **report_clock_jitter** command.

EXAMPLES

The following example specifies a cycle-to-cycle jitter of 0.5 and duty-cycle jitter of 0.7 on the clock mclk

prompt> **set_clock_jitter -clock [get_clocks mclk] -cycle 0.5 -duty_cycle 0.7**

set_clock_latency

Specifies the latency of a clock network.

SYNTAX

string **set_clock_latency**
[-clock *clock_list*]
[-rise]
[-fall]
[-min]
[-max]
[-source]
[-offset]
[-late]
[-early]
[-dynamic *dynamic_component_of_delay*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
delay
object_list

Data Types

clock_list	list
dynamic_component_of_delay	float
mode_list	list
corner_list	list
scenario_list	list
delay	float
object_list	list

ARGUMENTS

-clock *clock_list*

Specifies a list of clock objects to be associated with the latency that is placed on all pin/port objects in *object_list*. If the **-clock** option is supplied when *object_list* refers to clock objects, a warning is issued that the option is not relevant in this case and execution of the command proceeds as if **-clock** was not specified. A more specific clock latency setting overrides a more general one.

-rise

Specifies the clock rise latency.

-fall

Specifies the clock fall latency.

-min

Specifies the clock latency for the minimum operating condition.

-max

Specifies the clock latency for the maximum operating condition.

-source

Specifies the clock source latency. The **-offset** option must not be specified with this option.

-offset

Specifies the offset latency at clock network sink or clock pin of ICG cells. The **-source** option must not be specified with this option.

-late

Specifies the clock late latency.

-early

Specifies the clock early latency.

-dynamic ***dynamic_component_of_delay***

Specifies the dynamic component of clock source latency value.

-modes ***mode_list***

Specifies the scenarios to which the latency value is applied. If this option is given, all scenarios of the specified modes will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners ***corner_list***

Specifies the scenarios to which the latency value is applied. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios ***scenario_list***

Specifies the scenarios to which the latency value is applied. The **-modes** or **-corners** option must not be specified with this option.

delay

Specifies the clock latency value.

object_list

Specifies the clocks, ports, or pins.

DESCRIPTION

This command specifies clock latency for a design. Two types of clock latency can be specified for a design: clock network latency and clock source latency.

The clock network latency is the time required for a clock signal to propagate from the clock definition point to a register clock pin. The rise and fall latencies are the latencies for rising and falling transitions at the register clock pin, respectively. Inversion of the clock waveform, if present in the clock network, is not taken into consideration when computing clock network latencies at register clock pins. Note that this behavior is different than it was in previous releases.

Clock source latency is the time required for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. It can be used to model off-chip clock latency when the clock generation circuit is not part of the current design. You can use clock source latency for generated clocks to model the delay from master-clock to generated-clock definition point.

Dynamic clock latency is the component of the total clock source latency which is considered 'dynamic' in nature. A 'dynamic' value can differ along successive clock cycles and can only be used to calculate CRP if a zero-cycle path is being considered. A zero-cycle path is one in which the same clock edge both launches and captures.

The dynamic component of any clock latency can be specified using the **-dynamic** switch. It can only be specified if the **-source** switch and total clock latency is also specified with the command. Source latency, with dynamic component, can be specified for clocks and clock sources(pins/ports). For clock sources, it must be specified with a relative clock using **-clock** option.

The tool assumes ideal clocking, which means clocks have a specified network latency designated by the **set_clock_latency** command, or zero network latency, by default. Propagated clock network latency, designated by the **set_propagated_clock** command, is normally used for post-layout after final clock tree generation. Ideal clock network latency provides an estimate of the clock tree for pre-layout.

You can specify clock source latency for ideal or propagated clocks. The total clock latency at a register clock pin is the sum of clock source latency and clock network latency. If the rise and fall latencies are different, then the source latencies for a latch are picked based on the sense at the clock port and network latencies are picked based on the sense at the latch clock pin. Thus, source latency takes into account the clock inversions on the clock network, but network latency does not.

In the on-chip analysis mode, the min/max operating conditions are the variation bounds within the single corner analysis. Therefore, only the min-early and max-late latencies are used for the analysis. In the on_chip_variation mode, it is sufficient to specify either **-early**/**-late** options or **-min**/**-max** options for **set_clock_latency**.

Clock latency is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different latency values for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is specified, the command applies to all of the specified scenarios.

If the **-modes** option is specified, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is specified, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are specified, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

For internally-generated clocks, the tool automatically computes the clock source latency provided that the master clock of the generated clock has propagated latency and no user-specified value for the generated clock source latency exists. If the master clock is ideal, the master clock has source latency, and there is no user-specified value for the generated clock's source latency, then zero source latency is assumed.

If the **set_clock_latency** command is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports. Directly setting a network latency makes the affected registers ideal. A warning is issued if the **set_propagated_clock** command has previously set a propagated attribute on the same clock, pin, or port object. Clock source latencies are allowed only on clocks and clock source pins.

No check will be performed at the UI level that a clock specified with **-clock** passes through the pin or pins referenced in object_list

or not. If the clock specified does not pass through the pin, the command will have no effect but no warning of this fact is given.

To undo **set_clock_latency**, use the **remove_clock_latency** command.

To see clock network and source latency information (including dynamic component), use the **report_clocks** command with the **-skew** option.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example specifies a rise latency of **1.2** and a fall latency of **0.9** for a clock named **CLK1**.

```
prompt> set_clock_latency 1.2 \
  -rise [get_clocks CLK1]
prompt> set_clock_latency 0.9 \
  -fall [get_clocks CLK1]
```

The following example specifies an early rise and a fall source latency of **0.8** and a late rise and fall source latency of **0.9** for a clock named **CLK1**.

```
prompt> set_clock_latency 0.8 -source \
  -early [get_clocks CLK1]
prompt> set_clock_latency 0.9 -source \
  -late [get_clocks CLK1]
```

The following example specifies an early and late source latency of 3 and 5 respectively with dynamic components of 0.5.

```
prompt> set_clock_latency 3 -source \
  -early -dynamic 0.5 [get_clocks CLK1]
prompt> set_clock_latency 5 -source \
  -late -dynamic 0.5 [get_clocks CLK1]
```

The following example specifies an early and late source latency of 3 and 5 respectively with dynamic components of 0.5 on clock source port CLK with relative clock CLK1.

```
prompt> set_clock_latency 3 -source \
  -early -dynamic 0.5 -clock [get_clocks CLK1] [get_ports CLK]
prompt> set_clock_latency 5 -source \
  -late -dynamic 0.5 -clock [get_clocks CLK1] [get_ports CLK]
```

The following example specifies the source and the network latencies for three corners of the current mode: corner1, corner2 and corner3. The source latency for CLK1 for corner1 is set to 4 and network latency to 1.

```
prompt> set_clock_latency 4 -source \
  [get_clocks CLK1] -corners [get_corners {corner1}]
prompt> set_clock_latency 5 -source \
  [get_clocks CLK1] -corners [get_corners {corner2 corner3}]
prompt> set_clock_latency 1 [get_clocks CLK1]
prompt> set_clock_latency 2 [get_clocks CLK1] -corners [get_corners {corner2}]
prompt> set_clock_latency 3 [get_clocks CLK1] -corners [get_corners {corner3}]
```

set_clock_routing_rules

Specifies routing rules used in clock tree synthesis.

SYNTAX

status **set_clock_routing_rules**
[-clocks *clock_list*]
[-nets *net_list*]
[-net_type all | sink | internal | root]
[-min_routing_layer *min_layer*]
[-max_routing_layer *max_layer*]
[-rules *ndr_rule*]
[-default_rule]

Data Types

clock_list collection
net_list collection
min_layer string
max_layer string
ndr_rule string

ARGUMENTS

-clocks *clock_list*

Specifies the clock trees on which to apply the routing rule. You cannot specify generated clocks.

If you do not specify this option, the rule is applied to all clock trees in the design.

This option and the **-nets** option are mutually exclusive.

-nets *net_list*

Specifies the nets on which to apply the routing rule. The rules are propagated through the derived nets.

This option and the **-clocks** option are mutually exclusive.

-net_type *all* | *sink* | *internal* | *root*

Specifies the type of nets on which to apply the routing rule. The valid values are

- **sink** - the nets that connect to one or more clock leaf pins
- **root** - the nets that are driven by the clock source When synthesis inserts buffers, this type applies to the buffer chain before branching out.

- **internal** - the rest of the nets in the clock tree
- **all** (the default) - all nets

This option cannot be used with the **-nets** option.

-min_routing_layer ***min_layer***

Specifies the minimum routing layer for this clock routing rule. Specify the routing layer by using the layer names from the technology file; you can specify only one layer.

-max_routing_layer ***max_layer***

Specifies the maximum routing layer for this clock routing rule. Specify the routing layer by using the layer names from the technology file; you can specify only one layer.

-rules ***ndr_rule***

Specifies a nondefault routing rule used in clock tree synthesis. To define a nondefault routing rule, use the **create_routing_rule** command.

-default_rule

Applies the default routing rule to the clock nets.

DESCRIPTION

This command assigns the routing rules used in clock tree synthesis. You can associate a rule with specific clocks or nets. If a net already has a nondefault routing rule, this rule is also honored.

EXAMPLES

The following example assigns a nondefault rule named dblespacing to the sink-level nets of the clk1 clock.

```
prompt> set_clock_routing_rules -clocks clk1 -net_type sink \
  -rules dblespacing
```

SEE ALSO

remove_routing_rules(2)
report_clock_routing_rules(2)
report_routing_rules(2)
set_routing_rule(2)

set_clock_sense

The set_clock_sense command is deprecated. Use the set_sense command instead.

Multicorner-Multimode Support

This command works only on the current mode.

SEE ALSO

set_sense(2)
remove_sense(2)

set_clock_transition

Specifies the transition time for register clock pins.

SYNTAX

string **set_clock_transition** [-rise]
[-fall]
[-min]
[-max]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
transition
clock_list

mode_list list
corner_list list
scenario_list list
transition float
clock_list list

ARGUMENTS

-rise

Specifies clock transition time for rising clock edge.

-fall

Specifies clock transition time for falling clock edge.

-min

Specifies clock transition time for minimum conditions.

-max

Specifies clock transition time for maximum conditions.

-modes *mode_list*

Specifies the scenarios to which the transition time is applied. If this option is given, all scenarios of the specified modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners are used.

-corners *corner_list*

Specifies the scenarios to which the transition time is applied. If this option is given, all scenarios of the specified corners and the current mode are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners are used.

-scenarios ***scenario_list***

Specifies the scenarios to which the transition time is applied. The **-modes** or **-corners** option must not be specified with this option.

transition

Specifies transition time of clock pins.

clock_list

Provides a list of clocks in the design. The transition times on all register clock pins in the transitive fanout of specified clock are affected. You can only specify clocks with ideal latency in the list. When register clock pins in the fanout of a clock are marked with propagated latency, **set_clock_transition** values are ignored.

DESCRIPTION

This command overrides the calculated transition times on clock pins of registers.

This command is especially useful for pre-layout when clock trees are incomplete and calculated transition times at register clock pins can be highly pessimistic. The transition value specified with this command overrides the transition times of all nets directly feeding a sequential element clocked by the specified clock.

Use the **set_clock_transition** command only with ideal clocks. For propagated clocks, the calculated transition times are used. Propagated clocks are only set after the final clock tree is constructed.

If a clock transition is not specified for an ideal clock, and if the **time.ideal_clock_zero_default_transition** application option is **true** (the default), zero transition is used. Otherwise, the transition time is calculated as it is for other pins in the design.

Clock transition data is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different transitions for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the specified transition is applied to the current scenario. The command issues an error if there is no current scenario. If the **-scenarios** option is specified, the transition is applied to all of the specified scenarios. If the **-modes** option is specified, the transition will be applied to all scenarios of the specified modes. The command issues an error if none of the specified modes have any scenarios. If the **-corners** option is specified, the transition will be applied to all scenarios of the specified corners and the current mode. The command issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are specified, the transition is applied to all scenarios of the specified corners and the specified modes. The command issues an error if there are no such scenarios. It is an error to give -scenarios with **-modes** or **-corners**.

To undo **set_clock_transition**, use **remove_clock_transition**.

To list all clock transition values which have been set, use **report_clocks -skew**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

This example specifies a rise transition time of 0.38 and fall transition time of 0.25 for register clock pins clocked by "CLK1".

```
prompt> set_clock_transition 0.38 -rise [get_clocks CLK1]
prompt> set_clock_transition 0.25 -fall [get_clocks CLK1]
prompt> set_clock_transition 0.35 -corners [get_corners C1] [get_clocks CLK1]
prompt> set_clock_transition 0.45 -fall -corners [get_corners C2] [get_clocks CLK1]
```

set_clock_tree_options

Set target skew/latency constraints for clock trees.

SYNTAX

status **set_clock_tree_options**
[-clocks *clock_list*]
[-corners *corner_list*]
[-target_skew *skew_value*]
[-target_latency *latency_value*]
[-copy_exceptions_across_modes]
[-from_mode *original_mode*]
[-to_mode *mode_list*]
[-root_ndr_fanout_limit *fanout_limit_value*]
[-max_incr_repeater_levels *level_value*]]

Data Types

clock_list list or collection
corner_list list or collection
mode_list list or collection
original_mode object
skew_value float
latency_value float
fanout_limit_value integer
level_value integer

ARGUMENTS

-clocks *clock_list*

Specifies the clock trees to which target skew/latency is applied. If not specified, the constraints are applied to all clocks.

-corners *corner_list*

Specifies the corners to which target skew/latency is applied. If not specified, the constraints are applied to current corner.

-target_skew *skew_value*

Specifies the required value for maximum skew for the specified clock trees. The default value for this option is 0.

-target_latency *latency_value*

Specifies the minimum early insertion delay constraint for the specified clock trees. There is no default value for this option.

-copy_exceptions_across_modes

Enables the automatic copying of CTS balance points (considered for balancing) settings from the mode specified by the **-from_mode** option to the mode specified by the **-to_mode** option.

You must specify the **-copy_exceptions_across_modes**, **-from_mode**, and **-to_mode** options together.

You can specify only one group of **-from_mode** and **-to_mode** settings. If additional groups are needed, they need additional commands. The modes across different groups must be mutually exclusive.

The same corner that the balance point was defined on must be present in the mode specified by the **-to_mode** option for the copy to be successful.

-from_mode ***original_mode***

Specifies the mode from which to copy to CTS balance points. You can specify only one mode.

You must specify the **-copy_exceptions_across_modes**, **-from_mode**, and **-to_mode** options together.

-to_mode ***mode_list***

Specifies the modes to which to copy the CTS balance points. You can specify one or more modes.

You must specify the **-copy_exceptions_across_modes**, **-from_mode**, and **-to_mode** options together.

-root_ndr_fanout_limit ***fanout_limit_value***

Specifies the boundary on the clock nets where root NDR/layer or internal NDR/layer should be applied, depending on the number of transitive fanout of the clock net driver. The transitive fanouts include register CK pin that are valid sinks and does not include ignore pins and they are counted per master clock. If a net driver is on multiple (master) clock domain, the max of downstream transitive fanouts for each clock domain will be considered. If the downstream transitive fanout of a net driver is larger than or equal to this user-specified fanout limit, root NDR/layer would be used for that net; If the downstream transitive fanout of a net driver is smaller than this user-specified fanout limit, internal NDR/layer would be used for that net; This is also called fanout-based ndr.

-max_incr_repeater_levels ***level_value***

Specifies the maximum number of incrementally added repeater level during concurrent clock and data (CCD) optimization, depending on the repeater level of each sink. The **-clock** option could be used together to specify clock. Newer setting will overwrite the older one on the same clock and be treated the same as the first time it's being set.

DESCRIPTION

Specifies settings like target skew/latency for clocks, exception duplication across modes or fanout-based ndr limit.

If target skew is specified, clock tree synthesis engine minimizes skew to meet the specified target. After this target is met, the optimization concentrates more on other QoR goals, such as insertion delay and area.

If target latency is specified, clock tree synthesis engine minimizes latency to meet the specified target. After this target is met, the optimization concentrates more on other QoR goals, such as skew and area. If the insertion delay of this initial optimized clock tree is smaller than the specified value, the clock tree synthesis engine adds a chain of cells from the reference list as needed to meet this delay.

If fanout-based ndr is specified, clock tree synthesis engine will apply root/internal rules based on the limit setting. The sink ndr rule will not be affected and remain as sink ndr rule. Small net (e.g., bbox < 10um) will still have internal rules even if its fanout is larger than limit.

To report target skew/latency constraint settings, use **report_clock_tree_options**.

To remove target skew/latency constraints, use **remove_clock_tree_options**.

To report fanout-based ndr settings, use **report_clock_tree_options**.

To remove fanout-based ndr settings, use **remove_clock_tree_options**.

Multicorner-Multimode Support

EXAMPLES

The following example sets a target skew of 2.0 units for clock clk1.

prompt> **set_clock_tree_options -target_skew 2.0 -clock clk1**

The following example sets a target latency of 4.0 units for all clocks.

prompt> **set_clock_tree_options -target_latency 4.0**

SEE ALSO

report_clock_tree_options(2)

set_clock_tree_reference_subset

Specifies reference cells to be used in clock tree synthesis.

SYNTAX

status **set_clock_tree_reference_subset**
[-clocks *clock_list*]
[-lib_cells *references*]

Data Types

clock_list collection
references collection

ARGUMENTS

-clocks *clock_list*

Specifies the clock trees for which the lib_cells will be applied. A generated clock is not accepted in this command. This option is mandatory with **-lib_cells** option.

-lib_cells *references*

Specifies the list of references to be used in clock trees.

DESCRIPTION

The command specifies buffers, inverters, and clock gates to be used for clock tree synthesis. Specifying several references allows the clock tree synthesis engine more flexibility to build clock trees and provides improved clock tree results.

Clock tree synthesis will pick up lib_cells from intersection of **set_lib_cell_purpose -include cts <lib-cells>** and **set_clock_tree_reference_subset**.

You can use the **-clocks** option to apply reference lists on a per-clock basis. You can specify clock gates as reference cells during optimization for cell sizing. To size a gate, equivalent gates from reference lists are used.

If you issue the **set_clock_tree_references_subset** command several times for the same clock tree, the new references you specify will over write existing references for that clock tree. You can view the references of a given clock tree by using the **report_clock_tree_reference_subset** command. To remove references, use the **remove_clock_tree_reference_subset** command.

Clock tree synthesis will pick up union of lib_cells for overlapping clocks with clock-specific reference_subsets.

EXAMPLES

The following example specifies buf1 lib cell for clock tree synthesis for clock tree clk1.

prompt> **set_clock_tree_references_subset -clocks clk1 -lib_cells buf1**

SEE ALSO

set_lib_cell_purpose(2)
report_clock_tree_reference_subset(2)
remove_clock_tree_reference_subset(2)

set_clock_trunk_endpoints

Specifies pins or ports as clock trunk endpoints for clock trunk planning.

SYNTAX

status **set_clock_trunk_endpoints**
[-clock *clocks*]
[-corners *corners*]
[-delay *delay_behind_endpoint*]
[-auto_clock connected | local | all]
pins_or_ports

Data Types

clocks	collection
corners	list
delay_behind_endpoint	float
pins_or_ports	collection

ARGUMENTS

-clock *clocks*

Specifies the clocks for which to create specific endpoints. By default the specified endpoints apply to all clocks.

-corners *corners*

Specifies the corners for which to create specific endpoints. By default, the specified endpoints apply to all corners.

-delay *delay_behind_endpoint*

Specifies the phase delay from the endpoint to the clock sinks which should be assumed for clock trunk planning. If no phase delay is given, the phase delay is undefined and clock trunk planning estimates the phase delay.

pins_or_ports

Specifies the pins or ports to define as a clock trunk endpoint.

-auto_clock connected | local | all

Associates clocks at the block level with clocks at the top level. For example, your top-level clock might be called "SYS_CLK", and the same clock in the block might be called "CLK". You can set the association between block clock and top clock by using the **set_block_to_top_map** command, or by using **set_clock_trunk_endpoints -auto_clock** and specifying the same rule. See the **set_block_to_top_map** man page for more details. Note that the **-clocks** and **-auto_clock** options are mutually exclusive. You can select one of three rules for auto-clock mapping:

- **connected** - The "connected" rule associates block-level clocks with top-level clocks under the following conditions: If a block clock has its source at a block port (a boundary clock), it can be associated to a top-level clock that propagates to that port. If a block clock has its source on an internal pin sources (a local clock), the top-level clock source must be declared at the same pin.
- **local** - The "local" rule maps connected clocks. In addition, if a block clock has its source on an internal pin sources (a local clock) and has no associated top-level clock, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock.
- **all** - The "all" rule maps clocks as in the "local" rule. In addition, if a block clock has its source at a block port (a boundary clock) and no top-level clock propagates to that port, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock. The top-level boundary clock will allow timing analysis to be done, but it is not necessarily correct for signoff. You should consider removing or replacing this clock before signoff.

Note that if two block-level clocks are declared at the same boundary port, the "all" rule cannot resolve both of them. This is because it will not automatically declare two conflicting clocks in the top-level block. You must manually declare two top-level clocks, with the appropriate waveforms. After the top clocks exist, **-auto_clock** mapping can associate them with the block clocks.

DESCRIPTION

This command defines pins or ports as clock trunk endpoints for clock trunk planning. The clock trunk endpoints can be clock-specific. If you do not specify **-clock**, the tool applies the endpoint to all clocks.

In addition, you can specify a delay value from the endpoint to the clock sinks (flip-flops and other clocked cells) which should be assumed during clock trunk planing.

EXAMPLES

This example specifies block1/CLK as a clock trunk endpoint, and specifies a phase delay of 20 on the port.

```
prompt> set_clock_trunk_endpoints block1/CLK -delay 20
1
```

set_clock_uncertainty

Specifies the uncertainty (skew) of specified clock networks.

SYNTAX

string **set_clock_uncertainty**
uncertainty
[*object_list* |
-from *from_clock*
| -rise_from *rise_from_clock*
| -fall_from *fall_from_clock*
-to *to_clock*
| -rise_to *rise_to_clock*
| -fall_to *fall_to_clock*]
[-rise]
[-fall]
[-setup]
[-hold]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]

Data Types

uncertainty float
object_list list
from_clock list
rise_from_clock list
fall_from_clock list
to_clock list
rise_to_clock list
fall_to_clock list
mode_list list
corner_list list
scenario_list list

ARGUMENTS

-from *from_clock*

Specifies the source clock for interclock uncertainty. You must specify either the pair of **-from**/**-rise_from**/**-fall_from** and **-to**/**-rise_to**/**-fall_to**, or *object_list*; you cannot specify both.

-rise_from *rise_from_clock*

Same as the **-from** option, but indicates that *uncertainty* applies only to rising edge of the source clock. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-fall_from *fall_from_clock*

Same as the **-from** option, but indicates that *uncertainty* applies only to falling edge of the source clock. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-to *to_clock*

Specifies the destination clock for interclock uncertainty. You must specify either the pair of **-from**/**-rise_from**/**-fall_from** and **-to**/**-rise_to**/**-fall_to**, or *object_list*; you cannot specify both.

-rise_to *rise_to_clock*

Same as the **-to** option, but indicates that *uncertainty* applies only to rising edge of the destination clock. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-fall_to *fall_to_clock*

Same as the **-to** option, but indicates that *uncertainty* applies only to falling edge of the destination clock. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

object_list

Specifies a list of clocks, ports, or pins for simple uncertainty. The uncertainty is applied either to capturing latches clocked by one of the clocks in *object list*, or capturing latches whose clock pins are in the fanout of a port or pin specified in *object_list*. You must specify either the pair of **-from** and **-to** options, or *object_list*; you cannot specify both.

-rise

Applies *uncertainty* to only the rising edge of the destination clock. By default, the uncertainty applies to both rising and falling edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-rise_to** instead.

-fall

Applies *uncertainty* to only the falling edge of the destination clock. By default, the uncertainty applies to both rising and falling edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-fall_to** instead.

-setup

Indicates that *uncertainty* applies only to setup checks. By default, *uncertainty* applies to both setup and hold checks.

-hold

Indicates that *uncertainty* applies only to hold checks. By default, *uncertainty* applies to both setup and hold checks.

-modes *mode_list*

Specifies the scenarios that the uncertainty value will be applied to. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option must not be specified together with **-modes**. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners *corner_list*

Specifies the scenarios that the uncertainty value will be applied to. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option must not be specified together with **-corners**. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios *scenario_list*

Specifies the scenarios that the uncertainty value will be applied to. The **-modes** or **-corners** option must not be specified together with **-scenarios**.

uncertainty

Specifies the uncertainty value. *uncertainty* is a floating point number. Typically, clock uncertainty should be positive. Negative uncertainty values are supported for constraining designs with complex clock relationships. Setting the uncertainty value to a negative number could lead to optimistic timing analysis and should be used with extreme care.

DESCRIPTION

Specifies the clock uncertainty (skew characteristics) of the specified clock networks. This command can specify either interclock uncertainty or simple uncertainty. For interclock uncertainty, use the **-from**/**-rise_from**/**-fall_from** and **-to**/**-rise_to**/**-fall_to** options to specify the source clock and the destination clock; all paths between these receive the uncertainty value. For simple uncertainty, use *object_list*; the uncertainty value is either to capturing latches clocked by one of the clocks in *object list*, or capturing latches whose clock pins are in the fanout of a port or pin specified in *object_list*.

Set the uncertainty to the worst skew expected to the endpoint or between the clock domains. You can increase the value to account for additional margin for setup and hold.

When you specify interclock uncertainty, ensure that you specify it for all possible interactions of clock domains. For example, if you specify paths from CLKA to CLKB and CLKB to CLKA you must specify the uncertainty for both, even if the values are the same. For an example, see the EXAMPLES section.

Interclock uncertainty is more specific than simple uncertainty. If a command that specifies interclock uncertainty conflicts with a command that specifies simple uncertainty, the command that specifies interclock uncertainty takes precedence. For an example, see the EXAMPLES section.

If there is no applicable interclock uncertainty for a path, the value for simple uncertainty is used. For an example, see the EXAMPLES section.

Clock uncertainty is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different uncertainties for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the given uncertainty is applied to the current scenario. The command issues an error if there is no current scenario. If the **-scenarios** option is given, the uncertainty will be applied to all of the specified scenarios. If the **-modes** option is given, the uncertainty will be applied to all scenarios of the specified modes. The command issues an error if none of the specified modes have any scenarios. If the **-corners** option is given, the uncertainty will be applied to all scenarios of the specified corners and the current mode. The command issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the uncertainty will be applied to all scenarios of the specified corners and the specified modes. The command issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

To remove the uncertainties set by **set_clock_uncertainty**, use the **remove_clock_uncertainty** command.

To view clock uncertainty information, use the **report_clocks -skew** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example specifies that all paths leading to registers or ports clocked by CLK have setup uncertainty of 0.65 and hold uncertainty of 0.45.

```
prompt> set_clock_uncertainty -setup 0.65 [get_clocks CLK]
prompt> set_clock_uncertainty -hold 0.45 [get_clocks CLK]
```

The following example specifies interclock uncertainties between PHI1 and PHI2 clock domains.

```
prompt> set_clock_uncertainty 0.4 -from PHI1 -to PHI1
prompt> set_clock_uncertainty 0.4 -from PHI2 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI1 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI2 -to PHI1
```

The following example specifies interclock uncertainties between PHI1 and PHI2 clock domains with specific edges.

```
prompt> set_clock_uncertainty 0.4 -rise_from PHI1 -to PHI2
prompt> set_clock_uncertainty 0.4 -fall_from PHI2 -rise_to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI1 -fall_to PHI2
```

The following example shows conflicting **set_clock_uncertainty** commands, one for simple uncertainty and one for interclock uncertainty. The interclock uncertainty value of 2 takes precedence.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
prompt> set_clock_uncertainty 2 -from [get_clocks CLKB] -to [get_clocks CLKA]
```

The following example specifies the uncertainty from CLKA to CLKB and from CLKB to CLKA. Notice that both must be specified even though the value is the same for both.

```
prompt> set_clock_uncertainty 2 -from [get_clocks CLKA] -to [get_clocks CLKB]
prompt> set_clock_uncertainty 2 -from [get_clocks CLKB] -to [get_clocks CLKA]
```

The following example illustrates a situation in which simple uncertainty is used when there is no applicable interclock uncertainty for a path. The first command specifies a simple uncertainty of 5 for CLKA paths, and the second command specifies an interclock uncertainty of 2 for paths from CLKB to CLKA. If there are paths between CLKA and other clocks (for example, CLKC, CLKD, ...) for which interclock uncertainty has not been specifically defined, the simple uncertainty (in this case, 5) is used.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
prompt> set_clock_uncertainty 2 -from [get_clocks CLKB] -to [get_clocks CLKA]
```

remove_clock_uncertainty(2)
report_clocks(2)
set_clock_latency(2)
set_clock_transition(2)

set_colors

Sets a user-specified color on objects and their child objects.

SYNTAX

int **set_colors**
[-color *color_id*]
[-color_name *color_name*]
[-cycle_color]
[-hierarchy_types all | normal | boundary | soft_macro]
[-depth *hierarchy_depth*]
[-keep]
[*object_list*]

Data Types

color_id integer
color_name string
hierarchy_depth integer
object_list collection

ARGUMENTS

-color *color_id*

Specifies a color ID, which is used to set a color on objects. Valid *color_id* values are integers from 1 to 64.

-color_name *color_name*

Specifies a color name, which is used to set a color on objects. Valid values are: purple, blue, green, orange, red, light_purple, light_blue, light_green, light_orange, and light_red.

-cycle_color

Generates automatically different colors for each given hierarchical cell and the cells descended from the hierarchical cell, or for each given voltage area and the cells associated with the voltage area. If **-color** is also given, the color starts from the given ID. If **-color** is not given, the color starts with the ID following the last used color ID during auto-cycling.

A color ID is used to color all leaf cells in the given collection of cells, or all leaf cells owned by the top design if no collection is given. The ID is then incremented and is used to color the first hierarchical cell in the collection and its descendents, or the first voltage area and the associated cells. The ID is then incremented again and is used to color the second hierarchical cell in the collection and its descendents, or the second voltage area and its cells, and so on.

-hierarchy_types all | normal | boundary | soft_macro

Colors the hierarchical cells of the specified type. The command traverses the design hierarchy starting from the given cells to the

depth given by the **-depth** option argument and colors hierarchical cell of the given types with different colors. The allowed types are *normal*, *boundary*, *soft_macro*, or *all*. The last value, *all*, matches any hierarchical cell type.

If no cell collection argument is given, traversal of the hierarchy begins from the top design. If a cell collection is given, all hierarchical cells of given type in the given collection are colored with cycled colors.

If no **-depth** option argument is given but a cell collection is given, then the default depth of *0* is used, coloring hierarchical cells in the given cell collection. If neither a **-depth** option argument or a cell collection are given, then the default depth of *1* is used, coloring hierarchical cells that are the immediate children of the top design.

The **-hierarchy_types** option implies **-cycle_color**.

-depth *hierarchical_depth*

Specifies the levels of hierarchy to traverse to find hierarchical cells to color. This option is only meaningful when given with the **-hierarchy_types** option. The command traverses the design hierarchy starting from the given cells to the *hierarhcical_depth* value given to find cells of matching type to color.

A depth value of *0* traverses only the given cells. A depth value of *1* traverses the immediate children of the given cells. The special depth value of *all* means to traverse the hierarchy all the way to leaf descendents to find cells of the given type to color.

-keep

This option specifies that if a cell already has a color attribute, leave the current color undisturbed. This option is useful when incrementally adding object coloring.

object_list

Specifies a collection of objects on which to set the colors. The collection can include cells, designs, and voltage areas. If omitted, colors are set on cells starting from the current top design.

DESCRIPTION

The **set_colors** command sets the colors on cells descended from top hierarchical cells in the current design, or hierarchical cells in the specified collection, or voltage areas and their cells. The colors set on objects are used to paint the objects in some graphic views, such as the Layout View or the Hierarchy View.

If *objects* are specified and contains cells, the command sets the color on all cells in the collection and all cells descended from hierarchical cells in the collection. If *objects* are specified and contains voltage areas, the command sets the color of all the voltages areas in the collection and the cells associated with the voltage areas. If *objects* are not specified, the command sets the color of all cells in the current design.

When **-color** is specified, the specified color is used. If it is not specified, then the current default color is used. The set_colors command uses colors from the highcontrast color palette.

When **-cycle_color** is given and *objects* contains cells, the command generates a different color for each hierarchical cell in the collection, and sets the color on all cells descended from that hierarchical cell. All non-hierarchical cells in the collection are colored with one color different from the hierarchical cell colors.

When **-cycle_color** is given and *objects* contains voltage areas, the command generates a different color for each voltage area in the collection, and sets the voltage area color on all cells associated with the voltage area.

When **-cycle_color** is specified without *objects*, the command generates a different color for each top-level hierarchical cell in the current design, and sets the color on all cells descended from these hierarchical cells.

Hierarchy traversal and cell coloring stops at an instance of a referenced design, such as a soft macro. The instance itself is colored, but its children will not be colored.

EXAMPLES

The following example generates different colors for each top hierarchical cell in the current design, and sets the color on all descended cells in the hierarchical cell:

```
prompt> set_colors -cycle_color
```

The following example sets different colors on all physical boundaries, including hierarchy boundaries and committed soft macros, in the top design:

```
prompt> set_colors -depth all \
    -hierarchy_types {boundary soft_macro} [get_designs]
```

The following example sets different colors on all normal hierarchies in the top design. Note that the top design is implied by omitting the cells on which to operate:

```
prompt> set_colors -depth all \
    -hierarchy_types normal
```

The following example sets the color on all immediate hierarchical child cells of I_ORCA_TOP:

```
prompt> set_colors -hierarchy_types all \
     -depth 1 [get_cells I_ORCA_TOP]
```

The following example sets the color with color ID 30 on I_ORCA_TOP and all of its descendant cells while leaving already colored cells untouched:

```
prompt> set_colors -color 30 \
     -depth all [get_cells I_ORCA_TOP]
```

The following example sets the color with color Id 8 on RES_I113 cell and all cells inside the RES_I113 hierarchical cell:

```
prompt> set_colors -color 8 [get_cells RES_I113]
```

The following example sets the color with color Id 7 on the voltage area named myVoltageArea, and all cells associated with the voltage area.

```
prompt> set_colors -color 7 [get_voltage_areas myVoltageArea]
```

SEE ALSO

remove_colors(2)
gui_get_color_value(2)

set_command_option_value

Set a command option default or current value.

SYNTAX

string **set_command_option_value**
-default | -current

-command *command_name*

-option *option_name* | -position *positional_option_position*

-value *value* | -undefined

ARGUMENTS

-default

Set the default option value.

-current

Set the current option value.

-command *command_name*

Set the option value for an option of this command.

-option *option_name*

Set the option value for this option of the command.

-position *positional_option_position*

Set the option value for this positional option of the command.

-value *value*

Set the option value to this value.

-undefined

Set the option value to the "undefined value".

DESCRIPTION

Sets the current or default value of a command option.

Either -default must be specified (to specify setting the default value of the option), or -current must be specified (to specify setting the current value of the option). Unlike for get_command_option_values, one of -current or -default must be specified for set_command_option_value.

An option of a command must be specified (for value setting) by passing a command name via -command and either an option name (for an option of the command) via -option, or the position of a positional option via -position. The *option_name* passed via -option (for a dash option) must not have its leading dash character omitted. An option name passed via -option may be either the name of a dash option or the name of a positional option. A positional option may be specified either via -option or via -position. Positional option positions of a command are numbered 0, 1, 2, ... (N-1), where N is the number of positional options of the command.

To set the (current or default) value of the option, a string value should be passed via -value. Alternatively, you can pass -undefined to reset the option to have the "undefined value". (CAVEAT: For some "set value implementations" for numeric options, -undefined does not really "undefine" the value - instead the value is set to 0.)

Processing of the -value value does not include any CCI option checking of the value (such as checking whether the option value has correct syntax for its type).

The command "throws" a Tcl error for various conditions:
* the command does not exist
* the command exists but no such option of the command exists
* the set operation failed (could be due to a failed conversion for one of the "set value" implementations which does a conversion from string to one of integer, double, etc.)

The -undefined option is a mutually exclusive alternative to the -value option. -undefined has the effect of resetting the option value to the "undefined value".

A possible power user application: power users could put set_command_option_value commands in their home directory Tcl startup files for their favorite dialogs/commands to "seed" initial current values for these dialogs. This may lower the need for automatically saving replay scripts (of set_command_option_value commands for each command/dialog option/field) on exit from the application.

EXAMPLES

The following example sets the current value for the -bar option of the foo command to a value of abc.

```
prompt> set_command_option_value -current -command foo \
  -option "-bar" -value abc
```

The following example sets the current value for the first positional argument of the foo command to a value of xyz.

```
prompt> set_command_option_value -current -command foo \
  -position 1 -value xyz
```

get_command_option_values(2)
preview(2)

set_consistency_settings_options

Sets the corresponding options for the **check_consistency_settings** command. We need to specify some executable image and related script file before we run command **check_consistency_settings**.

SYNTAX

status **set_consistency_settings_options**
[-exec_path *path*]
[-tool *type*]
[-script *filename*]
[-saved_session *directory*]
[-tluplus *tluplus_filename*]
[-corner *corner_name*]
[-star_corner *corner_name*]
[-early]

Data Types

path string
filename string
directory string
type string
corner_name string
corner_name string

ARGUMENTS

-exec_path *path*

Specifies the UNIX path to the shell executable, like pt_shell. The path should be absolute.

-tool

Indicates the executable image type. The valid values are PT, ICC, ICC2, StarRC, and PrimePower.

-script *filename*

Specifies a Tcl file or command file that is sourced by the executable tool immediately after the tool is invoked.

-saved_session *directory*

Specifies a directory which was generated by PrimeTime command 'save_session' previously.

Tool restores PrimeTime design status based upon this directory. Then, collect corresponding variable settings for correlation check between the implementation tool and PrimeTime.

Option '-script' will be override by this option if specified.

-tluplus *tluplus_filename*

Specifies a process technology file (TLUPlus) that is using for process information checking with the StarRC process technology file (nxtgrd). If not specifies TLUPlus file, then will skip process information checking. This feature only supports StarRC version 2015.12-SP2 or later and encrypted TLUPlus file version 16 or later, otherwise process information checking will skip with Error messages. Every versions of non-encrypted TLUPlus files are supported.

-corner

Specifies a corner name. The values could be any pre-defined system corner name. This option may only use for extraction consistency settings. Default value is current corner of current scenario.

-star_corner

Specifies a StarRC corner name. The values could be any pre-defined StarRC corner name in its SMC(Simulteneous Multi Corner) scripts. This option may only use for extraction consistency settings in case of StarRC corner name is different than the corner name in the implementation tool. Default value is same corner name as the default corner name or -corner <corner_name> if -corner option has used.

-early

Specifies a corner type (early/late). This option may only use for extraction consistency settings. Default value is type late.

DESCRIPTION

This command sets the executable location and related running scripts for **check_consistency_settings**. With these information, correlation checker will automatically collect the variables settings information and then do consistency check.

Multicorner-Multimode Support

This command uses information for current scenario. Or user may specify specific corner name and type (early/late) for extraction consistency settings.

EXAMPLES

The following example runs the **set_consistency_settings_options** command.

```
prompt> set_consistency_settings_options \
  -exec_path /PrimeTime/linux/syn/bin -tool pt -script example.tcl
prompt> set_consistency_settings_options \
  -exec_path /StarRC/linux/syn/bin -tool starrc -script example.tcl \
  -corner maxCorner
```

SEE ALSO

check_consistency_settings(2)

set_constant_register_removal

Sets the **remove_constant_register** attribute on the specified cells or modules, allowing removing of the constant registers.

SYNTAX

status **set_constant_register_removal**
obj_list
[true | false]

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of cell or module names for which to remove constant registers. Cell names in *obj_list* must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true | **false**

Specifies the value with which to set the **remove_constant_register** attribute. When this option is set to true (the default), constant register removal is enabled on the specified objects (cells or modules). Constant register removal is performed on the specified objects provided that the application option **compile.seqmap.remove_constant_registers** is set to true.

A setting of false on a module do not remove constant registers for the whole module. A setting of false on an instance do not remove constant registers for the whole instance.

DESCRIPTION

The **set_constant_register_removal** command sets the **remove_constant_register** attribute on the specified *obj_list*. This attribute is used to specify that the cells or modules are to be remove constant registers.

If a cell with a specified name is found in the current design, the **remove_constant_register** attribute is set to the specified value on the cell. If no cell with a specified name is found, the tool searches for a module and the attribute set on the module.

EXAMPLES

The following example shows how to enable register removal during optimization for the sequential cells named U0 and U1 and how to disable register removal for the U2 cell:

```
prompt> set_constant_register_removal {U0 U1} true
prompt> set_constant_register_removal U2 false
```

SEE ALSO

compile(2)
get_attribute(2)

set_constraint_mapping_file

Loads a map file that contains a list of blocks and corresponding UPF, SDC, DEF, timing budget, blackbox timing, CTS constraint or PG constraint files for the blocks.

SYNTAX

status **set_constraint_mapping_file**
[-reset]
filename

Data Types

filename string

ARGUMENTS

-reset

Resets the constraint map for the current design.

This option can be used independently to remove the map from the current design. It can also be used together with the *fileName* option to replace the map saved with the current design with the new map in the provided *fileName*.

filename

Specifies the name of the file that contains block constraint map information.

When specified together with the *-reset* option, the map in the specified file replaces the existing map saved with the current design. When this option is specified without the *-reset* option, the map in the specified file is appended to the existing map saved with the current design.

DESCRIPTION

This command reads a file that contains a list of block names, constraint types, and constraint file names, and assigns the constraint file to the specified block. This command is used to assign UPF, SDC, DEF, timing budget, blackbox timing, clock nets, CTS constraint, PG constraint or floorplan files to specific blocks.

The syntax for each line in the mapping file is:

block_design_name constraint_type file_name

block_design_name is the reference block name for either the top-level design or a block-level module.

constraint_type is one of the following keywords:

- BUDGET
- CLKNET
- COMPILE_PG
- DEF
- ETM_UPF
- PG_CONSTRAINT
- CTS_CONSTRAINT
- SDC
- UPF
- BTM
- FLOORPLAN
- SCANDEF

file_name is the constraint file name with its UNIX path.

The **BUDGET** constraint type specifies the constraint file that contains timing budget information for the corresponding block.

The **CLKNET** constraint type specifies the file that contains attribute setting commands that would tell the tool which nets are clock nets. The file is typically generated by split_constraints.

The **COMPILE_PG** constraint type specifies the constraint file that contains application option settings and setup commands for the **compile_pg** command.

The **DEF** constraint type specifies that the file is a DEF file for the corresponding block.

The **ETM_UPF** constraint type specifies that the constraint file contains UPF constraints for the corresponding ETM block.

The **PG_CONSTRAINT** constraint type specifies that the constraint file contains power planning constraints for the corresponding block.

The **SDC** constraint type specifies that the constraint file contains timing constraints for the corresponding block, including mode and corner setups.

The **UPF** constraint type specifies that the constraint file contains UPF constraints for the corresponding block.

The **BTM** constraint type specifies that the constraint file contains blackbox timing model constraints for the corresponding block.

The **FLOORPLAN** constraint type specifies that the constraint file contains floorplan information of the corresponding block. The file is typically generated by write_floorplan.

The **SCANDEF** constraint type specifies that the file is a scan DEF file for the corresponding block.

Depending on the flow you are using, the **shape_blocks**, **create_placement -floorplan**, **estimate_timing**, **create_abstract -all_blocks**, and **create_abstract -cells {cell_list}** commands might require design or abstract views. To create the views, certain constraints must be loaded so the abstract view can access the constraint information. To make the constraints available, the **set_constraint_mapping_file** command sets the association between the blocks and the corresponding constraint files for the blocks.

During abstract creation with the **shape_blocks**, **create_placement -floorplan**, **estimate_timing**, **create_abstract -all_blocks**, or **create_abstract -cells** commands, the UPF constraint file is loaded internally with the **load_upf** command, if no UPF was loaded for

the block.

The SDC constraint file is loaded internally with the **source** command, if the block has no SDC constraint. The timing budget constraint file is always loaded internally with the **source** command.

The CLKNET constraint file is loaded internally with the **source** command. Once it's loaded, the block would have attribute *is_clknet_file_loaded* set to true, and the CLKNET constraint file would not be loaded again.

The DEF and scan DEF constraint file is loaded with the **read_def** command only when the tool detects that the block has no design view; the tool automatically expands the outline view to generate the design view.

The CTS constraints are loaded with **source** command when creating the block's estimated abstract.

If a block is blackbox and has BTM constraint, its BTM constraint would be loaded automatically with **source** command after the tool loads the SDC constraint for the block.

The user can also manually ask to the tool to load specific type of constraint for specific blocks with command **load_block_constraints**.

The FLOORPLAN constraint file is only loaded when the user specifically asks the tool to load it for specific blocks with command **load_block_constraints**.

EXAMPLES

The following example specifies the DEF, UPF and FLOORPLAN constraint files. The files are used in the hierarchical flow from Verilog input to block shaping. The design has a top-level and two child blocks: BLK_INST_A (whose reference design is BLK_A) and BLK_INST_B (whose reference design is BLK_B). The content of the constraint mapping file *map_file.1* is:

```
BLK_A  DEF ./constraints/BLK_A.def
BLK_A  UPF ./constraints/BLK_A.upf
BLK_A  FLOORPLAN ./floorplan/BLK_A/BLK_A.tcl
BLK_B  DEF ./constraints/BLK_B.def
BLK_B  UPF ./constraints/BLK_B.upf
BLK_B  FLOORPLAN ./floorplan/BLK_B/BLK_B.tcl
TOP    DEF ./constraints/TOP.def
TOP    UPF ./constraints/TOP.upf
TOP    FLOORPLAN ./floorplan/TOP.tcl
```

The following Tcl commands are used in the flow. The **shape_blocks** command determines that the two blocks are both outline views. The command loads each block, expands the outline view to generate design view, loads the corresponding DEF constraint file, loads the UPF constraint file, then creates the placement abstract view for the block. After generating placement abstract views for both blocks, the command loads the top-level design, expands the top-level outline view, loads the DEF for the top-level design, and loads the UPF for the top-level design. After these steps, block shaping is performed.

```
prompt> read_verilog_outline -top TOP design.v
prompt> commit_block BLK_A
prompt> commit_block BLK_B
prompt> set_constraint_mapping_file map_file.1
prompt> shape_blocks
```

The following Tcl commands can be used to load floorplan to the hierarchical design. When **load_block_constraints** is issued, the tool would see that the top level and the child blocks are outline view, then it would expand the child blocks to design view, load their corresponding floorplan files, create a placement abstract view for them, and come to the top level, expand it to design view and change the child blocks to reference to their abstract views, then load the top level floorplan file.

```
prompt> read_verilog_outline -top TOP design.v
```

```
prompt> commit_block BLK_A
prompt> commit_block BLK_B
prompt> set_constraint_mapping_file map_file.1
prompt> load_block_constraints -all_blocks -type FLOORPLAN
```

The following example specifies a constraint mapping file and runs **estimate_timing** on the design. The tool opens each block, loads the respective SDC constraint file, then loads the corresponding BUDGET constraint file, and creates a timing abstract with estimate_timing data, loads the top-level design, and loads the top-level SDC constraint file. In the final step, estimate timing at the top-level is performed. The content of the constraint mapping file *map_file.2* is:

```
BLK_A  SDC    ./constraints/BLK_A.sdc.tcl
BLK_B  SDC    ./constraints/BLK_B.sdc.tcl
BLK_A  BUDGET ./budgets/BLK_A.budget.tcl
BLK_B  BUDGET ./budgets/BLK_B.budget.tcl
TOP    SDC    ./constraints/TOP.sdc.tcl
```

The commands to perform the estimate_timing step by using the *map_file.2* are:

```
prompt> set_constraint_mapping_file map_file.2
prompt> estimate_timing
```

set_corner_status

Configures analysis settings for mode and corner combinations (obsolete).

SYNTAX

status **set_corner_status**
[-modes *mode_list*]
[-corners *corner_list*]
[-setup true | false]
[-hold true | false]
[-power true | false]
[-max_transition true | false]
[-max_capacitance true | false]
[-min_capacitance true | false]
[-active true | false]
[-label *label*]

Data Types

mode_list list
corner_list list
label string

ARGUMENTS

-modes *mode_list*

Specifies the mode names to configure. The command configures each combination of the modes specified the **-modes** option and the corners specified by the **-corners** option, based on other command options. If this option is not specified, the command uses the current mode. If neither a mode nor a corner list is given, the current-mode/current-corner combination is configured.

-corners *corner_list*

Specifies the corner names to configure. The command configures each combination of the modes specified the **-modes** option and the corners specified by the **-corners** option, based on other command options. If this option is not specified, the command uses the current corner. If neither a mode nor a corner list is given, the current-mode/current-corner combination is configured.

-setup true | false

Specifies whether setup analysis is activated for the specified mode and corner combinations.

-hold true | false

Specifies whether hold analysis is activated for the specified mode and corner combinations.

-power true | false

Specifies whether power analysis is activated for the specified mode and corner combinations.

-max_transition true | **false**

Specifies whether max-transition DRC is activated for the specified mode and corner combinations.

-max_capacitance true | **false**

Specifies whether max-capacitance DRC is activated for the specified mode and corner combinations.

-min_capacitance true | **false**

Specifies whether min-capacitance DRC is activated for the specified mode and corner combinations.

-active true | **false**

Specifies whether any previous or current analysis settings (setup, hold, power, etc) are active or disabled. If false, all analysis settings are temporarily disabled and can be reactivated by specifying **-active true** at a later time.

-label ***label***

Assigns the specified *label* to the mode and corner combinations. The label does not affect analysis and is only printed in reports created by the **report_timing** and **report_qor** commands. Multiple mode and corner combinations can have the same label. A blank string is a legal label value.

DESCRIPTION

This command enables analysis and DRC checking for mode and corner combinations in the current design. Setup analysis, hold analysis, and various types of DRC checking can be configured independently. By default, all analysis or DRC checking is done for a mode and corner combination. This command can be used to setup the analysis and DRC checking for only the appropriate mode and corner combinations.

Note: This command is obsolete, and has been replaced by the **set_scenario_status** command. Use **set_scenario_status** instead.

set_current_command_mode

SYNTAX

string **set_current_command_mode**

-mode *command_mode* | -command *command*

string *command_mode*
string *command*

ARGUMENTS

-mode *command_mode*

Specifies the name of the new command mode to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

-command *command*

Specifies the name of the command whose associated command mode is to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **set_current_command_mode** sets the current command mode. If there is a current mode in effect, the current mode is first canceled, causing the associated clean up to be executed. The initialization for the new command mode is then executed as it is made current.

If the name of the given command mode is empty, the current command mode is cancelled and no new command mode is made current.

A current command mode stays in effect until it is displaced by a new command mode or until it is cleared by an empty command mode.

If the command completes successfully, the new current command mode name is returned. On failure, the command returns the previous command mode name which will remain current and prints an error message unless error messages are suppressed.

EXAMPLES

The following example sets the current command mode to a mode called "mode_1"

shell> **set_current_command_mode -mode mode_1**

The following example clears the current command mode without setting a new mode.

shell> **set_current_command_mode -mode ""**

The following example sets the current command mode to the mode associated with the command "modal_command"

shell> **set_current_command_mode -command modal_command**

set_current_ems_database

Sets the current EMS database.

SYNTAX

collection **set_current_ems_database**
ems_database
[-reset]

Data Types

ems_database string

ARGUMENTS

ems_database

Sets *ems_database* as the current EMS database. The database must be opened and in memory. Use **get_ems_databases** to view the list of currently opened databases.

-reset

Removes the current EMS database. The database still remains opened and in memory.

DESCRIPTION

The **set_current_ems_database** command sets the specified EMS database as the current EMS database. The specified EMS database must be opened with the **open_ems_database** command or created with the **create_ems_database** or **check_design -open_message_browser** command, otherwise **set_current_ems_database** issues an error message. The **-reset** option clears the current EMS database, but leaves the database in memory.

EXAMPLES

The following example sets the current EMS database to EMS_DB_0.ems.

```
prompt> set_current_ems_database EMS_DB_0.ems
prompt> get_current_ems_database
{EMS_DB_0.ems}
```

The following example clears the current EMS database.

```
prompt> get_current_ems_database
{EMS_DB_0.ems}
prompt> set_current_ems_database -reset
prompt> get_current_ems_database
```

SEE ALSO

get_current_ems_database(2)

set_current_mismatch_config

Sets the current mismatch config

SYNTAX

status **set_current_mismatch_config**
config_name
[-enable library | netlist | upf | routing]

Data Types

config_name string

ARGUMENTS

config_name

Specify the mismatch config name to be set as current.

-enable

Specify list of categories to be enabled. All the mismatch types under that category will be enabled.

DESCRIPTION

The set_current_mismatch_config command sets the current mismatch config. The named mismatch config should exist, else, the command returns error. Any pre-defined or user defined configs can be used to set as current. -enable is optional. Without that, only the current mismatch config will be changed. If -enable is given, it will change the current mismatch config, and additionally, it will enable the mismatches of the specified category for the newly set config. The Action and Repair strategy of the enabled mismatches will match those of the pre-defined "auto_fix" config. In order to query the list of mismatch types corresponding to a category, the "category" attribute on the mismatch_type object can be queried.

EXAMPLES

The following example sets the current mismatch config to user_def1 and enables repairing of netlist and library related mismatches:

prompt> **set_current_mismatch_config user_def1 -enable {netlist library}**

```
1
prompt> get_current_mismatch_config
user_def1
prompt> set_current_mismatch_config user_def2
Warning: It is not recommended to switch between configs because there might
be some design mismatches already repaired in previous config. And those
mismatches will not be in sync with current config anymore. (DMM-010)
1
prompt> get_current_mismatch_config
user_def2
```

The following example uses non-existing mismatch config:

```
prompt> set_current_mismatch_config dont_exist
Error: Mismatch config 'dont_exist' do not exists. (DMM-015)
0
```

SEE ALSO

set_data_check

Sets data-to-data checks using the specified values of setup and hold time.

SYNTAX

status **set_data_check**
  -modes *mode_list*
  -corners *corner_list*
  -scenarios *scenario_list*
  -from *from_object*
    | -rise_from *from_object*
    | -fall_from *from_object*
  -to *to_object*
    | -rise_to *to_object*
    | -fall_to *to_object*
  [-setup | -hold]
  [-clock *clock_object*]
  [*check_value*]

Data Types

from_object	collection of 1 object
to_object	collection of 1 object
clock_object	collection of 1 object
check_value	float

ARGUMENTS

-modes *mode_list*

Set data check for scenarios of these modes (default is current mode, or current scenario if neither mode nor corner is specified)

-corners *corner_list*

Set data check for scenarios of these corners (default is current scenario if neither mode nor corner is specified)

-scenarios *scenario_list*

Set data check for these scenarios (default is current scenario)

-from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. Both rising and falling delays are checked.

You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-to ***to_object***

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. Both rising and falling delays are constrained.

You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-rise_from ***from_object***

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. This option applies only to rising delays at the related pin.

You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-fall_from ***from_object***

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. This option applies only to falling delays at the related pin.

You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-rise_to ***to_object***

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. This option applies only to rising delays at the constrained pin.

You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-fall_to ***to_object***

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. This option applies only to falling delays at the constrained pin.

You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-setup

Indicates that the data check value is for setup analysis only. If neither **-setup** nor **-hold** is specified, the value applies to both setup and hold.

-hold

Indicates that the data check value is for hold analysis only. If neither **-setup** nor **-hold** is specified, the value applies to both setup and hold.

-clock ***clock_object***

Specifies a single clock that launches the signal for the related pin of the data check.

check_value

Specifies the value of the setup or hold time for the check.

DESCRIPTION

The **set_data_check** command specifies a data-to-data check to be performed between the from object and the to object using the

specified setup or hold value.

The pulse relation between clocks of the related pin and the constrained pin is considered to be zero cycles. The normal sequential check uses one cycle. Data checks on clock pins are not supported. Both constraint point and related point of the check have to be on the data network for a valid check.

The data check is treated as nonsequential; that is, the path goes through the related and constrained pins and is not broken at these pins. To report the constraint related to the data check, use the **report_timing** command with the **-to** option to specify the data-check-constrained pin.

To remove information set by the **set_data_check** command, use the **remove_data_check** command.

Multicorner-Multimode Support This command applies to the current scenario only.

EXAMPLES

The following example creates a data-to-data check from pin and1/B to pin and1/A with respect to the rising edge of the signal at and1/B, using a setup and hold time of 0.4.

```
prompt> set_data_check -rise_from and1/B -to and1/A 0.4
```

The following example creates a data-to-data check from pin and1/B to pin and1/A with respect to the rising edge of the signal at and1/B, coming from the clock domain of CK1, and constraining only the falling edge of the signal at and1/A, using a setup time of 0.5 and no hold check.

```
prompt> set_data_check -rise_from and1/B -fall_to and1/A \
  -setup -clock [get_clock CK1] 0.5
```

SEE ALSO

remove_data_check(2)

set_datapath_architecture_options

Controls the strategies used when generating the datapath cell for arithmetic and shift operators.

SYNTAX

status **set_datapath_architecture_options**
[-all_options auto | true | false]
[-booth_encoding auto | true | false]
[-booth_radix8 auto | true | false]
[-booth_mux_based auto | true | false]
[-booth_cell auto | true | false]
[-mult_radix4 auto | true | false]
[-mult_nand_based auto | true | false]
[-mult_sign_mag auto | true | false]
[-tp_opt_tree auto | true | false]
[-tp_oper_sel auto | true | false]
[-inv_out_adder_cell auto | true | false]
[-4to2_compressor_cell auto | true | false]
[-optimize_for default | area | speed | area,speed]
[-mult_arch *architecture*]
[*module_or_cell_list*]

ARGUMENTS

-all_options auto | true | false

Specifies the value for all datapath architecture options. When **true** or **false** is specified, **-optimize_for** is not affected.

The **set_datapath_architecture_options** command always processes the value of the **-all_options** option before any other options when they are used together in the same command line.

-booth_encoding auto | true | false

Controls the uage of Booth-encoding architectures to implement multipliers.

When set to **auto**, the default, the tool uses the option only if there is a QoR benefit. When you set the **-booth_encoding** option to **true**, the tool always uses the option. When you set the **-booth_encoding** option to **false**, the tool never uses the option.

-booth_radix8 auto | true | false

Controls the usage of radix-8 Booth-encoding architectures to implement multipliers. This option is active only if the **-booth_encoding** option is set to **auto** or **true**.

When you set the **-booth_radix8** option to **auto**, the default, the tool uses the **-booth_radix8** option option only if there is a QoR benefit. The tool always uses the **-booth_radix8** option when it is set to **true** and never uses the **-booth_radix8** option when it is set to **false**.

-booth_mux_based auto | true | false

Controls the usage of MUX-based Booth encoding. MUX-based encoding provides better QoR for technologies with fast multiplexer cells. Otherwise, the tool uses XOP-based Booth encoding.

When you set the **-booth_mux_based** option to **auto**, the default, the tool uses the option only used if it determines there is a QoR benefit. When you set the **-booth_mux_based** option to **true**, the tool always uses the option. When you set the **-booth_mux_based** option to **false**, the tool never uses the option.

-booth_cell auto | true | false

Controls the usage of special Booth multiplier cells in the target library for compilation.

When you set the **-booth_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-booth_cell** option to **true**, the tool always uses the option if applicable. When you set the **-booth_cell** option to **false**, the tool never uses the option.

This option may not work if the special Booth multiplier cells are not availabe in the library.

-mult_radix4 auto | true | false

Controls the use of radix-4 non-Booth architectures to implement multipliers. This option cannot be used if the **-booth_encoding** option is set to **true**. The **-booth_encoding** option must be inactive (set to **auto** or **false**).

When you set the **-mult_radix4** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-mult_radix4** option to **true**, the tool always uses the option. When you set the **-mult_radix4** option to **false**, the tool never uses the option. This option is only available in when total power mode is on.

-mult_nand_based auto | true | false

Controls the usage of NAND-based multiplier structures. Non-Booth multipliers use AND gates or an INVERT-NOR structure to generate the partial-product bits. This option allows you to use the NAND gates to produce inverted bits that you can add directly. This can result in lower dynamic power and lesser glitches. This option is active only if the **-booth_encoding** option is set to **auto** or **false**.

When you set the **-mult_nand_based** option to **auto**, the default, the tool uses the option only when the total power mode is enabled and if it determines there is a QoR benefit. When you set the **-mult_nand_based** option to **true**, the tool always uses the option. When you set the **-mult_nand_based** option to **false**, the tool never uses the option.

-mult_sign_mag auto | true | false

Controls the usage of sign-magnitude multiplier architecture. When low-magnitude inputs into a signed multiplier change the sign frequently, all sign-extension bits toggle and introduce a lot of activity into the multiplier circuit. The sign-magnitude technique converts 2's-complement representation of inputs into sign-magnitude representation, and the multiplication is carried out on the unsigned magnitude alone without any sign-extension bits. The output is converted back to 2's-complement. This results in lower activity and dynamic power for signed multipliers with low magnitude inputs.

When you set the **-mult_sign_mag** option to **false**, the default, the tool never uses the option. When you set the **-mult_sign_mag** option to **true**, the tool always uses the option. Setting the **-mult_sign_mag** option to **auto** has the same effect as **false** since automatic selection on it is currently not supported.

This architecture usually degrades QoR of signed multipliers because it increases delay, area and dynamic power as reported by the tool. Dynamic power is only reduced when inputs have low magnitude most of the time (i.e. upper bits are just sign-extension and therefore correlated). Power reduction can only be measured using back-annotated activity from netlist simulation, because the synthesis tool does not process information about correlated input bits. Therefore, this option should only be set for individual signed multipliers that are known to have low-magnitude inputs, and power gains should be measured using simulation.

-tp_opt_tree auto | true | false

Controls the usage of carry-save adder tree for low power optimization based on transition probabilities (TP). This optimization reduces internal switching activity and therefore the dynamic power in SOPs when the inputs have a non-uniform transition

probability distribution.

When you set the **-tp_opt_tree** option to **auto**, the default, the tool uses the option only if it determines a QoR benefit and optimized dynamic power. When you set the **-tp_opt_tree** option to **true**, the tool always uses the option if dynamic power is optimized. When you set the **-tp_opt_tree** option to **false**, the tool never uses the option.

-tp_oper_sel auto | true | false

Controls the selection or ordering of multiplier input operands for low power based on transition probability (TP). This optimization can reduce internal switching activity and therefore dynamic power in booth multipliers when the inputs have significantly different transition probabilities.

When you set the **-tp_oper_sel** option to **auto**, the default, the tool uses the option only if it determines a QoR benefit and optimized dynamic power. When you set the **-tp_oper_sel** option to **true**, the tool always uses the option if dynamic power is optimized. When you set the **-tp_oper_sel** option to **false**, the tool never uses the option. The option only affects multipliers with booth encoding.

-inv_out_adder_cell auto | true | false

Controls the usage of full-adder cells with inverted sum-and-carry outputs in the target library for compilation.

When you set the **-inv_out_adder_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-inv_out_adder_cell** option to **true**, the tool always uses the option. When you set the **-inv_out_adder_cell** option to **false**, the tool never uses the option.

This option may not work if the special cells are not availabe in the library.

-4to2_compressor_cell auto | true | false

Controls the usage of 4-2 compressor cells in the target library for compilation.

When you set the **-4to2_compressor_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-4to2_compressor_cell** option to **true**, the tool always uses the option. When you set the **-4to2_compressor_cell** option to **false**, the tool never uses the option.

This option may not work if the special cells are not availabe in the library.

-optimize_for auto | area | speed | area,speed

Supplies a specific optimization goal for the specified cells.

When you set the **-optimize_for** option to **auto**, the default, the tool chooses the optimization mode based on QoR benefit. When you set the **-optimize_for** option to **area**, **speed** or **area,speed**, the tool always uses the specified optimization mode during compile.

-mult_arch *architecture*

Specifies the multiplier architecture to be implemented. This option is a concise representation for a subset of six architecture options. Valid values are **auto**, **and**, **nand**, **and_radix4**, **nand_radix4**, **benc_radix4**, **benc_radix8**, **benc_radix4_mux**, and **benc_radix8_mux**.

The different **-mult_arch** options translate to the following combinations of generation settings:

and: AND-based non-booth architecture -booth_encoding false -mult_radix4 false -mult_nand_based false

nand: NAND-based non-booth architecture -booth_encoding false -mult_radix4 false -mult_nand_based true

and_radix4: AND-based radix-4 non-booth architecture -booth_encoding false -mult_radix4 true -mult_nand_based false

nand_radix4: NAND-based radix-4 non-booth architecture -booth_encoding false -mult_radix4 true -mult_nand_based true

benc_radix4: radix-4 booth architecture -booth_encoding true -booth_radix8 false -booth_mux_based false

benc_radix8: radix-8 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based false

benc_radix4_mux: MUX-based radix-4 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based true

benc_radix8_mux: MUX-based radix-8 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based true

module_or_cell_list

An optional list of cells or modules. When present, the switch settings in this command affect only the specified objects. Otherwise the settings are applied on the whole design.

If you set datapath architecture options on a module and an instance that instantiates this module, the setting on the instance is used by the generator.

The option settings are always hierarchical. All datapath generation will use the same options under the hierarchy of specified objects. If the options are set on different objects in a hierarchy, the tool will use the settings of the closest object to the datapath cell. It will check the options of the cell itself, then the reference module of this cell, then the parent cell, and the reference module of the parent cell, and so on, till the top module. The global options on the whole design is the last one to check.

DESCRIPTION

The **set_datapath_architecture_options** command controls datapath generation strategies used in datapath synthesis.

The default value for all datapath architecture strategies is **auto**. By default, the best strategies are automatically chosen based on the given design constraints. Setting the options to **auto** is equivalent to not setting anything at all, and can be used to clean the existing settings.

When the datapath architecture options are specified without an object list, the specified options are automatically applied to the entire design. When the datapath architecture options are specified with an object list, the specified options are applied only on the specified objects. The object can be a module, a hierarchical cell, or a synthetic operator. The options do not take effect when they are applied on the generic GTECH cell or the cell that is already mapped to the technology library.

When the options are applied on a synthetic operator, and if the operator is extracted into DP_OP cell, the options will be merged with other operator's options and inherited to the DP_OP cell. All operators within this DP_OP cell will use the same options on this DP_OP cell.

When synthetic operators with different option values are extracted into a DP_OP cell, the DP_OP cell merges the option value based on the following priority: For the -optimize_for option, the option value **speed** has the highest priority, **area,speed** is the next, and **area** has the lowest priority. For the options take **true** and **false**, the option value **true** has the highest priority. **false** is the next, and **auto** has the lowest priority.

The synthetic operators could go through multiple complex transformations during compile_ultra. For example, two operators may be shared at the beginning and unshared later depending on the design constrains. When the synthetic operator with the datapath architecture options go through such transformations, it is possible that the initial option setting is not preserved.

When you specify the architecture options on the same object the second time, the new option values will be appended to existing options if no conflict, or overwrite the old values if conflict happens.

The option values set by set_datapath_architecture_options command can be checked by **get_attribute** command with attribute name "dpgen_options". The options can be cleaned by **remove_attribute** command, or by specifying **-all_options auto** with **set_datapath_architecture_options** command.

The **report_dpgen_options** command can report all architecture options user has ever set, including the ones set on module, cell, and the whole design, before compile. After compile, if the objects having architecture options are not ungrouped, their architecture options can also be reported by this command.

The datapath architecture options are also listed in the datapath optimization report by report_resources command. This is the options the tool used during compile, and may be different from what was initially set, due to complex datapath transformations.

EXAMPLES

The following example uses **set_datapath_architecture_options** to control the usage of booth encoded architectures when generating multipliers in current design.

```
prompt> set_datapath_architecture_options -booth_encoding true
```

The following example sets all the options to **auto**, except for **-booth_encoding**, which is set to **true** and overrides the value of **-all_options**:

```
prompt> set_datapath_architecture_options -all_options auto -booth_encoding true
```

The following example append the **-4to2_compressor** option to previous options. The final option value on U1 is **-booth_encoding true -booth_radix8 true -booth_mux_based false -4to2_compressor_cell true**.

```
prompt> set_datapath_architecture_options -mult_arch benc_radix8 [get_cells U1]
prompt> set_datapath_architecture_options -4to2_compressor_cell true [get_cells U1]
```

In following example, when combined with other datapath architecture options related to multiplier architecture, the **-mult_arch** option takes precedence. The final options is **-booth_encoding true -booth_radix8 true -booth_mux_based false.**

```
prompt> set_datapath_architecture_options -mult_arch benc_radix8 -booth_encoding false
```

set_datapath_gating_options

Controls the gating behavior when generating the datapath cell.

SYNTAX

status **set_datapath_gating_options**
[-enable true | false]
[-sequential true | false]
[-ungroup true | false]
[-reset]
[module_or_cell]

Data Types

module_or_cell list

ARGUMENTS

-enable true | false

Enable or disable datapath gating. True by default.

When you set the **-enable** option to **true**, the tool will do datapath gating if applicable, which is the default behavior. When you set the **-enable** option to **false**, the tool won't do datapath gating.

-sequential true | false

Enable or disable sequential datapath gating. False by default.

When you set the **-sequential** option to **true**, the tool will do the sequential datapath gating if applicable. When you set the **-sequential** option to **false**, the tool won't do sequential datapath gating, which is the default.

This option can only be set in global level. It can't be followed by modules or cells. This option is ignored if **-enable** is **false**.

-ungroup true | false

Specifies if the gated datapath cell should be ungrouped or not. True by default.

When you set the **-ungroup** option to **true**, the tool will always ungroup the gated datapath cell, which is the default behavior. When you set the **-ungroup** option to **false**, the tool won't ungroup the gated datapath cell.

This option takes effect only when the datapath cell is gated.

-reset

Reset all settings ever made on current design, including global, module, and instance level settings.

DESCRIPTION

The **set_datapath_gating_options** command sets an attribute on the list of specified modules or instances, or current design if no targets are specified. The attribute controls whether or not the datapath cells in a design is optimized by the datapath gating algorithm during the compile, and it can also control the gating options such as ungroup.

By default, the tool will gate or not gate a datapath, based on the power and timing trade off. Datapath internal gating will be attempted if applicable. Sequential datapath gating will be attempted only if it's explicitly turned on.

When the datapath gating options are specified without an object list, the specified options are automatically applied to the entire design. When the datapath gating options are specified with an object list, the specified options are applied only on the specified objects. The object can be a module, a hierarchical cell, or a synthetic operator. The options do not take effect when they are applied on the generic GTECH cell or the cell that is already mapped to the technology library.

Datapath gating related optimizations such as output selector extraction, sequential gating based port punching etc. can only be enabled or disabled when this command is called in global level. Datapath gating itself can be enabled or disabled in instance level, module level, or global level.

When the options are applied to a synthetic operator, and if the operator is extracted into DP_OP cell, the options will be merged with other operator's options and inherited to the DP_OP cell. All operators within this DP_OP cell will use the same options on this DP_OP cell.

When synthetic operators with different option values are extracted into one DP_OP cell, the DP_OP cell merges the option value based on the following priority: For the options take **true** and **false**, the option value **true** takes the highest priority.

The synthetic operators could go through multiple complex transformations during compile_ultra. For example, two operators may be shared at the beginning but unshared later depending on the design constrains. When the synthetic operator with the datapath gating options go through such transformations, it is possible that the initial option setting is not preserved.

When you specify the gating options on the same object the second time, the new option values will be appended to existing options if no conflict, or overwrite the old values if conflict happens.

When gating option is set on different level of hierarchy, the "closest" option to the synthetic instance will be used during datapath generation. By other words, the generator checks settings in the order of instance, parent instance, parent module, so on and so forth till the top design.

The **report_datapath_gating_options** command can report all gating options user has ever set, including the ones set on module, cell, and the whole design, before compile. After compile, if the objects having gating options are not ungrouped, their gating options can also be reported by this command.

The datapath gating options are also listed in the datapath optimization report by report_resources command. This is the options the tool used during compile, and may be different from what was initially set, due to complex datapath transformations.

EXAMPLES

In the following example, datapath gating is disabled on the datapath cells pertained to U4 and U5.

```
prompt> set_datapath_gating_options -enable false [get_cells {U4 U5}]
```

The following example specifies that the U3/U5 instance should not be ungrouped if it's gated by the tool:

```
prompt> set_datapath_gating_options -ungroup false [get_cells U3/U5]
```

The following example shows the cumulative behavior of the command. The datapath gating is disabled globally, then enabled for hierarchical cell **U1**/**U3**, later additionally disable the ungrouping for **U1**/**U3**/**add_8**. The effect of this is that all datapath blocks under U1/U3 will be eligible for gating, while others in the design won't be gated, and specially the datapath containing **U1**/**U3**/**add_8** won't be ungrouped (or **U1**/**U3**/**add_8** won't be ungrouped if not extracted to a datapath block) if it's actually gated.

```
prompt> set_datapath_gating_options -enable false
1

prompt> set_datapath_gating_options -enable true [get_cells U1/U3]
1

prompt> set_datapath_gating_options -enable true -ungroup false [get_cells U1/U3/add_8]
1
```

Th following example removes all previous datapath gating settings:

```
prompt> set_datapath_gating_options -reset
1
```

SEE ALSO

report_datapath_gating_options(2)

set_db_file_mapping

Creates a mapping between original input .db files(built into the reference ndm), and the new .db files to be used during PrimeTime delay calculation.

SYNTAX

string **set_db_file_mapping**
[-library *library*]
original_db_file_name
current_db_file_name

Data Types

library	collection
original_db_file_name	string
current_db_file_name	string

ARGUMENTS

-library *library*

Specifies the lib-cell library that has been created using the original DB file. If this is not specified, objects will be found in the current design.

original_db_file_name

Specifies the base name or full path name input DB file that has been used to generate the specified library.

current_db_file_name

Specifies the base name or full path name DB file that has been used to perform delay calculation.

DESCRIPTION

Create a mapping between original input .db files (which built into the reference ndm), and the new .db files to be used during PrimeTime delay calculation. When PrimeTime delay calculation enabled, the tool will try to find the same set of .db file names from the search path. If a different set of .db file names should be used now, you can use this command to map the old .db file names to the new ones.

The feature is supported when PrimeTime delay calculator is enabled or the **analyze_timing_correlation** command is used.

When the .db mapping is specified using this command, the mapped .db file name is searched using the following rules:

- If the mapping file uses full path for the new db, then the tool will just use the full path to locate the new .db
- If the mapping file use simple name for the new db, then the tool will search the db from the specified search_path.
- If the mapping file use relative path for the new .db file , then the tool will search the .db from the search_path/"relative path specified in the mapping".

EXAMPLES

The following example creates a mapping between input DB file and the current mapped DB file.

```
prompt> set_db_file_mapping /A/B/C/1.db    /E/F/G/1.db
```

SEE ALSO

set_density_gradient_options

Sets options for **report_placement -hard_macro_density_gradient_violations** command.

SYNTAX

status **set_density_gradient_options**
[-white_space_density {*layer_name_and_density_pairs*}]
[-edge_zone_width {*layer_name_and_inner_width_pairs*}]
[-outer_zone_width {*layer_name_and_outer_width_pairs*}]
[-gradient_tolerance {*layer_name_and_tolerance_value_pairs*}]
[-min_macro_size *min_macro_size*]
[-cluster_threshold *cluster_threshold*]

Data Types

layer_name_and_density_pairs list
layer_name_and_inner_width_pairs list
layer_name_and_outer_width_pairs list
layer_name_and_tolerance_value_pairs list
min_macro_size float
cluster_threshold float

ARGUMENTS

-white_space_density {*layer_name_and_density_pairs*}

Specifies the white space density. The white space density is measured at areas without metal density definition inside macros and areas outside of macros. Specify a list of layer names and white space density pairs in the curly braces. The layer name must be a string, such as OD, M1, M2 and so on. The data type of the white space density is float and the unit is micron. The pair format is:

{layer_name1 density1 layer_name2 density2 layer_name3 density3 ...}

By default, the command uses a density of 0.35 as the white space density for each layer. You can specify white space density from 0 to 1.

-edge_zone_width {*layer_name_and_inner_width_pairs*}

Specifies the width used to form the inner window inside the hard macro. The width is the distance extending inwards from the macro edge, and this distance along with the length of the macro edge forms the inner window. If the inner window extends outside the bbox of the hard macro, the window stops at the bounding box of the hard macro. The **report_placement -hard_macro_density_gradient_violations** command calculates the density of inner window for each layer. You can specify a list of layer name and edge zone width pairs. The layer name must be a string, such as OD, M1, M2 and so on. The data type of the width is float and the unit is micron. The pair format is:

{layer_name1 width1 layer_name2 width2 layer_name3 width3 ...}

By default, the command uses 150 microns as edge zone width for each layer.

-outer_zone_width {*layer_name_and_outer_width_pairs*}

Specifies the width used to form the outer window outside the hard macro. The width is the distance extending outward from the macro edge, and this distance along with the length of the macro edge forms the outer window. If the outer window extends outside the chip boundary, the window ends at the chip boundary. The **report_placement -hard_macro_density_gradient_violations** command calculates the density of outer window for each layer. You can specify a list of layer name and outer zone width pair. The layer name must be a string, such as OD, M1, M2 and so on. The data type of the width is float and the unit is micron. The pair format is:

{layer_name1 width1 layer_name2 width2 layer_name3 width3 ...}

By default, the command uses 150 microns as outer zone width for each layer.

-gradient_tolerance {*layer_name_and_tolerance_value_pairs*}

Specifies the gradient tolerance. If the density difference between inner window and outer window is larger than the gradient tolerance, the **report_placement -hard_macro_density_gradient_violations** command reports a violation. You can specify a list of layer name and gradient tolerance pair. The layer name must be a string, such as OD, M1, M2 and so on. The data type of the gradient tolerance is float and the unit is micron. The pair format is:

{layer_name1 value1 layer_name2 value2 layer_name3 value3 ...}

By default, the command uses 0.3 as gradient tolerance for each layer. You can specify gradient tolerance value from 0 to 1.

-min_macro_size *min_macro_size*

Specifies the minimum macro size for checking. If both the width and height of a hard macro are less than the minimum macro size, the **report_placement -hard_macro_density_gradient_violations** command skips checking this hard macro. Also during hard macro edge checking, if the length of an edge is less than half of minimum macro size, the **report_placement -hard_macro_density_gradient_violations** command skips checking this edge. The data type of minimum macro size is float and the unit is micron. By default, the command uses 500 as minimum macro size.

-cluster_threshold *cluster_threshold*

Specifies the cluster threshold. If the hard macros are placed within the distance cluster_threshold, the **report_placement -hard_macro_density_gradient_violations** command merges these hard macros into a cluster. The cluster is treated as a single hard macro for density gradient violations checking. The data type of cluster threshold is float and the unit is micron. By default, the command uses 5 as cluster threshold.

DESCRIPTION

This command sets checking options for the **report_placement -hard_macro_density_gradient_violations** command. This command is additive and can be run multiple times to set the options incrementally.

EXAMPLES

The following example shows the usage of this command.

```
prompt> set_density_gradient_options -white_space_density {M1 0 M2 0.4} \
```

```
-edge_zone_width  {M1 50 M2 60} \
-outer_zone_width {M1 50 M2 60} \
-gradient_tolerance{M1 0.3 M2 0.5} \
-min_macro_size 500 \
-cluster_threshold 5
```

SEE ALSO

set_design_attributes

Sets the specified attributes and their value on required cells.

SYNTAX

string **set_design_attributes**
[-elements *element_list*]
[-attribute *name_value_pair*]
[-models *model_list*]
[-exclude_elements *exclude_list*]
[-is_hard_macro *true*|*false*]
[-is_soft_macro *true*|*false*]

Data Types

element_list list
name_value_pair string
model_list list
exclude_list list

ARGUMENTS

-elements *element_list*

Specifies the collection of cells on which the attributes must be set.

-attribute *name_value_pair*

Specifies the name and value of the attribute to be set on the cells specified by the **-elements** option.

This option can be repeated multiple times to specify multiple attributes for the same set of cells in a single command.

-models *model_list*

Specifies the collection of models on which the attributes must be set.

-exclude_elements *exclude_list*

Specifies a list of elements to be excluded from the effective element list. This option is read and ignored by implementation tools. This option is only valid for attribute ret_mode, in other case, implementation tools drop this command and do not look at the **-elements**, **-models**, and **-exclude_elements** options, This option can be preserved in UPF' or UPF" files only if it is used with attribute ret_mode.

-is_hard_macro *true*|*false*

Specifies models in model_list to be hard-macro models or not. This option must be specified together with **-models** option.

-is_soft_macro *true*|*false*

Specifies if models in model_list are soft-macro models. This option must be specified together with **-models** option.

DESCRIPTION

This command sets the attributes and their value on a list of cells specified by the **-elements** or **-models** options.

Attributes can be set multiple times on the same cells. The last value prevails.

It is an error if the design attribute is specified with neither the **-elements** nor the **-models** options, except for the following design attributes: correlated_supply_group upf_chip_design

The supported attribute names and their associated values are as follows:

- **correlated_supply_group**
  This attribute can be set at the top scope of the design or on hierarchical instance of the design. The value must be one or more groups of supply net names bracketed by curly braces {}. The value can also be the wildcard character (*) alone, which means all supply nets in the design.

  This attribute specifies supply nets whose port state triplets and power state triplets should be considered correlated voltages. The tool considers only the minimum with minimum voltages, only nominal with nominal voltages, and only maximum with maximum voltages, without mixing between minimum, nominal, and maximum. This attribute only accepts dot (.) or a single hierarchical instance as the value for the **-elements** option.

- **derived_feedthrough_hierarchy**
  This attribute can be set on hierarchical cells of the design. The value must be **true** or **false**. The default of this attribute is **false**.

- **derived_iso_strategy**
  This attribute can be set on cell instances of the design. The value must be the name of an isolation strategy.

  This attribute specifies the isolation strategy name to ensure a unique name for the derived strategies in the power domain. It is used in a hierarchical flow to support location fanout.

- **enable_bias**
  This attribute can be set on the top design and also on any cell in the design. The value must be **true** or **false**. The default of this attribute is **false**.

- **enable_state_propagation_in_add_power_state**
  This attribute can be set at the top scope of the design and also on any hierarchical cell. The value must be **true** or **false**. The default of this attribute is **false**.

  When this attribute is set to **true**, the tool propagates the name of the supply set state (specified in the **add_power_state** command) to the functional net. After the state name is propagated to the functional net, you can use the net and the supply set state in the **create_pst** and **add_pst_state** commands. When the value is **true**, usage of the "&&" expression is not allowed in the **supply_expr** option of the **add_power_state** command.

  When this attribute is set to **false**, the supply set state name is not propagated to the functional nets. The state name specified in the **add_power_state** command is a property of the supply set, so the name is not propagated to the functional nets. To create power state tables, you must create GROUPS using the **create_power_state_group** command and refer to the supply set state names in the GROUP. You can no longer refer to the state names in the **add_pst_state** command. When the value is **false**, usage of the "&&" expression is allowed.

  The allowed attribute configurations are:

1. Attribute is set to **false** for the entire design
2. Attribute is set to **true** for the entire design
3. Attribute is set to **true** for the block, and set to **false** for the top design

The following configuration is NOT allowed: Attribute is set to **false** for the block, and set to **true** for the top design.

- **lower_domain_boundary**
  This attribute can be set at the top scope of the design and also on any hierarchical cell. The value must be **true** or **false**.

  When this attribute is set to **true**, the tool considers the domain boundary between a domain and another domain that is contained in a lower-level block as the scope of the first (higher hierarchical level) domain.

- **merge_domain**
  This attribute can be set on cell instances of the design. The value must be **true** or **false**.

  If set to **true**, this attribute implies that the elements that belong to the same power domain can be merged. The cells specified in the **-elements** option should not be the root cell of a power domain.

- **shared_voltage_area**
  This attribute can be set at the top scope of the design or on hierarchical instance of the design. The value must be one or more groups of power domain names bracketed by curly braces {}. This attribute specifies power domains that share a primary voltage area. This attribute only accepts dot (.) as the value for the **-elements** option.

- **SNPS_default_power_upf2sv_vct** and **SNPS_default_ground_upf2sv_vct**
  These attributes specify the default for the UPF-to-SystemVerilog value conversion table. These attributes can be used with the **-models** option.

- **SNPS_default_power_upf2vh_vct** and **SNPS_default_ground_upf2vh_vct**
  These attributes specify the default for the UPF-to-VHDL value conversion table. These attributes can be used with the **-models** option.

- **SNPS_default_power_sv2upf_vct** and **SNPS_default_ground_sv2upf_vct**
  These attributes specify the default for the SystemVerilog-to-UPF value conversion table. These attributes can be used with the **-models** option.

- **terminal_boundary**
  This attribute can be set at the top scope of the design and also on any cell in the list of **-elements** of the command **create_power_domain**. Typically, it is set on a block design, black box, or ETM cell. The value must be **true** or **false**.

  When this attribute is set to **true**, the tool considers the boundary of the cell as a terminal and checks, in the **check_mv_design** command, that the driver/load pin's related supply is consistent with the driver/receiver supply defined on the boundary pin (either by **set_port_attributes -driver_supply -receiver_supply** or by **set_related_supply_net**).

- **upf_chip_design** (used on the top-level design)
  This attribute can be set on the top-level design. The value must be **true** or **false**. It is used in the isolation strategy definition to support location fanout.

- **legacy_block** (used on the top-level design and on the hierarchical instances)
  This attribute can be set on the top-level design and on hierarchical instances. The value must be **true** or **false**. It is used defined if the design or an instance belongs to a legacy block.

- **upf_reconcile_boundary** (used on the top-level design)
  This attribute can be set on the top-level design and block level design. The value must be **skip** or **reconcile_voltages**. It is used in the PSTs merging. The tool will recognize the block UPF PST to be skipped entirely or supply voltages can be reconciled within threshold defined by set_variation command for the supply.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **correlated_supply_group** attribute to specify correlated voltage range comparison for port state triplets.

If a driver is powered by VDD1 and its load is powered by VDD2, a level shifter is not required because VDD1 and VDD2 are in the same correlated supply group and therefore treated as correlated voltage range during voltage comparison.

However, if the load is powered by VDD3, a level shifter is required because VDD1 and VDD3 are not in the same correlated supply group and therefore treated as independent voltage range during voltage comparison.

```
prompt> add_port_state VDD1 -state {HV 0.8 1.0 1.2}
1
prompt> add_port_state VDD2 -state {HV 0.8 1.0 1.2}
1
prompt> add_port_state VDD3 -state {HV 0.8 1.0 1.2}
1
prompt> add_port_state VDD4 -state {HV 0.8 1.0 1.2}
1
prompt> set_design_attributes \
  -elements {.} \
  -attribute correlated_supply_group "{VDD1 VDD2} {VDD3 VDD4}"
1
```

The following example sets the **SNPS_default_power_sv2upf_vct** attribute SV_LOGIC2UPF on model bot and libcell GTECH_NOT.

```
prompt> set_design_attributes \
  -models {bot GTECH_NOT} \
  -attribute SNPS_default_power_sv2upf_vct SV_LOGIC2UPF
1
```

The following example sets the **upf_chip_design** attribute on a top-level design.

```
prompt> set_design_attributes -elements {.} \
  -attribute upf_chip_design true
1
```

The following example sets the **merge_domain** attribute to **true** on cell mid1.

```
prompt> set_design_attributes \
  -elements {mid1} \
  -attribute merge_domain true
1
```

The following example sets the **derived_iso_strategy** attribute on mid11 with power domain MID11.

```
prompt> set_design_attributes \
  -elements {mid11} \
  -attribute derived_iso_strategy iso1
1
prompt> set_isolation iso1 \
  -domain MID11 -source sset1 \
```

```
  -elements {mid11/*} \
  -isolation_supply_set sset3
1
prompt> set_isolation_control iso1 \
  -domain MID11 \
  -isolation_signal in1 \
  -location fanout
1
```

The following example sets the **lower_domain_boundary** attribute to TRUE on the top scope and cell mid1.

```
prompt> set_scope
1
prompt> set_design_attributes /
  -elements {.} /
  -attribute lower_domain_boundary TRUE
Information: Resolving '.' to the current scope 'top'.
1
prompt> set_design_attributes /
  -elements {mid1} /
  -attribute lower_domain_boundary TRUE
1
```

The following example sets the **enable_state_propagation_in_add_power_state** attribute to **false** on the top scope and to **true** on cell mid1.

```
prompt> set_scope
1
prompt> set_design_attributes \
  -elements {.} \
  -attribute enable_state_propagation_in_add_power_state false
1
prompt> set_design_attributes \
  -elements {mid1} \
  -attribute enable_state_propagation_in_add_power_state true
1
```

The following example sets the **terminal_boundary** attribute to **true** on the top scope and cell mid1.

```
prompt> set_scope
1
prompt> set_design_attributes \
  -elements {.} \
  -attribute terminal_boundary true
1
prompt> set_design_attributes \
  -elements {mid1} \
  -attribute terminal_boundary true
1
```

The following example sets the **upf_reconcile_boundary** attribute to on the IP block.

```
prompt> set_design_attributes \
  -models {IP_A} \
  -attribute upf_reconcile_boundary skip
1
prompt> set_design_attributes \
  -models {IP_B} \
```

-attribute upf_reconcile_boundary reconcile_voltages
1

SEE ALSO

set_port_attributes(2)
set_related_supply_net(2)
set_variation(2)

set_design_rule_attribute

Set multiple attributes together for design rule object.

SYNTAX

collection **set_design_rule_attribute**
-list *name_value_list*
[-objects *object_list*]
[patterns]

Data Types

name_value_list	list
object_list	collection
patterns	collection

ARGUMENTS

-list *name_value_list*

Specifies a list of attribute name and value pairs which to set. The list must have an even number of tokens to be valid. Note that if any of the key invalid, that key will be ignored. if any of the value supplied is invalid, this command fails with no effect.

-objects *object_list*

Specifies a collection of design rule objects for which attribute needs to be set. Either one (and only one) of '-objects' or 'patterns' must be specified.

patterns

Specifies a collection of design rule objects for which attribute needs to be set. Either one (and only one) of 'patterns' or '-objects' must be specified.

DESCRIPTION

This command will allow user to set multiple attribute of design rule together. Currently, set_attribute command doesn't have the option to set multiple attributes together. Setting design rule attributes require sanity check on the updated design rule object. So to verify the sanity of updated design rule object, it might possible that multiple attributes update required. Hence this command will be useful in those scenarions.

EXAMPLES

The following example sets multiple attributes of a design rule in the technology object of the current library.

```
prompt> set_design_rule_attribute -list \
   {end_of_line_enc_5_neighbor_width_threshold 2.1 \
   end_of_line_enc_5_neighbor_cut_tbl_size 1 \
   end_of_line_enc_5_neighbor_cut_name_tbl Vs \
   end_of_line_enc_5_neighbor_max_spacing 1.2 \
   end_of_line_enc_5_neighbor_parallel_length 0.1 \
   end_of_line_enc_5_neighbor_extension_range 0.01 \
   end_of_line_enc_5_neighbor_min_enclosure 0.2 \
   end_of_line_enc_5_neighbor_check_length 1.1 \
   end_of_line_enc_5_neighbor_check_width 0.03 \
   end_of_line_enc_5_neighbor_corner_keepout_width 0.036 \
   end_of_line_enc_5_neighbor_min_spacing 0.063 \
   } DESIGN_RULE_0
```

The following example sets single attribute on multiple design rule objects.

```
prompt> set_design_rule_attribute -list {min_spacing 1.1} \
  -objects [get_design_rules DESIGN_RULE*]
```

set_design_top

Specifies the top-level design instance for simulation and verification tools.

SYNTAX

status **set_design_top**
instance_name

Data Types

instance_name	string

ARGUMENTS

instance_name

Specifies the top-level instance in the design.

DESCRIPTION

The **set_design_top** command specifies the top-level design instance. This information is used only by simulation and verification tools.

EXAMPLE

The following example shows how to use the **set_design_top** command:

```
prompt> set_design_top ALU07
```

set_device_group_type

This command specifies which device group names for library cells are wide, normal, or narrow type.

SYNTAX

string **set_device_group_type**
  -type *device_type*
  group_names

string *device_type*
list *group_names*

ARGUMENTS

-type *device_type*

Specifies the device type for the specified groups. Must be one of **wide**, **normal**, or **narrow**.

group_names

A list of device group names, which are stored as **device_group** attributes on lib_cell objects.

DESCRIPTION

This command specifies which device group names for library cells are wide, normal, or narrow device type.

It is to be noted that device group type information is non persistent

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example specifies that lib_cells with "device_group" attribute equal to "WIDE" or "wide" are considered as "wide" type for optimization.

prompt> **set_device_group_type -type wide {WIDE wide}**

SEE ALSO

set_attribute(2)

set_dft_clock_controller

Specifies the parameters for DFT-inserted clock controllers.

SYNTAX

status **set_dft_clock_controller**
-cell_name the_controller_cell_name
-ateclock the_slow_clock
-test_mode_port the_test_mode
-pllclocks pin_list
[-chain_count num_chain_count]
[-cycles_per_clock num_cycles]

Data Types

the_controller_cell_name string
the_slow_clock string
the_test_mode string
pin_list list
num_chain_count integer
num_cycles integer

ARGUMENTS

-cell_name the_controller_cell_name

Specifies the instance name of the clock controller that will be inserted by the **insert_dft** command.

-ateclock the_slow_clock

Specifies the slow clock used for scan shifting that you want to connect to the DFT clock controller.
The specified port must be defined as a RefClock signal using the set_dft_signal command.

-test_mode_port the_test_mode

Specifies the test mode port used to enable the clock controller.
The specified port must be defined as a TestMode signal with -usage occ using the set_dft_signal command.

-pllclocks pin_list

Specifies the list of PLL output clock pins to control.
The pins must be previously defined as [-type MasterClock -usage occ] signals using set_dft_signal command.

-chain_count num_chain_count

Specifies the number of clock chains to insert per clock controller. If not specified, the default is 1.

-cycles_per_clock num_cycles

Specifies the maximum number of capture cycles per clock.
If not specified, the default is 2.

DESCRIPTION

The **set_dft_clock_controller** command specifies the clock controller characteristics for the **insert_dft** command to insert and connect clock controllers and clock chains into the design.

A clock controller is a design that controls which clock signals will propagate into scan chains during scan shifting and capture. The clock controller selects between fast clocks coming from an on-chip clock generator (usually a phase-locked loop) and slow clocks coming from external ports.

A clock chain is a scan chain segment of one or more scannable control
registers. This chain allows for a per-pattern clock selection mechanism by ATPG. Clock selection values are loaded into the clock chain as part of the regular scan load process.

The clock controller cell must be included in a clock chain using the command:

set_scan_path the_occ_chain_name -include [list the_controller_names] -class occ

The number of the [set_scan_path -class occ] commands will determine the number of clock chains of the design.

EXAMPLES

```
prompt>set_dft_signal -type ScanDataIn -port OCC_SI
prompt>set_dft_signal -type ScanDataOut -port OCC_SO
prompt>set_dft_signal -type RefClock -port ate_clk -timing [list 45 55]
prompt>set_dft_signal -type MasterClock -hookup_pin pll_1/pll_clk -usage occ
prompt>set_dft_signal -type MasterClock -hookup_pin pll_2/pll_clk -usage occ
prompt>set_dft_signal -type testmode -port occ_test_mode -usage occ
prompt>set_dft_clock_controller -cell_name occ_ctrl -ateclock ate_clk -pllclocks {pll_1/pll_clk pll_2/pll_clk } -test_mode
occ_test_mode
prompt>set_scan_path my_occ_chain -scan_data_in OCC_SI -scan_data_out OCC_SO -include {occ_ctrl} -class occ
```

SEE ALSO

set_scan_path(2)
preview_dft(2)
insert_dft(2)

set_dft_clock_gating_configuration

Specifies the clock-gating configuration for a design.

SYNTAX

status **set_dft_clock_gating_configuration**
[-exclude_elements *object_list*]

Data Types

object_list cells, lib_cells, or clocks

ARGUMENTS

-exclude_elements *object_list*

Specifies a list of clock-gating cells, clock-gating observation cells, hierarchical cell instances containing these cells, lib_cells of these cells, or clocks of these cells that are to be excluded when the test control pins of clock-gating cells are connected during DFT insertion. These excluded clock-gating cells are not checked for unconnected test pins during **dft_drc**, and therefore they do not cause TEST-130 violations. Downstream registers driven by these excluded clock-gating cells will have DRC violations if their clocks are uncontrollable.

If a hierarchical cell instance is specified, all clock-gating cells and clock-gating observation cells in that instance are included in the specification.

If a clock-gating library cell is specified, all instances of that cell are included in the specification.

If a clock is specified, clock-gating cells in the respective clock domain are included in the specification. The clock must be defined with the **create_clock** command.

Cells with CTL models or inside CTL models are ignored and excluded from the specification.

This option accepts wild cards and collection inputs. This option is cumulative across multiple commands.

DESCRIPTION

This command specifies the clock-gating configuration for DFT flows. It affects how clock-gating logic is handled by the **dft_drc**, **insert_dft**, and **compile** commands.

Exclusion works by leaving the default deasserted constant value connected to the test pins of excluded clock-gating cells. If an exclusion applies to a clock-gating cell with an existing test pin connection other than the default deasserted constant value, that existing test pin connection remains in place.

The precedence of clock-gating cell test pin connection control methods is as follows, in order of highest to lowest priority:

- **set_dft_signal -connect_to** (highest priority)
- **set_dft_clock_gating_configuration -exclude_elements**

The **-exclude_elements** exclusion option will function with, but is not intended for, registers driven by user-defined clock-gating cells defined via **set_dft_clock_gating_pin** command. If you do not want to connect the test pins of these clock-gating cells, then they should not be defined. Registers driven by user-defined clock gating cells are traced through simple buffer and inverter logic only.

EXAMPLES

The following example excludes a particular clock-gating cell from having its test pin connected:

```
prompt> set_dft_clock_gating_configuration \
    -exclude_elements I_ADD/clk_gate_add_out_reg
```

The following example excludes clock-gating cells and clock-gating observation logic inside a hierarchical cell instance:

```
prompt> set_dft_clock_gating_configuration -exclude_elements U_block
```

The following example excludes all instances of a particular library cell of the 'slow' library:

```
prompt> set_dft_clock_gating_configuration \
    -exclude_elements [get_lib_cell slow/ABCD123XYZ]
```

The following example excludes a particular clock-gating observation leaf cell:

```
prompt> set_dft_clock_gating_configuration -exclude_elements Uclk_gate_obs
```

The following example excludes clock-gating cells in a particular clock domain:

```
prompt> create_clock -period 5 CLK

prompt> set_dft_clock_gating_configuration -exclude_elements CLK
```

set_dft_clock_gating_pin

Specifies the test pin of a clock-gating cell in a design. The main purpose of this command is to identify the unconnected test pins of the clock-gating cells that were not inserted by Power Compiler. These pins are connected to test ports when you run DFT insertion.

SYNTAX

status **set_dft_clock_gating_pin**
object_list
-pin_name *instance_pin_name*
[-control_signal ScanEnable | TestMode]
[-active_state 1 | 0]

Data Types

object_list list

ARGUMENTS

object_list

Specifies the clock-gating cell instances for which test pins are specified. This is a required argument.

Wildcards and collections are supported.

-pin_name *instance_pin name*

Specifies the name of the test pin on the specified instances. This pin name is common to all specified instances. This is a required argument.

-control_signal ScanEnable | TestMode

Specifies the type of control signal required by the test pin. DFT insertion connects the pin to a test port of the specified type. This argument is optional. By default, the control signal type is ScanEnable.

-active_state 1 | 0

Specifies the active state of the test pin. This argument is optional. By default, the active state is high, that is, 1.

DESCRIPTION

Specifies the test pins of clock-gating cells not inserted by Power Compiler for DFT flows. The command affects how clock-gating logic is handled by the **dft_drc**, **insert_dft**, and **compile** commands.

Identified cells can be connected to user-specified test ports by using the **set_dft_signal -connect_to** command. However, they are not connected when clock-domain-based connection is done, by using the **set_dft_signal -connect_to** command. For clock-domain-based connection, only clock-gating cells recognized and inserted by Power Compiler are supported.

You must be careful when specifying the instance pin name because the test pin name is common to all specified instances.

There is no checking for the specified cells. It is your responsibility to make sure that the specified cell and pin are actually a clock-gating cell and test pin that was not identified by Power Compiler. Specifying a cell that is not a clock gating cell can cause undesired results when you run DFT insertion.

Existing connections are maintained. If the specified test pin is already connected to a test port or logic, the tool command does not disconnect and reconnect the test pin. Also, the **dft_drc** command will not issue a TEST-130 message for the pin. Only test pins driven by a logic constant and not connected to a net or to a net without a driver are handled by the **dft_drc** command and subsequently connected by the tool.

EXAMPLES

The following examples identify a particular clock-gating cell.

```
# Identification using the default setting:

prompt> set_dft_clock_gating_pin {sub1/clk_gate_out1_reg} \
        -pin_name TE

# Identification using explicit specifications:

prompt> set_dft_clock_gating_pin {sub1/clk_gate_out1_reg} \
        -pin_name TE -control_signal ScanEnable -active_state 1

prompt> set_dft_clock_gating_pin {sub2/clk_gate_out1_reg} \
        -pin_name TE -control_signal ScanEnable -active_state 0

# Identification using explicit specifications with the test pin controllable by a test mode:

prompt> set_dft_clock_gating_pin {sub3/clk_gate_out1_reg} \
        -pin_name TE -control_signal TestMode

prompt> set_dft_clock_gating_pin {sub4/clk_gate_out1_reg} \
        -pin_name TE -control_signal TestMode -active_state 0

# Identify test pin SE on all instances of library cell MyCGCell with default settings:

prompt> set_dft_clock_gating_pin [get_cells * -hierarchical \
        -filter "ref_name == MyCGCell"] -pin_name SE
```

SEE ALSO

dft_drc(2)

set_dft_configuration

Sets the DFT configuration for the current design.

SYNTAX

status **set_dft_configuration**
[-scan enable | disable]
[-bsd enable | disable]
[-ait enable | disable]
[-hsio enable | disable]
[-wrapper enable | disable]
[-clock_controller enable | disable]
[-scan_compression enable | disable]
[-pipeline_scan_data enable | disable]
[-testability enable | disable]
[-logicbist enable | disable]
[-ieee_1500 enable | disable]
[-mode_decoding_style binary | one_hot]

ARGUMENTS

-scan enable | **disable**

Enables or disables the SCAN utility.

The default is **enable**.

-bsd enable | **disable**

Enables or disables the insertion of IEEE Std 1149.1/1149.6 compliant boundary-scan circuitry.

-ait enable | **disable**

Enables or disables the insertion of AIT Controller.

-hsio enable | **disable**

Enables or disables the insertion of HSIO Controller.

-wrapper enable | **disable**

Enables or disables the Core wrapper utilities. The specifications for the utilities are set with the **set_wrapper_configuration** command.

-clock_controller enable | **disable**

Enables or disables the clock controller insertion for on chip clocking.

-scan_compression enable | disable

Enables or disables the insertion of scan compression structures.

-pipeline_scan_data enable | disable

Enables or disables the insertion of pipeline scan data registers to scan chains. By default, the pipeline scan data utility is disabled.

-testability enable | disable

Enables or disables the testability test-point client (automatic test-point insertion and user-defined test points).

-logicbist enable | disable

Enables or disables the insertion of LogicBIST compression, which provides built-in self-test capability for scannable logic.

-ieee_1500 enable | disable

Enables or disables the IEEE 1500 test-mode control functionality.

Use this option to enable both the DFT-inserted IEEE 1500 controller flow and the existing IEEE 1500 controller flow.

-mode_decoding_style binary | one_hot

Specifies the type of port decoding to be used for the test modes controller. Allowed values are binary and one_hot. The default value is binary.

DESCRIPTION

The **set_dft_configuration** command specifies the DFT configuration for a design. The DFT configuration is specific to the current design. If you change the DFT configuration and then change the current design, your changes are no longer visible.

Use the **report_dft** command to display the current DFT configuration of the design.

EXAMPLES

The following command disables the stitching of scan chain during compile

prompt> **set_dft_configuration -scan disable**

SEE ALSO

insert_dft(2)
report_dft(2)
set_dft_signal(2)

set_dft_drc_configuration

Sets the DFT DRC configuration for the current design.

SYNTAX

status **set_dft_drc_configuration**
[-internal_pins enable | disable]
[-static_x_analysis enable | disable]
[-occ_bypass enable | disable]
[-pre_dft_drc_verbose_report_in_compile enable | disable]
[-pre_dft_drc_report_file_in_compile *filename*]
[-use_test_model true | false]
[-allow *drc_list*]
[-ignore *drc_list*]
[-allow_se_set_reset_fix true | false]
[-clock_gating_init_cycles *integer*]

Data Types

filename string
drc_list string

ARGUMENTS

-internal_pins

Enables the "internal pins" flow, in which internal pins can be specified as clock, reset, set, constant, scan-in, scan-out, scan-enable, and test_mode signals.

When **-internal_pins** is set to **enable**, you can specify internal pins to be as clock, reset, set, constant, scan-in, scan-out, scan-enable and test_mode signals. You can specify these internal pins using the **set_dft_signal** and **set_scan_path** commands. These signals are then used by the **dft_drc**, **preview_dft**, **insert_dft**, and **compile** commands. However, the protocol generated at the end of post-DFT DRC is not complete and cannot be used by the user.

-static_x_analysis enable | **disable**

Enables pre-DFT DRC to report static-X scan cell violations. The default is **disable**.

-occ_bypass enable | **disable**

Enables the on-chip clocking (OCC) bypass mode during post-DFT DRC.

-pre_dft_drc_verbose_report_in_compile disable | **enable**

Controls whether the pre-DFT DRC report generated by the **compile_fusion** command is reported in summary or verbose form. The default is the summary form.

-pre_dft_drc_report_file_in_compile *filename*

Controls whether the pre-DFT DRC report generated by the **compile_fusion** command is written to a file or included in the compile comand output. The default is to include it in the compile command output.

-use_test_model true | false

Replaces DFT-inserted blocks with their test model representations during DFT DRC and scan architecting. The default is **true**.

When this option is set to **false**, **dft_drc** uses the gates instead of the test model attached to a block. Use this only for blocks containing scan chains and complex test control structures, where the test model does not accurately describe the test control logic.

-allow *drc_list*

Specifies that for the specified DRC violations, DFT should allow violating cells to be included in scan chains. The violations are still reported.

-ignore *drc_list*

Specifies that for the specified DRC violations, DFT should completely ignore the violations. The violating cells are included in scan chains and the violations are not reported.

-allow_se_set_reset_fix true | false

Controls whether pre-DFT and post-DFT DRC allow internally generated reset signals that are gated by the scan-enable signal. When set to the default of **false**, DFT DRC does not allow scan cells to be driven by any internally generated reset; they are marked as violations and excluded from scan chains. When set to **true**, DFT DRC allows scan cells whose internally generated reset signals are gated by the scan-enable signal during scan shift.

Note that scan-enable signals driving existing testability logic in your design must be defined with the **-view existing_dft** option of the **set_dft_signal** command for pre-DFT DRC to consider them, even if they are already also defined with the **-view spec** option.

This option is equivalent to the **set_drc -allow_unstable_set_reset** option in TetraMAX ATPG.

-clock_gating_init_cycles *integer*

Adds the specified number of additional clock pulses to the test_setup section of the test protocol. This is useful for initialization of multiple cascaded sequential clock-gating cells. The default is zero.

DESCRIPTION

This command specifies the configuration for DFT DRC, which is performed explicitly by the **dft_drc** command and can be performed implicitly by the **preview_dft**, **insert_dft**, and **compile** commands if not previously run.

Allowing or Ignoring Certain DRC Violations

The **-allow** and **-ignore** options can be used to change how the following DRC rule violations are treated by DFT insertion:

- TEST-504 (warning) Cell %s has constant 0 value.
- TEST-505 (warning) Cell %s has constant 1 value.
- D17 (warning) D17 Clock input I of <type> S couldn't capture data.

By default, these DRC violations cause DFT to omit the violating cells from scan chains. You can use this command to include them in scan chains, with or without the violations being reported.

These options are similar to the **set_rules** command in TetraMAX in that both commands control how the tool treats DRC rule violations. However, they are different in that these options control how the scan chain hardware is built.

Note that the following commands take precedence over the **-allow** and **-ignore** options:

- If a flip-flop also has a **set_scan_element false** attribute applied, it takes precedence and this specification has no effect.
- If a flip-flop holds a constant value due to the **set_test_assume** command, this assumed constant value takes precedence and this specification has no effect.

EXAMPLES

prompt> **set_dft_drc_configuration -internal_pins enable**

SEE ALSO

dft_drc(2)
set_dft_signal(2)

set_dft_drc_rules

Alters how certain DRC rule violations affect DFT insertion for the specified cells.

SYNTAX

int **set_dft_drc_rules**
[-allow *drc_list*]
[-ignore *drc_list*]
[-cell *cell_list*]

Data Types

drc_list string
cell_list string

ARGUMENTS

-allow *drc_list*

Specifies that for the specified DRC violations, DFT should allow violating cells to be included in scan chains. The violations are still reported.

-ignore *drc_list*

Specifies that for the specified DRC violations, DFT should completely ignore the violations. The violating cells are included in scan chains and the violations are not reported.

-cell *cell_list*

Limits the DFT DRC specification to certain cells. If no cells are specified, the specification applies globally to all cells.

DESCRIPTION

The **set_dft_drc_rules** command can be used to change how certain DRC rule violations affect DFT insertion. The list of DRC rule violation IDs supported by this command is:

- TEST-504 (warning) Cell %s has constant 0 value.
- TEST-505 (warning) Cell %s has constant 1 value.
- D17 (warning) D17 Clock input I of <type> S couldn't capture data.

By default, these DRC violations cause DFT to omit the violating cells from scan chains. You can use this command to include them in scan chains, with or without the violations being reported.

The **set_dft_drc_rules** command in DFT Compiler is similar to the **set_rules** command in TetraMAX in that both commands control how the tool treats DRC rule violations. However, they are different in that the **set_dft_drc_rules** command controls how the DRC violations affect DFT insertion, while the **set_rules** command controls the severity of DRC violations for a static design.

Note that the following commands take precedence over a **set_dft_drc_rules** specification:

- If a flip-flop also has a **set_scan_element false** attribute applied, it takes precedence, and the **set_dft_drc_rules** specification has no effect.
- If a flip-flop holds a constant value due to the **set_test_assume** command, this assumed constant value takes precedence, and the **set_dft_drc_rules** specification has no effect.

EXAMPLES

The following example allows all cells that violate TEST-504 and TEST-505 to be included on scan chains, with the violations reported:

```
prompt> set_dft_drc_rules -allow {TEST-504 TEST-505}
```

The following example allows all cells that violate TEST-504 and TEST-505 to be included on scan chains in the hierarchical instance USPARE_GATES, with the violations not reported:

```
prompt> set_dft_drc_rules -ignore {TEST-504 TEST-505} -cell USPAREGATES
```

SEE ALSO

dft_drc(2)
insert_dft(2)
preview_dft(2)

set_dft_equivalent_signals

Sets a given list of DFT signals as equivalents.

SYNTAX

integer **set_dft_equivalent_signals**
signal_list

Data Types

signal_list list

ARGUMENTS

signal_list

Lists the signals to check against the primary signal for equivalency requirements. The first signal in the list is the primary signal. The primary signal is used to check for valid equivalences with the remaining signals in the list for type and other (if any) equivalency requirements. All the signals must have the same signal type.

DESCRIPTION

This command sets a specified list of scan signals as equivalent for scan architect. This is supported only for clock signal types (ScanClock, MasterClock, and ScanMasterClock), as specified by the **set_dft_signal** command or inferred by the **create_test_protocol** command.

Use this command to specify a set of clocks as equivalent for scan architect. This enables the architect to consider all flops driven by these clocks as if driven by the same clock, and the architect will not add any synchronization elements when they are mixed in a scan chain.

EXAMPLES

The following example illustrates setting two clocks as equivalent to clock clk1:

prompt> **set_dft_equivalent_signals [list clk1 clk2 clk3]**

set_dft_insertion_configuration

Sets the DFT insertion configuration for the current design

SYNTAX

status **set_dft_insertion_configuration**
[-unscan true | false]

ARGUMENTS

-unscan true | **false**

Specifies whether to unscan invalid scan-replaced cells during scan synthesis. A scan-replaced cell is invalid if it has a DRC violation. By default this option is set to false.

DESCRIPTION

The set_dft_insertion_configuration command specifies the configuration to use for the current design during the DFT insertion process. The settings apply only to the current design. If you change the DFT insertion configuration and then change the current design, your changes are no longer visible.

EXAMPLES

```
prompt>set_dft_insertion_configuration -unscan true
```

SEE ALSO

preview_dft(2)
compile(2)
set_scan_configuration(2)

set_dft_isolation

Specify the UPF isolation strategy to be used by dft connections.

SYNTAX

status **set_dft_isolation**
-ref_strategy *isolation_strategy*
-ref_domain *power_domain*
[-dft_target_domain *target_power_domain*]
[-type *type_list*]
[-exclude_type *exclude_type_list*]

Data Types

isolation_strategy string
power_domain string
target_power_domain *string*
type_list list
exclude_type_list list

ARGUMENTS

-ref_strategy *isolation_strategy*

Specify the strategy that will be applied to DFT ports. It shall be an existing element-based isolation strategy. If no **-type** is specified the strategy will apply to all DFT signal types in the domain. You can use **-type** for specific DFT signal types. Alternatively you can also use **-exclude_type** to exclude specific DFT signal types in the domain.

-ref_domain *power_domain*

Specify the domain where **-ref_strategy** is defined.

-dft_target_domain *target_power_domain*

Specify the target power domain of the connection.

-type *type_list*

Specify the connection types. Here is the list of supported connection types: scan_clock, scan_in, scan_out, scan_in_out, scan_enable, test_mode, wrp_clock, input_wrp_shift, output_wrp_shift, wrp_shift, wrp_ded_capture_in, wrp_ded_capture_out, wrp_ded_capture_inout, wrp_td_test, wrp_safe_in, wrp_safe_out, pse_clock, los_pipeline_enable, test_point_clock, test_point_test_mode.

-exclude_type *exclude_type_list*

Specify the connection types to be excluded. This option is mutually exclusive with **-type** option.

DESCRIPTION

This command specifies the strategy that will be applied to DFT ports punched by the tool.

EXAMPLES

The following example specifies isolation strategy iso1 on domain pd1 will be used for type scan_in.

prompt> **set_dft_isolation -ref_strategy iso1 -ref_domain pd1 -type scan_in**

SEE ALSO

set_isolation(2)
report_dft_isolation(2)

set_dft_location

Specifies the DFT hierarchy location for DFT insertion.

SYNTAX

status **set_dft_location**
dft_hier_name
[-include CODEC | WRAPPER | PLL | SERIAL_CNTRL]

Data Types

dft_hier_name string

ARGUMENTS

dft_hier_name

Specifies the hierarchical path name of an instance in the current design into which all DFT logic will be added during DFT insertion.

This argument is required.

-include CODEC | WRAPPER | PLL | SERIAL_CNTRL

Specifies the types of DFT logic to be included in the specified DFT location.

CODEC logic includes the compressor and decompressor (codec) logic inserted by the tool for compressed scan, serialized compressed scan, and streaming compressed scan modes.

PLL logic includes PLL controller and clock chain logic.

WRAPPER logic includes dedicated wrapper cells and wrapper mode logic.

SERIAL_CNTRL logic includes the serializer clock controller used in serializer insertion flows.

More than one type of DFT logic can be included with this option.

When this option is not specified, the location specification applies as a default to all DFT logic types.

DESCRIPTION

The **set_dft_location** command can be used to add all DFT logic into a user-specified hierarchy during DFT insertion.

If the **-include** option is not specified, the location specification applies as a default to all DFT logic types. Any type-specific specifications take precedence over this default location specification. You can use the **report_dft -location** command to report the resulting location specification.

In the normal serializer insertion flow, the deserializer and serializer registers are always placed inside the decompressor and compressor, respectively, whose location is specified with the CODEC logic type. To place the deserializer and serializer registers in a different hierarchy location than the combinational codec logic, use the serializer IP insertion flow and specify the register location with the SERIAL_REG logic type.

EXAMPLES

The following example specifies a DFT hierarchy location for the design top. All types of DFT logic are included in the specified location.

```
prompt> set_dft_location core_inst/dft_inst
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for wrapper logic. The codec logic is inserted at another DFT location. Any other DFT logic should not be inserted in these locations.

```
prompt> set_dft_location core_inst/dft_inst1 -include { WRAPPER }
Accepted DFT location specification.
1
prompt> set_dft_location core_inst/dft_inst2 -include { CODEC }
Accepted DFT location specification.
1
```

SEE ALSO

remove_dft_location(2)
report_dft(2)

set_dft_signal

Defines the dft signal type for a set of signals.

SYNTAX

status **set_dft_signal**
-type *signal_type*
[-view *view_name*]

[-associated_internal_clocks *clock_pins_list*]

Data Types

signal_type string
view_name string
mode_name_list list
port_list list
hookup_pin list
timing list
period float
use_type list
ctrl_bits_list list
clock_name string
object_list list
clocks_pins_list list

ARGUMENTS

-view

Indicates the view to which the specification applies. The following views are valid:

- **existing_dft** implies that the specification refers to the existing usage of a port. For example, when working with a design

that is already DFT-inserted, the command to indicate that port SE is used as a scan-enable port is as follows:

set_dft_signal -view existing_dft -port SE -type ScanEnable

- **spec** (the default) implies that the specification refers to ports that the tool must use during DFT insertion. For example, when preparing a design for DFT insertion, the command to specify that port SE is used as a scan-enable port for DFT insertion is as follows:

set_dft_signal -view spec -port A -type ScanEnable

-test_mode ***mode_name_list***

Specifies the test mode(s) to which the specification applies. Test modes are created with the **define_test_mode** command. A value of **all** or **all_dft** causes the specification to apply to all test modes.

If the **-test_mode** option is not specified, the command applies to the current test mode, which is determined by the last **define_test_mode** or **current_test_mode** command executed. If no test modes have been defined, the command applies to the default test mode.

-type ***signal_type***

Specifies the signal type. The valid signal types are as follows:

- **Reset** is the asynchronous set or reset of the design.
- **Constant** is a continuously applied value to a port.
- **TestMode** is a continuously applied value to a test mode port that may have different values between test modes.
- **ScanDataIn** is one of the scan inputs of the design.
- **ScanDataOut** is one of the scan outputs of the design.
- **ScanEnable** is the shift enable of a MUX-D scan design.
- **ScanClock** is a clock that performs both scan shift and capture in a MUX-D scan design. (This type is equivalent to defining the clock as both the MasterClock and ScanMasterClock types; there is no CTL signal type called ScanClock.)
- **ScanMasterClock** is the clock responsible for scan shift. In an LSSD scan style, the ScanMasterClock is the A clock, and in a clocked scan style it is the shift clock.
- **MasterClock** is the clock responsible for capture.

In general, the MasterClock is used for referring to the capture clock and ScanMasterClock for referring to the shift clock. Use the ScanClock signal type, which simultaneously specifies both MasterClock and ScanMasterClock types.
If **-usage occ** is used, MasterClock specifies the output pin of the on-chip clock generator or the output pin of the user-instantiated on-chip clock controller. In both cases, the **-hookup_pin** option must be used. This is a constantly running clock signal that never turns off.

- **RefClock** is a constant running external ATE clock.

The following signal types can be used in IEEE 1149 synthesis and integration:

- **tdi** specifies the TDI port or bsd reg tdi access pin.
- **tdo** specifies the TDO port or bsd reg tdo access pin.
- **tdo_en** specifies the TDO port enable pin.
- **tck** specifies the TCK port.
- **tms** specifies the TMS port.

- **trst** specifies the TRST port.
- **CaptureEn** signal enables capture flop.
- **ShiftEn** signal enables shift flop.
- **UpdateEn** signal enables capture flop.
- **Select** specifies the scan-path selection signal, which selects Test Data Register(TDR) register.
- **bsd_shift_en** specifies the register access pin to be hooked up to TAP shift_dr pin when the instruction that selects the register is active.
- **bsd_capture_en** specifies the register access pin to be hooked up to TAP sync_capture_en pin when the instruction that selects the register is active. This signal is also used in core integration.
- **bsd_capture_dr** specifies the register access pin to be hooked up to TAP Capture-DR state on the negative edge of TCK when the instruction that selects the register is active.
- **bsd_update_en** specifies the register access pin to be hooked up to TAP sync_update_dr pin when the instruction that selects the register is active. This signal is also used in core integration.
- **bsd_update_dr** specifies the register access pin to be hooked up to TAP Update-DR state on the negative edge of TCK when the instruction that selects the register is active.
- **capture_clk** specifies the register access pin to be hooked up to TCK/clock_dr pin when the instruction that selects the register is active.
- **update_clk** specifies the register access pin to be hooked up to TCK/update_dr pin when the instruction that selects the register is active.
- **inst_enable** specifies the register access pin to be held active when the instruction that selects the register is active.
- **bist_enable** specifies the register access pin to be held active when the instruction that selects the register is active and TAP is in Run-Test-Idle state.
- **bist_clk** specifies the register access pin to be hooked up to TCK when the instruction that selects the register is active and TAP is in Shift-DR state. This signal is also used in core integration.
- **bsd_reset** specifies the register access pin to be hooked up to the Test-Logic-Reset FSM state signal when the instruction that selects the register is active. When the bsd_reset signal is not part of any instruction's test data register definition, it is hooked up directly to the Test-Logic-Reset state signal.
- **bsd_test_logic_reset** specifies the Test-Logic-Reset TAP FSM state signal.
- **bsd_run_test_idle** specifies the Run-Test-Idle TAP FSM state signal.
- **bsd_select_dr_scan** specifies the Select-DR TAP FSM state signal.
- **bsd_capture_dr** specifies the Capture-DR TAP FSM state signal.
- **bsd_shift_dr** specifies the Shift-DR TAP FSM state signal.
- **bsd_exit1_dr** specifies the Exit1-DR TAP FSM state signal.
- **bsd_pause_dr** specifies the Pause-DR TAP FSM state signal.
- **bsd_exit2_dr** specifies the Exit2-DR TAP FSM state signal.
- **bsd_update_dr** specifies the Update-DR TAP FSM state signal.
- **bsd_select_ir_scan** specifies the Select-IR TAP FSM state signal.

- **bsd_capture_ir** specifies the Capture-IR TAP FSM state signal.
- **bsd_shift_ir** specifies the Shift-IR TAP FSM state signal.
- **bsd_exit1_ir** specifies the Exit1-IR TAP FSM state signal.
- **bsd_pause_ir** specifies the Pause-IR TAP FSM state signal.
- **bsd_exit2_ir** specifies the Exit2-IR TAP FSM state signal.
- **bsd_update_ir** specifies the Update-IR TAP FSM state signal.
- **bsd_mode_in** is the mode signal for input BSR cells.
- **bsd_mode_out** is the mode signal for output BSR cells.
- **bsd_mode1_inout** is the mode signal for mode1 of BC_7 BSR cells.
- **bsd_mode2_inout** is the mode signal for mode2 of BC_7 BSR cells.

The following signal types can be used in IEEE 1687:

- **iTdi** Specifies Test Data input port for IEEE 1687 IP.
- **iTdo** Specifies Test Data output port for IEEE 1687 IP.
- **iTck** Specifies Test Clock port for IEEE 1687 IP.
- **iTrst** Specifies Test reset port for IEEE 1687 IP.
- **iCaptureEn** iCaptureEn signal enables capture flop.
- **iShiftEn** iShiftEn signal enables shift flop.
- **iUpdateEn** iUpdateEn signal enables update flop.
- **iSelect** Specifies the scan-path selection signal, which selects Test Data Register(TDR) register.

The following signal types can be used in IEEE 1838:

- **stapTdi** Specifies Test Data input port for STAP of the design.
- **stapTdo** Specifies Test Data output port for STAP of the design.
- **stapTms** Specifies Test Mode Select port for STAP of the design.
- **stapTck** Specifies Test Clock port for STAP of the design.
- **stapTrstn** Specifies Test reset port for STAP of the design.

-timing

Specifies the rise time and fall time for clocks. For example:

```
set_dft_signal -view existing_dft -type ScanClock \
  -port CLK -timing [list 45 55]
```

-period ***period***

Specifies the period of the on-chip clocking (OCC) reference clock. The period value is a floating point number in nanoseconds. When **-period** is used, the values specified after **-timing** indicate the leading edge and the trailing edge of the reference clock. The **-period** option is valid only on signals of the RefClock type.

-hookup_pin

Specifies the pin to which signals are to be connected. By default, the tool connects wires to the core side of identified signal ports, jumping pads and buffers as needed. The **-hookup_pin** argument overrides this behavior and instructs the tool to connect wires to the specified pin. The pin can be either a leaf pin or hierarchical pin. Validation ensures that the pin direction (driver or load) is consistent with the signal type. Verify that a specific access pin is associated with only one design port.

When the **-type** is a scan clock and **-view** is set to **existing_dft**, the **-hookup_pin** argument allows you to specify internal pins for the scan clocks along with their associated top-level clock port specified with **-port**. The resulting protocol is accurate and complete with real top-level clocks.

If hookup pins are specified, only one port can be specified in the *port_list*.

However, if the internal pins flow is enabled (**set_dft_drc_configuration -internal_pins**), a hookup pin can be specified without specifying a port. The hookup pin specified should be either on a black box or should have a proper global driver. If a proper global driver is not found, the tool will not stitch to the specified hookup pin.

-internal_clocks single | **none** | **multi**

Specifies the setting for an internal clock. An internal clock is defined as an internal signal driven by a multiplexer (or multiple input gate) output pin. This option applies only to the multiplexed flip-flop scan style and it is ignored for other scan styles.

Note that the output of clock gating cells that are introduced by the Synopsys Power Compiler will not be treated as internal clocks, even if the **-internal_clocks** option is enabled.

The **-internal_clocks** option can be set to the following values:

- **single** specifies that the tool treats any internal clocks in the design as separate clocks for the purpose of scan chain architecting. The **single** value instructs the tool to stop at the first buffer or inverter driving the flip-flops clock.
- **none** (the default) specifies that the tool does not treat internal clocks as separate clocks.
- **multi** specifies that the tool treats any internal clocks in the design as separate clocks for the purpose of scan chain architecting. The **multi** value instructs the tool to jump over buffers and inverters, stopping at the first multi-input gate driving the flip-flops clock.

-port

Indicates the list of ports on which to apply the specifications.

-active_state

Specifies the active states for the following signal types:

- **ScanEnable**
- **Reset**
- **Constant**
- **TestMode**
- **pll_reset**
- **pll_bypass**

The active state can be 0 or 1 and it specifies the active sense of the port (high or low) or an internal hookup only pin (no port is associated with the hookup pin). Wildcards and collections are supported.

-usage

Specifies the usage of the signal.

This option specifies that the tool is to use the specified signal for that purpose only.

The signal must be defined with suitable valid values when using it to connect design elements using the **set_dft_signal -connect_to** command. The valid values for *use_type* are as follows:

- **occ** specifies that the signal is an output pin of a clock generator or a free running clock. This usage is valid only for **-type MasterClock** and **-type TestMode**. For example:

  ```
  set_dft_signal -view spec -type TestMode -port TM_OCC -usage occ
  set_dft_signal -view spec -type MasterClock -hookup_pin U_pll/PLLOUT -usage occ
  ```

- **clock_gating** specifies that the signal is to be connected to the test pin of identified clock gating cells during DFT insertion. This usage is valid only for **-type ScanEnable** and **-type TestMode**.

- **scan** specifies that the signal is to be connected to the enable of scan elements during DFT insertion. This usage is valid only for **-type ScanEnable**.

Multiple usages can be specified for a signal by specifying them as a list. For example, a ScanEnable can be used to connect to test pins of clock gating cells as well as enabling scan elements.

For example,

```
set_dft_signal -view spec -port SE \
-type ScanEnable -usage {scan clock_gating}
```

-ctrl_bits ***ctrl_bits_list***

Lists triplets that specify the sequence of control bits needed to enable the propagation of the clock generator outputs. This option is used in the on-chip clocking (OCC) flow. The first element of each triplet is the cycle number (integer) indicating when the clock signal will be propagated. The second element is the pin name of the control bit (a valid design hierarchical pin name). The third element is the active value (0 or 1) of the control bit. For example:

```
set_dft_signal -type ScanEnable -hookup_pin pll_controller/clk \
 -pll_clock pll_i/pll_clk -ate_clock ate_clk \
 -ctrl_bits [list \
   0 clk_chain_i/clk_ctrl_data[0] 1 \
   1 clk_chain_i/clk_ctrl_data[1] 1 \
   2 clk_chain_i/clk_ctrl_data[2] 1] \
 -view existing_dft
```

-pll_clock ***clock_name***

Specifies the port name of the pll clock. This option is used in the on-chip clocking (OCC) flow.

-ate_clock ***clock_name***

Specifies the port name of the ATE clock. This option is used in the on-chip clocking (OCC) flow.

-connect_to ***object_list***

Specifies that the DFT signal should be connected from the port or hookup pin to only the specified design objects.

You can use the **-connect_to** option to define ScanEnable, TestMode, wrp_shift or LOSPipelineEnable signals that should only be connected to a specific set of design objects. These are known as object-specific signal definitions. Depending on the signal type, only certain design object types can be specified and certain signal usages are supported. For the different signal types and usages defined with the **-type** and **-usage** options, the allowed object types for the **-connect_to** option are:

- **-type ScanDataIn**
  - **pin** (ScanDataIn pins of CTL-modeled cores)
- **-type ScanDataOut**

    - **pin** (ScanDataOut pins of CTL-modeled cores)
- **-type ScanEnable -usage scan**
    - **cell** (leaf scan cells)
    - **cell** (hierarchical cell containing scan cells)
    - **design** (designs containing scan cells)
    - **clock** (scan cells clocked by specified clocks)
    - **pin** (ScanEnable pins of CTL-modeled cores)
- **-type ScanEnable | TestMode -usage clock_gating**
    - **cell** (clock-gating cells)
    - **cell** (hierarchical cell containing clock-gating cells)
    - **design** (designs containing clock-gating cells)
    - **pin** (ScanEnable or TestMode pins of CTL-modeled cores)
- **-type wrp_shift | input_wrp_shift | output_wrp_shift**
    - **cell** (leaf wrapper cells) - highest priority
    - **pin** (specified wrp_shift pins of CTL-modeled cores)
    - **cell** (wrp_shift pins for all wrapper segments in CTL-modeled cores)
    - **port** (wrapper cells associated with specified ports)
    - **clock** (wrapper cells clocked by specified clocks) - lowest priority
- **-type LOSPipelineEnable**
    - **clock** (pipeline scan enable logic clocked by specified clocks)

For the **clock_gating** usage, you can specify ScanEnable or TestMode signal definitions, depending on the type of clock-gating control signal (scan-enable or test-mode) used by the specified objects.

Pins of CTL-modeled cores are not supported when performing simple HSS integration of standard scan cores.

When you specify a clock-domain-based signal specification by specifying clocks, they must be defined as valid test clocks with the **set_dft_signal** command. The propagation of the test clock determines the scope of the specification; the propagation of any underlying functional clocks at the clock source is not considered.

When using clock-domain-based signal specifications with CTL-modeled cores, the following requirements must be observed during core creation to ensure that the CTL models contain clock-domain information:

- Core-level ScanEnable signals must be defined using the **-usage** option of the **set_dft_signal** command. This ensures that the core's internal scan-enable signal is not used outside its intended usage.
- Core-level ScanEnable signals defined with a usage of **clock_gating** must also be defined as domain-specific signals using the **-connect_to** *clock_list* option of the **set_dft_signal** command. This ensures that clock-specific clock-gating annotations are included in the CTL model.

If the cores do not contain clock-domain information, you can directly specify the ScanEnable pins of the CTL-modeled core instead.

The following example defines two clock-domain-based ScanEnable signals:

```
set_dft_signal -view exist -type ScanClock -timing {45 55} \
  -port {CLK1 CLK2}

set_dft_signal -type ScanEnable -port SE1 -usage scan \
  -connect_to CLK1
set_dft_signal -type ScanEnable -port SE2 -usage scan \
  -connect_to CLK2
```

The following example defines a ScanEnable signal to be used only as the clock-gating control signal for a specific block:

```
set_dft_signal -type ScanEnable -port SE_CG_IP -usage clock_gating \
  -connect_to UIP_CORE
```

The **-connect_to** option is also used in the hierarchical on-chip clocking (OCC) flow to specify the correspondence between the top-level ATE clock port and the core-level ATE clock pins. For existing top-level connections, use the **-view existing** option. For connections to be made by DFT insertion, use the **-view spec** option. For example,

```
set_dft_signal -view spec -port TOP_CLK -type MasterClock \
  -connect_to {CORE1/ATECLK CORE2/ATECLK} -timing {45 55}
```

Clock-domain-based wrapper shift signals are supported.

-associated_internal_clocks ***clock_pins_list***

Specifies a list of internal pins associated to be associated with a clock source port.

The tool assumes that the port-driven clock signal is also driven at these internal pins, with the same timing waveform and polarity. The fanout from each internal clock pin is treated as a separate clock domain when architecting scan chains, and the pin names are shown as the clock names by the **preview_dft** command.

Only leaf pins can be specified; hierarchical pins are not supported.

For example,

```
set_dft_signal -type ScanClock -port CLK \
 -associated_internal_clocks [list U1/int_clk U2/int_clk1 U1/int_clk2] \
 -view existing
```

During pre-DFT DRC, the tool does not check for logical connectivity between the port and internal clock pins. This provides a method to bypass black boxes or other logic with unknown functionality in the clock network.

The connectivity is checked in post-DFT DRC.

DESCRIPTION

The **set_dft_signal** command can be used to specify one or more primary input or output ports as DFT signals. It can be used either to describe the existing usage or to prescribe the usage during implementation.

A DFT signal has a port and a signal type. You can specify multiple DFT signals, but you can specify only one signal type. Port directions must be consistent with the signal type.

You can use the **set_dft_signal** command to declare different DFT signals for different test modes. For example, each test mode can have different scan-in and scan-out ports, or different constant, set, or reset signals. However, all test modes share the same scan-enable signals. You cannot specify different scan-enable signals for different test modes.

The **set_dft_signal** commands are not incremental. A **set_dft_signal** command that identifies a port overwrites any previous **set_dft_signal** command that identifies the same port.

To review your DFT signal specifications, use the **report_dft** command.

Descriptive specification (using **-view existing_dft**) will invalidate test protocol and details about DFT structures.

EXAMPLES

The following example defines port myStapTdi for stapTdi signal.

```
prompt> set_dft_signal -type stapTdi -port myStapTdi
Information: Accepted stapTdi dft signal specification in partition 'default_partition' for all_dft mode (DFT-1405)
1
```

set_disable_auto_mux_clock_exclusivity

Disables automatic inference of MUXed clock exclusivity at specified cell output pins.

SYNTAX

int **set_disable_auto_mux_clock_exclusivity**
[object_list]

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of one or more MUX output pins for which automatic inference of MUXed clock exclusivity is disabled.

DESCRIPTION

Automatic inference of clock exclusivity at MUX output pins is enabled by setting the time.enable_auto_mux_clock_exclusivity app option to true.

To prevent automatic inference of a specific MUX cell output as an exclusivity point, apply this command to the MUX output pin.

To undo the set_disable_auto_mux_clock_exclusivity command, use the remove_clock_exclusivity command on the same output pin.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example prevents pins MUX02/Z and MUX04/Z from being automatically inferred as clock exclusivity points.

```
prompt> set_disable_auto_mux_clock_exclusivity {MUX02/Z MUX04/Z}
```

SEE ALSO

set_clock_exclusivity(2)
remove_clock_exclusivity(2)
report_clock(2)
time.enable_auto_mux_clock_exclusivity(3)

set_disable_clock_gating_check

Disables the clock gating check for specified cells and pins in the current design.

SYNTAX

string **set_disable_clock_gating_check**
object_list

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cells and pins for which the clock gating check is disabled.

DESCRIPTION

The **set_disable_clock_gating_check** command disables clock gating checks that are inferred automatically and possibly modified by the **set_clock_gating_check** command. It does not affect clock gating checks defined in the library for integrated clock-gating cells.

You can disable clock gating checks on cells or pins in the current design or its subdesigns. Specify cells at lower levels in the design hierarchy as *instance1*/*instance2*/*cell_name*. Specify pins at lower levels in the design hierarchy as *instance1*/*instance2*/*cell_name*/*pin_name*. For subdesigns in the hierarchy, specify instance names, not design names.

Specifying a cell disables all gating checks in the cell. Specifying a pin disables any gating check in which the pin is the gating clock pin or gating enable pin.

To restore gating checks previously disabled by the **set_disable_clock_gating_check**, use the **remove_disable_clock_gating_check** command. To globally disable all clock gating checks, including clock gating checks defined in the library, set the **time.disable_clock_gating_checks** application option to **true**.

EXAMPLES

The following command disables all clock gating checks on cell U123.

prompt> **set_disable_clock_gating_check [get_cells U123]**

The following command disables clock gating checks that use pin U123/I as a gating enable pin or gating clock pin.

prompt> **set_disable_clock_gating_check [get_pins U123/I]**

set_disable_tie_insert

To exclude some pins for the insertion of tie cell.

SYNTAX

status **set_disable_tie_insert**
[-objects *object_name_or_collection*]

Data Types

object_name_or_collection collection

ARGUMENT

-objects *object_name_or_collection*

Specifies the objects for exclusion during tie cell insertion. Currently supported object types are pins and ports.

DESCRIPTION

set_disable_tie_insert command marks the pins on which tie cell will not be inserted by add_tie_cells and optimization commands.

EXAMPLES

prompt>set_disable_tie_insert -objects [get_pins {h1/reg_2_/SE h1/reg_2_/SI}]

prompt>set_disable_tie_insert -object h1/reg_2_/SE

SEE ALSO

add_tie_cells(2)
reset_disable_tie_insert(2)
report_disable_tie_insert(2)

set_disable_timing

Disables timing arcs in a circuit.

SYNTAX

string **set_disable_timing**
[-from *from_pin_name* -to *to_pin_name*]
object_list

string *from_pin_name*
string *to_pin_name*
list *object_list*

ARGUMENTS

-from *from_pin_name*

Specifies that arcs only from this pin on the specified cell are to be disabled. The *from_pin_name* value must be a valid library pin name corresponding to the cell in *object_list*. When used, the **-from** and **-to** options must be specified together. The *object_list* must contain only cells, and the command specifies that arcs only between these two pins on the specified cells are to be disabled.

-to *to_pin_name*

Specifies that arcs only to this pin on the specified cell are to be disabled. The *to_pin_name* value must be a valid library pin name corresponding to the cell in *object_list*. When used, the **-from** and **-to** options must be specified together. The *object_list* must contain only cells, and the command specifies that arcs only between these two pins on the specified cells are to be disabled.

object_list

Specifies a list of cells, pins, lib-cells, lib-pins, ports, or timing-arcs to be disabled. This list can include library objects.

DESCRIPTION

Disables timing through the specified cells, pins, ports, or timing arcs in the **current_mode**, if library cells or pins are specified, it disables the timing arcs for all modes that utilize the library.

Any cell, pin, port, or timing arc in the **current_design** or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*. Pins at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*/*pin_name*. Ports at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*/*port_name*. Timing arcs have to be collected using the *get_timing_arcs* command.

Note: For subdesigns in the hierarchy, you must specify instance names instead of design names.

When the timing through a cell is disabled, only those cell arcs are disabled that lead to the output pins of the cell. When the timing through a pin or port is disabled, only those cell arcs that lead from a load pin and to a driver pin are disabled. For bidirectional pins or ports the cell arcs from the load side and to the driver side are disabled.

When **-from** and **-to** pins are specified, all arcs between these two pins on the cell are disabled.

To view disabled timing arcs in the current design, use the **report_disable_timing** command. To restore timing arcs disabled by **set_disable_timing**, use the **remove_disable_timing** command. The **reset_design** command removes all user-specified attributes from the current design, including those set by **set_disable_timing**.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

prompt> **set_disable_timing -from A -to Z [get_cells { CO }]**

prompt> **set_disable_timing [get_timing_arcs -from { CO/A } -to { CO/Z }]**

set_domain_supply_net

Sets the primary power net and primary ground net of an existing power_domain.

SYNTAX

int **set_domain_supply_net**
-primary_power_net *supply_net_name*
-primary_ground_net *supply_net_name*
domain_name

Data Types

supply_net_name string
domain_name string

ARGUMENTS

domain_name

Specifies the name of the power domain. If a power domain with the specified name does not exist, in the current scope, this command fails.

The domain_name option is a required option and must be specified.

-primary_power_net *supply_net_name*

Specifies the power net of the power domain. If a supply net with the specified name does not exist in the current scope, the command fails. If the supply net is not associated with specified power domain, the command fails.

This is a required option and must be specified.

-primary_ground_net *supply_net_name*

Specifies the ground net of the power domain. If a ground net with the specified name does not exist in the current scope, the command fails. If the ground net is not associated with specified power domain, the command fails.

This is a required option and must be specified.

DESCRIPTION

The *set_domain_supply_net* command enables sets the primary power net and the primary ground net of a power domain. All extent of the power domain shares the same power/ground supply until explicitly excluded. Here "explicitly excluded" means it is

explicitly connected with another supply_net (non primary power/ground supply_net) by the **connect_supply_net** command. This command errors out if power domain already has a primary power and ground net.

The supply_net must be created in the same power_domain at first before it could be set as the primary power or ground supply_net. Use the **create_supply_net** command to create a supply_net at a specified power_domain.

This command cannot be used to specify the supply nets of a power domain which was created with **create_power_domain -supply {primary ..}**.

Command returns 1 on success, returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates two supply_net on power_domain PD1, then set them as primary power or ground net.

```
prompt> create_power_domain PD1 -elements INST_1
PD1
prompt> create_supply_net A_VDD -domain PD1
A_VDD
prompt> create_supply_net A_VSS -domain PD1
A_VSS
prompt> set_domain_supply_net PD1 -primary_power_net A_VDD \
  -primary_ground_net A_VSS
1
```

SEE ALSO

create_power_domain(2)
create_supply_net(2)

set_dont_retime

Prevents retiming optimization from moving registers. Command can also be used to selectively re-enable retiming on registers.

SYNTAX

int **set_dont_retime**
object_list
[true | false]

Data Types

object_list collection

ARGUMENTS

object_list

Specifies collection of registers, hierarchical cells, modules or design. If hierarchical cells are specified, all registers inside hierarchical cell are excluded from (or included into) retiming. If modules are specified, all registers inside all instances of modules are excluded from (or included into) retiming. If design is specified, all registers inside design are excluded from (or included into) retiming.

true | **false**

True excludes objects from retiming. False includes registers into retiming. Default is true.

DESCRIPTION

set_dont_retime set to true excludes registers from retiming optimization. **set_dont_retime** set to false includes registers into retiming optimization.

Applying **set_dont_retime** to true(false) on a hierarchical cell prevents(allows) retiming of all registers inside hierarchical cell. Applying **set_dont_retime** to true(false) on a leaf register prevents(allows) retiming of that register. Applying **set_dont_retime** to true(false) on a module is same as applying **set_dont_retime** to true(false) on all instances of modules. Applying **set_dont_retime** true(false) to design prevents retiming (allows retiming) of all registers in the design.

Applying **set_dont_retime** on a hierarchical object (module or hierarchical instance) takes effect on all lower, nested hierarchies of objects.

You can apply **set_dont_retime** to false if you want to selectively allows retiming on the object whose parent object has **set_dont_retime** set to true. Example below illustrates one such use.

Please note, allowing register to retime does not necessarily mean that it will get retimed. Retiming optimization will make decision based on improvement to area or delay cost.

EXAMPLES

The following example excludes cells named *z1_reg* and *z2_reg* from retiming.

```
prompt> set_dont_retime [get_cells {z1_reg z2_reg}] true
```

The following example specifies that the cell named *H1/z_reg* is allowed to retime, but other sequential cells inside *H1* are not allowed into retiming.

```
prompt> set_dont_retime [get_cells "H1"] true
prompt> set_dont_retime [get_cells "H1/z_reg"] false
```

The following example specifies that no sequential cells inside any instance of module *Controller* can be moved by retiming.

```
prompt> set_dont_retime [get_modules "Controller"] true
```

SEE ALSO

compile(2)
set_optimize_registers(2)

set_dont_touch

Sets the **dont_touch** attribute on cells, nets, designs, and library cells to prevent the tool from replacing or modifying them during optimization.

SYNTAX

status **set_dont_touch**
[*object_list*]
[*value*]

Data Types

object_list collection
value Boolean

ARGUMENTS

object_list

Specifies the objects on which to set the **dont_touch** attribute. You can set the attribute on cells, nets, designs, and library cells.

value

Specifies the value of the **dont_touch** attribute. Valid values are true (the default) or false.

DESCRIPTION

This command sets the **dont_touch** attribute on cells and nets in the current design or on designs and library cells. The **dont_touch** attribute prevents modification or replacement of these objects during optimization.

Setting the **dont_touch** attribute on a hierarchical cell implies a **dont_touch** attribute on all cells below it.

Setting the **dont_touch** attribute on a design affects the design only when the design is instantiated within another design as a level of hierarchy. In this case, the **dont_touch** attribute on the design implies that all cells under that level of hierarchy have the **dont_touch** attribute. Setting the **dont_touch** attribute on the top-level design has no effect because it is not instantiated within any other design. If the **dont_touch** attribute is on a design that is removed, the attribute continues to apply to any cells that were instances of that design until the next time the current design is linked.

Setting the **dont_touch** attribute on a library cell implies a **dont_touch** attribute on all instances of that cell.

Note that the **dont_touch** attribute applied by the tool on the cells and nets in the transitive fanout of objects with the **dont_touch_network** attribute overrides the **dont_touch** attribute setting of false that is set by the **set_dont_touch** command. To

report the **dont_touch** value on cells or nets, use the **report_cell** or **report_net** command.

To remove the **dont_touch** attribute, use the **remove_attributes** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following commands prevent modification or removal of the block1 and analog1 cells during optimization but allow the N1 net to be modified.

```
prompt> set_dont_touch [get_cells {block1 analog1}]
1
prompt> set_dont_touch  [get_nets N1] false
1
```

The following example shows that the instances of a design inherit the **dont_touch** attribute setting from the design.

```
prompt> get_attribute [get_cells u1] ref_name
d1
prompt> get_attribute [get_cells u1] dont_touch
false
prompt> set_dont_touch [get_designs d1]
1
prompt> get_attribute [get_cells u1] dont_touch
true
```

SEE ALSO

get_attribute(2)
report_dont_touch(2)
set_dont_touch_network(2)

set_dont_touch_network

Sets **dont_touch_network** on clocks, pins, or ports in the current design to prevent cells and nets in the transitive fanout of the **set_dont_touch_network** objects from being modified or replaced during optimization.

SYNTAX

status **set_dont_touch_network**
[-no_propagate]
[-clock_only]
[-clear]
object_list

Data Types

object_list collection

ARGUMENTS

-no_propagate

Indicates that the dont_touch network is not propagated through logic gates. This option is ignored for dont_touch_network of clocks.

-clock_only

Indicates that the dont_touch network is propagated only through clock networks. This option is redundant for dont_touch_network of clocks.

-clear

Indicates that the pins, ports, or clocks should no longer be sources of dont_touch_network.

object_list

Specifies the pins, ports, or clocks in the current design on which to spread network dont_touch.

DESCRIPTION

This command sets the clocks, pins, or ports in the current design as source of network dont_touch. The tool will assign **dont_touch** attributes to all cells and nets in the transitive fanout of these objects so that they are not modified or replaced during optimization. A **dont_touch** attribute assigned by the tool using the **set_dont_touch_network** command overrides the **false dont_touch** attribute value from the **set_dont_touch** command.

If you specify a pin or a port, all nets and cells in its transitive fanout are recursively marked **dont_touch**. This recursion propagates through combinational cells but stops at registers (without marking the registers as **dont_touch**). An element is recognized as a register only if it is a timing endpoint. If you specify an input pin, its own cell is marked **dont_touch** but its connected net is not marked **dont_touch**. If you specify an output pin, its own cell is not marked **dont_touch** but its connected net is marked **dont_touch**.

If you specify a clock, the transitive fanout of all the clock's sources is affected. The **set_dont_touch_network** command is intended primarily for clock circuitry. Placing a **dont_touch_network** on a clock object prevents the tool from modifying the clock buffer network during optimization. The **-clock_only** and **-no_propagate** options will be ignored for clocks.

The **set_dont_touch_network** command does not prevent clock gating optimizations from modifying or removing clock gating cells. To prevent this, use the **set_dont_touch** command instead.

If you specify the **-no_propagate** option, the dont_touch network is not propagated through cell arcs.

To see the **dont_touch** value on the cells or nets, use the **report_dont_touch**, **report_cells** or **report_nets** commands. The **report_dont_touch** and **report_nets** commands display the nets that are implicitly **dont_touch** as a result of using the **set_dont_touch_network** command.

To remove **dont_touch_network** from a pin, port, or clock, use the **-clear** option with **set_dont_touch_network** command, on the specific object on which **dont_touch_network** had been set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following command sets **dont_touch_network** on a port named clock_in:

```
prompt> set_dont_touch_network clock_in
```

The following command clears **dont_touch_network** from the port named clock_in:

```
prompt> set_dont_touch_network -clear [get_port clock_in]
```

The following command sets **dont_touch_network** on a net named net1 and a cell named cell2 but not to the cell named cell1:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y cell2/A}
prompt> set_dont_touch_network [get_pins cell1/Y]
1
```

The following command sets **dont_touch_network** on a net named net1 and cells named cell1 and cell2 but not on the net named net0:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y cell2/A}
prompt> get_pins -of_objects [get_cells cell1]
{cell1/A cell1/Y}
prompt> get_nets -of_objects [get_pins cell1/A]
{net0}
prompt> set_dont_touch_network [get_pins cell1/A]
1
```

set_dont_touch(2)

set_drive

Sets the resistance to a specified value on specified input or inout ports in the current design.

SYNTAX

string **set_drive**
  [-rise] [-fall]
  [-min] [-max]
  [-modes *mode_list*]
  [-corners *corner_list*]
  [-scenarios *scenario_list*]
  resistance port_list

list *mode_list*
list *corner_list*
list *scenario_list*
float *resistance_value*
list *port_list*

ARGUMENTS

-rise

Indicates that *resistance_value* is to be used to drive the ports only for the rising case.

-fall

Indicates that *resistance_value* is to be used to drive the ports only for the falling case.

-min

Applies only to designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* is the minimum resistance.

-max

Applies only to designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* is the maximum resistance.

-modes *mode_list*

Specifies the scenarios that the resistance value will be applied to. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners will be used.

-corners *corner_list*

Specifies the scenarios that the resistance value will be applied to. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners will be used.

-scenarios ***scenario_list***

Specifies the scenarios that the resistance value will be applied to. The **-modes** or **-corners** option may not be given with this option.

resistance

Specifies a nonnegative port drive resistance value for the ports in *port_list*. The value must be >= 0; units must be the same as those in the technology library.

port_list

Specifies a list of input or inout ports in the current design, on which the *resistance_value* is to be set.

DESCRIPTION

Sets the resistance to a specified value on specified input or inout ports in the current design. The tool models the driver as a resistance and uses that value to calculate the wire delay of the port. To view the drive that is set, use **report_port -drive**.

Depending on the options used, **set_drive** sets these attributes on the specified ports:

drive_resistance_fall_max
drive_resistance_fall_min
drive_resistance_rise_max
drive_resistance_rise_min

If **set_drive** is issued without any options, the **drive_resistance_fall_max** and **drive_resistance_rise_max** attributes are set; in min-max mode, the other two attributes are also set.

If **set_drive** is issued with only the **-rise** option, only the **drive_resistance_rise_max** attribute is set; in min-max mode, **drive_resistance_rise_min** is also set.

If **set_drive** is issued with only the **-fall** option, only the **drive_resistance_fall_max** attribute is set; in min-max mode, **drive_resistance_fall_min** is also set.

Drive resistance is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different resistances for different scenarios by using **-modes**, **-corners**, and **-scenarios** options. By default, if none of these options are specified, the given resistance is applied to the current scenario. (It will be an error if there is no current scenario). If the **-scenarios** option is given, the resistance will be applied to all of the specified scenarios. If the **-modes** option is given, the resistance will be applied to all scenarios of the specified modes. (It will be an error if none of the specified modes have any scenarios.) If the **-corners** option is given, the resistance will be applied to all scenarios of the specified corners and the current mode. (It will be an error if none of the specified corners have any scenarios with the current mode.) If both the **-modes** and **-corners** options are given, the resistance will be applied to all scenarios of the specified corners and the specified modes. (It will be an error there are no such scenarios.) It is an error to give -scenarios with **-modes** or **-corners**. Drive resistance is the output resistance of the cell that drives the port, so that a higher drive resistance means less drive capability and longer delays. Thus, a drive *resistance_value* of 0 is infinite drive, or no delay between the ports and all ports connected to them. Setting *resistance_value* to 0 is the same as removing the drive resistance with **remove_drive_resistance**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets the drive resistance to 5 on all input ports in the current scenario of the current design, and displays the ports on which the drive resistance has been set.

```
prompt> set_drive 5 [all_inputs]
1
prompt> report_port -drive
****************************************
Report : port
       -drive
Design : counter
****************************************

                Resistance          Transition
Input Port    Rise      Fall      Rise      Fall
------------------------------------------------------------

P             5.00      5.00      --        --
RESET         5.00      5.00      --        --
T             5.00      5.00      --        --
```

SEE ALSO

remove_drive_resistance(2)
report_port(2)
set_load(2)

set_drive_resistance

Sets drive resistance for input or inout ports.

Note: This command is obsolete, and has been replaced by the **set_drive** command. Use **set_drive** instead.

SYNTAX

string **set_drive_resistance** [-rise]
[-fall]
[-min]
[-max]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
resistance
port_list

float *resistance*
list *port_list*
list *mode_list*
list *corner_list*
list *scenario_list*

ARGUMENTS

-rise

Specifies to use the resistance to drive the ports for the rising case.

-fall

Specifies to use the resistance to drive the ports for the falling case.

-min

Specifies to use the resistance to drive the ports for the minimum case.

-max

Specifies to use the resistance to drive the ports for the maximum case.

-modes *mode_list*

Specifies the scenarios that the resistance value will be applied to. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode

is specified by **-modes** and whose corner is specified by -corners will be used.

-corners ***corner_list***

Specifies the scenarios that the resistance value will be applied to. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners will be used.

-scenarios ***scenario_list***

Specifies the scenarios that the resistance value will be applied to. The **-modes** or **-corners** option may not be given with this option.

resistance

Specifies a nonnegative resistance value for the ports. Port drive resistance (value >= 0).

port_list

Specifies a list of input or inout port names of the current design on which the drive attributes are to be set.

DESCRIPTION

Model the driver as a resistance and use that value to calculate the wire delay of the port. **report_port -drive** can be used to view the drive which is set.

Drive resistance is the output resistance of the cell that drives the port; such that a higher drive resistance means less drive capability and longer delays. Thus, a drive *resistance* of 0 is infinite drive, or no delay between the ports and all connected to them. This is the same as removing the drive resistance with **remove_drive_resistance**.

Drive resistance must be in units with the technology library.

Drive resistance is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different resistances for different scenarios by using **-modes**, **-corners**, and **-scenarios** options. By default, if none of these options are specified, the given resistance is applied to the current scenario. (It will be an error if there is no current scenario). If the **-scenarios** option is given, the resistance will be applied to all of the specified scenarios. If the **-modes** option is given, the resistance will be applied to all scenarios of the specified modes. (It will be an error if none of the specified modes have any scenarios.) If the **-corners** option is given, the resistance will be applied to all scenarios of the specified corners and the current mode. (It will be an error if none of the specified corners have any scenarios with the current mode.) If both the **-modes** and **-corners** options are given, the resistance will be applied to all scenarios of the specified corners and the specified modes. (It will be an error there are no such scenarios.) It is an error to give -scenarios with **-modes** or **-corners**.

Multicorner-Multimode Support

This command works on the current scenario.

EXAMPLES

```
prompt> set_drive_resistance 5 [all_inputs]
1
prompt> report_port -drive
****************************************
```

```
Report : port
       -drive
Design : counter
****************************************

                Resistance         Transition

lib_cell_name string
lib_name string
pin_name string
from_pin_name string
factor float
rising_transition float
falling_transition float
clock_name string
mode_list list
corner_list list
scenario_list list
port_list list

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of the library cell used to drive the ports. You must use the **-pin** option if the cell has more than one output pin. If different cells are needed for the rising and the falling cases, use separate commands with the **-rise** or **-fall** option. Use the **-from_pin** option to choose between multiple input pins with arcs to this output pin. This option is required.

-rise

Sets driving cell information for only the rising port transition.

-fall

Sets driving cell information for only the falling port transition.

-min

Sets driving_cell information for only the minimum analysis. This option is valid only in min-max mode.

-max

Sets driving cell information for only the maximum analysis. This option is valid even when not in min-max mode. When not in min-max mode, the option is not required because it is the default.

-library *lib_name*

Specifies the name of the library containing the *library_cell_name* value. This is the library of the driving cell. By default, the libraries in the search path are searched for the cell.

-pin *pin_name*

Uses the driver for the specified output pin. This is the driving pin name. If you do not include the **-from_pin** option, the command uses an arbitrary pin arc ending at the specified pin.

-from_pin *from_pin_name*

Specifies an input pin on the specified cell so the command uses the driver of the timing arc from this pin to the specified pin.

-multiply_by *factor*

Multiplies the calculated transition time by the specified multiplier. *factor* must be greater than or equal to 0.

-dont_scale

Prevents operating condition scaling. When you specify this option, the timing analyzer does not scale the drive capability of the ports according to the current operating conditions. By default, the port drive capability is scaled for operating conditions exactly as the driving cell itself would have been scaled.

-no_design_rule

Skips the application of design rules from the driving cell to the port. If you do not include this option, the design rules (such as max_capacitance) of the library pin are applied to the port.

-input_transition_rise *rising_transition*

Specifies the input rising transition time associated with the **-from_pin** option. Use the **-input_transition_rise** and **-input_transition_fall** options to capture the accurate transition time associated with the *from_pin_name* value. By using this option, you can obtain more accurate information on the transition time and delay time at the output pin. If you do not specify this option, the default is 0.

-input_transition_fall *falling_transition*

Specifies the input falling transition time associated with the *from_pin_name* value. If you do not specify this option, the default value is 0.

-clock ***clock_name***

Sets the driving cell relative the specified clock.

-clock_fall

Specifies that driving cell is relative to the falling edge of the clock. The default is the rising edge.

-modes ***mode_list***

Specifies the scenarios to use for the driving cell. If this option is given, all scenarios of the specified modes will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners ***corner_list***

Specifies the scenarios to use for the driving cell. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios ***scenario_list***

Specifies the scenarios to use for the driving cell. The **-modes** or **-corners** option must not be specified with this option.

port_list

Provides a list of input ports. The list contains input or inout port names in the current design on which the driving cell information is set.

DESCRIPTION

Sets the port driving cell, and sets attributes on the specified input or inout ports in the current design to associate an external driving cell with the ports. The drive capability of the port is the same as if the specified driving cell were connected in the same context to allow accurate modeling of port drive capability for nonlinear delay models. If you omit the **-dont_scale** option, the drive capability of the port is scaled according to the current operating conditions. Use the **report_ports** command with the **-drive** option to view drive information on ports.

The driving cell can be relative to a clock by using **-clock** option. This means the driving cell apply only to those external paths driven by the clock. Using **-clock** or **-clock_fall** option can be meaningful only when timing_slew_propagation_mode is in worst_arrival mode. Note if it is in worst_slew mode, there must be a driving cell without any clock specified to see any driving cell on the port. If a clock-relative driving cell is set on a port, these driving-cell attributes will not be accessible via **get_attribute** until the **-clock** and **-clock_fall** options are supported for **set_driving_cell** in SDC.

Driving cell data is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different driving cell settings for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is given, the command applies to all of the specified scenarios.

If the **-modes** option is given, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is given, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

Use the **remove_driving_cell** command to remove driving cell information from ports.

Note: The **set_driving_cell** command removes any corresponding drive resistance or input transition attributes (from the **set_drive** command or the **set_input_transition** command) on the specified ports. If possible, always use the **set_driving_cell** command instead of the **set_drive** command, because **set_driving_cell** allows accurate calculation of port delay and transition time for library cells with nonlinear dependence on capacitance.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets port A of the AND cell as the driving cell.

```
prompt> set_driving_cell \
  -lib_cell AND [get_ports A]

prompt> report_ports -drive A
****************************************
Report : port
       -drive
 ...

****************************************

             Resistance        Transition
Input Port   Rise     Fall     Rise     Fall
------------------------------------------------------------
A            --       --       --       --

                Driving Cell
Input Port   Rise             Fall             Mult    Attrs
------------------------------------------------------------------------------
A            AND              AND              --
```

set_eco_placement_net_weight

Set different net weight for individual net as user-defined net weight priority.

SYNTAX

status **set_eco_placement_net_weight**
-nets collection_of_net -weight weight
| *-reset*

Data Types

collection_of_net list or collection
weight integer

ARGUMENTS

-nets *collection_of_net*

Set net weight for one or more nets and store them in memory. The two options *-nets* and *-weight* must be used together. The option *-nets* can not be used with *-reset*. They are mutually exclusive.

-weight *weight*

Specifies the net weight. The value is integer type and should be great than or equal to 1. If the option is not used, the default net weight is 1. The two options -nets and -weight must be used together.

The net weight represents the spring force between eco cells. The bigger the net weight, the higher the force. Currently the command **place_eco_cells** uses connectivity based coarse placement. By default, all net weight are same. So the eco cell is placed with even distance to driver and load. User can decide how close the eco cells by changing the net weight.

-reset

Clean up the internal net weight mapping table. All net weight is reset to 1. The option *-nets* can not be used with *-reset*. They are mutually exclusive.

DESCRIPTION

This command sets different net weight for individual net as user-defined net weight priority. It is used before *place_eco_cells -honor_user_net_weight*, that performs placement based on user-defined net weight setting. Please refer to the man page of place_eco_cells for the flow usage about user-defined net weight based coarse placement.

The second *set_eco_placement_net_weight -nets -weight* command overwrites the first one. If user adjusts the net weight before but wants to roll back these nets, he can do it like below. *set_eco_placement_net_weight -nets $n -weight 1*

Close_block and close_lib will internally clean up the net weight data in memory since the net weight setting will confuse the placement in next session and the data may be dirty for the next opened design.

If user wants to reuse the setting, he can use report_eco_placement_net_weight -output to dump the setting before close_block and close_lib and load it when necessary.

The three commands set_eco_placement_net_weight, report_eco_placement_net_weight and place_eco_cells -honor_user_net_weight will also check if the current lib and design is consistent with the lib and design stored in memory originally, if not, the command will clean up the net weight data in memory first and then apply the command to avoid inconsistent data and unexpected result.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets net weight.

```
prompt> set_eco_placement_net_weight \
    -nets $netList -weight 3
```

The following example resets net weight.

```
prompt> set_eco_placement_net_weight -reset
```

place_eco_cells(2)
report_eco_placement_net_weight(2)

set_eco_power_intention

This command updates power intention for ECO buffers.

SYNTAX

status **set_eco_power_intention**
[-cells *cells*]

Data Types

cells collection or list

ARGUMENTS

-cells *cells*

Specifies ECO cells to update power intention. The specified cells and cells in the **eco buffer trees** of the specified cells are target cells of this command. Here, **eco buffer trees** means a group of connected timing ECO cells, separated by cells of other types. If this option is not specified, all cells added by timing ECO commands will be updated.

DESCRIPTION

This command updates power intention for timing ECO buffers (or inverters) in primary voltage area. Here **timing eco buffers (or inverters)** means buffers (or inverters) added by create_cell and timing ECO commands, including **add_buffer**, **add_eco_repeater**, **split_fanout**, **add_buffer_on_route** and **size_cell** (in freeze_silicon).

The power intention includes supply net information and power domain information. This command will update supply nets for target cells. And if the power domain inherited from the hierarchy of a target cell is not consistent with the voltage area of this cell, the command will resolve the inconsistency issue by applying a physical feedthrough (PFT) or logical feedthrough (LFT) solution.

The buffer added on a physical feedthrough net will have the inconsistency issue that logically it belongs to the logic hierarchy of the net while physically it belongs to the voltage area where it is placed. Here the physical feedthrough net is a net which passes through a foreign voltage area in the physical view of its design.

The physical feedthrough (PFT) solution resolves this inconsistency by setting one power domain of the voltage area directly on the buffer (power domain on instance). And the logical feedthrough (LFT) solution resolves this inconsistency by moving the buffer to a logic hierarchy under a power domain of the voltage area. This command will try PFT solution first, and if PFT can not work, the LFT solution will be used if enabled by the settings.

The PFT solution is always enabled in this command. The LFT solution is not enabled by default and can be enabled or not by the command **create_voltage_area_rule** and the app option **mv.cells.mv_allow_logical_feedthrough**.

- When there is voltage area rule with the option **-allow_logical_feedthrough true**, the LFT solution is allowed without considering the app option **mv.cells.mv_allow_logical_feedthrough**.
- When there is voltage area rule with the option **-allow_logical_feedthrough false**, The LFT solution is not allowed without considering the app option **mv.cells.mv_allow_logical_feedthrough**.
- When there is no voltage area rule, the LFT solution is allowed if the app option **mv.cells.mv_allow_logical_feedthrough** is **true** and not allowed if the app option **mv.cells.mv_allow_logical_feedthrough** is **false**.

If there is any violation when updating power intention for a target cell, the power intention of the whole buffer tree that contains this cell will not be updated. This command can handle multiple buffer trees. If the processing for some trees fails during update power intention, the cells of the failed trees will be added to the collection $ecoUpdateSupplyFailedCells and a warning message is issued for each failing buffer tree. But these cells will not be removed by this command.

This command does not support undo.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples shows how to using the **set_eco_power_intention** command to update supply nets and power domain on instance for the specified cells.

```
prompt> set_eco_power_intention -cells {eco_cell_0}
```

The following examples shows how to enable LFT solution in the **set_eco_power_intention** command.

```
prompt> create_voltage_area_rule -name vaRule -allow_logical_feedthrough true
prompt> set_eco_power_intention -cells {eco_cell_0}
```

set_edit_setting

Sets common editing settings.

SYNTAX

string **set_edit_setting** [-ignore_fixed *state*]
[-ignore_locked *state*]
[-keep_pin_on_edge *state*]
[-self_intersection *state*]
[-update_floorplan *state*]
[-update_color_mask *state*]
[-auto_display_hidden *state*]
[-select_partial_object *state*]
[-select_edge *state*]
[-select_vertex *state*]
[-select_center_line *state*]
[-select_center_vertex *state*]
[-expand_hit_macro_cell *state*]
[-expand_hit_blockage *state*]
[-expand_hit_constraint *state*]
[-honor_ndr *state*]
[-hierarchical_routing *state*]
[-pin_layer_policy *layer_policy*]
[-specified_pin_layer *layer_name*]
[-default]

Data Types

state string or collection
layer_policy string or collection
layer_name string or collection

ARGUMENTS

-ignore_fixed *state*

Ignores the locks flag and modify fixed or locked objects. The option is synonym of **-ignore_locked** option.

-ignore_locked *state*

Ignores the locks flag and modify fixed or locked objects. The option is synonym of **-ignore_fixed** option.

-keep_pin_on_edge *state*

Keeps pins on parent edge of the pin.

-self_intersection *state*

Allows self intersection of shapes.

-update_floorplan *state*

Updates the floorplan when the cell boundary is changed. Pin locations are updated based on the change in cell boundary. If the changes are small or do not affect the original placement of the pins, the pins are moved only a small distance or not at all. When the change to cell boundary is large, the pins locations are updated to be useful in displaying connections, but you are expected to place the pins again pins at a later time.

-update_color_mask *state*

Updates the color mask for net shapes to match the tracks they are snapped to, if the track has a specified mask color.

-auto_display_hidden

Displays hidden objects automatically.

-select_partial_object *state*

Allows selection of an object by selecting only a part of the object, such as a vertex or edge.

-select_edge *state*

Allows objects to be selected by selecting only the edge of the object.

-select_vertex *state*

Allows objects to be selected by selecting only a vertex of the object.

-select_center_line *state*

Allows objects to be selected by selecting only the center line of the object.

-select_center_vertex *state*

Allows objects to be selected by selecting only the center vertex of the object.

-expand_hit_macro_cell *state*

Expands the hit type to include macro cells.

-expand_hit_blockage *state*

Expands the hit type to include blockages.

-expand_hit_constraint *state*

Expands the hit type to include constraints such as bounds, voltage areas, and so on.

-honor_ndr *state*

Honor non-default width and spacing during editing.

-hierarchical_routing *state*

Treats hierarchical nets as the same net for routing and tracing.

-pin_layer_policy *layer_policy*

Specifies the layer policy applied while moving pins between edges. Valid values are: **preferred**, **keep**, and **specified**.

- **preferred**: Determine the pin layer based on the preferred routing direction going through the edge. This is the default

setting.

- **keep**: Use the same layer
- **specified**: Use the specified layer

-specified_pin_layer *layer_name*

Specifies the pin layer name when the layer policy setting is "specified"

-default

Resets all options to their defaults.

DESCRIPTION

This command is used to specify common editing settings.

EXAMPLES

The following example enables self intersection of shapes while performing edits.

```
prompt> set_edit_setting -self_intersection true
1
```

SEE ALSO

get_edit_setting(2)

set_editability

Changes the hierarchical edit control of specified blocks.

SYNTAX

int **set_editability**
[-blocks *list_of_blocks*]
[-from_level *depth*]
[-to_level *depth*]
[-value *true* | *false*]
[-verbose]

Data Types

list_of_blocks string or collection
depth integer

ARGUMENTS

-blocks *list_of_blocks*

The hierarchical edit control of specified blocks would be changed with respect to the current top-level context. If this option is not specified, the default behavior shall change the hierarchical editability of the current_block.

-from_level *depth*

Specifies the design depth from which editability value is being specified. Thus it is applicable for hierarchies at the specified design depth and below. This option is mutually exclusive with the *-to_level* and *-blocks* options.

-to_level *depth*

Specifies the design depth to which editability value is being specified. Thus it is applicable for hierarchies at the specified design depth and above. This option is mutually exclusive with the *-from_level* and *-blocks* options.

-value *true* | *false*

A true value makes the specified blocks editable and false value makes the specified blocks uneditable. By default, this option is true.

-verbose

Display verbose information.

DESCRIPTION

This command changes the hierarchical edit control of specified blocks and returns an integer indicating the number of blocks with changed hierarchical edit controls.

EXAMPLES

The following example sets the hierarchical edit control of a single block to mark it as editable:

```
prompt> set_editability -blocks blk1
1
```

The following example sets the hierarchical edit control of multiple blocks to mark them as uneditable (read-only):

```
prompt> set_editability -blocks [get_blocks {blk1 blk2 blk3}] -value false
3
```

Let's assume a MPH design with 3 levels: top, mid and bot. The following example sets the hierarchical edit control for all levels of physical hierarchies to mark them as uneditable (read-only):

```
prompt> set_editability -from_level 0 -value false -verbose
Block lib:top.design is set uneditable (read-only) in the top-level context of top.
Block lib:mid.design is set uneditable (read-only) in the top-level context of top.
Block lib:bot.design is set uneditable (read-only) in the top-level context of top.
3
```

The following example sets the hierarchical edit control for all levels of physical hierarchies except top to mark them as editable:

```
prompt> set_editability -from_level 0 -value true
prompt> set_editability -to_level 0 -value false
```

SEE ALSO

set_edrc_setting

Sets common Editor DRC settings.

SYNTAX

status **set_edrc_setting**
[-name *string*]
[-value true | false]
[-rules *name_value_list*]
[-enclosed_via_spacing_rule true | false]
[-general_via_spacing_rule true | false]
[-minimum_edge_rule true | false]
[-minimum_length_and_area_rule true | false]
[-rdl_acute_angle_rule true | false]
[-rdl_right_angle_rule true | false]
[-via_density_rule true | false]
[-honor_ndr true | false]
[-dpt_odd_cycle true | false]
[-dpt_precolor true | false]
[-end_of_line_spacing_rule true | false]
[-via_enclosure_rule true | false]
[-metal_width_rule true | false]
[-metal_span_spacing_rule true | false]
[-filter_same_net_spacing true | false]
[-check_fill true | false]
[-max_error_limit *number*]
[-max_shape_limit *number*]
[-max_processing_time *number*]
[-show_error_browser true | false]
[-check_drc true | false]
[-default]

Data Types

number int

ARGUMENTS

-name *string*

Specifies the name of the rule to set with the -value argument

-value true | **false**

Controls whether the Editor DRC checks the rule specified by the -name argument

-rules *name_value_list*

Specifies a list of rule name value pairs to set. Mutually exclusive with the -name argument.

-enclosed_via_spacing_rule true | false

Controls whether Editor DRC checks the enclosed via spacing rule.

-general_via_spacing_rule true | false

Controls whether Editor DRC checks the general via spacing rule.

-minimum_edge_rule true | false

Controls whether Editor DRC checks the following minimum edge rules: maximum total number of short edge, maximum total short edge length, convex-concave minimum edge length, adjacent minimum edge length, and special notch.

-minimum_length_and_area_rule true | false

Controls whether Editor DRC checks the minimum length and general minimum area rules.

-rdl_acute_angle_rule true | false

Controls whether Editor DRC checks for acute angle violations for RDL routes.

-rdl_right_angle_rule true | false

Controls whether Editor DRC checks for right angle violations for RDL routes.

-via_density_rule true | false

Controls whether Editor DRC checks the via density rule.

-honor_ndr true | false

Controls whether Editor DRC checks the following nondefault routing rules: metal spacing and via spacing.

-dpt_odd_cycle true | false

Controls whether Editor DRC checks for the existence of double-patterning odd cycles.

-dpt_precolor true | false

Controls whether Editor DRC checks for double-patterning spacing violations for colored shapes.

-end_of_line_spacing_rule true | false

Controls whether Editor DRC checks the following end-of-line spacing rules: end-of-line to end-of-line spacing rule, one-neighbor end-to-end table-based spacing rule, one-neighbor end-of-line spacing rule, and two-neighbor end-of-line spacing rule.

-via_enclosure_rule true | false

Controls whether Editor DRC checks the following via enclosure rules: minimum enclosure rule, zero-neighbor end-of-line enclosure rule, and T-shape metal extension end-of-line enclosure rule.

-metal_width_rule true | false

Controls whether Editor DRC checks the following metal width rules: discrete metal width rule and signal routing maximum metal width rule.

-metal_span_spacing_rule true | false

Controls whether Editor DRC checks the following metal span spacing rules: metal span spacing and metal span orthogonal spacing rule.

-filter_same_net_spacing true | false

Controls whether Editor DRC checks for spacing violations between shapes of the same net.

-check_fill true | false

Controls whether Editor DRC checks shapes inside fill cells.

-max_error_limit *number*

Specifies the maximum number of DRC errors to report. The default is 200.

-max_shape_limit *number*

Specifies the maximum number of shapes for DRC checking. The default is 400.

-max_processing_time *number*

Specifies the maximum time (in seconds) for DRC checking. The default is 10.

-show_error_browser true | false

Controls whether the error browser is displayed when errors are detected.

-check_drc true | false

Controls whether Editor DRC is enabled during interactive editing.

-default

Resets all options to their defaults.

DESCRIPTION

This command specifies common Editor DRC settings.

By default, the editor checks shorts and the following spacing rules: minimum spacing, via corner spacing, u-shape spacing, fat metal spacing and minimum width, net-type based spacing, and via farm spacing.

You can use this command to enable and disable additional supported rules and other controls for Editor DRC.

EXAMPLES

The following example enables odd cycle design rule checking while performing edits.

```
prompt> set_edrc_setting -name {DPT Odd Cycle} -value {true}
1
```

The following example enables short and minimum spacing checking while performing edits.

```
prompt> set_edrc_setting -rules {{Short} {true} {Minimum Spacing} {false}}
1
```

SEE ALSO

get_edrc_setting(2)

set_equivalent

Declare that supply nets or supply sets are electrically or functionally equivalent.

SYNTAX

string **set_equivalent**
  [-function_only]
  [-nets *supply_net_list*]
  [-sets *supply_set_list*]

Data Types

supply_net_list list
supply_set_list list

ARGUMENTS

-function_only

Specifies that the supplies are functionally equivalent rather than electrically equivalent.

-nets *supply_net_list*

A list of supply port and/or supply net names that are equivalent.

-sets *supply_set_list*

A list of supply set names that are equivalent.

DESCRIPTION

The **set_equivalent** command declares that two or more supplies are equivalent. If **-function_only** is specified, then the supplies are declared to be functionally equivalent only; otherwise the supplies are declared to be electrically equivalent, which implies that they are also functionally equivalent.

If **-nets** is specified, the command defines equivalence for a list of supply ports and/or supply nets. If **-sets** is specified, the command defines equivalence for a list of supply sets and/or supply set handles. One or the other of these options, but not both, shall be specified.

EXAMPLES

The following example declares the supply nets 'vdda' and 'vddb' to be electrically equivalent.

```
prompt> set_equivalent -nets {vdda vddb}
```

The following example declares the supply sets 'ss1' and 'ss2 to be electrically equivalent.

```
prompt> set_equivalent -sets {ss1 ss2} -function_only
```

SEE ALSO

ARGUMENTS

-corners *corners*

Specifies the list of corners for which to apply the extraction options.

-late_cap_scale *late_cap_scale*

Specifies the late capacitance scaling factor. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-early_cap_scale *early_cap_scale*

Specifies the Early capacitance scaling factor. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-late_res_scale late_res_scale

Specifies the late resistance scaling factor. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-early_res_scale *early_res_scale*

Specifies the early resistance scaling factor. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-late_ccap_scale *late_ccap_scale*

Specifies the late coupling capacitance scaling factor. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-early_ccap_scale *early_ccap_scale*

Specifies the early coupling capacitance scaling factor. Will be deprecated and scales will be supported by

set_paraisitcs_derate.

-late_vr_horizontal_cap_scale ***late_vr_horizontal_cap_scale***

Specifies the late virtual route (vr) horizontal capacitance scaling factor.

-early_vr_horizontal_cap_scale ***early_vr_horizontal_cap_scale***

Specifies the early virtual route (vr) horizontal capacitance scaling factor.

-late_vr_vertical_cap_scale ***late_vr_vertical_cap_scale***

Specifies the late virtual route (vr) vertical capacitance scaling factor.

-early_vr_vertical_cap_scale ***early_vr_vertical_cap_scale***

Specifies the early virtual route (vr) vertical capacitance scaling factor.

-late_vr_horizontal_res_scale ***late_vr_horizontal_res_scale***

Specifies the late virtual route (vr) horizontal resistance scaling factor.

-early_vr_horizontal_res_scale ***early_vr_horizontal_res_scale***

Specifies the early virtual route (vr) horizontal resistance scaling factor.

-late_vr_vertical_res_scale ***late_vr_vertical_res_scale***

Specifies the late virtual route (vr) vertical resistance scaling factor.

-early_vr_vertical_res_scale ***early_vr_vertical_res_scale***

Specifies the early virtual route (vr) vertical resistance scaling factor.

-late_vr_via_res_scale ***late_vr_via_res_scale***

Specifies the late virtual route (vr) via resistance scaling factor.

-early_vr_via_res_scale ***early_vr_via_res_scale***

Specifies the early virtual route (vr) via resistance scaling factor.

-late_rde_cap_scale ***late_rde_cap_scale***

Specifies the late RDE capacitance scaling factor which is applied on top of late_cap_scale. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-early_rde_cap_scale ***early_rde_cap_scale***

Specifies the early RDE capacitance scaling factor which is applied on top of early_cap_scale. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-late_rde_res_scale late_rde_res_scale

Specifies the late RDE resistance scaling factor which is applied on top of late_res_scale. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-early_rde_res_scale ***early_rde_res_scale***

Specifies the early RDE resistance scaling factor which is applied on top of early_res_scale. Will be deprecated and scales will be supported by set_paraisitcs_derate.

-late_ccap_threshold ***late_ccap_threshold***

Specifies the late coupling capacitance filtering threshold. The units are user units. Default is 0.003 pF.

-early_ccap_threshold *early_ccap_threshold*

Specifies the early coupling capacitance filtering threshold. The units are user units. Default is 0.003 pF.

-late_ccap_ratio *late_ccap_ratio*

Specifies the late coupling capacitance filtering ratio. The default is 0.03 times the total capacitance.

Only *late_ccap_threshold* and *late_ccap_ratio* are used as global settings for filtering. The coupling capacitance between two nets is filtered, when both *late_ccap_threshold* and *late_ccap_ratio* conditions are satisfied.

For example, consider two coupled nets: netA and netB. The lumped coupling capacitance between them is 1ff, total capacitance (including pin capacitance) of netA is 50ff, and the total capacitance of netB is 20ff. The default ccap_threshold and ccap_ratio are used. Here is the filtering calculation, where "CC" represents coupling capacitance:

```
Example:
  CC(netA to netB) = 1
  TotalCap(netA)   = 50
  TotalCap(netB)   = 20

 Comparing ccap_threshold and cc_ratio:
  CC(netA to netB)          = 1 < 3            --> TRUE
  CC(netA to netB) / TC(netA) = 1/50 = 0.02 < 0.03 --> TRUE
  CC(netA to netB) / TC(netB) = 1/20 = 0.05 < 0.03 --> FALSE
```

Based on this calculation, this coupling pair is not filtered because the ratio of coupling capacitance (1) to total capacitance for netB (20) is 0.05, which is greater than the default of 0.03.

-early_ccap_ratio *early_ccap_ratio*

Specifies the early coupling capacitance filtering ratio. The default is 0.03 of the total capacitance.

-process_scale *process_scale*

Specifies the process scaling factor. The default is 1.0. Value should be specified greater than 0 and less than or equal to 1.0. If there is HALF_NODE_SCALE_FACTOR specified in ITF then extractor will honor ITF's HALF_NODE_SCALE_FACTOR.

-reference_direction vertical | horizontal | use_from_tluplus

Specifies the reference direction to which to apply the orientation-based etch tables. The reference direction applies to all corners. The default is **use_from_tluplus**.

- **vertical** - Specifies that the reference direction is vertical when applying the orientation-based etch tables, regardless of the **REFERENCE_DIRECTION** setting in the TLUPlus files.
- **horizontal** - Specifies that the reference direction is horizontal when applying the orientation-based etch tables, regardless of the **REFERENCE_DIRECTION** setting in the TLUPlus files.
- **use_from_tluplus** - Specifies that the reference direction is defined by the **REFERENCE_DIRECTION** setting in the TLUPlus files. The TLUPlus files are specified by the **set_parasitic_parameters** command.

-real_metalfill_extraction none | floating | grounded | auto

Specifies the models that can be used to extract metal fill. Metal fill are metal shapes that are inserted during chip finishing to create a more uniform metal density across the chip. When metal fill is inserted, the capacitance effect can be extracted based on the filler type: floating or grounded. To ignore the capacitance effects of metal fill, specify "none". By default, the setting is "none". When setting is "auto", metal fill type will be automatically detected and effects applied accordingly.

-virtual_metalfill_extraction none | floating | grounded

Specifies the models that can be used to virtual metal fill extraction. In ICC2, pre-route and post-route extractor emulate virtual metalfill based on the given virtual metal file parameter files for RC extraction. When metal fill is emulated, the capacitance effect can be extracted based on the filler type: floating or grounded. To ignore the capacitance effects of metal fill, specify "none". By default, the setting is "none".

-virtual_metalfill_parameter_file fileName

Specifies metal fill parameters used for ICC2 virtual metalfill emulation in RC extraction. The syntax of parameter file is: <db_layer_name A> <fill_widthA> <fill_spaceA> <db_layer_name B> <fill_widthB> <fill_spaceB> ..... <db_layer_name N> <fill_widthN> <fill_spaceN>

-virtual_metalfill_starrc_parameter_file fileName

Specifies metal file paramters used for StarRC inDesign virtual metalfill RC extracton. It is optional to use this file for ICC2 extractor virtual metalfill RC extraction, if "-virtual_metalfill_parameter_file fileName" is not specified. But only use fill_width, fill_route_w_spacing parameters in ICC2 extractor. The syntax of parameter file is: <db_layer_name A> <directionA> <fill_widthA> <min_fill_lengthA> <max_fill_lengthA> <fill_route_w_spacingA> <fill_route_l_spacingA> <fill_fill_w_spacingA> <fill_fill_l_spacingA> <fill_blockage_w_spacingA> <fill_blockage_l_spacingA> <fill_ndr_w_spacingA> <fill_ ndr _l_spacingA> <fill_chip_w_spacingA> < fill_chip_l_spacingA> <fill_blockage_excluded_cellsA>

<db_layer_name B> <directionB> <fill_widthB> <min_fill_lengthB> <max_fill_lengthB> <fill_route_w_spacingB> <fill_route_l_spacingB> <fill_fill_w_spacingB> <fill_fill_l_spacingB> <fill_blockage_w_spacingB> <fill_blockage_l_spacingB> <fill_ndr_w_spacingB> <fill_ ndr _l_spacingB> <fill_chip_w_spacingB> < fill_chip_l_spacingB> < fill_blockage_excluded_cellsB> ..... <db_layer_name N> <directionN> <fill_widthN> <min_fill_lengthN> <max_fill_lengthN> <fill_route_w_spacingN> <fill_route_l_spacingN> <fill_fill_w_spacingN> <fill_fill_l_spacingN>> <fill_blockage_w_spacingN> <fill_blockage_l_spacingN> <fill_ndr_w_spacingN> <fill_ ndr _l_spacingN> <fill_chip_w_spacingN> < fill_chip_l_spacingN> <fill_blockage_excluded_cellsN>

-virtual_shield_extraction true | false

This option applies only to postroute extraction. When this option is set to **true** (the default), the tool performs virtual shield extraction by considering the shielding rules. Otherwise, the shielding rules are not considered during extraction. Shielding rules are nondefault routing rules that are defined by using the **create_routing_rule** command. Both the nets with nondefault routing rules and their neighbors might see their RC values affected due to shielding effects when this option is set to **true**.

-enable_ccap_or_filtering true | false

Enables OR-style coupling capacitance filtering. Using this filtering, the coupling capacitance is filtered when one or both of the *ccap_threshold* and *ccap_ratio* settings are satisfied.

The default style is AND, which means that coupling capacitance is filtered when both the *ccap_threshold* and *ccap_ratio* settings are satisfied.

-include_pin_resistance true | false

Creates a resistor network for a pin with multiple connections, when set to **true**. There is only a resistance value within the pin, and no capacitance. This option can be applied when performing extraction on detail-routed designs. The default is **true**.

-honor_mask_constraints true | false

The default is **false**, which causes mask constraint (color) attributes to be ignored. When this option is set to **true**, the tool considers mask constraints during extraction. Colors of both victim and aggressor nets are considered. The design should have geometries with mask (color) attributes annotated. The TLUPlus file should define mask-dependent (color-dependent) etch-versus-width-spacing (EVWS) information.

-operating_frequency *operating_frequency*

Specifies the operating frequency value used for 3DIC. The unit is Hz.

-default

Resets all options to their defaults.

DESCRIPTION

This command sets extraction options used during RC extraction. The scaling options will be associated with default constraint corner, or ea list of constraint corners. Other options are global and not corner specific.

The default scaling factor value is 1.0, which means no scaling. This command supports 0 and positive scaling factor value, and checks and warns when abnormal negative scaling factors are specified.

The default filtering threshold is 3ff and 3 percent. If the total coupling capacitance between a net pair is less than 3ff and 3 percent of total capacitance of both nets, all coupling entries between the net pair are filtered.

Multicorner-Multimode Support

EXAMPLES

In the following example, extraction options are applied to the current constraint corner.

```
prompt> set_extraction_options -late_cap_scale 1.1 -early_cap_scale 1.05
1
```

set_false_path

Identifies paths in a design to mark as false, so that they are not considered during timing analysis.

SYNTAX

status **set_false_path**
[-setup] [-hold]
[-rise] [-fall]
[-reset_path]
[-from *from_list*
| -rise_from *rise_from_list*
| -fall_from *fall_from_list*]
[-through *through_list*]
[-rise_through *rise_through_list*]
[-fall_through *fall_through_list*]
[-to *to_list*
| -rise_to *rise_to_list*
| -fall_to *fall_to_list*]
[-comment *comment*]

Data Types

from_list list
rise_from_list list
fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
comment list

ARGUMENTS

-setup

Marks setup (maximum) paths as false. This option disables setup checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-hold

Marks hold (minimum) paths as false. This option disables hold checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-rise

Marks rising delays as false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, both rise and fall timing are marked false.

-fall

Marks falling delays as false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, rise and fall timing are marked false.

-reset_path

Removes existing point-to-point exception information from the specified paths. If used with **-to** only, all paths leading to the specified endpoints are reset. If used with **-from** only, all paths leading from the specified startpoints are reset. If used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise/fall setup/hold type is reset. This is equivalent to using the **reset_path** command with similar arguments before the **set_false_path** command is issued.

-from ***from_list***

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-rise_from ***rise_from_list***

Same as the **-from** option, except that the path must rise from the specified objects. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-fall_from ***fall_from_list***

Same as the **-from** option, except that the path must fall from the specified objects. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-through ***through_list***

Specifies a list of pins, ports, cells or nets through which the disabled paths must pass. You can specify **-through** more than one time in one command invocation. Nets are interpreted to imply the leaf-level driver pins.

If you do not specify any type of **through** option, all timing paths specified using the **-from** and **-to** options are affected.

For a detailed discussion of the use of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-rise_through ***rise_through_list***

Specifies a list of pins, ports, cells or nets through which the disabled paths must pass. The paths must have a rising transition at the through points.

If you do not specify any type of **-through** option, all timing paths specified using the **-from** and **-to** options are affected.

For a detailed discussion of the use of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-fall_through ***fall_through_list***

Specifies a list of pins, ports, cells or nets through which the disabled paths must pass. The paths must have a falling transition at the through points.

If you do not specify any type of **-through** option, all timing paths specified using the **-from** and **-to** options are affected.

For a detailed discussion of the use of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-to ***to_list***

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If you specify a cell, one path endpoint on that cell is affected.

You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-rise_to ***rise_to_list***

Specifies a list of timing path endpoint objects. but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source. The command takes into account any logical inversions along the clock path. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-fall_to ***fall_to_list***

Specifies a list of timing path endpoint objects, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-comment ***comment***

Attaches a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

The **set_false_path** command marks startpoint and endpoint pairs as false timing paths, that is, paths that cannot propagate a signal. The command removes timing constraints on these false paths, so that they are not considered during timing analysis. Path startpoints are input ports or register clock pins; path endpoints are register data pins or output ports. The command disables maximum delay (setup) checking and minimum delay (hold) checking for the specified paths.

The **set_false_path** command is a point-to-point timing exception command, and overrides the default single-cycle timing relationship for one or more timing paths. False path information always takes precedence over multicycle path information. Also, **set_false_path** commands override **set_max_delay** and **set_min_delay** commands.

You can use multiple **-through**, **-rise_through**, and **-fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

-from A1 -through B1 -through C1 -to D1

If more than one object is specified within one **-through**, **-rise_through**, or **-fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

-from A1 -through {B1 B2} -through {C1 C2} -to D1

To disable the timing at a particular cell along a path, use the **set_disable_timing** command.

To remove the false path designations set by **set_false_path**, use the **reset_paths** command.

For crosstalk analysis the false paths are treated as sensitizable. So, the aggressors on the false paths could still effect victim nets.

When the clocks are asynchronous to each other, use the **set_clock_groups -asynchronous** command instead of **set_false_paths** between the asynchronous clocks. Without the **set_clock_groups -asynchronous** command, the clocks will be treated as synchronized with each other.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example disables timing paths from ff12 to ff34.

```
prompt> set_false_path -from ff12 -to ff34
```

The following example disables rising timing paths from U14/Z to ff29/Reset.

```
prompt> set_false_path -rise_from U14/Z -to ff29/Reset
```

The following examples disables hold checking for endpoints clocked by CLK1.

```
prompt> set_false_path -hold -to [get_clocks CLK1]
```

The following example disables all timing paths from ff1/CP to ff2/D that pass through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C}.

```
prompt> set_false_path -from ff1/CP -through {U1/Z U2/Z} \
  -through {U3/Z U4/C} -to ff2/D
```

The following example disables all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall to one or more of {U3/Z U4/C}.

```
prompt> set_false_path -from ff1/CP \
  -rise_through {U1/Z U2/Z} \
  -fall_through {U3/Z U4/C} -to ff2/D
```

set_fanout_load

Sets fanout_load for output ports in the current design.

SYNTAX

string **set_fanout_load** *value port_list*

float *value*
list *port_list*

ARGUMENTS

value

Shows **fanout_load** value, in units consistent with the **fanout_load** and **max_fanout** values in the technology library.

port_list

Provides a list of output ports.

DESCRIPTION

Specifies a **fanout_load** for output ports in the current design. By default, ports are considered to have fanout_load of 0.0. Fanout load for a net is the sum of **fanout_load** attributes for all input pins and output ports connected to the net. Output pins may have maximum fanout limits, specified in the library.

report_port -design_rule shows port **fanout_load** values.

To remove **fanout_load** information from ports, use **remove_fanout_load**.

Multicorner-Multimode Support

EXAMPLES

This example sets the fanout_load on ports matching "OUT*" to 3.0.

prompt> **set_fanout_load 3.0 "OUT*"**

SEE ALSO

remove_fanout_load(2)
report_port(2)

set_fix_multiple_port_nets

Sets the **fix_multiple_port_nets** attribute to a specified value on the current module or a list of modules.

SYNTAX

int **set_fix_multiple_port_nets**
-default | -all
[-feedthroughs]
[-outputs]
[-constants]
[-buffer_constants]
[-no_rewire]
[-exclude_clock_network]
[*object_list (design_list | module_list | block_list)*]

ARGUMENTS

-default

Removes the **fix_multiple_port_nets** attribute so that **compile** will use its default priority, that is no multiple port nets fixing.

-all

Inserts the same as **-feedthroughs -outputs -constants**. Note that logic constants are duplicated, not buffered. To fix constant port nets by buffering them, use the **-buffer_constants** option. Rewiring will be attempted before buffering.

-feedthroughs

Inserts buffers to isolate input ports from output ports at all levels of the hierarchy. Rewiring will be attempted before buffering.

-outputs

Inserts buffers so that no cell driver pin drives more than one output port at any level of the hierarchy. Rewiring will be attempted before buffering.

-constants

Duplicates logic constants so that no constant drives more than one output port at any level of the hierarchy. Rewiring will be attempted before constant duplication.

-buffer_constants

Buffers logic constants instead of duplicating them. Rewiring will be attempted before buffering.

-no_rewire

Disables a rewiring attempt before buffering multiple port nets and constant port nets. **-no_rewire** only applies to

fix_multiple_port_nets optimization. Use **set_boudary_optimization** to restrain other optimizations from rewiring.

-exclude_clock_network

Excludes nets belonging to the clock network from multiple port net fixing.

object_list

Specifies a list of designs or modules or blocks. The default is the current design.

DESCRIPTION

Sets the **fix_multiple_port_nets** attribute on a list of designs. If you do not specify a design list, the current design is used.

This attribute controls whether **compile** inserts extra logic into the design to ensure that there are no feedthroughs, or that there are no two output ports connected to the same net at any level of hierarchy.

The **set_fix_multiple_port_nets** command first attempts to rewire port nets. If no rewiring opportunity is found, then buffers will be inserted. Use **-no_rewire** to disable rewiring for the entire design or use **set_boudary_optimization** to disable rewiring on a specific hierarchy.

Certain three-state nets cannot be buffered, because this changes the logic functionality of the design.

If **set_fix_multiple_port_nets** is specified more than once on a design, the most recent setting is used and the earlier values are removed. To undo **set_fix_multiple_port_nets**, use the **-default** option.

To view the current setting of the **fix_multiple_port_nets** attribute, use **report_attribute** or **get_attribute**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **fix_multiple_port_nets** attribute so that feedthroughs are buffered and constants are duplicated.

prompt> **set_fix_multiple_port_nets -feedthroughs -constants**

The following example sets the **fix_multiple_port_nets** attribute so that multiple outputs and constants are buffered.

prompt> **set_fix_multiple_port_nets -outputs -buffer_constants [get_modules *]**

The following example resets the **fix_multiple_port_nets** attribute so that no fixing is done.

prompt> **set_fix_multiple_port_nets -default**

SEE ALSO

compile(2)

current_design(2)

set_fixed_objects

Sets the specified objects to the fixed state. The command sets the value of **physical_status** attribute to either **fixed** or **unrestricted**;

SYNTAX

status **set_fixed_objects**
[*object_list*]
[-unfix]

object_list collection or selection

ARGUMENTS

object_list

Collection or selection set containing objects to set or unset fixed status. If this option is not specified, global selection set is used.

-unfix

Specifies if given objects should be unfixed

DESCRIPTION

Set the fixed state for the supplied objects.

EXAMPLES

The following example fixes all selected objects

prompt> **set_fixed_objects**
1

The alternative syntax uses collection to specify objects.

prompt> **set_fixed_objects [get_selection]**
1

set_floorplan_area_rules

Defines an area floorplan rule.

SYNTAX

set_floorplan_area_rules
-object_types *type_list*
-lib_cells *lib_cells*
-name *rule_name*
[-layers *layer_list*]
[-forbidden_list *area_list*]
[-forbidden_ranges {{*low high*} {*low1 high1*} ... }]
[-max *area*]
[-min *area*]
[-valid_list *area_list*]
[-valid_ranges {{*low high*} {*low1 high1*} ... }]

Data Types

type_list list
lib_cells collection
rule_name string
layer_list collection
area_list list
low float
high float
low1 float
high1 float
area float

ARGUMENTS

-object_types *type_list*

Specifies the list of object types for the area floorplan rule. The area of these type of objects will be checked. Valid values for this option are *block_boundary*, *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with **-lib_cells** and you must specify one or the other.

-lib_cells *lib_cells*

Specifies the collection of library cells for the area floorplan rule. The area of these library cells will be checked. This option is mutually exclusive with **-object_types** and you must specify one or the other.

-name *rule_name*

Specifies the name of the area floorplan rule. This is a mandatory option.

-layers ***layer_list***

Specifies the routing layers to be considered for the routing_blockage or shape object type. This option must be used together with **-object_types routing_blockage** or **-object_types shape**. This is an optional option.

-forbidden_list ***area_list***

Specifies a list of areas that are not allowed for the object or library cell. This option is mutually exclusive with **-valid_list**. Values specified cannot be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of area ranges that are not allowed for the object or library cell. The area must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-valid_ranges**. Values specified cannot be negative. This is an optional option.

-max ***area***

Specifies the maximum area for the object or library cell. The area cannot be greater than this value. The value specified cannot be negative. If **-min** is also specified then this value must be greater than the min value. This is an optional option.

-min ***area***

Specifies the minimum area of object or library cell. The area cannot be less than this value. The value specified cannot be negative. If **-max** is also specified then this value must be lesser than the max value. This is an optional option.

-valid_list ***area_list***

Specifies a list of allowed areas for the area of the object or library cell. This option is mutually exclusive with **-forbidden_list**. Values specified cannot be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of allowed area ranges for the object or library cell. The area must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-forbidden_ranges**. Values specified cannot be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_area_rules** command defines a named area floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If an area rule is defined for a library cell and another area rule is defined for a hard macro then the area rule defined for the library cell will take precedence over the area rule defined for hard macro when checks are done for that library cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates an area rule named a1 to check the area of block boundary and hard macro. The area can't be greater than 2400 and can't lie between 370 and 790.

```
prompt> set_floorplan_area_rules -name a1 \
  -object_types {block_boundary hard_macro} -max 2400 \
  -forbidden_ranges {{370 790}}
```

ARGUMENTS

-from_object_types *from_type_list*

Specifies the list of "from" object types for the enclosure floorplan rule. These type of objects will enclose the object types specified with **-to_object_types** or library cells specified with **-to_lib_cells**. Valid values for this option are *block_boundary*, *core_area*, *placement_blockage*, *routing_blockage*, *unplaceable_area* and *std_cell_area*. This is a mandatory option.

-to_object_types *to_type_list*

Specifies the list of "to" object types for the enclosure floorplan rule. These type of objects will be enclosed by other objects specified with **-from_object_types**. Valid values for this option are *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *soft_macro*, *unplaceable_area* and *std_cell_area*. This option is mutually exclusive with **-to_lib_cells** and you must specify one or the other.

-to_lib_cells *lib_cells*

Specifies the collection of library cells for the enclosure floorplan rule. These library cells are being enclosed by other objects specified in **-from_object_types**. This option is mutually exclusive with **-to_object_types** and either one of them must be specified.

-sides *side_list*

Specifies the sides or directions from which the "from" object encloses the "to" object. Spacing is checked between the objects. Valid values are *all*, *bottom*, *horizontal*, *left*, *right*, *top*, *vertical* and *manhattan*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This option is mutually exclusive with the **-from_corner** and **-to_corner** option pair. Either this option or **-from_corner** and **-to_corner** pair must be specified.

-from_corner *corner_type*

Specifies the corner from which the "from" object encloses the "to" object. Spacing is checked between the objects. Valid values are *all*, *bottom_left*, *bottom_right*, *top_left* and *top_right*. This option can be used when spacing must be checked from a corner instead of an edge. This option must be used together with **-to_corner** and is mutually exclusive with **-sides**.

-to_corner *corner_type*

Specifies the corner from which the "to" object is being enclosed by "from" object. Spacing is checked between the objects. Valid values are *all*, *bottom_left*, *bottom_right*, *top_left* and *top_right*. This option can be used when spacing must be checked from a corner instead of an edge. This option must be used together with **-from_corner** and is mutually exclusive with **-sides**.

-name *rule_name*

Specifies the name of the enclosure floorplan rule. This is a mandatory option.

-must_enclose

Specifies that the "from" object must completely enclose the "to" object from all sides. This is an optional option.

-follow_rotations

Specifies whether the sides specified by the **-sides** option should follow the rotations of library cells, that is, if the meaning of *horizontal* or *vertical* should change when the library cell has a 90-degree rotation. This option must be used together with **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro**. This is an optional option.

-ignore_rotate90

Specifies whether this rule can be ignored for library cells with 90-degree rotations. This option must be used together with **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro**. This is an optional option.

-layers *layer_list*

Specifies the routing layers to be considered for the *routing_blockage* object type. This option must be used together with **-from_object_types routing_blockage** or **-to_object_types routing_blockage**. This is an optional option.

-forbidden_list *distance_list*

Specifies a list of distances by which the "from" object cannot enclose the "to" object. This option is mutually exclusive with **-valid_list**. Values in the *distance_list* cannot be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges between which the "from" object cannot enclose the "to" object. The enclosing distance must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-valid_ranges**. Values cannot be negative. This is an optional option.

-max *distance*

Specifies the maximum distance by which the "from" object can enclose the "to" object. The distance cannot be greater than this value. The distance cannot be negative. If **-min** is also specified, this value must be greater than the min value. This is an optional option.

-min *distance*

Specifies the minimum distance by which the "from" object can enclose the "to" object. The distance cannot be less than this value. The value specified cannot be negative. If **-max** is also specified then this value must be less than the max value. This is an optional option.

-offset *distance*

Specifies a parameter in distance calculation between the "from" and "to" objects. This option must be used together with **-step**. This implies that the distance has to be an integer multiple of the **-step** value plus the **-offset** value. The value specified cannot be negative. This is an optional option.

-step *distance*

Specifies a parameter in distance calculation between the "from" and "to" objects. This option must be used together with **-offset**. This implies that the distance has to be an integer multiple of the **-step** value plus the **-offset** value. The value specified cannot be negative. This is an optional option.

-valid_list *distance_list*

Specifies a list of distances by which the "from" object can enclose the "to" object. This option is mutually exclusive with **-forbidden_list**. Values specified cannot be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges between which the "from" object can enclose the "to" object. The distance must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-forbidden_ranges**. Values specified cannot be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_enclosure_rules** command defines a named enclosure floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object types *core_area* and *std_cell_area*. The *core_area* object type is the core boundary region without cutting out any blockages and is typically applicable for the top level. The *std_cell_area* object type is the core boundary region after cutting out all blockages and is typically applicable for the block level.

If an enclosure rule is defined for a library cell and another enclosure rule is defined for a hard macro, the enclosure rule defined for the library cell takes precedence over the enclosure rule defined for hard macro when checks are done for that library cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates an enclosure rule named e1. This rule checks the enclosing of hard macros and core area by the block boundary. The check will be done for horizontal sides, both left and right, and only at the bottom in vertical side. Must be greater than 2 and less than 100, but cannot be in the range between 5 and 15. Also, the distance must be an integer multiple of 2 plus 10.

```
prompt> set_floorplan_enclosure_rules -name e1 \
  -from_object_types block_boundary \
  -to_object_types {hard_macro core_area} -sides {bottom horizontal} \
  -forbidden_ranges {{5 15}} -valid_list {2 20 30} -max 100 -min 2 \
  -offset 10 -step 2
```

set_floorplan_exception_rules

Defines an exception floorplan rule in the design.

SYNTAX

set_floorplan_exception_rules
-rules *rule_list*
-name *rule_name*
[-from_object_types *type_list*]
[-to_object_types *type_list*]
[-object_types *type_list*]
[-from_lib_cells *lib_cells*]
[-to_lib_cells *lib_cells*]
[-lib_cells *lib_cells*]
[-identical]
[-orientation_types *orientation_list*]
[-reason *reason*]

Data Types

rule_list list
rule_name string
type_list list
lib_cells collection
orientation_list list
reason string

ARGUMENTS

-rules *rule_list*

Specifies the list of floorplan rules for which this exception rule needs to be applied. It is not required that rules specified in this list has to pre-exist in the design. This is a mandatory option.

-name *rule_name*

Specifies the name of the exception floorplan rule. This is a mandatory option.

-from_object_types *type_list*

Specifies the list of "from" object types for the exception floorplan rule. These type of objects in the "from" objects of specified list of rules will be exempted from those rule's checking. Valid values for this option are *block_boundary*, *placement_blockage*, *routing_blockage*, *hard_macro*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with *-object_types*, *-from_lib_cells* and *-lib_cells*.

-from_lib_cells *lib_cells*

Specifies the collection of "from" lib cells for the exception floorplan rule. These lib cells in the "from" lib cells of specified list of rules will be exempted from those rule's checking. This option is mutually exclusive with *-from_object_types*, *-object_types*, and *-lib_cells*.

-to_object_types *type_list*

Specifies the list of "to" object types for the exception floorplan rule. These type of objects in the "to" objects of specified list of rules will be exempted from those rule's checking. Valid values for this option are *block_boundary*, *placement_blockage*, *routing_blockage*, *hard_macro*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with *-object_types*, *-to_lib_cells* and *-lib_cells*.

-to_lib_cells *lib_cells*

Specifies the collection of "to" lib cells for the exception floorplan rule. These lib cells in the "to" lib cells of specified list of rules will be exempted from those rule's checking. This option is mutually exclusive with *-to_object_types*, *-object_types*, and *-lib_cells*.

-object_types *type_list*

Specifies the list of both object types for the exception floorplan rule. These type of objects in any objects of specified list of rules will be exempted from those rule's checking. Valid values for this option are *block_boundary*, *placement_blockage*, *routing_blockage*, *hard_macro*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with *-from_object_types*, *-to_object_types*, *-from_lib_cells*, *-to_lib_cells* and *-lib_cells*.

-lib_cells *lib_cells*

Specifies the collection of both lib cells for the exception floorplan rule. These lib cells in any lib cells of specified list of rules will be exempted from those rule's checking. This option is mutually exclusive with *-from_object_types*, *-to_object_types*, *-object_types*, *-from_lib_cells* and *-to_lib_cells*.

-identical

Specifies whether this rule applies to hard macros of same reference.

-orientation_types *orientation_list*

Specifies the orientation of the two objects for the check to be enabled. Valid values are *align*, *mirror* and *partial*. *align* means both the objects should be of same orientation like R0, MX, MY or R180. *partial* means the orientation pair should be R0-R180 or MX-MY. *mirror* means the objects are mirrored in checked direction.

-reason *reason*

Specifies the reason for this exception rule to be specified.

DESCRIPTION

The **set_floorplan_exception_rules** command defines a named exception floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

The exception rule is to apply existing rules on a subset of objects or lib cells specified for those rules. If a spacing rule has all hard macro and soft macro and if user would like to exclude certain lib cells from that list then an exception rule can be created.

EXAMPLES

The following example creates an exception rule named exc1 to exempt checking of "from" std_cell_area and "to" an21* lib cells in the spacing floorplan rule s1 and enclosure floorplan rule e2.

```
prompt> set_floorplan_exception_rules -name exc1 -rules {s1 e2} \
  -from_object_types std_cell_area -to_lib_cells */an21* \
  -reason myReason
```

set_floorplan_extension_rules

Defines an extension floorplan rule in the design.

SYNTAX

set_floorplan_extension_rules
-rules *rule_list*
-name *rule_name*
-sides *side_list*
-target *target_type*
-value *distance*

Data Types

rule_list list
rule_name string
side_list list
target_type string
distance float

ARGUMENTS

-rules *rule_list*

Specifies the list of floorplan rules for which this extension rule needs to be applied. It is not required that rules specified in this list has to pre-exist in the design. This is a mandatory option.

-name *rule_name*

Specifies the name of the extension floorplan rule. This is a mandatory option.

-sides *side_list*

Specifies the sides or directions in which the target object in specified floorplan rules is to be extended. Valid values are *all*, *bottom*, *horizontal*, *left*, *right*, *top* and *vertical*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-target *target_type*

Specifies the target object in specified floorplan rules on which this extension rule needs to be applied. It can be "from" or "to" or both objects in that specified floorplan rule. Those objects will be extended by the value specified in this extension rule. This is a mandatory option.

-value *distance*

Specifies the extent by which the target objects of specified floorplan rules will be extended for that particular rule checking. This is a mandatory option.

DESCRIPTION

The **set_floorplan_extension_rules** command defines a named extension floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

The command specifies how the target objects either in "from" or "to" or both in specified floorplan rules need to be extended during that particular rule check.

EXAMPLES

The following example creates an extension rule named ex1 to extend the "from" objects in length floorplan rules le1 and le2 in directions top and left by a value of 17 during the check for le1 and le2.

```
prompt> set_floorplan_extension_rules -name ex1 \
  -rules {le1 le2} -target from \
  -sides {top left} -value 17
```

set_floorplan_forbidden_rules

Defines a forbidden floorplan rule in the design.

SYNTAX

set_floorplan_forbidden_rules
-lib_cells *lib_cells*
-name *rule_name*

Data Types

lib_cells collection
rule_name string

ARGUMENTS

-lib_cells *lib_cells*

Specifies the collection of library cells for the forbidden floorplan rule. Specified lib cells are not allowed to be placed in the design. This is a mandatory option.

-name *rule_name*

Specifies the name of the forbidden floorplan rule. This is a mandatory option.

DESCRIPTION

The **set_floorplan_forbidden_rules** command defines a named forbidden floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

The **set_floorplan_forbidden_rules** command is used to specify list of lib cells that are not allowed to be placed in the design.

EXAMPLES

The following example creates a forbidden rule named f1 to check that specified lib cells are not placed in the design.

```
prompt> set_floorplan_forbidden_rules -name f1 \
```

-lib_cells {*/an2* */aoi*}

ARGUMENTS

-from_object_types *from_type_list*

Specifies the list of "from" object types for the halo floorplan rule. These type of objects will form the halo around other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells**. Valid values for this option are *core_area*, *placement_blockage*, *routing_blockage*, *shape* and *std_cell_area*. This is a mandatory option.

-to_object_types *to_type_list*

Specifies the list of "to" object types for the halo floorplan rule. These type of objects will be surrounded by other objects specified with **-from_object_types**. Valid values for this option are *hard_macro*, *placement_blockage*, *routing_blockage*, *soft_macro*, *shape* and *std_cell_area*. This option is mutually exclusive with **-to_lib_cells** and either one of them must be specified.

-to_lib_cells *lib_cells*

Specifies the collection of library cells for the halo floorplan rule. These library cells will be surrounded by other objects specified with **-from_object_types**. This option is mutually exclusive with **-to_object_types** and you must specify one or the other.

-shielding_object_types *type_list*

Specifies the collection of object types for the halo floorplan rule as shielding objects so that the rule will not be applied when these object types form a shield between "from" and "to" objects. Valid values for this option are *hard_macro* and *std_cell_area*. This is an optional option.

-shielding_lib_cells *lib_cells*

Specifies the collection of library cells for the halo floorplan rule as shielding objects so that the rule will not be applied when these lib cells form a shield between "from" and "to" objects.

-sides *side_list*

Specifies the sides or directions from which the "from" object surrounds the "to" object. Spacing is checked between the objects. Valid values are *all*, *bottom*, *horizontal*, *left*, *right*, *top* and *vertical*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-type inner | **outer**

Specifies the halo type for the distance check. **-type inner** specifies the inner region of surrounding object to surrounded object needs to be checked. **-type outer** specifies the outer region of surrounding object to surrounded object needs to be checked. This is a mandatory option.

-name *rule_name*

Specifies the name of the halo floorplan rule. This is a mandatory option.

-must_enclose

Specifies that the "from" object must completely enclose the "to" object from all sides. This is an optional option.

-follow_rotations

Specifies whether the sides specified by the **-sides** option should follow the rotations of the library cells, that is, if meaning of *horizontal* or *vertical* should change when the library cell has a 90-degree rotation. This option must be used together with **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro**. This is an optional option.

-ignore_rotate90

Specifies whether this rule can be ignored for library cells with a 90-degree rotation. This option must be used together with **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro**. This is an optional option.

-layers *layer_list*

Specifies the routing layers to be considered for the *routing_blockage* or *shape* in from object type. This option must be used together with **-from_object_types routing_blockage** or **-from_object_types shape**. This is an optional option.

-to_layers *layer_list*

Specifies the routing layers to be considered for the *routing_blockage* or *shape* in to object type. This option must be used together with **-to_object_types routing_blockage** or **-to_object_types shape**. This is an optional option.

-forbidden_list *distance_list*

Specifies a list of distances by which the "from" object cannot enclose the "to" object. This option is mutually exclusive with **-valid_list**. Values in the *distance_list* cannot be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges between which the "from" object cannot enclose the "to" object. The enclosing distance must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-valid_ranges**. Values cannot be negative. This is an optional option.

-max *distance*

Specifies the maximum distance by which the "from" object can enclose the "to" object. The distance cannot be greater than this value. The distance cannot be negative. If **-min** is also specified, this value must be greater than the min value. This is an optional option.

-min *distance*

Specifies the minimum distance by which the "from" object can enclose the "to" object. The distance cannot be less than this value. The value specified cannot be negative. If **-max** is also specified then this value must be less than the max value. This is an optional option.

-offset *distance*

Specifies a parameter in distance calculation between the "from" and "to" objects. This option must be used together with **-step**. This implies that the distance has to be an integer multiple of the **-step** value plus the **-offset** value. The value specified cannot be negative. This is an optional option.

-step *distance*

Specifies a parameter in distance calculation between the "from" and "to" objects. This option must be used together with **-offset**. This implies that the distance has to be an integer multiple of the **-step** value plus the **-offset** value. The value specified cannot be negative. This is an optional option.

-valid_list *distance_list*

Specifies a list of distance by which "from" object can surround the "to" object. This option is mutually exclusive with **-forbidden_list**. Values specified cannot be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges between which the "from" object can enclose the "to" object. The distance must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-forbidden_ranges**. Values specified cannot be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_halo_rules** command defines a named halo floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If a halo rule is defined for a library cell and another halo rule is defined for a hard macro then the halo rule defined for the library cell will take precedence over the halo rule defined for hard macro when checks are done for that library cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates a halo rule by name h1 to check how hard macros and soft macros are surrounded by the core area. The check will be done for all sides for the inner region of core area. The distance can be one of 5, 7, 9 and 15. Also the distance must be an integer multiple of 3 plus 13.

```
prompt> set_floorplan_halo_rules -name h1 -from_object_types core_area \
  -to_object_types {hard_macro soft_macro} -must_enclose \
  -sides {all top} -type inner -valid_list {5 7 9 15} -offset 13 \
  -step 3
```

from_type_list list
to_type_list list
lib_cells collection
direction_list list
rule_name string
distance float
layer_list list

ARGUMENTS

-from_object_types *from_type_list*

Specifies the list of "from" object types for the length floorplan rule. Length between these type of objects and other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells** will be checked. Valid values for this option are *hard_macro*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with **-from_lib_cells** and you must specify one or the other.

-to_object_types *to_type_list*

Specifies the list of "to" object types for the length floorplan rule. Length between these type of objects and other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells** will be checked. Valid values for this option are *hard_macro*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with **-to_lib_cells** and you must specify one or the other.

-from_lib_cells *lib_cells*

Specifies the collection of library cells for the length floorplan rule. Length between these library cells and other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells** will be checked. This option is mutually exclusive with **-from_object_types** and you must specify one or the other.

-to_lib_cells *lib_cells*

Specifies the collection of library cells for the length floorplan rule. Length between these library cells and other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells** will be checked. This option is mutually exclusive with **-to_object_types** and you must specify one or the other.

-type parallel_run | projection_difference

Specifies the length type of the length check. Valid values are *parallel_run* and *projection_difference*. This is a mandatory option.

-direction *direction_list*

Specifies the sides or directions in which length of object or library cells needs to be checked. Valid values are *horizontal* and *vertical*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-name *rule_name*

Specifies the name of the length floorplan rule. This is a mandatory option.

-max_spacing *distance*

Specifies the maximum spacing between "from" and "to" objects for this rule to be applied. The specified value cannot be negative. This is an optional option.

-min_parallel_run_length *distance*

Specifies the minimum overlap length between "from" and "to" objects for this rule to be applied. This is an optional option.

-identical

Specifies whether this rule applies to hard macros of same reference. This is an optional option.

-mirror

Specifies whether this rule applies when hard macros face each other mirrored. This option must be used together with **-identical**. This is an optional option.

-asymmetric

Specifies whether this rule applies asymmetric or not. If specified, need to measure the difference only from object specified in **-from_object_types**. This option must be used along with **-type projection_difference**. This is an optional option.

-from_layers *layer_list*

Specifies the routing layers to be considered for **routing_blockage** or **shape** object types. This option must be used along with **-from_object_types routing_blockage** or **-from_object_types shape**. This is an optional option.

-to_layers *layer_list*

Specifies the routing layers to be considered for **routing_blockage** or **shape** object types. This option must be used along with **-**

to_object_types routing_blockage or **-to_object_types shape**. This is an optional option.

-max ***distance***

Specifies the maximum value of length type between "from" object or "from" library cell and "to" object or "to" library cell. The distance cannot be greater than this value. The specified value cannot be negative. If **-min** is also specified then this value must be greater than the min value. This is an optional option.

-min ***distance***

Specifies the minimum value of length type between "from" object or "from" library cell and "to" object or "to" library cell. The distance cannot be less than this value. The specified value cannot be negative. If **-max** is also specified then this value must be lesser than the max value. This is an optional option.

DESCRIPTION

The **set_floorplan_length_rules** command defines a named length floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If a length rule is defined for a library cell and another length rule is defined for a hard macro then the length rule defined for the library cell will take precedence over the length rule defined for hard macro when checks are done for that library cell.

EXAMPLES

The following example creates a length rule named le1 to check length between the standard cell area and the hard macro in the vertical direction, both top and bottom. The length must be at least 5.

```
prompt> set_floorplan_length_rules -name le1 \
  -from_object_types std_cell_area -to_object_types hard_macro \
  -direction vertical -min 5
```

ARGUMENTS

-from_object_types *type_list*

Specifies the list of "from" object types for the location floorplan rule. Location from these type of objects for a "from" location type will be checked with other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells**. Valid values for this option are *block_boundary*, *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with **-from_lib_cells** and you must specify one or the other.

-to_object_types *type_list*

Specifies the list of "to" object types for the location floorplan rule. Location to these type of objects for a "to" location type will be checked with other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells**. Valid values for this option are *block_boundary*, *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with *-to_lib_cells* and you must specify one or the other.

-from_lib_cells *lib_cells*

Specifies the collection of "from" lib cells for the location floorplan rule. Location from these lib cells for a "from" location type will be checked with other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells**. This option is mutually exclusive with *-from_object_types* and you must specify one or the other.

-to_lib_cells *lib_cells*

Specifies the collection of "to" lib cells for the location floorplan rule. Location to these lib cells for a "to" location type will be checked with other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells**. This option is mutually exclusive with *-to_object_types* and you must specify one or the other.

-from_type *location_type*

Specifies the "from" location type of the location check. Valid values are *all_corners*, *bbox_all*, *bbox_bottom_left*, *bbox_top_right*, *bottom_left* , *bottom_right*, *top_left* and *top_right*. This is a mandatory option.

-to_type *location_type*

Specifies the "to" location type of the location check. Valid values are *all_corners*, *bbox_all*, *bbox_bottom_left*, *bbox_top_right*, *bottom_left* , *bottom_right*, *top_left* and *top_right*. This is a mandatory option.

-follow_rotations

Specifies whether mentioned *direction* should follow the rotations of library cells, that is, if meaning of *horizontal* or *vertical* should change when library cell has a 90-degree rotations. This option must be used together with **-from_lib_cells** or **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro** or **-from_object_types hard_macro** or **-from_object_types soft_macro**. This is an optional option.

-ignore_rotate90

Specifies whether this rule can be ignored for library cells with a 90-degree rotation. This option must be used together with **-from_lib_cells** or **-to_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro** or **-from_object_types hard_macro** or **-from_object_types soft_macro**. This is an optional option.

-direction *direction*

Specifies the side or direction in which location of object or lib cells needs to be checked. Valid values are *horizontal* and *vertical*. The *horizontal* stands for both *left* and *right*. Similarly the *vertical* stands for both *bottom* and *top*. This is a mandatory option.

-from_layers *layer_list*

Specifies the routing layers to be considered for "from" routing_blockage or shape object type. This option must be used along with *-from_object_types routing_blockage* or *-from_object_types shape*. This is an optional option.

-to_layers *layer_list*

Specifies the routing layers to be considered for "to" routing_blockage or shape object type. This option must be used along with *-to_object_types routing_blockage* or *-to_object_types shape*. This is an optional option.

-name *rule_name*

Specifies the name of the location floorplan rule. This is a mandatory option.

-forbidden_list *distance_list*

Specifies a list of distance that should not be location of object or lib cell for the location type. This option is mutually exclusive with *-valid_list*. Values specified can't be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges that should not be location of object or lib cell for the location type. The distance must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with *-valid_ranges*. Values specified can't be negative. This is an optional option.

-max *distance*

Specifies the maximum location of object or lib cell. The distance can't be greater than this value. Value specified can't be negative. If *-min* is also specified then this value must be greater than the min value. This is an optional option.

-min *distance*

Specifies the minimum location of object or lib cell. The distance can't be lesser than this value. Value specified can't be negative. If *-max* is also specified then this value must be lesser than the max value. This is an optional option.

-offset *distance*

Specifies a parameter in location calculation of object or lib cell. This option must be used along with *-step*. This implies that the location has to be an integral multiple of *step value* plus *offset value*. Value specified can't be negative. This is an optional option.

-step *distance*

Specifies a parameter in location calculation of object or lib cell. This option must be used along with *-offset*. This implies that the location has to be an integral multiple of *step value* plus *offset value*. Value specified can't be negative. This is an optional option.

-valid_list *distance_list*

Specifies a list of distance that should be location of object or lib cell for the location type. This option is mutually exclusive with *-forbidden_list*. Values specified can't be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges that should be location of object or lib cell for the location type. The distance must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with *-forbidden_ranges*. Values specified can't be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_location_rules** command defines a named location floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If a location rule is defined for a lib cell and another location rule is defined for a hard macro then the location rule defined for the lib cell will take precedence over the location rule defined for hard macro when checks are done for that lib cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates a location rule by name l1 to check the locations of a soft macro and a placement blockage such that top-right of the soft macro is vertically (both the bottom and the top) within a maximum distance of 2300 of the bottom-right of the placement blockage.

```
prompt> set_floorplan_location_rules -name l1 -from_object_types soft_macro \
  -from_type top_right -to_object_types placement_blockage -to_type bottom_right \
  -direction vertical -max 2300
```

set_floorplan_reshape_rules

Defines a reshape floorplan rule in the design.

SYNTAX

set_floorplan_reshape_rules
-object_types *type_list*
-ignore_lib_cells *lib_cells*

Data Types

type_list	list
lib_cells	collection

ARGUMENTS

-object_types *type_list*

Specifies the list of object types for the reshape floorplan rule. Valid values for this option are *boundary_cell_region* and *std_cell_area*.

-ignore_lib_cells *lib_cells*

Specifies the collection of library cells for the reshape floorplan rule.

DESCRIPTION

The **set_floorplan_reshape_rules** command defines a named reshape floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

Reshape rule is used to connect objects underneath macro to make sure macros are enclosured with reshape object.

EXAMPLES

The following example creates a reshape rule named reshape1.

```
prompt> set_floorplan_reshape_rules -name reshape1 \
```

```
    -object_types std_cell_area \
    -ignore_lib_cells [get_lib_cells */adio*]
```

ARGUMENTS

-from_object_types *from_type_list*

Specifies the list of "from" object types for the spacing floorplan rule. Spacing between these type of objects and other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells** will be checked. Valid values for this option are *block_boundary*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro*, *unplaceable_area*, *boundary_cell_region* and *std_cell_area*. This option is mutually exclusive with **-from_lib_cells** and you must specify one or the other.

-to_object_types *to_type_list*

Specifies the list of "to" object types for the spacing floorplan rule. Spacing between these type of objects and other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells** will be checked. Valid values for this option are *block_boundary*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro*, *unplaceable_area*, *boundary_cell_region* and *std_cell_area*. This option is mutually exclusive with **-to_lib_cells** and you must specify one or the other.

-from_lib_cells *lib_cells*

Specifies the collection of library cells for the spacing floorplan rule. Spacing between these library cells and other objects specified with **-to_object_types** or library cells specified with **-to_lib_cells** will be checked. This option is mutually exclusive with **-from_object_types** and you must specify one or the other.

-to_lib_cells *lib_cells*

Specifies the collection of library cells for the spacing floorplan rule. Spacing between these library cells and other objects specified with **-from_object_types** or library cells specified with **-from_lib_cells** will be checked. This option is mutually exclusive with **-to_object_types** and you must specify one or the other.

-shielding_object_types *type_list*

Specifies the collection of object types for the halo floorplan rule as shielding objects so that the rule will not be applied when these object types form a shield between "from" and "to" objects. Valid values for this option are *hard_macro* and *std_cell_area*. This is an optional option.

-shielding_lib_cells *lib_cells*

Specifies the collection of library cells for the halo floorplan rule as shielding objects so that the rule will not be applied when these lib cells form a shield between "from" and "to" objects.

-directions *direction_list*

Specifies the sides or directions in which spacing between "from" object or from library cells and "to" object or to library cells needs to be checked. Valid values are *any*, *horizontal*, *vertical*, *left*, *right*, *bottom*, *top* and *nearest_corners*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-orientation_types *orientation_list*

Specifies the orientation of the two objects for the check to be enabled. Valid values are *align*, *mirror* and *partial*. *align* means

both the objects should be of same orientation like R0, MX, MY or R180. *partial* means the orientation pair should be R0-R180 or MX-MY. *mirror* means the objects are mirrored in checked direction.

-name *rule_name*

Specifies the name of the spacing floorplan rule. This is a mandatory option.

-min_parallel_run_length *distance*

Specifies the minimum overlap length of two "to" objects or to library cells kept side-by-side. This is an optional option.

-max_parallel_run_length *distance*

Specifies the maximum overlap length of two "to" objects or to library cells kept side-by-side. This is an optional option.

-follow_rotations

Specifies whether mentioned *sides* should follow the rotations of library cells, that is, if meaning of *horizontal* or *vertical* should change when library cell has a 90-degree rotations. This option must be used together with **-to_lib_cells** or **-from_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro** or **-from_object_types hard_macro** or **-from_object_types soft_macro**. This is an optional option.

-ignore_rotate90

Specifies whether this rule can be ignored for library cells with a 90-degree rotation. This option must be used together with **-to_lib_cells** or **-from_lib_cells** or **-to_object_types hard_macro** or **-to_object_types soft_macro** or **-from_object_types hard_macro** or **-from_object_types soft_macro**. This is an optional option.

-no_overlap

Specifies whether the shapes can overlap. By default the shapes can overlap. This is an optional option.

-identical

Specifies whether this rule applies to hard macros of same reference. This is an optional option.

-mirror

Specifies whether this rule applies when hard macros face each other mirrored. This option must be used together with **-identical**. This is an optional option.

-from_layers *from_layer_list*

Specifies the routing layers to be considered for **-from_object_types routing_blockage** or **-from_object_types shape**. This option must be used along with **-from_object_types routing_blockage** or **-from_object_types shape**. This is an optional option.

-to_layers *to_layer_list*

Specifies the routing layers to be considered for **-to_object_types routing_blockage** or **-to_object_types shape** object types. This option must be used along with **-to_object_types routing_blockage** or **-to_object_types shape**. This is an optional option.

-check_same_object

Specifies whether this rule will check the spacing between edges of same objects. This option must be used along with **-from_object_types std_cell_area** and **-to_object_types std_cell_area**. This is an optional option.

-forbidden_list *distance_list*

Specifies a list of distances that are not allowed between "from" objects or "from" library cell and "to" object or "to" library cell. This option is mutually exclusive with **-valid_list**. Values specified cannot be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges that are not allowed between "from" objects or "from" library cell and "to" object or to library cell. The distance must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-valid_ranges**. Values specified cannot be negative. This is an optional option.

-max *distance*

Specifies the maximum distance between "from" object or "from" library cell and "to" object or "to" library cell. The distance cannot be greater than this value. The specified value cannot be negative. If **-min** is also specified then this value must be greater than the min value. This is an optional option.

-min *distance*

Specifies the minimum distance between "from" object or "from" library cell and "to" object or "to" library cell. The distance cannot be less than this value. The specified value cannot be negative. If **-max** is also specified then this value must be lesser than the max value. This is an optional option.

-offset *distance*

Specifies a parameter in distance calculation between "from" and "to" objects. This option must be used together with **-step**. This implies that the distance has to be an integer multiple of *step value* plus *offset value*. Value specified cannot be negative. This is an optional option.

-step *distance*

Specifies a parameter in distance calculation between "from" and "to" objects. This option must be used together with **-offset**. This implies that the distance has to be an integer multiple of *step value* plus *offset value*. Value specified cannot be negative. This is an optional option.

-valid_list *distance_list*

Specifies a list of legal separation distances between the "from" object or "from" library cell and "to" object or "to" library cell. This option is mutually exclusive with **-forbidden_list**. Values specified cannot be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of distance ranges between with the "from" object or "from" library cell and "to" object or "to" library cell must be separated. The distance must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-forbidden_ranges**. Values specified cannot be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_spacing_rules** command defines a named spacing floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If a spacing rule is defined for a library cell and another spacing rule is defined for a hard macro then the spacing rule defined for the library cell will take precedence over the spacing rule defined for hard macro when checks are done for that library cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates a spacing rule named s1 to check spacing between the standard cell area and the block boundary in the vertical direction, both top and bottom. The spacing must be at least 5.

```
prompt> set_floorplan_spacing_rules -name s1 \
  -from_object_types std_cell_area -to_object_types block_boundary \
  -directions vertical -min 5
```

set_floorplan_unplaceable_area_extension_rules

Defines an unplaceable area extension floorplan rule.

SYNTAX

set_floorplan_unplaceable_area_extension_rules
-object_types *type_list*
-lib_cells *lib_cells*
-sides *side_list*
-value *distance*
-name *rule_name*
[-follow_rotations]

Data Types

type_list	list
lib_cells	collection
side_list	list
distance	float
rule_name	string

ARGUMENTS

-object_types *type_list*

Specifies the list of object types for the unplaceable area extension floorplan rule. The area of these type of objects will be checked. Valid values for this option are *std_cell_area* and *hard_macro*. This option is mutually exclusive with **-lib_cells** and you must specify one or the other.

-lib_cells *lib_cells*

Specifies the collection of library cells for the unplaceable area extension floorplan rule. This option is mutually exclusive with **-object_types** and you must specify one or the other.

-sides *side_list*

Specifies the sides or directions in which the target object in specified floorplan rules is to be extended. Valid values are *all*, *bottom*, *horizontal*, *left*, *right*, *top* and *vertical*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-value *distance*

Specifies the extent by which the target objects of specified floorplan rules will be extended for that particular rule checking. This is a mandatory option.

-name *rule_name*

Specifies the name of the unplaceable area extension floorplan rule. This is a mandatory option.

-follow_rotations

Specifies whether mentioned *sides* should follow the rotations of macro, that is, if meaning of *horizontal* or *vertical* should change when macro has a 90-degree rotations. This option must be used together with **-lib_cells** or **-object_types hard_macro**. This is an optional option.

DESCRIPTION

The **set_floorplan_unplaceable_area_extension_rules** command defines a named unplaceable area extension floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

If an unplaceable area extension rule is defined for a library cell and another unplaceable area extension rule is defined for a hard macro then the rule defined for the library cell will take precedence over the rule defined for hard macro when checks are done for that library cell.

EXAMPLES

The following example creates an unplaceable area extension rule named a1 to check the area of block boundary and hard macro. The area can't be greater than 2400 and can't lie between 370 and 790.

```
prompt> set_floorplan_area_rules -name a1 \
  -object_types hard_macro -sides {top left} \
  -value 2000
```

set_floorplan_width_rules

Defines a width floorplan rule.

SYNTAX

set_floorplan_width_rules
-object_types *type_list*
-lib_cells *lib_cells*
-type concave | incorner | jog | simple
-direction *direction_list*
-name *rule_name*
[-except_project_lib_cells *lib_cells*]
[-project_extension *distance*]
[-max_project_spacing *distance*]
[-layers *layer_list*]
[-forbidden_list *width_list*]
[-forbidden_ranges {{*low high*} {*low1 high1*} ... }]
[-max *distance*]
[-min *distance*]
[-offset *distance*]
[-step *distance*]
[-valid_list *distance_list*]
[-valid_ranges {{*low high*} {*low1 high1*} ... }]

Data Types

type_list list
lib_cells collection
direction_list list
rule_name string
layer_list list
width_list list
low float
high float
low1 float
high1 float
distance float
distance_list float

ARGUMENTS

-object_types *type_list*

Specifies the list of object types for the width floorplan rule. The width of these type of objects will be checked. Valid values for this option are *block_boundary*, *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro*, *unplaceable_area*, *boundary_cell_region* and *std_cell_area*. This option is mutually exclusive with **-lib_cells** and you must specify one or the other.

-lib_cells *lib_cells*

Specifies the collection of library cells for the width floorplan rule. The width of these library cells will be checked. This option is mutually exclusive with **-object_types** and you must specify one or the other.

-type concave | incorner | jog | simple

Specifies the width type of the width check. Valid values are *concave*, *incorner*, *jog* and *simple*. This is a mandatory option.

-direction *direction_list*

Specifies the sides or directions in which width of object or library cells needs to be checked. Valid values are *any*, *horizontal* and *vertical*. The *horizontal* argument includes both *left* and *right*. Similarly, the *vertical* argument includes both *bottom* and *top*. This is a mandatory option.

-name *rule_name*

Specifies the name of the width floorplan rule. This is a mandatory option.

-except_project_lib_cells *lib_cells*

Specifies the collection of library cells for the width floorplan rule where the rule will not be applied on the object if specified lib cells project on that object for a given projection distance. This is an optional option. This option is mutually exclusive with **-project_lib_cells** and you must specify one or the other.

-project_extension *distance*

Specifies the projection distance of lib cells specified with **-except_project_lib_cells** on the object so that this rule will not be applied for that object. The value specified cannot be negative. This option must be used together with **-except_project_lib_cells**. This is an optional option.

-max_project_spacing *distance*

Specifies the maximum spacing of lib cells specified with **-except_project_lib_cells** to the object within which this rule will not be applied for that object. The value specified cannot be negative. This option must be used together with **-except_project_lib_cells**. This is an optional option.

-layers *layer_list*

Specifies the routing layers to be considered for the *routing_blockage* or *shape* object type. This option must be used together with **-object_types routing_blockage** or **-object_types shape**. This is an optional option.

-project_lib_cells *lib_cells*

Specifies the collection of library cells for the width floorplan rule where the rule will be applied on the object if specified lib cells project on that object for a given projection distance. This option must be used together with **-object_types std_cell_area** and **-type simple**. This option is mutually exclusive with **-except_project_lib_cells** and you must specify one or the other.

-forbidden_list *width_list*

Specifies a list of widths that are not allowed for the object or library cell. This option is mutually exclusive with **-valid_list**. Values specified cannot be negative. This is an optional option.

-forbidden_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of width ranges that are not allowed for the object or library cell. The width must not lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-valid_ranges**. Values specified cannot be negative. This is

an optional option.

-max *distance*

Specifies the maximum width for the object or library cell. The width cannot be greater than this value. The value specified cannot be negative. If **-min** is also specified then this value must be greater than the min value. This is an optional option.

-min *distance*

Specifies the minimum width of object or library cell. The width cannot be less than this value. The value specified cannot be negative. If **-max** is also specified then this value must be lesser than the max value. This is an optional option.

-offset *distance*

Specifies a parameter in width calculation of object or library cell. This option must be used together with **-step**. This implies that the width has to be an integer multiple of *step value* plus *offset value*. Value specified cannot be negative. This is an optional option.

-step *distance*

Specifies a parameter in width calculation of object or library cell. This option must be used together with **-offset**. This implies that the width has to be an integer multiple of *step value* plus *offset value*. Value specified cannot be negative. This is an optional option.

-valid_list *distance_list*

Specifies a list of allowed widths for the width of the object or library cell. This option is mutually exclusive with **-forbidden_list**. Values specified cannot be negative. This is an optional option.

-valid_ranges {{*low high*} {*low1 high1*} ... }

Specifies a list of allowed width ranges for the object or library cell. The distance must lie within any of *low* and *high* in the specified list of ranges. This option is mutually exclusive with **-forbidden_ranges**. Values specified cannot be negative. This is an optional option.

DESCRIPTION

The **set_floorplan_width_rules** command defines a named width floorplan rule in the current design. The defined rule is persistent. If another floorplan rule by the same name exists then the command errors out.

There is a difference between the object type *core_area* and *std_cell_area*. The *core_area* object type means core boundary region without cutting out any blockages and is typically applicable for top level whereas *std_cell_area* object type means core boundary region after cutting out all blockages and is typically applicable for block level.

If a width rule is defined for a library cell and another width rule is defined for a hard macro then the width rule defined for the library cell will take precedence over the width rule defined for hard macro when checks are done for that library cell.

If the measured value falls inside valid range or is a member of the valid list then there is no violation given by **check_floorplan_rules** regardless of other constraints like min, max, etc. If this measured value is outside valid range or list then a violation is reported if other constraints are specified and they are not met or if no other constraints are specified.

EXAMPLES

The following example creates a width rule named w1 to check the concave width of block boundary and hard macro in horizontal direction, both left and right. The width must be at least 31 and can be at most 153. Also the distance needs to follow integral multiples of 2 plus 34.

```
prompt> set_floorplan_width_rules -name w1 \
  -object_types {block_boundary hard_macro} -type concave \
  -direction horizontal -max 153 -min 31 -offset 34 -step 2
```

set_freeze_ports

Sets the **freeze_ports** attribute on cells to prevent synthesis from modifying their port signature during optimization.

SYNTAX

string **set_freeze_ports** [-all|-clock|-data] *object_list* [*value*]

list *cell_list*
Boolean *value*

ARGUMENTS

-all|-clock|-data

Specifies the scope of the freeze setting and can limit it to clock ports, data ports, or both (the default).

cell_list

Specifies a list of cells on which to place the **freeze_ports** attribute.

value

Specifies the value with which to set the **freeze_ports** attribute. Allowed values are *true* (the default) or *false*.

DESCRIPTION

Sets the **freeze_ports** attribute on cells in the current design to prevent these objects from having ports added or removed during optimization. This attribute can be set separately to control clock and data port optimization.

The **freeze_clock_ports** and **freeze_data_ports** attributes on cells is entered by users.

EXAMPLES

The following commands specify not to modify the data ports of "block1" and "analog1" cells during synthesis.

```
prompt> set_freeze_ports -data [get_cells {block1 analog1}]
1
```

SEE ALSO

get_attribute(2)

set_grid

Updates a grid.

SYNTAX

collection **set_grid**
[-pg_strategy *strategy_name*]
[-layers *layers*]
[-site_rows *rows*]
[-site_arrays *site_arrays*]
[-x_step *step*]
[-y_step *step*]
[-x_offset *offset*]
[-y_offset *offset*]
[-orientations *allowed_orientations*]
[-reset]
grid

Data Types

strategy_name	string
layers	collection
rows	collection
step	float
offset	float
allowed_orientations	list_of_strings
grid	grid_object

ARGUMENTS

-pg_strategy *strategy_name*

Specifies the name of the PG strategy to be considered when updating the grid. This option is applicable only when updating a block grid. The tool derives the grid pitches and offsets from a combination of the specified PG strategy and any existing PG strategies and site rows of the grid. This is an option for auto-derived block grid. It is mutually exclusive with any option for manual block grid.

-layers *layers*

Specifies the tech layers to consider within the PG strategy. This option is applicable only when updating a block grid. A PG strategy might involve many routing layers. By default, all the layers in the specified PG strategy are used to derive the grid. If *-layers* is specified, only the specified layers in the PG strategy would be used. This is an option for auto-derived block grid. It is mutually exclusive with any option for manual block grid.

-site_rows *rows*

Specifies the site rows to be considered. This option is applicable only when updating a block grid. The tool derives the grid's pitches and offsets from the combination of the given site rows and any existing PG strategies and site rows. The specified site rows must be uniform and of the same type of unit site def. This option is used for auto-derived block grid. It is mutually exclusive with any option for manual block grid.

-site_arrays *site_arrays*

Specifies the site arrays to be considered. This option is applicable only when updating a block grid. The tool extracts the site rows from the array and then derives the grid's pitches and offsets from the combination of those site rows and any existing PG strategies and site rows. The specified site rows of site array must be uniform and of the same type of unit site def. This option is used for auto-derived block grid. It is mutually exclusive with any option for manual block grid.

-x_step *step*

Specifies the grid pitch in the x-direction. The default is the existing x_step of the grid. This option is applicable when updating either the user grid or block grid. Use this option for manual block grid. It is mutually exclusive with any option for auto-derived block grid.

-y_step *step*

Specifies the grid pitch in the y-direction. The default is the existing y_step of the grid. This option is used when updating either the user grid or block grid. This option is for manual block grid. It is mutually exclusive with any option for auto-derived block grid.

-x_offset *offset*

Specifies the grid offset to the design origin in the x-direction. The default is the existing x_offset of the grid. This option is used for updating either the user grid or the block grid. This option is for manual block grid. It is mutually exclusive with any option for auto-derived block grid.

-y_offset *offset*

Specifies the grid offset to the design origin in the y-direction. The default is the existing y_offset of the grid. This option is used for updating either the user grid or the block grid. This option is for manual block grid. It is mutually exclusive with any option for auto-derived block grid.

-orientations *allowed_orientations*

Specifies the allowed orientations for any associated block instance of the block grid being updated. This option is applicable only when updating a block grid. Specify one or more of: R0, MX, MY, R180. The default is the existing allowed orientations of the grid. This option is used for updating the manual block grid. It is mutually exclusive with any option for auto-derived block grid. The allowed orientations of an auto-derived block grid are derived automatically from the PG strategy, layer, and site rows.

-reset

Removes all existing options of the grid. If *-reset* is specified without other options, the grid is reset to the litho grid. You can either use **remove_grids** to delete the grid completely, or use **set_grid** with one or more of the above options to update the grid. This option is applicable to both user grid and block grid. If this option is specified with one or more of the above options, the tool resets the grid to litho grid and (in case of block grid) remove any existing PG strategy, layer or site rows from the grid, then apply the other options to update the grid.

grid

Specifies the grid to be updated.

DESCRIPTION

This command updates the options associated with a grid. Use this command to update both user grid and block grid.

Use the **set_block_grid_references** command to associate the block grid with a block reference design. Snapping the block instances to the block grid is done automatically inside **shape_blocks** and GUI editing with the snap setting. You can also use the **snap_cells_to_block_grid** command to move block instances to on block grid.

EXAMPLES

The following example creates an auto-derived block grid named gr1 from patterns on layers M4 and M5 of PG strategy s1. The **set_grid** command changes the grid to also include PG strategy s2.

```
prompt> create_grid -pg_strategy s1 -layers [get_layers {M4 M5}] gr1
prompt> set_grid -pg_strategy s2 gr1
```

The following example creates a manual block grid named gr2 with pitch of 20 microns in the y-direction. All associated block instances must be placed in orientation R0, or flipped around y-axis. The **set_grid** command changes the grid's pitch in both x- and y-direction to 10

```
prompt> create_grid -y_step 20 -orientations {R0 MY} gr2
prompt> set_grid -x_step 10 -y_step 10 gr2
```

The following example creates a user grid named ug1 with a pitch of 10 micron in both x- and y-directions. The **set_grid** command changes the pitch in y-direction to 20 microns.

```
prompt> create_grid -type user -x_step 10 -y_step 10 ug1
prompt> set_grid -y_step 20 ug1
```

set_gui_stroke_binding

Set the command binding for a stroke.

SYNTAX

set_gui_stroke_binding
dictionary_name
stroke_sequence
[-builtin *builtin_cmd_name*]
[-clear]
[-tcl_cmd *tcl_command*]
[-label *tcl_command_label*]

ARGUMENTS

dictionary_name

Specify the dictionary to set the binding into. Windows that support stroke commands have one or more dictionaries to use when evaluating stroke commands.

stroke_sequence

Specifies the sequence of grids that defines the path of the stroke. See the *Stroke Sequences* section, below, for more information.

-builtin *builtin_cmd_name*

Specifies the name of a built-in command option to be executed.

-clear

Clears the existing command for the specified stroke sequence.

-tcl_cmd *tcl_command*

Specifies the Tcl command to be executed when the stroke is entered.

-label *tcl_command_label*

Specifies the menu label for the tcl command. This menu is displayed for line and snap_line strokes after a delay to provide information on the current bindings.

DESCRIPTION

Select a stroke by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

You can use the **report_gui_stroke_builtins** command to determine the available built-in (non-Tcl) commands. You can use the **report_gui_stroke_bindings** command to determine the existing bindings.

Stroke Types

The stroke command facility supports the following modes for entering strokes: line-based, rectangle-based, and path-based. All stroke entry types generate stroke bindings that are the same.

If you are an occasional user, the line-based and rectangle-based entry modes are easier to specify, but they limit the number of strokes that can be generated. If you are an advanced user, the path-based entry mode, which is more difficult to specify, allows many more strokes to be generated.

See the man page for the **set_gui_stroke_preferences** command for complete information on stroke entry types,

Stroke Sequences

The path of a stroke is mapped onto a 3x3 grid. The size of the grid squares are determined to ensure that the stroke covers the width or height of the grid. The stroke is centered in the grid of horizontal or vertical strokes.

The grid is numbered as shown below:

1 2 3
4 5 6
7 8 9

The stroke is mapped onto the grid and converted to a sequence of these grid numbers, which is called a *stroke sequence*. For example, a diagonal stroke from the top-left corner of the grid to the bottom-right corner has a stroke sequence of **159**; a left-to-right horizontal stroke has a stroke sequence of **456**.

Since the strokes are path-based, a single grid might occur more than once in a sequence. For example, a stroke that moves horizontally left-to-right and right-to-left has a stroke sequence of **12321**.

Strokes also support the Shift, Control, and Alt modifier keys. If one or more of these modifiers are depressed when the stroke is started, they are applied to the stroke. The modifiers are prepended to the stroke sequence, with **s** delimiting Shift, **c** delimiting control, and **a** specifying Alt. The modifiers are separated from the sequence by using a colon (**:**). For example, a left-to-right horizontal stroke sequence is **123**, if unmodified; **s:123** with Shift; **c:123** with Control; and **sc:123** with Shift-Control modifiers.

A click is supported as a special (degenerate) case of a stroke. If the mouse down-click and mouse up-click event happen close enough together (in both time and location), the stroke is recognized as a click and a stroke sequence of **5** is generated.

The stroke facility also supports the definition of a default command binding that is to be used for any bindings not explicitly set. This default binding is specified by using a simple stroke sequence of **0**. If no binding is registered for a given set of modifiers and sequence, the tool searches for a stroke binding with the same modifiers and a sequence of **0** and uses that if it is found.

Built-In Commands

The application supporting stroke commands might support operations that are not available from the Tcl command language to be invoked via the stroke command. These commands are given a name, and you can use the **-builtin** option to specify a stroke binding to invoke these commands

The stroke facility always supports the built-in commands for zooming and panning listed below.

Zoom_In

Zoom in by a fixed percentage.

Zoom_Out

Zoom out by a fixed percentage

Zoom_In_Rect

Zoom in to fix the rectangle specified by the bounding box for the stroke.

Zoom_Out_Rect

Zoom out centering on the rectangle specified by the bounding box for the stroke.

Zoom_Full

Zoom and pan to fit the entire drawing centered in the window.

Pan_Center_Rect

Pan to center the rectangle specified by the bounding box for the stroke.

Tcl Command Bindings

The bindings support invoking Tcl-based commands to allow the functionality of the mechanism to be expanded. Tcl-based commands are allowed to contain key values that are substituted with data from the command before they are executed by the interpreter, thus allowing these commands to have access to the context information for the stroke. A leading percent (**%**) character specifies a key value..

The keys listed below are supported by tcl commands.

%rect

Substitutes the coordinates for the bounding box of the stroke. The value is a list of points {{*x1 y1*} {*x1 y2*}}, where you substitute bounding box coordinates for *x1*, *y1*,*x1*, and *y2*.

%startPoint

Specifies the starting point of the stroke. The value is in the form {*x y*}, where you substitute starting point coordinates for *x* and *y*.

%endPoint

Specifies the ending point of the stroke. The value is in the form {*x y*}, where you substitute starting point coordinates for *x* and *y*.

%sequence

Specifies the stroke sequence that invoked this command.

%modifiers

Specifies the modifiers of the stroke sequence that invoked this command.

EXAMPLES

The following example defines a left-to-right horizontal binding to execute the built-in operation that centers the location of the stroke in the viewport.

```
psyn_gui-t> set_gui_stroke_binding Graphics 123 \
```

-builtin Pan_Center_Rect

The following example calls a tcl command for the Shift-modified, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics  \
-tcl s:753 my_tcl_command
```

The following example calls a tcl command taking a rectangle as an argument for the Shift-control, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics \
ss:753 -tcl {my_tcl_command %rect}
```

SEE ALSO

report_gui_stroke_bindings(2)
report_gui_stroke_builtins(2)
set_gui_stroke_preferences(2)

set_gui_stroke_preferences

Set preferences controlling stroke command entry.

SYNTAX

set_gui_stroke_preferences
[-type *stroke_entry_type*]
[-shift]
[-ctrl]
[-alt]
[-extended_help_delay *ms_delay*]

ARGUMENTS

-type *stroke_entry_type*

Specifies the are **snap_line**, **line**, **rect**, **snap_path**, and **path**.

-shift

Sets the type for the shift modifier. This option is valid only when using the **-type** option.

-alt

Sets the type for the alt modifier. This option is valid only when using the **-type** option.

-ctrl

Sets the type for the ctrl modifier. This option is valid only when using the **-type** option.

-extended_help_delay *ms_delay*

Specifies the number of milliseconds to wait before showing the extended help (menu) for a stroke. A value of less than *500* makes the extended feedback immediate. Extremely large values suppress the extended feedback almost completely.

DESCRIPTION

Select a stroke command by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

Use this command to control the user interface behavior when you are specifying a stroke. The preferences allow the strokes to be

used by both application experts and occasional users of the application.

The two primary types of stroke entry mechanisms are the line-based type and the stroke type. The primary preference supported is the stroke type. A line-based type determines the stroke based on the values of the stroke's start and end points. The path between the points is ignored. A line-based stroke turns the stroke facility into a form of "pie-menu" that supports nine different menu items. A path-based type determines the stroke based on the path between the stroke's start and end points. This allows an extremely large number of unique strokes to be defined, and it also requires a significantly-higher amount of precision when specifying the stroke than when using the line-based type.

The snap_line, line, and rect stroke types are all line-based strokes: the snap_path and path are path-based strokes.

Stroke Types

snap_line

The line between the start and end points is snapped onto the nearest 45 degree angle. It allows the generation of eight different stroke sequences and the click stroke sequence.

line

The line between the start and end points specifies the stroke. It allows the generation of eight different stroke sequences and the click stroke sequence.

rect

The rectangle between the start and end points specifies the stroke. It allows the generation of four different stroke sequences and the click stroke sequence.

snap_path

This path-based stroke snaps the segments of the path onto the nearest 45 degree angle to make it easier to generate stroke sequences with diagonals and straight lines. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

path

This path-based stroke is a free-formed path from the start point to the end point. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

The unmodified stroke type is the default type for all modifiers when a type has not been specified for the modifier. Different stroke types can be used for each combination of modifiers by setting the stroke type for the modifier with this command.

EXAMPLES

The following example sets the stroke type to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -type \
snap_line
```

The following example sets the stroke type for Shift-Control modified strokes to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -shift  \
-ctrl -type snap_line
```

SEE ALSO

report_gui_stroke_bindings(2)
report_gui_stroke_builtins(2)
set_gui_stroke_binding(2)

set_host_options

Specify settings for multithreaded and distributed processing.

SYNTAX

status **set_host_options**
[-name *name*]
[-max_cores *core_count*]
[-num_processes *process_count*]
[-submit_command *command*]
[-submit_protocol *protocol*]
[-timeout *time_in_seconds*]
[-work_dir *path*]
[-target ICC2 | ICV | PrimeTime | StarRC | Hspice | RedHawk | ALL]
[-add_hosts]
[*host_names*]

Data Types

name string
core_count int
process_count int
command string
protocol string
time_in_seconds int
path string
host_names list

ARGUMENTS

-name *name*

Specifies a name for this collection of options. The name can later be specified in the *remove_host_options* command to remove only these particular options.

If you do not specify the **-name** or **-target** options, the options specified in this command are set as the global options.

-max_cores *core_count*

If this option is specified by itself, it controls the maximum number of cores that can be used by multicore commands in the current (main) job.

If it is specified as part of a host or pool specification, it controls the number of cores each distributed slave job can use.

In both cases, the value is a maximum; some commands might use fewer cores than the specified value, but in no case would

they use more.

-num_processes *process_count*

Controls the level of parallelism used for job submission.

If you are defining an LSF, GRD, or custom pool, this is the maximum total number of jobs that can be submitted to it. If you are defining a collection of named hosts, this is the maximum number of jobs per host that can be started on those hosts.

You can restrict the number of active jobs to a specified number based on hardware or license resource restrictions.

The default is 1.

-submit_command *command*

Specifies the full path name of the LSF, GRD, or custom job submission program along with any desired options.

If you are defining a simple pool of machines and do not specify this option, **rsh** is used as the submission program.

-submit_protocol *protocol*

Specifies the protocol over which to submit jobs. If not specified, the tool will choose what protocol to use.

Values specified for this option are standardized to all lowercase.

-timeout *time_in_seconds*

Specifies the job submission timeout value in seconds.

If the submitted jobs do not become running jobs within the specified time, they are killed. This is to prevent hanging jobs in the queuing system.

If you do not specify this option, the system waits as long as needed for jobs to start.

Note that this option applies only to rsh and ssh. It does not apply to LSF or GRD queues.

-work_dir *path*

Specifies the directory for distributed jobs to use for run files.

The default is "./work_dir".

-target ICC2 | ICV | PrimeTime | StarRC | Hspice | RedHawk | ALL

Specifies which tool the configuration applies to.

The target can later be specified in the *remove_host_options* command to remove only options related to that target.

If you do not specify this option, the configuration applies to all tools.

-add_hosts

Specifies the host option settings to be stored for child jobs of the target tool.

This option must be used with the **-target** option.

host_names

Specifies a list of hosts that are used to run distributed jobs.

DESCRIPTION

Some products support commands that can be run in distributed mode, in which a task is broken up into many pieces and each subproblem is run independently. The **set_host_options** command defines the parameters for running a command in distributed mode.

It allows for simple setup for the new user and also for arbitrarily complex setup for the user with more sophisticated needs.

In its simplest form, the command is used to control the number of cores used by multicore commands. A multicore command can use fewer cores than this maximum, but the command can never exceed the stated maximum.

The command is versatile enough to interface to LSF, GRD, or a custom job-submission system, and has a mode in which a listed set of machines are used with the rsh command to execute remote jobs without having a queuing system at all.

If you are using a queuing system such as LSF, GRD, or a custom queuing system, you use the **set_host_options** command to specify a path to the batch submission system along with a queuing-system-specific set of command-line options that are passed along to the queuing system. These are typically used to ask for specific resources or otherwise control the queuing system. You can also control the submit timeout to make sure that jobs don't get stuck forever in a queuing system.

If you are not using a queuing system, you can still use distributed processing by providing a list of host machines, which the tool then uses to launch remote jobs with the rsh command.

You can name the collection of options that the **set_host_options** command creates by using the **-name** option. You can use the name with the **remove_host_options** command to remove only the options of that name. If you do not specify a name, the tool sets the global options as specified.

You can store the options that the **set_host_options** command creates for any tool by using the **-target** option. You can use the target with the **remove_host_options** command to remove only the options of that target. If you do not specify the target, the configurations are applied to all tools.

You can use the **report_host_options** command to report information about the defined host option sets.

There is a great deal of power and flexibility in the **set_host_options** command. You should start by using a single set of options until you fully understand how host option sets are made and how they are used by distributed commands. The EXAMPLES section below provides examples growing in complexity from basic to complex.

EXAMPLES

The following example sets up multicore operation within the parent process.

```
prompt> set_host_options -max_cores 4
  ...
## The following command uses a maximum of 4 threads.
prompt> some_threaded_command ...
```

The following distributed job example shows the use of host mode.

```
prompt> set_host_options -num_processes 2 -max_cores 4 {sleepy doc}
```

Note that in the previous example there are a total of 8 cores available (4 each from sleepy and doc). This example is for the "global" mode (unnamed host option).

When using a named host option, together with a command that takes a -host_options parameter, the behavior is different (to be consistent with the other named-host-option behavior), as max_cores settings are then applied to the distributed tasks to control multi-threading (if applicable), and the total number of distributed tasks / licensing is controlled by the -num_processes parameter.

An equivalent example for a named host option:

```
prompt> set_host_options -name rshOpt -submit_command "rsh" -num_processes 8 {sleepy doc}
```

This example allows up to 8 distributed tasks total. The tasks are allocated in the order the hosts respond, and could be up to 8 on just one host - especially if localhost is one of the choices, as localhost usually responds faster than other hosts. To limit tasks on a per-host basis, the following syntax can be used:

```
prompt> set_host_options -name rshOpt -submit_command "rsh" \
   -num_processes 8 {sleepy:5 doc:4}
```

This limits overall tasks to 8, and restricts host sleepy to 5 tasks and host doc to 4 tasks maximum.

The following example shows the use of an LSF farm. It sets the maximum number of jobs that can submitted to 12, chooses the linux64 queue, and names this set of options lsfOptions. This name can be used later to identify or delete this set of options.

```
prompt> set_host_options -num_processes 12 \
  -name "lsfOptions" \
  -submit_command "/lsf/bin/bsub -q linux64"
  ...
```

The following example shows the use of a non-standard pool. It sets the maximum number of jobs that can submitted to 8, defines the custom script for job submission, and names this set of options customOptions. This name can be used later to identify or delete this set of options.

```
prompt> set_host_options -num_processes 8 -name "customOptions" \
   -submit_command /usr/local/bin/my_submit_command
   ...
```

The following example shows the use of storing the host option settings for child jobs of a target tool.

```
prompt> set_host_options -num_processes 8 -target PrimeTime \
   -submit_command /usr/local/bin/my_submit_command
prompt> set_host_options -num_processes 4 -target PrimeTime \
   -submit_command /usr/local/bin/my_submit_command2 -add_hosts
   ...
```

set_hpc_options

Apply HPC (High Performance Core) specific settings to current design

SYNTAX

status **set_hpc_options**
-list
-core core_name
-stage stage_name

Data Types

core_name string
stage_name string

ARGUMENTS

-list

List supported core names and stage names

-core core_name

Specifies the HPC core, use -list to see supported core names

-stage stage_name

Specifies the stage name, use -list to see supported stage names

DESCRIPTION

This command will apply HPC (High Performance Core) specific settings to current design. It sets the parameters and app options for synthesis, placement and route engines for better performance and power. Once the command is executed, all the controls will be applied to the design, the "hpc_core" attribute will be set to the design as well.

For advanced node such as 7nm, user needs to use set_technology command before invoking set_hpc_options.

EXAMPLES

In following example, list cores and stages supported in the tool:

```
prompt> set_hpc_options -list
cores: A53 A55 A72 A73 A75 A76
stages: place_opt clock_opt_cts clock_opt_opto route_auto route_opt
```

In following example, we apply HPC settings for a 7nm A76 core.

```
prompt> set_technology -node 7
prompt> set_hpc_options -core A76 -stage place_opt
prompt> place_opt
prompt> set_hpc_options -core A76 -stage clock_opt_cts
prompt> clock_opt -from build_clock -to route_clock
prompt> set_hpc_options -core A76 -stage clock_opt_opto
prompt> clock_opt -from final_opto
prompt> set_hpc_options -core A76 -stage route_auto
prompt> route_auto
prompt> set_hpc_options -core A76 -stage route_opt
prompt> route_opt
```

set_technology(2)

set_ideal_latency

Specifies ideal latency values for the pins in an ideal network.

SYNTAX

int **set_ideal_latency**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-rise] [-fall]
[-min] [-max]
value
object_list

float *value*
list *object_list*

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to apply the latency value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies latency for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to apply the latency value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies latency for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the latency value. Each of the specified scenarios is annotated separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command applies to the current scenario only.

-rise

Indicates that the *value* option represents the rise latency time. If you do not specify the **-rise** or **-fall** options, both values are set.

-fall

Indicates that the *value* option represents the fall latency time. If you do not specify the **-rise** or **-fall** option, both values are set.

-min

Indicates that the *value* option represents the minimum latency time. If you do not specify the **-min** or **-max** option, both values are set.

-max

Indicates that the *value* option represents the maximum latency time. If you do not specify the **-min** or **-max** option, both values are set.

value

Specifies an ideal latency value on leaf cell pins or top-level ports in an ideal network.

object_list

Specifies a list of leaf cell pins and top-level ports on which ideal latency is set.

DESCRIPTION

Sets an ideal latency value on leaf cell pins and top-level ports of an ideal network.

The tool uses ideal timing for ideal networks, which means that pins and ports have a specified ideal latency (from the **set_ideal_latency** command) or zero ideal latency by default. Ideal networks are normally used during pre-layout to avoid unnecessary DRCs. The specified ideal latency value provides an estimate of the latency time in the ideal network for pre-layout.

The specified latency value overrides the internally-estimated cell and net delay value and any other delay annotations. If the specified pins do not belong to an ideal network, a warning message is generated by the **report_ideal_network** command and the ideal latency *value* is ignored for those pins. Ideal latency values do not have any effect in ideal clock networks (for example, non-propagated clock networks).

The **set_ideal_latency** command affects all pins in the transitive fanout of the pins or ports on which ideal latency is specified. The total ideal latency at an ideal boundary pin is the sum of latency on the ideal network source and all ideal latencies on the path.

You can use the **set_ideal_latency** command for pins at lower levels of the design hierarchy.

To list ideal latency values, use the **report_ideal_network** command.

To remove the ideal latency values from a design, use the **remove_ideal_latency** or **reset_design** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example specifies a rise latency of *1.2* and a fall latency of *0.9* for ports named *A*, *B*, and *C*.

```
prompt> set_ideal_latency 1.2 -rise {A B C}
prompt> set_ideal_latency 0.9 -fall {A B C}
```

remove_ideal_transition(2)
report_ideal_network(2)
set_ideal_transition(2)
set_ideal_network(2)

set_ideal_network

Marks a set of ports or pins in the design as sources of an ideal network. This disables timing update of cells and nets in the transitive fanout of the specified objects.

SYNTAX

status **set_ideal_network**
[-no_propagate]
object_list

Data Types

object_list list

ARGUMENTS

-no_propagate

Indicates that the ideal network is not propagated through leaf cells. Ideal properties are enabled on all nets that are electrically connected to the ideal network sources.

object_list

Specifies the objects to mark as the sources of an ideal network. Ideal network source objects can be ports or pins of leaf cells at any hierarchical level of the design.

If you specify nets in the *object_list* argument, the global driver pins of the specified nets are marked as ideal network sources. You can specify nets only when you specify the **-no_propagate** option.

DESCRIPTION

This command marks a set of ports or pins in the design as sources of an ideal network. You specify only the source of the network. The tool marks all nets, cells, and pins in the transitive fanout of ideal sources as ideal. The ideal property is automatically spread by the tool and respread as necessary after the netlist changes. The criteria for propagating the ideal property, starting at the source pins and ports, are as follows:

- A pin is marked as ideal if you specify it by using the **set_ideal_network** command, if it is a driver pin whose cell is ideal, or if it is a load pin attached to a net that is ideal.
- A net is marked as ideal if all its driving pins are ideal.

- A combinational cell is marked as ideal if at least one of its input pins is ideal and all the other input pins are either ideal, unconnected, or attached to a logic constant net. Objects with case analysis set are not treated as constant.

Propagation traverses through combinational cells but stops at sequential cells.

Design rule checks (DRCs) are disabled on ideal network objects.

Ideal networks can be specified in the clock or data network.

By default, the latency and transition times of an ideal network are zero. To override them, use the **set_ideal_latency** and **set_ideal_transition** commands. Ideal timing values do not have any effect in ideal clock networks (for example, nonpropagated clock networks).

To reverse the effect of the **set_ideal_network** command, use the **remove_ideal_network** command and specify the source pins or ports for the network. The **reset_design** command removes all ideal networks.

EXAMPLES

The following example creates an ideal network on ports in a design named TOP.

```
prompt> current_design {TOP}
prompt> set_ideal_network {IN1 IN2}
```

SEE ALSO

remove_ideal_network(2)
reset_design(2)
set_ideal_latency(2)
set_ideal_transition(2)

set_ideal_transition

Specifies ideal transition values for the pins in an ideal network.

SYNTAX

int **set_ideal_transition**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-rise] [-fall]
[-min] [-max]
value
object_list

float *value*
list *object_list*

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to apply the transition value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies transition for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to apply the transition value. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is annotated separately. If this option is not given, the command applies transition for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the transition value. Each of the specified scenarios is annotated separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command applies to the current scenario only.

-rise

Indicates that *value* represents the rise transition time. If you do not specify **-rise** or **-fall**, both values are set.

-fall

Indicates that *value* represents the fall transition time. If you do not specify **-rise** or **-fall**, both values are set.

-min

Indicates that *value* represents the minimum transition time. If you do not specify **-min** or **-max**, both values are set.

-max

Indicates that *value* represents the maximum transition time. If you do not specify **-min** or **-max**, both values are set.

value

Specifies an ideal transition value on leaf cell pins or top-level ports in an ideal network.

object_list

Specifies a list of leaf cell pins and top-level ports on which ideal transition is set.

DESCRIPTION

Sets an ideal transition value on leaf cell pins and top-level ports of an ideal network.

The tool uses ideal timing for ideal networks, which means that pins and ports have a specified ideal transition (from the **set_ideal_transition** command) or zero ideal transition by default. Ideal networks are normally used during pre-layout to avoid unnecessary DRCs. The specified ideal transition value provides an estimate of the transition time in the ideal network for pre-layout.

The specified transition value overrides the internally-estimated cell and net transition value and any other transition annotations. If the specified pins do not belong to an ideal network, a warning message is generated by the **report_ideal_network** command and the ideal transition *value* is ignored for those pins. Ideal transition values do not have any effect in ideal clock networks (i.e. non-propagated clock networks).

You can use **set_ideal_transition** for pins at lower levels of the design hierarchy.

To list ideal transition values, use the **report_ideal_network** command.

To remove the ideal transition values from a design, use the **remove_ideal_transition** or **reset_design** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example specifies a rise transition of *1.2* and a fall transition of *0.9* for ports named *A*, *B*, and *C*.

```
prompt> set_ideal_transition 1.2 -rise {A B C}
prompt> set_ideal_transition 0.9 -fall {A B C}
```

set_ieee_1500_configuration

Sets the IEEE 1500 insertion configuration for the current design.

SYNTAX

integer **set_ieee_1500_configuration**
[-wir_width *integer*]
[-wby_width *integer*]

ARGUMENTS

-wir_width *integer*

Specifies the width of the IEEE 1500 wrapper instruction register (WIR) to be implemented by IEEE 1500 test-mode control insertion.

By default, the WIR width is automatically determined by the tool based on the number of test-mode encodings needed and the type of encoding specified by the **-mode_decoding_style** option of the **set_dft_configuration** command.

-wby_width *integer*

Specifies the width of the IEEE 1500 bypass register (WBY) to be implemented by IEEE 1500 test-mode control insertion.

By default, the WBY width is 1.

DESCRIPTION

This command specifies the configuration of the IEEE 1500 test-mode control logic to be inserted in the current design. Note that IEEE 1500 logic is implemented only when IEEE 1500 test-mode control is enabled by the **set_dft_configuration -ieee_1500 enable** command.

To configure IEEE 1500 control data registers, use the **set_scan_path** command.

EXAMPLES

The following command changes the WIR width to 4:

prompt> **set_ieee_1500_configuration -wir_width 4**

SEE ALSO

set_scan_path(2)

set_ignored_layers

Sets ignored routing layers for RC estimation and congestion analysis. This command can also set the minimum and maximum routing layers for the design.

SYNTAX

status **set_ignored_layers**
[-rc_congestion_ignored_layers *layer_names*]
[-min_routing_layer *min_name*]
[-max_routing_layer *max_name*]
[-verbose]

Data Types

layer_names list
min_name string
max_name string

ARGUMENTS

-rc_congestion_ignored_layers *layer_names*

Lists the routing layers to be ignored in congestion analysis and RC estimation. This option excludes the specified layers from both RC estimation and congestion analysis. The option does not affect the behavior of the router.

-min_routing_layer *min_name*

Specifies the minimum routing layer for the design. The router respects this setting. To ensure that RC estimation and congestion analysis stay synchronized with the router, when you set this option, the tool marks all routing layers below the specified layer as fully blocked for RC and congestion estimation.

-max_routing_layer *max_name*

Specifies the maximum routing layer for the design. The router respects this setting. To ensure that RC estimation and congestion analysis stay synchronized with the router, when you set this option, the tool marks all routing layers above the specified layer as fully blocked for RC and congestion estimation.

-verbose

Displays verbose ignored layers information.

DESCRIPTION

This command sets the routing layers that are ignored during congestion analysis and RC estimation. You can use this command when you do not want to route nets on certain routing layers.

If you set the minimum and maximum routing layers for a design by using this command, the router respects these settings. If you set the minimum routing layer for the design to a certain layer, this command automatically sets all the routing layers below this layer as fully blocked layers. The same behavior also applies to the maximum routing layer setting.

A layer can be set as either ignored layer or minimum/maximum routing layer, congestion and rc value impact are similar but not identical. Minimum/maximum routing layer means the layer is fully blocked, ignored layer means not to use this layer for rc estimation and doesn't change the layer blockage directly.

The minimum and maximum routing layer settings work in conjunction with other tool controls. You can adjust the hardness of these constraints by setting the following application options:

- **route.common.net_min_layer_mode**
- **route.common.net_max_layer_mode**
- **route.common.number_of_vias_over_net_min_layer**
- **route.common.number_of_vias_over_net_max_layer**

For more information about these options, see the man pages.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns the m5 and m6 layers to be ignored during congestion analysis and RC estimation:

```
prompt> set_ignored_layers -rc_congestion_ignored_layers {m5 m6}
```

The following example sets m2 as the minimum routing layer and m5 as the maximum routing layer. All layers below m2 and above m5 are set as ignored layers.

```
prompt> set_ignored_layers -min_routing_layer m2 -max_routing_layer m5
```

route.common_options(3)

set_implementation

Specifies the implementation to use for synthetic library cell instances in a design.

SYNTAX

status **set_implementation**
implementation_name
cell_list

Data Types

implementation_name	string
cell_list	list

ARGUMENTS

implementation_name

Specifies the name of the implementation used to implement the synthetic cells in the *cell_list*.

cell_list

Specifies the synthetic library cell instances to be implemented by *implementation_name*. If more than one instance name is specified, enclose the names in quotation marks ("") or in braces ({}).

DESCRIPTION

The **set_implementation** command tags specified synthetic library cell instances with the name of an implementation to use to implement them. When the **compile** command is run, the tool chooses the user-specified implementation to implement a cell instance. Otherwise, **compile** chooses the implementation it considers most appropriate for a cell instance.

The command is used to control the implementation of instantiated or inferred DesignWare components.

The **report_resources** command lists the current implementation of all synthetic library instances, and indicates whether the implementation has been locked by **set_implementation**.

Use the **report_attribute** or **get_attribute** command to check the status of **set_implementation** of given cells. The attribute name is "forced_implementation". The attribute can be cleaned by **remove_attribute** command.

EXAMPLES

The *Dw_div* (Combinational Divider) component has five implementations (*rpl*, *cla*, *cla2*, *cla3*, *mlt*). The following example directs compile to use *cla3* implementation for *DW_div* that is instantiated as *U1*:

```
prompt> set_implementation cla3 U1
```

When the DesignWare component is inferred as an RTL operator, the synethic module name must be specified as well as the implemenation name. This is because the synthetic operator could bind more than one synthetic module. The following example directs compile to use *DW_div_uns/cla2* implementation for an inferred unsigned divider as *div_3*:

```
prompt> set_implementation DW_div_uns/cla2 div_3
```

The following example removes any effects of **set_implementation** from all synthetic cells of the current module:

```
prompt> remove_attribute -name forced_implementation [get_cells *]
```

SEE ALSO

compile(2)
get_attribute(2)
report_attribute(2)

report_resources(2)

set_individual_pin_constraints

Sets pin constraints on individual pins or nets.

SYNTAX

status **set_individual_pin_constraints**
[-pins *pins*]
[-nets *nets*]
[-ports *ports*]
[-cells *cells*]
[-allow_feedthroughs true | false]
[-allowed_layers *metal_layers*]
[-pin_spacing *track_count*]
[-pin_spacing_distance *pin_spacing_distance*]
[-sides *side_numbers*]
[-exclude_sides *exclude_side_numbers*]
[-offset *offset_distance*]
[-width *pin_width*]
[-length *pin_length*]
[-off_edge]
[-location {*x y*}]

Data Types

pins	collection
nets	collection
ports	collection
cells	collection
metal_layers	list
track_count	integer
pin_spacing_distance	real
side_numbers	list of integers
exclude_side_numbers	list of integers
offset_distance	real
pin_width	real or list of layer-real pairs
pin_length	real or list of layer-real pairs
x	float
y	float

ARGUMENTS

-pins *pins*

Specifies the pins that receive the constraints. Specify the full pin name from top-level design.

-nets *nets*

Applies the constraints only to the nets specified in *nets*.

-ports *ports*

Specifies the ports that receive the constraints.

-cells *cells*

Associates the net-based constraints to the specified block cells. For example, you can specify a layer constraint for a particular block cell, then specify the **-nets**, **-cells**, and **-allowed_layers** option to create the constraint. Note that cells must be on the same physical hierarchy with specified nets.

-allow_feedthroughs true | false

Specifies whether feedthrough ports can be created for the specified net. When true, the global router can create feedthrough routing on a block cells for the specified nets. When a feedthrough is created on a top-level net, the net is split into a set of new top-level nets and child-level nets if feedthrough nets are created for the child nets. Directions are assigned for the new feedthrough ports, and the netlist is modified to accommodate the new ports in the block cell.

This option can only be specified together with the **-nets** option and cannot be used together with **-cells** option. To set feedthrough constraints on individual block cells for selected nets, create a pin constraints file and use the **read_pin_constraints** command.

This option can also be used to set feedthrough allowance for the push-down into a block of pre-routed nets using **push_down_objects**. That command will check this pin constraint, and if found to be set, and set to true, will create feedthroughs based upon the pre-route multiple crossing of a block's boundary.

-allowed_layers *metal_layers*

Specifies the set of metal layers allowed for pin placement. The argument is a list of metal layers.

By default, the metal layers from M2 to the maximum metal layer (specified earlier in the floorplanning flow) are allowed for pin placement. If the maximum metal layer has not been specified, the maximum available metal layer specified in the technology file is used as the default. If the maximum layer specified is beyond the maximum metal layer for the current design, then the maximum layer in the technology file is used.

-pin_spacing *spacing_number*

Specifies the minimum number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across block edge in the normal direction. Pins that are created are always snapped to wire tracks. The default pin-to-pin spacing is one wire track. The spacing number must be 0 or a positive integer.

-pin_spacing_distance *spacing_distance*

Specifies the minimum distance between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks.

-sides *side_numbers*

Specifies one or more block sides on which the pin must be placed.

A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the left-most vertical edge is the starting edge (side number 1). If there are multiple left-most edges, then the edge 1 is the lowest left-most edge. You cannot specify a value of 0 for this option.

This option is mutually exclusive with **-exclude_sides** option.

-exclude_sides *exclude_side_numbers*

Specifies the block edges on which pins cannot be placed. The *exclude_side_numbers* argument is a list of positive integers.

A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the left-most vertical edge is the starting edge (side number 1). If there are multiple left-most edges, then the edge 1 is the lowest left-most edge. You cannot specify a value of 0 for this option.

This option is mutually exclusive with **-sides** option.

-offset *offset_distance*

Specifies the distance in microns between the starting or ending point of a specified edge and the pin's center location. The starting point is the location where the edge begins as you proceed clockwise around the shape. The ending point is the location where the edge end as you proceed clockwise around the shape. The starting point of edge 1 is the lowest point of the edge, the ending point of edge 1 is the highest point of the edge the starting point of edge 2 is the leftmost point of the edge, and so on. Positive value means offset distance calculates from starting point of a specified edge and the pin's center location, vice versa for negative value.

A range can also be specified for this option. Specify range start and range end values within which the pins are allowed to place. The start and end values refer to the distances as measured to the starting point of the edge in microns (or the default unit). Negative value for range refer to the distances as measured to the ending point of the edge in microns (or the default unit). For example,

-offset {10 40}

You must specify the side information together with the offset. However, offset cannot be specified with multiple sides.

-width *pin_width*

Specifies the width of the pin. The width is perpendicular to the layer's preferred routing direction. The syntax can be a single real number to indicate the width is applied to all allowed layers (referred to as common pin width). Or alternatively, the width can be specified as a list of layer-real pairs as the following (referred to as per layer pin width):

-width {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its width should be 0.2 and if on M4 or M5, 0.3. On other layers, use the default width defined by the tech file.

If user first sets the pin width to be common pin width (or per layer pin width), then in a second **set_individual_pin_constraints** sets the pin width to be per layer width (or common pin width), then the width specified in the second command will override the first.

However, if user first sets the pin width to be per layer, then in a second command sets the pin width again to be per layer but with different layers or different values, then the combined per layer pin width will be the final constraints. For example, the following example:

set_individual_pin_constraints -pins {U1/P1} -width 0.3
set_individual_pin_constraints -pins {U1/P1} -width {{M2 0.3} {M3 0.3}}

The first common pin width constraint will be overridden by the second per layer pin width. The pin width should be 0.3 on layer M2 or M3, but default width on all other layers.

And for the following example:

set_individual_pin_constraints -pins {U1/P1} -width {{M3 0.4} {M4 0.4}}
set_individual_pin_constraints -pins {U1/P1} -width {{M2 0.3} {M3 0.3}}

The pin width should be 0.3 on layer M2 or M3, 0.4 on layer M4, and default width on all other layers.

-length *pin_length*

Specifies the length of the pin. The length is in parallel to the layer's preferred routing direction. The syntax can be a single real number to indicate the length is applied to all allowed layers (referred to as common pin length). Or alternatively, the length can be specified as a list of layer-real pairs as the following (referred to as per layer pin length):

-length {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its length should be 0.2 and if on M4 or M5, 0.3. On unspecified layers, the pin length is derived from the pin width. Refer to the manpage of **place_pins** for details.

-off_edge

Specifies whether the pin is created on the block boundary. This option is mutually exclusive with the **-sides** and **-offset** options.

-location ***{x y}***

Specifies the x- and y-location in the top-level design where the pin should be created. This option is mutually exclusive with the **-sides** and **-offset** options. When used together with the **-off_edge** option, the pin is placed on the closest wiretrack to the specified location. Note that in this case there will be no legalization of pin placement for off edge pins, as it is meant to be a basic placement where user is expected to give the legal location. If the location constraint is a hard constraint set by the **set_block_pin_constraints** command, the center of the pin is placed at the exact location specified by this option. If you do not specify the **-off_edge** option, the pins are placed on the edge that is closest to this location.

DESCRIPTION

This command sets pin placement constraints on individual pins, nets, or ports. The constraints are honored during pin placement. The pin placement constraints are saved in the design database. Except -allow_feedthroughs option, all the other options can be specified for either pins, ports or nets.

The **set_individual_pin_constraints** command is additive. The constraint values set in previous calls are retained unless they are explicitly overridden by subsequent calls. This command is aware of multiple levels of physical design hierarchy (MPH-aware).

The **set_editability** command can enable or disable the **set_individual_pin_constraints** command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the **set_editability** command.

This command returns 1 on success, 0 otherwise.

Please note, starting from 2019.12 release, a new command **create_pin_constraint** is introduced that can also creates the individual pin constraints (as well as bundle pin constraints) and has similar command line options. The major difference is that **create_pin_constraint** returns a collection of constraints it created, which under certain scenarios might be desired.

EXAMPLES

The following example sets the allowed pin layers for net clk to M2 and M3.

```
prompt> set_individual_pin_constraints -allowed_layers [get_layers {M2 M3}] \
  -nets [get_nets clk]
```

set_input_delay

Defines the arrival time relative to a clock.

SYNTAX

string **set_input_delay**
[-clock *clock_name*]
[-reference_pin *pin_port_name*]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
delay_value
port_pin_list

Data Types

clock_name list
pin_port_name list
mode_list list
corner_list list
scenario_list list
delay_value float
port_pin_list list

ARGUMENTS

-clock *clock_name*

Specifies the clock to which the specified delay is related. If you use **-clock_fall**, you must specify **-clock clock_name**. If you do not specify **-clock**, the delay is relative to time zero for combinational designs. For sequential designs, the delay is considered relative to a new clock with a period determined by considering the sequential cells in the transitive fanout of each port.

-reference_pin *pin_port_name*

Specifies the clock pin or port to which the specified delay is related. If you specify this option and if propagated clocking is being used, the delay value is related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The **-network_latency_included** and **-source_latency_included** options cannot be used at the same time as the **-reference_pin** option. For an ideal clock network, its the sum of source latency and network latency applied.

The pin specified with the **-reference_pin** option should be a leaf pin or port in a clock network, in the direct or transitive fanout of a clock source specified with the **-clock** option. If multiple clocks reach the port or pin where you are setting the input delay, and if the **-clock** option is not used, the command considers all of the clocks.

-clock_fall

Specifies that the delay is relative to the falling edge of the clock. When it is used with **-reference_pin** option, the delay is relative to the falling transition of the reference pin. The default is the rising edge or rising transition of a reference pin.

-level_sensitive

Specifies that the source of the delay is a level-sensitive latch. This allows the tool to derive setup and hold relationship for paths from this port as if it were a level-sensitive latch. If you do not use **-level_sensitive**, the input delay is treated as if it were a path from a flip-flop.

-rise

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If you do not specify **-rise** or **-fall**, rising and falling delays are assumed to be equal.

-fall

Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If you do not specify **-rise** or **-fall**, rising and falling delays are assumed to be equal.

-max

Specifies that *delay_value* refers to the longest path. If you do not specify **-max** or **-min**, maximum and minimum input delays are assumed to be equal.

-min

Specifies that *delay_value* refers to the shortest path. If you do not specify **-max** or **-min**, maximum and minimum input delays are assumed to be equal.

-add_delay

Specifies whether to add delay information to the existing input delay or to overwrite. Use the **-add_delay** option to capture information about multiple paths leading to an input port that are relative to different clocks or clock edges.

For example, **set_input_delay 5.0 -max -rise -clock phi1 {A}** removes all other maximum rise input delay from "A", because **-add_delay** is not specified. Other input delays with different clocks or with clock_fall are removed.

In another example, **-add_delay** is specified as **set_input_delay 5.0 -max -rise -clock phi1 -add_delay {A}**. If there is an input maximum rise delay for "A" relative to clock "phi1" rising edge, the larger value is used. The smaller value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise input delay relative to a different clock or different edge of the same clock, it remains with the new delay.

-network_latency_included

Specifies whether the clock network latency should not be added to the input delay value. If this option is not specified, the clock network latency of the related clock is added to the input delay value. It has no effect if the clock is propagated or the input delay is not specified with respect to any clock.

-source_latency_included

Specifies whether the clock source latency should not be added to the input delay value. If this option is not specified, the clock source latency of the related clock is added to the input delay value. It has no effect if the input delay is not specified with respect to any clock.

delay_value

Specifies the path delay. The *delay_value* must be in units consistent with the technology library used during analysis. The *delay_value* represents the amount of time that the signal is available after a clock edge. This usually represents a combinational path delay from the clock pin of a register.

port_pin_list

Provides a list of input port or internal pin names in the current design to which *delay_value* is assigned. If you specify more than one object, the objects are enclosed in braces ({}).

-modes ***mode_list***

Specifies the scenarios on which to set the input delay value. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners ***corner_list***

Specifies the scenarios on which to set the input delay value. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios ***scenario_list***

Specifies the scenarios on which to set the input delay value. The **-modes** or **-corners** option must not be given with this option.

DESCRIPTION

Sets input path delay values for the current design. Used with **set_load** and **set_driving_cell**, the input and output delays characterize the operating environment of the current design.

The **set_input_delay** command sets input path delays on input ports relative to a clock edge. Unless specified, input ports are assumed to have zero input delay. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay from a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the input delay relative to the rising clock edge. If the latch is negative enabled, set the input delay relative to the falling clock edge. If time is borrowed at that latch, add that time borrowed to the path delay from the latch when determining input delay.

If for a specific clock has a max delay that is less than the min delay, the tool makes the max delay equal to the min delay.

The tool adds input delay to path delay for paths starting at primary inputs, and to output delay for paths ending at primary outputs.

Input delay on a clock port is treated as clock source latency if the clock does not have a clock source latency defined. This way of defining clock source latency will not be supported for future releases. If the clock port leads to a D pin of a register and the clock port has both an input_delay and a clock source latency set on it, there might be double counting for the data-path report (both the input delay value and clock source latency will be added).

Input delay is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different delays for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the given delay is applied to the current scenario. It is an error if there is no current scenario. If the **-scenarios** option is given, the delay is applied to all of the specified scenarios. If the **-modes** option is given, the

delay is applied to all scenarios of the specified modes, and it is an error if none of the specified modes have any scenarios. If the **-corners** option is given, the delay is applied to all scenarios of the specified corners and the current mode, and it is an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the delay is applied to all scenarios of the specified corners and the specified modes, and it is an error there are no such scenarios. It is an error to give **-scenarios** with **-modes** or **-corners**.

To list input delays associated with ports, use **report_ports**. To remove input delay values, use **remove_input_delay** or **reset_design**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets an input delay of 2.3 for ports "IN1" and "IN2" on a combinational design. Because the design is combinational, no clock is needed.

```
prompt> set_input_delay 2.3 { IN1 IN2 }
```

The following example sets input delay of 1.2 relative to the rising edge of "CLK1" for all input ports in the design.

```
prompt> set_input_delay 1.2 -clock CLK1 [all_inputs]
```

The following example sets the input and output delays for the bidirectional port "INOUT1". The input signal arrives at "INOUT1" 2.5 units after the falling edge of "CLK1". The output signal is required at "INOUT1" at 1.4 units before the rising edge of "CLK2".

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall { INOUT1 }

prompt> set_output_delay 1.4 -clock CLK2 { INOUT1 }
```

The following example models the situation where there are three paths to input port "IN1". The first path is relative to the rising edge of "CLK1". The second path is relative to the falling edge of "CLK1". The third path is relative to the falling edge of "CLK2". The **-add_delay** option is used to indicate that new input delay information does not cause old information to be removed.

```
prompt> set_input_delay 2.2 -max clock CLK1 -add_delay { IN1 }

prompt> set_input_delay 1.7 -max clock CLK1 -clock_fall -add_delay { IN1 }

prompt> set_input_delay 4.3 -max clock CLK2 -clock_fall -add_delay { IN1 }
```

In the following example, two different maximum delays and two minimum delays for port "A" are specified using **-add_delay**. Since the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained (in this case, 5.0 and 1.1). If **-add_delay** is not used, the new information overwrites the old information.

```
prompt> set_input_delay 3.4 -max -clock CLK1 -add_delay { A }

prompt> set_input_delay 5.0 -max -clock CLK1 -add_delay { A }

prompt> set_input_delay 1.1 -min -clock CLK1 -add_delay { A }

prompt> set_input_delay 1.3 -min -clock CLK1 -add_delay { A }
```

set_input_transition

Sets a fixed transition time on input or inout ports.

SYNTAX

string **set_input_transition**
[-rise]
[-fall]
[-min]
[-max]
[-clock *clock_name*]
[-clock_fall]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
transition
port_list

Data Types

clock_name string
mode_list list
corner_list list
scenario_list list
transition float
port_list list

ARGUMENTS

-rise

Sets the rise transition only.

-fall

Sets the fall transition only.

-min

Sets the transition for minimum conditions.

-max

Sets the transition for maximum conditions.

-clock *clock_name*

The input transition is set relative the specified clock.

-clock_fall

Specifies that the transition is relative to the falling edge of the clock. The default is the rising edge.

-modes *mode_list*

Specifies the scenarios on which to apply the input transition values. If this option is given, all scenarios of the specified modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners *corner_list*

Specifies the scenarios on which to apply the input transition value. If this option is given, all scenarios of the specified corners and the current mode are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios *scenario_list*

Specifies the scenarios on which to apply the input transition value. The **-modes** or **-corners** option must not be specified with this option.

transition

Specifies the port transition value. This is a floating point number greater than or equal to zero.

port_list

Specifies a list of input or inout ports.

DESCRIPTION

The **set_input_transition** command specifies a fixed transition time for a list of input or inout ports. This transition time is not affected by the capacitance of the net connected to the port. The transition time calculates delays for nets and cells in the transitive fanout of the port. The port itself has no cell delay.

The transition time can be relative to a clock by using **-clock** option. This means the transition apply only those external paths driven by the clock. Using **-clock** or **-clock_fall** option can be meaningful only when timing_slew_propagation_mode is in worst_arrival mode.

Note that the worst of input transitions specified with this command are used for worst_slew mode, regardless of the clocks that are specified. If a clock-relative input transition is set on a port, these transitions will not be accessible with the **get_attribute** command until the **-clock** and **-clock_fall** options are supported for **set_input_transition** in SDC.

To display port transition or drive capability information, use the **report_ports -drive** command.

There are two other methods of describing port drive capability. The **set_driving_cell** command causes the port to have transition time calculated as if a specified library cell was driving the net. The **set_driving_cell** command also has a cell delay equal to the load-dependent portion of the delay driving the net of the library cell. The driving cell approach is accurate for nonlinear delay models, even if the capacitance is changed. Another method is to use **set_drive_resistance**, which models the driver as a linear resistance.

Input transition is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different transitions for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the specified transition is applied to the current scenario. The command issues an error if there is no current scenario.

If the **-scenarios** option is specified, the transition will be applied to all of the specified scenarios. If the **-modes** option is specified, the transition is applied to all scenarios of the specified modes. The command issues an error if none of the specified modes have any scenarios.

If the **-corners** option is specified, the transition is applied to all scenarios of the specified corners and the current mode. The command issues an error if none of the specified corners have any scenarios with the current mode.

If both the **-modes** and **-corners** options are specified, the transition is applied to all scenarios of the specified corners and the specified modes. The command issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

This example specifies that ports matching the pattern "DATA_IN*" have a transition time of 0.75 units.

```
prompt> set_input_transition 0.75 [get_ports DATA_IN*]
```

report_ports(2)
set_clock_transition(2)
set_drive_resistance(2)
set_driving_cell(2)

set_interfaces

Clean up the interfaces of bound designs.

SYNTAX

status **set_interfaces**
[-design *design*]
-force
reference

reference string or collection

ARGUMENTS

-design *design*

Specifies the design in which to clean up the interfaces. If no design is specified, the interfaces are cleaned up in the current design.

-force

Specifies to disconnect any nets connected to pins corresponding to any ports which may get deleted.

reference

Specifies the reference block for which the interface is to be cleaned. If more than one view of the reference block is bound, then the resulting ports will match that of the specified reference. Any view with a differing port interface will be unbound from the design.

DESCRIPTION

This command cleans up mismatched port interfaces in the current design (unless otherwise specified by -design). By default, the tool will attempt to cleanup all mismatched interfaces.

If "reference" is specified, the new port interface is matched to that of the specified reference. If the other views of the specified reference are also bound and have different ports, then those instances will be unbound. If any pin that will be deleted as a result of this command, is connected to a net, then "-force" must be used. Without "-force" the command will error out. When "-force" is used the ports and all corresponding pins on the instances will be first disconnected and then deleted.

EXAMPLES

The following example cleans up all mismatched instances

prompt> **set_interfaces**

The following example cleans up all mismatched instances bound to mid,

prompt> **set_interfaces design:mid.design**

SEE ALSO

link_block(2)

set_isolate_ports

Specifies the ports to be isolated from the internal fanouts of the driver nets.

SYNTAX

string **set_isolate_ports**
[-type *buffer or inverter*]
[-driver *cell_ref*]
[-force]
list *object_list*
boolean *value*

ARGUMENTS

-type

either buffer or inverter - by default a buffer is chosen.

-driver

driver libcell type for the isolation buffers. If the buffer libcell type is not available in the library, then this option will be ignored and the most optimal buffer libcells will be selected. It is possible that the buffers can be sized for better QoR. If the user does not want the buffers to be sized, then specify -force option.

-force

If a user libcell is specified with -driver,then -force ensures that the libcells arent sized.

object_list

A list of input or output port names in the current design that are to be isolated.

value

Specifies the value with which to set the attribute. Allowed values are *true* (the default) or *false*.

DESCRIPTION

The **set_isolate_ports** command specifies the input or output ports in the current design that are to be isolated. A buffer is inserted to isolate the input port from its fanout network, or between the output port and its driver.

Note that bidirectional ports cannot be isolated using this command. In addition, no isolation is performed on a port if the net connected to the port has a dont_touch attribute or if the port has been defined as a clock source or a power pin.

Use the **set_isolate_ports** command with false (see example below) or the reset_design command to remove a port from the list of ports to be isolated. Use the **report_isolate_ports** command to list the isolation status of these ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that isolation is required on the output port qout with a buffer.

prompt> **set_isolate_ports qout**

The following example removes the isolation buffer requirement constraint on the output port qout (in effect, undoing what the previous command did).

prompt> **set_isolate_ports [get_ports qout] false**

SEE ALSO

set_isolation

Defines the UPF isolation strategy for the power domains in the design.

SYNTAX

status **set_isolation**
isolation_strategy_name
-domain *power_domain*
[-isolation_power_net *isolation_power_net*]
[-isolation_ground_net *isolation_ground_net*]
[-isolation_supply *isolation_supply_set*]
[-clamp_value 0 | 1 | Z | latch]
[-isolation_signal *isolation signal*]
[-isolation_sense low | high]
[-location self | parent | fanout]
[-applies_to inputs | outputs | both]
[-applies_to_boundary upper | lower | both]
[-source *source_supply_set_name*]
[-sink *sink_supply_set_name*]
[-diff_supply_only true | false]
[-elements *objects*]
[-exclude_elements *exclude_objects*]
[-no_isolation]
[-name_prefix *prefix*]
[-name_suffix *suffix*]
[-update]

Data Types

isolation_strategy_name string
power_domain string
isolation_power_net string
isolation_ground_net string
isolation_supply_set string
isolation_signal string
source_supply_set_name string
sink_supply_set_name string
objects list
exclude_objects list
prefix string
suffix string

ARGUMENTS

isolation_strategy_name

Specifies the name of the UPF isolation strategy. The name of the isolation strategy should be unique within the specified power domain.

-domain ***power_domain***

Specifies the name of the power domain to which this UPF isolation strategy will be applied.

-isolation_power_net ***isolation_power_net***

Specifies the isolation power net that will be created for the isolation cells, based on this UPF isolation strategy.

-isolation_ground_net ***isolation_ground_net***

Specifies the isolation ground net that will be created for the isolation cells, based on this UPF isolation strategy.

-isolation_supply ***isolation_supply_set***

Specifies the supply set whose power and ground functions are to be used as the isolation power and ground nets respectively. When isolation_supply_set specified is {}, NOR/NAND-style isolation cell will be inserted based on clamp value. Currently NAND-style isolation cell is not supported. This option is mutually exclusive with the **-isolation_power_net** and **-isolation_ground_net** options.

-applies_to inputs | **outputs** | **both**

Specifies whether the given **set_isolation** command applies to all inputs or outputs or both types of ports of the power domain. The default value for this option is **outputs** without filters. The default value is **both** with any filters(-source/-sink/-diff_supply_only).

-applies_to_boundary upper | **lower** | **both**

Specifies the domain boundary that the given **set_isolation** command applies to. The default value for this option is **both** for a domain with the lower domain-boundary design attribute on, and **upper** for domains that do not have the lower domain-boundary design attribute set or have the lower domain-boundary attribute set to off.

-source ***source_supply_set_name***

Specifies the source supply set that applies to the elements of the strategy. It filters the ports and pins receiving a net that is driven by the logic that is powered by the supply set.

-sink ***sink_supply_set_name***

Specifies the sink supply set that applies to the elements of the strategy. It filters the ports and pins driving a net that fans out to the logic that is powered by the supply set.

-diff_supply_only true | **false**

Determines the isolation behavior between the driver and the receiver supply sets. If the driver is powered by the same supply set as the receiver of the port, no isolation cell is introduced into the path. The default for this options is **false**. The three options **-source**, **-sink**, **-diff_supply_only** cannot be used together at the same time.

-elements ***objects***

Specifies the objects to which this UPF isolation strategy will be applied. The objects can be pins of the root cells of the power domain or ports of the top level design for top level power domains.

-exclude_elements ***exclude_objects***

Specifies the objects to which this UPF isolation strategy won't be applied. The objects can be pins of the root cells of the power domain or ports of the top level design for top level power domains.

-clamp_value 0 | 1 | z | latch

Specifies the clamp value of the isolation cells that should be created based on this strategy. The default value of this option is 0.

-isolation_signal *isolation signal*

Specifies the isolation signal to use as the control signal of the isolation cells that should be created as a result of this isolation strategy. The *isolation_signal* can be a pin, port, or net.

-isolation_sense low | high

Specifies the isolation sense of the isolation cells that should be created as a result of this isolation strategy. The default value is high.

-location self | parent | fanout

Specifies the hierarchical location of the isolation cells that should be created as a result of this isolation strategy.

A value of self specifies that the isolation cell will be put in the hierarchy of the port being isolated. A value of parent specifies that isolation cells will be added in the parent hierarchy of the isolating port's hierarchy. A value of fanout specifies that the isolation cell will be put in the load domain.

The default value is self.

-no_isolation

Specifies that the elements that are affected by this **set_isolation** command should not be isolated.

-name_prefix *prefix*

Specifies the prefix to use for the isolation cell names.

-name_suffix *suffix*

Specifies the suffix to use for the isolation cell names.

-update

Indicates that this command adds *elements* or *exclude_elements* for a previous command with the same *strategy_name* and *domain_name* and executed in the same scope.

With the **-update** option, the command only accepts **-elements** or **-excluded_elements**, and the required option *strategy_name* and **-domain**. If specified other options with **-update**, the command will error out.

DESCRIPTION

This command defines the UPF isolation strategy for the ports of the specified power domain.

If the **-elements** and **-applies_to** options are not specified, then the isolation strategy will be applied to all output ports of the power domain.

If neither **-isolation_supply**, **-isolation_power_net** nor **-isolation_ground_net** are specified, the isolation power and ground nets are automatically set to the power and ground functions of the **default_isolation** handle of the power domain, for which the strategy is being defined.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF isolation strategy for all output ports of the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_isolation isolation_1 -domain PD1 \
 -isolation_power_net PN1 -isolation_ground_net GN1
```

The following example shows how to define a UPF isolation strategy for specific ports of the specified power domain:

```
prompt> set_isolation isolation_2 -domain PD1 \
      -isolation_power_net PN1 -isolation_ground_net GN1 \
 -elements shutdown_inst/special_port
```

The following example shows how to define a UPF isolation strategy using a supply set:

```
prompt> set_isolation isolation_2 -domain PD1 \
      -isolation_supply iso_supply_set \
 -elements shutdown_inst/special_port
```

The following example shows how a UPF isolation strategy can be defined without using a supply set or supply nets.

```
prompt> set_isolation isolation_2 -domain PD1 \
 -elements shutdown_inst/special_port
```

SEE ALSO

set_isolation_control(2)

set_isolation_control

Provides additional options needed for creating isolation cells. This command is needed with most **set_isolation** commands.

This command is deprecated in UPF 3.0. The **set_isolation** command now has all the options of the **set_isolation_control** command.

SYNTAX

status **set_isolation_control**
isolation_strategy_name
-domain *power_domain*
-isolation_signal *isolation signal*
[-isolation_sense low | high]
[-location self | parent | fanout]

Data Types

isolation_strategy_name string
power_domain string
isolation_signal string

ARGUMENTS

isolation_strategy_name

Specifies the name of a UPF isolation strategy previously created by the **set_isolation** command. The option settings apply to this strategy.

This argument is required.

-domain *power_domain*

Specifies the name of the power domain previously created by the **create_power_domain** command to which the strategy options apply.

This option is required.

-isolation_signal *isolation signal*

Specifies the name of the signal that enables and disables the isolation function of cells created by the isolation strategy. The *isolation_signal* argument can be a port, pin, or net.

This option is required.

-isolation_sense low | high

Specifies the sense of the isolation signal, either **low** or **high**, that enables the isolation function of cells created by the strategy.

The default is **high**.

-location self | **parent** | **fanout**

Specifies the hierarchical location for inserting isolation cells created by the strategy. Valid values are

- **self** (the default)
  Places the isolation cells inside the design being isolated.
- **parent**
  Places the isolation cells in the parent of the design being isolated.
- **fanout**
  Places the isolation cells at all fanout locations (sinks) of the port being isolated.

DESCRIPTION

This command specifies the isolation control signal for a specified isolation strategy, and optionally, the hierarchical location for inserting isolation cells on the domain boundary.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies the control signal, ENISO, that enables the isolation function for isolation cells inserted by the strategy named ISO1 in power domain PD1. A logic low on the signal enables the isolation function. The command also specifies that isolation cells are to be inserted in at the parent level, just outside the power domain boundary.

```
prompt> set_isolation_control ISO1 -domain PD1 \
  -isolation_signal ENISO -isolation_sense low \
  -location parent
```

SEE ALSO

create_power_domain(2)
set_isolation(2)

set_label_switch_list

Sets the value of the switch list for the specified design.

SYNTAX

status **set_label_switch_list**
[-reference *references*]
labels

Data Types

\reference list
labels list

ARGUMENTS

-reference *references*

Specifies the reference or references, for which to set the label switch list. If a references is not spscified, the label switch list applies to all references for which a specific label switch list has not been set.

labels

Sets the value for the designs's label switch list. Specify *labels* as a space-delimited list of view names, enclosed within curly brackets. Note that label switch lists are order dependent. Specifying an empty label switch list value clears the label switch list setting on the design.

DESCRIPTION

This command sets the label switch list of a design. A designs' label switch list is used during linking if block is the top design.

The label switch list is a precedence-ordered list of labels that is applied when binding a design. If the top design has its label switch list explicitly set, then that label switch list is used. If not, then the top design label is used.

When binding a reference, for which there is a label precedence swith list set, binding attempts to find the design of the preferred label. If not found, the binding default to the label of the top design.

EXAMPLES

The following example sets the label swith list for reference "bot":

prompt> **set_label_switch_list -reference {bot} {postlegal mapped}**

The following example clears the label switch list for reference "bot":

prompt> **set_label_switch_list -reference {bot} {}**

It is possible to set a label precedence order for all references, and a different one for some references:

prompt> **set_label_switch_list -reference {bot} {postlegal mapped}**

prompt> **set_label_switch_list {unmapped}**

SEE ALSO

get_label_switch_list(2)

set_latch_loop_breaker

Specifies transparent latch data pins to be used as loop breaker latch data pins.

SYNTAX

status **set_latch_loop_breaker**
-pin *pin_list*
[-remove]
[-avoid]

Data Types

pin_list list

ARGUMENTS

-pin *pin_list*

Specifies data pins of transparent latches to be loop breakers.

-remove

Removes the user-specified setting on pins.

-avoid

Avoids using the specified pins as loop breakers. Requests to avoid using specified pins as loop breaker pins cannot always be honored, especially if there is a loop from the pin through combinational logic to itself.

DESCRIPTION

When sequential loops of transparent latches exist in a design, the tool selects certain latch data pins for special analysis as loop breaker data pins.

Use the **set_latch_loop_breaker** command to guide the tool in selecting data pins as loop breaker data pins. By guiding the tool to select some latch data pins as loop breakers and not others, you can report the paths of interest.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example specifies that the L1/D pin is a loop breaker pin.

```
prompt> set_latch_loop_breaker -pin [get_pins L1/D]
```

set_latency_adjustment_options

Sets latency update directives for the **compute_clock_latency** command for the current mode.

SYNTAX

status **set_latency_adjustment_options**
[-clocks_to_update *list_of_clocks*]
[-reference_clock *clock_name*]
[-exclude_clocks *list_of_clocks*]
[-ocv_included]

Data Types

list_of_clocks list
clock_name list

ARGUMENTS

-clocks_to_update *list_of_clocks*

Specifies the clocks for which to update the propagated I/O latencies based on the propagated network latency from the clock specified in the **-reference_clock** option. The clocks can be either real clocks or virtual clocks.

-reference_clock *clock_name*

Specifies the clock from which to use the median propagated network latency to calculate the I/O latency for the clocks specified in the **-clocks_to_update** option.

-exclude_clocks *list_of_clocks*

Specifies the clocks to be excluded from the update.

-ocv_included

Specifies that the on-chip variation (OCV) for the updating clocks is already accounted for in their source latency and you do not want to apply extra OCV in the network latency.

By default, the **compute_clock_latency** command copies the network latency of the specified reference clock to the network latency of the updating clocks. If the early and late latencies of the reference clock are different because of OCV, the applied early and late latencies will also be different.

DESCRIPTION

The **set_latency_adjustment_options** command configures the I/O latency updates performed by the **compute_clock_latency** command. You can use this command to exclude clocks from latency updates or to set the reference clock for the updating clocks.

Note that the tool automatically runs the **compute_clock_latency** command as part of the integrated clock tree synthesis and optimization flows. Therefore, it is important to use the **set_latency_adjustment_options** command, even if you do not intend to call the**compute_clock_latency** command explicitly.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following examples show the typical usage.

```
prompt> set_latency_adjustment_options -reference_clock clkA -clocks_to_update {clkX clkY clkZ}
prompt> set_latency_adjustment_options -exclude_clocks  {clkM clkN clkJ}
```

SEE ALSO

clock_opt(2)
compute_clock_latency(2)

set_latency_budget_constraints

set_latency_budget_constraints

Specifies options for treatment of clocks during budgeting.

SYNTAX

int **set_latency_budget_constraints**
[-early_latency *delay*]
[-late_latency *delay*]
[-latency_offset *delay*]
[-source]
[-early_dynamic *delay*]
[-late_dynamic *delay*]
[-clock *budget_clock_spec*]
[-crp *delay*]
[-from_clock *budget_clock_spec*]
[-to_clock *budget_clock_spec*]
[-corner *corner_name* | -default]

Data Types

delay float
budget_clock_spec string
corner_name string

ARGUMENTS

-early_latency *delay*

Specifies the target early clock latency to be used during budgeting. The actual value of this latency is not particularly important. But the relative value of this latency compared to other budgeted clock latencies helps to determine the length of data paths being budgeted. Also, if early latency and late latency are different (implying OCV variance on the clock), this implies that datapath delays will be more tightly constrained. To avoid specifying this value manually, use the **-latency** option of the

compute_budget_constraints command to derive a value. By default, this option applies to all clocks. You can set a different latency in specific blocks and clocks by using the **-clock** option.

-late_latency ***delay***

Specifies the target late clock latency to be used during budgeting. The actual value of this latency is not particularly important. But the relative value of this latency compared to other budgeted clock latencies helps to determine the length of data paths being budgeted. Also, if early latency and late latency are different (implying OCV variance on the clock), this implies that datapath delays will be more tightly constrained.

To avoid specifying this value manually, use the **-latency** option of the **compute_budget_constraints** command to derive a value. By default, this option applies to all clocks. You can set a different latency in specific blocks and clocks by using the **-clock** option.

-latency_offset ***delay***

Specifies that the selected clock should have a different latency from other clocks. For example, setting a latency offset of 1 declares the intent that the clock should be 1ns behind other clocks in the design. Setting a latency offset of -1 declares the intent that the clock should be 1ns ahead of other clocks in the design. Specifying the latency offset is important when you are using the **-balance** option of the **compute_budget_constraints** command. By default, the **-balance** option assumes that all clocks in the design should be exactly balanced to the same latency. Setting latency offset will adjust the balance. You must specify **-clock** with this option.

-clock ***budget_clock_spec***

Applies **-early_latency**, **-late_latency**, or **-latency_offset** to only specific clocks or subtrees of a clock. If the latency is applied to a subtree of a clock, the latency value refers to the latency from the clock source, through the subtree, to the flip-flops. See the "Budget clock specs" section for details on how to select specific clocks.

-crp ***delay***

Sets clock reconvergence pessimism (CRP) in a budgeted timing path. When you have a delay variation (called OCV) in the latency of your clock paths, the early clock latency and late clock latency combine to make your budget paths shorter than they would otherwise be. In some cases, your long and short clock paths share a common set of gates, which causes OCV estimation to be pessimistic. The CRP value is used to offset the pessimism by making your budget paths longer. You must specify **-from_clock** and **-to_clock** with this option.

-source

Use this option along with the **-early_latency** and **-late_latency** options to specify source latency adjustments during the **split_constraints** command. Please refer to the section "Splitting Clock Latencies" below for more details.

-early_dynamic ***delay***

Use this option along with the **-early_latency** and **-source** options. The number specified here will be directly translated to the **-dynamic** option of **set_clock_latency** in the output SDC of the **split_constraints** command. Please refer to the section "Splitting Clock Latencies" below for more details.

-late_dynamic ***delay***

Use this option along with the **-late_latency** and **-source** options. The number specified here will be directly translated to the **-dynamic** option of **set_clock_latency** in the output SDC of the **split_constraints** command. Please refer to the section "Splitting Clock Latencies" below for more details.

-from_clock ***budget_clock_spec***

Applies **-crp** only to paths starting at particular clocks or subtrees of a clock. See the "Budget clock specs" section for details on how to select specific clocks.

-to_clock ***budget_clock_spec***

Applies **-crp** only to paths ending at particular clocks or subtrees of a clock. See the "Budget clock specs" section for details on how to select specific clocks.

-corner ***corner_name***

Specifies that values given for the other options should be applied in the process corner with the specified name.

-default

Specifies that values given for the other options should be applied in process corners do not have specific values given with the **-corner** option.

DESCRIPTION

Specifies options for treatment of clocks during budgeting. These options include the clock latency, OCV variance, CRP, and latency offset. See the option description for more details. By default, budgeting assumes that all of your clocks are aligned and have no OCV. You can change this assumption by using this command. Or you can use **compute_budget_constraints -latency_targets** to generate values automatically. You should set up these parameters before budgeting pins along your datapath, because they have an effect on allowable path delay.

You must supply either **-corner** or **-default** to this command.

Use the **set_budget_options** command to specify general options to be used during creation of timing budgets. To set other specific budget parameters, use the **set_pin_budget_constraints**, and **set_boundary_budget_constraints** commands.

Use the **write_budgets** command to generate SDC that can be applied to lower-level blocks. **compute_budget_constraints** can be used to set key budget parameters automatically. The **report_budget** command generates useful information about the current budget calculation, allocation, and whether that budget is currently being met. Use **write_script -include budget** to save a Tcl script that includes your current settings from this command.

This command returns 1 on success, 0 otherwise.

Budget clock specs

When specifying clocks for various budgeting options, you can provide extra information to limit the parameter to a specific subtree of the clock or edge of a clock. For example, you can set a parameter for the subtree of CLK1 which is inside of BLOCK1. And you can set a different parameter for the subtree of CLK1 which is inside of BLOCK2. In general, every time a clock tree passes into or out of a block, this will define a new part to the tree that you can control.

The syntax for specifying a budget_clock_spec is as follows. To specify all parts of a clock (in all blocks), use the clock name:

CLK1

To specify all clocks in all blocks, use "*":

*****

To specify the part of a clock in a selected block, append ":" and the name of the block instance:

CLK1:my_block

To specify all clocks in a selected block, use "*" followed by ":" and the name of the block instance:

***:my_block**

To specify the part of a clock that crosses into or out of a block at a particular block pin, use the clock name, followed by ":" and the name of the block pin. For example, use the following to specify the top-level portion of CLK1 that originates at the clock

output of my_block:

CLK1:my_block/CLKOUT

To specify a particular edge of a clock, use a second ":" followed by the word "rise" or "fall". This can be used in combination with any of the specifications above that name a particular clock. For example:

CLK1::rise
CLK1:my_block:fall
CLK1:my_block/CLKOUT:rise

Sometimes it is convenient to specify constraints for a master clock and all of the generated clocks downstream from the master clock. We refer to this as a constraint "clock group". To specify a clock group, follow the name of the master clock by a plus (+) character. The specify clock must a be regular clock, not a generated clock. The downstream generated clocks will be implicitly included in the group. Here are the legal usages of clock groups:

CLK1+
CLK1+::rise
CLK1+::fall

If this command is called multiple times for the same clock, the more specific parameter is applied. For example, if you set a parameter for "CLK:my_block" and you set a parameter for "CLK", the parameter for "CLK:my_block" will be used inside my_block and the parameter for "CLK" will be used everywhere else. More general parameters will not overwrite more specific ones.

Splitting Clock Latencies

By default, the **split_constraints** command does not attempt to apportion clock latencies across blocks. Clock latencies are pushed from the chip level down to each block, without change. For example, if the source clock latency of clock CLK1 is 2 at the top level, the source clock latency will still be 2 at the port boundary in the split constraints for each block.

You can use the **plan.budget.split_latencies** app option to cause the **split_constraints** command to reapportion and/or redefine clock latencies at block boundaries. This way you can adjust both the source latency and network latency seen during the synthesis of individual blocks.

Use the **-early_latency**, **-late_latency**, **-source**, **-early_dynamic**, and **-late_dynamic** options of **set_latency_budget_constraints** to control how latencies will be split. latencies should be assigned.

Please refer to the man page of plan.budget.split_latencies for more details.

Multicorner-Multimode Support

EXAMPLES

The following example sets a latency offset for clock CLK in block core/mmu:

```
prompt> set_latency_budget_constraints -latency_offset 0.2 \
    -clock CLK:core/mmu -default
```

The following example sets latency targets for the portion of clock CLK whose source in block core/cpu is "clockin". Note that this pin is the source in this block, not necessarily the global source.

```
prompt> set_latency_budget_constraints -early_latency 3.8 -late_latency 4.2 \
    -clock CLK:core/cpu/clockin -corner C1
```

Same as the last example, but only applies to the rising edge of the clock.

```
prompt> set_latency_budget_constraints -early_latency 3.8 -late_latency 4.2 \
    -clock CLK:core/cpu/clockin:rise -corner C1
```

The following example sets CRP on paths from and to specific clock subtrees in specific blocks.

```
prompt> set_latency_budget_constraints -crp 0.2 -corner C2 \
    -from_clock CLK:core/cpu \
    -to_clock CLK:core/mmu
```

The following example selects values for splitting clock latencies to be used by split_constraints.

```
prompt> set_latency_budget_constraints -clock CLK1 \
        -early_latency 0.50 -late_latency 0.60 -default
prompt> set_latency_budget_constraints -clock CLK1:B1 -source \
        -early_latency 0.42 -late_latency 0.50 -default
prompt> set_app_options -name plan.budget.split_latencies -value prects
prompt> split_constraints
```

set_layer_map_file

Saves a layer mapping file into a library.

SYNTAX

status **set_layer_map_file**
-format gds | starrc
[-library *library_name*]
-map_file *layer_map_file*

Data Types

library_name string
layer_map_file string

ARGUMENTS

-format gds | **starrc**

Specifies the format of the layer mapping file, either **gds** for GDSII or **starrc** for StarRC.

-library ***library_name***

Specifies the name of the library in which to store the layer mapping file. If not specified, it uses the current open library. This option is available only an implementation tool. The library manager (lm_shell) always saves the file in the current open library.

-map_file ***layer_map_file***

Specifies the name of the layer mapping file to save into the library.

DESCRIPTION

This command saves a layer mapping file into a library. In that case, the saved file is used as the default layer mapping file when you perform layout validation with the IC Validator tool or parasitic extraction with the StarRC tool.

EXAMPLES

The following example saves a GDS layer mapping file named gds.map into the library named testLib:

```
prompt> set_layer_map_file \
    -format gds \
    -library testLib \
    -map_file gds.map
```

SEE ALSO

set_legalizer_preroute_keepout

This command specifies the keepout margin that is applied to prerouted net shapes during legalization and check_legality. The keepouts may optionally be set to impact only a collection of library pins or instance pins. The keepouts are not persistent in NDM.

SYNTAX

status **set_legalizer_preroute_keepout**
-layer *metal layer name*
-type *prerouted net shape type [strap | via]*
-keepout *keepout {x_keepout y_keepout}*
[-lib_pins] *library pins*
[-pins] *instance pins*

Data Types

layer_name string
type string
keepout pair_of_double
lib_pins collection
pins collection

ARGUMENTS

-layer *layer_name*

Specifies the metal routing layer name, as defined in the technology file

-type *type*

Specifies the type of prerouted net shape the keepout is to be applied. Allowed keywords are "strap" and "via".

-keepout *keepout {x_keepout y_keepout}*

Specifies the keepout values in X and Y directions independently. The keepout values are specified in user units.

-lib_pins *library pins*

Specifies the collection of library pins that are impacted by the set keepout. Optional option. Mutually exclusive with "-pins" option.

-pins *instance pins*

Specifies the collection of instance pins that are impacted by the set keepout. Optional option. Mutually exclusive with "-lib_pins" option.

DESCRIPTION

This command specifies the keepout margin that is applied to prerouted net shapes during all legalization instantiations, including legalize_placement, check_legality, as well as during meta_commands, such as place_opt, clock_opt, etc.

EXAMPLES

The following examples show how to specify keepout on M2 straps (first) and M3 vias (second).

prompt> **set_legalizer_preroute_keepout -layer M2 -type strap -keepout {0.1 0.05}**

prompt> **set_legalizer_preroute_keepout -layer M2 -type via -keepout {0.05 0.08}**

The following examples show how to specify keepout on M2 straps for lib_pins (first) or pins (second).

prompt> **set_legalizer_preroute_keepout -layer M2 -type strap -keepout {0.1 0.05} -lib_pins [get_lib_pins */AND*/Z]**

prompt> **set_legalizer_preroute_keepout -layer M2 -type strap -keepout {0.1 0.05} -lib_pins [get_pins core/*/Z]**

SEE ALSO

legalize_placement(2)
check_legality(2)

set_level_shifter

Sets a strategy for level shifting during implementation.

SYNTAX

status **set_level_shifter**
level_shifter_name
-domain *domain_name*
[-elements *list*]
[-exclude_elements *exclude_objects*]
[-applies_to inputs | outputs | both]
[-source *source_supply_set_name*]
[-applies_to_boundary upper | lower | both]
[-sink *sink_supply_set_name*]
[-threshold *value*]
[-rule low_to_high | high_to_low | both]
[-location self | parent | automatic]
[-input_supply input_supply_set_name]
[-output_supply output_supply_set_name]
[-no_shift] [-force_shift]
[-name_prefix *prefix*]
[-name_suffix *suffix*]
[-update]

Data Types

level_shifter_name string
domain_name string
list list
exclude_objects list
source_supply_set_name string
sink_supply_set_name string
input_supply_set_name string
output_supply_set_name string
value float
prefix string
suffix string

ARGUMENTS

level_shifter_name

Specifies the level shifter strategy name, which is used only for reporting. This argument is required.

-domain *domain_name*

Specifies the domain for which the strategy is applied. This argument is required.

-elements *list*

Specifies a list of design elements, pins, or ports to which this strategy is applied.

-exclude_elements *exclude_objects*

Specifies the objects to which this strategy won't be applied. The objects can be pins of the root cells of the power domain or ports of the top level design for top level power domains.

-applies_to inputs | outputs | both

Specifies whether the given **set_level_shifter** command applies to all inputs or outputs or both types of ports of the power domain. The default value for this option is **both**.

Use following app option to turn off the default applies_to as always both:

>set_app_options -as_user_default -list {mv.upf.ls_default_applies_to_both false}

The default will follow following rule:

1. BOTH : if specified with any filter (-source/-sink/-diff_supply_only), -element, -exclude_elements.

2. OUTPUT : otherwise.

-applies_to_boundary upper | lower | both

Specifies the domain boundary that the given **set_level_shifter** command applies to. The default value for this option is **both** for a domain with the lower domain-boundary design attribute on, and **upper** for domains that do not have the lower domain-boundary design attribute set or have the lower domain-boundary attribute set to off.

-source *source_supply_set_name*

Specifies the source supply set that applies to the elements of the strategy. It filters the ports and pins receiving a net that is driven by the logic that is powered by the supply set.

-sink *sink_supply_set_name*

Specifies the sink supply set that applies to the elements of the strategy. It filters the ports and pins driving a net that fans out to the logic that is powered by the supply set.

-threshold *value*

Specifies the voltage threshold (in volts) for determining when level shifters are required. The default is 0.

-rule low_to_high | high_to_low | both

Specifies which type of level shifters are required. The default is both.

-location self | parent | automatic

Specifies where the level shifter is placed in the logic hierarchy. The default is automatic.

-input_supply *input_supply_set_name*

Specifies the input supply set that applies to the elements of the strategy. Level shifter cell inserted base on this strategy should connect the input supply with the specified supply.

-output_supply *output_supply_set_name*

Specifies the output supply set that applies to the elements of the strategy. Level shifter cell inserted base on this strategy should connect the output supply with the specified supply.

-no_shift

Prevents the insertion of level shifters on the specified ports, pins, and nets when used with the **-elements** option.

The **-no_shift** and **-force_shift** options are mutually exclusive; you must use only one.

-force_shift

Unconditional insertion of a level shifter on the specified elements.

The **-no_shift** and **-force_shift** options are mutually exclusive; you must use only one.

When **-force_shift** is specified with **-threshold**, the **-threshold** is dropped.

-name_prefix *prefix*

Specifies the prefix to use for the level-shifter cell names.

-name_suffix *suffix*

Specifies the suffix to use for the level-shifter cell names.

-update

Indicates that this command adds *elements* or *exclude_elements* for a previous command with the same *strategy_name* and *domain_name* and executed in the same scope.

With the **-update** option, the command only accepts **-elements** or **-excluded_elements**, and the required options of *strategy_name* and **-domain**. If other options are specified with **-update**, the command will error out.

DESCRIPTION

The **set_level_shifter** command is used to set a strategy for level shifting during implementation. Level shifters are placed on the signals that have sources and sinks operating at different voltages, as their associated design elements are connected to different supply nets. If a level shifter strategy is not specified on a power domain, the default level shifter strategy consists of all elements in the power domain, and uses the default strategy settings. Power state table (PST) and operating conditions are considered to determine if level shifters are needed for design elements on the boundaries of power domains. If **-elements** *list* is specified, the elements must be in the domain specified by **-domain** *domain_name*. The **-threshold** option defines how large the voltage difference between the driver and the sink needs to be before level shifters are inserted. Normally, this threshold value is determined from the cell libraries. Use the **-threshold** option to override the library values. The **-rule** value can be low_to_high, high_to_low, or both.

- If low_to_high is specified, signals going from a lower voltage to a higher voltage get a level shifter when the voltage difference exceeds that specified by **-threshold**.
- If high_to_low is specified, signals going from a higher voltage to a lower voltage get a level shifter when the voltage difference exceeds that specified by **-threshold**.
- If both is specified, it is equivalent to having specified both rules in the strategy.

The **-location** option defines where the level shifter cells are placed in the logic hierarchy. All necessary supplies need to be available in the specified location. The option values are as follows:

- If -input/-output_supply is(are) specified, the level shifter cell inserted base on this strategy must have the input/output

power/ground supplies connected with the coresponding supply(ies). If the specified supply(ies) is(are) not available in the candidate domain of the level shifter suppposed to be inserted, the insertion will not happen. User needs to make the supply(ies) to be used available explicitely. If the -input/-output_supply specified will cause new violations, no level shifter will be inserted if the new violation cannot be fixed.

- self specifies that the level shifter cell is placed inside the model or cell being shifted.
- parent specifies that the level shifter cell is placed in the parent of the cell or model being shifted.
- automatic specifies that the implementation tool chooses the appropriate locations.

Level shifter insertion is normally conditional, and level-shifters will not always be inserted even when a strategy is present. With the -force_shift option, level-insertion becomes mandatory. In the following situations, level shifters will be inserted only if the -force_shift option is used:

- Cases where there is no voltage violation. This can mean the driver and loads of the net operate at the same voltage, or the voltage difference between them is less than that specified by the **-threshold** option.
- Cases where there is no real driver or load. If no real driver or load for the net can be found, then the domain primary supply will be used to force level shifter insertion. If no supplies are available, a level shifter will not be inserted.
- Cases where the driver is logic-zero. With **-force_shift**, a level shifter will be inserted with the domain primary as the driver supply.

The **-update** option adds design elements to the -elements and -exclude_elements of an existing level shifter strategy, as if they had been specified with the original command. Adding design elements to the -elements list is allowed only if the first **set_level_shifter** command which defined the strategy also included the **-elements** option. In other words, a domain-based strategy cannot be changed to an elements-based strategy. The level-shifter name, strategy name, domain name, and at least one of the **-elements** or **-exclude_elements** options are required when specifying the **-update** option. No other option is allowed.

Note that this command does not apply to inout ports. Also, it is an error if the specified location is not within the logic design starting at the design root.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the level shifter strategy on PowerDomainZ:

```
prompt> set_level_shifter shift_up -domain PowerDomainZ -applies_to outputs \
    -threshold 0.02 -rule both
```

SEE ALSO

add_port_state(2)
add_pst_state(2)
create_pst(2)
report_pst(2)

set_lib_cell_purpose

Specifies valid purposes for library cells.

SYNTAX

status **set_lib_cell_purpose**
[-include *include_list*]
[-exclude *exclude_list*]
[-reset]
lib_cell_list

Data Types

include_list list
exclude_list list
lib_cell_list collection

ARGUMENTS

-include *include_list*

Specifies the purposes for which the library cells specified in the *lib_cell_list* argument can be used. Valid values are

- **cts** for clock tree synthesis
- **optimization** for delay and electrical design rule optimization
- **hold** for hold fixing
- **power** for power optimization
- **all** for no restrictions on inserting the specified cells
- **none** to prevent insertion of the specified cells for any purpose

This option is mutually exclusive with the **-exclude** option; you must specify one of these options.

-exclude *exclude_list*

Specifies the purposes for which the library cells specified in the *lib_cell_list* argument cannot be used. Valid values are

- **cts** for clock tree synthesis
- **optimization** for delay and electrical design rule optimization
- **hold** for hold fixing

- **power** for power optimization

This option is mutually exclusive with the **-include** option; you must specify one of these options.

-reset

Resets the purposes of the specified library cells. In the library manager (lm_shell), this sets their purposes to all. In an implementation tool, this removes their design-specific purpose overrides from the current block.

This option is mutually exclusive with the **-include** and **-exclude** options.

lib_cell_list

Specifies the affected library cells. The specified library cells must be in a library already loaded into the tool.

Library cell names must contain a library prefix. If more than one object is included, they must be enclosed in quotes or braces ({}).

DESCRIPTION

Defines the valid purposes for the specified library cells.

To remove the purpose information set by this command, use the **set_lib_cell_purpose -include all $lib_cell** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the G1 and G2 library cells in the tech_lib library should never be inserted by the tool:

prompt> **set_lib_cell_purpose -include none {tech_lib/G1 tech_lib/G2}**

The following command specifies that the library cells in the tech_lib library whose names start with "buf" should not be used for clock tree synthesis:

prompt> **set_lib_cell_purpose -exclude cts {tech_lib/buf*}**

The following command specifies that the delaybuf library cell in the tech_lib library should be used only for hold fixing:

prompt> **set_lib_cell_purpose -include hold {tech_lib/delaybuf}**

SEE ALSO

get_attribute(2)
report_lib(2)

set_libcell_subset

Sets the library cell subset for sequential cells or instantiated combinational cells to be used for optimization

SYNTAX

status **set_libcell_subset**
-object_list *cells*
-family_name *name*

Data Types

cells list
name string

ARGUMENTS

-object_list *cells*

Specifies a list of sequential cells or instantiated combinational cells for which the specified library cell family is used during optimization. The cells must be either unmapped or instantiated to one of the library cells in the specified library cell family.

-family_name *name*

Specifies the library cell family to be used for optimization of these cells. A family is a subset of library cells and is defined by the **define_libcell_subset** command.

DESCRIPTION

The **set_libcell_subset** command specifies a family of library cells that are available for use during the optimization of the specified instances. A family is defined by the **define_libcell_subset** command.

To remove the library cell family from an instance, use the **remove_libcell_subset** command.

EXAMPLES

The following example sets the library cell subset for the u1 and u2 instances to special_flops, which consists of lib1/SDFLOP1 and lib1/SDFLOP2.

```
prompt> define_libcell_subset \
  -libcell_list [get_lib_cells lib1/SDFLOP1 lib1/SDFLOP2] \
  -family_name special_flops
prompt> set_libcell_subset \
  -object_list [get_cells u1 u2] \
  -family_name special_flops
```

SEE ALSO

remove_libcell_subset(2)
report_libcell_subset(2)
set_libcell_subset(2)
define_libcell_subset(2)

set_load

Sets the capacitance to a specified value on the specified ports in the current design.

SYNTAX

Boolean **set_load**
[-min]
[-max]
[-rise]
[-fall]
[-subtract_pin_load]
[-pin_load]
[-wire_load]
value
objects

value float
objects list

ARGUMENTS

-min

Indicates that the *capacitance* is the minimum capacitance. Applies only to designs in min-max mode (minimum and maximum operating conditions).

-max

Indicates that the *capacitance* is the maximum capacitance. Applies only to designs in min-max mode (minimum and maximum operating conditions).

-rise

Indicates that the *capacitance* is the rise capacitance. This option can be used in combination with **-min** or **-max**. Use this option only with ports. An error message is generated if the *objects* list contains nets.

-fall

Indicates that the *capacitance* is the fall capacitance. This option can be used in combination with **-min** or **-max**. Use this option only with ports. An error message is generated if the *objects* list contains nets.

-subtract_pin_load

This option exists for backwards compatibility, but is ignored.

-pin_load

Indicates that the specified *capacitance* is a pin capacitance. Pin capacitance is not subject to "scaling" using tree_type. Use this option only with ports. An error message is generated if the *objects* list contains nets.

If you do not specify either the **-pin_load** or the **-wire_load** option, or both, **-pin_load** is the default.

-wire_load

Indicates that the specified *capacitance* is a wire capacitance. Pin capacitance is subject to "scaling" using tree_type. Use this option only with ports. An error message is generated if the *objects* list contains nets.

If you do not specify either the **-pin_load** or the **-wire_load** option, or both, **-pin_load** is the default.

value

Specifies the capacitance value to be set on the ports in *objects*. It is in the units of the technology library.

objects

Specifies a list of ports in the current design, on which the *capacitance* is to be set. For backwards compatibility, net objects are accepted, but they are ignored, and a warning message is generated.

DESCRIPTION

This command sets the capacitance to a specified value on specified ports in the current design. If the current design is hierarchical, you must link it using the **link** command. Depending on the options used, **set_load** sets these attributes on the specified objects:

pin_capacitance_max
pin_capacitance_min

If this command is issued without any options, the **pin_capacitance_max** attribute is set; in min-max mode, the **pin_capacitance_min** attribute is also set.

For ports, if **set_load** is issued with only the **-wire_load** option, then the **wire_capacitance_max** attribute is set on the specified ports; in min-max mode, the **wire_capacitance_min** attribute is also set. However, the value is actually counted as part of the total wire capacitance and not as part of the pin/port capacitance.

In min-max mode, using either the **-min** or **-max** option sets only the ***_min** or ***_max** attributes, respectively.

If **-rise** is specifed, the **pin_capacitance_max_rise** and **pin_capacitance_min_rise** attributes are set. You can use this option in conjunction with **-min** or **-max** to set only one of the two attributes. The same conditions apply for the **-fall** option and the **pin_capacitance_*_fall** attributes.

To view capacitance values on ports, use the **report_port** command. To remove a capacitance value, set it to zero. You can remove annotated capacitances from the full design by using the **reset_design** command.

Multicorner-Multimode Support

This command works only on the current corner.

EXAMPLES

The following example sets a capacitance of *2* units on the port named *the_answer*.

prompt> **set_load 2 the_answer**

The following example sets a wire capacitance of *5* units on the port named *the_answer*.

prompt> **set_load -wire_load 5 the_answer**

set_locked_objects

Sets the specified objects to the locked state. The command sets the value of **physical_status** attribute to either **locked** or **unrestricted**;

SYNTAX

status **set_locked_objects**
[-unlock]
[*object_list*]

Data Types

object_list collection

ARGUMENTS

-unlock

Unlocks the specified objects.

object_list

Specifies the collection or selection set of objects for which to change locked status. If this option is not specified, the global selection set is used.

DESCRIPTION

This command sets the locked status for the specified objects. If no objects are specified, the global selection set is used.

EXAMPLES

The following example locks all selected objects.

```
prompt> set_locked_objects
1
```

The alternative syntax uses collection to specify objects.

```
prompt> set_locked_objects [get_selection]
1
```

The following example locks all hard macros.

```
prompt> set_locked_objects [get_cells -physical_context -filter "is_hard_macro && !is_physical_only"]
1
```

SEE ALSO

set_fixed_objects(2)
change_selection(2)
get_selection(2)

set_logicbist_configuration

set_logicbist_configuration

Specifies the LogicBIST compression configuration for the design.

SYNTAX

status **set_logicbist_configuration**
[-chain_count *chain_count*
| -max_length *max_chain_length*]
[-clock *clock_name*]
[-xtolerance high | extended | low]
[-pattern_counter_width *register_width*]
[-shift_counter_width *register_width*]
[-prpg_width *register_width*]
[-misr_width *register_width*]
[-occ_clock_weights *weight_list*]
[-test_mode *logicbist_mode_name*]

Data Types

chain_count integer
max_chain_length integer
clock_name string
register_width integer
weight_list list
base_mode_name string
logicbist_mode_name string

ARGUMENTS

-chain_count *chain_count*

Specifies the number of scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-max_length ***max_chain_length***

Specifies the maximum allowed length of the compressed scan chains. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-xtolerance high | **extended** | **low**

Specifies whether to enable XLBIST or Extended Xtol capability. This option is mandatory, and **low** would be supported in future.

-clock ***clock_name***

Specifies the scan clock to be used for the LogicBIST codec (compressor and decompressor) to be inserted. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. By default, the tool selects the first-defined scan clock.

-pattern_counter_width ***register_width***

Specifies the width of the pattern counter register. The maximum number of patterns is determined by the width of this register as follows:

max_patterns == (2 ^ pattern_counter_register_width) - 2

The default is 8, which allows a maximum of 254 patterns.

-shift_counter_width ***register_width***

Specifies the width of the shift counter register, which counts down the shift cycles for each pattern.

By default, the tool sizes this register according to the longest shift chain in the design. You normally do not need to specify this value.

-prpg_width ***register_width***

Specifies the width of the pseudo-random pattern generator (PRPG) register. This register generates pattern data that feeds the compressed scan chains through an XOR phase shifter. The PRPG seed value is also this width.

By default, the tool sizes this register using a heuristic based on the number of compressed scan chains.

-misr_width ***register_width***

Specifies the width of the multiple-input signature register (MISR). This register captures data from the compressed scan chains through an XOR compactor. The final MISR signature value is also this width.

If this register width is set to the same value as the number of compressed scan chains, the tool does not implement an XOR compactor.

By default, the tool sizes register this using a heuristic based on the number of compressed scan chains.

-occ_clock_weights ***weight_list***

Specifies a list of clock signal groups and their weights.

By default, all OCC clocks capture in each pattern. If asynchronous cross-clock paths exist, you can use this option to group clocks into capturing groups. Each capture group has a weight value that specifies its probability of capture relative to the other groups.

Each group is itself a list containing an integer weight value followed by one or more clock signals:

-occ_clock_weights {{75 SYSCLK} {25 CLK33 CLK66}}

-test_mode ***logicbist_mode_name***

Specifies the LogicBIST test mode to which the specification applies. The default is *all_dft*, except when **define_test_mode** is

used. In this case, the default is the value of the last *test_mode* defined.

Note that this is the test mode used by TetraMAX for seed/signature computation; it is not the test mode used for autonomous self-test operation.

DESCRIPTION

The **set_logicbist_configuration** command allows you to specify certain LogicBIST insertion parameters prior to using the **insert_dft** command. The parameters include specifications such as compressed scan chain count, pattern count register width, and MISR and PRPG register widths.

There are two related options to control the number of compressed scan chains for LogicBIST insertion, **-chain_count** and **-max_length**. You must specify one of these options to configure LogicBIST compression. If both are specified, the **-max_length** option takes precedence over the **-chain_count** option.

SEE ALSO

define_test_mode(2)
insert_dft(2)
preview_dft(2)

set_macro_constraints

Sets constraints on hard macro or I/Os cells.

SYNTAX

status **set_macro_constraints**
[-allowed_orientations *orientation_list*]
[-preferred_location *relative_location*]
[-alignment_grid *grid_name*]
[-alignment_point *align_point*]
[-align_pins_to_tracks]
[-alignment_orientation_set all | R0 | R90]
hard_macro_or_IO_list

Data Types

orientation_list	list of orientations in DEF syntax
relative_location	pair of relative ordinates in interval [0, 1]
grid_name	grid name
align_point	point in the macro master coordinates
hard_macro_or_IO_list	list of hard macros or I/Os

ARGUMENTS

-allowed_orientations *orientation_list*

Specifies one or more allowed placement orientations for the specified list of cells. The list of orientation values can contain one or more of the following values: R0, R90, R180, R270, MX, MXR90, MY, MYR90. The behavior is different between hard macros and I/Os. For hard macros, the list of legal orientations defined in the library takes precedence over this option, and the list of orientations specified here further restricts the legal placement orientations. For I/Os, the setting made here overrides the legal orientations setting in the library. This option is optional.

-preferred_location *location_list*

Specifies the preferred location that is applied to the given list of hard macros. The location is specified in the coordinate system relative to the encompassing block, where coordinate (0, 0) is mapped to the lower-left corner of the block's bounding box, while (1, 1) is mapped to the upper right corner of the block's bounding box. This option is optional,

-alignment_grid *grid_name*

Specifies the name of the grid to align macros to. This option is optional and is mutually exclusive with the **-align_pins_to_tracks** option. If **-align_pins_to_tracks** has been previously specified for the same macro and orientation, specifying an alignment grid removes the **-align_pins_to_tracks** setting.

-alignment_point *align_point*

Specifies the point, in the macro master coordinates, that must be on grid. The default is the origin. This option requires the **-alignment_grid** option.

-align_pins_to_tracks

If this option is specified, the command aligns signal pins to the grid derived based on the tracks on the layers that the pin shape belongs to. If there is track color (mask) and pin color information, the color-matching rules will be enforced. This option is optional and is mutually exclusive with the **-alignment_grid** and **-alignment_point** options. If an alignment grid has been specified previously for the same macro and orientation, specifying this option removes the grid specification.

-alignment_orientation_set all | **R0** | **R90**

Specifies the set of macro orientations with the same footprint that the grid applies to, either R0 = {R0, R180, MX, MY} or R90 = {R90, R270, MXR90, MYR90}. Each set is denoted by its canonical representative, R0 or R90. This option is optional. The default is all. Requires one of **-alignment_grid** and **-align_pins_to_tracks**.

hard_macro_list

Specifies the list of hard macros for which to create constraints. This list of hard macros is required.

DESCRIPTION

This command is used to set placement constraints on hard macros or I/Os. These constraints are respected by the **create_placement -floorplan** command.

EXAMPLES

The following example sets two possible orientations for the specified cell.

```
prompt> set_macro_constraints -allowed_orientations {R0 R180} [get_selection]
1
```

The following example sets the preferred location for the selected macro to the center bottom of the encompassing block it belongs to.

```
prompt> set_macro_constraints -preferred_location {0.5 0} [get_selection]
1
```

SEE ALSO

create_placement(2)
derive_preferred_macro_locations(2)
report_macro_constraints(2)
remove_macro_constraints(2)

set_macro_relative_location

Specifies a constraint to place a hard macro or macro array relative to an anchor object.

SYNTAX

status **set_macro_relative_location**
-target_object *target_object*
-target_orientation *target_orientation*
-target_corner bl | br | tl | tr
[-anchor_object *anchor_objecf*]
-anchor_corner bl | br | tl | tr
-offset *xy_distance* | *xy_factor* | {*x_distance*
y_distance} | {*x_factor* | *y_factor*}
[-offset_type { fixed|scalable fixed|scalable }]
[-used_length *xy_distance* | {*x_distance y_distance*}]
[-scale_edge *xy_edge* | {*x_edge y_edge*}]

Data Types

target_object hard macro, macro array edit group
target_orientation orientation in DEF syntax
anchor_object IO pad cell, hard macro, block, port, pin, macro
array edit group, move bound, voltage area, voltage area shape, core area
x_distance float
y_distance float
xy_distance float
x_factor float
y_factor float
xy_factor float
x_edge unsigned integer
y_edge unsigned integer
xy_edge unsigned integer

ARGUMENTS

-target_object *target_object*

Specifies the required hard macro or macro array edit group for which to create macro relative location constraint. The target object should not be fixed.

-target_orientation *target_orientation*

Specifies the allowed placement orientation for the hard macro cell. The orientation value can contain one of the following values: R0, R90, R180, R270, MX, MXR90, MY, MYR90. The orientation specified here further restricts the legal placement

orientation, and should not be conflict with the list of legal orientations defined in the library or set by command **set_macro_options**. For macro array, the target orientation is always R0.

-target_corner bl | tl | tr | br

Specifies which corner of the target macro or macro array to apply the constraint. Valid target corner values are: bl, tl, tr, br. These four keywords represent bottom-left, top-left, top-right, bottom-right respectively.

-anchor_object *anchor_object*

Specifies the anchor object for which to create macro relative location constraint on target hard macro or macro array. The anchor object can be IO pad cell, hard macro, block, port, pin, macro array edit group, move bound, voltage area or voltage area shape, core area and should be in the same design with target hard macro or macro array. By default the anchor object is the target object's current parent block.

-anchor_corner bl | tl | tr | br | 1 | 2 | 3 | 4 | 5 | ...

Specifies which corner of the boundary bbox for rectangle anchor object or which corner for rectilinear anchor block to apply the constraint. Valid anchor corner values are: bl, tl, tr, br for rectangle or 1, 2, 3, 4, 5... for each corner of a shape. A rectilinear corner number is a positive integer that starts at one, and increments by one as you proceed around each edge in the shape clockwise. Given any rectilinear shape, the bottom corner of the lowest left-most edge is the starting corner (corner number 1). You cannot specify a value of 0 for this option. The keywords bl, tl, tr, br represent bottom-left, top-left, top-right, bottom-right respectively. The boundary bbox is used for macro and block, and bounding box for other anchor objects.

-offset *xy_distance* | *xy_factor* | {*x_distance*

y_distance} | {*x_factor* | *y_factor*}" Specifies the distance from the target corner to the anchor corner in X and Y dimension or a factor controlled by -offset_type option. The distance value can be positive, negative or zero. A positive value would indicate the target corner being on the right/top side of the anchor corner, and a negative value would result in the target corner being on the left/bottom side of the anchor corner, while a value of zero would mean the target corner has the same coordinate as the anchor corner. If option -offset_type is set "scalable" then this option value is a factor, the actual_offset = factor * (scale_edge_length - used_length_as_specified _in_set_macro_relative_location). The calculation may have some precision loss.

-offset_type { fixed|scalable fixed|scalable }

Specifies whether the value set in option -offset is the distance from the target corner to the anchor corner in X and Y dimension or a factor. Default is fixed type.

-used_length *xy_distance* | {*x_distance y_distance*}

Specifies the macro occupied distance in X and Y dimension according to the scale_edge of block/core_area/movebound/voltage_area_shape.

-scale_edge *xy_edge* | {*x_edge y_edge*}

Specifies scale edge number in X and Y dimension. The scale edge number should be 1, 2, 3... for each edge. A edge number is a positive integer that starts at 1, and increments by one as you proceed around each edge in the shape clockwise. Given any rectilinear shape, the lower leftmost vertical edge is the starting edge (edge number 1). Scale_edge is for the scalable offset. When offset_type is scalable, the actual offset value in terms of microns will be calculated at the time of macro placement, using the length of the parent_block/core_area/move_bound(if anchor object is movebound)/voltage_area_shape(if anchor object is VA) edge specified through scale_edge option and the value from offset option. If user doesn't specify scale_edge with offset scalable, the width/height of the block/core_area/ movebound/voltage_area_shape boundary bbox is used instead of the length of any particular edge.

DESCRIPTION

This command is used to set relative location constraint on hard macro or macro array relative to an anchor object. The location of the macro or macro array is determined by the parameters given. These placement constraints are respected by the **create_placement -floorplan** command.

EXAMPLES

The following example specifies a relative location constraint on the top-right corner of hard macro T1 with respect to the top-left corner of anchor macro A1.

```
prompt> set_macro_relative_location -target_object [get_cell T1]
        -target_orientation R180 -target_corner tr
        -anchor_object [get_cell A1] -anchor_corner tl
        -offset {150 100}
1
```

The following example specifies a relative location constraint on the bottom-right corner of hard macro T1 with respect to the bottom-left corner of anchor port P1.

```
prompt> set_macro_relative_location -target_object [get_cell T1]
        -target_orientation R270 -target_corner br
        -anchor_object [get_port P1] -anchor_corner bl
        -offset {300}
1
```

The following example specifies a relative location constraint on the top-right corner of macro array T1 with respect to the top-left corner of anchor voltage area P1.

```
prompt> set_macro_relative_location -target_object [create_macro_array
        -num_rows 2 -num_cols 2 [get_selection] -name T1]
        -target_orientation R0 -target_corner tr
        -anchor_object [get_voltage_area P1] -anchor_corner tl
        -offset {0.8 0.9} -offset_type {scalable scalable}
        -used_length {2.355 3.255} -scale_edge {2 1}
1
```

set_max_capacitance

Sets the maximum capacitance for ports, library cell pins, leaf cell pins, clocks or designs.

SYNTAX

string **set_max_capacitance**
value
[-clock_path]
[-data_path]
[-modes *mode_list*]
[-corners *corner_list*]
[-db *file_name*]
[-scenarios *scenario_list*]
object_list

Data Types

value	float
mode_list	list
corner_list	list
file_name	string
scenario_list	list
object_list	list

ARGUMENTS

value

Specifies the capacitance limit. The *value* setting must be greater than zero. This is the maximum total capacitance (pin plus wire capacitance) in library capacitance units.

-clock_path

Specifies all pins that are in the network of the specific clocks in *object_list*.

-data_path

Specifies all pins that are in the data paths launched by the specific clocks in *object_list*.

-modes *mode_list*

Specifies the scenarios to which to apply the capacitance limit. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option must not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners *corner_list*

Specifies the scenarios to which to apply the capacitance limit. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option must not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-db ***file_name***

Specifies the full or partial DB file name that matches a unique DB file for library cell pins, to which capacitance limit is applied. This option is valid only for library cell pin objects.

-scenarios ***scenario_list***

Specifies the scenarios to which to apply the capacitance limit. The **-modes** or **-corners** option must not be specified together with this option.

object_list

Provides a list of ports, library cell pins, leaf cell instance pins, clocks or designs on which to set maximum capacitance.

DESCRIPTION

Specifies a maximum capacitance on ports, library cell pins, leaf cell instance pins, clocks or designs for the current scenario. If maximum capacitance is set on a port, the net connected to that port is expected to have a total capacitance less than the specified *capacitance_value*. If specified on a design, the default maximum capacitance for that design is set. Library cell pins also can have a maximum capacitance value specified in the library.

If maximum capacitance is specified for library cell pin objects using this command, it overrides the values specified in the library for the specified scenarios. The library cell pin limits are stored as design specific overrides in the scenarios of the current design and are only applicable to the current design.

A maximum capacitance for leaf cell instance pin object creates an implicit size_only attribute on the pin. This is to preserve the constraint and may restrict optimization. It is recommended to minimize number of pin constraints to avoid restricting optimization. Also, pin constraints may not be able to satisfy user intent. A dominating pin constraint on a driver pin will remove driver sizing as possible solution.

Constraining max_capacitance, used in costing, is the most restrictive of design, clock, lib_pin and pin constraint for a pin.

Use the **-db** option to specify library cell pin constraints for a specific DB library that was used to create the NDM library. The command doesn't access the file itself but uses the name to find matching panes to apply the constraints. The **report_lib** and **report_cells** commands can be used to find the DB file names. *file_name* can be a library name, a local DB file name or a full path name that matches a unique DB file. Constraints with **-db** files have higher precedence than without it. Use **remove_max_capacitance** to remove all library cell pin constraints including **-db** files.

If maximum capacitance is set on a clock, the maximum capacitance is applied to all pins in this specified clock domain. Within a clock domain, you can optionally restrict the constraint further to clock paths only or data paths only.

The most restrictive of the design, clock and pin or port limit is used.

Maximum capacitance limits are managed on a per-scenario basis. For designs with multiple scenarios, you can specify different limits for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the given limit is applied to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is given, the limit is applied to all of the specified scenarios.

If the **-modes** option is given, the limit will be applied to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is given, the limit will be applied to all scenarios of the specified corners and the current mode. The tool issues

an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the limit will be applied to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to give **-scenarios** with **-modes** or **-corners**.

The **report_ports -design_rule** command shows port maximum capacitance limits. The **report_design** command shows the default maximum capacitance setting for the scenarios of the current design.

To remove maximum capacitance limits from designs or ports, use the **remove_max_capacitance** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets a maximum capacitance limit of 2.0 units on ports "OUT*".

```
prompt> set_max_capacitance 2.0 [get_ports "OUT*"]
```

The following example sets the default maximum capacitance limit of 5.0 units on the current scenario of the current design.

```
prompt> set_max_capacitance 5.0 [current_design]
```

The following example sets a maximum capacitance limit of 0.8 units on all pins of the clock network of CLK.

```
prompt> set_max_capacitance 0.8 [get_clocks CLK] -clock_path
```

The following example sets a maximum capacitance limit of 0.7 units on all pins of the data path of CLK.

```
prompt> set_max_capacitance 0.7 [get_clocks CLK] -data_path
```

The following example sets a maximum capacitance limit of 0.01 units on lib_pin for the current mode for specified full path name of db files. Full path name is used to uniquely identify slow.db file.

```
prompt> set_max_capacitance 0.01 -db /top/a/b/slow.db [get_lib_pin slow/BUF/Y]
prompt> set_max_capacitance 0.01 -db /top/a/c/slow.db [get_lib_pin slow/BUF/Y]
```

fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
comment string
delay_value float

ARGUMENTS

-rise

Specifies that the tool constrains only rising path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are constrained.

-fall

Specifies that the tool constrains only falling path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are constrained.

-reset_path

Removes existing point-to-point exception information from the specified paths. If used with **-to** only, all paths leading to the specified endpoints are reset. If used with **-from** only, all paths leading from the specified startpoints are reset. If used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise or fall setup or hold type is reset. Using this option is equivalent to using the **reset_paths** command with similar arguments before issuing **set_max_delay**.

-ignore_clock_latency

Indicates that the launch and capture clock latencies is to be ignored when computing slack on the specified paths. Note that these paths will be considered as clock-less, and therefore, reporting these paths by their respective ignored clocks will result in unconstrained paths. To report these paths with ignore_clock_latency, the user may specify the launched and/or captured devices as options in the report_timing command.

-from *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the specified objects. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the specified objects. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of pins, ports, cells, and nets through which the paths must pass for maximum delay definition. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** more than one time in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-rise_through *rise_through_list*

This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than one time in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-fall_through *fall_through_list*

This option is similar to the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than one time in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-to *to_list*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-comment ***comment***

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

delay_value

Specifies a floating point number that represents the required maximum delay value for specified paths. *delay_value* must have the same units as the technology library used during analysis. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output delay specified, that delay is added into the path delay.

DESCRIPTION

This command specifies a required maximum delay for timing paths in the current design. The path length for any startpoint in *from_list* to any endpoint in *to_list* must be less than *delay_value*.

The value of a **max_rise_delay** attribute cannot be less than that of a **min_rise_delay** attribute on the same path (and similarly for fall attributes). If this condition occurs, the older attribute is removed.

Individual maximum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, refer to the **create_clock**, **set_input_delay**, and **set_output_delay** command man pages.

The **set_max_delay** command is a point-to-point timing exception command. For example, the command overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_multicycle_path**, **set_min_delay**, and **set_false_path**. A **set_max_delay** or **set_min_delay** command overrides a **set_multicycle_path** command.

The more general commands apply to more than one path. For example, either **-from** or **-to** is used (but not both), or clocks are used in the specification. Within a given point-to-point exception command, the more specific command overrides the more general. The following list of commands is arranged in order, from the highest to the lowest precedence (more specific to more general).

1. set_max_delay -from *pin* -to *pin*
2. set_max_delay -from *clock* -to *pin*
3. set_max_delay -from *pin* -to *clock*
4. set_max_delay -from *pin*
5. set_max_delay -to *pin*
6. set_max_delay -from *clock* -to *clock*

7. set_max_delay -from *clock*

8. set_max_delay -to *clock*

You can use multiple **-through**, **-rise_through**, and **fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If more than one object is specified within one **-through**, **-rise_through**, or **-fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

To list the **max_delay**, **min_delay**, **multicycle_path**, and **false_path** information for the design, use the **report_exceptions** command.

To remove information set by **set_max_delay**, use the **reset_path** or **reset_design** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example specifies that any delay path to port "Y" must be less than 10.0 units.

```
prompt> set_max_delay 10.0 -to {Y}
```

The following example specifies that all paths from ff1a or ff1b to ff2e must have delays less than 15.0 units.

```
prompt> set_max_delay 15.0 -from {ff1a ff1b} -to {ff2e}
```

The following example specifies that all paths to endpoints clocked by PHI2 must have delays less than 8.5 units.

```
prompt> set_max_delay 8.5 -to [get_clocks PHI2]
```

The following example sets a requirement that all paths leading to ports named "busA[*]" must have delays less than 5.0.

```
prompt> set_max_delay 5.0 -to "busA[*]"
```

The following example specifies that all timing paths from ff1/CP to ff2/D that pass through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C} must have delays less than 8.0 units.

```
prompt> set_max_delay 8.0 -from ff1/CP -through {U1/Z U2/Z} -through {U3/Z U4/C} -to ff2/D
```

The following example specifies that all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall through one or more of {U3/Z U4/C} must have delays less than 8.0 units.

```
prompt> set_max_delay 8.0 -from ff1/CP -rise_through {U1/Z U2/Z} \
  -fall_through {U3/Z U4/C} -to ff2/D
```

set_max_fanout

NOTE

set_max_fanout

This command is not supported.

set_max_lvth_percentage

This command specifies a soft constraint for the target percentage of low-threshold-voltage cells. The set_max_lvth_percentage command is deprecated. Use the set_multi_vth_constraint command instead.

SYNTAX

status **set_max_lvth_percentage**
percent_value

Data Types

percent_value float

ARGUMENTS

percent_value

Specifies the target percentage of low-threshold-voltage cells.

DESCRIPTION

This command specifies a target percentage (cell count) for low threshold voltage cells to be used in the design. This is a soft constraint and optimization tries to honor it if timing convergence is not affected by this limit.

Note that the percentage is computed based on cell count.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example specifies that no more than three percent of the design's cell count can be from low-threshold-voltage cells.

```
prompt> set_max_lvth_percentage 3
1
```

SEE ALSO

set_threshold_voltage_group_type(2)
remove_max_lvth_percentages(2)
set_multi_vth_constraint(2)

set_max_time_borrow

Limits time borrowing for latches.

SYNTAX

string **set_max_time_borrow**
delay_value
object_list
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]

float *delay_value*
list *object_list*
list *mode_list*
list *corner_list*
list *scenario_list*

ARGUMENTS

delay_value

Specifies the value to which the **max_time_borrow** attribute is set. Defines the desired limit of time borrowing on the latches specified in **object_list**. *delay_value* must be between zero and the default maximum derived from the waveform. By default, the maximum is derived from the ideal clock waveform driving each latch, and is equal to (closing_edge - open_edge). Library setup and data-to-Q propagation times are automatically taken into account. *delay_value* is in the same units as those in the technology library used during analysis.

object_list

Specifies a list of objects for which time borrowing is to be limited to *value*. The objects can be clocks, latch cells, data pins, or clock (enable) pins. If a cell is specified, all enable pins on that cell are affected.

-modes *mode_list*

Specifies the scenarios that the time borrow limit will be applied to. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners will be used.

-corners *corner_list*

Specifies the scenarios that the time borrow limit will be applied to. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option may not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by -corners will be used.

-scenarios *scenario_list*

Specifies the scenarios that the time borrow limit will be applied to. The **-modes** or **-corners** option may not be given with this option.

DESCRIPTION

Sets the **max_time_borrow** attribute to **value** to constrain the amount of time borrowing possible for level-sensitive latches. To meet delay targets, **set_max_time_borrow** prevents automatic use of all or part of the enabling clock pulse on a latch.

Max_time_borrow settings are managed on a per-scenario basis. For designs with multiple scenarios, you can specify different values for different scenarios by using **-modes**, **-corners**, and **-scenarios** options. By default, if none of these options are specified, the given value is applied to the current scenario. (It will be an error if there is no current scenario). If the **-scenarios** option is given, the value will be applied to all of the specified scenarios. If the **-modes** option is given, the value will be applied to all scenarios of the specified modes. (It will be an error if none of the specified modes have any scenarios.) If the **-corners** option is given, the value will be applied to all scenarios of the specified corners and the current mode. (It will be an error if none of the specified corners have any scenarios with the current mode.) If both the **-modes** and **-corners** options are given, the value will be applied to all scenarios of the specified corners and the specified modes. (It will be an error there are no such scenarios.) It is an error to give -scenarios with **-modes** or **-corners**.

To get **max_time_borrow** attributes on the design, use **get_attribute**.

To undo **set_max_time_borrow**, use **remove_max_time_borrow**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example restricts time borrowing on latches **latch1a** and **latch2f** to 4.0 units.

prompt> **set_max_time_borrow 4.0 { latch1a latch2f }**

The following example specifies that no time borrowing will take place on **latch1c**.

prompt> **set_max_time_borrow 0.0 { latch1c }**

SEE ALSO

remove_max_time_borrow(2)
get_attribute(2)

set_max_transition

Sets maximum transition for ports, library cell pins, leaf cell pins, clocks or designs with respect to the main library trip-points.

SYNTAX

string **set_max_transition**
value
[-clock_path]
[-data_path]
[-modes *mode_list*]
[-corners *corner_list*]
[-db *file_name*]
[-scenarios *scenario_list*]
object_list

Data Types

value float
mode_list list
corner_list list
file_name string
scenario_list list
object_list list

ARGUMENTS

value

Specifies the transition limit. The *value* must by greater than zero. This setting is the maximum transition time in user-defined input time units.

-clock_path

Specifies all pins that are in the network of the specific clocks in the *object_list*.

-data_path

Specifies all pins that are in the data paths launched by the specific clocks in *object_list*.

-modes *mode_list*

Specifies the scenarios to which to apply the transition limit. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option must not be specified together with the **-modes** option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners *corner_list*

Specifies the scenarios to which to apply the transition limit. If this option is given, all scenarios of the specified corners and the current mode will be used. The **-scenarios** option must not be specified together with the **-corners** option. If both **-modes** and **-corners** are specified, the command uses scenarios whose mode is specified by **-modes** and whose corner is specified.

-db ***file_name***

Specifies the full or partial DB file name that matches a unique DB file for library cell pins, to which transition limit is applied. This option is valid only for library cell pin objects.

-scenarios ***scenario_list***

Specifies the scenarios to which to apply the transition limit. The **-modes** or **-corners** option must not be specified together with the **-scenarios** option.

object_list

Provides a list of ports, library cell pins, leaf cell instance pins, clocks or designs on which to set maximum transition.

DESCRIPTION

Specifies a maximum transition on ports, library cell pins, leaf cell pins, clocks or designs for the current scenario. If maximum transition is set on a port, the port must have a transition time less than the specified *transition_value*. If specified on a design, the default maximum transition for that design is set. Library cell pins can also have a **max_transition** value specified in the library.

If you specify a maximum transition for library cell pin objects, the command overrides the values specified in the library for the specified scenarios. The library cell pin limits are stored as design specific overrides in the scenarios of the current design and are only applicable to only the current design.

A maximum transition for leaf cell instance pin object creates an implicit size_only attribute on the pin. This is to preserve the constraint and may restrict optimization. It is recommended to minimize number of pin constraints to avoid restricting optimization. Also, pin constraints may not always be able to satisfy user intent.

Constraining max_transition, used in costing, is the most restrictive of design, clock, lib_pin and pin constraint for a pin.

The **-db** option specifies library cell pin constraints for a specific DB library that was used to create the NDM library. The command does not access the file itself, but uses the name to find matching panes to apply the constraints. The **report_lib** and **report_cells** commands can be used to find the DB file names. The *file_name* argument can be a library name, a local DB file name or a full path name that matches a unique DB file. Constraints with **-db** files have higher precedence than without it. Use **remove_max_transition** command to remove all library cell pin constraints including **-db** files.

The most restrictive of the design, clock and pin or port limit is used. If the user-specified limit is the most restrictive limit, it is scaled to that of the pin trip-points during slack computation.

If maximum transition is set on a clock, the maximum transition is applied to all pins in this specified clock domain. Within a clock domain, you can optionally restrict the constraint further to clock paths only or data paths only, and to rising transitions only or falling transitions only.

The **-clock_path** and **-data_path** options can be used only if the list of objects is a clock list, not a port list or design list. If a clock list is specified without **-clock_path** or **-data_path**, both clock path and data path for both rising and falling transitions are considered by default.

Maximum transition limits are managed on a per-scenario basis. For designs with multiple scenarios, you can specify different limits for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the given limit is applied to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is given, the limit is applied to all of the specified scenarios.

If the **-modes** option is given, the limit will be applied to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is given, the limit will be applied to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the limit will be applied to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to give **-scenarios** with **-modes** or **-corners**.

The **report_ports -design_rule** command shows the maximum transition limits for the specified ports. The **report_design** command shows the default maximum transition setting for the scenarios of the current design.

To remove maximum transition limits from designs or ports, use **remove_max_transition**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets a maximum transition limit of 2.0 units on ports "OUT*".

```
prompt> set_max_transition 2.0 [get_ports "OUT*"]
```

The following example sets the default maximum transition limit of 5.0 units on the current scenario.

```
prompt> set_max_transition 5.0 [current_design]
```

The following example sets a maximum transition limit of 2.0 units on all pins in the clock network of CLK.

```
prompt> set_max_transition 2.0 [get_clocks CLK] -clock_path
```

The following examples sets a maximum transition limit of 2.0 units on the specified library cell pins for the current mode for all corners and specific corner.

```
prompt> set_max_transition 2.0 [get_lib_pin slow/BUF/A]
prompt> set_max_transition 2.0 [get_lib_pin slow/BUF/A] -corner {c1}
```

The following example sets a maximum transition limit of 2.0 units on library cell pin for the current mode for specific corner for specified DB file name max.db. Only one max.db used in library preparation.

```
prompt> set_max_transition 2.0 -db max.db [get_lib_pin maxlib/BUF/A] -corner {c1}
```

The following example sets a maximum transition limit of 2.0 units on library cell pin for the current mode for specified full path name of DB files. Specifying full path name to uniquely identify max.db file.

```
prompt> set_max_transition 2.0 -db /top/a/b/max.db [get_lib_pin maxlib/BUF/A]
prompt> set_max_transition 2.0 -db /top/a/c/max.db [get_lib_pin maxlib/BUF/A]
```

set_message_info

Set some information about diagnostic messages.

SYNTAX

string **set_message_info** -id message_id [-limit max_limit|-stop_on|-stop_ff]

string *message_id*
integer *max_limit*

ARGUMENTS

-id *message_id*

Information is to be set for the given *message_id*. The message must exist. Although different constraints allow different message types, no constraint allows severe or fatal messages.

-limit *max_limit*

Set the maximum number of occurrences for *message_id*. This is an integer greater than or equal to zero. If you set it to zero, that means the number of occurrences of the message is unlimited. Messages which occur after a limit is reached are automatically suppressed.

-stop_on

Force Tcl error if message is emitted.

-stop_off

Turn off a previous -stop_on directive

DESCRIPTION

The **set_message_info** command sets constraints on diagnostic messages (typically error, warning, and informational messages).

Currently, you can set a upper limit for the number of occurrences of a message. You can set this to zero to indicate that there is no limit. You can retrieve the current limit for a message using the **get_message_info** ***command. When the limit is exceeded, all future occurrences of the message are automatically suppressed. A count of total occurrences (including those suppressed) can be retrieved using get_message_info.***

EXAMPLES

The following example uses **set_message_info** to set a limit on the number of APP-027 messages to 100. When the 101st APP-027 message is about to be issued, you will be warned that the limit has been exceeded, and that all future occurrences will be suppressed.

```
prompt> set_message_info -id APP-027 -limit 100
prompt> do_command
Warning: can't find node U27.1 (APP-027)
Warning: can't find node U27.2 (APP-027)
Warning: can't find node U27.3 (APP-027)
 ...
Warning: can't find node U27.100 (APP-027)
Note - message 'APP-027' limit (100) exceeded.  Remainder will be suppressed.
1
```

set_min_capacitance

Sets minimum capacitance for ports, library cell pins or designs.

SYNTAX

string **set_min_capacitance**
value
[-modes *mode_list*]
[-corners *corner_list*]
[-db *file_name*]
[-scenarios *scenario_list*]
object_list

Data Types

value float
mode_list list
corner_list list
file_name string
scenario_list list
object_list list

ARGUMENTS

value

Sets the capacitance limit. The value is greater than or equal to zero. This is the minimum total capacitance (pin plus wire capacitance) in library capacitance units.

-modes *mode_list*

Specifies the scenarios for which to apply the capacitance limit. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option must not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-corners *corner_list*

Specifies the scenarios for which to apply the capacitance limit. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option must not be given with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-db *file_name*

Specifies the full or partial DB file name that matches the unique DB file for library cell pins, to which to apply the capacitance limit. Option is valid only for library cell pin objects.

-scenarios *scenario_list*

Specifies the scenarios for which to apply the capacitance limit. The **-modes** or **-corners** option must not be given with this option.

object_list

Provides a list of input or inout ports, library cell pins or designs on which to set minimum capacitance.

DESCRIPTION

Specifies a minimum capacitance on input/inout ports, library cell pins or designs for the specified scenarios. If minimum capacitance is set on a port, the net connected to that port is expected to have total capacitance greater than the specified *capacitance_value*. If specified on a design, the default minimum capacitance for that design is set. Library cell pins can also have a **min_capacitance** value specified in the library.

If minimum capacitance is specified for library cell pin objects by using this command, the setting overrides the values specified in the library for the specified scenarios. The library cell pin limits are stored as design specific overrides in the scenarios of the current design and are only applicable to the current design.

The **-db** option is provided to specify library cell pin constraints for a specific DB library that was used to create the NDM library. The command doesn't access the file itself but uses the name to find matching panes to apply the constraints. The **report_lib** and **report_cells** commands can be used to find the DB file names. File_name can be a library name, a local DB file name or a full path name that matches a unique DB file. Constraints with **-db** files have higher precedence than without it. Use **remove_min_capacitance** to remove all library cell pin constraints including **-db** files.

The most restrictive of the design limit and the pin or port limit is used.

Minimum capacitance limits are managed on a per-scenario basis. For designs with multiple scenarios, you can specify different limits for different scenarios by using the **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the **-scenarios** option is specified, the command applies to all of the specified scenarios.

If the **-modes** option is specified, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the **-corners** option is specified, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are specified, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**.

The **report_ports -design_rule** command shows port minimum capacitance limits. The **report_design** command shows the default minimum capacitance setting for the scenarios of the current design.

To remove minimum capacitance limits from designs or ports, use **remove_min_capacitance**.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets a minimum capacitance limit of 0.2 units on ports "IN*".

```
prompt> set_min_capacitance 0.2 [get_ports "IN*"]
```

The following example sets the default minimum capacitance limit of 0.1 units on the current scenario of the current design.

```
prompt> set_min_capacitance 0.1 [current_design]
```

The following example sets a minimum capacitance limit on a library cell pin for the current mode for specified DB files.

```
prompt> set_min_capacitance 1.0 -db slow1v95.db [get_lib_pin slow/BUF/Y]
prompt> set_min_capacitance 1.1 -db slow1v40.db [get_lib_pin slow/BUF/Y]
```

set_min_delay

Specifies a minimum delay for timing paths.

SYNTAX

status **set_min_delay**
[-rise]
[-fall]
[-reset_path]
[-ignore_clock_latency]
[-from *from_list*
| -rise_from *rise_from_list*
| -fall_from *fall_from_list*]
[-through *through_list*]
[-rise_through *rise_through_list*]
[-fall_through *fall_through_list*]
[-to *to_list*
| -rise_to *rise_to_list*
| -fall_to *fall_to_list*]
[-comment *comment*]
delay_value

Data Types

from_list list
rise_from_list list
fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
comment string
delay_value float

ARGUMENTS

-rise

Specifies that the tool constrains only rising path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are constrained.

-fall

Specifies that the tool constrains only falling path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are constrained.

-reset_path

Removes existing point-to-point exception information from the specified paths. If used with **-to** only, all paths leading to the specified endpoints are reset. If used with **-from** only, all paths leading from the specified startpoints are reset. If used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise or fall setup or hold type is reset. Using this option is equivalent to using the **reset_paths** command with similar arguments before issuing **set_min_delay**.

-ignore_clock_latency

Indicates that the launch and capture clock latencies is to be ignored when computing slack on the specified paths. Note that these paths will be considered as clock-less, and therefore, reporting these paths by their respective ignored clocks will result in unconstrained paths. To report these paths with ignore_clock_latency, the user may specify the launched and/or captured devices as options in the report_timing command.

-from *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of pins, ports, cells, and nets through which the paths must pass for maximum delay definition. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** more than one time in one command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-rise_through *rise_through_list*

This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than one time in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-fall_through *fall_through_list*

This option is similar to the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than one time in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-to *to_list*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to ***rise_to_list***

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to ***fall_to_list***

Same as the **-to** option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

delay_value

Specifies a floating point number that represents the required minimum delay value for specified paths. *delay_value* must have the same units as the technology library used during analysis. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input external delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output external delay specified, that delay is added into the path delay.

-comment ***comment***

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

This command specifies a required minimum delay for timing paths in the current design. The path length for any startpoint in *from_list* to any endpoint in *to_list* must be greater *delay_value*.

Use **set_min_delay** in the following two cases:

1. To set a target minimum delay for output ports in a combinational design.

2. To override the default single cycle timing for paths, where **set_multicycle_path** is not sufficient.

The value of the **min_rise_delay** attribute cannot be greater than that of the **max_rise_delay** attribute for the same path (and similarly for fall attributes). If this condition occurs, the older attribute is removed.

Individual minimum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, refer to the **create_clock**, **set_input_delay**, and **set_output_delay** command man pages.

The **set_min_delay** command is a point-to-point timing exception command; it overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_multicycle_path**, **set_max_delay**, and **set_false_path**. A **set_max_delay** or **set_min_delay** command overrides a **set_multicycle_path** command.

The more general commands apply to more than one path; either **-from** or **-to** is used (but not both), or clocks are used in the specification. Within a given point-to-point exception command, the more specific command overrides the more general. The following list of commands is arranged in order, from highest to lowest precedence (more specific to more general):

1. set_min_delay -from *pin* -to *pin*

2. set_min_delay -from *clock* -to *pin*

3. set_min_delay -from *pin* -to *clock*

4. set_min_delay -from *pin*

5. set_min_delay -to *pin*

6. set_min_delay -from *clock* -to *clock*

7. set_min_delay -from *clock*

8. set_min_delay -to *clock*

You can use multiple **-through**, **-rise_through**, and **fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If more than one object is specified within one **-through**, **-rise_through**, or **fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

To remove information set by **set_min_delay**, use the **reset_paths** or **reset_design** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following command specifies that any delay path to port "Y" must be greater than 12.5 units.

```
prompt> set_min_delay 12.5 -to Y
```

The following command specifies that all paths from A1 and A2 to Z5 must have delays greater than 4.0 units.

```
prompt> set_min_delay 4.0 -from {A1 A2} -to Z5
```

The following example specifies that all timing paths from ff1/CP to ff2/D that pass through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C} must have delays greater than 3.0 units.

```
prompt> set_min_delay 3.0 -from ff1/CP -through {U1/Z U2/Z} -through {U3/Z U4/C} -to ff2/D
```

The following example specifies that all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall through one or more of {U3/Z U4/C} must have delays greater than 3.0 units.

```
prompt> set_min_delay 3.0 -from ff1/CP -rise_through {U1/Z U2/Z} \
  -fall_through {U3/Z U4/C} -to ff2/D
```

set_min_pulse_width

Sets a minimum pulse width constraint for clocks or clock pins.

SYNTAX

status **set_min_pulse_width**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-low]
[-high]
value
object_list

Data Types

mode_list list
corner_list list
scenario_list list
value float
object_list list

ARGUMENTS

-modes *mode_list*

Specifies the scenarios on which to set the input delay value. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners *corner_list*

Specifies the scenarios on which to set the input delay value. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios *scenario_list*

Specifies the scenarios on which to set the input delay value. The **-modes** or **-corners** option must not be given with this option.

-low

Indicates that the minimum pulse width constraint specified by *value* applies only to low clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

-high

Indicates that the minimum pulse width constraint specified by *value* applies only to high clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

value

A positive floating-point value that specifies the minimum pulse width check to be applied to clock signals.

object_list

Specifies a list of clocks or clock pins in the current design to which the minimum pulse width check is applied. If you specify a clock, the constraint is applied to all clock pins connected to the clock.

DESCRIPTION

The **set_min_pulse_width** command specifies a minimum pulse width check to be applied to clock signals at clock pins of sequential devices. This value overrides the default values for clock tree minimum pulse width checks. Use this command for sequential clock pin pulse width checks to add a more restrictive value than the one specified in library. This setting is applied for current scenario.

To generate a report of pulse width constraints, use **report_min_pulse_width**. To remove minimum pulse width constraints set by **set_min_pulse_width**, use the **remove_min_pulse_width** command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets a minimum pulse width requirement of 2.0 for both low and high pulses of clock signals.

```
pt_shell> set_min_pulse_width 2.0 [get_clocks CK1]
```

The following example sets a minimum pulse width requirement of 2.5 for the low pulse of the clock signal on the clock pin reg1/CK.

```
pt_shell> set_min_pulse_width -low 2.5 reg1/CK
```

SEE ALSO

remove_min_pulse_width(2)
report_min_pulse_width(2)

set_missing_via_check_options

Sets missing via check options for the RedHawk Analysis Fusion check missing via analysis flow. The settings are not saved in the IC Compiler II database, so you must be set the checking options in each session.

SYNTAX

status **set_missing_via_check_options**
[-redhawk_script_file *redhawk_script_file*]
[-exclude_stack_via]
[-check_valid_vias]
[-exclude_cell *exclude_cell_masters*]
[-exclude_inst *exclude_cell_instances*]
[-exclude_regions *regions*
[-sort_by_hot_inst]
[-threshold *voltage_value*]
[-min_width *min_width_value*]
[-pitch *pitch_value*]
[-ignore_inter_met]
[-toplayer *toplayer_name*]
[-bottomlayer *bottomlayer_name*]
[-gds]

Data Types

redhawk_script_file string
exclude_cell_masters list
exclude_cell_instances collection
regions list
voltage_value float
min_width_value float
pitch_value float
toplayer_name string
bottomlayer_name string

ARGUMENTS

-redhawk_script_file *redhawk_script_file*

Uses an existing RedHawk script file for missing via checking. You must source the user-given script file before exiting from RedHawk. This option allows you to reuse an existing RedHawk script which has filtering options specified in a previous run.

-exclude_stack_via

Excludes stack vias from missing via check.

-check_valid_vias

Reports if metal overlap can accommodate a valid via model.

-exclude_cell *exclude_cell_masters*

Excludes the area covered by all instances of the specified list of cells from missing via check.

-exclude_inst *exclude_cell_instances*

Excludes the area covered by the specified list of cell instances from missing via check.

-exclude_regions *regions*

Excludes the specified rectangular regions from missing via check. To specify a rectangular region, use the following format to specify the lower-left and upper-right corners of the rectangle:

{{*x1 y1*} {*x2 y2*}}

-sort_by_hot_inst

Sorts missing vias by voltage drop.

-threshold *voltage_value*

Specifies a voltage threshold that triggers a missing via check.

The default is 1mV. To disable voltage check filtering, set this option to -1.

-min_width *min_width_value*

Ignores segments with less than specified width.

-pitch *pitch_value*

Specifies pitch for missing via check on parallel wires crossing or touching GDS blocks.

-ignore_inter_met

Ignores wires on all layers between the -toplayer and the -bottomlayer.

-toplayer *toplayer_name*

Specifies the top layer

-bottomlayer *bottomlayer_name*

Specifies the bottom layer

-gds

Reports missing vias both inside the GDS block region and in routes cross over GDS blocks.

EXAMPLES

The following example configures settings for the current missing via check to report if metal overlap can accommodate a valid via model.

```
prompt> set_missing_via_check_options -check_valid_vias
```

SEE ALSO

analyze_rail(2)
report_missing_via_check_options(2)
remove_missing_via_check_options(2)
set_app_options(2)

set_msg

Configures messages and options to control tool output

SYNTAX

integer **set_msg**
[msgTag]
[-level *msgLevel*]
[-limit printLimit]
[-width lineWidth]
[-reset_to_default]
[-only_level msgLevel]
[-add_filter pattern]
[-remove_filter pattern]

Data Types

msgLevel 'off', 'debug', 'verbose', 'info', 'warning', 'error', 'serror' or 'fatal'
printLimit uint
lineWidth uint
pattern string

ARGUMENTS

msgTag

Tag pattern to which the setting applies. This can be a specific message tag ('ABC-1234') or use wildcards to match arbitrary sets of messages. E.g. 'ZRT-*' matches all zroute messages.

-level *msgLevel*

Sets the level of the matching message(s). To stop a message from printing (that is suppress the message) set it level to 'off'. Setting a message whose level is verbose to 'info' or higher causes it to become printable. A message level of 'verbose' and below does not print. If message level is set to 'serror' (Severe_error), execution will stop at the end of the TCL command the produced the message. A message level 'fatal' will cause the tool to crash when the error occurs.

-limit *printLimit*

Sets the maximum number of times that a message may be printed per TCL file. A value of 0 means no print restrictions. The limit applies per TCL file. At the end of a TCL file a summary of the messages that overstepped their limit will be printed.

-width *lineWidth*

Causes message and all other tool output to wrap when line width exceeds the given value. The default is unlimited.

-reset_to_default

Resets the message level back to its default setting.

-only_level *msgLevel*

Applies setting only to messages of the indicated level.

-add_filter *pattern*

Causes all (non-message) output that matches 'pattern' to be suppressed. This is useful to remove garbage output from overflowing the log file. The filter only applies to non-message output that does not have a tag.

-remove_filter *pattern*

Removes a previously set filter

RETURN VALUE

1 upon success

DESCRIPTION

The **set_msg** command changes the properties of existing messages or other tool output. Use this to turn off the printing of tedious tool output, or - conversely - to cause the tool to print extra verbose output.

The tool contains many thousands of built-in messages, each identified by unique 'tag' in the form 'ABC-123' or 'ABC-1234'. Use 'report_msg' to find and list the available messages, or to list the messages that were printed until now. Each message has a default level:
off The message is suppressed and will not print. By default no messages are at level 'off'
debug Internal debug message that does not print by default. Only accessible by Synopsys developers
verbose Additional information that does not print by default
info Generic information output. This message prints by default
warning Warning message: abnormal issue that warrants attention but is not show-stopping
error Error message: an abnormality that must be addressed by the user
serror Severe_Error message: a show-stopping error. This will stop flow execution at the end of the TCL command.
fatal Deadly error, causing the tool to crash immediately

Using *set_msg -level* the severity ('level') of any message can be changed: downgraded to non-printing, or upgraded to printing or worse. To suppress a specific message: look up its tag and switch it off like this:

```
prompt> set_msg ABC-1234 -level off
```

It is also possible to set a limit on the number of times a message is printed using '-limit'. The tool meticulously registers the occurrence of a message, whether printing on not. Using 'get_msg' it is easy to detect whether a particular message occurred. This is a clean alternative to searching the log file, because the user can take conditional action when the message occurred (printed or not)
In addition to controlling what messages are printed or suppressed, *set_msg -filter* allows the user to suppress unwanted tool output that is not tagged as a message. There are many tens of thousands of those in the tool.

EXAMPLES

Suppress the printing of a specific noisy message:

```
set_msg ABC-2001 -level off
```

Upgrade a specific 'verbose' message CVG-2001 such that it will be printed:

```
set_msg CVG-2001 -level info
```

Upgrade all verbose messages of the FLW package such that they are printed:

```
set_msg FLW* -only_level verbose -level info
```

Upgrade a specific set of (debug) messages:

```
set_msg FLW*52* -level info
```

Upgrade all Verilog warning messages to 'Serious_error', such that the flow stops:

```
set_msg VER* -only_level warning -level serror
```

Suppress a specific Error message by downgrading it to a warning:

```
set_msg ZRT-510 -level warning
```

Downgrade all VER* error messages to a warning. So this is effectively a continue_on_error but only for specific Verilog errors.

```
set_msg VER* -only_level error -level warning
```

Reset the level of all messages back to default

```
set_msg * -reset_to_default
```

Limit the number of times the message is printed to 4

```
set_msg ABC-123 -limit 4
```

Remove the print limit by setting it back to 0

```
set_msg ABC-123 -limit 0
```

Remove all print limits on any message

```
set_msg * -limit 0
```

Suppress any tool output that contains the string 'processing module'

```
set_msg -filter "processing module"
```

SEE ALSO

report_msg(2)
get_msg(2)

set_multi_input_switching_coefficient

Sets delay coefficients for multi-input switching (MIS) analysis for a specified list of library cells.

SYNTAX

int **set_multi_input_switching_coefficient**
[-rise]
[-fall]
-delay *coeff_value*
object_list

Data Types

coeff_value float
object_list list

ARGUMENTS

-rise

Applies the coefficients to rise transitions only.

-fall

Applies the coefficients to fall transitions only.

-delay *coeff_value*

Indicates the base coefficient of the cell delay for multi-input switching analysis when the specified library cell is used.

object_list

Specifies a list of library cells for multi-input switching analysis.

DESCRIPTION

This command sets the base coefficients for the cell delay during multi-input switching (MIS) analysis. To enable multi-input switching analysis, set the application option **time.enable_multi_input_switching_analysis** to true; the default of this application option is false.

If the application option **time.enable_multi_input_switching_timing_window_filter** is set to true, the tool uses the base coefficient value to derive the actual MIS factor by considering the arrival windows of the input pins and their overlap analysis.

If the application option **time.enable_multi_input_switching_timing_window_filter** is set to false, the base coefficient value is directly applied to the MIS factor. The default of application option **time.enable_multi_input_switching_timing_window_filter** is true.

If you use the **set_multi_input_switching_coefficient** command multiple times on the same library cell, the last specified coefficient overwrites the previously specified coefficients.

To apply MIS coefficient to library cell in one specific pane, specify the db file name together with the library cell using **get_lib_cell**, otherwise it's applied to all panes. For the same library cell, the pane specific setting will override global setting.

In scaling flow, if the applied PVT matches one of the source db in the scaling group, then that source db is checked for pane specific setting first, if not found we will check if there is global setting, if not, we will check the next best matching db in the scaling group.

EXAMPLES

The following example sets the delay coefficient value of 0.7 for all instances of library cell AND2 in the library MY_LIB:

```
prompt> set_multi_input_switching_coefficient -delay 0.7 [get_lib_cells MY_LIB/AND2]
```

The following example sets the delay coefficient value of 0.8 for all instances of library cell AND2, and the PVT matches MY_LIB.db:

```
prompt> set_multi_input_switching_coefficient -delay 0.8 [get_lib_cells MY_LIB.db:MY_LIB/AND2]
```

enable_multi_input_switching_analysis(3)
enable_multi_input_switching_timing_window_filter(3)

set_multi_vth_constraint

Enable percentage vth flow, set low vth percentage limit and cost type

SYNTAX

set_multi_vth_constraint
-low_vt_percentage *percentage_limit*
[-cost *cost_type*]

Data Types

percentage_limit float: in range [0.0, 100.0]
cost_type string: cell_count or area

ARGUMENTS

-low_vt_percentage *percentage_limit*

Specifies low vth percentage limit based on cost type. This is a required option. Default value is 100.0.

-cost *cost_type*

Specifies how low vth percentage limit is calculated. The low vth percentage can be based on cell count or cell area. Default value is cell_count.

DESCRIPTION

This command enables percentage vth flow and sets percentage vth constraints, including low vth percentage limit and cost type. These settings are persistent across shell sessions.

If percentage vth flow is enabled, optimization commands including **compile_fusion**, **place_opt**, **clock_opt** and **route_opt** will honor the low vth percentage limit based on cost type.

PREREQUISITES

Low_vt percentage constraint needs to be provided, and at least one threshold voltage group needs to be assigned to low_vt type. For example:

prompt> **set_attribute [get_lib_cells *lvt*/*] threshold_voltage_group LVT**
prompt> **set_threshold_voltage_group_type -type low_vt LVT**

EXAMPLES

```
prompt> set_multi_vth_constraint -low_vt_percentage 10 -cost area
Percentage vth flow  : enabled
Percentage vth limit : 10.000 (%)
Percentage vth cost  : area
```

SEE ALSO

reset_multi_vth_constraint(2)
report_multi_vth_constraint(2)
report_threshold_voltage_group(2)
set_vth_threshold_controls(2)
set_threshold_voltage_group_type(2)

set_multibit_options

Specifies the options to use for multibit cell mapping during compile.

SYNTAX

status **set_multibit_options**
[-exclude *object_list*]
[-stage *stage_name*]
[-bus_registers_only]
[-name_prefix *prefix_string*]
[-name_concatenation_character *concatenate_string*]
[-input_map_file *file_name*]
[-exclude_library_cells *library_cells*]
[-slack_threshold *slack_value*]
[-verbose_file *file_name*]

ARGUMENTS

-exclude *object_list*

Specifies the netlist objects to exclude from multibit banking during compile. The *object_list* might contain collections of individual cells, buses, or modules. For buses, all the contained scalar elements are excluded from multibit banking. For modules, all relevant cells in the top-level hierarchy are excluded from multibit banking.

This option can combine with "-stage" to specify at which stage multibit exclusion will be effective (see "-stage" option below).

-stage *stage_name*

Specifies the stage that "-exclude" option should be applied to. Valid stage names are *rtl*, *physical*, and *all*.

This "-stage" option can only be combined with "-exclude" option; it cannot be combined with any other options of set_multibit_options.

If "-stage" option is absent, the behavior will be identical to "-stage all".

-bus_registers_only

Specifies that cells should be banked with other cells of same bus only.

-name_prefix *prefix_string*

Specifies the string to prefix the instance names created from multibit banking.

-name_concatenation_character *concatenate_string*

Specifies the string to be used to concatenate the names of the instances created from multibit banking.

-input_map_file *file_name*

Specifies the name of the input map file that contains functional group information and mapping information about which multibit register bank replaces which single-bit registers for each functional group.

If this option is not specified, the tool identifies the single-bit registers that can be replaced by available multibit registers in the libraries based on the functional information of the library cells; the tool then uses that information to control mapping.

The format for the input map file is described in the FILE FORMATS section of this man page.

-exclude_library_cells *library_cells*

Specifies the list of library cells whose instances are excluded from multibit banking.

-slack_threshold *slack_value*

Specifies the slack value for a register to be considered for multibit banking. Registers having slack value below this number are ignored from multibit banking. By default, the tool considers all registers for multibit banking.

-verbose_file *file_name*

Specifies the file name in which verbose messages and Summary related to banking is dumped.

This file consists of information related to cells ignored during banking flow and it's reason. It also contains information regarding names of cells getting banked with their corresponding newly created cell names.

This command option will only work with physical aware multibit banking and not with RTL banking.

FILE FORMATS

Format for specifying -input_map_file

You can specify the input map file sequence as shown:

reg_group_name {*list_of_reference_of_single_bit_flops* }
bits { *number_of_instances ref_multibit_flop* } { ... }
bits { *number_of_instances ref_multibit_flop* } { ... }

Where *reg_group_name* specifies the name of the register group, *list_of_reference_of_single_bit_flops* specifies the list of references of single-bit registers. **bits** specifies the number of single-bit registers in a group to be replaced, *number_of_instance* specifies the number of multibit registers to be used, and *ref_multibit_flop* specifies the reference multibit library cell to be used.

For example:

```
reg_group_1 {REGX1 REGX2 REGX4}
2 {1 MREG2}
3 {1 MREG2}
4 {1 MREG4}
5 {1 MREG4}
6 {1 MREG2} {1 MREG4}
reg_group_2 {REGNX1 REGNX2 REGNX4}
2 {1 MREG2N}
3 {1 MREG2N}
4 {1 MREG4N}
5 {1 MREG4N}
6 {1 MREG2N} {1 MREG4N}
```

reg_group_1 {REGX1 REGX2 REGX4} means that single-bit registers whose reference is either REGX1, REGX2, or REGX4 can be grouped together. **4 {1 MREG4}** specifies that a group of four single-bit registers can be replaced by one cell whose reference is MREG4. Similarly, **6 {1 MREG2} {1 MREG4}** means a group of six single-bit registers can be replaced using one instances of MREG2 and one instance of MREG4.

EXAMPLES

The following example excludes cell reg[1] from multibit banking:

prompt> **set_multibit_options -exclude [get_cells "reg[1]"]**

The following example excludes the reg bus from multibit banking:

prompt> **set_multibit_options -exclude [get_cell_buses "reg"]**

The following example excludes the reg bus from RTL multibit banking (but "reg" will not be excluded from physical multibit banking or any other types of multibit banking):

prompt> **set_multibit_options -exclude [get_cell_buses "reg"] -stage rtl**

The following example excludes all sequential cells of the mod subdesign in the top-level hierarchy from multibit banking:

prompt> **set_multibit_options -exclude [get_modules "mod"]**

The following example queries cells that are excluded from multibit banking using the **set_multibit_options** command:

prompt> **get_attribute -objects [get_cells {reg[1]}] -name exclude_multibit**

path_multiplier

Data Types

from_list list
rise_from_list list
fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
comment string
path_multiplier int

ARGUMENTS

-setup

Uses the specified *path_multiplier* for setup (maximum delay) calculations. Note that changing the *path_multiplier* for setup also affects the default hold check. If neither **-setup** nor **-hold** is specified, *path_multiplier* is used for setup calculations and 0 is used for hold calculations.

-hold

Uses the specified *path_multiplier* for hold (minimum delay) calculations. Note that changing the *path_multiplier* for setup also affects the default hold check. If neither **-setup** nor **-hold** is specified, *path_multiplier* is used for setup calculations and 0 is used for hold calculations.

-rise

Uses *path_multiplier* only for rising path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are affected. Rise refers to a rising value at the path endpoint.

-fall

Uses *path_multiplier* only for falling path delays. If neither **-rise** nor **-fall** is specified, both rising and falling delays are affected. Fall refers to a falling value at the path endpoint.

-start

Specifies that the multicycle information is relative to the period of the start clock. The **-start** and **-end** options are needed only for multifrequency designs; otherwise, start and end are equivalent. The start clock is the clock source related to the register or primary input at the path startpoint.

The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with **-start** moves the relation backward one cycle of the start clock. A hold multiplier of 1 with **-start** moves the relation forward one cycle of the start clock.

-end

Specifies that the multicycle information is relative to the period of the end clock. The **-start** and **-end** options are needed only for multifrequency designs; otherwise, start and end are equivalent. The end clock is the clock source related to the register or primary output at the path endpoint.

The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with **-end** moves the relation forward one cycle of the end clock. A hold multiplier of 1 with **-end** moves the relation backward one cycle of the end clock.

-reset_path

Removes the existing point-to-point exception information from the specified paths. If used with **-to** only, all paths leading to the specified endpoints are reset. If used with **-from** only, all paths leading from the specified startpoints are reset. If used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise/fall setup/hold type is reset. Using this option is equivalent to using the **reset_paths** command with similar arguments before issuing **set_multicycle_path**.

-from *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified, one path startpoint on that cell is affected. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of pins, ports, cells and nets through which the multicycle paths must pass. Nets are interpreted to imply the leaf-level driver pins. If you omit **-through**, all timing paths specified using the **-from** and **-to** options are affected. You can specify **-through** multiple times in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-rise_through *rise_through_list*

This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** multiple times in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-fall_through *fall_through_list*

This option is similar to the **-through** option, but applies only to paths with a fall transition at the specified objects. You can specify **-fall_through** multiple times in a single command invocation. For a discussion of multiple **-through**, **rise_through**, and **fall_through** options, see the DESCRIPTION section.

-to *to_list*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-comment *comment*

Specifies a user-defined comment.

path_multiplier

Specifies the integer number of cycles the data path must have for setup or hold, relative to the startpoint or endpoint clock, before data is required at the endpoint. For example, specifying a *path_multiplier* of 2 for setup implies a 2-cycle data path. If you use **-setup**, *path_multiplier* is applied to setup path calculations. If you use **-hold**, *path_multiplier* is applied to hold path calculations. If you do not specify either **-setup** or **-hold**, *path_multiplier* is used for setup and 0 is used for hold. Note that changing the multiplier for setup affects the hold check as well.

-comment *comment*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

This command specifies the number of cycles that the data path must have for setup or hold, so that designated timing paths in the current design have no default setup or hold relations.

Single cycle timing relationships are determined for paths between clocked elements; the rules are based on active edges. For flip-flops, a single active edge both launches and captures data. For latches, the open edge launches data and the close edge latches data.

The setup check ensures that the correct data signal is available on destination registers in time to be correctly latched. The default setup behavior, called single-cycle setup, is as follows:

For multifrequency designs, there can be multiple setup relations between two clocks. For every latch edge of the destination clock, the setup check determines the nearest launch edge that precedes each latch edge. The smallest value of (setup_latch_edge - setup_launch_edge) determines the maximum delay requirement for this path.

You can override this default relationship by applying **set_multicycle_path** or **set_max_delay** to clocks, pins, ports, or cells. For example, setting the setup path multiplier to 2 with the **set_multicycle_path** command delays the latch edge one clock pulse. Note that changing the setup multiplier also affects the default hold check.

Most often, the setup check moves relative to the end clock. This move changes the data latch time at the path endpoint. In multi-frequency designs, use **set_multicycle_path -setup -start** to move the data launch time backward. The hold check ensures that data from the source clock edge that follows the setup launch edge is not latched by the setup latch edge, and also ensures that data from the setup launch edge is not latched by the destination clock edge that precedes the setup latch edge.

The hold check is determined relative to each valid setup relationship, after applying multicycle path multipliers. The most restrictive (largest) difference of (hold_latch_edge - hold_launch_edge) is used as a minimum delay requirement for the path.

Important Note: The hold relation is conservative. In some cases you need to override the default hold relation. For multifrequency designs, it is more straightforward to use the **set_min_delay** command to override the default instead of using **set_multicycle_path -hold**.

There are separate setup and hold multipliers for rise and fall. In most cases, these are set to the same value. You can use the **-rise** or **-fall** option to apply different values.

The **set_multicycle_path** command is a point-to-point timing exception command. The command can override the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_max_delay**, **set_min_delay**, and **set_false_path**. False path information always takes precedence over multicycle path information. A specific **set_max_delay** or **set_min_delay** command overrides a general **set_multicycle_path** command.

The more general commands apply to more than one path; either **-from** or **-to** (but not both), or clocks are used in the specification. Within a given point-to-point exception command, the more specific command overrides the more general. The following list shows commands from highest to lowest precedence (more specific to more general):

1. set_multicycle_path -from *pin* -to *pin*
2. set_multicycle_path -from *pin* -to *clock*
3. set_multicycle_path -from *pin*
4. set_multicycle_path -from *clock* -to *pin*
5. set_multicycle_path -to *pin*
6. set_multicycle_path -from *clock* -to *clock*
7. set_multicycle_path -from *clock*
8. set_multicycle_path -to *clock*

You can use multiple **-through**, **-rise_through**, and **-fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If more than one object is specified within one **-through**, **-rise_through**, or **fall_through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

To undo a **set_multicycle_path** command, use the **reset_paths** command. The **reset_design** command removes all constraints and user settings from the design, including those set by **set_multicycle_path**.

To disable setup and hold calculations for paths, use **set_false_path**. To list the exceptions on a design, use **report_exceptions**.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example sets all paths between latch1b and latch2d to 2-cycle paths for setup. Hold is measured at the previous edge of the clock at latch2d.

```
prompt> set_multicycle_path 2 -from { latch1b } -to { latch2d }
```

The following example moves the hold check to the preceding edge of the start clock.

```
prompt> set_multicycle_path -1 -from { latch1b } -to { latch2d }
```

The following example is a two-phase level-sensitive design, where the designer expects paths from phi1 to phi1 to be zero cycles.

```
prompt> set_multicycle_path 0 -from phi1 -to phi1
```

The following example uses **-start** to specify a 3-cycle path relative to the clock at the path startpoint. Clock sources are specified, affecting all sequential elements clocked by that clock, or ports with input or output delay relative to that clock.

```
prompt> set_multicycle_path 3 -start -from { clk50mhz } -to { clk10mhz }
```

The following example sets all rising paths to ff12/D to 2 cycles, and falling paths to 1 cycle.

```
prompt> set_multicycle_path 2 -rise -to { ff12/D }
prompt> set_multicycle_path 1 -fall -to { ff12/D }
```

The following multifrequency example shows a 20ns clock to 10ns clock with multicycle path of 2. Assume a path from ff1 (clocked by CLK2) to ff2 (clocked by CLK1).

```
prompt> create_clock -period 20 -waveform {0 10} CLK2
prompt> create_clock -period 10 -waveform {0 5} CLK1
prompt> set_multicycle_path 2 -setup -from ff1/CP -to ff2/D
```

The single-cycle setup relation is from the CLK1 edge at 0ns to the CLK2 edge at 10ns. With the multicycle path, the setup relation is now 20ns (from CLK1 edge at 0ns to CLK2 edge at 20ns). The hold relations are determined according to that setup relation.

1. Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge. This implies a hold relation of 0ns (from CLK1 edge at 20ns to CLK2 edge at 20ns).

2. Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge. This implies a hold relation of 10ns (from CLK1 edge at 0ns to CLK2 edge at 10ns).

The most restrictive (largest) hold relation is used, so the minimum delay requirement for this path is 10ns. This is a conservative check which might not apply to certain designs. Often you know that the destination register is disabled for the clock edge at 10ns. You can modify this default hold relation with the following to get an 0ns requirement.

```
prompt> set_multicycle_path 1 -hold -end -from ff1/CP -to ff2/D
```

However, a simpler approach is to use the following:

```
prompt> set_min_delay 0 -from ff1/CP -to ff2/D
```

The following example sets all timing paths from ff1/CP to ff2/D which passe through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C} to 2 cycle paths for setup.

```
prompt> set_multicycle_path 2 -from ff1/CP -through {U1/Z U2/Z} \
  -through {U3/Z U4/C} -to ff2/D
```

SEE ALSO

reset_paths(2)
set_false_path(2)
set_max_delay(2)
set_min_delay(2)

set_multisource_clock_subtree_constraints

Defines constraints for structural synthesis of multisource clock tree synthesis (CTS) subtrees.

SYNTAX

status **set_multisource_clock_subtree_constraints**
[-name *name*]
-clock *clock_name*
[-cells *cell_list*]
[-pins *pins_or_ports*]
[-ignore_for_icg_reordering]
[-target_level *levels*]

Data Types

name string
clock_name string or collection
cell_list collection of cells
pins_or_ports list or collection
levels integer

ARGUMENTS

-name *name*

Specifies the structural multisource subtree set to be constrained. The **-name** option is optional. It allows you to reference multiple subtree sets per clock. Without this option, the set is named as the clock object. Names must be unique for all defined set of subtrees.

-clock *clock_name*

Specifies a clock which will be balanced for the specified set of subtrees. This option is required.

-cells *cell_list*

Specifies a collection of cells on which constraints such as "ignore for ICG reordering" will be applied. The constraints on the cells are honored by the **synthesize_multisource_clock_subtrees** command.

-pins *pins_or_ports*

Specifies a collection of pins on which constraints such as "target level" will be applied. The pins must be the sinks of the clock tree. The constraints on the pins are honored by the **synthesize_multisource_clock_subtrees** command.

-ignore_for_icg_reordering

Ignores cells specified by the **-cells** option during the integrated clock gating (ICG) reordering step for the

synthesize_multisource_clock_subtrees command. This option can only be used together with the **-cells** option.

-target_level ***levels***

Defines the exact number of levels in the **-pins** option to synthesize with the **synthesize_multisource_clock_subtrees** command. This option can only be used together with the **-pins** option. The minimum level value is 0, the maximum level is restricted to 100. A target level of 0 or level less than the existing level would mean the level would be maintained.

DESCRIPTION

The **set_multisource_clock_subtree_constraints** command applies synthesis constraints on cells or pins for structural multisource CTS synthesis with the **synthesize_multisource_clock_subtrees** command.

This command extends the **set_multisource_clock_subtree_options** command for setting cell- or pin-specific option or constraints.

To better control subtree logic level balancing, specify the **-target_level** option. To better control subtree synthesis transforms for ICG reordering, specify the **-ignore_for_icg_reordering** option.

If a setting has already been applied for a subtree set and is reapplied for the same set, then the new setting is additive to the existing list.

Use the **remove_multisource_clock_subtree_constraints** command to clear constraints set with the **set_multisource_clock_subtree_constraints** command. Use the **report_multisource_clock_subtree_constraints** command to report constraints set with the **set_multisource_clock_subtree_options** command. Use the **synthesize_multisource_clock_subtrees** command to synthesize the subtrees that are constrained by the **set_multisource_clock_subtree_constraints** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

This example specifies a target level for a pin.

```
prompt> set_multisource_clock_subtree_constraints \
  -clock [get_clock clk] -pins [get_pins {reg1/ck reg2/ck}] \
  -target_level 5
```

This example ignores ICG cells during ICG reordering in subtree synthesis:

```
prompt> set_multisource_clock_subtree_constraints \
  -clock [get_clock clk] -cells [get_cells {icg1 icg2}] \
  -ignore_for_icg_reordering
```

SEE ALSO

remove_multisource_clock_subtree_constraints(2)
remove_multisource_clock_subtree_options(2)
report_multisource_clock_subtree_constraints(2)

set_multisource_clock_subtree_options(2)
synthesize_multisource_clock_subtrees(2)

set_multisource_clock_subtree_options

Defines constraints for structural synthesis of multisource clock tree synthesis (CTS) subtrees.

SYNTAX

status **set_multisource_clock_subtree_options**
[-name *name*]
-clock *clock_name*
-driver_objects *pins_or_ports_or_nets*
[-max_total_wire_delay *wire_delay*]
[-corners *corner_list*]
[-dont_merge_cells *cell_list*]
[-balance_levels true | false]
[-target_level *levels*]
[-enable_icg_reordering true | false]

Data Types

name string
clock_name collection
pins_or_ports_or_nets collection
wire_delay float
corner_list collection
cell_list collection
levels integer

ARGUMENTS

-name *name*

Specifies the structural multisource subtree to constrain. During synthesis, sinks and clock logic can be assigned to any subtree within their set of driver objects, and all sinks in that set will be balanced together.

The **-name** option is optional. It allows the user to define multiple subtree sets per clock. Without this option the set is named as the clock object. Names must be unique for all defined set of subtrees.

-clock *clock_name*

Specifies a clock to balance for the specified set of subtrees. This option is required. All sinks reachable from the driver objects are balanced for only one clock.

If sinks in the set do not receive the specified clock, then an error will be issued when running the **synthesize_multisource_clock_subtrees** command.

-driver_objects *pins_or_ports_or_nets*

Specifies driver objects whose fanouts and sinks can be redistributed. This option is required. The driver object can be a standard cell output pin, a clock input port, or a net. If a net name is used, the driver pin of that net is inferred as the driver object.

For example, if clock buffers are driven by the clock mesh directly, then the output pins of these buffers can be specified as the driver objects. Alternatively, if a top-level mesh is pushed down to the block-level and the mesh straps act as the drivers themselves, the ports for each mesh strap can be specified as driver objects.

Each driver object should have a common clock propagating through it, because every subtree in a set is synthesized for one clock only.

-max_total_wire_delay ***wire_delay***

Specifies the maximum wire delay from any subtree driver to any sink reachable form the driver objects.

This value is an absolute amount of wire delay on the clock paths from the subtree driver to the sink, not a percentage. The wire delay is specified in time units as configured with the **set_user_units** command. By default, time is specified in nanoseconds.

If **-max_total_wire_delay** is specified, then **-corners** must also be specified to determine the corner or corners to which the total wire delay setting applies.

-corners ***corner_list***

Specifies the corner or corners to which the max_total_wire_delay constraint applies. This option has no meaning when paired with other options of this command. If **-max_total_wire_delay** is used, then corners is a required option.

-dont_merge_cells ***cell_list***

Specifies a collection of cells which should not be merged with other cells by the **synthesize_multisource_clock_subtrees** command.

-balance_levels true | false

Enables or disables level balancing. The default is false and level balancing is disabled.

-target_level ***levels***

Defines the number of levels to the sinks which the command **synthesize_multisource_clock_subtrees** should synthesize. This option can only be used together with the **-balance_levels** option. The minimum level value is 2 while the maximum is restricted to 100.

-enable_icg_reordering true | false

Reorders ICG cells with a driving buffer.

DESCRIPTION

The **set_multisource_clock_subtree_options** command applies synthesis constraints for structural multisource CTS synthesis using the **synthesize_multisource_clock_subtrees** command.

Typically, a multisource CTS approach involves some mesh, H-tree, or other global clock distribution structure that drives a collection of driver cells. Sometimes, there are no explicit driver cells, and the mesh straps themselves act as the driver objects. In either case, the clock trees after the driver objects are called subtrees, and this command is used to specify the implementation requirements on those subtrees.

Each subtree is driven by a unique driver object. Multiple subtrees can be grouped together for skew balancing and sink assignment across those subtrees.

This command performs four main functions:

- Defines set of subtrees for balancing and sink assignment
- Defines which clock to balance in each set
- Defines structural synthesis constraints for each set
- Defines the number of levels at which the sinks should be synthesized

First, subtree sets are defined by specifying their driver objects. These subtrees are balanced together during structural synthesis. The subtrees are also considered equivalent to each other when reassigning sinks to different subtrees. Any sink of any subtree in a set can be reassigned to another subtree of that set, based on the placement of the sinks and the driver objects.

The subtrees that belong to a set are defined by their driver objects as specified with the **-driver_objects** option. Each subtree has a single driver object. Driver objects are typically either the output pins of buffers attached to the mesh, or are clock input ports associated with pushed-down mesh topologies from the top-level design. In general, a driver object can be any clock cell output pin, clock input port, or clock net. If a clock net is used, then the driver pin of that net is considered the driver object.

With the **-driver_objects** and **-clock** options, subtrees should now be completely assigned into sets and the correct clock specified for balancing in each of those groups. Now constraints for each set can be defined.

You can define the maximum amount of wire delay on the path from any subtree driver to the sinks of that set of driver objects. This is specified with the **-max_total_wire_delay** option. The max_total_wire_delay setting is a time value specifying an absolute maximum amount of wire delay for each clock path. The **-corners** option is required if specifying **-max_total_wire_delay**, and is used to constrain for which corner or corners that maximum total wire delay value applies.

You can optionally enable level balancing of the subtrees. If a target level is not given by this command, the subtrees are buffered such that all sinks are at the same level, i.e. have the same number of clock cells on the path to its driver object. Use the **-target_level** option to explicitly define the number of levels.

If a particular setting has already been applied for a subtree set, and then it is applied again for the same set, then the original setting is overwritten by the new setting.

Use the **remove_multisource_clock_subtree_options** command to clear constraints that have been set with this command. Use the **report_multisource_clock_subtree_options** command to report constraints set with this command. Use the **synthesize_multisource_clock_subtrees** command to synthesize the subtrees, as constrained by this command.

EXAMPLES

This example assigns subtree driver objects to a clock.

```
prompt> set_multisource_clock_subtree_options -clock [get_clock clk] \
  -driver_objects [get_pins {driver1/Z driver2/Z}]
prompt> set_multisource_clock_subtree_options -clock [get_clock clk] \
  -max_total_wire_delay 0.300 -corners [get_corners {c1 c2}]
```

This example performs the exact same function as the two commands in the previous example. It illustrates that it's not necessary to split the constraints into separate command calls. All constraints are associated to the set, whether they are specified together or separately.

```
prompt> set_multisource_clock_subtree_options \
  -driver_objects [get_pins {driver1/Z driver2/Z}] \
  -clock [get_clocks clk] \
  -max_total_wire_delay 0.300 -corners [get_corners {c1 c2}]
```

This example shows an incorrect way to specify multiple driver objects for a given option set, and the correct way to specify the command. Each option can be applied to a clock one time; if called a second time, then the second setting overwrites the first.

```
## Incorrect second constraint overwrites the first
prompt> set_multisource_clock_subtree_options -clock clk \
  -driver_objects [get_pins driver1/Z]
prompt> set_multisource_clock_subtree_options -clock clk \
  -driver_objects [get_pins driver2/Z]
## Correct way to specify both driver objects together for the group
prompt> set_multisource_clock_subtree_options -clock clk \
  -driver_objects [get_pins {driver1/Z driver2/Z}]
```

This example excludes two cells from getting merged.

```
prompt> set_multisource_clock_subtree_options \
  -driver_objects [get_pins {driver1/Z driver2/Z}] \
  -clock [get_clocks clk] \
  -dont_merge_cells [get_cells {u1 u2}]
```

This example enables automatic level balancing.

```
prompt> set_multisource_clock_subtree_options \
  -driver_objects [get_pins {driver1/Z driver2/Z}] \
  -clock [get_clocks clk] \
  -balance_levels true
```

This example enables automatic level balancing with an explicit number of levels.

```
prompt> set_multisource_clock_subtree_options \
  -driver_objects [get_pins {driver1/Z driver2/Z}] \
  -clock [get_clocks clk] \
  -balance_levels true \
  -target_level 5
```

set_multisource_clock_tap_options

Defines constraints for multisource clock tap assignment

SYNTAX

status **set_multisource_clock_tap_options**
[-name *name*]
-clock *clock_name*
-driver_objects *pins_or_ports_or_nets*
-num_taps *value*
[-dont_merge_cells *cell_list*]
[-relax_split_restrictions_for_cells *cell_list*]

Data Types

name string
clock_name collection
pins_or_ports_or_nets collection
value integer
cell_list collection

ARGUMENTS

-name *name*

Specifies a name for the multisource tap option set being constrained. The name can be referenced durin tap assignment. The **-name** option is optional. It allows the user to define multiple option sets per clock. Without this option the constraint set is named as the clock object. Names have to be unique for all defined set of options.

-clock *clock_name*

Specifies a clock which will considered during tap assignment for the specified set of driver objects. This option is required. All sinks reachable form the driver objects for the given clock are reassigned during tap assignment.

If the driver objects do not receive the specified clock, then an error will be issued during **synthesize_multisource_clock_taps**.

-driver_objects *pins_or_ports_or_nets*

This required option specifies driver objects (tap drivers) whose fanouts and sinks can get redistributed among them. If a net name is used, then the driver pin of that net is inferred as the driver object.

For example, if tap driver buffers are driven by the clock mesh directly, then the output pins of the tap drivers could be specified as the driver objects. Alternately, if a top-level mesh is pushed down to the block-level and the mesh straps act as the drivers themselves, then the ports for each mesh strap can be specified as driver objects.

Each driver object should have some common clock propagating through it, because tap assignment is performed for one clock

only.

-num_taps *value*

Specifies the number of tap drivers to be used during tap assignment. For the current version of the tool, the specified value has to equal the number of driver objects. This option has been introduced to support future extensions of the tool where tap drivers will be automatically synthesized.

-dont_merge_cells *cell_list*

This option accepts a collection of cells which should not get merged with other cells by the tap assignment command.

-relax_split_restrictions_for_cells *cell_list*

This option accepts a collection of cells to be considered for splitting even if those cells are set with user_dont_touch/user_size_only. These cells will be split for optimization during tap assignment as required, similar to any other cell without user_dont_touch/user_size_only.

DESCRIPTION

The **set_multisource_clock_tap_options** command is used to apply tap assignment constraints for multisource CTS synthesis using the **synthesize_multisource_clock_taps** command.

Typically, a multisource CTS approach involves some mesh, H-tree, or other regular clock structure that drives a collection of tap driver cells. Sometimes, there may not be explicit tap driver cells, and the mesh straps themselves act as the tap drivers. In either case, the clock trees after the tap drivers are called subtrees, and this command is used to specify the tap drivers and constraints for tap assignment.

Each subtree is driven by a unique driver object, called a tap driver. Multiple subtrees can be grouped together for the purposes of skew balancing, and sink assignment across those subtrees.

This command performs two main functions:

Defines a set of tap drivers for sink assignment
Defines which clock to be considered for sink identification

The **-driver_objects** option defines a set of tap drivers (cell output pins or input ports) which are considered as equivalent for multisource CTS tap assignment. This means that any sink reachable from one of these tap drivers can be reassigned to one of the other driver objects.

By default, a set of tap drivers is named according to the specified clock. In case sets of tap drivers for a particular clock should be kept separate, then the \-name option can be used to distinguish the individual tap driver subsets.

If a particular setting has already been applied for an option set, and then it is applied again for the same option set, then the original setting is overwritten by the new setting.

When a list of cells is specified using the switch relax_split_restrictions_for_cells, tap assignment allows splitting of these cells even if they are set with user_dont_touch/user_size_only.This option is especially helpful with integrated tap assignment in place_opt for cases where certain cells are allowed to split during tap assignment while all other optimizations in place_opt/CTS must honour its user_dont_touch/user_size_only. These cells once split, will not be merged back if synthesize_multisource_clock_taps is called consecutively. Hence, user needs to ensure to use a pre-tap assignment block when exploring tap driver locations using multiple calls to synthesize_multisource_clock_taps.

The **remove_multisource_clock_tap_options** command can be used to clear constraints that have been set with this command.

The **report_multisource_clock_tap_options** command can be used to report constraints set with this command.

The **synthesize_multisource_clock_taps** command is used to synthesize the subtrees, as constrained by this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

This example shows a typical case of how tap driver objects can be assigned to a clock.

```
set_multisource_clock_tap_options -clock [get_clock clk]
 -driver_objects [get_pins {tap_driver1/Z tap_driver2/Z}]
 -num_taps 2
```

This example performs the exact same function as the previous example but makes use of a collection of pins.

```
set tap_drivers [get_pins {tap_driver1/Z tap_driver2/Z}]
set_multisource_clock_tap_options
 -driver_objects $tap_drivers
 -num_taps [sizeof_collection $tap_drivers]
 -clock [get_clocks clk]
```

This example excludes two cells from merging..

```
set_multisource_clock_tap_options
 -driver_objects $tap_drivers
 -num_taps [sizeof_collection $tap_drivers]
 -clock [get_clocks clk]
 -dont_merge_cells [get_cells {u1 u2}]
```

set_net_estimation_rule

Sets rules for estimating timing on nets.

SYNTAX

status **set_net_estimation_rule**
[-parameter *param_name*]
[-unset]
[-value *value*]
[-horizontal_value *value*]
[-vertical_value *value*]
[-cell *cell*]
rule_name

Data Types

rule_name
param_name string
value string
rule_name string
cell collection

ARGUMENTS

rule_name

Specifies the name of a net estimation rule to set. If you call **set_net_estimation_rule** repeatedly for the same name, you can set or unset various parameter in the rule.

-parameter *param_name*

Specifies a parameter to set or unset. A summary of the available parameters is listed in the "Parameters" section below.

-unset

Removes a manually set value for a rule parameter. This option must be accompanied by *-parameter*.

-value *value*

Sets a value for the given parameter. The value will apply to both horizontal and vertical segments of the nets. Note that different parameters require different kinds of values. Some parameters have string values and others are floating point numbers. This option must be accompanied by *-parameter*.

-horizontal_value *value*

Sets a value for the given parameter. The value will apply only to horizontal segments of the nets. Note that different parameters

require different kinds of values. Some parameters have string values and others are floating point numbers. This option must be accompanied by *-vertical_value* and *-parameter*.

-vertical_value *value*

Sets a value for the given parameter. The value will apply only to vertical segments of the nets. Note that different parameters require different kinds of values. Some parameters have string values and others are floating point numbers. This option must be accompanied by *-horizontal_value* and *-parameter*.

-cell *cell*

Specifies the physical cell for which to create/set the net estimation rule.

By default, the current block is used to set/create the specified net estimation rule.

DESCRIPTION

This command defines parameters to be used when doing timing analysis on nets. The parameters are used, for example, to determine the proper spacing of flip-flops on a pipelined route. Using this command you can specify parameter values for some or all of the parameters described below in the "Parameters" section of this man page.

You can optionally choose to leave some parameters unspecified. In that case, the tool will derive intelligent values for you. For example, if you specify a metal layer to use, the tool can automatically derive the resistance of the wire. The derivation methods are described below.

Whether parameters are manually specified or derived automatically, you can query the parameter values using the **report_net_estimation_rules** or **get_net_estimation_rules** commands. So you can use the **set_net_estimation_rule command** to explore different net configurations. For example, you could explore the effects of changing metal layers on your register spacing.

Note that net estimation rules are only supported for certain tool features. Currently, 2 features support the net estimation rule. Pipeline register planning, using command **create_busplans** supports the net estimation rule and virtual optimization using command **estimate_timing** supports the net estimation rule. In the near future other features will support this. Consult the specific tool feature you are using to determine what exactly is supported.

NET ESTIMATION RULES AND HIERARCHY

Net estimation rules can be created in any physical block at any level of the hierarchy and multiple blocks can have different rules with the same name. However, rules are often stored/retrieved by name, and doing this can cause confusion as to which rule is being used by a given command. Generally, the "current" (top) block's list of rules is searched by commands such as *estimate_timing*. This means that if you define rule R1 in "top" and rule R1 in block "B1", if you make block B1 the current block, commands will use B1's R1. When you go back to top, top's R1 is used. To avoid confusion, use globally unique rule names and define them at the top - they will be propagated to child blocks during distributed commands as necessary. Rules in child blocks that have the same name as rules in top may also be overwritten during distributed commands.

Parameters

layer

Specify the preferred metal layer on which the nets should be routed. The value should be the name of a routing layer in your technology. You can set a different value for horizontal and vertical. If you do not set a value, the middle layer of the current min and max routing layers will be used.

utilization

Specify the routing utilization that should be assumed for the metal layer you have chosen. The value should be a floating point

number between 0 and 1.0, where 1.0 is 100% utilization. You can set a different value for horizontal and vertical. If you do not set a value, 0.7 will be assumed.

delay_derate

Specify a derating factor for ns_per_mm. You must not specify a separate value for horizontal and vertical. If you do not set a value, default is 1.

sdc_stage_delay

Specify the clock period minus clock uncertainty. You must not specify a separate value for horizontal and vertical. If you do not set a value it will be derived based on the clock parameter.

ndr

Specify an NDR routing rule to be used by your nets wires. The value should be the name of an existing NDR rule. You must not specify a separate value for horizontal and vertical. If you do not set a value, the default routing rule will be used.

corner

Specify the optimization corner to be used when analyzing nets. You must not specify a separate value for horizontal and vertical. If you do not set a value, the slowest active corner will be used.

ff_per_mm

Specify a value for the capacitance of your nets wires (in ff per mm). You can set a different value for horizontal and vertical. If you do not set a value, the value will be derived based on the metal layer, ndr rule, corner, xtalk_fraction, and utilization.

ohms_per_mm

Specify a value to set the resistance of your nets wires (in ohms per mm). You can set a different value for horizontal and vertical. If you do not set a value, the value will be derived based on the metal layer, ndr rule, corner, and utilization.

buffer

Specify the buffer or inverter that you would like along your nets. The value should be the name of a buffer or inverter in your library. You must not specify a separate value for horizontal and vertical. If you do not set a value, a good buffer will automatically be chosen based on your corner, ff_per_mm, ohms_per_mm.

buffer_spacing

Specify the amount of distance that you want between the buffers on your nets (in microns). You can specify a separate value for horizontal and vertical. If you do not set a value, an optimal value will be calculated based on your corner, ff_per_mm, ohms_per_mm and buffer.

buffer_pattern

Specify the buffer pattern name (string) uesd to insert buffers into the corresponding topology edge. Separate horizontal and vertical buffer patterns are supported, or they can both be the same.

ns_per_mm

Specify the speed of propagation along a buffered net (in ns per mm). This will include both buffer delay time and wire delay time. You can specify a separate value for horizontal and vertical. If you do not set a value, the value will be calculated based on your corner, ff_per_mm, ohms_per_mm, buffer, delay_derate, and buffer_spacing.

clock

Specify the name of the clock used by registers along your path. You must not specify a separate value for horizontal and vertical. If you do not set a value, the value will be net specific and will be taken from the clock on the flip-flop that drives the net (if available).

stage_margin

Specify extra timing margin in pipeline stages along a path (in ns). You must not specify a separate value for horizontal and vertical. If you do not set a value, zero will be assumed.

register

Specify the name of the flip-flop to use for pipeline stages along your path. You must not specify a separate value for horizontal and vertical. If you do not set a value, an ideal register (no delay) will be assumed for timing calculations.

register_spacing

Specify the maximum spacing of flops along a pipeline path. You can set a different value for horizontal and vertical. If you do not set a value, the value will be derived based on the corner, register, clock, stage_margin, and ns_per_mm.

register_pattern

Specify the register pattern name (string) uesd to insert registers into the corresponding topology edge. Separate horizontal and vertical register patterns are supported, or they can be the same.

launch_block_budget

Specify the delay used inside of your driving block before reaching the block's output pin. You must not set a different value for horizontal and vertical. If you do not set a value, the value will zero.

capture_block_budget

Specify the delay used inside of your load block after reaching the block's input pin. You must not set a different value for horizontal and vertical. If you do not set a value, the value will zero.

EXAMPLES

The following example sets the corner parameter for the net estimation rule named rule1.

```
prompt> set_net_estimation_rule rule1 -parameter corner -value WCCOM
```

The following example sets the layer parameter for the net estimation rule named rule1.

```
prompt> set_net_estimation_rule rule1 -parameter layer \
  -horizontal_value M4 -vertical_value M5
```

The following example sets the buffer parameter for the net estimation rule named rule1.

```
prompt> set buffer BUFX8
prompt> set_net_estimation_rule rule1 -parameter buffer -value $buffer
```

The following example sets the buffer and layer parametesr for the net estimation rule named rule1, and then set rule1 as the *estimate_timing_net_rule* attribute for net n101 so *estimate_timing* would use the *ns_per_mm* value of rule1 to estimate the delay on net n101.

```
prompt> set buffer BUFX8
prompt> set_net_estimation_rule rule1 -parameter buffer -value $buffer
prompt> set_net_estimation_rule rule1 -parameter layer \
  -horizontal_value M4 -vertical_value M5
prompt> set_attribute -name estimate_timing_net_rule -value rule1 [get_nets n101]
prompt> estimate_timing
```

set_net_type

Set the net type of a net.

SYNTAX

status **set_net_type**
-net *net*
-type *net_type*

Data Types

net collection
net_type string

ARGUMENTS

-net *net*

Specifies the net whose type will be set. This is a mandatory option.

-type *net_type*

Specifies the type of the net. Allowed values are *analog_ground*, *analog_power*, *analog_signal*, *clock*, *deep_nwell*, *deep_pwell*, *ground*, *nwell*, *power*, *pwell*, *reset*, *scan*, *signal*, *tie_high*, *tie_low and unset. This is a mandatory option.*

DESCRIPTION

The **set_net_type** command sets the net type of the given net by changing the net type of all the segments of that net.

EXAMPLES

The following example sets the net type of the net u1/i1 to power.

prompt> **set_net_type -net u1/i1 -type power**

SEE ALSO

set_attribute(2)

set_net_weight_effort

Sets the net weight effort for coarse placement.

SYNTAX

status **set_net_weight_effort**
-nets *collection_of_nets*
-weight_effort low | medium | high | ultra | none
-virtual_flat
-verbose

Data Types

collection_of_nets collection

ARGUMENTS

-nets *collection_of_nets*

Specifies the collection of nets for setting the weight effort.

-weight_effort low | **medium** | **high** | **ultra** | **none**

Specifies the weight effort to be used in coarse placement. The default for a net is low. If set to "none", the placer will ignore the net.

-virtual_flat

Propagate the net weight on the input top-level net to associated segments of the same flat net in all child blocks.

-verbose

If true, output further information about nets (such as which dangling nets are being skipped).

DESCRIPTION

The **set_net_weight_effort** command sets the net weight effort on nets for coarse placement. Note that effort might not always be strictly followed for high-fanout nets or for situations with other competing priorities, such as density, exist. Use the **report_net_weight_effort** command to list weight efforts for nets, and the **remove_net_weight_effort** command to remove them.

EXAMPLES

The following example sets the net weight effort for the net n123 to medium.

```
prompt> set_net_weight_effort -nets [get_nets n123] -weight_effort medium
```

SEE ALSO

remove_net_weight_effort(2)
report_net_weight_effort(2)

set_noise_margin

Specifies the noise margin for a library pin, port, or pin.

SYNTAX

status **set_noise_margin**
[-above]
[-below]
[-low]
[-high]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
margin_value
object_list

Data Types

mode_list list
corner_list list
scenario_list list
margin_value float
object_list list

ARGUMENTS

-above

Specifies the noise margin for above ground or power rail noise analysis region.

-below

Specifies the noise margin for below ground or power rail noise analysis region.

-low

Specifies the noise margin for ground rail noise.

-high

Specifies the noise margin for power rail noise.

-modes *mode_list*

Specifies the scenarios on which to set the noise margin value. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose

mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners ***corner_list***

Specifies the scenarios on which to set the noise margin value. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios ***scenario_list***

Specifies the scenarios on which to set the noise margin value. The **-modes** or **-corners** option must not be given with this option.

margin_value

Specifies a margin value. The value is the input height in voltage units.

object_list

Specifies a list of library pins, ports, or pins.

DESCRIPTION

Each library cell input can tolerate a certain amount of noise without causing a failure at the cell output. This characteristic is called noise immunity. This command specifies noise immunity at library pins to determine whether noise failures occur as well as the amount of noise slack.

Noise immunity in the library can be specified as noise immunity curves, polynomials, or tables or in terms of noise margins.

This command specifies a noise margin for a library pin, design port, or pin. It can be used in the absence of library-specified noise immunity characteristics, or to override the library-specified characteristics by replacing them with noise margins. For a library pin, this command is set for current corner when without **-corners** option, and only supports **-corners** option to specify corners. For a design port or pin, this command is for current scenario when without **-scenarios**, **-corners** and **-modes** options, or using the three options to specify scenarios.

Noise margins consider only the bump heights at the cell inputs. Using height-only noise margins are faster and more conservative than the other methods.

For high, narrow noise bumps, using height-only noise margins is pessimistic because it treats some bumps as noise failures that would otherwise pass with the immunity curve model. However, for wide noise bumps, using noise margins gives the same results as using noise immunity curves.

Noise immunity characteristics can vary for different noise bump types, so there can be four different noise margins associated with each input: below low, above low, below high, and above high. Specify all values as positive numbers for all four types of noise bumps.

EXAMPLES

This example specifies a noise margin of 4 for above-the-ground rail noise for the A pin of the IV library cell in the lsi_10k library:

prompt> **set_noise_margin -above -low 4 lsi_10k/IV/A**

SEE ALSO

remove_noise_margin(2)

set_object_layer

Sets the layer(s) of different objects in the current design.

SYNTAX

collection **set_object_layer**
[-force]
-of_objects collection
-layers collection

ARGUMENTS

-force

Ignore locked status of the objects. If this option is not provided and any of the affected objects has locked status, command will fail generating tcl error.

-of_objects *collection*

Specifies the collection of objects whose layer needs to be modified. This can be a list of strings or output of *get_* commands.

-layers *collection*

Specifies the collection of layers. This can be a list of strings or output of *get_layers* command.

DESCRIPTION

The **set_object_layer** command enables you to modify the layers of some of the objects. The type of objects whose layer can be modified are shapes, terminals, pin_blockages, pin_guides, routing_blockages and routing_guides.

Changing layer of shapes and terminals creates a new shape object and deletion of existing shape. For terminals, the new shape object is attached to the terminal. For shapes, terminals and routing blockages only the first layer is picked from the collection of layers specified.

EXAMPLES

The following example sets layer of shape RECT_32 to METAL2. The RECT_32 shape will no longer exist. A new shape will be created and returned by the command.

prompt> **set_object_layer -of_objects [get_shapes RECT_32] \ -layers METAL2**

The following example sets layer of routing blockage RB_11 to METAL2 and layers of pin guide PG_10 to METAL2 and METAL3.

prompt> **set_object_layer -of_objects "RB_11 PG_10" \ -layers "METAL2 METAL3"**

set_object_shape

Sets the shape of a set of objects to one of the standard rectilinear shapes.

SYNTAX

status **set_object_shape**
-shape *shape_type*
-lengths *list_of_lengths*
[-utilization *utilization*]
[-area *area*]
[-keep_area]
[-rotate 0 | 90 | 180 | 270 | CW90 | CW180 | CW270 | CCW90 | CCW180 | CCW270 | FLIPX | FLIPY]
[*object_list*]

Data Types

shape_type string
list_of_lengths list
utilization real
area real
object_list collection or selection

ARGUMENTS

object_list

Collection or selection set containing objects to set the shape. If this option is not specified, the global selection set is used.

-shape *shape_type*

This is either a rectangular (**rect**), L (**l**), T (**t**), U (**u**), or cross (**cross**) shape.

Only objects that can be resized can be set to a **rect** shape.

Only objects that can be rectilinear can be set to a **l**, **t**, **u**, or **cross** shape.

This is a required option.

-lengths *lengths*

Specifies the absolute lengths in microns or length ratios of the sides of the shape.

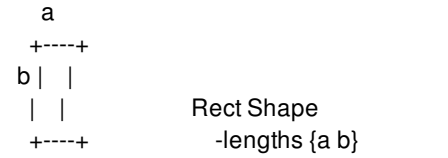
Absolute lengths are assumed unless you use one of the following options: **-utilization**, **-area**, or **-keep_area**.

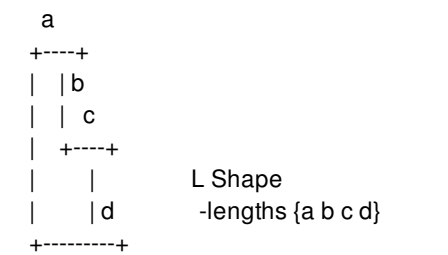
If you specify length ratios, the resultant shape has sides with the corresponding ratios. For example, if the ratios are all one, all lengths are the same. If one ratio is two and the others are one, that side is twice as long as the others.

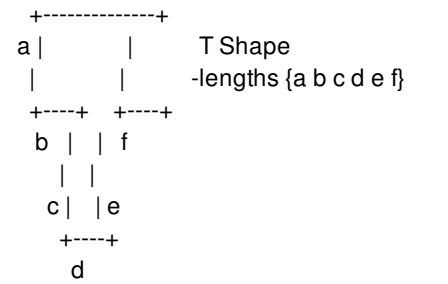
Each shape requires a different number of values as described below:

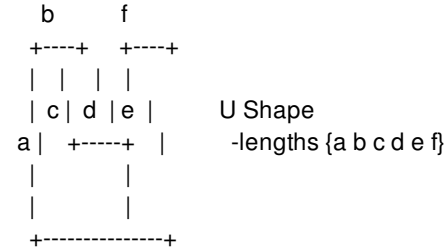
- rect - requires 2 values
- l - requires 4 values
- t - requires 6 values
- u - requires 6 values
- cross - requires 6 values

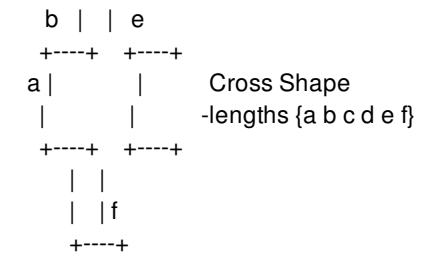
See the following diagrams for a cross reference between length parameter positions in the list and the corresponding edge on each shape, where a is first value, b is second value, and so on:











This is a required option.

-utilization ***utilization***

Specifies that the new shape should have the specified utilization.

Utilization is defined as the physical_area divided by the placement area and is most commonly used for placement objects and utilization where the enclosed area can be larger than the associated child physical objects.

Utilization must be positive and nonzero.

Note: This implies that lengths are ratios and not absolute values.

-area ***area***

Specifies that the new shape should have the specified area.

Note: This implies that lengths are ratios and not absolute values.

The default is 1.0.

-keep_area

Specifies that the new shape should have the same area as the current object.

Note: This implies that lengths are ratios and not absolute values.

-rotate 0 | **90** | **180** | **270** | **CW90** | **CW180** | **CW270** | **CCW90** | **CCW180** | **CCW270** | **FLIPX** | **FLIPY**

Specifies that the base shape is geometrically rotated from the default orientation (see the diagram above) before being applied to the object.

Note: This option cannot be used with the **-shape rect** option.

The default is 0.

DESCRIPTION

This command sets the shape of the boundary of one or more objects.

EXAMPLES

The following example sets the boundary of the selected objects to an L shape with all sides of equal length and a utilization of 0.7.

```
prompt> set_object_shape -shape l -lengths {1 1 1 1} -utilization 0.7
```

The following example uses an alternate syntax to specify an L shape for the current collection of selected objects.

```
prompt> set_object_shape [get_selection] -shape l -lengths {1 1 1 1} -utilization 0.7
```

SEE ALSO

get_selection(2)
change_selection(2)

set_operating_conditions

Specifies the operating conditions that are used to establish the process number, voltage, and temperature for the current corner of the current design.

SYNTAX

status **set_operating_conditions**
[-analysis_type single | bc_wc | on_chip_variation]
[-library *lib*]
[*condition*]
[-min *min_condition*]
[-max *max_condition*]
[-min_library *min_lib*]
[-max_library *max_lib*]
[-object_list *objects*]

Data Types

lib	collection
condition	string
min_condition	string
max_condition	string
min_lib	collection
max_lib	collection
objects	list

ARGUMENTS

-analysis_type single | bc_wc | on_chip_variation

This option is ignored, as the tool always uses the **on_chip_variation** analysis type.

-library *lib*

Specifies the library that contains the definitions of the operating conditions to be used. This is either a library name or a collection object. If the name refers to a logic library file, the command uses the reference library that was built from that logic library.

condition

Specifies the name of the operating condition use for both minimum and maximum delays and hold violations.

-min *min_condition*

Specifies the operating condition used for checking minimum delays and hold violations.

If you use this option, you must also use the **-max** option.

-max ***max_condition***

Specifies the operating condition used for checking maximum delays and setup violations.

If you use this option, you must also use the **-min** option.

-min_library ***min_lib***

Specifies the library that contains the minimum operating condition. This is either a library name or a collection object. If the name refers to a logic library, the command uses the reference library that was built from that logic library.

If you use this option, you must also use the **-min** option.

-max_library ***max_lib***

Specifies the library that contains the maximum operating condition. This is either a library name or a collection object. If the name refers to a logic library, the command uses the reference library that was built from that logic library.

If you use this option, you must also use the **-max** option.

-object_list ***objects***

Specifies the cells or ports on which to set the operating conditions.You can specify both leaf cells and hierarchical blocks.

If you do not use this option, operating conditions are set on the design.

You cannot use this option with the **-analysis_type** option.

DESCRIPTION

Specifies the operating conditions that are used to establish the process number, voltage, and temperature for the current corner of the current design. The tool treats an operating condition as an alias for a set of values for process number, voltage, and temperature.

The specified operating conditions must be defined in one of the reference libraries specified in the **-library** option, the **-min_library** option (for the minimum operating condition only), or the **-max_library** option (for the maximum operating condition only).

Operating conditions set by using the **-object_list** option override the operating conditions set on the design or on higher levels of hierarchy.

You can also specify the desired PVT parameters with the **set_process_label**, **set_process_number**, **set_voltage**, and **set_temperature** commands. You should avoid using the **set_operating_conditions** command for new designs, and use the commands mentioned above instead. Reference libraries can contain multiple operating conditions with the same name, which were obtained from the various logic libraries used to build them.

If you do not specify any operating conditions or PVT parameters for a design, the tool uses the default PVT conditions of the library to which the cell is linked.

To view the operating conditions and other PVT parameters being used for any particular corner, use the **report_corner** command. To view the operating conditions defined in a particular library, use the **report_lib** command. To view the PVT parameters appplicable to any particular cell or block, use the **report_cell** or **report_pvt** commands.

To remove the operating condition settings from a corner, use the **remove_sdc** or **reset_design** command.

Multicorner-Multimode Support

This command works only on the current corner.

set_optimize_registers

Adds (or removes) retiming on specific modules during the **compile** command

SYNTAX

int **set_optimize_registers**
[-modules *module_list*]
[-print_critical_loop]
[-justification_effort low | medium | high]
[true | false]

Data Types

module_list collection

ARGUMENTS

-modules *module_list*

Specifies a collection of modules that should (or should not) be retimed during the **compile** command. The default is the module of the current design.

-print_critical_loop

Indicates that the critical loop of the design, as seen during retiming, is to be displayed. The critical loop is defined as the sequence of directly-connected combinational and sequential cells whose total combinational delay divided by the number of registers in the loop has a higher value than any other loop in the design. The critical loop limits the minimum clock period that can be achieved by retiming. Use this option to help troubleshoot problem areas of the design if the intended clock period cannot be achieved with the given number of sequential cells in the design. If you are pipelining a data path, you might need to add pipeline stages in the HDL code.

-justification_effort low | medium | high

Specifies the justification effort level that is to be used during backward justification of registers. You can specify a value of low, medium, or high. Specifying low ensures that justification terminates very quickly, but the QoR may be bad. Specifying medium provides good QoR with considerable runtime. Specifying high provides the best QoR without any regard for runtime. The default value for this option is **medium**.

true | false

For a given set of modules, the value **true** adds retiming to the **compile** command's optimizations, and the value **false** removes retiming from the **compile** command's optimizations. The default is *true*.

DESCRIPTION

The **set_optimize_registers** command adds retiming to the **compile** command's optimizations for a specified set of modules.

Retiming is a sequential optimization that moves registers across combinational logic to meet a target clock period or, if that is not possible, to minimize negative slack. Retiming raises the level of design abstraction: RTL modules targeted for retiming need not be pipelined explicitly but instead can be described as combinational datapaths with banks of registers at the I/Os. Such RTL-style increases the area reduction opportunities for many optimizations, especially datapath extraction. Since retiming occurs at the gate-level instead the RTL operator-level, it can often find solutions that are difficult or impossible to express in RTL. Retiming is ideally suited for balancing multiple pipeline stages within combinational logic and hence is primarily applicable to datapath blocks.

When retiming is invoked during the **compile** command, the target clock period is extracted from the timing requirements of the module being retimed. Within a targeted module, retiming may create new and/or remove existing registers.

To remove retiming from the **compile** command's optimizations, execute the **set_optimize_registers** command with the last parameter set to **false**.

EXAMPLES

In the following example, retiming is enabled on the module **TEST**.

prompt> **set_optimize_registers -modules [get_modules TEST]**

In the following example, retiming is enabled on the current design and disabled on the module **OLD**.

prompt> **set_optimize_registers**

prompt> **set_optimize_registers -modules [get_modules OLD] false**

set_output_delay

Sets output path delay values for the current design.

SYNTAX

string **set_output_delay**
[-clock *clock_name*]
[-reference_pin *pin_port_name*]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-group_path *group_name*]
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
delay_value
port_pin_list

Data Types

clock_name list
pin_port_name list
group_name string
mode_list list
corner_list list
scenario_list list
delay_value float
port_pin_list list

ARGUMENTS

-clock *clock_name*

Specifies the name of a clock to which to relate the specified delay. If you specify **-clock_fall**, you must also specify **-clock**.

-reference_pin *pin_port_name*

Specifies the clock pin or port to which to relate the specified delay. If you use this option, and if propagated clocking is being used, the delay value is related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The options **-network_latency_included** and **-source_latency_included** cannot be used together with the **-reference_pin** option. For ideal clock network, the delay is the sum of source latency and network latency applied.

The pin specified with the **-reference_pin** option should be a leaf pin or port in a clock network, in the direct or transitive fanout of a clock source specified with the **-clock** option. If multiple clocks reach the port or pin where you are setting the input delay, and if the **-clock** option is not used, the command considers all of the clocks.

-clock_fall

Specifies that the delay is relative to the falling edge of the clock. If you specify **-clock_fall** with **-reference_pin**, the delay is relative to the falling transition of the reference pin. If you specify **-clock**, the default is the rising edge or the rising transition of the reference pin. If you specify **-clock_fall**, you must also specify **-clock**.

-level_sensitive

Specifies that the destination of the delay is a level-sensitive latch. The tool derives the setup and hold relationships for paths to this port as if it were a level-sensitive latch. If you do not use **-level_sensitive**, the output delay is treated as if it were a path to a flip-flop.

-rise

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If you do not specify **-rise** or **-fall**, rising and falling delays are assumed to be equal.

-fall

Specifies that *delay_value* refers to a falling transition on the specified ports of the current design. If you do not specify **-rise** or **-fall**, rising and falling delays are assumed to be equal.

-max

Specifies that *delay_value* refers to the longest path. If you do not specify **-max** or **-min**, maximum and minimum output delays are assumed to be equal.

-min

Indicates that *delay_value* refers to the shortest path. If you do not specify **-max** or **-min**, maximum and minimum output delays are assumed to be equal.

-add_delay

Specifies that delay information is to be added to the existing output delay, instead of overwriting the output delay. Using **-add_delay**, you can capture information about multiple paths leading from an output port that are relative to different clocks or clock edges. For example, **set_output_delay 5.0 -max -rise -clock phi1 {OUT1}** removes all other maximum rise output delays from **OUT1**, because **-add_delay** is not specified. Other output delays with a different clock or with **-clock_fall** are removed.

In another example, **-add_delay** is specified: **set_output_delay 5.0 -max -rise -clock phi1 -add_delay {Z}**. If there is an output maximum rise delay for Z relative to the clock phi1 rising edge, the larger value is used. The smaller value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is a maximum rise output delay relative to a different clock or different edge of the same clock, it remains with the new delay.

-network_latency_included

Specifies whether the clock network latency should not be added to the output delay value. If this option is not specified, the clock network latency of the related clock will be added to the output delay value. It has no effect if the clock is propagated or the output delay is not specified with respect to any clock.

-source_latency_included

Specifies whether the clock source latency should not be added to the output delay value. If this option is not specified, the clock source latency of the related clock will be added to the output delay value. It has no effect if the output delay is not specified with respect to any clock.

-group_path ***group_name***

Specifies the name of a group into which paths ending at the specified ports or pins are to be added. If the group does not already exist, one is created. This is equivalent to specifying the separate command **group_path -name group_name -to port_pin_list** in addition to **set_output_delay**. If you do not specify **-group_path**, the existing path grouping does not change.

-modes ***mode_list***

Applies the delay value to the specified scenarios. If this option is given, all scenarios of the given modes will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by a **-corners** will be used.

-corners ***corner_list***

Applies the delay value to the specified scenarios. If this option is given, all scenarios of the given corners and the current mode will be used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are given, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** will be used.

-scenarios ***scenario_list***

Specifies the scenarios that the delay value will be applied to. The **-modes** or **-corners** option must not be specified with this option.

delay_value

Specifies the path delay in units consistent with the technology library used during analysis. The *delay_value* represents the amount of time before a clock edge that the signal is required. For maximum output delay, this represents a combinational path delay to a register plus the library setup time of that register. For minimum output delay, this value is usually the shortest path delay to a register minus the library hold time.

port_pin_list

Specifies a list of output port or internal pin names in the current design to which *delay_value* is assigned. If more than one object is specified, the objects are enclosed in braces ({}).

DESCRIPTION

This command sets output path delay values for the current design. The input and output delays characterize the operating environment of the current design when used with **set_load** and **set_driving_cell**.

The **set_output_delay** command sets output path delays on output ports relative to a clock edge. Output ports have no output delay unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay to a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the output delay relative to the rising clock edge. If the latch is negative-enabled, set the output delay relative to the falling clock edge. If time is borrowed at that latch, subtract that time from the path delay to the latch when determining output delay.

The tool adds input delay to path delay for paths starting at primary inputs and to output delay for paths ending at primary outputs.

The **-group_path** option modifies the path grouping. Path grouping affects the maximum delay cost. The worst violator within each group adds to the cost.

If a reference pin is not reachable by any given clock, zero arrival time is assumed. If no clock is specified with a reference pin and

this reference pin is not reachable by any clock, an unconstrained path is reported. This behavior is changed after X0506. The new behavior is these invalid constraints will be ignored and path will be constrained by whatever it should be as if no such constraints are defined at all. The **check_timing** command generates a warning if the reference pin is not reachable by any active clock, or if multiple clocks reach the reference pin and no clock is specified in the command.

Output delays are managed on a per-scenario basis. For designs with multiple scenarios, you can specify different delays for different scenarios by using **-modes**, **-corners**, and **-scenarios** options.

By default, if none of these options are specified, the given delay is applied to the current scenario. It is an error if there is no current scenario. If the **-scenarios** option is given, the delay will be applied to all of the specified scenarios. If the **-modes** option is given, the delay will be applied to all scenarios of the specified modes. It is an error if none of the specified modes have any scenarios. If the **-corners** option is given, the delay will be applied to all scenarios of the specified corners and the current mode. It is an error if none of the specified corners have any scenarios with the current mode. If both the **-modes** and **-corners** options are given, the delay will be applied to all scenarios of the specified corners and the specified modes. It is an error if there are no such scenarios. It is an error to specify **-scenarios** with **-modes** or **-corners**. To list output delays associated with ports, use **report_ports**.

To remove output delay values, use **remove_output_delay** or **reset_design**. To modify paths grouped with the **-group_path** option, use the **group_path** command to place the paths in another group or the default group.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example sets an output delay of 1.7 relative to the rising edge of CLK1 for all output ports in the design.

```
prompt> set_output_delay 1.7 -clock CLK1 [ all_outputs ]
```

The following example sets the input and output delays for the bidirectional port INOUT1. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall { INOUT1 }
prompt> set_output_delay 1.4 -clock CLK2 { INOUT1 }
```

The following example models the situation where there are three paths from output port OUT1. One of the paths is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The **-add_delay** option indicates that new output delay information does not cause the removal of old information.

```
prompt> set_output_delay 2.2 -max clock CLK1 -add_delay { OUT1 }

prompt> set_output_delay 1.7 -max clock CLK1 -clock_fall -add_delay { OUT1 }

prompt> set_output_delay 4.3 -max clock CLK2 -clock_fall -add_delay { OUT1 }
```

In the following example, two different maximum delays and two minimum delays for port Z are specified using **-add_delay**. Because the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained (in this case, 5.0 and 1.1). If **-add_delay** is not used, the new information overwrites the old information.

```
prompt> set_output_delay 3.4 -max -clock CLK1 -add_delay { Z }

prompt> set_output_delay 5.0 -max -clock CLK1 -add_delay { Z }
```

prompt> **set_output_delay 1.1 -min -clock CLK1 -add_delay { Z }**

prompt> **set_output_delay 1.3 -min -clock CLK1 -add_delay { Z }**

The following example uses the **-group_path** option to add ports into a named group. Note that without this option, paths to these ports are included in the CLK group.

prompt> **set_output_delay 4.5 -max -clock CLK -group_path busA {busA[*]}**

set_parasitic_parameters

Sets parasitic parameters such as parasitic spec (TLU+) and temperature.

SYNTAX

string **set_parasitic_parameters**
[-corners *corners*]
[-early_spec *early_spec*]
[-early_temperature *early_temperature*]
[-late_spec *late_spec*]
[-late_temperature *late_temperature*]
[-library *library_name*]

Data Types

corners list
early_spec string
early_temperature float
late_spec string
late_temperature float
library_name string

ARGUMENTS

-corners

Sets the parasitic parameter to the constraint corner. If this option is not specified, current conrer will be applied.

-early_spec *early_spec*

Specifies the early parasitic tech specification name.

-early_temperature *early_temperature*

Specifies the early temperature value.

-late_spec *late_spec*

Specifies the late parasitic tech specification name.

-late_temperature *late_temperature*

Specifies the late temperature value.

-library *library_name*

Specifies the library name that contains the specified parasitic specification.

DESCRIPTION

Sets the parasitic parameters required for RC extraction. The command associates the parasitic parameters with the default constraint corner or a list of constraint corners.

Multicorner-Multimode Support

EXAMPLES

The following example sets parasitic parameters to the current constraint corner.

```
prompt> set_parasitic_parameters -early_spec file.tlup -early_temperature 25
1
```

set_parasitics_derate

Sets parasitic derating factors that influence extraction for DR/GR/CTO/RDE. Basically, most options are in aglignment with PrimeTime behavior.

SYNTAX

string **set_parasitics_derate**
[-corners *corners*]
[-ground_capacitance_factor *gcap_scale*]
[-coupling_capacitance_factor *ccap_scale*]
[-resistnace_factor *res_scale*]
[-cap_scale_by_layer *layer_cap_scale*]
[-ccap_scale_by_layer *layer_coupling_cap_scale*]
[-res_scale_by_layer *layer_res_scale*]
[-min | -max]
[-data | -clock]

Data Types

corners	list
gcap_scale	float
ccap_scale	float
res_scale	float
layer_cap_scale	string
layer_coupling_cap_scale	string
layer_res_scale	string

ARGUMENTS

-corners *corners*

Specifies the list of corners for which to apply the extraction options. Derating factors will be applied to default corner without -corners.

-ground_capacitance_factor *gcap_scale*

Specifies the ground capacitance derating factor. In pre-route stage, it works as total capacitance derating factor.

-coupling_capacitance_factor *ccap_scale*

Specifies the coupling capacitance derating factor. It affects coupling capacitance of total capacitance without SI impact. It doesn't change coupling capacitance. It is in alignment with PrimeTime behavior.

-resistance_factor *res_scale*

Specifies the resistance derating factor.

-cap_scale_by_layer ***layer_cap_scale***

Specifies layer based capacitance derating factors.

-caap_scale_by_layer ***layer_ccap_scale***

Specifies layer based resistance derating factors.

-res_scale_by_layer ***layer_res_scale***

Specifies layer based resistance derating factors.

-min

Specifies derating factor for min analysis.

-max

Specifies derating factor for max analysis.

-data

Specifies derating factor for signal nets.

-clock

Specifies derating factor for clock nets.

DESCRIPTION

This command sets derating factors used during RC extraction. The derating options will be associated with default constraint corner, or each list of constraint corners.

The default derating factor value is 1.0, which means no derating. This command supports 0 and positive derating factor value, and checks and warns when abnormal negative derating factors are specified.

Multicorner-Multimode Support

EXAMPLES

In the following example, extraction options are applied to the current constraint corner.

```

set_parasitics_parameters

Sets parasitic parameters such as parasitic spec (TLU+) and temperature.

SYNTAX

string **set_parasitic_parameters**
[-corners *corners*]
[-early_spec *early_spec*]
[-early_temperature *early_temperature*]
[-late_spec *late_spec*]
[-late_temperature *late_temperature*]
[-library *library_name*]

Data Types

corners list
early_spec string
early_temperature float
late_spec string
late_temperature float
library_name string

ARGUMENTS

-corners

Sets the parasitic parameter to the constraint corner. If this option is not specified, current conrer will be applied.

-early_spec *early_spec*

Specifies the early parasitic tech specification name.

-early_temperature *early_temperature*

Specifies the early temperature value.

-late_spec *late_spec*

Specifies the late parasitic tech specification name.

-late_temperature *late_temperature*

Specifies the late temperature value.

-library *library_name*

Specifies the library name that contains the specified parasitic specification.

DESCRIPTION

Sets the parasitic parameters required for RC extraction. The command associates the parasitic parameters with the default constraint corner or a list of constraint corners.

EXAMPLES

The following example sets parasitic parameters to the current constraint corner.

```
prompt> set_parasitic_parameters -early_spec file.tlup -early_temperature 25
1
```

set_partial_on_translation

Defines the translation of PARTIAL_ON to FULL_ON or OFF for purposes of evaluating the power state of supply sets and power domains.

SYNTAX

status **set_partial_on_translation**
[*default_translation*]
[-full_on_tools {*tools*}]
[-off_tools {*tools*}]

Data Types

default_translation string
tools list

ARGUMENTS

default_translation

Specifies the default translation for unlisted tools. Valid values are FULL_ON, OFF and UNDETERMINED.

-full_on_tools {*tools*}

Specifies the tools in which PARTIAL_ON is translated to FULL_ON. The tool names are determined by simulation tool and implementation tool doesn't need to do any tool name check for the specified value.

-off_tools {*tools*}

Specifies the tools in which PARTIAL_ON is translated to OFF. The tool names are determined by simulation tool and implementation tool doesn't need to do any tool name check for the specified value.

DESCRIPTION

This command defines the translation of PARTIAL_ON to FULL_ON or OFF for purposes of evaluating the power state of supply sets and power domains. This command does not affect implementation and is intended to be used by simulation tools, to read and write transparently.

EXAMPLES

The following example sets the partial_on_translation to FULL_ON.

```
prompt> set_partial_on_translation FULL_ON \
    -off_tools {OTHER-TOOL}
```

set_path_margin

Specifies a margin to adjust required times for paths in the design.

SYNTAX

status **set_path_margin**
[-setup]
[-hold]
[-rise]
[-fall]
[-from *from_list*
| -rise_from *rise_from_list*
| -fall_from *fall_from_list*]
[-through *through_list*]*

[-scenarios *scenario_list*]
margin_value

Data Types

from_list list
rise_from_list list
fall_from_list list
through_list list
rise_through_list list
fall_through_list list
to_list list
rise_to_list list
fall_to_list list
comment string
mode_list list
corner_list list
scenario_list list
margin_value float

ARGUMENTS

-setup

Specifies that setup (maximum delay) calculations are to use the specified *margin_value* for the specified paths. By default, both **-setup** and **-hold** constraints are adjusted.

-hold

Specifies that hold (minimum delay) calculations are to use the specified *margin_value* for the specified paths. By default, both **-setup** and **-hold** constraints are adjusted.

-rise

Specifies that timing adjustment applies only to paths having a rising signal. If neither **-rise** nor **-fall** is specified, both rising and falling delays are affected. Rise refers to a rising value at the path endpoint.

-fall

Specifies that timing adjustment applies only to paths having a falling signal. If neither **-rise** nor **-fall** is specified, both rising and falling delays are affected. Fall refers to a falling value at the path endpoint.

-from *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, or a pin that has input delay specified. If you specify a clock, all path startpoints related to that clock are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the to_list are adjusted by the margin_value. If you don't specify to_list, all paths from from_list are affected.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of pins, ports, cells and nets through which the paths must pass. The margin value applies only to paths that pass through one of the points in the *through_list*. You can specify **-through** more than one time in a single command invocation. If you specify the **-through** option multiple times, the margin values apply to paths that pass through a member of each *through_list* in the order in which the lists were given. If you use the **-through** option together with the **-from** or **-to** option, the margin adjustment applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than one time in a single command invocation.

-fall_through *fall_through_list*

This option is similar to the **-through** option, but applies only to paths with a fall transition at the specified objects. You can specify **-fall_through** more than one time in a single command invocation.

-to *to_list*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs

related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of **-to**, **-rise_to**, and **-fall_to**. All paths to the endpoints in the *to_list* are adjusted by margin_value. If you don't specify a *from_list*, all paths to *to_list* are affected. If you specify a clock, all path endpoints related to that clock are affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Specifies that existing point-to-point exception information is to be removed from the specified paths. If used with **-to** only, all paths leading to the specified endpoints are reset. If used with **-from** only, all paths leading from the specified startpoints are reset. If used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise or fall setup or hold type is reset. Using this option is equivalent to using the **reset_paths** command with similar arguments before issuing **set_path_margin**.

-comment *comment*

Associates a string description with the command for tracking purposes. This can be useful for optimization engines to track which flow or engine applied the margin values and hence useful for setting and clearing the values.

-modes *mode_list*

Specifies the scenarios to which the path margin delay value is applied. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners *corner_list*

Specifies the scenarios to which the path margin delay value is applied. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios *scenario_list*

Specifies the scenarios to which the path margin delay value is applied. The **-modes** or **-corners** option must not be given with this option. Note that when the -scenarios option is specified and clocks are specified for one or more of the -from, -rise_from, -fall_from or -to, -rise_to, -fall_to options, then only scenarios of current_mode, are considered.

margin_value

Specifies the value of the margin by which to adjust the required time for the specified paths. A positive value results in a more restrictive or tighter check. A negative value results in a less restrictive or looser check.

DESCRIPTION

This command adjusts the data required time for specified paths by the specified *margin_value* amount. The required time for any startpoint in *from_list* to any endpoint in *to_list* is adjusted by *margin_value*. A positive margin value results in a more restrictive or tighter check, whereas a negative margin value results in a less restrictive or looser check. Based on the type of timing constraint,

either setup or hold, the margin value is either subtracted from or added to the default data required time.

The **set_path_margin** command is a point-to-point timing exception command, that is, it adjusts the required time of the path and the endpoint slack for the timing paths.

Other point-to-point timing exception commands include the **set_multicycle_path**, **set_min_delay**, and **set_false_path**, **set_max_delay** commands.

If a path satisfies multiple timing exceptions, the following rules are applied to determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. If one exception is a **set_false_path** exception, and the other is a **set_path_margin** exception, the **set_false_path** exception takes precedence.

2. If one exception is a **set_path_margin** exception and the other is a **set_max_delay**, **set_min_delay**, or **set_multicycle_path** exception, no conflict occurs and both constraints are honored.

3. If one exception has a **-from** pin or **-from** cell and the other does not, the former takes precedence.

4. If one exception has a **-to** pin or **-to** cell and the other does not, the former takes precedence.

5. If one exception has any **-through** points and the other does not, the former takes precedence.

6. If one exception has a **-from** clock and the other does not, the former takes precedence.

7. If one exception has a **-to** clock and the other does not, the former takes precedence.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example adjusts the required time to a port named OUT by 12 units for corner C1. The adjustment results in a more restrictive, tighter timing constraint because the margin value is positive.

```
prompt> set_path_margin 12 -to {OUT} -corners C1
```

This example specifies that the required time of all paths from cell FF1 that pass through cell I1 and end at cell FF2 must be adjusted by 15.0 units for corner C2.

```
prompt> set_path_margin 15 -from {FF1} -through {I1} -to {FF2} -corners C2
```

This example specifies that all paths to endpoints clocked by CLK must be adjusted by 10 units for corners C1 and C2.

```
prompt> set_path_margin 10 -to [get_clocks CLK] -corners {C1 C2}
```

set_pg_mask_constraint

Sets a PG mask constraint. The constraints includes PG strap width, PG strap alignment mode with colored routing tracks, and so on.

SYNTAX

status **set_pg_mask_constraint**
name
-track_alignment_mode *mode_list*
[-width *value_list*]
[-track_alignment_offset *value_list*]

Data Types

name string
mode_list list
value_list list

ARGUMENTS

name

Specifies the name of the PG mask constraint.

-track_alignment_mode *mode_list*

Specifies the routing track alignment checking mode in this constraint. The argument for **-track_alignment_mode** is one of *aligned* or *inverse*. *aligned* aligns the center of the PG strap with routing track of the same mask color. *inverse* aligns the center of the PG strap with routing track of the opposite mask color. This is a required option.

-width *value_list*

Specifies the valid width values of the PG wires in this constraint. Only PG straps with one of the specified width values can be created. The number of values you specify must be the same as number of alignment modes in "-track_alignment_mode" option. This is not required. By default, any width is valid if this option is not specified.

-track_alignment_offset *value_list*

Specifies the routing track alignment offset in this constraint. The offset value is defined with respect to track, that is, the center of the strap minus the offset value is checked against the routing track based on aligned or inverse modes. The number of values needs to be the same as number of alignment modes in **-track_alignment_mode** option. By default the offset is 0 which means the center of the strap is checked against routing track.

DESCRIPTION

This command sets a PG mask constraint which includes PG strap width, PG strap alignment mode with colored routing tracks, and so on. PG straps are checked against the specified PG mask constraint in wire pattern, mesh pattern or atomic commands.

EXAMPLES

The following example sets a PG mask constraint named "mask_constraint", where allowed PG strap location and width values are {track: aligned, offset: 0.5, width 3}, {track: inverse, offset: -0.5, width 2}, and {track: aligned, offset: 0.2, width 1}.

```
prompt> set_pg_mask_constraint\
   mask_constraint \
   -track_alignment_mode {aligned inverse aligned} \
   -track_alignment_offset {0.5 -0.5 0.2} \
   -width {3 2 1}
```

set_pg_strategy

Specifies the power ground network creation strategy.

SYNTAX

status **set_pg_strategy**
strategy_name
[-core | -design_boundary | -voltage_areas *voltage_areas* |
-polygon {*polygon_area*} | -macros *macro_names* |
-blocks *block_names* | -pg_regions *pg_region_names*]
-pattern *pattern_expr*
[-extension {*extension_spec*}]
[-blockage {*blockage_spec*}]

Data Types

strategy_name	string
voltage_areas	collection
polygon_area	list
macro_names	collection
block_names	collection
pg_region_names	list
pattern_expr	specification
extension_spec	specification
blockage_spec	specification

ARGUMENTS

The options **-core**, **-design_boundary**, **-voltage_areas**, **-polygon**, **-macros**, **-blocks** and **-pg_regions** are mutually exclusive. One and only one of these options needs to be specified.

strategy_name

Specifies the name of the strategy.

-core

Uses the core area as the power ground region.

-design_boundary

Uses the design boundary as the power ground region.

-voltage_areas *voltage_area*

Uses the specified voltage area as the power ground region.

-polygon {*polygon_area*}

Uses the specified polygon area as the power ground region. The polygon area is specified by a list of coordinate points.

-macros {*macro_names*}

Uses the specified macros as the power ground region.

-blocks {*block_names*}

Uses the specified blocks as the power ground region.

-pg_regions *pg_region_names*

Uses the power ground regions created by the **create_pg_region** command as the power ground regions. Multiple regions can be specified in the list *pg_region_names*.

-pattern *pattern_expr*

Specifies the power ground pattern to be instantiated in this strategy. The pattern can be wire, composite, mesh, ring, macro connection, standard cell rail connection, or special pattern. Only one pattern can be specified and this is a required option.

For wire, composite, mesh, connection or special pattern, the strategy instantiates the pattern inside the routing area by repeating the pattern. For macro connection pattern, the strategy instantiates the pattern by applying the pattern to macros inside the routing area. For a standard cell rail connection pattern, the strategy instantiates the pattern by creating standard cell rails inside the routing area. The pattern expression *pattern_expr* is specified as follows:

{name: *pattern_name*}
{nets: *real_net_list*}
{parameters: *var_list*}
{offset: {*x_offset y_offset*}}
{offset_start: boundary | {*x y*}}

The **name** keyword followed by *pattern_name* specifies the name of the pattern. For standard cell connection pattern, if the specified pattern name is **std_cell_rail** and this pattern does not exist, a default standard cell rail pattern **std_cell_rail** is created.

The **nets** keyword followed by *real_net_list* specifies the list of net names to be mapped into the symbolic list of nets in *pattern_name*.

The **parameters** keyword followed by *var_list* specifies the parameter list. The parameter list is passed as arguments into the pattern *pattern_name*.

The **offset** keyword followed by {*x_offset y_offset*} specifies the horizontal and vertical offsets when creating the first pattern. By default, the offset is 0 for both horizontal and vertical offsets. Offset does not apply to the scattered pin macro connection pattern or the standard cell rail pattern.

The **offset_start** keyword specifies the offset reference point in routing area for pattern offsets. The **boundary** keyword refers to the lower-left point of the routing area bounding box. Any other point can also be specified as the reference point by coordinate {*x y*}. By default, boundary is used. Offset start does not apply to scattered pin macro connection pattern or standard cell rail pattern.

For a ring pattern, the strategy instantiates the pattern around the routing area. The pattern expression *pattern_expr* is specified as follows:

{name: *pattern_name*}
{nets: *real_net_list*}
{parameters: *var_list*}
{offset: {*x_offset y_offset*}}
{skip_sides: *id_list*}
{side_offset: *side_offset_spec*}

The **pattern** keyword followed by *pattern_name* specifies the pattern name.

The **nets** keyword followed by *real_net_list* specifies the net name list. The nets are mapped into the symbolic list of nets in *pattern_name*.

The **parameters** keyword followed by *var_list* specifies the parameter list which will be passed as arguments into the pattern *pattern_name*.

The **offset** keyword followed by {*x_offset y_offset*} specifies the horizontal and vertical offsets when creating ring segments around the routing area. The offset is the distance between innermost ring to the routing area boundary. By default, the offset is 0 for both horizontal and vertical offsets.

The **skip_sides** keyword specifies the edge ID list to be skipped. *id_list* specifies the edge ID list to be skipped for ring creation. Each edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there is more than one leftmost edge, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction. By default, no edge is skipped for ring creation.

The **side_offset** keyword specifies the offset for each edge. Each edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there is more than one leftmost edge, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction. *side_offset_spec* specifies the offset for each edge as a pair of **edge_id** and **offset** keywords. An example is as follows:

{{side: *edge_id*}{offset: *edge_offset*}}

where *side* and *offset* specify the edge ID and edge offset respectively. The offset unit is defined in the technology file. You can specify negative offsets to shrink the region. If you do not specify offsets for all edges, the offset for the remaining edges is either 0 or the uniform offset for all edges set by **-offset** option.

-extension {*extension_spec*}

Specifies how a group of power and ground nets should extend beyond the power grid. You can specify multiple extension specifications separated by braces. Each specification contains the keywords **nets**, **side**, **layers**, **direction** and **stop** as follows:

{{nets: *nets*}
{side : *id_list*}
{layers : *layer_list*}
{direction: *directions*}
{stop: *stop_target*}}

The net names following the *nets* keyword are a subset of the nets specified by **-nets** in *pattern_expr* from **-pattern** option. If you do not specify the **nets** keyword, the extension applies to all the nets in the strategy.

The **side** keyword specifies the ring segment IDs or macro side IDs by *id_list*. Each ring edge or macro boundary is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there is more than one leftmost edge, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction. If not specified, the extension applies to all ring edges or all macro boundary sides. This keyword can be only applied to ring or macro connection type pattern.

The **direction** keyword specifies the extension direction. *directions* contains one or more of the letters "L", "R", "T" or "B"; "L" refers to left, "R" refers to right, "T" refers to top, and "B" refers to bottom. If this entry is not specified, the extension applies to all directions.

The **layers** keyword specifies the extension specifications only applied to the particular layer list by *layer_list*, which contains a list of routing layer names. If this keyword is not specified, the extension applies to all layers.

The specification following the **stop** keyword can be a distance specified in microns, a collection or a list of PG pins, or one of the following keywords: **core_boundary**, **first_target**, **innermost_ring**, **outermost_ring**, **pad_ring**, **half_space**, **design_boundary**, and **design_boundary_and_generate_pin**. **core_boundary** specifies the core area boundary. **first_target** specifies the first wire segment of the same net. **collection_of_pins** specifies the collection of pins to be extended to. **innermost_ring** specifies the innermost ring of the same net, **outermost_ring** specifies the outermost ring of the same net, **pad_ring** specifies the pad ring segment or pad ring pins of the same net, **half_space** specifies half spacing rule to the specified region of the strategy. and **design_boundary** specifies the boundary of the current design. **design_boundary_and_generate_pin** specifies extension to the

design boundary and generating pins. If you specify a distance, the shape extends by the distance from the boundary of the routing region if the pattern is wire pattern, composite pattern, mesh pattern, or standard cell connection pattern, or from the corner of ring segments for ring pattern, or from macro pins for macro connection pattern. You can also make the shapes to extend to a pre-specified set of macro pins. There are two ways to specify the set of pins, use a list of pin names or a collection of pins. For this stop option to work, both nets and layers options need to be specified as well.

Collection of pins example set gnd_pins [get_pins -all -of_objects [get_cell $powerSwitches] -filter "name==GND"] set_pg_strategy -extension {{{nets: GND} {stop: $gnd_pins} ...}...}...

List of pin names example set gnd_pinNames "GND0 GND1 GND2 ..." set_pg_strategy -extension {{{nets: GND} {stop: $gnd_pinNames} ...}...}...

-blockage {*blockage_spec*}

Specifies the routing blockage in the power ground network. You can specify multiple blockages within the braces, one blockage per group. Blockages are separated by braces and contain the keywords **nets:**, **layers:**, and a target specification as follows:

{{nets: *nets*} {layers: *layers*} {*target*}

where *target* is a voltage area, block, macro, macro with hard keep-out-margin (KOM), PG region, hard placement blockage, or polygon that is specified as follows:

{voltage_areas : *voltage_areas* | macros : *macro_names* |
macros_with_keepout : *macro_names* | placement_blockages : all |
polygon : {*polygon_area*} | blocks : *blocks* |
pg_regions : *region_list* }

The net names following the *nets* keyword are a subset of the nets specified by **-nets** in *pattern_expr* from **-pattern** option. If you do not specify the **nets** keyword, the blockage applies to all the nets in the strategy. The layer names following the **layers** keyword are the routing layers on which power or ground straps are blocked. If you do not specify the **layers** keyword, the blockage applies to all routing layers. Use one of the **voltage_areas**, **macros**, **polygon**, **blocks** or **pg_regions** keywords to represent the blockage area. *polygon_area* is specified as a list of coordinate points.

DESCRIPTION

This command specifies the strategy for creating power ground network elements. The command specifies the power ground pattern, power ground nets, power ground routing area, the net extension strategy and the blockage area.

For wire, composite, mesh and special patterns, the strategy instantiates the pattern inside the routing area by repeating the pattern. For a ring pattern, the strategy instantiates the pattern around the routing area. For macro connection pattern, the strategy instantiates the pattern by applying the pattern to macros inside the routing area. For standard cell rail connection pattern, the strategy instantiates the pattern by creating standard cell rails inside the routing area. Blockage and extension can be further specified.

EXAMPLES

The following example defines a power ground strategy s1 for a composite pattern comp_pattern. Parameters 5 and 3 are passed into the pattern for wire width and spacing respectively. The routing area is inside the voltage area VA1. The real net names are VDD and VSS. Both nets extend to the outermost VDD and VSS rings. Macro hm1 inside this voltage area is treated as blockage for VDD but not for VSS.

```
prompt> set_pg_strategy \
```

```
  s1 \
  -voltage_areas {VA1} \
  -pattern {{name: comp_pattern}{nets:{VDD VSS}}{parameters:{5 3}}}\
  -blockage {{nets: VDD}{macros: rf0/x0/t_al}}\
  -extension {stop: outermost_ring}
```

The following example defines a power ground strategy s2 for a ring pattern ring_pattern. Parameters 4, 1, 5, 2 are passed into the pattern for horizontal width, spacing, and vertical width, spacing respectively. The ring is around the routing area defined by power ground region r1. The net names are Vdd and Vss. Horizontal and vertical offsets are 10 and 20 respectively. The ring segment with edge ID 1 is extended in the top direction to the pad ring.

```
prompt> set_pg_strategy \
  s2 \
  -pg_regions {r1} \
  -pattern {{name: ring_pattern}{nets:{Vdd Vss}} \
        {parameters:{4 1 5 2}}{offset:{10 20}}} \
  -extension {{side: 1}{direction: T}{stop: pad_ring}}
```

The following example defines a power ground strategy s3 for a ring pattern ring_pattern. The ring is around the routing area defined by power ground region r1. The net names are Vdd and Vss. Horizontal and vertical offsets are 10 and 20 respectively. The ring segment with edge IDs 1 and 2 is extended in the both bottom and right directions to the design boundary with pin created, and edge ID 3 in the top direction to design boundary with pin created.

```
prompt> set_pg_strategy \
  s3 \
  -pg_regions {r1} \
  -pattern {{name: ring_pattern}{nets:{Vdd Vss}} \
        {offset:{10 20}}} \
  -extension {{{side: 1 2}{direction: B R }{stop: design_boundary_and_generate_pin}} \
         {{side: 3}{direction: T}{stop: design_boundary_and_generate_pin}}}
```

The following example defines a power ground strategy s4 for a macro connection pattern macro_pattern. The nets are Vdd and Vss. The macros to be connected are hm1 and hm2. For the pins at boundary sides indexed by 1, 2 and 3, the extension stops at the first target. For the pins at the side indexed by 4, the extension stops at the innermost ring.

```
prompt> set_pg_strategy \
  s4 \
  -macros "$macro1 $macro2" \
  -pattern {{name: macro_pattern}{nets:{Vdd Vss}}} \
  -extension {{{side: 1 2 3}{stop: first_target}} \
          {{side: 4}{stop: innermost_ring}}}
```

The following example defines a power ground strategy s5 for a standard cell rail connection pattern std_pattern. The nets are Vdd and Vss. The routing area is the core area. The routing layers are M1 and M2 as parameters passed into the pattern. The rails at layer M2 are extended out of the core area by 10 um.

```
prompt> set_pg_strategy \
  s5 \
  -core \
  -pattern {{name: std_pattern}{nets: {Vdd Vss}}{parameters: {M1 M2}}}\

set_pg_strategy_via_rule

Specifies the via rule between strategies and collections of existing shapes.

SYNTAX

status **set_pg_strategy_via_rule**
rule_name
-via_rule *via_rule_spec*

Data Types

rule_name string
via_rule_spec specification

ARGUMENTS

rule_name

Specifies the name of the via rule.

-via_rule *via_rule_spec*

Specifies the via rule *via_rule_spec* between strategies, and also between the strategies and existing shapes. The via rule defines the intersection locations and the via at the locations. Note that *-via_rule* defined in **create_pg_mesh_pattern** and **create_pg_composite_pattern** only applies to the intersections of wires in the same pattern, and do not apply to the intersection of wires of different patterns. The *-via_rule* defined in **create_pg_mesh_pattern** and **create_pg_composite_pattern** do not also apply to the intersection of pattern wires and existing wires.

There are three methods to define the intersection locations in the specification *via_rule_spec*, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules

The first method is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any two orthogonal shapes including straps, rings, standard cell rails created by strategies or any existing shapes in any different layers.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword and **adjacent** refers to all intersections between any two orthogonal shapes only in adjacent layers.

The third method is to define the intersections based on two sets of shapes using *list_of_filter_rules*, which contains a list of filtering rule. Each filtering rule is specified inside a curly brace pair. The syntax of each filtering rule is as follows:

{{*set_1*}{*filter_1*}}{{*set_2*}{*filter_2*}}{*via_def*} |
{**intersection** : undefined}{*via_def*}

where *set_1* refers to the first set of shapes and *filter_1* refers to the filtering operations for this set. *set_2* and *filter_2* refer to the second set of shapes and the filtering operations for the second set, respectively. *set_1* or *set_2* is defined as follows:

{**strategies** : *strategy_name_list*} |
{**existing** : *shape_type* } |
{**macro_pins** | **terminals** : all | *pin_names* }
{**tags**: *{tag_names}* }

where **strategies** is the keyword for strategies, **existing** is the keyword for existing PG wires, **macro_pins** is the keyword for macro pins and **terminals** is the keyword for terminals. Strategy names are specified by *strategy_name_list*. Existing wires are specified by shape type *shape_type*. Valid *shape_type* options are: ring, strap, macro_conn, follow_pin and std_conn. The keywords ring, strap, follow_pin, std_conn, and macro_conn specify ring-type, strap-type, follow pin type, standard cell connection-type, macro pin connection-type and respectively. Macro pins or terminals could be specified by the all keyword, or by a list of pin names *pin_names*. Tags could be specified by list of tag names. The filtering operations of strategy shapes, existing shapes and tags are defined as follows:

{**nets** : *net_list*}
{**layers** : *layer_list*}
{**width** : {*lower_w upper_w*}}

nets, **layers**, **width** keywords can be used to specify the wire net names by *net_list*, wire layer names by *layer_list* or width range by {*lower_w upper_w*}.

The filtering operations of macro pins are defined as follows:

{**nets** : *net_list*}
{**layers** : *layer_list*}
{**width** : {*lower_w upper_w*}}
{**height** : {*lower_h upper_h*}}
{**width_height_ratio** : {*lower_r upper_r*}}

height and **width_height_ratio** refer to pin height and width height ratio respectively.

By specifying two sets of shapes by strategy names, existing shapes or macro pins, and certain filtering operations by net names, layer names, wire width ranges or types, the via locations are the intersections between these two subsets of shapes. For those intersections which do not belong to any filtering rule, the via definition can be specified by

{**intersection** : undefined}{*via_def*}

where **intersection** is the keyword, **undefined** refers to the remaining intersections which do not belong to any filtering rule. By default, vias are only created at the intersections which belong to a filtering rule, unless otherwise specified. Multiple via filtering rules, such as intersection location and via definition, can be defined and separated by curly braces where each filter rule is in one curly brace pair.

With the intersection definition, the via specification {*via_def*} is in the following format:

{**via_master** : *via_master_list*}

where **via_master** is the keyword for both via masters and via master rules. *via_master_list* specifies the list of via masters. Via masters include the via contact code defined in the technology file or user-defined via cells. *via_rule_list* is a list of PG via rules. Via master rules are defined by **set_pg_via_master_rule** command. **NIL** can be used as a keyword to indicate that no via is created. **default** can be used to describe the default vias in the specified location. For each specified intersection, vias are created based on the specified via masters or via master rules. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection of orthogonal wires in different layers.

DESCRIPTION

Specifies the via rule between two different strategies or a strategy and existing objects. The via rule can be used with the **compile_pg** command when creating the power and ground network.

EXAMPLES

The following example specifies a via rule with name r1 where vias will be created only between adjacent layers.

```
prompt> set_pg_strategy_via_rule r1 \
   -via_rule {{intersection: adjacent}{via_master: default}}
```

The following example specifies a via rule with name r2 which includes a list of filtering rules. Vias VIA23 will be created at the intersection between the shapes from strategy s1 at layer M2 and the shapes from strategy s2 at layer M3. VIA34 will be created at the intersection between the shapes from strategy s2 at layer M3 and all existing ring shapes. Vias will not be created at other intersections between strategy shapes and existing shapes.

```
prompt> set_pg_strategy_via_rule r2 \
  -via_rule { \
      {{{strategies: s1}{layers: M2}}{{strategies: s2}{layers: M3}} \
           {via_master: VIA23}} \
      {{strategies: s2}{existing : ring} \
           {via_master : VIA34}} \
      {{intersection: undefined}{via_master: NIL}} \
  }
```

The following example specifies a via rule with name r3 which includes a list of filtering rules. Vias VIA23 and VIA34 will be created at the intersection between parallel shapes from strategy s1 at layer M2 and the shapes from strategy s2 at layer M4. Vias will not be created at all other intersections.

```
prompt> set_pg_strategy_via_rule r3 \
    -via_rule { \
      { {{strategies: s1} {layers: M2}} \
        {{strategies: s2} {layers: M4}}{via_master: {VIA23 VIA34}} \
        {between_parallel: true} } \
      { {intersection: undefined}{via_master: NIL} } \
  }
```

The following example specifies a via rule with name r4 which includes a list of filtering rules. Vias VIA23 and VIA34 will be created at the intersection between parallel shapes from strategy s1 at layer M4 and the shapes from existing std rail at layer M2. Vias will not be created at all other intersections.

```
prompt> set_pg_strategy_via_rule r4 \
    -via_rule { \
      {{{strategies: s1} {layers: M4}}{{existing: std_conn} {layers: M2}} \
        {via_master: {VIA23 VIA34}}{between_parallel: true}} \
       {{intersection: undefined}{via_master: NIL}} \
  }
```

The following example specifies a via rule with name r5 which includes a list of filtering rules. Default vias will be created at the intersection between shapes from strategy s1 and the existing shapes with tag name std_rail. Vias will not be created at all other intersections.

```
prompt> set_pg_strategy_via_rule r5 \
```

```
  -via_rule { \
    {{strategies: s1}{tags: {std_rail}}{via_master: {default}}} \
     {{intersection: undefined}{via_master: NIL}} \
}
```

The following example specifies a via master "staple_via" with contact code VIA12C, cuts of 2 columns and 1 row, horizontal pitch 0.2. The via rule rail_rule includes a list of filtering rules. Via master staple_via will be created at the intersection between parallel shapes from strategy std_1 and the shapes from existing straps at layer M2. Vias will not be created at all other intersections.

```
prompt> set_pg_via_master_rule staple_via -contact_code VIA12C \
  -via_array_dimension {2 1} -allow_multiple {0.2 0}
prompt> create_pg_std_cell_conn_pattern rail_pattern -layers M1
prompt> set_pg_strategy std_1 -core \
  -pattern {{pattern: rail_pattern} {nets: VDD VSS} }
prompt> set_pg_strategy_via_rule rail_rule \
  -via_rule { \
    { {strategies: {std_1}} \
      {{existing: strap}{layers: M2}} \
      {via_master:staple_via} {between_parallel: true} } \
    { {intersection: undefined}{via_master: NIL} }}
prompt> compile_pg -strategies {std_1} -via_rule {rail_rule}
```

set_pg_strategy(2)
set_pg_via_master_rule(2)

set_pg_via_master_rule

Creates a new via master rule for the power and ground network. The via rule is defined by the contact code, location of contact code inside the intersection box, cut spacing, multiplication, and so on.

SYNTAX

status **set_pg_via_master_rule**
rule_name
[-contact_code *via_contact_code*]
[-via_array_dimension {*column row*}]
[-offset_start center | lower_left]
[-offset {*x_offset y_offset*}]
[-orient R0 | R90]
[-allow_multiple {*x_pitch y_pitch*}]
[-cut_spacing {*x_spacing y_spacing*}]
[-via_site_ratio {*x_ratio y_ratio*}]
[-track_alignment *alignment_mode*]
[-cut_mask mask_one | mask_two | mask_three]
[-snap_reference_point {*x y*}]

Data Types

rule_name string
via_contact_code string
column integer
row integer
x_offset float
y_offset float
x_pitch float
y_pitch float
x_spacing float
y_spacing float
x_ratio float
y_ratio float
alignment_mode string
x float
y float

ARGUMENTS

rule_name

Specifies the name of the power ground via rule. This option is required.

-offset {*x_offset y_offset*}

Specifies the horizontal (*x_offset*) and vertical (*y_offset*) values to use when creating a contact code inside the intersection box. The units are um. The offset is applied with respect to the center of the intersection box. By default, the offset is 0.

-offset_start center | lower_left

Specifies the offset reference point in the intersection box. Keyword **center** refers to the center of the intersection box. Keyword **lower_left** refers to the lower-left corners of the intersection box.

-contact_code *via_contact_code*

Specifies the via master or contact code used to create the via rule. By default, the tool uses the default contact codes.

-via_array_dimension {*column row*}

Specifies the via array dimension size by integer values for *column* and *row*. This option can only be applied to a simple symmetric contact code. The tool creates the via array based on the specified contact code. If the contact code is not symmetric, this option is ignored. By default, *column* and *row* are calculated based on the size of the intersection, and the tool fills the intersection with via cuts.

-orient R0 | R90

Specifies the orientation of the contact code by keywords **R0** and **R90** respectively. By default, the via has orientation R0 and is not rotated.

-cut_mask mask_one | mask_two | mask_three

Specifies the cut mask for this via master rule by keywords **mask_one**, **mask_two** or **mask_three**. By default, the via cut mask is not colored. Via metal enclosure masks follow PG wire masks.

-allow_multiple {*x_pitch y_pitch*}

Specifies the horizontal (*x_pitch*) and vertical (*y_pitch*) values when filling an intersection with multiple repetitions of the contact code or via array. The unit is defined in the technology file. If the via array is created with the **-via_array_dimension** option, the via array is repeated. Otherwise, the contact code defined by the **-contact_code** option is repeated. By default, the contact code or via array is not repeated.

-cut_spacing {*x_spacing y_spacing*}

Specifies the horizontal (*x_spacing*) and vertical (*y_spacing*) values between cuts in a simple array via. The spacing values are ignored if smaller than the minimum cut spacing. The unit of cut spacing is in um. By default, the default cut spacing is used.

-via_site_ratio {*x_ratio y_ratio*}

Specifies the via site horizontal and vertical ratio by *x_ratio* and *y_ratio*. The valid range for ratio is from 0.0 to 1.0 while 0.0 is invalid. By default, the ratio is 1.0 and the whole intersection is used for via creation. When specified, the intersection box is shrunk by the specified ratio for via creation.

-track_alignment *alignment_mode*

Specifies the track alignment option for this via master rule. Valid values are **track**, **half_track**, **top_track_bottom_half_track**, **top_half_track_bottom_track**, **top_track_only**, **top_half_track_only**, **bottom_track_only**, and **bottom_half_track_only**.

By default vias created by this rule do not align to routing track or half routing track. The top and bottom of a via can be aligned to track or half-track respectively. The alignment can be applied to both of layers or just one of the top and bottom layers.

-snap_reference_point {*x y*}

Specifies the reference point for repeating vias. This option needs to be used together with the "-allow_multiple" option for repeating vias. When specified, the origin of the first via or the lower-left via created inside the intersections with this via master rule will be snapped to the specified point, or the specified point plus a multiple of pitch values if the reference point is outside the

intersection. The "-offset_start" or "-offset" options cannot be used together with this option. If not specified, repeating vias will honor offset options or get evenly distributed inside intersection bounding boxes.

DESCRIPTION

Specifies the power ground via rules such as the location of contact code inside the intersection box, orientation and multiplication etc. The PG via rule can be used during pattern definition and when creating the power and ground network.

EXAMPLES

The following example defines a power ground via rule with the name via_rule_1 using contact code VIA34. The offsets are 3 um and 4 um with respect to the center of the intersection. The via array size is 5x5.

```
prompt> set_pg_via_master_rule \
  via_rule_1 -contact_code VIA34 \
  -offset {3 4} -via_array_dimension {5 5} \
```

[-to_clock *clock*]
[-to_clock_rise]
[-to_clock_fall]

[-modes *mode_list*]
[-all_modes]

[-all_pins | -all | *pin_list*]

Data Types

percent float (percent value between 0 and 100)
delay float (delay value in input time units)
margin float
boundary_name string
port_name string
clock string
mode_list collection
pin_list collection of pins

ARGUMENTS

-from_percent *percent*

Specifies the percent of a budget path which should be allocated between the start of the path and the budgeted pin. Any delay remaining in a budget path will be allocated between the budgeted pin and the end of the path. This option cannot be specified with any other delay or percent specification.

-from_delay *delay*

Specifies the delay which should be allocated between the start of the path and the budgeted pin. Any delay remaining in a budget path will be allocated between the budgeted pin and the end of the path. This option cannot be specified with any other delay or percent specification.

-to_percent *percent*

Specifies the percent of a budget path which should be allocated between the budgeted pin and the end of the path. Any delay remaining in a budget path will be allocated between the start of the path and the budgeted pin. This option cannot be specified with any other delay or percent specification.

-to_delay *delay*

Specifies the delay which should be allocated between the budgeted pin and the end of the path. Any delay remaining in a budget path will be allocated between the start of the path and the budgeted pin. This option cannot be specified with any other delay or percent specification.

-internal_percent *percent*

Specifies the percent of a budget path which should be allocated to the inside of a pin's block. Any delay remaining in a budget path will be allocated outside of the block. This option automatically sets the **-internal** option, so a budget with this option will not be applied to feedthrough paths. Setting **-input -internal_percent** is equivalent to setting **-input -internal -to_percent**. Setting **-output -internal_percent** is equivalent to setting **-output -internal -from_percent**. This option cannot be specified with any other delay or percent specification.

-internal_delay *delay*

Specifies the delay which should be allocated to the inside of a pin's block. Any delay remaining in a budget path will be allocated outside of the block. This option automatically sets the **-internal** option, so a budget with this option will not be applied to feedthrough paths. Setting **-input -internal_delay** is equivalent to setting **-input -internal -to_delay**. Setting **-output -internal_delay** is equivalent to setting **-output -internal -from_delay**. This option cannot be specified with any other delay or percent specification.

-none

Specifies that no budget constraint should be generated for a pin.

-early_boundary *boundary_name*

Specifies that a previously defined *budget boundary* should be associated with the given pins. Budget boundaries are defined using the **set_boundary_budget_constraints** command. They control how **set_driving_cell** and **set_load** are applied in the final budget. This option controls what boundary constraints should be used for early (hold time) budgets. Budget boundaries are applied to all timing modes, not just the current mode.

-late_boundary *boundary_name*

Specifies that a previously defined *budget boundary* should be associated with the given pins. Budget boundaries are defined using the **set_boundary_budget_constraints** command. They control how **set_driving_cell** and **set_load** are applied in the final budget. This option controls what boundary constraints should be used for late (setup time) budgets. Budget boundaries are applied to all timing modes, not just the current mode.

-frozen

Specifies that the budgeted constraint for a pin should not be changed by this command or by the automatic budget calculation of the **compute_budget_constraints** command.

-not_frozen

Reverses the effect of the **-frozen** option and allow a pin's budget to be changed.

-reset

Removes any budget specification previously assigned to a pin by this command or by the **compute_budget_constraints** command.

-same_as_mib

Forces the budget constraint to be the same across multiply instantiate block instances. If a pin has this attribute set, it will get the same budget constraint as an identical pin on another multiply instantiated instance that also has this attribute set. By default, all internal budget constraints have this attribute set. Feedthrough constraints do not have this attribute set by default. You must also specify **-internal** or **-feedthrough** when you use this option.

-not_same_as_mib

Reverses the effect of the **-same_as_mib** option. Only the specified pins are affected by this option. Note that internal constraints have **same_as_mib** set by default, and you will need to use the **-not_same_as_mib** option to change the default for internal constraints.

-same_as_pin *port_name*

Forces the budget constraint on specified pins to be the same as the constraint on the named port specified by *port_name*. The named port must be found on the same instance as the specified pins. For example, to give all pins in a bus the same constraint, you might set all of the pins U1/U2/bus[*] to be the same as port bus[0]. See the EXAMPLES section for an example of the **-same_as_pin** option. You must also specify **-internal** or **-feedthrough** when you use this option.

-not_same_as_pin

Reverses the effect of the **-same_as_pin** option for the specified pin. Only the specified pins are affected by this option.

-same_as_modes *modes*

Forces the budget constraint on specified pins to be the same as the constraint on the same pin in another modes. See the EXAMPLES section for an example of the **-same_as_modes** option. You must also specify **-internal** or **-feedthrough** when you use this option.

-not_same_as_modes

Reverses the effect of the **-same_as_modes** option. Pins that are not specified will not be affected.

-same_as_feedthrough

Forces the budget constraints for the two paths to be the same for pins that have both internal paths and feedthrough paths. This option will probably be rarely used. You must also specify **-internal** when you use this option.

-not_same_as_feedthrough

Reverses the effect of the **-same_as_feedthrough** option. Only the specified pins are affected by this option.

-inputs

Specifies that the applied budget parameter should only apply to paths that pass through input pins of blocks. Budget parameters for other pins are not changed. For inout pins, the budget parameter is only applied to paths in the input direction.

-outputs

Specifies that the applied budget parameter should only apply to paths that pass through output pins of blocks. Budget parameters for other pins are not changed. For inout pins, the budget parameter will only be applied to paths in the output direction.

-feedthrough

Specifies that the applied budget parameter should only apply to paths that feed through the specified block pin. That is, there must be a combinational path between a block input and block output. The budget for paths through input pins that end in the block will not be affected. The budget for paths that start in the block and pass through output pins will not be affected.

-internal

Specifies that the applied budget parameter should only apply to paths that start or end in the given pin's block. That is, there must either be a path through input pins that ends in the block, or there must be a path that starts in the block and passes through output pins. The budget for combinational paths between a block input and block output will not be affected.

-from_clock ***clock***

Specifies that the applied budget parameter should only apply to paths with the specified launching clock. Any timing path whose clock does not match the specified clock will be untouched. Previous budget parameters for other clocks, if any, will be maintained. The specified clock will come from the current mode. You must not specify this option together with the **-modes** or **-all_modes** options.

-from_clock_rise

If this option is specified along with **-from_clock**, only paths which trigger on the rising edge of the clock (at the clock source) will be affected. The default is that the clock edge does not matter.

-from_clock_fall

If this option is specified along with **-from_clock**, only paths which trigger on the falling edge of the clock (at the clock source) will be affected. The default is that the clock edge does not matter.

-to_clock ***clock***

Specifies that the applied budget parameter should only apply to paths with the specified capturing clock. Any timing path whose clock does not match the specified clock will be untouched. Previous budget parameters for other clocks, if any, will be maintained. The specified clock will come from the current mode. You may not specify this option along with the **-modes** or **-all_modes** options.

-to_clock_rise

If this option is specified along with **-to_clock**, only paths which trigger on the rising edge of the clock (at the clock source) will be affected. The default is that the clock edge does not matter.

-to_clock_fall

If this option is specified along with **-to_clock**, only paths which trigger on the falling edge of the clock (at the clock source) will be

affected. The default is that the clock edge does not matter.

-modes *mode_list*

By default, budgets are only applied in the current mode. Use this option to specify that the budget should be applied in the specified mode or modes.

-all_modes

Applies the budget to all modes. By default, budgets are only applied in the current mode.

-all_pins

Applies the specified budget to all pins of all budget blocks. The budget will only be applied to the current mode, unless you use the **-modes** or **-all_modes** options. The budget will not be applied for pins that are filtered out by the **-from_clock**, **-to_clock**, **-internal**, **-feedthrough**, **-inputs**, or **-outputs** options.

-all

Applies the specified budget to all pins of all budget blocks in all modes. However, the budget will not be applied for pins that are filtered out by the **-from_clock**, **-to_clock**, **-internal**, **-feedthrough**, **-inputs**, or **-outputs** options. This option is equivalent to specifying **-all_pins -all_modes**.

pin_list

Specifies a list of pin names on budget blocks of your design where a budget should be applied. If a specified pin is not on a budgeted block (as specified by the **set_budget_options** command), a warning is issued. The budget only applies to the current mode, unless you use the **-modes** or **-all_modes** options. The budget is not changed for pins that are filtered out by the **-from_clock**, **-to_clock**, **-internal**, **-feedthrough**, **-inputs**, or **-outputs** options.

DESCRIPTION

This command specifies how to allocate budgeted delay at selected pins. To set a constraint, you must choose one of the budget style options: **-from_delay**, **-to_delay**, **-internal_delay**, **-from_percent**, **-to_percent**, **-internal_percent**, **-none**, or **-reset**.

The budget is applied to the specified pins or all budget pins if **-all_pins** or **-all** is specified. The budget is only applied in the current timing more, unless you specify **-modes**, **-all_modes** or **-all**.

This command provides filters to select only specific pins out of the possible choices. The possible filter options are: **-from_clock**, **-from_clock_fall**, **-to_clock**, **-to_clock_fall**, **-feedthrough**, **-internal**, **-inputs**, and **-outputs**. If more than one budget parameter is applied to the same pin, the more specific parameter is applied. For example, if all paths through a pin (which is less specific) have a **-from_percent** constraint of 30%, but paths with **-to_clock sysclk** (which is more specific) have a **-from_percent** setting of 40%, the 40% constraint is applied wherever possible. The order in which constraints are applied in your script is not important.

Two important filters are **-internal** and **-feedthrough**. Feedthrough budgets only apply to paths that feed through the given pin's block. That is, there must be a combinational path between a block input and block output. Internal budgets only apply to paths that start or end in the given pin's block. That is, there must either be a path through input pins that ends in the block, or there must be a path that starts in the block and passes through output pins.

You can use this command to create "same_as" links between different constraints. The possible same_as options are: **-same_as_mib**, **-not_same_as_mib**, **-same_as_pin port_name**, **-not_same_as_pin**, **-same_as_modes modes**, **-not_same_as_modes**, **-same_as_feedthrough**, and **-not_same_as_feedthrough**. By using these options, you can force the budget constraints for many pins to be the same as other pins. For example, you can set all of the bits of a bus to the same constraint. Or you can apply the same budget constraints to all instances of a MIB (multiply instantiate block). After a "same_as" link has been made, if you set a **-from_***, **-to_*** or **-internal** budget constraint on one pin of the set, the other pins will also get the same constraint.

The same_as controls apply both to manually-set budgets and to automatically-generated budgets. However, the same_as controls do **not** apply to budget constraints set by **-from_clock** or **-to_clock**. By default, internal budgets have *set_same_as_mib* set. Feedthrough budgets do not.

Delay allocations in a budget are based on "budget paths". The total delay in a budget path depends on many things, such as clock period, clock uncertainty, clock latency, and various reserved budget margins. See the **set_budget_options** and **set_latency_budget_constraints** commands for a description of budget margins. You can use the **report_budget** command to see the total delay along various budget paths.

Budget boundary constraints (**set_driving_cell** and **set_load**) can be associated with budgeted pins by using the **-early_boundary** and **-late_boundary** options. Boundary constraints apply across all timing modes.

Use the **set_budget_options** command to specify general options to be used during creation of timing budgets. To set other specific budget parameters, use the **set_latency_budget_constraints**, and **set_boundary_budget_constraints** commands.

Use the **write_budgets** command to generate SDC that can be applied to lower level blocks. The **compute_budget_constraints** command can be used to set key budget parameters automatically. The **report_budget** command generates useful information about the current budget calculation, allocation, and whether that budget is currently being met. Use the **write_script -include budget** command to save a Tcl script that includes your current settings from this command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following declares that 30% of each budget path be allocated inside each pin's block:

```
prompt> set_pin_budget_constraints -internal_percent 30 -all
```

For the outputs of the "CPU", allocate 40% inside the block. Note that inputs of the CPU block are not affected:

```
prompt> set_pin_budget_constraints -internal_percent 40 -outputs core/CPU/*
```

For any block input from a "tstclk" clock register, set so the budgeted path delay leading to the block is 2.5ns:

```
prompt> set_pin_budget_constraints -from_delay 2.5 \
  -inputs -from_clock "tstclk" -all
```

For any block output to a "tstclk" clock register, set so no budget is created:

```
prompt> set_pin_budget_constraints -none \
  -outputs -to_clock "tstclk" -all
```

The following example declares a driving cell that is applied to the input pins of "block1". An additional 0.1 of capacitance is also applied to the input:

```
prompt> set_boundary_budget_constraints -name DCbuf8 -driving_cell bufX8
prompt> set_boundary_budget_constraints -name DCbuf8 -default -fanin_capacitance 0.1
prompt> set_pin_budget_constraints -late_boundary DCbuf8 -inputs block1/*
```

The following example sets output loads for all budgeted pins. The value is different for different corners.

```
prompt> set_boundary_budget_constraints -name OUTload -default   -load_capacitance 0.1
prompt> set_boundary_budget_constraints -name OUTload -corner c1 -load_capacitance 0.15
prompt> set_boundary_budget_constraints -name OUTload -corner c2 -load_capacitance 0.05
prompt> set_pin_budget_constraints -late_boundary OUTload -outputs -all
```

Set the same budget for all of the pins of the specified bus:

```
prompt> set_pin_budget_constraints -internal -same_as_pin my_bus[0] \
  -internal U1/U2/my_bus[*]
```

Set the constraints to match the constraints in mode TEST for all pins of block1:

```
prompt> set_pin_budget_constraints -internal -same_as_modes TEST \
  -internal block1/*
```

Set the same budget for the feedthrough of two multiply instantiated instances:

```
prompt> set_pin_budget_constraints -same_as_mib -feedthrough \
  {mib_block1/* mib_block2/*}
```

Set the budgets so that the internal paths of a multiply instantiated instance does not get the same budget as other instances: (By default, internal budgets are the same for multiply instantiate blocks.)

```
prompt> set_pin_budget_constraints -not_same_as_mib -internal mib_block1/*
```

set_pin_name_synonym

Set pin name synonym for pin object search.

SYNTAX

status **set_pin_name_synonym**
[-full_name]
[-force]
pin_name_synonym *pin_name_synonym*
pin_name *pin_name*

Data Types

pin_name_synonym string *pin_name* string

ARGUMENTS

-full_name

Indicates that a pin name synonym is a full name synonym.

-force

Overwrites the existing pin name synonym if a conflict occurs.

DESCRIPTION

This command defines pin name synonyms, which are supported in pin object queries.

The pin_name_synonym is an alternative pin name for a pin object. For example, if the U1/U2/data_in name is defined as the synonym for the U1/U2/D pin, pin query commands can find the pin object named U1/U2/D when the commands could not find the pin with the given name U1/U2/data_in.

Pin name synonyms are only applicable to pins on leaf-level sequential cells. This feature can also be applicable to physical and logic library pin names.

The tool supports two types of pin name synonyms: full name synonyms and simple name synonyms. The set_pin_name_synonym command defines simple name synonyms unless the -full_name option is used. When defining a full name synonym, you specify the full hierarchical name for the pin object in both the pin_name_synonym and pin_name fields. Pin query commands use full name synonyms exactly as they are defined. Simple name synonym definitions use short names for pin objects. For library pin, only the simple name is needed. Pin query commands use a simple pin name synonym to construct a full pin name during a synonym-based pin object search.

You can get full name and simple name synonyms for pin objects by querying the full_name and name attributes for pin objects.

Wildcards and regular expressions are not supported in pin name synonym definitions. Simple name synonyms do not support the forward slash (/) since it is considered a hierarchical separator.

When you use the pin name synonyms for pin queries, the full name synonym, when applicable, supersedes the simple name synonym. And, the finder commands for pin name synonym can be enabled or disabled by app option of "design.enable_rule_based_query".

EXAMPLES

The following examples use set_pin_name_synonym to define pin name synonyms and show how get_pins command uses the synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD
1

prompt> set_pin_name_synonym -full_name \
      this/is/a/synonym mid1/FJK2SP_at_mid/TI
1

prompt> set_pin_name_synonym -full_name \
      mid1/FJK2SP_at_mid/J mid2/bot2/LSR0P_at_bot/Q
1
```

SEE ALSO

remove_pin_name_synonym(2)
report_pin_name_synonym(2)

set_pipeline_scan_data_configuration

Specifies the pipeline scan data configuration for the design.

SYNTAX

status **set_pipeline_scan_data_configuration**
[-head_pipeline_clock *clock_name*]
[-tail_pipeline_clock *clock_name*]
[-head_pipeline_stages *total_depth*]
[-tail_pipeline_stages *total_depth*]
[-head_shared_pipeline_stages *shared_top_level_depth*]
[-tail_shared_pipeline_stages *shared_top_level_depth*]
[-head_scan_flop true | false]
[-tail_scan_flop true | false]

Data Types

clock_name string
total_depth integer
shared_top_level_depth integer

ARGUMENTS

-head_pipeline_clock *clock_name*

Specifies the shift clock for the head pipeline scan data registers. The specified clock must be previously declared as a scan clock using the **set_dft_signal** command.

-tail_pipeline_clock *clock_name*

Specifies the shift clock for the tail pipeline scan data registers. The specified clock must be previously declared as a scan clock using the **set_dft_signal** command.

-head_pipeline_stages *total_depth*

Specifies the number of head pipeline stages. The default is 1. You can choose not to insert head pipeline stages by specifying a depth of 0.

-tail_pipeline_stages *total_depth*

Specifies the number of tail pipeline stages. The default is 1. You can choose not to insert tail pipeline stages by specifying a depth of 0.

-head_shared_pipeline_stages *shared_top_level_depth*

Specifies the number of top-level shared head pipeline stages to use when shared codec input connections are used for core

integration.

When set, the tool uses the specified number of shared pipeline registers along the shared scan input path, then it uses dedicated pipeline registers as needed for the remaining stages to meet the total head pipeline depth target. A value of 0 uses only dedicated top-level stages. The default is to use the largest number of shared top-level stages possible given the constraints, which minimizes the number of dedicated top-level stages.

This option is only used when shared codec input connections are specified with the **-shared_inputs** option of the **set_scan_compression_configuration** command.

-tail_shared_pipeline_stages ***shared_top_level_depth***

Specifies the number of top-level shared tail pipeline stages to use when shared codec output connections are used for core integration.

When set, the tool uses the specified number of shared pipeline registers along the shared scan output path, then it uses dedicated pipeline registers as needed for the remaining stages to meet the total tail pipeline depth target. A value of 0 uses only dedicated top-level stages. The default is to use the largest number of shared top-level stages possible given the constraints, which minimizes the number of dedicated top-level stages.

This option is used only when shared codec input connections are specified with the **-shared_inputs** and **-shared_outputs** options of the **set_scan_compression_configuration** command.

-head_scan_flop true | **false**

When set to **true**, scan-replaced registers are used for the head pipeline stages. The scan data input of each head pipeline scan register is used for the pipeline shift path. The functional data input of each register is driven by that register's output, so that the register holds state during scan capture. The default is **true**, which inserts scan head pipeline registers.

-tail_scan_flop true | **false**

When set to **true**, scan-replaced registers are used for the tail pipeline stages. The scan data input of each tail pipeline scan register is used for the pipeline shift path. The functional data input of each register is driven by that register's output, so that the register holds state during scan capture. The default is **false**, which inserts nonscan tail pipeline registers.

DESCRIPTION

This command specifies the pipeline scan data configuration for the design.

EXAMPLES

prompt> **set_dft_signal -type MasterClock -port pipeClk -timing [list 45 55]**

prompt> **set_pipeline_scan_data_configuration -head_pipeline_stages 1 -head_pipeline_clock pipeClk**

prompt> **set_pipeline_scan_data_configuration -tail_pipeline_stages 1 -tail_pipeline_clock pipeClk**

SEE ALSO

set_dft_signal(2)
preview_dft(2)

set_pipeline_scan_enable_configuration

Specifies the configuration used for inserting DFT pipeline scan enable logic in the design.

SYNTAX

status **set_pipeline_scan_enable_configuration**
[-exclude *object_list*]
[-exclude_types *type_list*]

Data Types

object_list list
type_list list

ARGUMENTS

-exclude *object_list*

Specifies which elements must be excluded from pipeline scan enable. Those will be connected directly to the relevant scan enable signal instead. The following design elements can be specified as exclusion parameters:

- DFT clock pins: all scan elements clocked by the specified clock pin will be excluded.
- Hierarchies: all scan elements contained by this hierarchy (or any of its subhierarchies) will be excluded.
- Instances or pins: scan enable connections to the specified instance or pin will be excluded.

-exclude_types *type_list*

Specifies which classes of scan elements must be excluded from pipeline scan enable. The available types are:

- shared_wrapper
- dedicated_wrapper
- input_wrapper
- output_wrapper
- input_shared_wrapper
- output_shared_wrapper
- input_dedicated_wrapper
- output_dedicated_wrapper

- testpoint
- clock_gate

DESCRIPTION

The **set_pipeline_scan_enable_configuration** command must be used to specify parameters to further fine-tune insertion of Pipeline Scan Enable (PSE) logic during DFT scan synthesis. However, the master switch to enable this feature is located at **set_scan_configuration -pipeline_scan_enable**.

EXAMPLES

To exclude all elements clocked by a particular clock:

```
> set_dft_signal -type MasterClock -port tclk
> set_pipeline_scan_enable_configuration -exclude tclk
```

The exclusion specification can be a list, and can mix types of elements:

```
> set_pipeline_scan_enable_configuration -exclude { tclk ctl_hier alu/q[1] actl/SE1 }
```

SEE ALSO

set_dft_signal(2)
set_scan_configuration(2)

set_placement_ir_drop_target

Set placer IR drop targets

SYNTAX

string **set_placement_ir_drop_target** [-irdrop]
voltage_area
type
percentage

list *voltage_area*
string *type*
float *percentage*

ARGUMENTS

-irdrop

Specifies that the percentage is a voltage drop number, as a percentage of the effective voltage supply voltage

voltage_area

Specifies the voltage area for settings the IR drop targets

type

Specifies the type of IR drop target setting, either low or high

percentage

Specifies the percentage between 0.0-100.0 of the IR drop target

DESCRIPTION

This command set the IR aware placement target settings for the given voltage area. By default, it set the population percentages. The voltage drop percentages are set, if the option **-irdrop** is used. If the **type** is set to low it will either set the low voltage drop target or the middle bin population, based on the **-irdrop** option is used or not. If the **type** is set to high, it will either set the high voltaged drop target or the upper bin population.

EXAMPLES

The following example sets for the voltage area DEFAULT_VA the low voltage drop target to 4.5% of the effective supply voltage and the high target to 1% of the population

```
prompt> set_placement_ir_drop_target DEFAULT_VA low 4.5 -irdrop
prompt> set_placement_ir_drop_target DEFAULT_VA high 1.0
prompt> get_placement_ir_drop_target DEFAULT_VA
{ { DEFAULT_VA low 4.500000 -irdrop } { DEFAULT_VA high 1.000000 } }
```

set_placement_spacing_label

Specify the placement spacing label that applies to a collection of library cells on left or right side, in R0 orientation, or both.

SYNTAX

status **set_placement_spacing_label**
-name *name*
-side left | right | both
-lib_cells *lib cells*
[-row *row number*]

Data Types

name	string
lib cells	collection of library cells
row number	integer

ARGUMENTS

-name *name*

Specifies a name for this label. This is a required option.

-side *left* | *right* | *both*

Specifies which side, in R0 orientation of the library cell this label applies. Must be one of "*left*", "*right*", or "*both*". This is a required option.

-lib_cells *lib cells*

Specifies the collection of library cells to which to apply this label. This is a required option.

-row *row number*

Specifies row of library cell to apply the label to. The row is in units of the library cell's site_def height. Row number is an integer in range [0..N-1] where N is the number of rows of the library cell. Only applies to multi-height cells. If row number is not provided for multi-height cell, then the label is applied to all the rows of the cell. This is an optional option.

DESCRIPTION

This command assigns labels to a collection of reference (library) cells in order to enable the legalization tool to obey intercell spacing constraints. A label is a string assigned by the user to the left and/or right of a standard cell. This command works in concert

with the command set_placement_spacing_rule that defines the range of spacing between two adjacent labels that is illegal. All spacing rules specified by set_placement_spacing_rule commands need to be satisfied to produce a legal placement. With intercell spacing rule specified, it is no longer assumed that any two standard cells can be placed next to each other with a certain spacing.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells.

Spacing labels and rules are persistent in the NDM.

EXAMPLES

The following example sets labels on a collection of library cells.

```
prompt> set_placement_spacing_label -name X \
  -side both -lib_cells [get_lib_cells -of [get_cells]]
```

The following example sets label on row 1 for a specific multi-height library cell.

```
prompt> set_placement_spacing_label -name X \
  -side left -lib_cells [get_lib_cells -of [get_cell U0]] -row 1
```

SEE ALSO

set_placement_spacing_rule(2)
remove_placement_spacing_rules(2)
report_placement_spacing_rules(2)

set_placement_spacing_rule

Specify the placement spacing rule between library cells that have been assigned labels with set_lib_cell_spacing_label command.

SYNTAX

status **set_placement_spacing_rule**
-labels *label names*
{*min max*}

Data Types

label names	pair of strings
min max	pair of integers

ARGUMENTS

-labels {*label names*}

Lists placement spacing labels. The list must contain exactly two labels specified by the set_placement_spacing_label command. This is a required option.

{*min max*}

Specifies illegal spacing range given in units of sites, where max >= min. This is a required option.

DESCRIPTION

This command assigns inter-cell spacing constraints between reference cells that have been assigned labels with the set_placement_spacing_label command. Cells with the given labels are prohibited from being placed adjacent to one another within the range given by min and max. The range is specified in units of placement sites. Given two adjacent standard cells with an empty space in between, each label from the right side of the left cell is checked against each label from the left side of the right cell to see if any spacing rules are violated. Such pair wise checking of labels is applied to all adjacent cells to ensure placement legality of a chip.

A label typically represents some layout features inside a standard cell. A label is associated with the left or right boundary of a standard cell in the R0 orientation when specified. When a cell is flipped, its associated labels will also be flipped.

All spacing rules specified by set_placement_spacing_rule commands need to be satisfied to produce a legal placement. With placement spacing rule specified, it is no longer assumed that any two standard cells can be placed next to each other with a certain spacing.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of

standard cells.

Built-in label 'SNPS_BOUNDARY' may be used to specify spacing rules between library cells and various types of placement boundaries: chip boundary, hard macro edge, hard macro keepout margin, hard placement blockage edge, or voltage area guard bands.

Spacing labels and rules are persistent in the NDM.

EXAMPLES

The following example sets placement spacing rules for labels, X and Y, where spacings of 0, 1, and 2 site units between the cells are illegal.

```
prompt> set_placement_spacing_rule -labels {X Y} {0 2}
```

In the following example, cells with labels "X" are prohibited to be spaced within range 0 to 1 placement sites from placement boundary.

```
prompt> set_placement_spacing_rule -labels {X SNPS_BOUNDARY} {0 1}
```

SEE ALSO

set_placement_spacing_label(2)
remove_placement_spacing_rules(2)
report_placement_spacing_rules(2)

set_placement_status

Sets the placement status of a cell or port.

SYNTAX

status **set_placement_status**
status
object_list

Data Types

status string
object_list collection

ARGUMENTS

status

Specifies the placement status. Valid values are:

- **unplaced**
  The cell or port instance has not yet been placed.
- **placed**
  The cell or port instance has been placed, but can be moved by subsequent operations.
- **legalize_only**
  The cell instance has been placed and can be moved only by the legalizer. This value applies only to cells.
- **fixed**
  The cell or port instance has been placed and the tool cannot move it during subsequent optimization commands, such as **place_opt**. However, you can move the cell or port instance manually, either by using manual editing commands, such as **set_attribute**, or by moving it in the GUI.
- **application_fixed**
  The tool has marked the cell as fixed. This status is similar to the **fixed** status, but the tool can modify this setting and then move the cell. This value applies only to cells.
- **locked**
  The cell or port instance has been placed and cannot be moved either manually or by the tool.

object_list

Specifies the cells or ports for which to set the placement status.

DESCRIPTION

This command sets the placement status of a cell or port.

To query this setting, use the **get_attribute** command to get the value of the **physical_status** attribute for the cell or port.

EXAMPLE

The following example shows how to set the placement status to **fixed** to prevent the placer from moving the cell instance named INST_1.

```
prompt> set_placement_status fixed INST_1
```

The following example shows how to query the placement status.

```
prompt> get_attribute [get_cells INST_1] physical_status
fixed
```

SEE ALSO

set_cell_location(2)
create_placement(2)
get_attribute(2)

set_pocvm_corner_sigma

Selects the standard deviation to be used for parametric on-chip variation analysis when calculating corner values from statistical quantities.

SYNTAX

status **set_pocvm_corner_sigma**
[-corners *corner_list*]
corner_sigma

Data Types

corner_list list
corner_sigma float

ARGUMENTS

-corners *corner_list*

Specifies the corners that the corner sigma value applies to. If this option is not given, the current corner is used.

derate_value

Specifies the corner sigma value.

DESCRIPTION

Parametric on-chip variation (POCV) analysis internally computes arrival times, required times, and slack values based on statistical distributions. When performing comparisons between these statistical quantities, the tool needs to know what values in the distribution are considered worst-case.

The default behavior is to choose values at 3.0 standard deviations away from the mean value. In other words, for an arrival time distribution, the worst-case early arrival is 3.0 standard deviations below the mean, and the worst-case late arrival is 3.0 standard deviations above the mean.

You can use this command set a different number of standard deviations away from the mean to determine the worst-case values for timing reports. Use a lower value such as 2.5 for less worst-case variation and more relaxed timing constraints. Conversely, use a higher value such as 3.5 for more worst-case variation and more restrictive timing constraints.

Note that **set_pocvm_corner_sigma** has higher priority than **time.pocvm_corner_sigma**. When they are both specified, only **set_pocvm_corner_sigma** will be honored.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

The following example sets a corner sigma value 3.5 on current corner:

prompt> **set_pocvm_corner_sigma 3.5**

SEE ALSO

time.pocvm_enable_analysis(3)
time.pocvm_corner_sigma(3)

set_pop_up_object_options

Sets options for the **pop_up_objects** command.

SYNTAX

string **set_pop_up_object_options**
-object_type *types*
[-block_action keep | remove]
[-routing_overlap_check true | false]
[-pins_as_terminals true | false]

Data Types

types string

ARGUMENTS

-object_type *types*

Specifies the types of the objects for which to set options. Specify one or more of the supported object types by using the following keywords:

- **pg_routing**
  The **pg_routing** objects include wires, paths, vias, via arrays and terminals that connect to power and ground nets.
- **signal_routing**
  The **signal_routing** objects include wires, paths, vias, via arrays and terminals that connect to signal nets.
- **routing_guide**
  The **routing_guide** objects include all the rectangular route guides.
- **blockage**
  The **blockage** objects include all the placement blockages.
- **pin_guide**
  The **pin_guide** objects include all the rectangular and rectilinear pin guides.
- **pin_blockage**
  The **pin_blockage** objects include all the rectangular and rectilinear pin blockages.
- **cells**
  The **cells** objects include cell instances in child blocks.
- **marker_layer**
  When specifying **marker_layer**, the marker layer shapes in the hard macro cells that are specified in the **pop_up_objects** command are popped up to the top block. When specifying **marker_layer**, you should always specify the **-block_action**

keep.

This is a required option.

-block_action keep | remove

Specifies how to process the objects at the block level. You can specify only one block action type. By default, the block action is remove. If the object_type is **cells**, the only supported block_action is remove.

If you specify **-block_action remove**, the **pop_up_objects** command creates a copy of the object at the top level and deletes the object from the block level. If **-block_action keep** is specified, the **pop_up_objects** command creates a copy of the object at the top level, but keeps the object in the block level. Note that object_type **cells** does not support **-block_action keep**.

-top_action copy | merge

Specifies whether or not to merge the popped up routing path with top level path(s). You can specify only one top action type. By default, the top action is merge.

When **-top_action merge**, then the popped up routing path will be merged with any top level path if 1.they have the same direction; 2.they are logically connected; 3.they can be perfectly merged into one single path. When **-top_action copy**, then the popped up routing path will remain exactly the same as it was in the block.

-routing_overlap_check true | false

Specifies whether overlap checking is performed before popping up the routing objects. This option is valid only for *remove* block action type. The command checks only the overlap of the same type objects. You must use more specific DRC checks to prevent DRC violations and shorts. If overlap exists in the design, the command errors out without popping up the object. By default, the *-routing_overlap_check* option is *false* and the command does not perform overlap checking.

-pins_as_terminals true | false

Specifies whether to create top-level terminals in the parent level, based upon a block pin, when the parent-level net has a top-level port connection. This option can only be used in conjunction with object types pg_routing and signal_routing. A terminal will be created if the child net has been specified for pop-up, or if the block terminal has been specified for pop-up. If a specific object of a child net has been specified in the collection, but not the entire net, and not the specific block terminal, then no terminal will be created.

DESCRIPTION

This command sets options for the **pop_up_objects** command. You can review the options with the **report_pop_up_object_options** command.

EXAMPLES

The following example sets *block_action* to *keep* for *pg_routing* popping up and specifies a routing overlap check before popping up objects.

```
prompt> set_pop_up_object_options -object_type pg_routing \
    -block_action keep \
    -routing_overlap_check true
```

The following example specifies pins to be popped up as top-level terminals if the net is port-connected in the parent level.

```
prompt> set_pop_up_object_options -object_type signal_routing \
        -pins_as_terminals true
```

SEE ALSO

pop_up_objects(2)
remove_pop_up_object_options(2)
report_pop_up_object_options(2)

set_port_antenna_property

Sets antenna attribute values on the specified port.

SYNTAX

collection **set_port_antenna_property**
-port *port*
-data *data*
[-add]
[-replace]

Data Types

port string
data string

ARGUMENTS

-port *port*

Specifies the port (or library cell pin) for which to set the antenna property. This option is required.

-data *data*

Specifies the data used to set the antenna property. This option is required.

-add

Appends additional data to the existing antenna property data for a port or library cell pin. The command replaces only the data that is specified in the command. This mode is optional. If this mode is not specified, **-replace** mode is used.

-replace

Replaces any existing data on the port or library cell pin, even for layers that are not specified in the given data. This mode is optional. By default, **-replace** mode is used.

DESCRIPTION

This command sets antenna property data on the specified port or library cell pin. It returns the data as a Tcl array in the form described in the **get_port_antenna_property** command. If the command is not successful, it returns an empty list.

The format used to specify the antenna data can be in either of the two forms (single- or multiple layer data) as follows;

```
# Single layer data
{
 {[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size gate_data
  mode1_area mode1_data mode2_ratio mode2_data mode3_area mode3_data
  mode4_area mode4_data mode5_ratio mode5_data mode6_area mode6_data}
}

# Multiple layer data
{
 {{[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size gate_data1 ...}}
 {{[well_type] [oxide_model <type>] metalLayer metalLayer2 gate_size gate_data1 ...}}
 ...
}
```

For ease of use, you can create a simpler list which contains the data values with the following format:

```
{{[well_type] [oxide_model_type] metalLayer1 gate_data mode1_data mode2_data mode3_data
 mode4_data mode5_data mode6_data}}
```

The data for multiple layers can be set simultaneously by using the following syntax:

```
{
 {{[well_type] [oxide_model_type] metalLayer1 gate_data1 ...}}
 {{[well_type] [oxide_model_type] metalLayer2 gate_data2 ...}}
 ...
}
```

EXAMPLES

The following example sets the antenna property on port p3 for a single layer.

```
prompt> set_port_antenna_property -port p3 \
  -data {{M1 0.3436 6.664 2.05346 12.708 17.5392 7.04044 12.682}}
{metalLayer M1 gate_size 0.3436 mode1_area 6.664
mode2_ratio 2.05346 mode3_area 12.708 mode4_area 17.5392
mode5_ratio 7.04044 mode6_area 12.682}
```

The following example sets the antenna property on port p3 for multiple layers and well dependent.

```
prompt> set_port_antenna_property -port p3 \
   -data {{{M1 0.3436 6.664 2.05346 12.708 17.5392 7.04044 12.682}} \
        {{well2 M2 0.3436 6.664 2.05346 12.708 17.5392 7.04044 12.682}}}
{{metalLayer M1 gate_size 0.3436 mode1_area 6.664
mode2_ratio 2.05346 mode3_area 12.708 mode4_area 17.5392
mode5_ratio 7.04044 mode6_area 12.682} {well2 metalLayer M2 gate_size
0.3436 mode1_area 6.664 mode2_ratio 2.05346 mode3_area 12.708
mode4_area 17.5392 mode5_ratio 7.04044 mode6_area 12.682}}
```

set_port_attributes

Sets the specified attributes and their value on the ports.

SYNTAX

status **set_port_attributes**
[-ports *port_list*]
[-elements *element_list*]
[-exclude_ports *exclude_port_list*]
[-exclude_elements *exclude_element_list*]
[-model *lib_cell_name*]
[-applies_to inputs | outputs | both]
[-attribute *name_value_pair*]
[-clamp_value 0 | 1 | Z | latch]
[-driver_supply *supply_set*]
[-receiver_supply *supply_set*]
[-repeater_supply *supply_set*]
[-feedthrough]
[-unconnected]
[-is_analog]
[-literal_supply *supply_set* | {*supply_net supply_net*}]

Data Types

port_list list
element_list list
exclude_port_list list
exclude_element_list list
supply_set string
direction string
name_value_pair string
supply_set string
supply_net string
model string

ARGUMENTS

-ports *port_list*

Specifies the collection of ports on which the attributes must be set.

-elements *element_list*

Specifies the current scope or list of instance names for whose ports or pins the attributes are applicable.

One of the **-ports** or **-elements** options should be specified for this command.

-exclude_ports *exclude_port_list*

Specifies the collection of ports on which the attributes should not be applied.

-exclude_elements *exclude_element_list*

Specifies the current scope or list of instance names for whose ports or pins the attributes should not be applied .

-model *lib_cell_name*

Specifies the name of lib cell on which the attributes must be set.

-applies_to direction

Specifies whether the given **set_port_attributes** command applies to all input ports or output ports or both input/output ports of the specified element. The argument must be used in conjunction with **-elements** argument. The default value for this argument is **both**. An inout port won't be included with *-applies_to input* or *-applies_to output*.

-attribute *name_value_pair*

Specifies the name and value of the attribute to be set on the ports specified by the **-ports** option.

-clamp_value 0 | 1 | z | latch

Specifies the clamp value to be set on the port.

-driver_supply *supply_set*

Specifies the supply for the logic driving the port.

When an inout port is applied, the value of **-driver_supply** should be electrical equivelant to the value of **-receiver_supply** if specified.

-receiver_supply *supply_set*

Specifies the supply for the logic reading the port.

When an inout port is applied, the value of **-receiver_supply** should be electrical equivelant to the value of **-driver_supply** if specified.

-repeater_supply *supply_set_ref*

Specifies the supply used by the repeater driving the port.

This option is not supported for ports and pins of direction inout.

-feedthrough

Specifies the attribute "feedthrough".

-unconnected

Specifies the attribute "unconnected".

-is_analog

Specifies the attribute "is_analog" to mark the port as an analog port.

-literal_supply ***supply_set*** | **{*supply_net supply_net*}**

Specifies the supply to be used when implementing a literal constant driving the attributed port.

User is expected to give either a supply set reference or a pair of supply net references where the first supply net corresponds to the power supply and the second to the ground supply.

DESCRIPTION

This command sets the attributes and their value on a list of ports specified by the **-ports** option or on a list of instances specified by **-elements** option.

If an attribute is defined with both the **-ports** and **-elements** options, the one specified with the **-ports** option has precedence over the one specified with the **-elements** option regardless of the order in which they are specified.

One of the **-attribute**, **-driver_supply -receiver_supply** or **-repeater_supply** options is required for this command.

Option **-model** and **-element** are mutually exclusive.

Option **-repeater_supply** and **-attribute repeater_power_net|repeater_ground_net** are mutually exclusive.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

1, The following example sets the receiver supply of the port:

prompt> **set_port_attributes -ports {in1} -receiver_supply SS1**

2, The following example sets the receiver supply of the port in1 only, because in2 is in the option exclude_port:

prompt> **set_port_attributes -ports {in1 in2} -exclude_ports {in2} -receiver_supply SS1**

3, The following examples set a literal supply for two different ports using the supply set and supply net pair options

prompt> **set_port_attributes -ports {macro_inst/in1} -literal_supply SS1**

prompt> **set_port_attributes -ports {macro_inst/in2} -literal_supply {VDD VSS}**

SEE ALSO

set_design_attributes(2)
set_related_supply_net(2)

set_power_budget

Sets power budget on different power components for either the current design or a list of cells in the current design.

SYNTAX

status **set_power_budget**
[-scenarios *scenario_list*]
[-exclude *exclude_list*]
[-exclude_groups *group_names*]
[-cell *cell_list*]
[-rails *rail_list*]
budget_value

Data Types

scenario_list list
exclude_list list
group_names list
cell_list list
rail_list list
budget_value float

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the budget_value is applied. If no scenario is specified the current_scenario is used.

-exclude *cell_list*

Specifies the list of cells which are not to be considered while applying power budget.

-exclude_groups *group_names*

Cells belonging to the specified power groups are not considered while applying power budget.

-cell *cell_list*

Specifies the list of hierarchical instances on which the specified power budget would be applied.

-rails *rail_list*

Specifies a list of supply nets for applying supply-net-specific power budget on the specified hierarchical instances.

budget_value

Specifies the power budget that would be applied on the specified hierarchical instances. Budget value is the expected total power for the specified block/cell in user output unit for power.

DESCRIPTION

Sets power budget on a list of hierarchical instances in the design. The specified power budget and actual computed power for the hierarchical instance would be used to calculate a scaling factor to scale power for all the instance in the hierarchical block, so that scaled power matches the specified power budget for the instance. With power budget set on design, report_power would report scaled power for the design.

Total power budget applied on the hierarchical instance should not be smaller than the calculated actual total leakage power for the hierarchical instance.

Supply-net-specific power budget can also be applied on the hierarchical blocks in which case power associated with the supply net would only be scaled.

Budget can be applied across multiple hierarchy levels - precedence increases with moving down the hierarchy levels in the design. Setting power budget on a hierarchical instance overrides previously set budget, if any.

reset_power_budget command can be used to clear the applied budget(s) on the design.

Applying power budget overwrites the previously specified derate factors. Also, if budget has been applied on the design or on a cell, set_power_derate will not be able to set a derating factor on the design/cell, unless the budget is first cleared using reset_power_budget.

Multicorner-Multimode Support

EXAMPLES

The following example sets a power budget of value 9.5e+04 on hierarchical instance u3/u4 for the scenario SC1.

```
prompt> set_power_budget -scenarios SC1 -cell {u3/u4} 9.5e+04
```

The following example sets a power budget of value 5.2e+07 on the current design.

```
prompt> set_power_budget 5.2e+07
```

The following example sets a power budget of value 2.5e+05 on the rail VDD1 for the hierarchical instance u2/u3.

```
prompt> set_power_budget -cell {u2/u3} -rails {VDD1} 2.5e+05
```

SEE ALSO

get_power_budget(2)
reset_power_budget(2)

report_power_budget(2)
report_power(2)

set_power_clock_scaling

Specifies the clock frequency scaling for power analysis.

SYNTAX

status **set_power_clock_scaling**
[-period *period*]
[-ratio *ratio*]
[-scenarios *scenario_list*]
[*clock_list*]

Data Types

period float
ratio float
scenario_list list
clock_list list

ARGUMENTS

-period *period*

Specify the period of clock which is used in simulation. This option cannot be used if clock obj has not been specified.Period and ratio options cannot be used together.One of period or ratio option needs to be specified.

-ratio *ratio*

Specify the clock period ratio (clock_period_used_in_SAIF / clock_period_used_in_SDC). Period and ratio options cannot be used together.One of period or ratio option needs to be specified.

-scenarios *scenario_list*

Specify the list of scenarios for storing the scaling factors specifed. If not specified, the current scenario is used.

clock_list

Specify a list of clocks in the design. If this option is not used then scenario and ratio needs to be specified.

DESCRIPTION

The clock frequency used in Switching Activity Interchange Format (SAIF) files, from logic simulation for functional verification can differ from the clock frequency used in the Synopsys Design Constraints (SDC) file for timing and power analysis. This command

tells the tool what frequency is used in logic simulation so that that tool can scale averaged power numbers properly.

The *clock_list* argument is a list of clocks in the design that have the specified period or ratio values used in simulation for SAIF generation. Here the ratio is defined as period-in-simulation / period-in-analysis. The command can be used multiple times, once for each clock. If the same clock is used more than once, a warning message will be issued and the clock specified last takes effect. The '-period' and '-ratio' options cannot be used simultaneously. If no clock object is specified, only the ratio option is allowed and the ratio value is applied to all the nets that do not have an associated simulation clock.

The tool only scales the switching activities which are of only SIMULATED type. The command returns 1 on success and 0 on failure.

Note that we will not save the scaled values in the design as they will happen on demand during activity retrieval. For example, if a net has an original toggle rate 1.0 and the -ratio option of the set_power_clock_scaling command is set to 0.1, the scaling results in the net's toggle rate of 0.1 (the original toggle rate 1.0 is not replaced). On retrieving again the value will again be reported as 0.1 and not 0.01.

When period value is specified for a clock, then the scaling ratio is calculated as the ratio of (period of the clock from set_power_clock_scaling cmd) / (period of the fastest clock of an object). This ratio is applied to the retrieved simulated activity of the object. If the ratio value is specified then it is directly applied as the scaling ratio. This ratio is applied to the retrieved simulated activity of the object.

It is to be noted that scaling information is persistent given that the app option 'power.enable_activity_persistency' is set to 'on'.

If the scenario list is empty , the clocks specified will be checked if they have the same mode as the current scenario. If not then the message will be given that the "clock 'clkname' does not have the same mode as the current scenario".If the scenario list is not empty, the clocks specified will be checked if they have the same mode as any of the scenarios. Only if the clock does not have the same mode as any of the scenarios present in the specified list the message will be given that the "clock 'clkname' does not have the same mode as any of the scenarios specified."

EXAMPLES

The following examples describe the behavior of the cmd.

```
prompt> set_power_clock_scaling -period 2.6 clk1
```

The following example sets the ratio for the clock clk1

```
prompt> set_power_clock_scaling -ratio 2.6 clk1
```

The following example sets the ratio for the current scenario.

```
prompt> set_power_clock_scaling -ratio 2.6
```

In the following example the current scenario is sc1 with mode sc1.mode. By default, the clocks have the same mode as the current scenario, unless the mode option is used with get_clocks cmd.

```
prompt> set_power_clock_scaling -ratio 2.6 -scenarios {sc2 default} {clk1}
The clock 'clk1' does not have the same mode as any of the scenarios specified. (POW-045)
```

In the following example the clk1 is fetched for mode sc2.mode which is the mode for the sc2 scenario. Even though clk1 mode is different from the default scenario, the message is not issued as there is one scenario for which the data can be filled.

```
prompt> set_power_clock_scaling -ratio 2.6 -scenarios {sc2 default} \
  [get_clocks -mode sc2.mode {clk1}]
1
```

In the following example there is no scenario specified, but the clk1 is fetched for mode sc2.mode which is the mode for the sc2

scenario. So the message is issued for the current scenario.

```
prompt> set_power_clock_scaling -ratio 2.6 \
  [get_clocks -mode sc2.mode {clk1}]
The clock 'clk1' does not have the same mode as the current scenario. (POW-045)
```

set_power_derate

Sets power derating factors on different power components for either the current design, a list of cells, library cells or all cells in a power group in the current design.

SYNTAX

status **set_power_derate**
[-scenarios *scenario_list*]
[-leakage]
[-switching]
[-internal]
[-groups *group_names*]
derate_value
[*object_list*]

Data Types

scenario_list list
group_names list
derate_value float
object_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

-leakage

Indicates that the derate_value specified should be applied to leakage power only.

-switching

Indicates that the derate_value specified should be applied to switching power only.

-internal

Indicates that the derate_value specified should be applied to internal power only.

-group *group_names*

Specifies the power group to which the derate_value is applied. The derate_value applies directly to each cell object in the power group. Note groups and object_list are mutually exclusive option.

derate_value

Specifies the power derating factor that is applied to the specified power components as a scalar multiplicative factor.

object_list

Specifies current design or a list of cells or library cells to which the specified power derating factor is applied. Note groups and object_list are mutually exclusive option.

DESCRIPTION

Sets power derating factors on different power components for either the current design, a list of cells, or library cells in the current design. If no object or power group is specified, the power derating factor is set on the current design. The power derating factors are used as a scalar multiplicative factor in power calculation.

Power derating factors affect power analysis results in power reports and power attributes. Power analysis results are multiplied by the derating factors. If power derating factors are not specified, the value of 1.0 is assumed.

If the set_power_derate command is used with the -leakage, -internal or -switching, the specified power derating factor is only applied to leakage, internal or switching power accordingly. If none of -leakage, -internal or -switching is specified the power derating factor applies to all power components, which includes internal, switching, and leakage power. First set a generic power derating factor that applies to all power components, and then refine it by setting specific power derating factors for particular power components on particular design objects.

The object_list option can be used to set power specific derating factors on instances (cells or library cells) in the design. On each instance the -switching, -internal, and -leakage options can be used in the same way as previously described to specify exactly how the derating factors should be applied to each instance in the object list.

When applying power derating factors the following priority is used (in decreasing order of precedence):

1) Leaf Cell or Power Group

2) Hierarchical Cell

3) Library Cell

4) Design

When power derating factors are being applied for a cell the tool first checks if they have been set for the cell itself. It then checks if it has been set for any of the cells hierarchical parents. If no derate factors are found, it checks for the library cell and after that it uses the factors set globally on the design.

Use the -group option to set specific derating factors on all the cell objects in particular power groups. Power group can be user generated or default, such as clock_network, memory, register. They are considered as a collection of leaf and hierarchical cells. If a derate factor is set on a power group, the specified derating factors are applied to all cell objects in the power group.

Power derating factors affect power values shown in power reports. The intended usage mode of this command is to first set global or default derates on the design. Then use the object_list option to set specific derate values for cells or library cells in the design. To set derates globally on the design simply issue the command with no object list specified.

Note that if a power budget has been applied on the design or on a specific hierarchical cell by the set_power_budget command, then set_power_derate will not be able to set a derating factor on that design/cell, unless the previously applied budget is first reset using reset_power_budget.

To set derating values back to the default use the reset_power_derate command.

Multicorner-Multimode Support

EXAMPLES

The following example sets a power derating factor of value 0.95 on all cells in the design for the scenario SCN1.

prompt> **set_power_derate -scenario SCN1 0.95**

The following example sets switching power derate and internal power derate to 0.9

prompt> **set_power_derate 0.9 -switching -internal**

The following example sets the power derating factors to 0.5 for all power components on the memory power group

prompt> **set_power_derate 0.5 -groups { memory }**

The following example sets a leakage power derating factor of 1.1 on all instances of library cell IV in the library MY_LIB

prompt> **set_power_derate -leakage 1.1 [get_lib_cells MY_LIB/IV]**

Assuming that cell, "inv" is a particular instantiation of MY_LIB/IV in the design the following command overwrites the power derating factor for the instance "inv" only

prompt> **set_power_derate -leakage 1.05 [get_cells inv]**

SEE ALSO

get_power_derate(2)
reset_power_derate(2)
report_power_derate(2)

set_power_domain_constraints

Sets power domain specific constraints.

SYNTAX

status **set_power_domain_constraints**
[-name *name*]
-object_list *list_of_domains*
[-always_on_strategy single_power | dual_power]
[-disallow_forward_biasing true | false]
[-disallow_reverse_biasing true | false]

Data Types

name string

list_of_domains collection

ARGUMENTS

-object_list *list_of_domains*

Specifies one or more power domains for which the constraints are defined. This is a required option.

-always_on_strategy single_power | dual_power

Specifies the type of always-on cells to be used, either single-power cells or dual-power cells with backup power. The default is **dual_power**.

DESCRIPTION

This command specifies the power domain related constraints.

"-always_on_strategy" specifies the always-on strategy for specified shutdown power domains. The strategy indicates the type of cells to be used for always-on buffering. You can choose to use standard cells with single-power cells, or dual-power cells with a backup supply. This information drives cell selection during optimization.

The dual-power strategy uses special-purpose, always-on cells. Each of these cells has two power pins: a primary pin connected to the primary supply and a backup pin connected to a backup supply net. The cell also has an attribute called always_on which is set to true at the cell level. This type of cell is known as a dual-rail, always-on cell. Specifying dual-power allows optimization to use either single-rail or dual-rail cells.

The single-power strategy uses standard, single-power cells that are placed in dedicated always-on site rows of the power domain's corresponding voltage area. If single-power is specified, only single-rail cells are used by optimization. These always-on sites are powered by the backup power supply. During optimization, the tool does not make any changes to these always-on site rows, so it leaves these cells on the always-on paths. You should create an always-on site row to place the buffer. If you do not create the site rows and the buffering strategy requires it, the tool inserts single-rail cells and issues an MV-058 warning message.

The dual-power strategy does not require always-on site rows and the cells can be placed anywhere in the voltage area.

The "-disallow_forward_biasing" and "-disallow_reverse_biasing" options, can be used respectively, to disallow forward or reverse biasing in all the power domains specified. A cell is forward biased if the supply voltage on a bias PG pin is lower than its related power, or if it is higher than its related ground and reverse biased if the supply voltage on a bias PG pin is higher than its related power, or if it is lower than its related ground. By default, the tool is not constrained and can choose Forward or Reverse biased cells during optimization.

If there are lib-cells specified with map_level_shifter/map_isolation/map_retention strategies on a given domain and the domain also has constraints defined with set_power_domain_constraints; optimization will only pick cells from the map_* strategies. If there are specific insulated-well/forward biased/reverse biased cells that the user wants the tool to pick, these cells must be specified with the -lib_cells options of the map_* strategies.

EXAMPLE

The following example sets the always-on strategy on *switchable_domain* to use single-power standard cells:

```
prompt> set_power_domain_constraints \
        -object_list switchable_domain \
        -always_on_strategy single_power
1
```

set_power_group

Sets user specified power groups on cells and libcells.

SYNTAX

status **set_power_group**
object_list
-name *group_list*

Data Types

object_list	list
group_list	list

ARGUMENTS

-name *group_list*

Specifies the user specified power group names that needs to be set on specified *object_list*.

object_list

Specifies list of cells and/or libcells for which the *group_list* needs to be set.

DESCRIPTION

This command sets user specified power groups on the specified object list. object list can contain both cell and libcells. If user specified power groups is again set on a cell/libcell which already has user specified power groups, the last set overrides the previous one.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example sets power group 'macro1' on a libcell and cell.

```
prompt> set_power_group -name macro1 {CORE_NPPL_umc13sp/AND2X1M u3/S_reg_0}
```

SEE ALSO

report_power_groups(2)
get_power_group_objects(2)
report_power(2)

set_power_io_constraints

Sets power constraints related to the placement of I/O driver pads within the specified I/O guides.

SYNTAX

status **set_power_io_constraints**
[-reference_cell *cell_list*]
[-io_guide_object *io_guide_list*]
[-share *bump_share_specification*]
[-ratio *ratio_specification*]
[-spacing *spacing_specification*]
[-offset *offset_specification*]
[*individual_power_constraint_description*]

Data Types

cell_list string
io_guide_list list
bump_share_specification string
ratio_specification string
spacing_specification string
offset_specification string
individual_power_constraint_description string

ARGUMENTS

-reference_cell *cell_list*

Specifies the lib cell names of the power pads. No more than two names can be specified. This option is required.

-io_guide_object *io_guide_list*

Specifies the names or collection of the target I/O guides. If this option is not specified, all I/O guides are selected.

-share *bump_share_specification*

Specifies the maximum number of power pads that can share the same bump. In general, the **place_io** command tries to assign a unique bump to each pad. However, if this option is used with values larger than 1, multiple power pads can be connected to the same bump. The default value is 1.

The *bump_share_specification* accepts the following syntax:

```
-share {maximum_number library_cell}
-share {{maximum_number_1 library_cell_1} {maximum_number_2 library_cell_2}}
```

The maximum number of power pads is specified for each power pad library cell. The value must be a positive integer. The

library_cell value is the corresponding lib cell name. The value-name pair is placed within curly brackets. If two pairs are given, they are placed within a pair of outer curly brackets.

-ratio *ratio_specification*

Specifies the maximum number of signal driver pads that can be placed between two consecutive power pads of the specified type. The option value is given for each lib cell name of the power pads.

The *ratio_specification* accepts the following syntax:

```
-ratio {maximum_number library_cell}
-ratio {{maximum_number_1 library_cell_1} {maximum_number_2 library_cell_2}}
```

The maximum_number value must be a positive integer. The value-name pair is placed in curly brackets. If two pairs are given, they are placed within a pair of outer curly brackets. If this option is not specified, there is no limit to the number of signal pads that can exist between two consecutive power pads of the corresponding type.

Note that in flip-chip designs, signal pads are defined as pads that have at least one signal pad pin with the bump class label (RDL connection). In nonflip-chip designs, signal pads are defined as pads that have at least one signal pad pin.

-spacing *spacing_specification*

Specifies the maximum spacing between consecutive power pads of the corresponding type.

The *spacing_specification* accepts the following syntax:

```
-spacing {maximum_spacing library_cell}
-spacing {{maximum_spacing_1 library_cell_1} {maximum_spacing_2 library_cell_2}}
```

The maximum spacing value is given for each lib cell name of the power pads. The value must be a positive value. The specification format contains a spacing value followed by the corresponding lib cell name. The value-name pair is placed in curly brackets. If two pairs are given, they are placed within a pair of outer curly brackets. If this option is not used, there is no limit on the spacing for two consecutive power pads of the corresponding type.

-offset *offset_specification*

Specifies the maximum distance between the starting point of the I/O guide and the closest edge of the first power pad of the corresponding type.

The *offset_specification* accepts the following syntax:

```
-offset {maximum_offset library_cell}
-offset {{maximum_offset_1 library_cell_1} {maximum_offset_2 library_cell_2}}
```

The offset value is given for each lib cell name of the power pads. The value must be a positive value. The specification format contains a value followed by the corresponding lib cell name. The value-name pair is placed in curly brackets. If two pairs are given, they are placed within a pair of outer curly brackets. If this option is not used, the space can be any value between the starting point of the I/O guide and the closest edge of the first power pad of the corresponding type.

individual_power_constraint_description

Specifies an individual power constraint. This option is mutually exclusive with all options except for *-io_guide_object*. Use this individual power constraints description format to assign multiple power constraints for any I/O guide. The net connectivity of the new power pads can be described. User can also specify the prefix string for all newly created power pads due to the power constraint.

The individual power constraints description accepts the following syntax:

```
{{reference: library_cell_name}
 {ratio: ratio_value}
 {spacing: spacing_value}
```

```
 {offset: offset_value}
 {prefix: prefix_string}
 {connect: {pin_name_1 supply_net_name_1} {pin_name_2 supply_net_name_2} ...}
}
```

The keywords have the following function:

- reference: Specifies the library cell name, similar to the **-reference_cell** option.
- ratio: Specifies the maximum number of signal driver pads that can be placed between two consecutive power pads, similar to the **-ratio** option.
- spacing: Specifies the maximum spacing between consecutive power pads, similar to the **-spacing** option.
- offset: Specifies the maximum distance between the starting point of the I/O guide and the closest edge of the first power pad of the corresponding type, similar to the **-offset** option.
- prefix: Specifies a string that is inserted into the cell instance name.
- connect: Specifies the connection between power pad pins and power nets.

The *connect*: keyword is optional. If you specify this keyword, you must specify a connection for all pins, otherwise the power constraint is not valid and the tool issues a warning message. The pin name is the reference cell pin and the power net name is the net name is a PG net name in the design. The power pads of the same constraint are connected in the same way. If you do not specify a connection for a port, that port of any newly added power pads is unconnected and the tool issues a warning message. In this case, you must connect the unconnected ports using another command.

DESCRIPTION

This command specifies how power driver pads are placed within I/O guides by the **place_io** command, which inserts power pads and places them to satisfy the power constraints specified by this command and the **set_signal_io_constraints** command. The netlist can be changed during I/O placement.

All value-based options are used to set maximum values. As a result, the actual design results can be less than those values. All power I/O constraints are combined with all signal constraints. You are responsible for eliminating any constraint conflicts and avoiding impossible constraints.

Currently, this command can support two styles when specifying constraints. The first style uses the *-reference_cell*, *-ratio*, *-spacing*, and *-offset* command options to describe the all constraints for any I/O guide. With this style, the tool accepts only two types of power driver pads at most and you cannot specify power pad name prefixes or net connectivity. In addition, the latest power constraint setting of an I/O guide overrides all previous settings on the same I/O guide.

The second style specifies individual power constraints using the following format.

```
{{reference: library_cell_name}
 {ratio: ratio_value}
 {spacing: spacing_value}
 {offset: offset_value}
 {prefix: prefix_string}
 {connect: {pin_name_1 supply_net_name_1} {pin_name_2 supply_net_name_2} ...}
}
```

Power constraints are identified based on reference cell and connection. The prefix is not considered. A power constraint is overwritten if both reference cell and connectivity are identical in the separate commands. In this case, the existing values for spacing, ratio, and offset will be overridden. If no power constraint has been defined, the current power constraint is added to the existing power constraint settings on the corresponding I/O guide. As a result, a single I/O guide can have a large number of power

constraints, each with a unique reference cell and pin connectivity specification. The tool issues warning messages if there are more than 10 power constraints for an I/O guide.

Other power pads outside of the constraint set are not considered even if they belong to the same reference type or are named in the same way. It is your responsibility to delete all unused pads before performing power pad synthesis. The prefix specification is used only when new power pads are added into the netlist and is not used to determine which pad can be used for power constraint. If you do not provide a connection specification, pads with different pin connectivity can potentially be used for the power constraint if they belong to the same reference cell. You are responsible to connect these power pads to nets.

EXAMPLES

The following example sets power constraints on two I/O guides named "north" and "south". For power pads of type "VDD", the maximum spacing between any two pads is 650 micron. There can only be 7 signal pads between two consecutive "VDD" pads. The first "VDD" pads cannot be 100 micron away from the starting point of the selected I/O guides. At most 2 "VDD" pads can share the same bump instances.

```
prompt> set_power_io_constraints -io_guide_object {"north" "south"} \
  -reference_cell VDD -offset {100 VDD} -ratio {7 VDD} -share {2 VDD} \
  -spacing {650 VDD}
```

The following example sets power constraints on all I/O guides in the design. There are two types of power pads, with lib cell names as "VDD" and "VSS", respectively. For both types of pad cells, the maximum spacing between power pads of the same type is 650 microns. There can only be 7 signal pads between two consecutive "VDD" pads and 8 signal pads between two consecutive "VSS" pads. There is no offset requirement. Each power pad must have its own bump instance.

```
prompt> set_power_io_constraints \
  -reference_cell {VDD VSS} -ratio {{7 VDD} {8 VSS}} \
  -spacing {{650 VDD} {650 VSS}}
```

Three examples are given below using individual constraints. The three lines are additive because they define different power constraints. The first command defines a constraint for reference cell "libCell1", with a ratio of 6. Any pads inserted will the "VDD" string inserted into the instance name. The "VDD" pin will be connected to the "VDD" supply net, the "VDDIO" pin will be connected to the "VDDIO_R" supply net, and the "VSSIO" pin to the "VSS" supply net. This constraint is restricted to the specified I/O guides. The second command uses the same reference but with a different prefix and different connections, and a different I/O guide. The third is a specification for a different reference cell and applies to all I/O guides.

```
prompt> set_power_io_constraints \
  -io_guide_object {ring1.top ring1.right ring1.bottom} \
  {{reference: libCell1}
   {ratio: 6}
   {prefix: VDD}
   {connect: {VDD VDD} {VDDIO VDDIO_R} {VSSIO VSS}}}

prompt> set_power_io_constraints \
  -io_guide_object {ring1.left} \
  {{reference: libCell_1}
   {ratio: 4}
   {prefix: VDD3}
   {connect: {VDD VDD3} {VDDIO VDDIO_R} {VSSIO VSS}}}

prompt> set_power_io_constraints \
  {{reference: libCell_2}
   {ratio: 6}
   {prefix: VSS}
   {connect: {VDDIO VDDIO_R} {VSS VSS} {VSSIO VSS}}}
```

set_power_strategy_attribute

Set power strategy attribute on specified power cells.

SYNTAX

int **set_power_strategy_attribute**
cells
power strategy

Data Types

cells collection or string
power strategy collection of single object

ARGUMENTS

cells

Specifies a collection of the power cells to be associated with specified power strategy.

power strategy

Specifies the power strategy to be associated with specified cells.

DESCRIPTION

This command associates power cells (isolation, level shifter, power switch, and retention cell) with UPF power strategies.

EXAMPLES

The following associates isolation cells with isolation strategies specified.

prompt> **set_power_strategy_attribute iso* [get_power_strategies -domain TOP iso1]**
1

SEE ALSO

set_isolation(2)
set_level_shifter(2)
create_power_switch(2)
set_retention(2)
get_power_strategies(2)

set_power_switch_placement_pattern

Defines a power switch placement pattern.

SYNTAX

status **set_power_switch_placement_pattern**
[-name *pattern_name*]
[-placement_type ring | array]
[-driver *lib_cell*]
[-direction horizontal | vertical]
[-connect_mode hfn | daisy]
[-pattern *pattern_spec*]
[-port_net_name *prefix*]

Data Types

pattern_name string
lib_cell string
pattern_spec string
prefix string

ARGUMENTS

-name *pattern_name*

Specifies the pattern name to use as a handler for the **create_power_switch_array** and **create_power_switch_ring** commands. If a pattern with same name already exists, the pattern definition is updated with the new pattern syntax and settings.

-placement_type ring | array

Specifies the pattern placement type. A pattern can be either *ring* for a pattern or *array* for an array pattern. By default, the value is *array*.

-driver *lib_cell*

Specifies the driver cell for the pattern. *lib_cell* is a library cell name. **-driver** must be specified for an array pattern. This option is ignored when you specify **-placement_type ring**.

-direction horizontal | vertical

Specifies the direction of the pattern. The pattern can be placed either horizontally or vertically. By default, the value is *vertical*. This option is ignored when you specify **-placement_type ring**.

-connect_mode hfn | daisy

Specifies the intra-pattern connection mode. Specify *hfn* to connect the patterns in high fanout mode, or *daisy* to connect the

patterns in daisy chain mode. By default, the value is *hfn*. This option is ignored when you specify **-placement_type ring**.

-pattern *pattern_spec*

Specifies the pattern syntax used in power switch insertion. An example pattern syntax is as follows:

{cell1 {SPACE number} {cell2 n1} {SPACE number} {cell3 n2} }

where

- cell1, cell2 and cell3 are the reference cell names.
- n1 and n2 are integers that specify the number of cell instances to insert. If you do not specify the instance count, the command inserts one instance of the reference cell.
- SPACE is a keyword and must be followed by a number (double or integer) that represents the size of the space in microns. If you do not specify SPACE, the default space is 0.

The following simple pattern example places one instance of cell1, one instance of cell2, and five instances of cell3. The space between cell1 and cell2 is 10 microns and the space between cell2 and cell3 are 0.

-pattern {cell1 {SPACE 10} cell2 {cell3 5})

The **-pattern** option supports nested patterns. The following nested pattern example places one instance of cell1, places three instances of the pattern group {cell2 cell3}, and places one instance of cell1.

-pattern {cell1 {{cell2 cell3} 3} cell1}

-port_net_name *prefix*

Specifies the net name prefix for intra-pattern connection net. If not specified, the default intra-pattern connection net name will be p*, where * is the net number.

DESCRIPTION

This command specifies the power switch placement pattern and the placement options. If the placement pattern is already defined, the tool updates the definition with the new options. Placement pattern settings are not persistent in the database.

EXAMPLES

The following example defines an array pattern named pattern1 with a vertical direction and HFN connection mode. The driver switch is HEADX2_LVT.

```
prompt> set_power_switch_placement_pattern -name pattern1 \
  -placement_type array -direction vertical -connect_mode hfn \
  -driver HEADX2_LVT \
  -pattern {HEADX2_LVT {SPACE 10} {{HEADX4_LVT {SPACE 8}} 3} }
```

The following example defines a ring pattern named pattern2.

```
prompt> set_power_switch_placement_pattern -name pattern2 \
  -placement_type ring \
  -pattern {HEADX2_LVT {SPACE 10} {{HEADX4_LVT {SPACE 8}} 3} }
```

create_power_switch_array(2)
report_power_switch_placement_patterns(2)

set_process_label

Sets the process label for one or more corners, for part or all of the current design, or only for cells from specific reference libraries.

SYNTAX

string **set_process_label**
[*label*]
[-early *label*]
[-late *label*]
[-clear]
[-corners *corner_list*]
[-object_list *object_list*]
[-library *library*]

list *corner_list*
list *object_list*
object *library*
string *label*

ARGUMENTS

label

The process label to be used for both early and late analysis. If this option is given, the **-early** and **-late** options cannot be given. A value of "*" represents a wildcard: any available process label will be acceptable. In this case, the **set_process_number** command should be used to specify the desired process condition.

-early *label*

The early process label.

-late *label*

The late process label.

-clear

If this option is given, any early/late process label settings on the given objects and/or libs will be removed.

-corners *corner_list*

The corner(s) to apply the process label to. If this option is not given, the current corner is used.

-object_list *object_list*

The cell or port object(s) to apply the process label to. If this option is not given, the process label is applied to the entire current design.

-library ***library***

The reference library to apply the process label to. If this option is not given, the process label is applied to cells from all reference libraries.

DESCRIPTION

The **set_process_label** command is used set the process label parameters that will be used for timing analysis and delay calculation. If no **-object_list** option is given, the given parameters will used for the entire design. If the **-object_list** option specifies a hierarchical block, the parameters will be applied to all leaf cells within that block. If the **-library** option is given, the parameters will be applied only to cells from that library.

It is often necessary to specify one process label for the main cell libraries, and a different label for cells (such as memory or IP blocks) from a specialized library. In the past this was accomplished by giving a separate **set_process_label**, or **set_operating_conditions** command for every cell from the specialized library. When the **-library** option is used, it is only necessary to give a single command, and it will automatically be applied to all cells from that library.

Note that when you set a process label for a design object with **set_process_label**, the tool will look for timing information in a similarly labeled reference library that was created during library preparation. During library preparation, process labels are associated with reference libraries by using the **read_lib**, **read_db**, or **set_process** command.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

This example shows how to set the early and late process labels to the same values for an entire design.

```
prompt> set_process_label WORST
```

This example shows how to set the early and late process labels to different values for an entire design.

```
prompt> set_process_label -late WORST -early BEST
```

This example shows how to give default process labels for the design, as well as different process labels for cells from a particular reference library.

```
prompt> set_process_label -late WORST -early BEST
prompt> set_process_label -library mem_lib -late SLOW -early FAST
```

This example shows how to give default process labels for the design, but have process labels be ignored for cells from a particular reference library.

```
prompt> set_process_label -late WORST -early BEST
```

```
prompt> set_process_label -library pll_lib *
```

SEE ALSO

set_process(2)
set_process_number(2)
set_temperature(2)
set_voltage(2)

set_process_number

Sets the process number for one or more corners, for part or all of the current design, or only for cells from specific reference libraries.

SYNTAX

status **set_process_number**
[*number*]
[-early *number*]
[-late *number*]
[-clear]
[-corners *corner_list*]
[-object_list *object_list*]
[-library *library*]

Data Types

number float
corner_list list
object_list list
library string

ARGUMENTS

number

Specifies the process number to be used for both early and late analysis.

If you specify this option, you cannot specify the **-early** and **-late** options.

-early *number*

Specifies the early process number.

If you specify option, you must also specify the **-late** option.

-late *number*

Specifies the late process number.

If you specify option, you must also specify the **-early** option.

-clear

Removes any early or late process label settings on the specified objects and libraries.

-corners ***corner_list***

Specifies the corners to which to apply the process number.

If you do not specify this option, the tool applies the process number to the current corner.

-object_list ***object_list***

Specifies the cells or ports to which to apply the process number. If you specify a hierarchical block, the tool applies the process number to all leaf cells within that block.

If you do not specify this option, the tool applies the process number to the entire current design.

-library ***library***

Specifies the reference library to which to apply the process number. The tool applies the process number to all cells in the specified library.

You can use this option to specify one process number for the main cell libraries and a different number for cells such as memory or IP blocks from a specialized library.

If you do not specify this option, the tool applies the process number to the entire current design.

DESCRIPTION

The **set_process_number** command sets the process numbers that are used for timing analysis and delay calculation.

This command should not be confused with the **set_process** command, which exists only in the library manager, and is used to define the process numbers of a reference library being built.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

This example sets the same early and late process number for an entire design.

```
prompt> set_process_number 1.0
```

This example sets separate early and late process numbers for an entire design.

```
prompt> set_process_number -late 1.5 -early 0.8
```

This example sets default process numbers for the design, as well as different process numbers for cells from a particular reference library.

```
prompt> set_process_number -late 1.5 -early 0.8
prompt> set_process_number -library mem_lib 1.0
```

SEE ALSO

set_process_label(2)

report_pvt(2)

set_programmable_spare_cell_mapping_rule

Creates a mapping rule for programmable spare cells (PSC). The rule is used during spare cell mapping with the **place_freeze_silicon** command.

SYNTAX

status **set_programmable_spare_cell_mapping_rule**
-psc_type_id *id_list* | -compatible *id_list*
[-dont_overlap_pg_stripe_layer *layers*]
[-partial_overlap_pg_stripe_layer *layers*]
[-multi_height_split *id_list*]
[-multi_height_merge *id_list*]

Data Types

id_list list
layers collection

ARGUMENTS

-psc_type_id *id_list*

Specifies the list of target psc_type_id for which to set the mapping rule. The list can have one or more ids. This option is mutually exclusive with the **-compatible** option.

-compatible *id_list*

Specifies a list of psc_type_ids which are compatible and must have the same site height. PSC cells of these types can be derived from each other. PSC cells can be used to map ECO cells of compatible types. Note that the PSC mapping between these compatible ids should also honor the other mapping rules set on these type, such as the **-dont_overlap_pg_stripe_layer**. The PSC mapping should consider the PG rules without any PG rule violation. This option is mutually exclusive with the **-psc_type_id** option.

-dont_overlap_pg_stripe_layer *layers*

Specifies the layers of PG stripes that cannot overlap target PSC types. This option must be used together with the **-psc_type_id** option. This option is mutually exclusive with the **-partial_overlap_pg_stripe_layer**, **-multi_height_split**, and **-multi_height_merge** options.

-partial_overlap_pg_stripe_layer *layers*

Specifies the layers of PG stripes and cells of the target PSC types that can partially overlap PG stripes. The allowed overlap area is the right two sites of the cell. This option must be used together with the **-psc_type_id** option. This option is mutually exclusive with the **-dont_overlap_pg_stripe_layer**, **-multi_height_split** and **-multi_height_merge** options.

-multi_height_split *id_list*

Specifies a list contain one psc_type_id which can be derived by splitting from the current PSC types specified by **-psc_type_id**. The multiheight PSC cells of the current PSC types can be split to several small site height PSC cells of the types specified in this option. Especially the PSC types in this list must have different site height. This option must be used together with the **-psc_type_id** option.

-multi_height_merge *id_list*

Specifies a list of psc_type_ids which can be derived by merging the current PSC types specified by **-psc_type_id**. The multiheight PSC cells of the current PSC types can be merged from the small site height PSC cells of the types specified in this option. This option must be used together with the **-psc_type_id** option.

DESCRIPTION

This command sets rules for specified psc_type_ids used during PSC mapping with the **place_freeze_silicon** command. The PSC mapping engine considers these rules during mapping.

You can review the current mapping rules with the **report_programmable_spare_cell_mapping_rule** command. You can remove mapping rules with the **remove_programmable_spare_cell_mapping_rule** command. To ignore all mapping rules, remove all mapping rules before running the **place_freeze_silicon** command.

The currently supported mapping rules are as follows:

1. Don't overlap with PG stripes of the specified layers.

When setting this rule for a psc_type_id, ECO cells of this psc_type_id are not allowed to overlap PG stripes of the specified layers. This means that any part of the cell is not allowed to overlap with these stripes.

2. Partial overlap with PG stripes of the specified layers.

When setting this rule for a psc_type_id, ECO cells of this psc_type_id can only partially overlap PG stripes of the specified layers on the right two sites of the cell. Other areas of the cell are not allowed to overlap with these stripes.

3. Multiple height PSC cells can be split to small site height cells.

When setting this rule for a psc_type_id, PSC cells of this psc_type_id can be derived by splitting to small site height PSC cells of the psc_type_id specified by the **-multi_height_split** option.

4. Multiple height PSC cells can be merged from small site height cells.

When setting this rule for a psc_type_id, PSC cells of this psc_type_id can be derived by merging from small site height PSC cells of the psc_type_id specified in the option **-multi_height_split**.

5. PSC types are compatible

When setting this rule for list of psc_type_ids, PSC cells of these types can be derived from each other.

For rules 3, 4 and 5, the newly derived PSC cells can be used to map ECO cells of the corresponding types. Note that when using newly derived PSC cells from other types by merging, split or compatible conversion, the PSC mapping should also honor PG overlap rules specified by **-dont_overlap_pg_stripe_layer** and **-partial_overlap_pg_stripe_layer** and so on. The PSC mapping should consider the PG rules without any PG rule violation.

When setting rules such as the compatible rule and split/merge rule for deriving new PSC cells, each PSC type should have the same PG stripe layer setting or have no PG rule. Otherwise, the rule setting command reports an error and does not create the rule. It is recommended that you set overlap PG rules before the compatible and split/merge rules to avoid errors during rule setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that ECO cells with type 1 are not allowed to be overlapped with PG stripes of M1 layers.

```
prompt> set_programmable_spare_cell_mapping_rule \
  -psc_type_id 1 -dont_overlap_pg_stripe_layer {M1}
```

The following example specifies that ECO cells with psc_type_id 2 or 3 are only allowed to partially overlap on the right side with PG stripes of M1 layers.

```
prompt> set_programmable_spare_cell_mapping_rule -psc_type_id {2 3} \
  -partial_overlap_pg_stripe_layer {M1}
```

The following example specifies that ECO cells with psc_type_id 3 are multiple site height (3 site height) and can be split to small site height cells with type 1 or 2 (type 1 is single site height, type 2 is double site height).

```
prompt> set_programmable_spare_cell_mapping_rule \
  -psc_type_id 3 -multi_height_split {1 2}
```

The following example specifies that ECO cells with psc_type_id 3 are multiple site height (3 site height) and can be merged from small site height cells with type 1 or 2 (type 1 is single site height, type 2 is double site height).

```
prompt> set_programmable_spare_cell_mapping_rule \
  -psc_type_id 3 -multi_height_merge {1 2}
```

The following example specifies that ECO cells with type 1 and 2 are compatible and have the same site height. ECO cell with type 1 can be mapped to PSC cell with type 2 and the ECO cell with type 2 also can be mapped to PSC cell with type 1.

```
prompt> set_programmable_spare_cell_mapping_rule -compatible {1 2}
```

SEE ALSO

place_freeze_silicon(2)
remove_programmable_spare_cell_mapping_rule(2)
report_programmable_spare_cell_mapping_rule(2)

set_propagated_clock

Specifies propagated clock latency.

SYNTAX

string **set_propagated_clock** *object_list*

list *object_list*

ARGUMENTS

object_list

Specifies a list of clocks, ports, or pins.

DESCRIPTION

Specifies that delays be propagated through the clock network to determine latency at register clock pins. If not specified, ideal clocking is assumed. Ideal clocking means clock networks have a specified latency (designated by the **set_clock_latency** command), or zero latency, by default. Propagated clock latency is used for post-layout, after final clock tree generation. Ideal clock latency provides an estimate of the clock tree for pre-layout.

If the **set_propagated_clock** command is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports. If it is applied to an object (clock, port, or pin) on which network latency is already defined, then a warning is issued.

Virtual clocks do not have any source, and they cannot affect any register in the design. Thus, virtual clocks cannot be made propagated, and a warning is issued if set_propagated_clock is applied on a virtual clock.

To undo **set_propagated_clock**, use the **remove_propagated_clock** command or use the **set_clock_latency** command to provide an ideal latency.

To see propagated clock attributes on clocks, use the **report_clock** command.

Multicorner-Multimode Support

This command works on the current mode.

EXAMPLES

The following example specifies to use propagated clock latency for all clocks only in the current mode in the design.

```
prompt> set_propagated_clock [all_clocks]
```

The following example specifies to use propagated clock latency for all real clocks in the design.

```
prompt> foreach_in_collection mode [all_modes] {
      set_propagated_clock [get_clocks -mode $mode -filter defined(sources)]
    }
```

WARNING: After clock tree synthesis, if we explicitly make all clocks propagated, it can cause I/O clock latencies to become zero. This does not happen if we have either used independent virtual clocks for the I/Os or when the clock network latencies are included in the I/O data path delay. Virtual clocks are not propagated.

SEE ALSO

timing_remove_clock_reconvergence_pessimism(3)
remove_propagated_clock(2)

set_clock_latency(2)

set_pt_options

Sets configuration options to optimize the current design with PrimeTime ECO.

SYNTAX

status **set_pt_options**
[-pt_exec *path_name*]
[-host_option *option_name*]
[-scenario_scripts *pair_list*]
[-scenario_constraints *pair_list*]
[-pre_dmsa_script *file_name*]
[-pre_link_script *file_name*]
[-link_script *file_name*]
[-post_link_script *file_name*]
[-work_dir *directory_name*]
[-hold_fix_buffers *buffer_list*]
[-verilog_options *options*]
[-reset]

Data Types

path_name string
option_name string
pair_list list
file_name string
directory_name string
buffer_list list

ARGUMENTS

-pt_exec *path_name*

Specifies the path to the 'pt_shell' PrimeTime executable.

-host_option *option_name*

Specifies the option name defined by the **set_host_options** command. After you specify host options like the number of cores and submit command, PrimeTime slave process will be launched based on the specified options. But **set_host_options -target PrimeTime** has higher priority than **-host_option** for launching PrimeTime slave process. In hierarchical ECO fusion, this host option is passed to the **run_block_script** command in the background to export data for blocks or implement ECO changes using distributed processing. This option is mandatory for hierarchical ECO fusion. After setting the host options, use the **check_host_options** command to validate the settings.

-scenario_scripts *pair_list*

Specifies a signoff script for each signoff scenario using the following format:

{{scen1 script1} ... {scenN scriptN}}

By default, eco fusion will write out verilog, upf, parastics and saif if applicable and define **eco_fusion_verilog**, **eco_fusion_upf**, **eco_fusion_parastic**, **eco_fusion_parasitic_corner_name** and **eco_fusion_read_saif_callback** TCL variables or call back functions to point to corresponding files in the top-level wrapper script assembled for each scenario. These TCL variables could be referred to in end-user provided signoff scripts, which are sourced at end of the top-level wrapper script. But if either number of scenarios or scenario names does not match ICC scenarios exactly, it will only provide pointer to verilog and upf while not parasitic and saif. Then end-users need to prepare the saif/parasitics on their own.

To avoid checking out PrimePower license in eco fusion, eco fusion defines **eco_fusion_read_saif_callback** and calls it automatically from the master process. so end-users should not read saif or call **eco_fusion_read_saif_callback** directly in provided signoff script. But end-user could refine **eco_fusion_read_saif_callback** in provided signoff scripts to read saif file prepared by themselves.

As for hierarchical eco fusion flow, end-users should call **eco_fusion_read_parasitic_callback** to read parasitics for top-block and sub blocks as eco_fusion_parasitic only points to top-block parasitic.

-scenario_constraints ***pair_list***

Specifies a signoff constraint file for each active scenario using the following format:

{{scenario_1 /path_to_file_1} {scenario_2 /path_to_file_2} ...}

where the path is an absolute path to the file. This option is mandatory for the hierarchical ECO fusion flow when a complete full-chip constraint is not available in memory for the **eco_opt** command to export. This can occur when one or more blocks are linked to abstract view instead of the design view.

-pre_dmsa_script ***file_name***

Specifies the file that contains a custom PrimeTime script, which is executed on master before dmsa is launched.

-pre_link_script ***file_name***

Specifies the file that contains a custom PrimeTime script, which is executed on slave before linking in PrimeTime. Use PrimeTime commands that do not require the current design.

-link_script ***file_name***

Specifies the file that contains a custom PrimeTime script, which is executed on slave immediately after linking in PrimeTime. Use PrimeTime commands that require the current design.

-post_link_script ***file_name***

Specifies the file that contains a custom PrimeTime script, which is executed on slave after linking but before update timing in PrimeTime.

-work_dir ***directory_name***

Specifies the directory where PrimeTime files and logs are generated. If you don't specify a working directory, a directory is automatically created under your current working directory.

-hold_fix_buffers ***list***

Specifies a list of library buffer names for hold time fixing.

-verilog_options ***options***

Specifies custom options for write_verilog.

-reset

Resets all command options.

DESCRIPTION

This command specifies options to run PrimeTime from within an implementation tool. For example, you must specify a path to the PrimeTime executable to run PrimeTime ECO.

You can reset to default values for all options by specifying the **-reset** option.

The tools are configured as in the **analyze_timing_correlation** command. If you want to have a different setting for PrimeTime, use the **-pre_link_script** or **-post_link_script** to specify your own PrimeTime setting. The setting will be applied across all scenarios.

For example, if you have turned off crosstalk analysis but want PrimeTime to run in crosstalk analysis mode, create a Tcl script that contains the following PrimeTime command.

```
set_app si_enable_analysis true
```

Suppose the file name is my_sta_setting.tcl. With the following command, PrimeTime will run in SI mode.

```
prompt> set_pt_options -pre_link_script my_sta_setting.tcl
```

To create a setting that requires the current design, you can use the **-post_link_script** option as follows:

```
prompt> set_pt_options -post_link_script my_post_link_setting.tcl
```

If you have multiple scenarios in your design, PrimeTime runs Distributed Multi Scenario Analysis (DMSA) with separate slave processes. If you don't specify any submit commands, the tool launches PrimeTime master and slave processes on the same host machine as the current session. If you specify a submit command, PrimeTime slaves will be launched using the submit command. To specify a submit command, first use the **set_host_options** command to define your host option name. Next, use this option name to specify the **-host_option** option of the **set_pt_options** command. The following example shows the commands using the bsub command to use LSF farm.

```
prompt> set_host_option -name pteco_host_option -submit_command "/lsf/bin/bsub -R \"rusage\[mem=4000\]\""
prompt> set_pt_options -host_option "pteco_host_option"
prompt> report_pt_options
```

EXAMPLES

The following example sets a specific PrimeTime executable.

```
prompt> set_pt_options -pt_exec /u/mgr/bin/pt_shell
```

The following example sets a specific PrimeTime executable and enable In-Design StarRC for extraction.

```
prompt> set_pt_options -pt_exec /u/mgr/bin/pt_shell
```

set_push_down_object_options

Sets options for the **push_down_objects** command to push down objects.

SYNTAX

string **set_push_down_object_options**
-object_type *types*
[-top_action keep | remove]
[-block_action {"values are object-type dependent"}]
[-routing_overlap_check true | false]
[-ignore_misalignment true | false]
[-allow_multi_rail_cells true | false]
[-location_based_terminal_naming true | false]
[-collinear_margin *distance*]
[-pin_meet_fatwire_rule true | false]

Data Types

types list
distance float

ARGUMENTS

-object_type *types*

Specifies the types of the objects for which to set options. Specify one or more of the supported object types by using the following keywords:

- **pg_routing**
  The **pg_routing** objects include wires, paths, vias, via arrays and terminals that connect to power and ground nets. Note that this object type is also used to specify push-down options for routing shapes that have no net association.

  The block_actions available for pg_routing push-down are copy, create_blockage, center_pin_from_wire, and create_pin_shape. **copy** and **create_blockage** and **center_pin_from_wire** are mutually exclusive actions. **create_pin_shape** can be used in combination with either of the other 2 block actions. When **copy** is specified, a real copy of the routing (path, via, rectangle) is created in the block. But if **create_blockage** is specified, then a routing blockage is created with the same dimensions as the original routing object. The blockage has no net association, so there is no change to the netlist when routing is pushed down in the form of blockages. And the original routing objects are retained in the top cell. If the **center_pin_from_wire** action is specified, the command will create a center pin from a wire that is in the center of the block. Use caution with this action as it creates a center pin for any wire in the interior of the block; be sure to use this option only with a limited number of wires. And be sure to turn this option back off for normal push-down behavior. The default block_action for pg_routing is **create_pin_shape**.

  The **-collinear_margin** and **-pin_meet_fatwire_rule** options are DRC-avoidance options and are exclusive to power and ground (PG) routing push-down.

The **-collinear_margin** option specifies a distance within which PG routes parallel to (but don't overlap) the block boundary are considered collinear PG routes. A normal collinear PG strap is one that runs parallel to an edge, but overlaps it so that one edge is inside the boundary and the other edge is outside the boundary. Normally, PG straps which run parallel, but do not overlap the boundary, are not treated as collinear straps. Collinear straps are only created in the child block as copies of the original top-level strap, and the original strap is left untouched in the top. With this option, the command will include non-overlapping PG straps and include them as copies in the child block so that their DRC effect can be observed in the block. These will appear outside of the block boundary in the child reference block.

Vias are also processed with this option. However, vias don't typically have a vertical or horizontal direction, and are included by the tool whenever they fall within the extended collinear margin. They are copied into a block with the "copied-down" shadow status, and the original source via in the top is left there.

By default, this option is -1, meaning that the command will only consider overlapping parallel PG straps as collinear straps, and overlapping vias as collinear vias.

If the value of the **-collinear_margin** option is 0 (as in microns), only non-overlapping parallel straps which exactly abut a boundary edge will be pushed into the block as a collinear strap. If the value is greater than zero, any PG strap running parallel to a block edge will be copied into the block as a collinear strap if the closest edge of the strap is within the distance specified in the option.

The **-pin_meet_fatwire_rule** Boolean option is false by default. If this option is true, the command ensures that the size of the PG pin is big enough to trigger fat-wire spacing rules within the block. To do this, the command creates a pin that is as long (in the direction perpendicular to the edge) as it is wide. This length is created inside the boundary if it can safely be done. But if the strap which was the basis for the pin only overlapped the block less than that length, then the pin can protrude outside the boundary.

- **signal_routing**
  The **signal_routing** objects include wires, paths, vias, via arrays and terminals that connect to signal and clock nets. Note that the options set for **signal_routing** apply only to nets that are specifically included in the object collection passed into the **push_down_objects** command. This option does not affect routes between cells that are pushed down; routes between cells and routing associated with internal nets are automatically pushed down when the cells are pushed down. Please note also that this object type is not used to specify push-down options for routing shapes that have no net association. For such non-net shapes, set options by using the pg_routing object type.

  The block_actions available for signal_routing push-down are copy, create_blockage, center_pin_from_wire, and create_pin_shape. **copy** and **create_blockage** are mutually exclusive actions. **create_pin_shape** can be used in combination with either of the other two block actions. When **copy** is specified, a real copy of the routing (path, via, rectangle) is created in the block. But if **create_blockage** is specified, then a routing blockage is created with the same dimensions as the original routing object. The blockage has no net association, so there is no change to the netlist when routing is pushed down in the form of blockages. And the original routing objects are retained in the top cell. If the **center_pin_from_wire** action is specified, the command will create a center pin from a wire that is in the center of the block. Use caution with this action as it creates a center pin for any wire in the interior of the block; be sure to use this option in only with a limited number of wires. And be sure to turn this option back off for normal push-down behavior. The default block_action for signal_routing is **create_pin_shape**.

- **routing_guide**
  The **routing_guide** objects include all the rectangular route guides.

- **routing_corridor**
  The **routing_corridor** objects include all routing corridors. The top_actions available are restricted to just one, "keep", which is the default value. And the only block action available is "copy" (also the default, meaning that the copied-down object will be a routing corridor like the original).

- **blockage**
  The **blockage** objects include all the placement, shaping, and routing blockages.

- **pin_guide**
  The **pin_guide** objects include all the rectangular and rectilinear pin guides.

- **pin_blockage**
  The **pin_blockage** objects include all the rectangular and rectilinear pin blockages.

- **cells**
  The **cells** object_type is used for specifying options related to pushing down cell instances into blocks. The only supported top and block actions for **cells** are **-top_action remove** and **-top_action keep** (just for physical-only cells), and **-block_action: copy | {create_blockage create_route_blockage_from_cell} and retain_obsolete_ports**. The default top action is remove and the default block action is copy. A mutually exclusive action to copy is {create_blockage create_route_blockage_from_cell}. The block_actions create_blockage and create_route_blockage_from_cell are both mutually exclusive to copy, and can be used together or alone, as long as it is not used in combination with copy.

  The create_blockage action will cause the **push_down_objects** command to create a placement blockage in the block rather than an actual cell. The create_route_blockage_from_cell action will similarly cause the **push_down_objects** command to create a routing blockage in the block rather than an actual cell. In both of these blockage cases, there is no change to the netlist in the top block or in the push-down block. When a placement blockage is created in the block as a result of using the create_blockage block action, the new placement or routing blockage is given a shadow status of "copied-down". Such blockages cannot be popped back up, as no objects are eligible for pop-up if they have the "copied-down" shadow status. The block_action for cells, retain_obsolete_ports, will direct the **push_down_objects** command to suppress the deletion of ports that have become obsolete as the result of pushing down cells. This usually occurs when a cell being pushed down has an existing connection to the block, but does not connect to anything else, so that when the cell is pushed down, the port becomes obsolete and the net becomes an internal net in the block.

  If the top_action is "keep", the command only processes physical-only cells in that push-down session, and disregards any non-physical-only cells passed into the command. The physical-only cells are created in the destination block with the "copied-down" shadow status, and the physical-only cells in the top are left in the top. No port changes are made on the block, and no nets are created or modified.

  The **cells** object type includes an option, **-allow_multi_rail_cells true | false** option described below.

- **charging_station**
  The **charging_station** objects include all non-primary voltage areas. The only available top_action is "remove", which is the default value. And the only block action available is "copy".

- **marker_layer**
  When specifying **marker_layer**, the marker layer shapes which are provided to **push_down_objects** command will be pushed down into the overlapped blocks. When specifying **marker_layer**, user should always specify the block action to be "copy".

This option is required.

-top_action keep | remove

Specifies how to process the objects at the top level. You can specify only one top action type. The detailed descriptions for top action types for each object type is described in the **push_down_objects** command man page.

-block_action *{values are object_type dependent}*

Specifies how to process the objects at the block level. You can specify one or more supported block action types. The detailed descriptions of block action types for each object type is described in the **push_down_objects** command man page.

-routing_overlap_check true | false

Specifies whether overlap checking is performed before pushing down the routing objects. This option is valid only when you specify **-block_action copy**. By default, this option is false and no overlap checking is performed before pushing down routing objects.

-ignore_misalignment true | false

Specifies whether the *push_down_objects* command pushes down objects if there are misaligned objects among multiple instantiated blocks (MIBs). If this option is *true*, the *push_down_objects* command issues a warning message and continues

pushing down objects into blocks, even if routing or site rows are misaligned in an MIB design. This option can only be used in combination with object_type pg_routing. By default, this option is false and the **push_down_objects** command does not push down objects if a misalignment exists.

-allow_multi_rail_cells true | false

Specifies whether the *push_down_objects* command pushes down multivoltage (MV) cells with multi-rails if the cell has no associated MV strategy. Note that **-allow_multi_rail_cells true** should be used with caution; the command does not update MV constraints, nets, or ports associated with the cell. It is your responsibility to update the UPF.

This option can only be used in combination with object_type **cells**. By default, this option is false and the **push_down_objects** command does not push down multi-rail UPF cells.

-location_based_terminal_naming true | false

Specifies whether the *push_down_objects* command creates pins with names that are location- and layer-based. By default, the *push_down_objects* command always creates the first pin for a particular port by using the same name as the port; if subsequent pins are created again for that same port, the name is uniquified by appending a incremented number for each additional pin for that port. But this default naming scheme does not ensure that a particular pin at a particular location and layer will always have the same incremented counter number, so the name is not guaranteed to be persistent across multiple runs of this command. So this option allows you to specify that an absolutely unique name will be used for a given location and layer of a pin created for a port. The location is the center point of the pin in the block coordinate system, and the layer is the layer that the pin is created in. This is primarily used in cases where multiple pins shapes can be created for the same port on the block (EEQ pins). This option can only be used in combination with object_type pg_routing or signal_routing. By default, this option is false. Note that this terminal naming option will only be observed in the push-down of routing for nets that have NOT been specified to allow feedthroughs.

-collinear_margin *distance*

Specifies a distance within which PG routes parallel to (but not overlapping) the block boundary are considered collinear PG routes. See a complete description of this option under **pg_routing** in the **-object_type** description.

-pin_meet_fatwire_rule true | false

Ensures that the size of the PG pin is big enough to trigger fat-wire spacing rules within the block, when this option is true. By default, this option is false. For more information, see the description under **pg_routing**.

DESCRIPTION

This command sets options for the **push_down_objects** command. You can review the options with the **report_push_down_object_options** command.

EXAMPLES

The following example sets *block_action* to *copy* and *create_pin_shape* for *pg_routing* pushing down.

```
prompt> set_push_down_object_options -object_type pg_routing \
    -block_action {copy create_pin_shape}
```

The following example sets *block_action* to *copy* and *create_pin_shape* for *signal_routing* pushing down.

```
prompt> set_push_down_object_options -object_type signal_routing \
```

-block_action {copy create_pin_shape}

The following example sets the block actions for cell pushdown to include retain_obsolete_ports.

prompt> **set_push_down_object_options -object_type cells** \
-block_action {copy retain_obsolete_ports}

The following example sets the "cells" object-type-specific option **-allow_multi_rail_cells**.

prompt> **set_push_down_object_options -object_type cells** \
-allow_multi_rail_cells true

SEE ALSO

push_down_objects(2)

report_push_down_object_options(2)

set_pvt_configuration

Sets the allowable PVTs for the current session.

SYNTAX

string **set_pvt_configuration**
[-add]
[-name *new_rule_name*]
[-rule *rule_name*]
[-clear_filter *filter_type*]
[-process_labels *label_list*]
[-process_numbers *number_list*]
[-voltages *voltage_list*]
[-temperatures *temp_list*]

Data Types

filter_type string
label_list list of string
number_list list of float
voltage_list list of float
temp_list list of float
rule_name string
new_rule_name string

ARGUMENTS

-add

Add a new rule to the configuration, making it the current rule, and apply the rest of the arguments to the new rule. This option is exclusive with *-rule*.

-name *new_rule_name*

Used along with -add, optionally gives the new rule a specific name. Without *-name*, new rules receive names like rule_1. This option is exclusive with *-rule*.

-rule *rule_name*

Make *rule_name* the current rule, and apply the rest of the arguments to it. This option is exclusive with *-add*.

-clear_filter *filter_type*

Specifies which filters you want to clear, that is, which of process label, process number, voltage, or temperature you do not want filtered. This is applied to the current rule before any of the other filters. Valid values are:

- **all** Clears all filters
- **process_label** Clears only the process label filter
- **process_number** Clears only the process number filter
- **voltage** Clears only the voltage filter
- **temperature** Clears only the temperature filter

-process_labels ***label_list***

Specifies process labels that you want included in the current rule in the configuration.

-process_numbers ***number_list***

Specifies process numbers that you want included in the current rule in the configuration.

-voltages ***voltage_list***

Specifies voltages that you want included in the current rule in the configuration.

-temperatures ***temp_list***

Specifies temperatures that you want included in the current rule in the configuration.

DESCRIPTION

The **set_pvt_configuration** command is used to limit the process, voltage, and temperature combinations which are allowed in the current session. The concept is the same across all applications using the command, but there are details which vary. These will be described below.

The configuration is a sequence of rules, each of which specifies process labels, process numbers, voltages, and temperatures to match. Generally, if you want all data matching a specific set of PVTs, a single rule is sufficient. When you have a specific subset of many PVTs that you want to match, multiple rules are needed. See examples below. New rules are created with *-add*. If desired, you can name a new rule with *-name*. Otherwise, they are automatically named. You can change the rule that the command is operating on with the *-rule* option. The result of the command is the name of the current rule. If neither *-add* or *-rule* is used, the current rule is used. If no rules exist, an initial rule is created for you. At least one of the filtering options - *-process_labels*, *-process_numbers*, *-voltages*, *-temperatures* and *-clear_filter* - is required if you use *-add* or *-rule*.

By default, all PVTs are allowed. Each of the filters allows a list of values, and these add to previous values already in the configuration. If you want to overwrite a particular filter, you would use the *-clear_filter* option in combinations with the other arguments which change a rule in the configuration. You can also do the same thing in two commands: one to clear, and one to add. Note that rules with no constraints are deleted.

The output from the **set_pvt_configuration** command shows the current configuration. For categories that are unfiltered in a particular rules (that is, for which you have not provided any specific configuration), the output will say that all are included. See the examples below. If you just want to show the current configuration, use the command without any arguments.

Configuration in the Library Manager

In the library manager, the **set_pvt_configuration** command limits the process, voltage, and temperature combinations which a DB or .lib file can have in the session. As these files are read, they are compared to the rules in the configuration to determine if they meet the criteria. If they do not pass, they are excluded from the session. This allows you to declare the needed processes, voltages and temperatures, then cast a wide net over a set of DB or .lib files, without having to depend on a file naming convention, as the rules are applied to the data in the file (or data added to the file when it was read). The voltage values

considered are the nominal values, that is, the values from a default operating condition. Other voltage rails are not considered.

Note that the configuration does not apply to the aggregate, edit, or verification flows.

For all other flows, the **set_pvt_configuration** command can be used before or after **create_workspace**. Changing the configuration after files have been read will enable, disable, or reread files as needed. Changing the process of a library using **set_process** may also have an impact on the configuration.

It is very possible to have a different number of files known to the configuration, available from **get_libs**, or attached to the workspace (visible with **report_workspace**). The **get_libs** command provides all libraries which have been successfully read (and not removed). **report_workspace** shows files which currently match the configuration. Finally, the configuration internally keeps track of "greyed out" files - those which were passed to **read_db** or **read_lib**, may or may not have been read into memory, but do not match the current configuration. There is an option to see the greyed out files in the GUI.

Configuration in an Implementation Tool

In an implementation tool, the **set_pvt_configuration** command limits the process, voltage, and temperature combinations which an NDM reference library can have have in the session. In contrast to the library manager, the configuration must be established before **open_lib** is used. Changes made to the configuration are NOT applied to libraries that are already open. If your current configuration blocks all panes in a particular library, a warning will be issued for that library. If you have created a configuration, then any panes that do match will be listed after **open_lib**. If you have not created a configuration, all panes match, and no messages are listed. If you have created a configuration which is so restrictive that no panes match, a LIB-072 warning is issued. You can always use **report_lib** to show more information about the panes.

EXAMPLES

The following example sets the configuration to allow any process label, any process number, voltages 0.8 and 0.9, and temperatures 0, 125, and -40.

```
prompt> set_pvt_configuration -clear_filter all -voltages {0.8 0.9} -temperatures {0 125 -40}
Current PVT Configuration
 rule_1:
  Process Labels :  <All included>
  Process Numbers:  <All included>
  Voltages       :  0.8, 0.9
  Temperatures   :  -40, 0, 125

rule_1
prompt>
```

To add the limitation for only process labels SS and FF:

```
prompt> set_pvt_configuration -process_labels {SS FF}
Current PVT Configuration
 rule_1:
  Process Labels :  "FF", "SS"
  Process Numbers:  <All included>
  Voltages       :  0.8, 0.9
  Temperatures   :  -40, 0, 125

rule_1
prompt>
```

Now if you read DB files and some are screened out you might see messages like the following, which indicate that the file was not loaded. This would be expected based on the setting from the previous example. The voltage does not match.

```
prompt> read_db [glob ${DBDIR}/*.db]
Information: Loading db file '/path/stdcell_ss_0.815V_0C.db' (FILE-007)
Warning: Did not load /path/stdcell_ss_0.815V_0C.db because its
PVT (label='SS', P=1.0, V=0.815, T=0) does not match the current
configuration (LM-133)
```

If you wanted to allow files which never had a process label applied, you do that with the empty string. Assuming that all files had a process label, you would not see any messages about file activation.

```
prompt> set_pvt_configuration -process_label [list ""]
Current PVT Configuration
 rule_1:
  Process Labels :  "", "FF", "SS"
  Process Numbers:  <All included>
  Voltages       :  0.8, 0.9
  Temperatures   :  -40, 0, 125

rule_1
prompt>
```

Numerical comparisons are made with a very tight tolerance. So 0.8 will not match 0.815.. In the library manager, if you realize that your voltages are really 0.815 and 0.92, you can clear voltages without impact on the rest of the configuration, and apply new ones. Now, the file that was screened out above is already known, so it is re-activated, and in this case, re-read since it was never loaded into memory.

```
prompt> set_pvt_configuration -clear_filter voltage \
   -voltages [list 0.815 0.92]
Current PVT Configuration
 rule_1:
  Process Labels :  "", "FF", "SS"
  Process Numbers:  <All included>
  Voltages       :  0.815, 0.92
  Temperatures   :  -40, 0, 125
Information: Configuration change re-activates file
/path/stdcell_ss_0.815V_0C.db (LM-132)
Information: Loading db file '/path/stdcell_ss_0.815V_0C.db' (FILE-007)

rule_1
prompt>
```

In the library manager, if you were to remove a temperature that matches files, you would see de-activation messages:

```
prompt> set_pvt_configuration -clear_filter temperature \
   -temperatures {125 -40}
 rule_1:
  Process Labels :  "", "FF", "SS"
  Process Numbers:  <All included>
  Voltages       :  0.815, 0.92
  Temperatures   :  -40, 125
Information: Configuration change de-activates file
/path/stdcell_ss_0.815V_0C.db (LM-132)

rule_1
prompt>
```

If you want to capture 0.88 volts but only for "SS", you could add a second rule:

```
prompt> set_pvt_configuration -add -process_label SS -voltages 0.88
 rule_1:
  Process Labels :  "", "FF", "SS"
  Process Numbers:  <All included>
  Voltages       :  0.815, 0.92
  Temperatures   :  -40, 125
 rule_2:
  Process Labels :  "SS"
  Process Numbers:  <All included>
  Voltages       :  0.88
  Temperatures   :  <All included>

rule_2
prompt>
```

Here is an example where multiple rules come into play. Let's say you have these panes in a reference library and you want to use configuration to load panes 1 and 4:

```
 Pane 0: process = "SS" (1),  voltages:  0.6; temperatures: 0
 Pane 1: process = "SS" (1),  voltages:  1.2; temperatures: 0
 Pane 2: process = "SS" (1),  voltages:  1.2; temperatures: 125
 Pane 3: process = "TT" (1),  voltages:  0.6; temperatures: 0
 Pane 4: process = "FF" (1),  voltages:  0.6; temperatures: 0
 Pane 5: process = "FF" (1),  voltages:  0.7; temperatures: 125
 Pane 6: process = "FF" (1),  voltages:  0.9; temperatures: 125
```

You can use these commands and get the configuration shown:

```
 set_pvt_configuration -voltages 1.2 -temperatures 0
 set_pvt_configuration -add -name FF -process_label FF -voltages 0.6

Current PVT Configuration:
 rule_1:
  Process Labels :  <All included>
  Process Numbers:  <All included>
  Voltages       :  1.2
  Temperatures   :  0
 FF:
  Process Labels :  "FF"
  Process Numbers:  <All included>
  Voltages       :  0.6
  Temperatures   :  <All included>
```

If you open this library, you will get the two panes you want:

```
prompt> open_lib p7.ndm
Information: Loading library file 'p7.ndm' (FILE-007)

Panes activated based on PVT configuration (7 possible panes):
  Pane 1: process = "SS" (1),  voltages:  1.2; temperatures: 0
  Pane 4: process = "FF" (1),  voltages:  0.6; temperatures: 0
```

You would not be able to achieve this with a single rule. If you tried to include the above processes, voltage, and temperature in a single rule, it would match panes 0, 1 and 4. This is where multiple rules can help.

set_qor_strategy

Applies or reports optimization metrics and application settings for the current design.

SYNTAX

status **set_qor_strategy**
[-output *file_name*]
[-report_only]
[-diff_only]
[-reduced_effort]
[-metric {area congestion leakage_power timing total_power} | {timing}
| {leakage_power} | {total_power}]
-stage pnr | synthesis

Data Types

file_name string

ARGUMENTS

-output *file_name*

Specifies the name of the output file name for writing the application options.

-report_only

Writes out the application options to the console in tabular format.

-diff_only

Writes out the application options to the console in tabular format for application options that are not set to their target settings.

-reduced_effort

When specified with one of the single metric targets of timing, leakage_power, or total_power, the -reduced_effort enables a lower effort recipe. This sets the engines to work toward the specified metric target but tradeoff some performance for runtime. This is aimed for designs that are easier to close and where faster runtime is more desirable.

-metric *{area congestion leakage_power timing total_power} | {timing} | {leakage_power} | {total_power}*

Specifies one or more metrics to use when configuring application options. Valid metric names are "area", "congestion", "leakage_power", "timing", and "total_power". When more than one metric is specified, the tool defaults to the old behavior. The metric targets are additive and can be set again. When only one metric is specified, and it is either "timing" or "leakage_power" or "total_power", the tool enacts new behavior. Application options are set to optimize the specified target only.

-stage pnr | **synthesis**

Specifies the stage name. Valid stage names are "synthesis" or "pnr". You can specify only one stage name.

DESCRIPTION

This command applies metric-specific settings to the current design. It sets the application options for the synthesis, placement, and routing engines for better performance in terms of one or more of the following metrics: area, congestion, leakage_power, total_power and timing. By default, the command applies the application option settings to the design based on the **-metric** and **-stage** options, and sets the metric_target attribute on the block.

Use the **-output file_name** or **-report_only** options to preview the application option settings before applying them to the design. The **-output file_name** option writes the application option settings as Tcl commands which can be applied by using the **source** command. The **-report_only** option writes out the application option settings to the console.

The **-reduce_effort** option is for trading off performance for runtime by lowering the efforts of the tool engines. The **set_qor_strategy** command still optimizes toward the single metric target specified in **-metric**.

EXAMPLES

The following example writes the application option settings to the console, but does not change the application option settings, for the "area" metric and the "pnr" stage.

```
prompt> set_qor_strategy -metric area -stage pnr -report_only
Metric(s) : area
+-----------------------------------+---------------+------------+------------+----------+
|         Option Name               | Metric Group  | Tool       | Current    | Target   |
|                                   |               | Default    | Setting    | Setting  |
+-----------------------------------+---------------+------------+------------+----------+
| route.global.timing_driven        | *All metrics* | false      | false      | true     |
| time.enable_clock_to_data_analysis | *All metrics* | false      | false      | true     |
...
```

The following example applies the application option settings for the area, total_power and timing target metrics for the pnr (placement and routing) stage (old behavior).

```
prompt> set_qor_strategy -stage pnr -metric {area total_power timing}
prompt> place_opt
```

The following example applies the application option settings for the total_power target metric for the pnr (placement and routing) stage (new behavior).

```
prompt> set_qor_strategy -stage pnr -metric {total_power}
prompt> place_opt
```

set_query_rules

Defines query rules.

SYNTAX

status **set_query_rules**
[-hierarchical_separators *separators*]
[-bus_name_notations *bus_notations*]
[-class *class_list*]
[-regsub *regsub*]
[-wildcard]
[-suffix *suffix_list*]
[-nocase]
[-verbose]
[-show]
[-reset]

Data Types

separators list
bus_notations list
class_list list
regsub list
suffix_list list

ARGUMENTS

-hierarchical_separators *separators*

Specifies a list of equivalent hierarchy separators in object names. There must be at least two elements in the list. The default list is {/ _ .}. The elements are preferably all single characters, although at most one multi-character element is allowed. No more than one alphabetical character a-z or A-Z is allowed as a hierarchical separator. The alphabetical character is also mutually exclusive with the multi-character element. The following special characters are not supported as hierarchy separators nor are they allowed as one of the characters for the multi-character hierarchy separator: 0-9, '*', '?', '\\', '+', '^', '[', ']'.

-bus_name_notations *bus_notations*

Specifies a list of equivalent bus name notations in object names. There must be at least two elements in the list, and the list element must be two characters. The first character of the element is the opening bus name character, and the second character is the closing bus name character. The default list is {[] __ ()}. No more than one matching pair of alphabetical characters a-z or A-Z is allowed as bus name notations. The following characters are not supported as opening or closing bus name characters: 0-9, '*', '?', '\\', '+', '^', and '/'. Bracketed bus notations must be paired. For example, "[)" are not properly paired brackets, so they are not supported. For nonbracket bus name notations, the opening and closing bus name character must be the same. For example, "-_" is not a supported bus name notation.

-class *class_list*

Specifies a list of object class names for which the query rules are applied. The following object classes are supported: *cell*, *port*, *pin*, *net*, *power_domain*, *supply_net*, *supply_set*, *supply_port*, and *power_switch*. You can specify a subset of the above object classes. By default, the command applies the query rules to all supported classes.

-regsub *regsub*

Specifies a list of options for the **regsub** Tcl command. Each list should include three string elements {{switches}, {match_regexp}, {substitution_exp}}. The options can be specified multiple times in one **set_query_rules** command. In addition to the Tcl built-in switches, the -class switch {**-class cell** | **pin** | **net** | **port**} is supported to enable object class-specific regsub rules.

This option is applicable to pin, port, net or leaf level cells. In case the option is given for cell, it could also be applied to the cell of a pin. If **-regsub** is used without other query rules, the default values for the other options are still used. In order to save runtime, use this option only if the existing rule-based matching scheme fails to match an object.

-wildcard

Enables wildcard support.

-suffix *suffix_list*

Predefined suffix rules {_reg _tri} could be enabled with this option to match register or tri-state cells. This rule is not applicable to other type of cells.

-nocase

Enables case-insensitive rule-based matching.

-verbose

Enables verbose messages.

-show

Shows the current definition of the query options. When **-show** is used alone,the existing query rules are not cleared in the current design. If used with other options, the new query options will be set first and then displayed.

-reset

Resets query rules to the program default.

DESCRIPTION

The **set_query_rules** command allows you to define query rules. The purpose of the rule-based matching is to resolve naming differences, such as differences in hierarchical separators and bus naming notations.

This command clears all query rules in the current design, and then sets the new query rules in the current design. The new rule settings will replace the previous settings.

EXAMPLES

Show program default.

```
prompt> set_query_rules -show

set_rail_scenario

Associates a rail result with a design scenario.

SYNTAX

status **set_rail_scenario**
-design_scenario *design_scenario*
-result_name *rail_result_name*
[-percentage_threshold *percentage_threshold*]
[-priority_weight *priority_weight*]

Data Types

string *design_scenario*
string *rail_result_name*
float *percentage_threshold*
float *priority_weight*

ARGUMENTS

-design_scenario *design_scenario*

Specifies a design scenario name to be associated with a rail result.

-result_name *rail_result_name*

Specifies a rail result name to be associated with a design scenario.

-percentage_threshold *percentage_threshold*

Specifies a percentage threshold such that any voltage drop ratio (voltage drop divided by ideal supply voltage) greater than this threshold is considered a violation.

-priority_weight *priority_weight*

Specifies a priority weight to be coupled to the voltage drop ratio. Set a higher priority weight to the smaller voltage drop values such that these voltage values are shown with similar priority to those with bigger voltage drop values. Without the priority weight setting, small voltage drop values from one rail result might be totally ignored during optimization.

DESCRIPTION

When multiple rail results are loaded to memory, the command associates a design scenario with a rail result name. By default, all

results are associated with the current scenario if users does not explicitly associate a result with a design scenario with the **set_rail_scenario** command.

Through the command, users can also specify the voltage drop threshold and priority weight values for rail results. Voltage drop threshold and the priority weight are used during optimization. Voltage drop threshold determines which cells are of violations, while priority weight determines priority when cells are optimized when specified together with the voltage drop threshold.

This command has to be invoked after multiple rail results are loaded to memory through the **open_rail_result** command.

EXAMPLES

The following example loads three different rail results, then sets the association between each of the rail results and a design scenario. Since static result is loaded with two dynamic results, a higher priority weight is set on static result, so it will be treated equally with dynamic results during optimization.

```
prompt> open_rail_result { static_result vcd_result vector_free_result } \P
prompt> set_rail_scenario -design_scenario fast -result_name
      static_result -percentage_threshold 0.02 -priority_weight 5.0
prompt> set_rail_scenario -design_scenario typical -result_name
      vcd_result -percentage_threshold 0.1 -priority_weight 1.0
prompt> set_rail_scenario -design_scenario slow -result_name
      vector_free_result -percentage 0.1 -priority_weight 1.0
```

SEE ALSO

open_rail_result(2)

set_ref_libs

Sets the reference library list for a design library.

SYNTAX

set_ref_libs
[-library *name*]
-ref_libs {*paths*}

set_ref_libs
[-library *name*]
-ref_libs {*paths*}
-use_technology_lib *path*

set_ref_libs
[-library *name*]
-add *path*
[-before *path*]

set_ref_libs
[-library *name*]
-remove *path*

set_ref_libs
[-library *name*]
-clear

set_ref_libs
[-library *name*]
-rebind

ARGUMENTS

-library *name*

Which library to set the reference library list. The library must be open. If no library is specified, the current library is used.

-ref_libs {*paths*}

A list of reference library paths or names to set on this library. The entry can be either library paths or library names. A library can have an in-memory name that is different from its path. If a library name different from its path is specified, it is resolved with libraries already in-memory, and the full path of the library, not the in-memory name, will be set on the library.

Besides full pre-build reference libraries, this option also accept physical source data, like frame libraries, LEF files and Milkyway libraries. The tool will automatically build reference libraries based on these physical source data.

-use_technology_lib ***path***

Specify one library on the ref_lib list as a dedicated technology library. To be used in combination with the -ref_libs option. It is an error if the specified technology library does not have a technology section.

-add ***path***

Adds *path* to the end of the library's reference library list.

-before ***path***

Places the **-add path** before the named *path* in the reference library list.

-remove ***path***

Remove the named *path* from the reference library list. This also marks all open blocks of the library as needed to be bound.

-clear

Remove all paths from the reference library list. This also marks all open blocks of the library as needed to be bound.

-rebind

Rebind each reference library path to libraries currently loaded in memory using the search_path.

DESCRIPTION

The **set_ref_libs** command modifies the list of libraries searched for design objects referenced from this library. This is a list of paths used in conjunction with the library's parent directory, and the **search_path** to find libraries. Paths may be library names, partial paths to libraries, or full path names. If it is a partial path, it is resolved using the current search_path setting, except when the partial path is relative, path that starts with "./" or "../", in which case it is resolved relative to the parent directory of the library.

The library's reference library path list can be set with the **-ref_libs** option directly. Alternatively, it can also be automatically created and set by specifying physical source data with the **-ref_libs** option. The supported physical source data includes frame libraries, LEF files and Milkyway libraries. When physical source data is specified with **-ref_libs** option, it will create reference libraries according to these physical source data and the link_library setting. The created reference libraries will be put in the directory indicated by the **lib.configuration.local_output_dir** application option. The **lib.configuration.default_flow_setup** application option can be used to point to a Tcl script with customized settings for the reference library creation. For more information about how to use these application options, see their man pages.

A ref lib list may not contain multiple libraries that resolve to the same name in the tool. For example, two different source libraries with the same name, say <myPath1>/myLib and <myPath2>/myLib where myPath1 and myPath2 are different are not allowed in the same ref lib list. The command will fail if the result of the operation would add duplicate lib names. Furthermore, by convention the tool does not treat most .nlib/.ndm suffixes as part of the lib name, so libraries that differ only in a .nlib/.ndm suffix are subject to the duplicate name restriction. In the previous example, if the given libraries are <myPath1>/myLib and <myPath2>/myLib.ndm they are still not allowed in the same ref lib list as the name myLib.ndm resolves to myLib.

When the reference library list is set, each path is bound to a currently open library on the search path with that name. This binding is recreated when the library is re-opened in a later session. If the **search_path** is changed, the bindings can be updated with **set_ref_libs -rebind**.

Note that rebinding the reference library list with **-rebind** does not affect the bindings of any blocks in memory. Block references within a design can be rebound with **link_block -rebind**.

The list of ref_libs on a library can be retrieved with the get_attribute command.

EXAMPLES

The following example sets two reference libraries on the current library, adds a third path, then removes one path.

```
prompt> set_ref_libs -ref_libs {r4000 macros/TSMC24}
r4000 macros/TSMC24
prompt> set_ref_libs -add r6000 -before TSMC24
r4000 r6000 macros/TSMC24
prompt> set_ref_libs -remove r4000
r6000 macros/TSMC24
prompt> get_attribute [get_libs mylib] ref_libs
r6000 macros/TSMC24
prompt>
```

set_reference

Changes the reference for the specified cells.

SYNTAX

integer **set_reference**
[-design *design*]
[-block *new_block*]
[-to_block *new_block*]
[-to_module *new_module*]
[*cells*]
[-of_object *old_block*]
[-reference *reference*]
[-pin_map *name_map*]
[-pin_rebind safe | force | test | none]
[-pin_verbose]

Data Types

design collection
new_block collection
new_module string
cells collection
old_block collection
reference string
name_map list

ARGUMENTS

-design *design*

Specifies the top-level design in which to look for the specified objects.

If you do not specify this option, the command looks for the objects in the current design.

-block *new_block*

Specifies the new block or library cell to which to bind the specified cells. The argument can be a name or a collection of one object. If you specify the block name, use the following format:

[*lib*:]*block*[/*label*][.*view*]

The **-block** has been deprecated. Please use option **-to_block** instead.

-to_block *new_block*

Specifies the new block or library cell to which to bind the specified cells. The argument can be a name or a collection of one object. If you specify the block name, use the following format:

[*lib*:]*block*[/*label*][.*view*]

The **-to_block** and **-to_module** options are mutually exclusive; you must specify one.

-to_module ***new_module***

Specifies the new module to which to bind the specified cells. The argument must be the name of one object.

The **-to_block** and **-to_module** options are mutually exclusive; you must specify one.

cells

Binds the new reference to the specified cells. The argument can be a list of cell names or a collection of cells.

The *cells* argument, **-of_object** option, and **-reference** option are mutually exclusive; you must specify one.

-of_object ***old_block***

Binds the new reference to all cells in the current block that reference the specified block or library cell. The argument can be a name or a collection of one object.

The *cells* argument, **-of_object** option, and **-reference** option are mutually exclusive; you must specify one.

-reference ***reference***

Binds the new reference to all cells bound to the specified reference. Use the following format to specify the reference name:

[*lib*:]*block*[/*label*]

The reference name cannot include the view name.

The *cells* argument, **-of_object** option, and **-reference** option are mutually exclusive; you must specify one.

-pin_map ***name_map***

Specifies the pin name mappings between the old block and the new block. Use the following format to specify the pin mapping:

{*old_pin1 new_pin1 old_pin2 new_pin2* ...}

The list must have an even number of entries. Each entry must be unique (you cannot map multiple old pins to the same new pin). To remove a pin, specify a new pin name of "".

You can also use a Tcl associative array to specify the name mapping. For an example, see the EXAMPLES section.

-pin_rebind safe | **force** | **test** | **none**

Specifies how to handle pin rebinding.

Valid values are

- **safe** (the default)
  Changes the reference for a cell only when the change does not drop any pins that have a net connection.
- **none**
  Changes the reference for a cell only if the old and new port interfaces are identical.
- **force**
  Always changes the cell reference and drops net connections that do not map to the new reference.
- **test** Checks the pin interface, but does not change the reference for the cell.

-pin_verbose

Displays the old-to-new pin mapping for the cell before the cell reference is changed.

Use this option with the **-pin_rebind test** option to describe the changes that would be made to the pins if the **set_reference** command changed the cell's reference.

DESCRIPTION

The **set_reference** command changes the reference, and optionally the view, of the specified cells. Use one of the following methods to specify the cells:

- Specify the cells explicitly by using the *cells* argument.
- Specify the block or library cell referenced by the cells by using the **-of_object** or **-reference** option.

All the specified cells must have the same current reference, which differs from the new reference.

The command binds the specified cells to the specified reference or module. If you specify the view for the new reference, the command changes the cell view. The command does not use the view switch list, which is specified by the **set_view_switch_list** command, to select the view for the cells.

The command maps cell pins to reference ports by name. To specify the pin mapping, use the **-pin_map** option. By default, the command updates the cell pins to match the reference ports if no cell pin net connections are lost. If a cell pin net connection would be lost, the command issues a warning does not change that cell's reference. To change the pin rebinding method, use the **-pin_rebind** option.

Once all the invocations of **set_reference** are done, a follow up call to the command **"link_block -force" is to be done in some cases. This should be done when the block to which the cell is to be changed is either of module or blackbox design type. The following are the cases where a follow up call to command "link_block -force" is not required.**

- changing the reference from a lib-cell to another lib-cell.
- changing the reference from a design to module.
- changing the reference from a module to design.

EXAMPLES

The following example changes the reference of the u1/u7 cell to alu_1.

```
prompt> set_reference -to_block [get_blocks alu_1] u1/u7
1
```

The following example changes the reference of the specified cells to the abstract view of the xLib:RAMctrl block.

```
prompt> set_reference -to_block [get_blocks xLib:RAMctrl.abstract] \
  {uLL/uRAMctrl1 uLR/uRAMctrl14 uTOP/uRAMctrl7}
3
```

The following example changes the reference of all cells with a reference of cellLib/NAND2X2 to cellLib/NAND2X4.

```
prompt> set_reference -to_block cellLib/NAND2X4 \
```

```
  -of_object [get_lib_cells cellLib/NAND2X2]
14573
```

The following example changes the reference of all cells with a reference of cellLib/INVx16 to the timing view of cellLib:INVx2.

```
prompt> set_reference -to_block cellLib:INVx2.timing \
  -of_object [get_lib_cells cellLib/INVx16]
101277
```

The following example changes the reference of all cells that reference the MID block in the current library to the MID block in the newLib library.

```
prompt> set_reference -to_block newLib:MID -reference MID
2
```

The following example changes the reference of all cells that reference the MID block in the myLib library to the MID block in the newLib library.

```
prompt> set_reference -to_block newLib:MID -reference myLib:MID
2
```

The following example uses pin mapping specified with a Tcl associative to update the pin connections while changing the reference of the cell. Note that the pins change both name and order.

```
prompt> set pinMap(aa) AA
AA
prompt> set pinMap(bb) BB
BB
prompt> set pinMap(cc) CC
CC
prompt> set_reference -to_block newLib:MID.design u2/uMID \
  -pin_map [array get pinMap] -pin_verbose
Pin mapping from 'myLib:MID' to 'newLib:MID.design':
 Pin   0 i1 stays at pin   0.
 Pin   1 i2 stays at pin   1.
 Pin   2 i3 stays at pin   2.
 Pin   3 i4 stays at pin   3.
 Pin   4 i5 stays at pin   4.
 Pin   5 i6 stays at pin   5.
 Pin   6 i7 stays at pin   6.
 Pin   7 o1 stays at pin   7.
 Pin   8 aa moved to pin   9 renamed to 'AA'.
 Pin   9 bb moved to pin   8 renamed to 'BB'.
 Pin  10 cc stays at pin  10 renamed to 'CC'.
1
```

The following example shows the results for the various pin rebinding modes when the port interface differs between the old and new reference.

```
prompt> set_reference -to_block newLib:MID u2/uMID \
  -pin_rebind none
Error: Block 'newLib:MID.design' port interface is different from 'myLib:MID'.
(NDMUI-088)
Error: problem in set_reference
       Use error_info for more info. (CMD-013)

prompt> set_reference -to_block newLib:MID u2/uMID \
  -pin_rebind safe
Warning: Skipping cell 'u2/uMID' to avoid dropping cell pin net connection.
```

```
(NDMUI-089)
0

prompt> set_reference -to_block newLib:MID u2/uMID  \
  -pin_rebind test -pin_verbose
Pin mapping from 'myLib:MID' to 'newLib:MID.design':
  Pin    0 i1 stays at pin    0.
  Pin    1 i2 stays at pin    1.
  Pin    2 i3 stays at pin    2.
  Pin    3 i4 stays at pin    3.
  Pin    4 i5 stays at pin    4.
  Pin    5 i6 stays at pin    5.
  Pin    6 i7 stays at pin    6.
  Pin    7 o1 stays at pin    7.
  Pin    8 aa removed.
  Pin    9 bb removed.
  Pin   10 cc removed.

Removing pin 'u2/uMID/aa' would drop connection to net 'u2/nx1'.
Removing pin 'u2/uMID/bb' would drop connection to net 'u2/nx2'.
0

prompt> set_reference -to_block newLib:MID u2/uMID -pin_rebind force
Information: Disconnecting net 'u2/nx1' from pin 'u2/uMID/aa'. (NDMUI-097)
Information: Disconnecting net 'u2/nx2' from pin 'u2/uMID/bb'. (NDMUI-097)

set_register_merging

Sets the **register_merging** attribute on the specified cells or modules, allowing register merging optimization on the objects.

SYNTAX

status **set_register_merging**
obj_list
[true | false]

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of cell or module names for which to enable register merging optimization. Cell names in *obj_list* must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true | **false**

Specifies the value with which to set the **register_merging** attribute. When this option is set to true (the default), register merging is enabled on the specified objects (cells or modules). Register merging is performed on the specified objects provided that the application option **compile.seqmap.enable_register_merging** is set to true.

A setting of false on a module disables register merging for the whole module. A setting of false on an instance disables register merging for the whole instance.

DESCRIPTION

The **set_register_merging** command sets the **register_merging** attribute on the specified *obj_list*. This attribute is used to specify that the cells or modules are to be optimized using register merging.

If a cell with a specified name is found in the current design, the **register_merging** attribute is set to the specified value on the cell. If no cell with a specified name is found, the tool searches for a module and the attribute set on the module.

EXAMPLES

The following example shows how to enable register merging optimization during optimization for the sequential cells named U0 and U1 and how to disable register merging for the U2 cell:

```
prompt> set_register_merging {U0 U1} true
prompt> set_register_merging U2 false
```

SEE ALSO

compile(2)
get_attribute(2)

set_register_output_inversion

Instructs the tool to force or prevent sequential output inversion on the specified objects.

SYNTAX

status **set_register_output_inversion**
obj_list
[true | false]

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of registers or module names for which to control the register output inversion. Cell names in obj_list must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true*|*false

When the value is true, sequential output inversion is forced. When the value is false, sequential output inversion is prevented.

DESCRIPTION

The set_register_output_inversion command Instructs the tool to force or prevent sequential output inversion on the specified objects.

The command overrides the settings on the global app option compile.seqmap.enable_output_inversion

EXAMPLES

For the example below sequential output inversion will be forced on all u1/count_reg* instances

prompt> **set_register_output_inversion [get_cells {u1/count_reg*}] true**

For the example below sequential output inversion will be prevented on u1/A1_reg

```
prompt> set_register_output_inversion u1/A1_reg false
```

SEE ALSO

set_register_replication

Sets the **register_replication** attribute on the specified sequential cells, thus allowing register replication on the objects.

SYNTAX

int **set_register_replication**
[-max_fanout *max_fanout_value*]
[-num_copies *copy_value*]
[-include_fanin_logic *cell*]
[-include_fanout_logic *cell*]
[-driven_by_original_register *end_points_list*]
object_list

Data Types

max_fanout_value integer
copy_value integer
cell string
end_points_list list
object_list list

ARGUMENTS

-max_fanout *max_fanout_value*

Specifies the maximum fanout of the register after the replication.

-num_copies *copy_value*

Specifies the number of copies the specified register is replicated.

-include_fanin_logic *cell*

Specifies the combinational cell in the fanin of the register for path replication.

-include_fanout_logic *cell*

Specifies the combinational cell in the fanout of the register for path replication.

-driven_by_original_register *end_points_list*

Specifies the endpoints objects (registers or primary output ports) that should remain connected to the original register.

object_list

Specifies the set of registers to replicate.

DESCRIPTION

Sets the **register_replication** attribute on *object_list*. This attribute is used to specify how many copies the sequential cells are replicated. When you specify the **-num_copies** option, the **register_replication** attribute value is the value of the **-num_copies** option. Otherwise, it is the value of the **-max_fanout** option.

The **-include_fanin_logic** and **-include_fanout_logic** options can be used to replicate a path. A single combinational cell is specified for these options and denotes the start or end of the path. Only a single object can be specified in the **object_list** when **-include*** options are used.

The **-driven_by_original_register** option can be used to keep specified endpoints objects (registers or primary output ports) connected to the original register when replicating registers.

If a sequential cell with a specified name is found in the *current design*, the **register_replication** attribute is set to the specified value in the cell.

EXAMPLES

The following example shows how to replicate sequential cell U0 three times and how to replicate sequential cell U1 so that its fanout is less than or equal to four.

```
prompt> set_register_replication -num_copies 3 U0
prompt> set_register_replication -max_fanout 4 U1
```

The following example shows how to get an additional copy of the path from the A_reg register to the U1 cell, which lies in the fanout of the register:

```
prompt> set_register_replication -num_copies 2 A_reg -include_fanout_logic U1
```

get_attribute(2)

set_regular_multisource_clock_tree_options

It sets options for command synthesize_regular_multisource_clock_trees to perform auto tap synthesis and global clock tree synthesis for regular multisource clock trees.

SYNTAX

status **set_regular_multisource_clock_tree_options**
-clock *clock*
[-net *net*]
[-tap_template_cells *cells*]
-topology htree_only
-tap_boxes *integer_pair*
[-tap_lib_cells *lib_cell_list*]
-htree_lib_cells *lib_cell_list*
[-tap_boundary *poly_rect*]
[-prefix *string*]
[-max_displacement *distance*]
[-keepouts *poly_rect_list*]
[-htree_layers *layer_list*]
[-htree_routing_rule *routing_rule*]

Data Types

clock a clock in the design
net a clock net in the block
cells list of cell instances
integer_pair list of two positive integers {columns rows}
distance distance in user units
poly_rect a polygon definition (see create_poly_rect for format)
poly_rect_list list of poly_rect
lib_cell_list list of lib_cells
string a string value
layer_list list
routing_rule string

ARGUMENTS

-clock *clock*

This is a required switch. Specifies the clock on which auto tap synthesis must be performed. The synthesis command will use the given clock to get clock related constraints and sinks.

-net *net*

This is optional switch. If -net is not specified then root net of clock specified with -clock is picked up as the net for autotap synthesis. Use this switch if autotap synthesis must be run on a net different than the clock root net. When -tap_template_cells are not present, the tap drivers are inserted on this net. When -tap_template_cells are given, the net should be on the template cell's input pin and H tree will be built on this net.

-topology *htree_only*

This is a required switch. Specifies the type of the global clock distribution structure on top of the tap drivers. Use htree_only when topology includes Htree directly driving tap drivers. Tap synthesis will perform Htree feasibility check. The switch will be extended to support other topologies like clock mesh and clock mesh with Htree in furture

-tap_boxes *integer_pair*

This is a required switch. The **-tap_boxes** option accepts a list of two positive integers defining the number of columns and rows of a location grid. The bounding box of the boundary is subdivided in equally sized boxes according to the specified number of columns and rows. Then the preferred locations are formed by the centers of these boxes. The boundary is derived from the sink distribution rooted from the net given by -net option. The exception is when it is specified explicitly using the **-tap_boundary** option.

-tap_lib_cells *lib_cell_list*

This is a required switch. Specifies a list of buffer lib_cells that can be used as tap driver cells. All specified lib_cells should have lib_cell purpose **cts** included. In case multi voltage support is required single and dual rail versions of the repeaters can be given. For each preferred location, the corresponding voltage area is queried, and the **first** lib_cell in the list that qualifies for that voltage area will be used for the location. If none of the provided driver types qualifies, then no buffer is inserted at that location. This options is mutually exclusive with the **-tap_template_cells** option.

-htree_lib_cells *lib_cell_list*

This is a required switch. Specifies a list of library cells of type buffer or inverter which are allowed to be used during synthesis. They need not have any purpose assigned but should not be marked dont_touch. In case multi voltage support is required single and dual rail versions of the repeaters can be given. The order of the given library cells play a role. The first, second etc. occurrence of a single rail buffer/inverter is matched with first, second etc. occurrence of a dual rail buffer/inverter. It is assumed that these pairs of repeaters are electrical equivalent in terms of input capacitance and delay. Any single or dual rail repeater which is not matched with a counterpart is dropped.

-tap_boundary *poly_rect*

This is optional switch. Specifies the area in which the inserted cells should be placed. By default, boundary is derived from the sink distribution rooted from the net specified. This switch can be used to specify a bodundary different than the default value. If the preferred location of any of the cells to be inserted is not covered by the area enclosed by the boundary, then the cell will not be inserted.

-prefix *string*

This is optional switch. All newly created cells will get this prefix in front of their name. This same prefix is also applied to the names of new nets or ports that are created for a clock driver. The default value is **clk_drv** for tap drivers and msgts for htree drivers.

-max_displacement *distance*

This is optional switch. The inserted clock drivers are legalized taking fixed cells, macros, blockages, and other clock cells into account. When after legalization the distance of the cell center to the preferred location is larger than the distance specified with the **-max_displacement** option, no driver will be inserted near that preferred location. By default, no maximum displacement is in effect, and cells will be legalized as close as possible to the preferred location. This impacts only tap driver insertion

-keepouts *poly_rect_list*

This is optional switch. Specifies a list of poly_rects where no tap driver driver cells should be placed. If a preferred location is in one of the poly_rects, then no driver will be placed at that location.

-htree_layers *layer_list*

This is optional switch. Specifies the layers used in routing the H tree. If not specified then command will pick the layers from clock tree settings

-htree_routing_rule *routing_rule*

This is optional switch. Specifies the non-default routing rule used in routing the H tree. If not specified then command will pick the NDR from clock tree settings

DESCRIPTION

The *set_regular_multisource_clock_tree_options* command takes user options for performing regular multisource clock tree synthesis. To do multiple clock synthesis using synthesize_regular_multisource_clock_trees, the order of the synthesis will follow the order of calls to this option command when -clocks under the synthesis command is not given.

Multicorner-Multimode Support

This applies the settings to clock in current_mode.

EXAMPLES

The following example inserts tap drivers in 4 columns and 2 rows for clock clk ensuring Htree compatibility and builds Htree automatically to drive the tap drivers using specified library cells, NDR and layer list.

```
prompt> set_regular_multisource_clock_tree_options -clock clk -topology htree_only -prefix MSCTS \
 -tap_boxes {4 2} -tap_lib_cells [get_lib_cells */CKBUF*] \
 -htree_lib_cells [get_lib_cells */CKINV*] -htree_layers "m9 m10" -htree_routing_rule "htree_ndr"

prompt> synthesize_regular_multisource_clock_trees
```

set_related_supply_net

Associates supply net(s) to the port of the design or the pin of a cell.

SYNTAX

status **set_related_supply_net**
[-object_list *objects*]
[-ground *ground_supply_net_name*]
[-power *power_supply_net_name*]

Data Types

objects	list
ground_supply_net_name	string
power_supply_net_name	string

ARGUMENTS

-object_list *objects*

Specifies the list of ports (pins) to be associated with power/ground nets or reset. If this option is not specified, all the ports are considered.

-ground *ground_supply_net_name*

Specifies the name of the ground supply net.

-power *power_supply_net_name*

Specifies the name of the power supply net.

DESCRIPTION

This command is used to associate supply nets with design ports or leaf pins. The tool uses this information for constraining and checking the design. The level-shifter insertion tool also uses supply nets to determine if level shifter is required between a port (pin) and the logic connected to the port (pin).

If this command is not specified, the tool assumes that ports are externally connected to the primary supply net of the domain of the top design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the *VDD_EXT* power supply net and *VSS_EXT* ground supply net with *INPUT* port.

```
prompt> set_related_supply_net -object_list\
[get_ports INPUT] -power VDD_EXT -ground VSS_EXT
```

SEE ALSO

get_ports(2)

set_repeater

Defines the UPF repeater strategy for the power domains in the design.

SYNTAX

status **set_repeater**
repeater_strategy_name
-domain *power_domain*
[-repeater_supply *repeater_supply_set*]
[-applies_to inputs | outputs | both]
[-applies_to_boundary upper | lower | both]
[-elements *objects*]
[-exclude_elements *exclude_objects*]
[-name_prefix *prefix*]
[-name_suffix *suffix*]
[-update]

Data Types

repeater_strategy_name string
power_domain string
repeater_supply_set string
objects list
exclude_objects list
prefix string
suffix string

ARGUMENTS

repeater_strategy_name

Specifies the name of the UPF repeater strategy. The name of the repeater strategy should be unique within the specified power domain.

-domain *power_domain*

Specifies the name of the power domain to which this UPF repeater strategy will be applied.

-repeater_supply *repeater_supply_set*

Specifies the supply set whose power and ground functions are to be used as the repeater power and ground nets respectively.

-applies_to inputs | **outputs** | **both**

Specifies whether the given **set_repeater** command applies to all inputs or outputs or both types of ports of the power domain.

-applies_to_boundary upper | lower | both

Specifies the domain boundary that the given **set_repeater** command applies to. The default value for this option is **both** for a domain with the lower domain-boundary design attribute on, and **upper** for domains that do not have the lower domain-boundary design attribute set or have the lower domain-boundary attribute set to off.

-elements *objects*

Specifies the objects to which this UPF repeater strategy will be applied. The objects can be pins of the root cells of the power domain or top level ports or root cells of the power domain.

-exclude_elements *exclude_objects*

Specifies the objects to which this UPF repeater strategy won't be applied. The objects can be pins of the root cells of the power domain or top level ports or root cells of the power domain.

-name_prefix *prefix*

Specifies the prefix to use for the repeater cell names.

-name_suffix *suffix*

Specifies the suffix to use for the repeater cell names.

-update

Indicates that this command adds *elements* or *exclude_elements* for a previous command with the same *strategy_name* and *domain_name* and executed in the same scope.

With the **-update** option, the command only accepts **-elements** or **-excluded_elements**, and the required option *strategy_name* and **-domain**. If other options are specified with **-update**, the command will error out.

DESCRIPTION

This command defines the UPF repeater strategy for the ports of the specified power domain.

If the **-elements** and **-applies_to** options are not specified, then the repeater strategy will be applied to all ports of the power domain.

If **-repeater_supply** is not specified, then the command will error out.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF repeater strategy for all output ports of the specified power domain PD1.

```
prompt> set_repeater repeater_1 -domain PD1 -repeater_supply PD1.primary -applies_to output\
```

The following example shows how to define a UPF repeater strategy for specific ports of the specified power domain:

```
prompt> set_repeater repeater_2 -domain PD1 \
        -repeater_supply rptr_supply_set \
 -elements inst/special_port
```

The following example shows how to define a UPF repeater strategy using **-exclude_elements**:

```
prompt> set_repeater repeater_3 -domain PD1 \
        -repeater_supply rptr_supply_set \
 -elements inst \
        -exclude_elements inst/special_port
```

SEE ALSO

set_port_attributes(2)

set_repeater_group

Define a group of repeaters.

SYNTAX

status **set_repeater_group**
-group_id *group_id*
[-cells *cell_list*]
[-cutline *{ {{x1 y} {x2 y}} | {{x y1} {x y2}} }*]
[-driver_group_id *group_id*]
[-path_drivers *pin_port_list*]
[-path_loads *pin_port_list*]
[-override]

Data Types

group_id	integer
cell_list	collection
pin_port_list	collection

ARGUMENTS

-group_id *group_id*

Specifies the group ID for a group of repeaters.

-cells *cell_list*

Specifies the list of repeaters belonging to the group.

-cutline *{ {{x1 y} {x2 y}} | {{x y1} {x y2}} }*

Specifies the cutline of the group of repeaters.

-driver_group_id *group_id*

Specifies the driver group ID when there is a chain of repeater groups. For example, the first group in the chain is considered the driver group for the second group.

-path_drivers *pin_port_list*

Specifies the macro pins or top ports as drivers and connect to the cells in the first group when there is a chain of repeater groups.

-path_loads *pin_port_list*

Specifies the macro pins or top ports as loads and connect to the cells in the last group when there is a chain of repeater groups.

-override

Used to override all cells in the cell list of an existing repeater group. Must be specified with **-cells**.

DESCRIPTION

This command defines a group of repeaters for cutline support.

EXAMPLES

The following examples show the usages of command.

```
prompt> set_repeater_group -group_id 1 -cells $buf_group_1
-cutline {{250  90} {250 105}} -path_drivers $driver_pins
prompt> set_repeater_group -group_id 2 -cells $buf_group_2
-cutline {{190 130} {205 130}} -driver_group_id 1
prompt> set_repeater_group -group_id 3 -cells $buf_group_3
-cutline {{165 155} {165 175}} -driver_group_id 2
prompt> set_repeater_group -group_id 4 -cells $buf_group_4
-cutline {{110 155} {110 175}} -driver_group_id 3 -path_loads $load_pins_group_4
prompt> set_repeater_group -group_id 5 -cells $buf_group_5
-cutline {{135 220} {150 220}} -driver_group_id 3 -path_loads $load_pins_group_5
```

The following examples shows usages of overriding cells of an existing repeater group.

```
prompt> set_repeater_group -group_id 6 -cells $buf_group_6
-cutline {{145 230} {155 230}} -path_drivers $driver_pins6
prompt> set_repeater_group -group_id 6 -cells $buf_group_7 -override
```

SEE ALSO

report_repeater_groups(2)
place_group_repeaters(2)

set_repeater_group_constraints

Sets constraints for a group of repeaters.

SYNTAX

status **set_repeater_group_constraints**
-type *type_list*
[-horizontal_repeater_spacing] *spacing*
[-vertical_repeater_spacing] *spacing*
[-layer_cutting_distance *layer_scale_list*]

Data Types

type_list list
spacing integer
layer_scale_list list

ARGUMENTS

-type *type_list*

Specifies the types of repeater group constraints, The valid values are, "placement" and "insertion". Use this command to set the constraints, globally. However, constraints set using this command has lower priority than the equivalent command options in the add_group_repeaters and place_group_repeaters commands.

-horizontal_repeater_spacing *spacing*

Specifies the horizontal spacing between two adjacent repeaters in the horizontal direction in terms of number of site width. For example, if the width of the repeater is 9 cell site, then the minimum horizontal spacing is 9 um. When you specify the spacing to be less than 9, this option automatically extends the spacing to 9 um. To achieve the checkerboard pattern, in this example, the horizontal spacing should be 9,13,17,21....

-vertical_repeater_spacing *spacing*

Specifies the vertical spacing between repeaters in the vertical direction in terms of number of site height. When cell is single site height, the minimum vertical spacing is 1 site height. To achieve a checkerboard pattern, in this example, the vertical spacing should be 1,5,9.... When you specify the vertical spacing as 4, this option automatically rounds it to 5. For a double site height library cell, to ensure checkerboard pattern, you can specify 2,6,10....

-layer_cutting_distance *layer_scale_list*

Specifies the layer cutting distance list. Using this option, you can define input routes and output routes to cell center distances. Specify the option by using the following format: {{layer1 cutting_distance_in_1 cutting_distance_out_1} {layer2 cutting_distance_in_2 cutting_distance_out_2} ...}

DESCRIPTION

This command defines the constraints for a group of repeaters. Constraints set using the set_repeater_group_constriants command has lower priority than the corresponding command options in add_group_repeaters and place_group_repeaters commands. Constraints set using the set_repeater_group_constriants command for insertion and placement are independent. You can overwrite the constraints using another command run.

EXAMPLES

The following examples show the usages of command.

prompt> **set_repeater_group_constraints -type insertion**
-horizontal_repeater_spacing 10 -vertical_repeater_spacing 3
-layer_cutting_distance { {M3 3 4} {M4 4 5} }
prompt> **set_repeater_group_constraints -type placement -horizontal_repeater_spacing 4**

SEE ALSO

add_group_repeaters(2)
place_group_repeaters(2)
remove_repeater_group_constraints(2)
report_repeater_group_constraints(2)

set_report_configuration

Specifies content and format information for a report command.

SYNTAX

status **set_report_configuration**
-report *report_name*
[-columns *column_specs*]
[-filler_string *filler*]
[-overflow_method allow | truncate_left | truncate_middle | truncate_right]
[-dynamic_width *dynamic_flag*]
[-default]

Data Types

report_name string
column_specs list
filler string
dynamic_flag Boolean

ARGUMENTS

-report *report_name*

Specifies the name of the report to configure. Only certain reports are configurable by this command; in particular reports that accept a **-columns** option.

-columns *column_specs*

Specifies the columns to include in the report, their order, and optionally column width and number of significant digits for each column. Each entry is a column spec, which can take the following forms. If just a column name is specified, such as "area", it will use report-specific default column width and significant digits. A column spec such as "area:10" means to use a column width of 10. A column spec such as "area:10.4" means to use a column width of 10 and 4 significant digits. The significant digits information only applies to floating point values. If any column spec is "all", all valid columns will be included for this report.

-overflow_method allow | truncate_left | truncate_middle | truncate_right

Specifies behavior when a value needs more characters than the column width. The default is **allow**, which means to print the value as is and displace values in following columns for that row. Specifying one of the truncation approaches will cause the value to be shortened by truncating characters at the left, middle or right of the value and printing a single "*" character in place of the missing characters. For example, "abcdefghi" will be printed as "abcde*" if the column width is 6 and the overflow method is **truncate_right**. Note that numeric values are never truncated (except by the number of significant digits) because doing so would result in misleading information.

-filler_string *filler*

Specifies a string to be printed in place of empty values. By default, if the value is empty, the value will be printed as blank spaces to fill the column width. Specifying a different string such as "##" for the filler can make the report easier to parse by scripts.

-dynamic_width ***dynamic_flag***

Specifies whether to dynamically increase column widths to fit contents. If true (the default), any column that does not have a user-specified width will be at least as many characters wide as the widest value string for that column. In that case, the column values will not be truncated. If false, columns that do not have user-specified width will have a default width, and values larger than the column width will be truncated unless the overflow_method is **allow**. Dynamic width is usually preferred, unless the overall row width needs to be limited. Note that a report with many rows in a single table will run slightly slower with dynamic width set to true.

-default

Restores the configuration of this report to a default configuration.

DESCRIPTION

This command modifies the format of certain reports, by specifying which columns to show, the order of the columns, the column width, the number of significant digits for the column (for floating point values), a filler string to show instead of empty values, and the behavior in case the value is too large for its column.

EXAMPLES

The following example specifies the configuration to use for **report_lib_cells**. The "full_name" column will be displayed with a width of 10, the "area" column will be displayed with a width of 10 and 4 significant digits, and the "pin_count" column will be displayed with a default width.

```
prompt> set_report_configuration -report report_lib_cells \
 -columns {full_name:20 area:10.4 pin_count} -overflow_method truncate_left
```

SEE ALSO

report_lib_cells(2)

set_retention

Defines the UPF retention strategy for the power domains in the design.

SYNTAX

status **set_retention**
retention_strategy
-domain *power_domain*
[-retention_power_net *retention_power_net*]
[-retention_ground_net *retention_ground_net*]
[-retention_supply *retention_supply_set*]
[-no_retention]
[-elements *objects*]
[-save_signal {*save_signal save_sense*}]
[-restore_signal {*restore_signal restore_sense*}]
[-save_condition *{boolean_function}*]
[-restore_condition *{boolean_function}*]
[-retention_condition *{boolean_function}*]
[-update]

Data Types

retention_strategy string
power_domain string
retention_power_net string
retention_ground_net string
retention_supply_set string
objects list
save_signal string
save_sense high|low
restore_signal string
restore_sense high|low
boolean_function string

ARGUMENTS

retention_strategy

Specifies the name of the UPF retention strategy. The name of the retention strategy must be unique within the specified power domain.

-domain *power_domain*

Specifies the name of the power domain to which this UPF retention strategy should be applied.

-retention_power_net ***retention_power_net***

Specifies the retention power net for the retention cells inferred by this UPF retention strategy.

-retention_ground_net ***retention_ground_net***

Specifies the retention ground net for the retention cells inferred by this UPF retention strategy.

-retention_supply ***retention_supply_set***

Specifies the supply set whose power and ground function associations to be used as the retention power and retention ground nets respectively. This argument is mutually exclusive with **-retention_power_net** and **-retention_ground_net** options.

-no_retention

Specifies that the specified objects in the power domain have no retention.

-elements ***objects***

Specifies the objects to which this UPF retention strategy applies. The objects can be hierarchical cells, leaf cells, HDL blocks, and nets.

-save_signal {*save_signal save_sense*}

Specifies the save signal and the save signal sense for the retention cells under this retention strategy.

-restore_signal {*restore_signal restore_sense*}

Specifies the restore signal and the restore signal sense for the retention cells under this retention strategy.

-save_condition ***{boolean_function}***

Controls the saving of the current register's value in the retention register's shadow latch.

-restore_condition ***{boolean_function}***

Controls the restoration of the value from the register's shadow latch to the register.

-retention_condition ***{boolean_function}***

Controls the preservation of the saved value in the shadow register.

-update

Adds the specified elements to an existing retention strategy. It is an error if the strategy specified does not exist.

-use_retention_as_primary

Specifies that the retention supply powers the output driver of the retention register, and the driver supply of the data output of the retention register is therefore the retention supply.

DESCRIPTION

If you use the **-no_retention** option, the storage elements specified by this strategy do not have retention. This is useful when you want to exclude descendant cells from a different retention strategy that is applied to a hierarchical cell.

If the **-elements** option is not specified, the retention strategy is applied to all the sequential cells in the power domain. If the **-elements** is specified, the UPF retention strategy is applied to all the sequential cells that are under the objects from **-elements**.

If the **-retention_supply** option is not specified and neither the **-retention_power_net**, nor the **-retention_ground_net** options are specified, the retention power and ground nets are automatically set to the power and ground functions of the **default_retention** supply set handle of the power domain for which the strategy is being defined.

If the **-use_retention_as_primary** option is specified with either **-no_retention** option or **-update** option, it is an error.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF retention strategy in the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_retention retention_1\
-domain PD1\
-retention_power_net PN1 B\
-retention_ground_net GN1
```

The following example shows how to define a UPF retention strategy in the objects under the specified power domain:

```
prompt> set_retention retention_2\
-domain PD1\
-retention_power_net PN1\
-retention_ground_net GN1\
-elements shutdown_inst/mid_inst
```

The following example shows how to define a UPF retention strategy that excludes register R_reg from retention of its parent cell:

```
prompt> set_retention retention_3\
-domain PD1\
-no_retention\
-elements shutdown_inst/mid_inst/R_reg
```

The following example shows how to define a UPF retention strategy using a supply set:

```
prompt> set_retention retention_2 -domain PD1 \
     -retention_supply ret_supply_set \
     -elements shutdown_inst/mid_inst/R_reg
```

The following example shows how a UPF retention strategy can be defined without using a supply set or supply nets.

```
prompt> set_retention retention_2 -domain PD1 \
     -elements shutdown_inst/mid_inst/R_reg
```

SEE ALSO

set_retention_control(2)
map_retention_cell(2)

set_retention_control

Defines the UPF retention control signals for the defined UPF retention strategy.

SYNTAX

status **set_retention_control**
retention_strategy
-domain *power_domain*
-save_signal {*save_signal save_sense*}
-restore_signal {*restore_signal restore_sense*}
[-assert_r_mutex {*net_name sense*}]
[-assert_s_mutex {*net_name sense*}]
[-assert_rs_mutex {*net_name sense*}]

Data Types

retention_strategy	string
power_domain	string
save_signal	string
save_sense	high|low
restore_signal	string
restore_sense	high|low
net_name	string
sense	high|low

ARGUMENTS

retention_strategy

Specifies the UPF retention strategy name. The retention strategy should have already been defined using **set_retention** command

-domain *power_domain*

Specifies the power domain where this UPF retention strategy is applied.

-save_signal {*save_signal save_sense*}

Specifies the save signal and the save signal sense for the retention cells under this retention strategy.

-restore_signal {*restore_signal restore_sense*}

Specifies the restore signal and the restore signal sense for the retention cells under this retention strategy.

-assert_r_mutex {*net_name sense*}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the restore signal.

-assert_s_mutex {*net_name sense*}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the save signal.

-assert_rs_mutex {*net_name sense*}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the save or restore signals. If the signal name and value are not specified, it indicates the save and restore signals are mutually exclusive.

DESCRIPTION

This command defines the UPF retention control signals and control signal sense for the retention strategy. The specified control signals are applied to the retention cells of the retention strategy.

The **-assert_r_mutex**, **-assert_s_mutex**, and **-assert_rs_mutex** options create assertions, which can be used as triggers by the verification and simulation tools.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define the retention control signals on the defined UPF retention strategy *retention_1* of the power domain *PD1*.

```
prompt> set_retention_control retention_1 \
-domain PD1 \
-save_signal {save_net high} \
-restore_signal {restore_net low}
```

The following example shows how to define the assertion options for the retention strategy retention_2 of the power domain PD1.

```
prompt> set_retention_control retention_2 \
    -domain PD1 \
    -save_signal {sleep high} \
    -restore_signal {wake_up low} \
    -assert_r_mutex {wake_up high} \
    -assert_s_mutex {sleep low} \
    -assert_rs_mutex {wake_up low}
```

The following example shows how to define the assertion options when the save signal and restore signal are mutually exclusive.

```
prompt> set_retention_control retention_3 \
    -domain PD1 \
    -save_signal {sleep high} \
    -restore_signal {wake_up low} \
```

-assert_rs_mutex {}

SEE ALSO

set_retention(2)
map_retention_cell(2)

set_retention_elements

Create a named list of elements whose collective state shall be maintained if retention is applied to any of the elements in the list.

SYNTAX

status **set_retention_elements**
retention_list_name
-elements *objects*

Data Types

retention_list_name	string
objects	list

ARGUMENTS

retention_list_name

Specifies the name of the retention element list.

-elements *objects*

Specifies the objects as part of the retention element list.

DESCRIPTION

The set_retention_elements command defines a list of state elements whose collective state shall be maintained coherently if retention is applied to any of these elements.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a retention element list is defined with elements "r1" and "r2".

prompt> **set_retention_elements ret_list -elements {r1 r2}**

SEE ALSO

set_retention(2)

set_route_opt_target_endpoints

Assigns rules to determine the targeted endpoint optimization guidelines for the **route_opt** command.

SYNTAX

integer **set_route_opt_target_endpoints**
[-setup_endpoints *file*]
[-setup_timing *file*]
[-hold_endpoints *file*]
[-hold_timing *file*]
[-ldrc_objects *file*]
[-setup_endpoints_collection *pin_list*]
[-hold_endpoints_collection *pin_list*]
[-ldrc_objects_collection *pin_list*]
[-scenario *mode*]
[-reset]

Data Types

file string
pin_list list of pins/ports
mode string

ARGUMENTS

-setup_endpoints *file*

Specifies the name of a file which includes list of endpoints to be considered for setup optimization.

-setup_endpoints_collection *pin_list*

Specifies the list of endpoint pins/ports to be considered for setup optimization.

-setup_timing *file*

Specifies the name of a file which includes list of endpoints and their relevant timing constraints for which max timing adjustments must be considered during the setup optimization.

-hold_endpoints *file*

Specifies the name of a file which includes list of endpoints to be considered for hold optimization.

-hold_endpoints_collection *pin_list*

Specifies the list of endpoint pins/ports to be considered for hold optimization.

-hold_timing *file*

Specifies the name of a file which includes list of endpoints and their relevant timing constraints for which min timing adjustments must be considered during hold optimization.

-ldrc_objects *file*

Specifies the name of a file which includes list of driver terms to be considered for LDRC optimization.

-ldrc_objects_collection *pin_list*

Specifies the list of driver terms to be considered for LDRC optimization.

-scenario *mode*

Specifies the name of a scenario which will be used as the default scenario during application of timing adjustment rules.

-reset

Clears all the targeted endpoint constraints, including marking of the endpoint and/or driver terms for target endpoint optimization, and all min/max timing adjustments on all modified endpoints.

DESCRIPTION

This command reads input files and mark certain endpoints or driver terms to be considered for targeted endpoint optimization using **route_opt** command. User can define these endpoints for setup, and/or, hold, and/or LDRC optimizations. The **route_opt** command will determine which endpoints must be optimized for any of setup, hold and LDRC qualities.

The min/max timing adjustment information on certain endpoints can also be defined by using this command. This can be useful for fixing timing correlations.

This command must be defined prior to the **route_opt** command in order to have proper effect.

NOTE: The intended usage of the targeted optimization flow is to fix very few remaining violations after successfully executing at least two full **route_opt** calls.

Please make sure the bulk of all violations (setup/hold/ldrc) have already been addressed and fixed through executing default flow and by using full **route_opt** command(s).

Unlimited number of violations (for each setup/hold/ldrc) are allowed to get passed to this command. But, Targeted flow will enabled from third route_opt call onwards. That is, user should run route_opt two times prior to running targeted route_opt flow. Please make sure the list of the passed objects to the command are reviewed carefully and only pass those targeted objects that are necessary to be optimized.

EXAMPLES

The following example, reads a sample file 'test.txt' which contains a list of targeted endpoints for setup optimization. Using this setting, the **route_opt** command only performs setup optimization on those specific endpoints listed in 'test.txt' file.

prompt> **set_route_opt_target_endpoints -setup_endpoints test.txt**

SEE ALSO

route_opt(2)

set_routing_rule

Assigns a non-default or default routing rule to specific nets.

SYNTAX

integer **set_routing_rule**
[-rule *rule* | -default_rule | -no_rule]
[-min_routing_layer *layer*]
[-max_routing_layer *layer*]
[-min_layer_mode *mode*]
[-max_layer_mode *mode*]
[-min_layer_mode_soft_cost *cost*]
[-max_layer_mode_soft_cost *cost*]
[-min_layer_is_user true|false]
[-max_layer_is_user true|false]
[-clear]
[*net_list*]

Data Types

rule	string or collection
layer	list or collection
mode	string
cost	string
net_list	list or collection

ARGUMENTS

-rule *rule*

Specifies the name or collection of the non-default routing rule to be assigned to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

-default_rule

Specifies that the default routing rule should be assigned to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

-no_rule

Removes the current routing rule, if any, from the nets. This allows the tool to automatically assign a non-default rule or the default rule to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

-min_routing_layer *layer*

Specifies the minimum routing layer for the nets. Only one layer can be specified.

-max_routing_layer *layer*

Specifies the maximum routing layer for the nets. Only one layer can be specified.

-min_layer_mode *mode*

Specifies the minimum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

-max_layer_mode *mode*

Specifies the maximum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

-min_layer_mode_soft_cost *cost*

Specifies the minimum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

-max_layer_mode_soft_cost *cost*

Specifies the maximum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

-min_layer_is_user true|false

Indicates whether or not the minimum routing layer is user-generated. True indicates it is user-generated. False indicates it is tool-generated. Default value is true.

-max_layer_is_user true|false

Indicates whether or not the maximum routing layer is user-generated. True indicates it is user-generated. False indicates it is tool-generated. Default value is true.

-clear

Clears the nets' values. This resets the nets' routing rule, min/max routing layers, min/max layer modes, and min/max soft costs back to their default values. If this option is specified along with other options, the nets' values are cleared first and then set to the new values specified by the other options.

net_list

Lists of nets to which a routing rule is assigned.

DESCRIPTION

This command assigns a non-default rule, default routing rule, or no rule to specific nets. This command also assigns minimum and maximum routing layer, mode, and cost constraints to the nets.

Non-default rules are defined by using the **create_routing_rule** command and can have associated user-defined width and spacing rules.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example, assigns a non-default rule named *WideMetal* to a net named *B_CLK*.

prompt> **set_routing_rule {B_CLK} -rule WideMetal**

SEE ALSO

create_routing_rule(2)
remove_routing_rules(2)
report_routing_rules(2)

set_rp_group_options

Sets relative placement constraints on the specified relative placement groups.

SYNTAX

int **set_rp_group_options**
rp_group_list
[-tiling_type bit_slice | horizontal_compression | vertical_compression]
[-group_orientation R0 | R180 | MX | MY]
[-alignment left | right | pin [-pin_name *pin_name*]]
[-anchor_corner bottom_left | bottom_right | top_right | top_left | rp_location]
[-x_offset *offset*]
[-y_offset *offset*]
[-anchor_row *row_number*]
[-anchor_column *column_number*]
[-move_effort low | medium | high]
[-optimization_restriction size_only | size_in_place | no_opt | all_opt]
[-rp_only_keepout_margin {*left bottom right top*}]
[-place_around_fixed_cells standard | physical_only | none | all]
[-utilization *utilization_value*]
[-allow_non_rp_cells]
[-allow_non_rp_cells_on_blockages]

Data Types

rp_group_list list or collection
pin_name string
offset float
left float
bottom float
right float
top float
utilization_value double
row_number integer
column_number integer

ARGUMENTS

rp_group_list

Specifies the list of names or collection of relative placement groups, to which the given relative placement constraints will be applied.

-tiling_type bit_slice | **horizontal_compression** | **vertical_compression**

Specifies how to place cells in relative placement groups. The default is bit_slice.

The *bit_slice* value specifies that both row and column alignments are preserved. The next row starts after the tallest object in the current row and the next column starts after the widest object in the current column

The *vertical_compression* value specifies that only column alignment must be preserved. The columns are compressed such that no gap exists between leaf cells, lower-level hierarchical relative placement groups, and blockages in a column.

The *horizontal_compression* value specifies that only row alignment must be preserved. The rows are compressed such that no gap exists between leaf cells, lower-level hierarchical relative placement groups, and blockages in a row.

This option does not propagate to child relative placement groups.

-group_orientation R0 | R180 | MX | MY

Specifies the orientation of a relative placement group. This option does not propagate to child relative placement groups.

-alignment left | right | pin

Specifies the alignment method to use when placing leaf cells and relative placement groups in the specified relative placement groups. If you do not specify this option, the tool uses left alignment. This option does not propagate to child relative placement groups.

-pin_name *pin_name*

Specifies the default alignment pin for the specified relative placement groups. During placement, the tool uses the location of pin to align the cells within a column when you use the pin alignment type. If via regions are present in a pin, the tool tries to align via regions.

You can override the alignment pin for a specific leaf cell when you add the cell to the group with the **add_to_rp_group** command.

-anchor_corner bottom_left | bottom_right | top_right | top_left | rp_location

Specifies the corner for the anchor point that is set by using the **-x_offset** and **-y_offset** options. The valid *corner* values are *bottom_left*, *bottom_right*, *top_left* or *top_right*.

If you specify *bottom_left* (the default), the anchor point corner is the lower-left corner of the relative placement group.

If you specify *bottom_right*, the anchor point corner is the lower-right corner of the relative placement group.

If you specify *top_left*, the anchor point corner is the upper- left corner of the relative placement group.

If you specify *top_right*, the anchor point corner is the upper- right corner of the relative placement group.

If you specify *rp_location*, the anchor point corner is the starting location of object at the row and column specified by the *-anchor_row* and *-anchor_column* options. The options *-anchor_row* and *-anchor_col* are required and the specified location must not be empty.

This option applies to top-level relative placement groups only and is ignored for hierarchical relative placement groups.

A slight deviation from the specified anchor point might occur for non *bottom_left* anchor corners, whenever there is some change in the size of the relative placement group because of optimization or new fixed objects in the vicinity.

-x_offset *offset*

Specifies the x-coordinate of the anchor_corner of the group, in microns, relative to the lower-left corner of the chip area. If you specify only an x-offset, the tool can slide the rp group in the y-direction.

-y_offset *offset*

Specifies the y-coordinate of the anchor_corner of the group, in microns, relative to the lower-left corner in the chip area. If you

specify only a y-offset, the tool can slide the rp group in the x-direction.

-anchor_row ***row_number***

Specifies the row of the object for which the **-anchor_corner rp_location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp_location** option and is not accepted for other values of the **-anchor_corner** option.

-anchor_column ***integer***

Specifies the column of the object for which the **-anchor_corner rp_location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp_location** and is not accepted for other values of the **-anchor_corner** option.

-move_effort low | **medium** | **high**

Controls the extent to which a relative placement group can be moved from its initial location to preserve the relative placement without violating relative placement constraints. **-move_effort high** examines a larger area for possible placement, and **-move_effort low** examines a smaller area.

Coarse placement estimates an initial location for every top-level relative placement group. The relative placement groups may break, if those groups are placed at the same locations returned by coarse placement, which would violate the relative placement constraints for those groups.

Specify **-move_effort high** to allow a larger displacement of a relative placement group from its initial location. The high effort maintains the relative placement constraints and potentially avoids breaking the relative placement group. The trade-off for maintaining the relative placement group is reduced QoR, because the group is moved from the location initially determined by coarse placement.

Specify **-move_effort low** effort to place the relative placement group as close as possible to the initial location returned by coarse placement. The trade-off for maintaining the location is a higher potential for breaking the relative placement groups and violating the relative placement constraints for some relative placement groups.

By default, the tool uses *medium* effort.

-optimization_restriction size_only | **size_in_place** | **no_opt** | **all_opt**

Specifies how to treat the cells in the relative placement group during optimization.

If you specify *size_only*, the cells in the relative placement group can only be sized.

If you specify *size_in_place*, the cells in the relative placement group can only be sized in place.

If you specify *no_opt*, no any optimization will be done on relative placement cells.

If you specify *all_opt*, all the optimization capabilities can be applied to cells in the relative placement group. This might result in losing some cells from the relative placement group because cells can be decomposed or deleted from the netlist.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

Please note that only down sizing is done during *route_opt* for optimization restrictions *size_only*, *size_in_place* and *all_opt*.

By default, the cells in the relative placement group are treated as *size_only* and can only be sized.

-rp_only_keepout_margin {*left bottom right top*}

Specifies the padding margin to be maintained outside of the relative placement group in microns. The specified margin is restricted for other relative placement groups only. The non relative placement cells or the cells of failed relative placement groups can be placed over this margin. If specified margin cannot be respected then relative placement group will be placed

without margin.

The margin parameters must be positive and all four parameters are required.

-place_around_fixed_cells standard | physical_only | none | all

Specifies the legalization strategy for placing relative placement groups.

If you specify *standard*, the relative placement groups are legalized around fixed standard cells and the legalization engine avoids fixed physical-only cells.

If you specify *physical_only*, the relative placement groups are legalized around fixed physical-only cells, and the legalization engine avoids fixed standard cells.

If you specify *none*, the legalization engine avoids both fixed standard and fixed physical-only cells during legalization of relative placement groups.

If you specify *all*, the relative placement groups are legalized around both fixed standard and fixed physical-only cells.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups.

By default, relative placement groups are legalized around both fixed standard and fixed physical-only cells.

-utilization *utilization_value*

Specifies the utilization percentage for placement of relative placement group. The empty space for meeting utilization is spread throughout the relative placement group after each column. The specified utilization should be between 0.1 and 1.0. The default value for utilization is 1.0, representing 100 percent utilization.

-allow_non_rp_cells

Specifies to allow non relative placement cells in the unused spaces of relative placement group during coarse placement and refine placement. Please note that non relative placement cells are allowed in unused spaces during legalization and optimization.

-allow_non_rp_cells_on_blockages

Specifies to allow non relative placement cells to overlap with relative placement group blockages during coarse placement,refine placement, legalization and optimization.Please note that non relative placement cells are allowed in unused spaces of relative placement group too.

This option has higher priority than **allow_non_rp_cells when both are enabled to set on the relative placement group.**

DESCRIPTION

The **set_rp_group_options** command sets the placement constraints of the specified relative placement groups.

EXAMPLES

The following example uses the **set_rp_group_options** command to change the constraint for a relative placement group.

```
prompt> set_rp_group_options grp_ripple -tiling_type bit_slice
1
```

```
prompt> set_rp_group_options grp_ripple -utilization 0.5
1

prompt> set_rp_group_options grp_ripple \
  -rp_only_keepout_margin {.64 .64 .64 .64}
1

prompt> set_rp_group_options grp_ripple -anchor_corner rp_location \
  -anchor_row 1 -anchor_column 2 -x_offset 100.0 -y_offset 100.0
1
```

set_safety_logic_port_map

Defines the port mapping for the module or lib-cell used for voting logic in functional safety flow.

SYNTAX

status **set_safety_logic_port_map**
[-module *module_list*]
[-mapping *lib_cell_list*]
-input *names*
[-voting *name*]
[-error *name*]

Data Types

module_list	collection
lib_cell_list	collection
names	string_list
name	string

ARGUMENTS

-module *module_list*

Specifies one or more the modules for which the port mapping is applied. Either objects or names can be specified.

-mapping *lib_cell_list*

Specifies one or more libcells for which the port mapping is applied. Either objects or names can be specified.

-input *names*

Specifies list of input ports. This is a compulsory option.

-voting *name*

Specifies the voting logic output. This is optional since some safety logic might not have output port.

-error *name*

Specifies the error port. This is optional since some safety logic might not have error port.

DESCRIPTION

This command marks the different ports of the given module or libcells as inputs, voting outputs or error ports. If different modules and libcells have same port names with same functionality, then multiple such modules and/or libcells can be specified together in the same command invocation. Either -module or -mapping must be specified. Either -voting or -error must be specified.

EXAMPLES

The following example defines a safety logic port map for a lib-cell

prompt> **set_safety_logic_port_map -mapping MAJ3 -input { A B C } -voting { OUT }**

The following example defines a safety logic port map for a module

prompt> **set_safety_logic_port_map -module DMR_LOGIC -input { A1 A2 } -error E**

SEE ALSO

report_safety_logic_port_map(2)
create_safety_register_rule(2)
write_safety_register_script(2)

set_safety_register_rule

Associates the registers with the rules.

SYNTAX

status **set_safety_register_rule**
-rule *safety_register_rule*
-registers *registers*
-error_signal *pin_or_port*

Data Types

safety_register_rule object
registers collection
pin_or_port object

ARGUMENTS

-rule *safety_register_rule*

Specifies the safety_register_rule to apply to the registers. This must an existing and valid rule object or rule name.

-registers *registers*

Explicitly specifies the register(s) on which the constraint should be applied.

-error_signal *pin_or_port*

An existing pin or port in the design to which the error signal generated from voting logic should be tied. This option is compulsory for rules of type dual_mode, otherwise it is optional. It can not be specified for rules of type fault_tolerant. Either a hierarchical or leaf-level pin or an output port can be specified, but it must exist in the design.

DESCRIPTION

Sets the safety_register_rule on all the specified registers. If a specified register already has another rule associated with it, that register will be skipped and the original rule will remain applied to it.

EXAMPLES

The following example creates an association of a rule with registers.

```
prompt> set_safety_register_rule -rule rule1 \
   -registers {flop1 flop2 flop3 flop4}
```

The following example associates a dual_mode rule to registers and specifies an error port

```
prompt> set_safety_register_rule -rule dmr1 \
   -registers {flopA flopB} -error_signal [get_ports Err_out]
```

SEE ALSO

set_scaling_lib_group

Specifies the scaling library groups (previously defined by the **define_scaling_lib_group** command) to use for a particular corner of the current design.

SYNTAX

status **set_scaling_lib_group**
[*group*]
[-min]
[-max]
[-all]
[-none]
[-corners *corner_list*]

Data Types

group	string
corner_list	collection

ARGUMENTS

group

Specifies a scaling library group that may be used for maximum and/or minimum delay analysis. It is an error if there is no defined scaling group with the specified name.

-min

Specifies that the specified scaling library group be used for minimum delay analysis. If neither of the **-min** or **-max** options is specified, the scaling library group applies to both minimum and maximum delay analysis.

-max

Specifies that the specified scaling library group be used for maximum delay analysis. If neither of the **-min** or **-max** options is specified, the scaling library group applies to both minimum and maximum delay analysis.

-all

Allow all defined scaling groups to be used in the specified corner(s), for both minimum and maximum delay analysis. This option cannot be used with any other option besides **-corners**.

-none

Prevent any defined scaling groups from being used in the specified corner(s). This option cannot be used with any other option besides **-corners**.

-corners *corner_list*

The corner(s) to apply the scaling group(s) to. If this option is not given, the current corner is used.

DESCRIPTION

The **set_scaling_lib_group** command allows specific scaling library groups to be used for analysis in the specified corner(s). The tool performs interpolation between libraries in this group for voltage, temperature, or both voltage and temperature. You can set scaling library for maximum, minimum, or both maximum and minimum delay analysis. You can set multiple allowable scaling library groups on a corner. By default, all defined scaling groups may be used on every corner.

Multicorner-Multimode Support

EXAMPLES

The following example defines a scaling library group named g1 and applies it to corner C3, for both minimum and maximum delay analysis.

```
prompt> define_scaling_lib_group -name g1 { 0.9.db 1.1.db 1.3.db }
prompt> set_scaling_lib_group -corners C3 g1
```

The following example shows how to prevent any scaling groups from being used for analysis.

```
prompt> set_scaling_lib_group -none -corners [all_corners]
```

[-shift_power_chain_length *chain_length*]
| -shift_power_chain_ratio *chain_ratio*]
[-shift_power_clock *clock_name*]
[-shift_power_disable *test_control_name*]
[-test_mode *mode_name*]

Data Types

number_of_inputs integer
number_of_outputs integer
number_of_shared_inputs integer
number_of_shared_outputs integer
chain_count integer
max_chain_length integer
mode_name string
chain_length integer
chain_ratio integer
clock_name string
test_control_name string

ARGUMENTS

-inputs

Specifies the number of scan inputs to load scan data for scan compression.

-outputs

Specifies the number of scan outputs to observe scan data for scan compression.

-shared_inputs ***number_of_shared_inputs***

Specifies the number of top-level scan inputs to share across all codecs. The minimum allowed value is the widest input width across all codecs. The maximum allowed value is the sum of all codec input widths, which disables codec I/O sharing. By default, codec I/O sharing is disabled.

-shared_outputs ***number_of_shared_outputs***

Specifies the number of top-level scan outputs to share across all codecs. The minimum allowed value is the widest output width across all codecs. The maximum allowed value is the sum of all codec output widths, which disables output sharing. By default, the outputs are fully shared when codec I/O sharing is enabled by the **-shared_inputs** option.

The **-shared_outputs** option by itself does not enable codec I/O sharing; the feature is only enabled if the **-shared_inputs** option is also specified.

-shared_codec_controls false | true

When set to **true**, the tool adds gating logic at the inputs of the output sharing compressor to selectively disable shared codecs from being observed.

-chain_count

Specifies the number of compressed scan chains to build.

-max_length

Specifies the maximum allowed length of the compressed scan chains.

-xtolerance high | default

Enables the insertion of fully X-tolerant scan compression structures when the value is set to high (the default). When set to default, the tool does not insert fully X-tolerant scan compression structures.

-streaming false | true

When **true**, the specification is a streaming compression configuration. The default is a combinational scan compression configuration.

-serialize false | true

When **true**, the specification is a serialized compression configuration. The default is a combinational scan compression configuration.

-clock ***clock_name***

Specifies the scan clock to be used for the sequential codec (compressor and decompressor) to be inserted. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. By default, the tool selects the dominant scan clock, which typically results in the fewest lockup latches at the decompressor outputs and compressor inputs.

-shift_power_groups false | true

Enables the shift power groups feature. This feature implements a shift power control chain that allows ATPG to selectively gate groups of compressed chains for shift power reduction. The gated chains still shift, but they shift constant (non-toggling) values into the chains, which reduces toggle activity.

When this feature is enabled, the following options are also required:

- **-shift_power_chain_length** or **-shift_power_chain_ratio**

- **-shift_power_clock**

The default is **false**, which does not implement the control chain or gating logic.

-shift_power_chain_length ***chain_length***

Specifies the length of the shift power control (SPC) chain. This value directly controls the number of compressed chain groups.

Use this option to keep the length of the SPC chain constant as the compression architecture changes.

-shift_power_chain_ratio ***chain_ratio***

Specifies the ratio of compressed chains to each shift power control (SPC) register. This value directly controls the number of compressed chains in each group.

Use this option to keep the group size constant as the compression architecture changes.

-shift_power_clock ***clock_name***

Specifies the clock to use for the shift power control chain. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. This option is required when using shift power groups.

-shift_power_disable ***test_control_name***

Specifies the signal that, when asserted to its active value, disables the shift power logic. The specified signal must be previously declared as a TestControl signal using the **set_dft_signal** command. By default, the shift power logic is always active and no shift power disabling logic is implemented.

-test_mode ***mode_name***

Specifies the scan compression test mode to which the specification applies. The default is *all_dft*, except when **define_test_mode** is used. In this case, the default is the value of the last *test_mode* defined.

DESCRIPTION

This command specifies the scan compression configuration for the design.

EXAMPLES

```
prompt> set_scan_compression_configuration -inputs 10 -outputs 10 -chain_count 100
```

SEE ALSO

preview_dft(2)
insert_dft(2)

set_scan_configuration

Specifies the scan configuration for the design.

SYNTAX

status **set_scan_configuration**
[-chain_count *chain_count*
| -max_length *max_chain_length]*
[-clock_mixing no_mix | mix_edges | mix_clocks | mix_clocks_not_edges]
[-add_test_retiming_flops begin_and_end | begin_only | end_only | none]
[-internal_clocks none | single | multi]
[-test_mode *mode_name*]
[-pipeline_scan_enable true | false]
[-pipeline_fanout_limit *max_scan_cells*]
[-insert_terminal_lockup true | false]
[-lockup_type latch | flip_flop]
[-exclude_elements exclude_list]
[-voltage_mixing true | false]
[-power_domain_mixing true | false]

Data Types

chain_count integer
max_chain_length integer
mode_name string
max_scan_cells integer
exclude_list list

ARGUMENTS

-chain_count

Specifies the number of scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-max_length

Specifies the maximum allowed length of the scan chains. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-clock_mixing no_mix | mix_edges | mix_clocks_not_edges | mix_clocks

Specifies whether scan chains can include cells from different clock domains. The following allowed values control what scan elements can be included in the same scan chain:

- **no_mix** (the default)
  Cells must be clocked by the same edge of the same clock.
- **mix_edges**
  Cells must be clocked by the same clock, but the clock edges can be different
- **mix_clocks_not_edges**
  Cells must be clocked by the same clock edge, but the clocks can be different.
- **mix_clocks**
  Cells can be clocked by different clocks and different clock edges.

-add_test_retiming_flops begin_and_end | begin_only | end_only | none

Specifies whether the tool can insert leading edge retiming lockup flip-flops to scan chains clocked with trailing edge scan elements. If a scan chain contains only leading edge scan elements, a retiming lockup flip-flop is not inserted. The following allowed values control the lockup flip-flop insertion during scan insertion:

- **begin_and_end**
  Retiming lockup flip-flops are added to the scan chain beginning and end.
- **begin_only**
  Retiming lockup flip-flop is added only to the scan chain beginning.
- **end_only**
  Retiming lockup flip-flop is added only to the scan chain end.
- **none** (the default)
  No retiming flip-flop is inserted.

-internal_clocks single | none | multi

This option applies only to the multiplexed flip-flop scan style; it is ignored for other scan styles.

The **-internal_clocks** option can be set to the following values:

- **single**
  The **insert_dft** command treats internal clock network regions driven by any combinational gate, including buffers and inverters, as separate clocks for the purposes of scan chain architecture.
- **none**
  The **insert_dft** command does not perform internal clock analysis. This is the default.
- **multi**
  The **insert_dft** command treats internal clock network regions driven by multiple-input gates, such as MUX cells, as separate clocks for the purposes of scan chain architecture. Buffers and inverters are transparent for the analysis.

Integrated clock-gating cells are transparent for the determination of internal clocks.

-test_mode *mode_name*

Indicates which test mode the scan configuration applies to. The default is the last test mode specified with the **current_test_mode** command, or the last test mode created by **define_test_mode** if no current test mode has been set.

-pipeline_scan_enable true | false

When set to **true**, the tool creates a scan-enable pipelining stage for each scan-enable signal. The default is **false**.

-pipeline_fanout_limit *max_scan_cells*

When set to a positive integer value, the tool creates each scan-enable signal so that the number of flip-flops driven by the same scan-enable signal does not exceed the value. This option only takes effect if the **-pipeline_scan_enable** or **-**

domain_based_scan_enable option (or both) is set to **true**. The default is to not apply a limit.

-lockup_type latch | flip_flop

Specifies the kind of cell to use for synchronization between different clock domains. If not specified, the default will be 'latch'.

- **latch**
  Use a level-sensitive latch as clock synchronization element.
- **flip_flop**
  Use an edge-triggered flip-flop as clock synchronization element.

-insert_terminal_lockup

When set to true, inserts synchronization element at the end of scan chains. The default is false.

-exclude_elements

Specifies the list or collection of design objects to exclude from scan chain insertion.

-voltage_mixing true | false

When set to **true**, allows scan elements from different voltage domains into the same scan chain. This requires you to insert level shifters after scan insertion is complete. The default is **false**.

-power_domain_mixing true | false

When set to **true**, allows scan elements from different power domains into the same scan chaini. The default is **false**.

DESCRIPTION

This command specifies the scan configuration for the design.

EXAMPLES

```
prompt> set_scan_configuration -chain_count 10 -max_length 10
```

SEE ALSO

preview_dft(2)
insert_dft(2)

set_scan_element

Sets the **scan_element** attribute on specified design objects, to determine whether scan replacement replaces them with scan cells.

SYNTAX

status **set_scan_element**
true | false
cell_design_ref_list

Data Types

cell_design_ref_list list

ARGUMENTS

true | **false**

The Boolean value with which to set the **scan_element** attribute on the *cell_design_ref_list*. When **true**, (the default), the specified objects are replaced by sequential cells in the design. When **false**, scan replacement is disabled.

cell_design_ref_list

A list of design objects for scan replacement. Objects must be of the following sequential types: - cells (such as flip-flops and latches) - hierarchical cells (containing flip-flops or latches) - references - library cells - designs Wildcards and collections are supported.

DESCRIPTION

Sets the scan_element attribute to true on objects in cell_design_ref_list, indicating that scan replacement is to replace them with equivalent scan cells and make them part of the scan path. This command affects scan replacement performed by compile commands.

The default attribute value is true, which replaces all nonviolated sequential cells with equivalent scan cells for full scan designs. It is only necessary to explicitly set this value to true if you are altering the attribute value of a cell whose attribute was previously set to false.

Nonscan sequential cells determined to be violations by the dft_drc command are not scan-replaced, even if their scan_element attribute is set to true.

Sequential cells with the scan_element attribute set to false are not to be replaced by equivalent scan cells. If the attribute is applied before the first test-ready compile, the cells are never scan-replaced. If the attribute is set to false after a previous test-ready compile, the following behaviors apply:

- Subsequent test-ready compile commands will not unscan them.

For hierarchical cells, the scan_element attribute value applies to all sequential leaf cells within the hierarchical cell. For references, library cells, or designs, the scan_element attribute value applies to the instances of these objects, or to the sequential leaf cells within the hierarchy of the instances.

The effects of the scan_element attribute are applied hierarchically in a design. The value of the scan_element attribute on a lower-level object in the design takes precedence over the value of the scan_element attribute on a higher level object in the design. For example, if the value of the scan_element attribute on a higher-level object in the hierarchy is false and the value of the scan_element attribute on a sequential element inside the higher-level object is true, the sequential element is scan replaced.

The scan_element attribute value on a cell instance takes precedence over the scan_element value on the reference for that cell. The scan_element attribute value on a library cell is treated as a technology limitation and cannot be overwritten in any way.

The set_scan_element command supports full instance-based specification. However, the scan_element attributes on instances are specific to the current design. For example, if you start with a lower-level design, use the set_scan_element command to put scan_element attributes on instances in this context, and change the current design to a higher-level design, the scan_element attributes are no longer visible at the higher level.

To remove individual scan_element attributes, use the **remove_attributes** command. To remove all attributes, use the reset_design command.

To disable scan connections for CTL-modeled custom scan cells that do not use the synthesis-based scan replacement flow, use the set_scan_configuration -exclude command instead.

This command does not affect DFT connections to clock-gating cell test pins; use the set_dft_clock_gating_configuration -exclude_elements command instead.

EXAMPLES

The following example specifies that the compile command is not to scan replace three sequential cells in the current design.

```
prompt> set_scan_element false {U3_1 U3_2 U3_3}
```

The following example specifies that the compile command is not to scan replace instances of library cell DLATCH.

```
prompt> set_scan_element false tech_lib/DLATCH
```

The following example specifies that the compile command is not to scan replace instances of design REGFILE (sequential cells within REGFILE are not to be replaced by equivalent scan cells).

```
prompt> set_scan_element false [get_designs REGFILE]
```

SEE ALSO

preview_dft(2)

set_scan_group

Specifies an unordered group of cells that are not yet connected, but should be kept together within a scan chain. Also identifies existing logic in the current design that is to be designated as a scan segment.

SYNTAX

status **set_scan_group**
scan_group_name
[-access *signal_type_pin_pairs*]
[-include_elements *member_list*]
[-serial_routed false | true]
[-lockup_exists false | true]
[-segment_length *length_of_virtual_segment*]
[-clock *top_level_clock_port*]
[-edge rising | falling]
[-class occ | wrapper | input_wrapper | output_wrapper]

Data Types

scan_group_name string
signal_type_pin_pairs
member_list
length_of_virtual_segment
top_level_clock_port

ARGUMENTS

scan_group_name

Specifies the name of the scan group. The scan group must be uniquely identified as a design object. The name of the scan group name must also be unique.

-access *signal_type_pin_pairs*

Lists ordered pairs, each consisting of a scan signal type and a design pin, indicating how the tool should access the scan group. Valid signal types are ScanClock, ScanMasterClock, ScanSlaveClock, ScanEnable, ScanDataIn, and ScanDataOut. Validation ensures that specified signal types are consistent with the design scan style. Note that this list is mandatory when the **-serial_routed** option is set to **true**. This option is not supported when **-serial_routed** is set to **false**.

-include_elements *member_list*

Specifies an list of scan group components.

If the **-serial_routed** option is set to **false**, the list is unordered, and you can specify sequential cells, segment names, and design

instances.

If the **-serial_routed** option is set to **true**, the list is ordered, and you can specify only sequential cells.

-serial_routed false | **true**

Identifies whether the scan group is composed of serially routed sequential cells or that you are specifying an unordered group of sequential cells. The default is **false**.

-lockup_exists false | **true**

Identifies whether the serially routed scan group has a lock-up latch at the end. The default is **false**.

-segment_length ***length_of_virtual_segment***

Specifies the length of the virtual scan segment. This option can be used only when **-serial_routed** is set to **true**. With this option, you must also use **-access** to specify the correct input and output access pins, and use **-clock** for top-level clock specifications with respect to this segment.

-clock ***top_level_clock_port***

Specifies the top level clock port or pin associated with the virtual scan segment.

-edge rising | **falling**

Specifies the edge of the clock associated with the virtual scan segment. The scan architect uses this information for architecting the scan chains.

-class occ | **wrapper** | **input_wrapper** | **output_wrapper**

Specifies the class of the scan group.

The **occ** keyword specifies that the scan group describes an on-chip clocking (OCC) clock chain segment. Scan groups of **-class occ** are used only during OCC flows.

The **wrapper** keyword specifies that the scan group describes a wrapper chain segment. Scan groups of **-class wrapper** are used only during core wrapping flows.

The **input_wrapper** keyword specifies that the scan group describes an input wrapper chain segment. Scan groups of **-class input_wrapper** are used only during core wrapping flows.

The **output_wrapper** keyword specifies that the scan group describes an output wrapper chain segment. Scan groups of **-class output_wrapper** are used only during core wrapping flows.

DESCRIPTION

The **set_scan_group** command identifies existing logic in the current design that is to be designated as a scan group. Scan groups implement scan in a particular scan style. DFT Compiler can include scan groups in scan chains by connecting their access pins (when serially routed), or maintain the cells' grouping without assuming they are serially connected to each other. The tool does not scan-replace scan group members explicitly.

When the **-serial_routed** option is set to **true**, the **set_scan_group** command allocates sequential cells to scan groups and identifies design pins as scan group access pins with particular scan signal-type semantics.

The **set_scan_group** command options are not incremental. A **set_scan_group** option that specifies a scan group name overwrites any previous **set_scan_group** command specification of the same name and scan style.

The **set_scan_group** command accepts a list of members. By default, the list of members is unordered and not serially connected.

This list must be ordered when **-serial_routed** is set to **true**.

The scan group members should belong to the same clock domain and same edge. If the scan group is provided with elements from a different clock domain, an error message is displayed during scan architecting and the scan group specification is discarded.

The **set_scan_group** command does not accept collections as input.

The **set_scan_group** command accepts design instances as scan group members. It adds every scannable cell in the design instance to the scan group at the specified position, in alphanumeric order. This specification is valid only when **-serial_routed** is set to **false**.

The **-segment_length** option specifies the length of the virtual scan segment. Virtual segments are segments for which you specify the scan segment input and the scan segment output using the **-access** option, and the scan segment clock association using **-clock** option. If you do not specify the **-include_elements** option but you want specify the length of a segment, use the **-segment_length** option. The tool connects only to the hookup points during scan chain construction and does not trace within the hookup points (or virtual scan segment). The segment length you provide is considered for top-level scan chain balancing.

Note that the post-DFT DRC and SCANDEF generation support is not available when virtual scan segments are present in the scan chain.

The **-clock** option specifies the top-level clock that drives the virtual scan segment. If you specify the **-segment_length** option, you must also specify a valid **-clock** specification.

Ensure that the clock name specified as part of the **-clock** option is already defined using the **set_dft_signal** command. Alternatively, run the **set_scan_group** command after creating the test protocol and inferring the clocks and asynchronous signals.

The **-edge** option specifies the controlling edge of the clock with respect to the virtual scan segment. The controlling edge is specified as **rising** or **falling**. The default is **rising**.

When the **-access** option is used, the access pin signal types must be consistent with the segment scan style. Access pin directions must be consistent with their signal types. Access pins cannot be associated with more than one signal type. Scan groups cannot have more than one ScanDataIn or ScanDataOut access pin. Scan groups cannot contain duplicate members; sequential cells cannot belong to more than one scan group. Scan group members cannot also belong to scan chains. In other words, a sequential cell element that belongs to a scan group cannot be specified as part of the **set_scan_path** command.

A scan group does not accept another scan group as a member; nested scan groups are not supported.

Valid scan group error messages are TEST-400 and TEST-700. TEST-400 is displayed when scan group elements belong to more than one clock domain or have the same clock domain but a different edge. TEST-700 is displayed when scan group elements have a nonexistent element specified as part of the scan group specification.

Use the **preview_dft** command to all to review your scan group specifications.

EXAMPLES

The following example identifies an embedded shift register in the multiplexed flip-flop scan style. This specification can be completed in a single **set_scan_group** command by including the identification of the ScanEnable access pin in the first **-access** option specification.

```
prompt> set_scan_group my_shift_reg \
    -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
    -include_elements [list P/B/U7 P/B/U8 P/B/U9] \
    -serial_routed true

prompt> set_scan_group my_unconnected_group \
    -include_elements [list U1 U2]
```

The following is an example of a virtual scan segment controlled by the rising edge of the clock tck:

```
prompt> set_scan_group virtual_scan_segment \
      -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
      -segment_length 20 \
      -clock tck \
 -edge rising \
      -serial_routed true
```

The following is an example of a virtual scan segment controlled by the falling edge of the clock tck:

```
prompt> set_scan_group virtual_scan_segment \
      -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
      -segment_length 20 \
      -clock tck \
 -edge falling \
      -serial_routed true
```

SEE ALSO

preview_dft(2)

set_scan_path

Specifies a scan chain for the current design.

SYNTAX

status **set_scan_path**
chain_name
[-scan_data_in *port_name*]
[-scan_data_out *port_name*]
[-class scan | wrapper | occ | spc | ieee_1838_3dcr]
[-include_elements *element_list*]
[-ordered_elements *element_list*]
[-head_elements *element_list*]
[-tail_elements *element_list*]
[-complete true | false]
[-scan_enable *port_name*]
[-test_mode *mode_name*]
[-input_wrapper_cells_only enable | disable]
[-outputt_wrapper_cells_only enable | disable]
[-scan_master_clock *clock_name*]
[-edge rising | falling]

Data Types

chain_name string
port_name string
element_list list
mode_name string
clock_name string

ARGUMENTS

chain_name

Specifies a name for the scan chain being specified.

-scan_data_in *port_name*

Specifies a scan-in port to be associated with a scan chain. The specified scan_in_port must be previously declared as a ScanDataIn using the **set_dft_signal** command.

-scan_data_out *port_name*

Specifies a scan-out port to be associated with a scan chain. The specified scan_out_port must be previously declared as a ScanDataOut using the **set_dft_signal** command.

-class scan | **wrapper** | **occ** | **spc** | **ieee_1838_3dcr**

Specifies the usage of the current **set_scan_path** command. The allowed values are:

- **scan (default)** specifies that the chain is a scan chain. Chains of class **scan** are used only during scan insertion.
- **wrapper** specifies that the chain is a wrapper chain of a wrapped core. Chains of class **wrapper** are used only during core wrapping insertion.
- **occ** specifies that the chain is a clock chain for an on-chip clocking (OCC) controller. Chains of class **occ** are used only in an OCC flow.
- **spc** specifies that the chain is a shift power control (SPC) chain, used by the shift power groups feature. Chains of class **spc** are used only when the SPC feature is enabled.
- **ieee_1838_3dcr** "specifies that the chain is 3DCR register. This needs IEEE1838 enabled as a prerequisite. An instruction must be defined to target the 3DCR register.

Scan chains defined as a certain class automatically include elements of that class, unless limited or explicitly specified by other options of this command. The exceptions are the **occ** and **spc** classes, which require the scan elements to be explicitly specified if cores containing occ or spc chains are present.

-include_elements ***element_list***

Specifies a list of scan chain elements to be included in the scan chain. Unlike an ordered list, the scan architect is free to place them anywhere in the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards and collections are not supported.

-ordered_elements ***element_list***

Specifies an ordered list of scan chain elements to be included in the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards and collections are not supported.

-head_elements ***element_list***

Specifies an ordered list of scan chain elements to be placed at the beginning of the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards and collections are not supported.

-tail_elements ***element_list***

Specifies an ordered list of scan chain elements to be placed at the end of the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards and collections are not supported.

-complete true | **false**

Indicates whether the tool can add components to a specified scan chain. When **true**, the tool does not add any other scan cells to this scan chain and treats it as a complete scan chain. When **false** (the default), the tool can add more scan cells to this specification to balance scan chains. The new scan cells are embedded at the beginning of the scan chain (after any **-head_elements** scan cells).

-scan_enable ***port_name***

Specifies a scan enable to be associated with a scan chain. The scan architect takes the specified scan-enable port into consideration while allocating a scan-enable signal to the scan chain. The specified scan-enable port is dedicated to the scan chain; it will not be used to drive scan enable pins of flip-flops in other chains. If the internal pins flow is enabled using the **set_dft_drc_configuration** command, a hookup pin can be specified as a scan-enable signal for a scan chain. The specified scan_enable must be previously declared as a ScanEnable using the **set_dft_signal** command.

-test_mode ***mode_name***

Indicates the test mode to which the scan path constraint applies. The default is the current test mode, if user-defined test modes have been created, or the **Internal_scan** mode if no test modes have been created. Note that unlike most commands, the **set_scan_path** command does not apply a global specification to all test modes when the **-test_mode** option is omitted and no current test mode has been defined. To apply a scan path specification to all test modes, you must explicitly specify the **-test_mode all_dft** option.

-input_wrapper_cells_only enable | **disable**

Specifies whether or not only input wrapper cells should be used in the chain. This option is specific to chains of class **wrapper**. The default for this option is disable.

-output_wrapper_cells_only enable | **disable**

Specifies whether or not only output wrapper cells should be used in the chain. This option is specific to chains of class **wrapper**. The default for this option is disable.

-scan_master_clock ***clock_name***

Specifies a clock to be associated with a scan chain. The scan architect takes the user-defined clock domain into consideration while building scan chains. The clock edge is determined by the **-edge** option, which defaults to rising-edge scan cells. If the same clock edge specification applies to more than one scan chain specification, the scan architect attempts to balance the clock domain elements across the scan chains.

-edge rising | **falling**

Specifies the edge of the scan_master_clock associated with the scan chain. The scan architect includes only the elements controlled by the specified edge of the scan_master_clock in the scan chain. The default is rising.

DESCRIPTION

This command specifies a scan chain for the current design. The command allocates scan cells, scan segments, and scan links to scan chains, and specifies scan chain orderings.

Scan chain elements cannot belong to more than one chain. When **set_scan_path** options conflict, the most recent command is rejected.

The **set_scan_path** options are not incremental. A **set_scan_path** option specified for a given chain name overwrites any previous **set_scan_path** option previously applied to that same chain name.

Scan segments can be subdesign scan chains. Suppose the hierarchical design instance *instance_name* has a scan chain of **report_dft**. The **-scan_path** option reports as "Complete scan chain #n". You can include this subdesign scan chain in a scan chain by referring to it as *instance_name/n*.

Scan chain orderings must satisfy clock domain constraints asserted by using the **set_scan_configuration** command with the **-clock_mixing option**. The tool resynchronizes nonfunctional scan chains by using lockup latches.

The **set_scan_path** command does not invalidate **dft_drc** modeling information.

Use the **report_scan_path** command to review your scan chain specification. Use **compile** or **insert_dft** commands to implement the scan chain.

In the case of multimode scan insertion, if you have previously defined several test modes using the **define_test_mode** command, the default **set_scan_path** command is not associated with any mode and is not honored. Use the **-test_mode** option to specify the test mode to which you want your scan path constraint to apply.

EXAMPLES

The following example defines a complete scan chain named C1, consisting of sequential cells A, B, and C in reverse alphanumeric order.

```
prompt> current_design WC66
{WC66.design}
prompt> set_scan_path C1 -ordered_elements {C B A} -complete true
1
```

The following example shows how to use the **-head_elements** and **-tail_elements** options to specify that the instances U4/1 and U4/2 are at the beginning of the chain and the instances U5/1 and U5/2 are at the end of the chain. The **-include_elements** option ensures that the U2/2 segment is included somewhere in scan chain C1. The instances U3/2 and U3/1 are ordered and scan architect does not change the order of the elements in these instances during architecting.

```
prompt> set_scan_path C1 -view spec -head_elements {U4/1 U4/2} \
      -include_elements {U2/2} -ordered_elements {U3/2 U3/1} \
      -tail_elements {U5/1 U5/2}
1
```

The following example shows how to specify the DFT signals and scan path for a design with existing scan chains:

```
prompt> set_dft_signal -view existing_dft -type ScanDataIn -port test_si
Accepted dft signal specification for all_dft mode
1
prompt> set_dft_signal -view existing_dft -type ScanDataOut -port test_so
Accepted dft signal specification for all_dft mode
1
prompt> set_dft_signal -view existing_dft -type ScanEnable -port test_se
Accepted dft signal specification for all_dft mode
1
prompt> set_scan_path C1 -scan_data_in test_si \
      -scan_data_out test_so -scan_enable test_se
1
```

The following examples show how to use **set_scan_path** with the **-class occ** option. The clock controllers occ_ctrl and occ_ctrl2 have 2 chain_counts.

```
prompt> set_dft_clock_controller -cell_name occ_ctrl \
      -ateclock ate_clk -pllclocks {...} -chain_count 2
1
prompt> set_dft_clock_controller -cell_name occ_ctrl2 \
      -ateclock ate_clk -pllclocks {...} -chain_count 2
1
```

A basic case with 1 clock chain:

```
prompt> set_scan_path C1 -scan_data_in SI10 -scan_data_out SO10 \
      -include_elements {occ_ctrl1 occ_ctrl2} -class occ
1
```

This next example define 2 clock chains. In this case, the clock chains of the clock controllers can be specified using indexes as follows:

```
prompt> set_scan_path C2 -scan_data_in SI10 -scan_data_out SO10 \
```

```
        -include {occ_ctrl:1 occ_ctrl2:0} -class occ
1
prompt> set_scan_path C3 -scan_data_in SI11 -scan_data_out SO11 \
        -include {occ_ctrl:0 occ_ctrl2:1} -class occ
1
```

The following examples show how to use the **-edge** option along with the **-scan_master_clock option**. First, the **set_scan_path** command assigns all elements controlled by the rising edge of the clk1 clock to C1, and then assigns all elements controlled by the falling edge of the clk1 clock to C2.

```
prompt> set_scan_path C1 -scan_master_clock clk1 -edge rising
1
prompt> set_scan_path C2 -scan_master_clock clk1 -edge falling
1
```

Consider **set_scan_path** specifications for C3 and C4 below. If there are 10 elements controlled by the rising edge of clock clk2, then C3 and C4 will get 5 elements each.

```
prompt> set_scan_path C3 -scan_master_clock clk2 -edge rising
1
prompt> set_scan_path C4 -scan_master_clock clk2 -edge rising
1
```

insert_dft(2)
preview_dft(2)
report_scan_path(2)
set_dft_clock_controller(2)

set_scan_rp_group

Configures a DFT Scan relative placement group in the given design.

SYNTAX

status **create_rp_group**
rp_group_list
-routing *direction*
[-starting_corner *corner*]
[-max_length *size*]

Data Types

rp_group_list list or collection
direction string
corner string
size positive integer

ARGUMENTS

rp_group_list

Specifies the name, a list or a collection of the relative placement groups.

-routing *direction*

Specifies the direction that the DFT Scan Synthesis tool should use to stitch the RP group cells into Scan chains.

The valid *direction* values are as follows:

- **horizontal** indicates the RP Scan cells must be stitched in an order following the rows of the RP group.
- **vertical** indicates the RP Scan cells must be stitched in an order following the columns of the RP group.

-starting_corner *corner*

Specifies the corner of the RP group where the DFT Scan stitching should start from.

The valid *corner* values are as follows:

- **ll** indicates the RP Scan cells must start stitching RP Group Scan cells from the lower-left corner of the RP group.
- **lr** indicates the RP Scan cells must start stitching RP Group Scan cells from the lower-right corner of the RP group.
- **ul** indicates the RP Scan cells must start stitching RP Group Scan cells from the upper-left corner of the RP group.

- **ur** indicates the RP Scan cells must start stitching RP Group Scan cells from the upper-right corner of the RP group.

The default value for this option Is **ll** (lower-left).

If in the selected corner position of the RP group there is no available Scan cell to be stitched, the next cell available in the direction defined by the -routing option will be selected as the starting cell for DFT Scan stitching.

-max_length *size*

Specifies the desired size of the +ORDERED groups to be created while stitching the RP Scan cells. Default value is 0, and therefore each +ORDERED group will contain all cells of each row or column, depending of the -routing direction selected.

If a positive value is set for -max_length, the RP Group will stitch as many cells as possible in a single +ORDERED group until it reaches the desired max_size or if completes a row/column of cells of the RP group.

If the specified *size* is smaller than the amount of Scan cells of one row/column, at least a complete row/column will be set as an +ORDERED group.

If the specified *size* is greater than the amount of Scan cells of one row/column, one or more than one row/columns will be set into the same +ORDERED group, but always grouping complete rows/columns of RP cells.

Specifying a *size* equal or greater than the value of rows times columns of the RP group will imply all Scan cells of the RP group will be stitched in a single big +ORDERED group, following a stitching order given by the provided *direction* and *corner*, in a snake-like order.

DESCRIPTION

The **set_scan_rp_group** command defines a dedicated DFT Scan stitching style to be applied to specific relative placement (RP) groups previously defined by the **create_rp_group** command.

DFT Scan Synthesis normally can freely choose available Scan cells of the design to architect the Scan chains, including cells belonging to RP groups. This freedom can produce multiple new Scan path routing to ScanInput or ScanOutput, and those tracks will also be added to the RP group; as RP groups cells are very tightly placed, the Scan stitching process can introduce congestion in the RP group while competing with functional Data path scarce routing resources.

Using the new **set_scan_rp_group** command, user can define a preferred Scan stitching direction for the RP group. If set orthogonal to the functional data path routing direction, it helps easing overall routing of the relative placement group. Besides, the RP group cells will be stitching in a strict order following the RP cell location, reducing the Scan stitching net length inside the RP group.

Depending on the specified Scan routing direction, the command will define one or more Scan groups of RP cells, with the cells or the RP groups ordered by their correlative RP position. This will produce multiple Scan groups that will keep their relative order even after DFT Optimizations. For that objective, the Scan groups formed by the rows or columns of RP cells will be set as an +ORDERED component in ScanDEF file.

The +ORDERED components created from the RP group cells will retain their internal stitching RP cell order unchanged during the flow, but the order in which the multiple +ORDERED groups are stitched together is not fixed, and DFT Scan architecting or DFT optimizations (Scan reordering or repartitioning) are free to change their stitching order to reach other Scan requirements like Scan chain length/balancing or Scan chain net length.

The **set_scan_rp_group** command will honor the RP cell group position and the specified Scan routing *direction*, creating +ORDERED groups from the specified starting *corner*, following a snake-like traversal. For example, if routing "horizontal" is selected together with starting corner "ll", the bottom row of the RP group will be stitched as an +ORDERED group from left to right, the row above the bottom will be stitched as an +ORDERED group from right to left, then the next row above will be stitched as an +ORDERED group from left to right, and so on.

Calling **set_scan_rp_group** command over the same RP groups already set will overwrite the previous defined setup. A warning message will be issued.

The expected result of the command will be observed in the DFT Scan stitching process. Using this command after the design was DFT inserted during commands **compile_fusion** or **insert_dft**, and therefore the Scan chains were already stitched, will not change the original stitching outcome.

The Scan RP groups defined by command **set_scan_rp_group** can be reported using command **report_scan_rp_group** or deleted using command **remove_scan_rp_group**. In the last case only the Scan stitching setup is removed, but the relative placement group remains untouched.

EXAMPLES

The following example creates a Scan relative placement setup for RP group named "top_rp", using "vertical" Scan stitching routing direction, starting from the upper right corner.

```
prompt> set_scan_rp_group top_rp -routing horizontal -starting_corner ur
```

The following example creates a Scan relative placement setup for all RP group that match the pattern "*bottom_rp*" using "horizontal" Scan stitching routing direction, starting from the lower left corner (default value).

```
prompt> set_scan_rp_group top_rp -routing vertical [get_rp_groups *bottom_rp*]
```

set_scan_skew_group

Defines a scan skew group of scan cells, which might have a different clock latency characteristic than other parts of the design.

SYNTAX

status **set_scan_skew_group**
scan_skew_group_name
-include_elements *object_list*

Data Types

scan_skew_group_name string
object_list list

ARGUMENTS

scan_skew_group_name

Specifies the name of the scan skew group to define.

A scan skew group is referenced by name. You can use any name, as long as it has not previously been used to define another scan path or scan skew group. Scan skew group names are used by the **report_scan_skew_group**, **remove_scan_skew_group**, and **preview_dft** commands.

-include_elements *object_list*

Specifies the cells to include in the scan skew group. The object list can contain leaf cells, hierarchical cells, and CTL-modeled cells. Hierarchical cells include all scan cells in their hierarchy. CTL-modeled cells include all their scan segments. Wildcards and collections are supported.

DESCRIPTION

You can use scan skew groups to provide manual guidance for lock-up latch insertion. A scan skew group is a group of scan cells that might have a different clock latency characteristic than other parts of the design. The DFT architect treats the scan skew group as if it were a unique clock domain.

Scan skew groups override the normal scan clock domain identification behaviors such as

- Scan clock name
- The **-internal_clocks** option of the **set_scan_configuration** command

If clock mixing is disabled, the cells in a scan skew group are not mixed in the same scan chain as other scan cells. If clock mixing is enabled, the cells in a scan skew group can be mixed in the same scan chain as other scan cells, with lock-up latches inserted as needed.

EXAMPLES

The following example defines a scan skew group for a particular design register:

```
prompt> set_scan_skew_group G1 -include_elements {Z1P_reg[10] Z1P_reg[11] Z1P_reg[12]}
1
```

set_scenario_status

Configures analysis settings for scenarios.

SYNTAX

status **set_scenario_status**
scenario_list
[-setup true | false]
[-hold true | false]
[-leakage_power true | false]
[-dynamic_power true | false]
[-max_transition true | false]
[-max_capacitance true | false]
[-min_capacitance true | false]
[-cell_em true | false]
[-signal_em true | false]
[-active true | false]
[-all | -none]

Data Types

scenario_list list

ARGUMENTS

scenario_list

Specifies the scenario(s) to configure. The command configures each of these scenarios based on other command options. This option must be specified.

-setup true | false

Specifies whether setup analysis is turned on for the specified scenarios.

-hold true | false

Specifies whether hold analysis is turned on for the specified scenarios.

-leakage_power true | false

Specifies whether leakage power analysis is turned on for the specified scenarios.

-dynamic_power true | false

Specifies whether dynamic power analysis is turned on for the specified scenarios.

-max_transition true | **false**

Specifies whether max-transition DRC is turned on for the specified scenarios.

-max_capacitance true | **false**

Specifies whether max-capacitance DRC is turned on for the specified scenarios.

-min_capacitance true | **false**

Specifies whether min-capacitance DRC is turned on for the specified scenarios.

-cell_em true | **false**

Specifies whether cell EM analysis is turned on for the specified scenarios.

-signal_em true | **false**

Specifies whether signal EM analysis is turned on for the specified scenarios.

-active true | **false**

Specifies whether any analysis will be actually done on the scenario. If true, analysis will actually be performed, if any analysis settings are turned on. If false, all analysis settings are temporarily disabled and can be reactivated by specifying **-active true** at a later time.

-all

Turns on all analysis types. The "active" setting will not be affected. If the scenario is inactive, analysis will not be done.

-none

Turns off all analysis types. The "active" setting will not be affected. Only one of the **-all** and **-none** options may be given.

DESCRIPTION

This command enables or disables timing analysis, power analysis, and DRC checking for scenarios in the current design. Setup analysis, hold analysis, power analysis, and various types of DRC and EM checking can be configured independently.

Note that the **create_scenario** command creates a scenario and makes it active for all analysis types except cell and signal EM. The **set_scenario_status** command will generally be needed after a scenario is created to set only the desired analysis types.

The **-all** or **-none** options may be given with the individual analysis type options. In this case, all analysis types will first be set (or cleared), and then the individual analysis options will be applied.

The **-min_capacitance** option also needs **-hold** option to see the min_capacitance violations.

EXAMPLES

The following commands set analysis and DRC options for the func::RCworst and func::RCbest scenarios.

```
prompt> set_scenario_status func::RCworst \
  -setup true -max_capacitance true -max_transition true \
  -min_capacitance false -hold false -leakage_power false \
```

```
    -dynamic_power false -active true

  prompt> set_scenario_status func::RCbest \
    -setup false -max_capacitance true -max_transition true \
    -min_capacitance true -hold true -leakage_power false \
    -dynamic_power false -active true
```

The following command will turn on hold analysis for the scenario, and leave all other analysis settings unchanged.

```
  prompt> set_scenario_status func::RCworst -hold true
```

The following command will ensure that the scenario is configured only for hold analysis, no matter what its previous settings were.

```
  prompt> set_scenario_status func::RCworst -none -hold true -active true
```

The following command will ensure that the scenario is configured for all analysis types except power, no matter what its previous settings were.

```
  prompt> set_scenario_status func::RCworst -all -leakage_power false \
    -dynamic_power false -active true
```

report_scenario(2)
remove_scenario(2)

set_scope

Specifies the hierarchical scope of the design for subsequent commands.

SYNTAX

string **set_scope**
[*instance*]

Data Types

instance string

ARGUMENTS

instance

Specifies the working instance on which subsequent commands operate:

- If omitted, the focus moves to (or remains at) the top level of the current design.
- If an instance name, the focus moves down to the named instance in the current level. Use multiple names separated by slash characters to traverse multiple levels down the hierarchy.
- If a single period character ".", the tool stays as the current working instance.
- If two periods "..", the context moves up one level in the hierarchy of the current design.
- If a slash character "/" followed by an instance name, the tool moves to the named working instance in the top level of the design. Use multiple names separated by slash characters to traverse multiple levels down the hierarchy, starting from the top.

DESCRIPTION

The **set_scope** command specifies the hierarchical scope in which subsequent commands operate.

Functionally, this command is similar to the **current_instance** command but gives a different return value. Upon success, the **set_scope** command returns the scope *before* execution of the command as a full path string without a leading slash character, whereas the **current_instance** command returns the name of the current instance *after* execution of the command, with a leading slash character.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command sets the scope to the U1/U8 hierarchical cell. Cell U1 must exist at the current level of hierarchy and cell U8 must exist in the U1 cell.

```
prompt> set_scope U1/U8
```

The following command sets the scope to two levels of hierarchy above the current instance, and then down one level to the U4 cell.

```
prompt> set_scope ../../U4
```

The following script sets the scope to one block and then another, and defines a different power domain in each scope.

```
set_scope U1
create_power_domain PD1
set_scope ..
set_scope U2
create_power_domain PD2
set_scope ..
```

SEE ALSO

current_design(2)
current_instance(2)

set_segment_budget_constraints

Sets a manual constraint for a segment along a budget path.

SYNTAX

int **set_segment_budget_constraints**
-delay *delay*
-remove
[-from *pin*]
[-to *pin*]
[-rule *rule_name*]

Data Types

delay float
pin string
rule_name string

ARGUMENTS

-delay *delay*

Specifies the amount of fixed delay to be allocated to the specified segment of a budgeted path. You must specify either the **-delay** or **-remove** option.

-remove

Removes any previously set segment delay on the specified segment. You must specify either the **-delay** or **-remove** option.

-from *pin*

Specifies a budgeted pin at the start of the segment you want to constrain. If you omit this option, you will constrain the first budget segment from random logic to the given "to" pin. You must specify either **-from** or **-to**, or both options. When they are both specified, the **-from** pin has to be different than the **-to** pin.

-to *pin*

Specify a budgeted pin at the end of the segment you want to constrain. If you omit this option, you will constrain the last budget segment from the given "from" pin to random logic. You must specify either **-from** or **-to**, or both options. When they are both specified, the **-from** pin has to be different than the **-to** pin.

-rule *rule_name*

Specifies the name of a net estimation rule that was used to derive the delay in this constraint. This option is for record keeping only. It does not affect the actual operation of the budgeter. The rule name will be preserved when you save your design. See the **set_net_estimation_rule** man page for more details.

DESCRIPTION

This command sets a manual delay constraint for a segment along a budget path. When the delay is set, the **compute_budget_constraints** command will try very hard to honor the delay constraint. The budget will be allocated such that the delay along the given segment is no more or no less than the delay you have specified. If the path through the selected segment has positive or negative slack, the slack will be allocated to segments along the path that do not have a segment budget constraints.

The budget segment is specified by using the **-from** and **-to** options. The segment delay constraint is applied to the part of the budgeted path between the given pins. It is required that the "from" and "to" pins are two different pins on blocks that were declared as budget blocks by the **set_budget_options** command. You also need to pick pins which are adjacent along a timing path. If the specified "from" and "to" pins are separated by yet another budget pin, then the constraint will be ignored.

You can use the **create_budget_busplan** command and the **-busplans** option of the **compute_budget_constraints** command to define many segments constraints automatically.

EXAMPLES

Constrain the part of a budget path between block1 and block2 to be 1.5.

```
prompt> set_segment_budget_constraints -delay 1.5 \
  -from block1/outpin -to block2/inpin
```

SEE ALSO

write_budgets(2)

set_self_gating_objects

Controls the behavior of self gating insertion for the specified objects. Objects can be of type register, hierarchical cell, power domain, or module.

SYNTAX

status **set_self_gating_objects**
[-include *object_list*]
[-force *object_list*]
[-exclude *object_list*]
[-tree_type *combinational_logic*]
[-clear *object_list*]
[-reset]
[-tree_type *combinational_logic*]

Data Types

object_list list
combinational_logic xor | or | nand | auto

ARGUMENTS

-include *object_list*

Specifies a list of objects in the current design for which self gating should be done as per the options specified by the **set_self_gating_options** command. This is the default for all objects in the design. This option cannot be used in combination with the other ones, except for **-tree_type**.

-force *object_list*

Specifies a list of objects in the current design for which self gating will forcefully be done as options specified by the **set_self_gating_options** command. The specified objects will be self gated even if they don't pass the internal filters. This option will take precedence to the interaction with clock gates setting. This option cannot be used in combination with the other ones, except for **-tree_type**.

-exclude *object_list*

Specifies a list of objects in the current design to be excluded from self gating. This option cannot be used in combination with any other.

-clear *object_list*

Specifies a list of objects in the current design for which the settings previously stored by the command should be removed. This option cannot be used in combination with any other.

-reset

Removes the settings previously stored by the command from all objects in the design. This option cannot be used in combination with any other.

-tree_type *combinational_logic*

Specifies the type of combinational cell which will be used for self gating a register. The available combinational cells are XOR, OR and NAND cells. By default, self gating will use XOR cells. This option should be used in combination with *-include* or with *-force*, and its type specification will be applied to the objects specified by those options.

DESCRIPTION

This command specifies the objects on which self gating is to be either enabled, forced or disabled on its registers, as well as the type of combinational logic that should be used as comparison function.

Use the **-include** option to specify that self gating is allowed on the specified objects, letting the tool decide when the insertion actually happens based on quality of results analysis.

Use the **-force** option to specify that self gating should be forcefully done on the specified objects.

Use the **-exclude** option to specify that self gating should not be done on the specified objects.

Use the **-tree_type** option to specify the type of combinational logic to be used as comparison when self gating the objects specified by the **-include** or the **-force** options.

It is possible to specify different properties such as minimum and maximum bitwidth or the way self gating interacts with tool-inserted clock gates, that are applicable to each type of comparison logic. This has to be specified by using separate command **set_self_gating_options**.

Please note that the option defines the type of logic to be used, but not the actual type of cell to be inserted, so for instance when **nand** is chosen the tool synthesizes the necessary cells to form a NAND comparison function, but it can be implemented using any available cells, not necessarily a NAND gate.

When either **xor**, **or** or **nand** are selected, the self-gating banks are created in such a way all registers sharing a given self gate use the same type of comparison logic. On the other hand, when **auto** is selected, the tool is allowed to mix different types of comparison logic in the same self-gating bank.

Use the **-clear** option to remove the previously stored criteria from the specified objects.

Use the **-reset** option to remove the previously stored criteria from all objects.

When the command is executed for an object that already has a previously set criterion, this is overwritten by the new setting.

For modules and power domains, the settings are stored on the hierarchical instances associated to the specified objects at the moment the command is executed. As a consequence, if for example there is a module 'bot' with instances 'b1' and 'b2', after following command sequence all objects under both hierarchical instances 'b1' and 'b2' are excluded from self gating because the second command overwrites on 'b1' the previous setting:

```
prompt> set_self_gating_objects -include {b1}
prompt> set_self_gating_objects -exclude {bot}
```

If there is no setting directly stored by the command on a particular register, the setting stored at the closest upper-level hierarchical instance, or the top level design, is applicable to it. If there is no setting stored at any upper-level object, the tool assumes that the register is included as candidate for self gating, and XOR logic is used as comparison function.

The **set_self_gating_objects** command must be run before executing the **compile** command. The options are persistent in the design library.

EXAMPLES

The following example excludes the register bank A_reg from self gating:

```
prompt> set_self_gating_objects -exclude [get_cells A_reg[*]]
```

The following example disables self gating at the top level design, but allows it for registers under hierarchical instance mid1, using OR logic as comparison function for them:

```
prompt> set_self_gating_objects -exclude [get_designs top]
prompt> set_self_gating_objects -include [get_cells mid1] -tree_type or
```

The following example removes the directive to include, force or exclude self gating from the registers in ADDER:

```
prompt> set_self_gating_objects \
      -clear [get_cells {ADDER/out1_reg[*] ADDER/out2_reg[*]}]
```

The following example removes the directive to include, force or exclude self gating from all objects:

```
prompt> set_self_gating_objects -reset
```

The following example forces self gating on module mid, chooses NAND logic as the comparison function and uses **set_self_gating_options** command to specify the bank sizes that are applicable in that case:

```
prompt> set_self_gating_objects -force mid -tree_type nand
prompt> set_self_gating_options -objects mid \
                  -min_bitwidth 3 \
                  -max_bitwidth 6 \
                  -tree_type nand
```

The following example lets the tool decide automatically what type of combinational logic is used as comparison function for all registers, and uses **set_self_gating_options** command to specify the interaction with clock gating and the bank sizes that are applicable in that case:

```
prompt> set_self_gating_objects -tree_type auto -include [all_registers]
prompt> set_self_gating_options -interaction_with_clock_gating collapse \
  -min_bitwidth 4 -max_bitwidth 8 -tree_type auto
```

SEE ALSO

compile_fusion()
set_self_gating_options(2)

set_self_gating_options

Controls the structural options for self gating insertion.

SYNTAX

status **set_self_gating_options**
[-min_bitwidth *bitwidth*]
[-max_bitwidth *bitwidth*]
[-interaction_with_clock_gating *interaction_type*]
[-tree_type *combinational_logic*]
[-objects *object_list*]

Data Types

bitwidth integer
interaction_type none | insert | collapse
combinational_logic xor | or | nand | auto
object_list list

ARGUMENTS

-min_bitwidth *bitwidth*

Specifies the minimum accumulated bitwidth that a self gate can gate. It is an integer value, greater than or equal to one. This setting is optional, and if not set it defaults to 4. The specified value must be less than or equal to the max bitwidth value.

-max_bitwidth *bitwidth*

Specifies the maximum accumulated bitwidth that a self gate can gate. It is an integer value, greater than or equal to one. This setting is optional, and if not set it defaults to 8. The specified value must be higher than or equal to the min bitwidth value.

-interaction_with_clock_gating *interaction_type*

Specifies how to interact with the presence of tool-inserted clock gates when inserting self gating. The value should be one of the following: **none**, **insert** or **collapse**. If set to **none**, registers that are already clock gated by the tool are discarded from self gating insertion. If set to **insert**, registers that are already clock gated by the tool are valid candidates for self gating insertion. If set to **collapse**, registers that were already clock gated by the tool are valid candidates for self gating insertion, and when this is done, the tool collapses the clock gate and the self gate into one cell which adopts properties from both self gates and regular clock gates. By default, value **none** is assumed.

-tree_type *combinational_logic*

Specifies that the self-gating options are applied when the register being self gated is configured to use the specified combinational logic as comparison function. The value should be one of the following: **xor**, **or**, **nand** or **auto**. This configuration is done along with the **set_self_gating_objects** command. By default, value **xor** is assumed.

-objects ***object_list***

Specifies that the self-gating options are applied to the specified list of design objects. Valid objects are hierarchical instances, power domains and modules. If this option is not used, the self-gating options are set for the entire design.

DESCRIPTION

Each instance of this command controls the structural options for self gating insertion, such as minimum/maximum bitwidth or the way it should interact with tool-inserted clock gates, that are applicable to all objects using a given type of comparison logic.

Use the **-min_bitwidth** and **-max_bitwidth** options to specify the expected bitwidth range that is applicable to all registers configured to use the type of comparison logic specified by option **-tree_type**, that are under the hierarchical objects specified by option **-objects**.

Use the **-interaction_with_clock_gating** option to specify the way self gating should behave for registers that are already clock gated by the tool, that is applicable to all registers configured to use the type of comparison logic specified by option **-tree_type**, that are under the hierarchical objects specified by option **-objects**.

When the command is executed for an object that already has options stored for the same type of comparison logic as the one specified by the current instance of the command, the previous options are overwritten by the new ones.

For modules and power domains, the options are stored on the hierarchical instances associated to the specified objects at the moment the command is executed. As a consequence, if for example there is a module 'bot' with instances 'b1' and 'b2', after following command sequence all objects under both hierarchical instances 'b1' and 'b2' are configured to form self-gating banks with bitwidth in the range 4-6, because the second command overwrites on 'b1' the previous setting:

```
prompt> set_self_gating_options -min_bitwidth 3 \
                    -max_bitwidth 5 \
                    -objects {b1}
prompt> set_self_gating_options -min_bitwidth 4 \
                    -max_bitwidth 6 \
                    -objects {bot}
```

If there is no setting directly stored by the command on a particular hierarchical instance for a given type of comparison logic, the setting stored at the closest upper-level hierarchical instance, or the top level design, is applicable to it. If there is no setting stored for that type of comparison logic at any upper-level object, the tool assumes a minimum bitwidth of 4, a maximum bitwidth of 8 and interaction with clock gating **none** for that type of comparison logic.

The options are persistent in the design library.

EXAMPLES

The following example specifies the self-gating options described below:

```
prompt> set_self_gating_options -min_bitwidth 6 \
                    -max_bitwidth 8
The following self gating options for xor-based tree type are applied to: top-level (design)
Minimum bitwidth: 6
Maximum bitwidth: 8
Interaction with Clock Gating: none
1
```

```
prompt> set_self_gating_options -min_bitwidth 3 \
                    -max_bitwidth 5 \
                    -interaction_with_clock_gating insert \
                    -tree_type or
The following self gating options for or-based tree type are applied to: top-level (design)
Minimum bitwidth: 3
Maximum bitwidth: 5
Interaction with Clock Gating: insert
1

prompt> set_self_gating_options -min_bitwidth 4 \
                    -max_bitwidth 6 \
                    -interaction_with_clock_gating collapse \
                    -tree_type nand
The following self gating options for nand-based tree type are applied to: top-level (design)
Minimum bitwidth: 4
Maximum bitwidth: 6
Interaction with Clock Gating: collapse
1

prompt> set_self_gating_options -min_bitwidth 3 \
                    -max_bitwidth 8 \
                    -interaction_with_clock_gating insert \
                    -tree_type auto
The following self gating options for auto-based tree type are applied to: top-level (design)
Minimum bitwidth: 3
Maximum bitwidth: 8
Interaction with Clock Gating: insert
1
```

The following examples specifies that, when comparison logic **xor** is selected (the default), the tool must create self-gating banks in the bitwidth range 3-6 for the whole design, except for the objects under mid1, for which the specified range is 4-8.

```
prompt> set_self_gating_options -min_bitwidth 3 \
                    -max_bitwidth 6
The following self gating options for xor-based tree type are applied to: top-level (design)
Minimum bitwidth: 3
Maximum bitwidth: 6
Interaction with Clock Gating: none
1

prompt> set_self_gating_options -objects [get_cells mid1] \
                    -min_bitwidth 4 \
                    -max_bitwidth 8
The following self gating options for xor-based tree type are applied to: mid1 (hier inst)
Minimum bitwidth: 4
Maximum bitwidth: 8
Interaction with Clock Gating: none
1
```

SEE ALSO

set_self_gating_objects(2)
report_clock_gating(2)

set_sense

Specifies the unateness propagating forward for pins with respect to the clock source.

SYNTAX

string **set_sense**
[-type *type* | -stop_propagation | -clock_leaf | -positive |
-negative | -non_unate | -pulse *pulse_type*]
[-clocks *clock_list*]
object_list

Data Types

type string
pulse_type string
clock_list list
object_list list

ARGUMENTS

-type clock | data

Specifies whether the type of sense being applied refers to clock networks or data networks. The possible values for the type variable are *clock* and *data*. Note that if **-type** data is given, the **-stop_propagation** and **-clocks** options must be used as well. By default, the **-type** is *clock*.

-stop_propagation

Stops the propagation of specified clocks in the *clock_list* from the specified pins or cell timing arcs in *object_list*. Only clock used as clock is stopped if used with **-type clock**. To stop propagation for both clock as clock and clock as data, you need two commands: one with **-type clock** and one with **-type data**. The cell timing arcs are not supported in the *object_list* if **-type** data is used. **-stop_propagation** cannot be specified with **-positive**, **-negative** or **-pulse**.

-clock_leaf

Stops the propagation of specified clocks in the \fclock_list from the specified pins in the \fobject_list. Also, it specifies the pin as a clock consumer, so that the clock branches reaching this pin will be considered as clock consumer as well. In other words, the attribute "is_clock_used_as_clock" will be true for all the pins of the clock branches that reach the clock leaf pin. You cannot use the **-clock_leaf** option with the **-positive**, **-negative**, **-stop_propagation** or **-pulse** options.

-positive

Specifies positive unateness applied to all pins in *object_list* with respect to the clock source. **-positive** cannot be specified with **-negative** or **-non_unate** or **-pulse** or **-type data**.

-negative

Specifies negative unateness applied to all pins in *object_list* with respect to the clock source. **-negative** cannot be specified with **-positive** or **-non_unate** or **-pulse** or **-type data**.

-non_unate

Launches both the positive-unate sense and the negative-unate sense of the clock from the clock source. If you use the **-non_unate** option, you must also use the **-clocks** option. Please note that this option is only valid for clock source pins/ports. **-non_unate** cannot be specified with **-positive** or **-negative** or **-pulse** or **-type data**.

-pulse *pulse_type*

Specifies the type of pulse clock applied to all pins in *object_list* with respect to the clock source. The possible values for pulse_type are: rise_triggered_high_pulse, fall_triggered_high_pulse, rise_triggered_low_pulse, and fall_triggered_low_pulse. **-pulse** cannot be specified with **-negative** or **-positive** or **-type data**.

-clocks *clock_list*

Specifies a list of clock objects to be applied with the given unateness that is placed on all pin objects in *object_list*. By default, all clocks passing through the given pin objects are considered.

object_list

Specifies the list of pins or cell timing arcs with specified unateness to propagate. The timing arcs object can be used only with the **-stop_propagation** option. The cell timing arcs are not supported in the *object_list* if **-type** data is used.

DESCRIPTION

This command restricts unateness at pin (to positive or negative unate) with respect to the clock source. However, the specified unateness only applies within the non-unate clock network. In this case, user-defined sense propagates forward from the given pins.

If the **-clocks** option is specified, only the specified clock domains are applied. Otherwise, all clocks passing through the given pin objects will be considered.

The tool issues a warning message if the specified sense on given pins cannot be respected in case there is predefined unateness for given pins. Hierarchical pins are not supported.

In addition, you can completely stop propagation of certain clocks in clock networks or data networks by using **-stop_propagation** option together with the **-type** option.

Use the **remove_sense** command to undo **set_sense** settings.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example specifies a positive unateness for a pin named **XOR/Z** with respect to clock **CLK1**.

```
prompt> set_sense -positive -clocks [get_clocks CLK1] XOR/Z
```

The following example specifies negative unateness for a pin named **MUX/Z** for all clocks.

prompt> **set_sense -negative MUX/Z**

The following example stops clock propagation in data networks from **AND/Z** for clock **CLK1**.

prompt> **set_sense -type data -stop_propagation -clocks CLK1 AND/Z**

SEE ALSO

remove_sense(2)

set_serialize_configuration

Specifies the serializer configuration for the design.

SYNTAX

status **set_serialize_configuration**
[-inputs *number_of_deserializer_inputs*]
[-outputs *number_of_serializer_outputs*]
[-update_stage true | false]
[-exclude_clocks *list_of_clock_names_to_exclude*]
[-serializer_clock *clock_for_serializer_controller*]
[-wide_duty_cycle true | false]

Data Types

inputs integer
outputs integer
parallel_mode string
test_mode string

ARGUMENTS

-inputs *number_of_deserializer_inputs*

Specifies the number of inputs used to load scan data in the deserializer for scan compression. The inputs are a subset of the scan inputs used for base mode (reconfigurable scan mode).

The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-outputs *number_of_serializer_outputs*

Specifies the number of outputs used to observe scan data from the serializer for scan compression. The outputs are a subset of the scan outputs used for base mode (reconfigurable scan mode).

The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-update_stage true | false

Adds an update stage to the deserializer.

The default is **false**.

-wide_duty_cycle true | false

When set to **true**, the serializer clock controller generates the internally generated scan shift clocks and the update stage clock with a duty cycle closer to 50%, which helps prevent timing issues.

The default is **false**, which generates these clocks by passing through selected high-frequency clock pulses from the clock source.

-exclude_clocks ***list_of_clock_names_to_exclude***

Specifies the list of clock names to be excluded from gating in the serializer clock controller. The specified clock must be previously declared as a test clock using the **set_dft_signal** command.

The default is null (no value specified).

-serializer_clock ***clock_for_serializer_controller***

In hierarchical flows, when **set_scan_compression_configuration -serialize** is set to **core_level**, you can specify the clock to be used for the deserializer-serializer. The specified clock must be previously declared as a test clock using the **set_dft_signal** command.

The default is null (no value specified).

DESCRIPTION

The **set_serialize_configuration** command allows you to specify certain DFTMAX insertion parameters prior to using the **insert_dft** command.

The command also enables the configuration of the number of serial scan inputs and serial scan outputs that are to be used for a particular serial scan compression mode.

The other parameters are used to specify the clocks that can be excluded from clock-gating using the **-exclude_clocks** option, as well as the serializer clock in core-level flows using the **-serializer_clock** option.

An update stage can be inserted along with the deserializer to enable fast clocking schemes when the **-update_stage** option is set to **true**.

set_shaping_group_order

Adjusts the order of element within a shaping groups.

SYNTAX

none **set_shaping_group_order**
[-object *group_object*]
[-before *group_object*]
[-after *group_object*]
[-move_left]
[-move_right]
[-make_first]
[-make_last]
[-set *order*]
shaping_group

Data Types

group_object object
order list of objects
shaping_group object

ARGUMENTS

-object *group_object*

Specifies the object within the group to reorder.

-before *group_object*

Specifies an object within the group to place the target object immediately to the left of.

-after *group_object*

Specifies an object within the group to place the target object immediately to the right of.

-move_left

Moves the target object one space to the left. If the target object is already at the front of the group, no change is performed.

-move_right

Moves the target object one space to the right. If the target object is already at the end of the group, no change is performed.

-make_first

Moves the target object to the front of the group.

-make_last

Moves the target to the end of the group.

-set *order*

Sets the order of the group to the given value. The list of objects must consist of exactly the objects that exist in the group.

shaping_group

Specifies the shaping group on which to perform the ordering operation.

DESCRIPTION

The command modifies the order of elements with a shaping group. You may move an individual object using the basic move arguments or provide a new order for the entire group. The modifications are undoable.

EXAMPLES

The following commands show the effect of running the **set_shaping_group_order** command on a sample shaping group.

prompt> **set SG [create_group -shaping -name mySG "U1 U2 U3 U4 U5"]**
prompt> **get_attribute -name objects $SG**
{U1 U2 U3 U4 U5}
prompt> **set_shaping_group_order -object U1 -make_last $SG**
prompt> **get_attribute -name objects $SG**
{U2 U3 U4 U5 U1}
prompt> **set_shaping_group_order -object U4 -move_left $SG**
prompt> **get_attribute -name objects $SG**
{U2 U4 U3 U5 U1}
prompt> **set_shaping_group_order -set "U4 U2 U1 U3 U5"**
prompt> **get_attribute -name objects $SG**
{U4 U2 U1 U3 U5}

SEE ALSO

create_group(2)
group(3)

set_shaping_options

Specifies the shaping and placement options to apply with the **shape_blocks** command. Options specified using the **set_shaping_options** command are persistent throughout the session and are changed only by a subsequent **set_shaping_options** command. Options specified directly to the **shape_blocks** command are not persistent.

SYNTAX

int **set_shaping_options**
[-min_channel_size *size*]
[-guard_band_size *guard_band*]
[-utilization_slack *slack_value*]
[-keep_top_level_together true | false]
[-add_channel_blockages none | partial | soft | hard]
[-reset]

Data Types

size float
guard_band float
slack_value float

ARGUMENTS

-min_channel_size *size*

Specifies the minimal required channel size, in microns, between the following objects:

- Hierarchical cell (block) to hierarchical cell
- Hierarchical cell and fixed top-level macro
- Hierarchical cell and core boundary

This option is valid only when you specify **shape_blocks -channels**. By default, the minimal channel size is 0.

-guard_band_size *guard_band*

Specifies the guard band size, both width and height, for the voltage areas created by the **shape_blocks** command. The units are microns. When the **shape_blocks** command encounters a power domain with no voltage area, it shapes the power domain and creates the corresponding voltage area with the specified guard band size. The **shape_blocks** command will not change the guard band size of existing voltage areas. By default, the guard band size is 0.

-utilization_slack *slack_vale*

Specifies the utilization slack to use during incremental shaping.

During incremental shaping, utilization slack specifies the allowable difference between actual block utilization and target utilization. For example, consider a design with a target utilization of 0.7. The design contains two blocks, BLOCKA and BLOCKB, with utilizations of 0.8 and 0.7 respectively. Without utilization slack, the utilization for BLOCKA cannot be reduced because area cannot be "borrowed" from any other block; there are no other blocks with utilization less than 0.7.

With utilization slack, the utilization for BLOCKB can be increased above the target utilization in order to reduce the utilization for BLOCKA. For example, the tool can increase the utilization for BLOCKB from 0.7 to 0.75, then reduce the utilization for BLOCKA from 0.8 to 0.75 (if both blocks have the same size). If BLOCKB is significantly larger than BLOCKA, utilization slack allows the tool to add a small increase in utilization for BLOCKB to greatly reduce the utilization for BLOCKA.

By default, the utilization slack value is 0.1 (10 percent).

-keep_top_level_together true | **false**

Specifies whether the placement regions of the top level cells are kept together during non-incremental shaping. By default, the setting is true such that top level cells are not separated by blocks.

-add_channel_blockages none | **partial** | **soft** | **hard**

Specifies the type of placement blockages to insert into congested channels by using the **shape_blocks -incremental congestion_driven** command. By default, the command inserts soft blockages.

-reset

Resets all shaping options to their defaults.

DESCRIPTION

This command specifies the shaping options for the current session. The shaping options are applied by the **shape_blocks** command.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example sets the minimal required channel size to 50 microns.

prompt> **set_shaping_options -min_channel_size 50**

The following example sets the guard band size to 5 microns for the voltage areas created by the **shape_blocks** command.

prompt> **set_shaping_options -guard_band_size 5**

SEE ALSO

shape_blocks(2)

set_signal_io_constraints

Sets constraints for the placement of I/O driver pads within an I/O guide.

SYNTAX

status **set_signal_io_constraints**
[-io_guide_object *io_guide*]
[-constraint *io_guide_constraints*]
[-file *file_name*]
[-csv *csv_file_name*]
[-map_file *map_file_name*]

Data Types

io_guide list
io_guide_constraints string
file_name string
csv_file_name string
map_file_name string

ARGUMENTS

-io_guide_object *io_guide*

Specifies the name of a single I/O guide or a collection that contains a single I/O guide. You can use the **get_io_guides** command to return the I/O guide object, however, the collection must contain only one I/O guide.

-constraint *io_guide_constraints*

Specifies the I/O constraint. This option must be used with **-io_guide_object** option. It describes the detailed constraints for the guide specified by **-io_guide_object** option. There are three types of signal constraints: order-based constraints, location constraints, and boundary-spacing control constraints.

The first type of signal I/O constraint is an order-based constraint. An order-based constraint specifies the relative order of I/O driver pads within the I/O guide. This constraint is described by an ordered sequence of basic elements, which consist of I/O driver pads and constraint keywords or values. There are four basic formats that can be used to describe each element. The first order-based constraint format uses the order_only keyword in curly brackets followed by a sequence of pad cell names. The {order_only} keyword and pad cell names are surrounded by curly brackets. The pads must be placed in the specified order, although additional spacing and other pad cells can be inserted between adjacent pads. An example format is as follows:

{{order_only} pad1 pad2 pad3}

The second order-based constraint format contains a floating value within curly brackets, which represents white space without any pads placed. An example format is as follows:

{*spacing_value*}

The third order-based constraint format contains a sequence of pad names and spacing values to indicate the pad ordering and spacing. If no spacing value is specified between two pads, the two pads are placed with no gap between them. An example format is as follows:

{pad1 spacing1 pad2 spacing2 pad3 spacing3 pad4}

The fourth order-based constraint format contains a pitch value in curly brackets followed by a sequence of pad instance names. The pads are placed in the given order with the specified pitch. An example format is as follows:

{{pitch} pad1 pad2 pad3}

The order-based constraint can contain several elements in any of the four formats. All elements are placed in outer curly brackets. Additional space and pads can be inserted between adjacent elements. If users do not allow anything between adjacent elements, they should merge those elements into a single element. Alternatively, they can put those elements into a pair of curly brackets. In the following example, pad3 and pad4 will be placed next to each other.

{ {{50} pad1 pad2 pad3} {pad4 20 pad5} }

The order-based constraint follows a clockwise orientation. The pad instances at the front of the list are placed closer to the starting point of the I/O guide than later pad instances.

The second type of signal I/O constraint is a location constraints. The format begins with the keyword {absolute} in curly brackets, followed by a pad name and an offset value. The offset is with respect to the starting point the I/O guide. The constraints of fixed locations are independent of constraints in the other four formats. An example format is as follows:

{{absolute} pad offset}

You can specify multiple fixed pad locations as follows:

{{absolute} pad1 offset1}{{absolute} pad2 offset2}

The third type of signal I/O constraint is boundary-spacing control constraints. The format begins with the {no_space} keyword in curly brackets, followed by a **begin**, **end**, or **both** keyword. Use this constraint type to determine whether space can be added between the starting-point of I/O guide and the first I/O pad, or between the ending-point of I/O guide and the last pad. If this constraint is not used, space can be added. Note that if a corner cell is already placed in the I/O guide, the pad will not overlap with the corner cell. An example format is as follows:

{{no_space} both}

The boundary-spacing control constraint and order-based constraint can be combined to achieve the same effect of hard location constraints. The pad locations are described using the gap between the I/O guide starting point and the first pad and the gaps between all adjacent pads. Specifically, you must create one and only one element in the third order-based constraint format mentioned above. In addition, they add the following:

{{no_space} begin}

The location constraint and order-based constraint can be combined. For instance, to place a sequence of three pads (pad1, pad2, and pad3) with a gap of 50 microns between adjacent pads and starting at a guide offset of 700 microns, the following two constraints can be used. The location constraint specifies the first pad location. The order-based constraint describes the sequence and relative locations among all pads.

{pad1 50 pad2 50 pad3}

{{absolute} pad1 700}

It is important to point out that the spacing in order-based constraint specifies an empty gap in which no pad can be placed, including any fixed pads not in any constraints. No power pads can be inserted into the gap either. To create a gap in which pads can be inserted later, you must use a location constraint. The following constraints create a gap of 500 micron in which other pads can be placed, assuming that the width of pad1 is 5 micron and there is no other constraint.

{{absolute} pad1 500}{{absolute} pad2 1005}

The following constraints create a gap of 500 micron in which no pads can be inserted. The locations of the two pads are the same as the example above.

{{absolute} pad1 500}

{pad1 500 pad2}

Only a single **-constraint** option is used for each I/O guide. As a result, the last **set_signal_io_constraints** command overrides all previous commands if they are applied to the same I/O guide. The specification following the **-constraint** option must be placed in a pair of curly brackets.

-file ***file_name***

Specifies the name of the file that contains I/O signal constraints for one or more I/O guides. For each I/O guide, the specification begins with the guide name, followed by the I/O signal constraint. The format is the same as that in the **-constraint** option. A semicolon (;) terminates the I/O signal constraint for the I/O guide.

You can add comments in a signal I/O constraint file. Each comment line must start with a # character or // characters. The entire line must be either comments or constraints. Currently, the combination of comments and constraints in a single line is not supported.

-csv ***csv_file_name***

Specifies the name of the comma-separated values file that contains I/O signal constraints. You must specify the **-csv** option together with the **-io_guide_object** option to assign the I/O guide to use. Only one option, **-constraint** or **-csv**, can be used along with the specified I/O guide.

The CSV file specified by this option should contain the constraint data in the form of comma-separated values. The two required field names are "Pad Name" and "Offset Value". The first line in the CSV file must contain all the field names and the field names can appear in any order. If a required field is missing, the command issues an error message and exits. The CSV file can contain additional fields, however, unsupported field names are ignored and no error message is issued. All entries in a specific line must be separated by a comma. You can specify the following kinds of constraints using the CSV file:

1) Order only constraints: In this type of constraints, the specified pads must be placed in the order in the file, although additional pad cells and other pads might be inserted between adjacent pad cells. For order only constraints the "Offset Value" field should not be specified.

2) Location constraints: Constraints are specified as pairs of pad name and offset values. The offset values are based on the starting point of the I/O guide. This ensures that during I/O placement the pad will be placed at its desired offset on the I/O guide.

Note the following restrictions for the contents of the CSV file:

- No standard field should be repeated.
- The number of fields should be equal for each line in the file.
- There should be no missing or extra field entries in each line. For example, if you specify an offset value for one of the pads in the CSV file, an offset value must be specified for all other pad names in the file.

-map_file ***map_file_name***

Specifies an optional CSV file which maps custom column names in the connections file to standard Synopsys column names. The format for each line is <custom_name>,<standard_name>.

For example, the map file contents could be as follows:

Cell Name,Pad Name
Distance,Offset Value

Where "Cell Name" and "Distance" are custom column names which can be used in the constraint CSV file. The custom column names should not be same as the standard column names.

DESCRIPTION

This command specifies how pad instances are placed within their I/O guides.

If a pad instance described in the I/O signal constraints is not assigned to any I/O guides, it will be assigned to the I/O guide. Otherwise, the command will error out if assigned to another I/O guide. If a pad instance assigned to the I/O guide is not part of the I/O signal constraint, it will be placed without violating the constraint.

EXAMPLES

The following example forces a specific order of placement of four pad instances in the I/O guide named "north". The actual spacing between adjacent pads is determined by the I/O placer.

```
prompt> set_signal_io_constraints -io_guide_object north \
  -constraint {{pad1} {pad2} {pad3} {pad4}}
```

The following example forces a specific order of placement of four pad instances in I/O guide named "north". The first two pads are placed next to each other. There is a 100 micron spacing between the last two pads. The spacing between the second pad and third pad is determined by the I/O placer.

```
prompt> set_signal_io_constraints -io_guide_object north \
  -constraint {{pad1 pad2} {pad3 100 pad4}}
```

The following example forces a specific order of placement of four pad instances in I/O guide named "north". The pitch of all pads is 200 micron.

```
prompt> set_signal_io_constraints -io_guide_object north \
  -constraint {{200} pad1 pad2 pad3 pad4}
```

The following example forces a specific placement of three pad instances in I/O guide named "north". All pad locations are exactly calculated based on the spacing in the constraints. Specifically, the distance before pad1 is 20 micron. The gap between pad1 and pad2 is 45 micron. Pad2 and pad3 are abutted. There might be space after pad3 if the I/O guide is very wide.

```
prompt> set_signal_io_constraints -io_guide_object north \
  -constraint {{{no_space} begin} {20 pad1 45 pad2 pad3} }
```

set_signoff_check_drc_icv_live

Sets ICV-Live rules to check.

SYNTAX

set_signoff_check_drc_icv_live
[-reset]
[-select_rules *rule_names*]
[-unselect_rules *rule_names*]
[-description *description*]

Data Types

rule_names	list
description	string

ARGUMENTS

-reset

Reset ICV-Live manager and check all rules with ICV-Live run. If specified, a reset is the first action to be performed.

-select_rules *rule_names*

Specifies the list of rule names to check with ICV-Live run. Mutually exclusive with the -unselect_rules argument.

-unselect_rules *rule_names*

Check all rules with ICV-Live run except this specified list of rule names. Mutually exclusive with the -select_rules argument.

-description *recipe/preset_description*

Specifies the description of set of rules to check with ICV-Live

DESCRIPTION

This command specifies the rules to check with ICV-Live run.

By default, ICV-Live checks all run-set rules.

You can use this command to setup the rules to check.

EXAMPLES

The following example setup specific rules to check.

prompt> **set_signoff_check_drc_icv_live -select_rules { "M2.DN.1" "DM1.R.1" "M1.A.1" "M1.A.2" }**

SEE ALSO

signoff_check_drc_icv_live(2)

signoff.check_drc_live.run_dir(3)
signoff.check_drc_live.default_layers(3)

set_simstate_behavior

Specify the simulation simstate behavior for a model or library.

SYNTAX

status **set_simstate_behavior**
<ENABLE | SIMSTATE_ONLY | PORT_CORR_ONLY | DISABLE>
[-lib *name*]
[-models *model_list*]
[-elements *element_list*]
[-exclude_elements *exclude_list*]

Data Types

name	string
model_list	list
element_list	list
exclude_list	list

ARGUMENTS

<ENABLE | SIMSTATE_ONLY | PORT_CORR_ONLY | DISABLE>

Define the type of simulation behavior for the specified model(s).

-lib *name*

The library name.

-model *model_name*

One or more model names.

-elements *element_list*

A list of instances.

-exclude_elements *exclude_list*

A list of instances to exclude from the effective_element_list.

DESCRIPTION

This command specifies the simulation behavior for models or instances.

This command is for functional verification only does not have any impact on the implementation tools.

Implementation tool will not parse and check the options and it will not preserve this command in save_upf.

EXAMPLES

```
prompt> set_simstate_behavior DISABLE \
        -lib library1
        -models ANDX7_power_aware
```

SEE ALSO

sim_corruption_control(2)

set_site_array_stack_order

Sets the stack order of a site array in the current design.

SYNTAX

collection **set_site_array_stack_order**
[-above *site_array*]
[-below *site_array*]
[-raise]
[-lower]
[-top]
[-bottom]
site_array

Data Types

site_array string or collection

ARGUMENTS

-above *site_array*

Specifies the reference site array above which to place the given site array. This option is mutually exclusive with **-below**, **-raise**, **-lower**, **-top** and **-bottom**.

-below *site_array*

Specifies the reference site array below which to place the given site array. This option is mutually exclusive with **-above**, **-raise**, **-lower**, **-top** and **-bottom**.

-raise

Specifies that the given site array is to be raised by one position. This option is mutually exclusive with **-above**, **-below**, **-lower**, **-top** and **-bottom**.

-lower

Specifies that the given site array is to be lowered by one position. This option is mutually exclusive with **-above**, **-below**, **-raise**, **-top** and **-bottom**.

-top

Specifies that the given site array is to be placed at the top. This option is mutually exclusive with **-above**, **-below**, **-raise**, **-lower** and **-bottom**.

-bottom

Specifies that the given site array is to be placed at the bottom. This option is mutually exclusive with *-above*, *-below*, *-raise*, *-lower* and *-top*.

site_array

Specifies the site array, either a name or collection, whose stack order needs to be modified.

DESCRIPTION

The **set_site_array_stack_order** command modifies the stacking order of a site array. The given site array can be moved to the top or bottom of the stack, can be raised or lowered by one position from its current stack position or can be moved above or below a specified reference site array. All of these options are mutually exclusive.

This re-ordering of the stack can cause effective region and constituent site row recomputation of all site arrays if the given site array is opaque. The given site array's site rows will also be recalculated.

EXAMPLES

The following example moves a site array named 'SA1' to the top of the stack.

```
prompt> set_site_array_stack_order -top SA1
```

The following example moves the site array named 'SA1' below another site array named 'SA2'.

```
prompt> set_site_array_stack_order -below SA2 SA1
```

SEE ALSO

create_site_array(2)
get_site_arrays(2)
remove_site_arrays(2)

set_size_only

Controls whether the specified leaf cells can only be sized during optimization.

SYNTAX

status **set_size_only**
[-all_instances]
cell_list
[true | false]

Data Types

cell_list collection

ARGUMENTS

-all_instances

Controls how the size-only setting is applied to child instances of multiply instantiated designs.

When you use this option, if a specified cell is in a multiply instantiated instance of a subdesign, the tool applies the size- only setting to the similar cells in all instances of that sub- design.

This is especially useful to avoid changing the current design to issue this command in different designs.

cell_list

Specifies the leaf cells on which to apply the size-only setting.

true | **false**

Specifies the value of the size-only setting.

The default is **true**, so **set_size_only U1** has the same effect as **set_size_only U1 true**.

DESCRIPTION

This command applies size-only settings to the specified leaf cells.

When you apply a size-only setting of **true** to leaf cell, optimization can perform only sizing operations on that cell. A setting of **false** removes the size-only settings for the specified leaf cells, unless the presence of constraints on the cell is also causing it to be size_only.

For example, if apply a size-only setting of **true** to a cell, the tool attempts to optimize this cell by replacing it with a cell of the same function. The size-only setting on a cell does not prevent changes to the net driven by this cell. For example buffers can be added to this net. To prevent changes to the net, use the **set_dont_touch** command to set the **dont_touch** attribute on the net.

Please note, size_only can not be set on unmapped DesignWare cell. Before compile, unmapped DesignWare cells appear to be leaf cells. However, after compile, they will become hierarchical cells. Currently we do not allow setting size_only on unmapped DesignWare cells.

To report the size-only settings, use the **report_size_only** or **report_cell** commands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example applies a size-only setting of **true** to the cell named U1.

```
prompt> set_size_only U1
```

The following example removes the size-only setting from the cell named U1.

```
prompt> set_size_only U1 false
```

The following example uses the **-all_instances** option.

```
prompt> set_size_only -all_instances mid1/bot1/c1
Information: '3' cells set to 'size_only'. (CSTR-020)
1
```

set_skew_macros

Specifies the macros for which slack needs to be improved via skew.

SYNTAX

int **set_skew_macros**
-bank_name *name*
-macros *macro_list*
[-improve_side *input*|*output*|*both*]

Data Types

macro_list collection

ARGUMENTS

-bank_name *name*

Specifies a unique name for the collection of related macros to be skewed. If the bank name is already used in some prior specification of set_skew_macros, the old specification is overridden.

-macros *macro_list*

Specifies a collection of macros in the bank. A macro can be in at most one bank. If a macro in the collection was in a prior **set_skew_macros** command, then that macro is removed from the prior bank and added to the new bank.

-improve_side *input* | *output* | *both*

Specifies which side of the macro needs to be improved through skew. The default is *output*.

DESCRIPTION

The **set_skew_macros** command specifies a set of macros for which slack needs to be improve by skew.

Macros such as RAMs have complex timing paths around them that need clock skewing to achieve the target period. Traditionally, this is done by using the set_clock_latency commands on macros and/or registers around the macros, to provide more time to close timing on macro paths. This method is tedious due to the requirement to understand the topology around macros and to compute the skew values.

The **set_skew_macros** command specifies a bank which is a collection of related macros (e.g. data RAMs where each RAM represents a specific bit range such as data_ram[31:0], data_ram[63:32]). It also specifies which side of the bank needs to be improved through skew.

The tool automatically detects the best way to improve the failing timing paths. For example, if improve_side is input, to the slack on the macro's inputs can be improved by preponing the input registers, postponing the macros, and/or postponing the output registers. The tool makes such decisions along with the amount of skew.

EXAMPLES

The example below specifies a bank 'data1' with macros named '*u_data_ram*' and the improve_side to be input side of the bank.

prompt> **set_skew_macros -bank_name data1 -macros [filter_coll**
[get_cells -hier -filter is_hard_macro] full_name=~*u_data_ram*] -improve_side input

SEE ALSO

remove_skew_macros(2)
report_skew_macros(2)

set_slice_preservation

Specifies which buses of registers should be optimized with slice-preservation

SYNTAX

status **set_slice_preservation**
[-bus *list_of_buses*]
[-exclude]
[-register *list_of_registers*]
[-slack_threshold *percentage_value*]
[-verbose]

Data Types

list_of_buses list of cell_bus objects
list_of_registers list of cell objects
percentage_value float

ARGUMENTS

-bus *list_of_buses*

Specifies the specific cell buses on which this command will act. If both *-bus* and *-register* are omitted, then this command will act on all well-formed register buses in the design of size greater than or equal to 16.

-exclude

Mandates that slice-preservation optimization should not be done on the indicated buses.

-register *list_of_registers*

Specifies the registers upon whose cell buses this command will act. If both *-bus* and *-register* are omitted, then this command will act on all well-formed register buses in the design of size greater than or equal to 16.

-slack_threshold *percentage_value*

If given, during timing optimization the *compile* command will disable slice preservation for any buses whose normalized negative slack is less than this threshold value. We define the normalized slack as follows: For a given path between startpoint S and endpoint P, let NS be the most negative slack at P. Let RT be the required time at P, and let AT be the arrival time at S. To normalize NS we divide it by (RT - AT): the difference between the required time at the path endpoint and the arrival time at the path startpoint. The percentage_value is thus the ratio between the negative slack and the maximum amount of time a path from S to P can take before it becomes critical.

-verbose

Mandates that the command print information about its actions.

DESCRIPTION

The *set_slice_preservation* command adds a uniformity requirement to register mapping in compile. This directive specifies that some specific buses of registers will be mapped uniformly, if possible. In this case, we say that a given bus of registers must be mapped into N identical *slices*. A *slice* may be a single single-bit register or a single multi-bit register; in either case, the bus must be mapped exactly into N of these devices. We call this uniform mapping "slice-preservation," and we refer to buses of registers that have been mapped in this way to be "slice-preserved."

We require that buses which are slice-preserved should be well-formed. See the section below for a precise definition; basically this means that the bus of registers has to be mappable in a uniform way. Optimization will seek to provide a uniform implementation, but we also allow that timing optimization may selective choose to lift this requirement for buses that contain registers which are 'too critical'. That criticality is determined as a percentage of the normalized negative slack, as described above for the *-slack_threshold* argument. During timing optimization within the *compile* command any register which is a path endpoint or startpoint for a register whose normalized slack is less than the slack threshold will no longer be slice-preserved. If the slack threshold is not given, then registers will be mapped uniformly regardless of criticality.

The *-bus* or *-register* arguments allow the caller to give bus or cell arguments. In the latter case, the bus(es) owning the indicated cell(s) will be operated on by this command. If neither argument is given, then all well-formed buses in the design will be considered for slice preservation.

The *-exclude* argument causes the given buses to not be slice-preserved. It is useful in overriding an earlier more general *set_slice_preservation*. See the EXAMPLES sections for more information on this.

Well-Formed Buses

In order for a bus of unmapped registers to be "slice-preserved" it must be implemented in a way that makes a correct uniform mapping possible. This means that all asynchronous and synchronous control pins are connected to either the same net or to the same logic value. It also means that each unique register input (typically data pins) or output (typically Q or QN pins) is connected to a bus of nets, in an increasing or decreasing ordering, without bits being unconnected, or swapped. This 'regular connection' requirement allows us to simplify the connection of identical slices.

EXAMPLES

In the following example, because neither the *-bus* nor the *-register* argument are given, slice preservation is set on all well-formed registers in the given design with size greater than or equal to 16 elements. A normalized slack threshold of -80% is given for possible register ungrouping, and the *-verbose* argument is used to get information about this buses are being slice-preserved.

```
prompt> set_slice_preservation -verbose -slack_threshold -80.0
Warning: bus abc/def_reg (width 4) will not be slice-preserved.
Information: bus gh/ij_reg (width 32) will be slice-preserved.
Information: bus qrs/tuv_reg (width 32) will be slice-preserved.
Information: bus wx/yz_reg (width 48) will be slice-preserved.
Information: Slice Preservation will be set on 3 buses
1
```

In the following example, slice-preservation is set as before, but a second invocation of the command using the *-exclude* argument disables slice preservation on a specific bus

```
prompt> set_slice_preservation -verbose -slack_threshold -80.0
Warning: bus abc/def_reg (width 4) will not be slice-preserved.
```

```
Information: bus gh/ij_reg (width 32) will be slice-preserved.
Information: bus qrs/tuv_reg (width 32) will be slice-preserved.
Information: bus wx/yz_reg (width 48) will be slice-preserved.
Information: Slice Preservation will be set on 3 buses
1

prompt> set_slice_preservation -exclude -verbose -bus gh/ij_reg
Information: bus gh/ij_reg (width 32) will not be slice-preserved.
1
```

In the following example, slice preservation is set on the bus which owns a particular register.

```
prompt> set_slice_preservation -verbose -register a/b/q_reg[0]
Information: bus q/b/q_reg (width 32) will be slice-preserved.
Information: Slice Preservation will be set on 1 bus
1
```

In the following example, slice preservation is set on the buses which are given in the list by *get_cell_buses* using the *-bus* argument

```
prompt> set_slice_preservation -verbose -bus [get_cell_buses "a*"]
Information: bus a1_reg (width 32) will be slice-preserved.
Information: bus a2_reg (width 32) will be slice-preserved.
Information: Slice Preservation will be set on 2 buses
1
```

SEE ALSO

report_cell_buses(2)

set_snap_setting

Sets snapping settings.

SYNTAX

string **set_snap_setting**
-enabled true | false
-class *class_type*
| -cursor_edge true | false
| -object_edge true | false
| -edge_radius *radius*
| -preferred_track true | false
| -fix_orientation true | false
| -macro_by_color true | false
[-snap *snap_type*]
[-user_grid *grid_name*]
[-default]

Data Types

class_type string
radius integer
snap_type string
grid_name string

ARGUMENTS

-enabled true | false

Specifies that snapping is enabled or disabled.

-class *class_type*

Specifies the object type for which to change the snapping setting. Valid class_types and object types are mapped in the following way:

- edit_group : Corresponds to edit groups
- io_cell : Corresponds to flip chip drivers, IO cells
- macro_cell : Corresponds to soft macros, hard macros, blackboxes, plan groups(partitions)
- metal_shape : Corresponds to wires, pins, shapes, vias, via matrices
- other : Corresponds to io guides, via regions

- placement_constraint : Corresponds to move bounds, shaping blockages, placement blockages, voltage areas, voltage area shapes, site arrays, site rows, rp groups, rp blockages, keepouts
- std_cell : Corresponds to standard cells
- wiring_constraint : Corresponds to routing blockages, route guides, pin guides, pin blockages, pg regions, routing corridors, routing corridor regions

-cursor_edge true | false

Specifies that the cursor should snap to visible object edges.

-object_edge true | false

Specifies that the moving or stretched object should snap to other object edges.

-edge_radius *radius*

Specifies an integer value for the search radius for snapping to object edges.

-preferred_track true | false

Specifies that only preferred tracks should be used if snapping to tracks is on.

-fix_orientation true | false

Specifies that cell orientation should be automatically fixed to match site rows or I/O guides

-macro_by_color true | false

Specifies that soft and hard macros should snap so that their colored pins are snapped to matching colored tracks.

-snap *snap_type*

Specifies the snapping type for the specified object type. Valid snap_types are:

- block
- finfet
- halfwiretrack
- litho
- mid_row_site
- row_site
- user
- wiretrack

-user_grid *grid_name*

Specifies the name of the user grid to use for snapping.

-default

Resets all options to their defaults.

DESCRIPTION

This command sets different snap settings in editing. See the argument list for details on each snapping option.

EXAMPLES

The following example enables snapping.

```
prompt> set_snap_setting -enabled true
1
```

SEE ALSO

create_grid(2)
get_snap_setting(2)

set_stage

Applies stage based settings for the current design.

This command works per stage to apply features that are flow dependent and is intended to be used with the RM flow.

SYNTAX

status **set_stage**
  [-step *step_name*]
  [-high_effort_timing]
  [-report]

Data Types

step_name string

ARGUMENTS

-step *step_name*

Specifies the step name. Valid step names are "synthesis", "placement", "cts", "post_cts_opto", "route", or "post_route". You can specify only one step name.

-high_effort_timing

Enables high-effort timing flow for the synthesis step. Only works with the "synthesis" step.

-report

Writes out the application options to the console in tabular format.

DESCRIPTION

This command applies stage-specific settings to the current design. This command is intended for the RM flow and should be used after running **set_qor_strategy** command.

The command also can read the RM Tcl variables to enable special features. If these variables are defined and set to the correct value then it enables application options for that feature. These would normally be set in the RM setup scripts to configure the RM flow. The following variables are checked:

ENABLE_PERFORMANCE_VIA_LADDER = false | true : For stage synthesis or placement, if this is true it sets the application

options **opt.common.enable_via_ladder_insertion**, **route.auto_via_ladder.update_during_route**, **place.legalize.enable_via_ladder_checks**, and **vl.flow.enable_convergence_flow** to true. It also runs the **setup_performance_via_ladder -effort high** and source a file output from the command. For non-RM users the feature can also be enabled with the Tcl variable_synopsys_rm_enable_performance_via_ladder set to true.

ENABLE_SPG = false | true : For stage placement, if this is set to true **place_opt.flow.do_spg** is set to true for the **place_opt** flow.

ENABLE_DPS = false | true : For stage placement, if this is set to true **opt.common.power_integrity** is set to true and **ccd.dps.flow_reporting** is set to {*}. This feature also requires a Digital-AF license and checks for its availability before enabling the application options. For non-RM users this feature is also enabled with the Tcl variable _synopsys_rm_enable_dps set to true.

CTS_STYLE = standard | MSCTS : For stage placement, if this is set to MSCTS then it sets the application option **place_opt.flow.enable_multisource_clock_trees** to true. It also checks if the variable TCL_REGULAR_MSCTS_FILE is defined and is pointing to a valid file path. This is sourced during place_opt.tcl.

ENABLE_HIGH_UTILIZATION_FLOW = false | true : For stage placement, in place_opt.tcl a special feature flow is enabled and this turns the **time.delay_calc_waveform_analysis_mode** to disabled.

ENABLE_IRAP = false | true : For stage post_cts_opto, if this is set to true then **opt.common.power_integrity** is set to true and **clock_opt.flow.skip_placement** is set to false to ensure placement is not skipped. This feature also requires a Digital-AF license and checks for its availability before enabling the application options. This feature also checks if the TCL_IRAP_CONFIG_FILE variable is defined and is pointing to a valid file path.

ENABLE_GRE = false | true : For stage route, if this is set to true then the **route_opt.flow.enable_power** is set to true and **time.si_enable_analysis** is set to false. The **time.si_enable_analysis** is turned to true after **clock_opt -from global_route_opt**.

ENABLE_ROUTE_AUTO_RESHIELD = after_route_opt | incremental | none : For stage post_route, if this is set to incremental then the application option **route.common.reshield_modified_nets** is set to true. It also checks if the variable ROUTE_AUTO_CREATE_SHIELDS is defined and set to either before_route_auto or after_route_auto.

ENABLE_ECO_OPT = false | true : For stage post_route, if this is set to true then it checks that the Digital-AF license is available and that the ROUTE_OPT_ECO_OPT_PT_PATH is defined and set to a valid path. No application options or commands are run but this checking is performed to avoid errors in running eco_opt later in the RM scripts.

EXAMPLES

The following example shows the usage of command in the flow.

```
prompt> set_qor_strategy -metric timing -stage pnr
prompt> set_stage -step placement
...
```

The following example applies the high effort timing flow in addition to the **compile_fusion** stage specific settings intended for the RM flow.

```
prompt> set_stage -step synthesis -high_effort_timing
```

The following example shows the RM Tcl variable ENABLE_SPG being set to true and applying the **set_stage -step placement** to enable the application option to run the Synopsys Physical Guidance flow in **place_opt**.

```
prompt> set ENABLE_SPG true
prompt> set_stage -step placement
Stage Option Version : 2.0
Step placement running
Stage-Info: Apply placement settings...
-------------------------------------
```

RM Feature: Synopsys Physical Guidance Flow = true
Report only: set_app_options -name place_opt.flow.do_spg -value true
...

SEE ALSO

set_qor_strategy(2)

set_starrc_in_design

Loads and validates a configuration file for running In-Design or fusion extraction with the StarRC engine.

SYNTAX

status **set_starrc_in_design**
-config *config_file*

-validate *true*

-mode *icc2_centric* | *starrc_centric*

Data Types

config_file string

validate boolean

mode string

ARGUMENTS

-config *config_file*

Specifies the name of the configuration file. The configuration file contains settings needed to run the StarRC tool. The syntax is described in the DESCRIPTION section.

-validate *true*

Applies the validation procedure to check if the RC network from StarRC is valid. If the RC data is invalid, StarRC In-Design fails and does not annotate the StarRC RC data onto the design. It's not applied to fusion extraction

-mode *icc2_centric* | *starrc_centric*

icc2_centric is to derive extraction options from ICC2 settings. starrc_centric is to use starrc settings from starrc command file or the starrc default settings. By default, it is icc2_centric mode. It's not applied to fusion extraction

DESCRIPTION

This command loads and validates a configuration file for running In-Design or fusion extraction with the StarRC engine. The configuration file recognizes asterisk (*) as a comment character and supports the following keywords:

- SIGNOFF_IMAGE : The location of the StarXtract executable

- CORNER_GRD_FILE : The file that lists each corner and the corresponding StarRC nxtgrd file
- MAPPING_FILE : The StarRC layer mapping file to map database physical connection layers to the layer in nxtgrd file. The same mapping file used in standalone StarRC.
- COMMAND_FILE : The StarRC command file

You can specify either MAPPING_FILE or COMMAND_FILE, however, MAPPING_FILE is the recommended setting. COMMAND_FILE is not recommended for fusion extraction as design info and setting are from ICC2/FC directly.

If a setting in the StarRC command file conflicts with the tool's setting, the tool uses its setting. For example, if the coupling capacitance threshold specified by the **set_extraction_options** command is 1.0 ff and the StarRC command file sets COUPLING_ABS_THRESHOLD to 0.5 ff, StarRC In-Design extraction uses 1.0 ff.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example specifies a configuration file that uses the MAPPING_FILE keyword to define a layer mapping file for the StarRC command.

```
prompt> set_starrc_in_design -config file1.cfg
prompt> sh cat file1.cfg

* file1.cfg
SIGNOFF_IMAGE:   /global/apps/bin/StarXtract
MAPPING_FILE:    ./tcad/nxtgrd.mapping
CORNER_GRD_FILE: ./tcad/cornerGrd.mapping
```

The following example specifies a configuration file that uses the COMMAND_FILE keyword to reference a StarRC command run file. The file contains corner and mapping file settings.

```
prompt> set_starrc_in_design -config file2.cfg
prompt> sh cat file2.cfg

* file2.cfg
SIGNOFF_IMAGE:   /global/apps/bin/StarXtract
COMMAND_FILE:    starRC.cmd
CORNER_GRD_FILE: cornerGrd.mapping
```

The following example of CORNER_GRD_FILE which defines ICC2 corner mapped with STARRC nxtgrd file

```
cold.corner /remote/TLU_GRD/cln28hp_1p10m+alrdl_7x2z_cworst.nxtgrd
hot.BC.corner /remote/TLU_GRD/cln28hp_1p10m+alrdl_7x2z_cbest.nxtgrd
hot.WC.corner /remote/pv/TLU_GRD/cln28hp_1p10m+alrdl_7x2z_cworst.nxtgrd
```

report_starrc_in_design(2)
check_starrc_in_design(2)

set_starrc_options

Loads and validates a configuration file for running starrc signoff extraction with the StarRC tool used in PT ECO fusion flow.

SYNTAX

status **set_starrc_options**
-config *config_file*

Data Types

config_file string

ARGUMENTS

-config *config_file*

Specifies the name of the configuration file. The configuration file contains settings needed to run the StarRC. The syntax is described in the DESCRIPTION section.

DESCRIPTION

This command loads and validates a configuration file for running PT ECO fusion with the StarRC tool. User needs to specify StarRC command file. The configuration file recognizes asterisk (*) as a comment character and supports the following keywords:

- SIGNOFF_IMAGE : The location of the StarXtract executable
- CORNER_GRD_FILE : The file that lists each corner and the corresponding StarRC nxtgrd file
- MAPPING_FILE : The StarRC layer mapping file
- COMMAND_FILE : The StarRC command file

EXAMPLES

prompt> **set_starrc_options -config file1.cfg**
prompt> **sh cat file1.cfg**

* file1.cfg

```
SIGNOFF_IMAGE:  /global/apps/bin/StarXtract
MAPPING_FILE:   ./tcad/nxtgrd.mapping
CORNER_GRD_FILE: ./tcad/cornerGrd.mapping
COMMAND_FILE:   starRC.cmd
```

SEE ALSO

report_starrc_options(2)

set_stub_chain

Sets the specified stub chain in the current design.

SYNTAX

status **set_stub_chain**
[-at *index*]
[-remove |
[-remove_element_with_pin pin |
[-remove_all |
[-add_floating_elements *element_lists* |
[-add_ordered_elements *element_lists]*
stub_chain

Data Types

index int
elements_lists list

ARGUMENTS

-at *index*

Position within the *stub_chain* to add/remove element_lists.

-remove

Remove the element list at the specified position in the *stub_chain*.

-remove_element_with_pin pin

Remove the single element associated with the specified *pin*.

-remove_all

Remove all element_lists from the *stub_chain*.

-add_floating_elements *element_lists*

Add floating element lists at the specified positon within the *stub_chain*. If position is not specified, list is added at the end of the *stub_chain*. The scan-in and scan-out pin of each triplet must be from the same scan cell. List Format: {{{scan_in_pin_name scan_out_pin_name bit_length}...}...}

-add_ordered_elements *element_lists*

Add ordered element lists at the specified positon within the *stub_chain*. If position is not specified, list is added at the end of the *stub_chain*. The scan-in and scan-out pin of each triplet must be from the same scan cell. List Format: {{{scan_in_pin_name scan_out_pin_name bit_length}...}...}

stub_chain

Name or collection of the stub_chain to be updated.

DESCRIPTION

The **set_stub_chain** command updates the specified stub_chain in the current design. *index* must be specified with -remove, -add_floating_elements and -add_ordered_elements. Option -remove_all removes all the element_lists and doesn't require *index*. Option -remove_element_with_pin can only be specified with pin. For adding element_lists, *index* range can be from 0 to length of stub_chain, for removing element_lists, *index* range can be from 0 to length of stub_chain minus 1.

EXAMPLES

The following example sets floating element_lists at index 1 on a stub_chain named stub1

```
prompt> set_stub_chain -at 1 -add_floating_elements {{{u1/pin1 u1/pin1 4} {u1/pin3 u1/pin4 4}}} stub1
1
```

The following example removes element_lists at index 2 from a stub_chain named stub1.

```
prompt> set_stub_chain -at 2 -remove stub1
```

set_supernet_exceptions

Sets the supernet transparency for cells and pins in the design.

SYNTAX

status **set_supernet_exceptions**
-pins *pins_list* | -disable_cells *cells_list*

Data Types

pins_list list
cells_list list

ARGUMENTS

IP "*pins_list*" Specifies the pins in the design which are to be marked as transparent for supernets. The pins in the list must belong to the same instance.

cells_list

Specifies the cells in the design whose supernet transparent settings are to be removed. If the specified cell is a repeater then it is marked as being non-transparent. If the specified cell is non-repeater then supernet transparent settings on its pins are removed.

DESCRIPTION

This command marks cells and pins as being transparent for supernets from the design.

EXAMPLES

The following example marks the pins A1 and Z of the cell cntrl/U166 as transparent to supernets.

prompt> **set_supernet_exceptions -pins {cntrl/U166/A1 cntrl/U166/Z}**

The following example disables the repeater cell i_clock7. The cell is marked as non-transparent to supernets.

prompt> **set_supernet_exceptions -disable_cells {i_clock7}**

SEE ALSO

remove_supernet_exceptions(2)
report_supernet_exceptions(2)

set_supply_net_probability

Annotates switching probability on selected supply nets in the current design.

SYNTAX

status **set_supply_net_probability**
-static_probability *static_probability*
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
object_list

Data Types

static_probability float
scenario_list list
mode_list list
corner_list list
object_list list

ARGUMENTS

-static_probability *static_probability*

Specifies the value of the *static_probability* of the switching activity of a supply net. The *static_probability* value represents the percentage of time the supply net is in the 'on' state. For a power net the 'on' state is the logic state '1', for a ground net the 'on' state is the logic state '0'. For example, a *static_probability* of 0.25 indicates that the supply net is in the 'on' state 25% of the time.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Probability is set separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, probability is set for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

object_list

Specified a supply net in the current design for which the value of static probability are set.

DESCRIPTION

This command annotates design supply nets with different kinds of switching activity. The activity of a supply net is used to scale leakage power and dynamic power of the cells connected to the supply net. The scaling of leakage power is governed by app option *power.scale_leakage_power_at_power_off* (by default true), the scaling of dynamic power by app option *power.scale_dynamic_power_at_power_off* (by default false). The scaling factor for a cells is the lowest static_probability of all its supply nets.

The supply nets that are annotated with switching activity can be specified explicitly as a list of objects.

If a combination of a mode and corner is specified that does not represent a valid scenario, those are ignored.

Multicorner-Multimode Support

EXAMPLES

The following **set_supply_net_probability** command annotates a static_probability of 0.9 on a supply net

```
prompt> set_supply_net_probability -static_probability 0.9 [get_supply_net VSS]
```

SEE ALSO

get_supply_net_probability(2)
reset_supply_net_probability(2)
power.scale_leakage_power_at_power_off(3)
power.scale_dynamic_power_at_power_off(3)

set_svf

Specifies the file into which the Formality setup information is written.

SYNTAX

status **set_svf**
[*file_name*]
[-append]
[-off]

Data Types

file_name string

ARGUMENTS

file_name

Names the file into which Formality setup information will be recorded. You must specify the file name unless the **-off** option is specified.

-append

Appends to the specified file. If another Formality setup verification file is already open then it will be closed before opening the specified file. If -append is not used then set_svf will overwrite the named file, if it exists.

-off

Closes the SVF files and stops recording Formality setup information. If this option is specified before any setup information has been recorded, it prevents the default SVF file from being created. No other options can be combined with **-off**.

DESCRIPTION

This command specifies the file name that should be used for recording setup information for Formality, the Synopsys formal verification tool.

If the **set_svf** command is not issued, the tool will create a file automatically, using a date-stamped, host name, and pid name like "default-20200210_dcamd66_1522.svf". An informational message will be printed when the default file is created. You can prevent the default file from being created by issuing the **set_svf -off** command at the beginning of the session, before any setup information is recorded.

The SVF ("Setup Verification for Formality") file that is produced contains Formality "guide" commands, like "guide_environment"

and "guide_uniquify", that are used by Formality during the matching step to facilitate the alignment of compare points. The tool might create additional files in the SVF file to pass checkpoint or DesignWare implementation information.

The SVF file is used to account for changes to the hierarchy or to netlist object names that occur during synthesis. Certain operations performed by the compile command perform transformations that are also recorded in the SVF file.

Further information on SVF files can be found in the Formality User Guide.

Because the SVF output is buffered internally, the SVF files might not be complete until recording is stopped. You can stop recording by running **set_svf** *-off* or by exiting from the tool. Running **set_svf** with a new file name will write out and close the original SVF file before starting the new one in the new file.

The SVF information is stored in encrypted format.

To record setup information for formal verification products other than Formality, use the **set_vsdc** command, instead.

This command returns a Boolean value indicating whether **set_svf** succeeded (true) or not (false).

EXAMPLES

In this example, we query the name of the SVF file and find out that setup information is not being recorded yet. Then we specify the file name and repeat the query.

```
prompt> get_svf
SVF guidance is not enabled.
1
prompt> set_svf cache_ctrl_svf
1
prompt> get_svf
The current SVF file is /project/chip/cache_ctrl/cache_ctrl_svf.
1
```

set_vsdc(2)
Formality User Guide

set_switching_activity

Annotates switching activity on selected nets, pins, ports and cells in the current design.

SYNTAX

status **set_switching_activity**
-static_probability *static_probability*
-toggle_rate *toggle_rate_value*
[-state_condition *condition_name*]
[-path_sources *path_sources*]
[-period *period_value*]
[-base_clock *clock*]
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
[-clock_derate *clock_derate_value*]
object_list

Data Types

static_probability float
toggle_rate_value float
condition_name string
path_sources list
period_value float
clock string
scenario_list list
mode_list list
corner_list list
clock_derate_value float
object_list list

ARGUMENTS

-static_probability *static_probability*

Specifies the value of the *static_probability* in the switching activity. The *static_probability* value represents the percentage of time the signal is at the logic state '1'. For example, a *static_probability* of 0.25 indicates that the signal is in the logic state '1' for 25% of the time.

-toggle_rate *toggle_rate_value*

Specifies the value of the toggle rate in the switching activity. The rate is a floating point number that represents the number of 0->1 and 1->0 glitch free transitions that the signal makes during a period of time. You can specify the period with the *-period*

option. Alternatively, you can annotate a related clock using the *-base_clock* option, and the specified toggle rate is relative to the related clock period.

-state_condition *condition_name*

Specifies the state condition when annotating state-dependent activities. State dependent activities can be annotated when the internal power of the library cell pin is characterized with state-dependent power tables. The state condition specified with this argument must match to a state condition in the internal power characterization. Use **-state_condition** default to specify the default state condition.

-path_sources *path_sources*

Specifies the path sources when annotating path-dependent activities. This can be used when the library cell pin has path-dependent internal power characterization. The path sources specified with this argument must be the same as those in the internal power characterization. If **-path_sources** option is used to specify the path_sources value, then **-state_condition** option must be specified to specify the value of the path_sources.

-period *period_value*

Specifies the time period for which the number of transitions given in the *toggle_rate_value* occur. The time units for this value are those specified in the main technology library. When this argument is used, the value of toggle rate specified by the *-toggle_rate* option is divided by the given *period_value*. The resulting toggle rate is then annotated to the objects provided in the **set_switching_activity** command. If the *-period* option is not specified, a default *period_value* of '1.0' is assumed.

-base_clock *clock*

Specifies a clock to which toggle rate value are related to. This clock is referred to as the object's related clock. When this option is used, the value of toggle rate specified by the *-toggle_rate* option is divided by the clock period. The resulting toggle rate is then annotated to the objects provided in the **set_switching_activity** command. When the *-base_clock* value is set to "*", the toggle rate is divided by the period of the fastest related clock, if fastest related clock is not found then fastest design clock is used.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Activity is set separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the activity is set for the current scenario in the design.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

-clock_derate *clock_derate_value*

Can be used as an alternative for **-toggle_rate** option. If specified, the toggle_rate_value used will be the toggle_rate_value of the fastest related clock of the object multiplied by the clock_derate_value.

object_list

Specifies a list of nets, pins, ports or cells in the current design on which the *static_probability* or/and *toggle_rate* values of switching activity are to be set. In case of cells, the probability values can be set for the state_conditions which are already present in the internal library characterization for the corresponding library cells of the cells.

DESCRIPTION

Use this command to annotate design nets, ports, pins and cells with the different kinds of switching activity. These include toggle rate and static probability on nets, ports and pins, along with state_condition based probability values on cells.

You can specify a related clock using the *-base_clock* option. The annotated toggle rate is divided by the related clock period and the resultant toggle rate value is annotated on the design objects. Only one of the *-period* or *-base_clock* option can be specified.

The design objects that are annotated with switching activity can be specified explicitly as a list of objects.

If a combination of a mode and corner is specified that does not represent a valid scenario, those are ignored.

For statistics on the switching activity annotation on the current design, use the **report_switching_activity** command.

It is to be noted that activity information is persistent given that the application option 'power.enable_activity_persistency' is set to 'on' or 'lazy'. Default value of 'power.enable_activity_persistency' is 'lazy'.

Multicorner-Multimode Support

EXAMPLES

The following **set_switching_activity** command annotates a toggle rate value of '0.9' and static probability value of '0.8' on a net.

```
prompt> set_switching_activity -static_probability 0.8 -toggle_rate 0.9 {Product[21]}
```

The following example annotates a toggle rate value of '0.6' and static probability value of '0.9' for the input port 'MemWriteBus[26]'. The clock 'clock' is specified as the base clock for the input port.

```
prompt> set_switching_activity MemWriteBus[26] -static_probability 0.9 \
        -toggle_rate 0.6 -base_clock "clock"
```

The toggle rate value of '0.6' is divided by the clock period of '3.0'. The resulting toggle rate value of '0.2' is annotated on the input port.

get_switching_activity(2)
read_saif(2)
report_switching_activity(2)
reset_switching_activity(2)
power.enable_activity_persistency(3)

set_synlib_dont_use

Disables the use of given synthetic implementations or modules during the compilation of the current design.

SYNTAX

status **set_synlib_dont_use** *obj*

Data Types

obj string

ARGUMENTS

obj

Specifies the affected synthetic modules or implementations. The specified modules or implementations must be in a synthetic library already loaded into the tool.

The format of this argument is */library/module/implementation*. The *implementation* is optional. A wildcard pattern can be used. If more than one pattern is included, they must be enclosed in quotation marks or braces ({}).

DESCRIPTION

Directs the tool not to use the specified synthetic modules or implementations during compile. The setting is stored as an attribute in the current design, and can be removed by **remove_attribute** command with attribute name **synlib_dont_use**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the *cla* and *rpl* implementation of *DW_div* module in the *dw_foundation* and *standard* library should never be used by the tool:

prompt> **set_synlib_dont_use {dw_foundation/DW_div/cla standard/DW_div/rpl}**

The following command specifies that all *rtl* implementations of all synthetic modules should never be used by the tool:

```
prompt> set_synlib_dont_use */*/rtl
```

SEE ALSO

get_attribute(2)
remove_attribute(2)

set_tap_package_model

Creates package models by setting the parasitic resistance, capacitance, and inductance values to the tap points or the package SPICE models.

SYNTAX

status **set_tap_package_model**
[-power]
[-ground]
[-R *value*]
[-L *value*]
[-C *value*]
[-type *type_name*]

Data Types

float *value*
string *type_name*
list *tap_list*

ARGUMENTS

-power

Model parameters is for power.

-ground

Model parameters is for ground.

-R *value*

Assigns the specified resistance value to the taps.

-L *value*

Assigns the specified inductance value to the taps.

-C *value*

Assigns the specified capacitance value to the taps.

-type *type_name*

Specifies the tap package model when two or more parasitic elements are applied to the taps. The valid *typename* values are

package, *wirebond*, or *pad*.

DESCRIPTION

The **set_tap_package_model** command provides a number of built-in electrical models that are effective in modeling many package configurations. You can select these built-in models by using the -type *type_name* option with the -power, -ground, -R,-L, and -C options to specify the parasitic values of the various model components.

The -R,-L, and-C options are used to define the resistance, inductance, and capacitance values for the model components. When an -R,-L, and -C option is not specified, by default the value is set to 0, meaning the corresponding model component is not used.

When modeling a single electrical component between the tap and the external ideal voltage, specify either of -the R,-L, and -C options. In this case, specifying the -type option is not required.

EXAMPLE

The following example sets a resistance value of 5 units (in SI units) on all power pads. point:

prompt> **set_tap_package_model -R 5 -type pad -power**

The following example sets a resistance value of 0.5 units, and an inductance value of 5 units (in SI units) on the package:

prompt> **set_tap_package_model -type package -R 0.5 -L 5**

SEE ALSO

analyze_rail(2)
set_tap_package_model(2)
rail.database(3)
rail.redhawk_path(3)

set_target_library_subset

Sets target library subsets on the top block and hierarchical cells.

SYNTAX

status **set_target_library_subset**
[-objects *objects*]
[-top]
[-data | -clock]
[-merge none | inherited | current]
[-dont_use *lib_cells*]
[-use *lib_cells*]
[-only_here *lib_cells*]
[*target_libs*]

Data Types

objects	list or collection
lib_cells	list or collection
target_libs	list or collection

ARGUMENTS

-objects *objects*

Specifies the hierarchical cells on which to set the target library subset. The cells must be in the current block.

For each hierarchical cell, the subset restriction applies to the cell for optimization and CTS. The subset also applies to the cell's children, if they are not explicitly assigned their own target library subsets. The cell must reference a hierarchy within the current block. It cannot reference another block.

If you do not specify this option or the **-top** option, the tool uses the **-top** option by default. Specifying both options is also supported.

-top

Sets the target library subset on the top block. The subset also applies to all cells in the hierarchy, if they are not explicitly assigned their own target library subsets.

If you do not specify this option or the **-objects** option, the tool uses the **-top** option by default. Specifying both options is also supported.

-data | -clock

Indicates whether the target library subset applies only to the data paths or clock paths. If not specified, the target library subset applies to all paths. The -data and -clock options are mutually exclusive, you may specify only one.

-merge none | inherited | current

Specifies how the new subset is to be merged with the existing subset, if any, on each of the specified hierarchies.

If the merge style is set to **none**, no merging will occur. The new subset overwrites the existing subset on each hierarchy. This is the default setting when no merge style is specified.

If the merge style is set to **inherited**, the new subset is merged with the inherited subset on each hierarchy. The inherited subset is the one on the parent hierarchy of the hierarchy.

If the merge style is set to **current**, the new subset is merged with the current subset on each hierarchy. The current subset may be inherited from above or previously assigned to the hierarchy.

-dont_use *lib_cells*

Specifies the library cells that cannot be used for optimization and CTS within the specified objects. This is in addition to the restrictions imposed by the *target_libs* option.

The library cells must exist in the reference library list. You can specify library cells by name, such as "mylib/AN2", or by collections, such as "get_lib_cells */AN2". You can also use wildcards. Wildcards are expanded according to the library cells in memory at the time the command is issued.

The **-dont_use** and **-use** options are mutually exclusive; you can use only one.

You must specify at least one of **-dont_use**, **-use**, **-only_here**, or *target_libs*.

-use *lib_cells*

Specifies the library cells that can be used for optimization and CTS within the specified objects. This is in addition to the libraries listed in the *target_libs* option.

The library cells must exist in the reference library list. The syntax for the **-use** and **-dont_use** options are identical.

If a library cell's dont_use attribute is true, it is not used here even if it is listed in the **-use** option. You could use the **get_attribute** and **set_attribute** commands to check and modify the library cell's dont_use attribute.

The set of usable library cells is not stored, instead the complementary set is calculated and stored as the set of library cells that cannot be used. This is equivalent to specifying the **-dont_use** option with the complementary library cell set. So to check this setting, check the attributes and reports pertaining to the **-dont_use** option.

The **-dont_use** and **-use** options are mutually exclusive; you can use only one.

You must specify at least one of **-dont_use**, **-use**, **-only_here**, or *target_libs*.

-only_here *lib_cells*

Specifies the library cells that can be used for optimization and CTS within the specified objects, but cannot be used in other objects unless they also list the library cell in an **-only_here** option. The library cells must exist in the reference library list.

The syntax for the **-only_here** and **-dont_use** options are identical. If a library cell is listed in both, the **-only_here** option overrides the **-dont_use** option.

If a library cell's dont_use attribute is true, it is not used here even if it is listed in the **-only_here** option. You could use the **get_attribute** and **set_attribute** commands to check and modify the library cell's dont_use attribute.

You must specify at least one of **-dont_use**, **-use**, **-only_here**, or *target_libs*.

target_libs

Specifies the libraries that are available for optimization and CTS within the specified objects. The libraries must be a subset of the reference library list.

If you do not specify this option, all reference libraries can be used.

You must specify at least one of **-dont_use**, **-use**, **-only_here**, or *target_libs*.

DESCRIPTION

This command sets the target library subset on the top block and hierarchical cells. Target library subsets restrict optimization and CTS on the specified objects to a subset of reference libraries and library cells.

Optimization is constrained by the target library subsets on the top block and hierarchical cells. Usually during optimization, a library cell is selected from the reference libraries. The set_target_library_subset command allows you to specify or filter the library cells to be used for cells within the top block or specified objects. The subset restriction applies only to cells that are created or modified during optimization. The subset does not affect any unoptimized portions of the block.

When target library subsets are specified on multiple ancestor hierarchies for a given cell, precedence is given to the subset on the hierarchy nearest to the cell. A subset on the lower level completely overrides a subset specified at a higher level.

Use the **remove_target_library_subset** command to remove the target library subset from a top block or hierarchical cell.

Use the **report_target_library_subset** command to report the target library subset of a top block or hierarchical cell.

As with most block constraints, the subset specifications are tied to the current block. If you change the current block to another block, and you want the subset to affect optimization at that level, you must reapply the **set_target_library_subset** command.

EXAMPLES

The following example sets a target library subset on the top hierarchy.

```
prompt> set_target_library_subset -top \
  -only_here [get_lib_cells lib1/AND*] \
  -dont_use  [get_lib_cells lib1/INV*] \
  [get_libs lib1]
```

The following example sets a target library subset on a hierarchical cell.

```
prompt> set_target_library_subset -objects [get_cells top/mid] \
  -only_here [get_lib_cells lib2/AND*] \
  -dont_use  [get_lib_cells lib2/INV*] \
  [get_libs lib2]
```

SEE ALSO

report_target_library_subset(2)
remove_target_library_subset(2)

set_technology

Apply technology node specific settings to current design

SYNTAX

status **set_technology**
-node node_number
-report_only

Data Types

node_number string

ARGUMENTS

-node node_number

Specifies the technology node, such as "7" or "12". User has to specify one of the supported technology node names.

-report_only

Report the list of public app options without applying them.

DESCRIPTION

This command will apply technology specific settings to current design. It sets the parameters for placement and route engines to satisfy advanced node design rules. It also sets some app options to control the tool work correctly. Use -report_only to list the app option names and values to be set. Once the command is executed, all the tecnology node specific controls will be applied to the design, the "technology_node" attribute will be set to the design as well.

It is recommended to use set_technology at the beginning of design flow, e.g. after design is loaded and linked, prior to place and route. The settings are persistent and saved in design database, so that user don't have to call this command multiple times in their flow. However, when user switch to a newer release, it is suggested to use set_technology again just in case the internal settings may be upgraded in the newer release.

EXAMPLES

In the following example, we apply technology node specific settings to a design using 7nm technology.

```
prompt> set_technology -node 7
technology_node=7
1
```

SEE ALSO

set_temperature

Sets the operating temperature for one or more corners, for part or all of the current design.

SYNTAX

status **set_temperature**
temperature
[-min *temperature*]
[-corners *corner_list*]
[-object_list *object_list*]
[-clear]

Data Types

object_list collection
corner_list collection
temperature float

ARGUMENTS

temperature

The temperature to be used.

-min *temperature*

The early temperature, if different than the late temperature.

-corners *corner_list*

The corner(s) to apply the temperature to. If this option is not given, the current corner is used.

-object_list *object_list*

The cell or libcell object(s) to apply the temperature. If this option is not given, the temperature is applied to the entire current design.

-clear

Remove all existing temperature settings on the given corners. The main library nominal temperatures will be used. If this option is given, the **temperature**, **-min temperature**, and **-object_list** options cannot be given.

DESCRIPTION

The **set_temperature** command is used set the operating temperature that will be used for timing analysis and delay calculation.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

This example shows how to change the temperature for an entire design, for the current corner.

```
prompt> set_temperature 125.0 -min -40.0
```

This example shows how to change the temperature for an entire design, for all corners.

```
prompt> set_temperature 125.0 -min -40.0 -corner [all_corners]
```

set_test_assume

Sets the **test_assume** attribute to a logic value to be assumed on specified cell output pins throughout test design rule checking.

SYNTAX

integer **set_test_assume**
zero_or_one_value
pin_list

Data Types

zero_or_one_value	string
pin_list	list

ARGUMENTS

zero_or_one_value

Specifies the fixed value of the output pins. To assume a constant value of logic one, *zero_or_one_value* must be "1", "one", or"ONE." To assume a constant value of logic zero, *zero_or_one_value* must be "0","zero", or"ZERO."

pin_list

Lists the hierarchical pins in the current design for which values are specified. If more than one pin is specified, they must be enclosed in braces ({ }).

DESCRIPTION

The **set_test_assume** command sets the **test_assume** attribute to *zero_or_one_value* on the cell output pins on *pin_list*. The **dft_drc** command uses **test_assume** to freeze the assumed value on the specified pins throughout test design rule checking.

Use **set_test_assume** to set conditions that would otherwise be unknown to **dft_drc**, such as the state of a non-scan register, or the output of a RAM. Known values are often applied to the design circuitry to facilitate testing by configuring the design circuitry into the desired test mode. For example, during testing, a state could be preloaded into the non-scan registers of an on-chip test controller. This condition could configure the scan chains in the design to form multiple parallel scan chains. Or, if it is known that prior to testing, all address locations of an on-chip RAM are preloaded with a fixed pattern, this pattern can be assumed at the data output pins of the RAM when testing the surrounding functional logic. You can communicate these preloaded values to the testing software through the **test_assume** attribute.

Note: The specified conditions must exist throughout testing, regardless of other changes in the design state. Otherwise, incorrect design rule checking reports can result. If the assumed state is not attainable or not held throughout the scan test sequence, it is

considered best practice to use the initialization protocol to provide initialization vectors that perform the assumed setup, instead of using **set_test_assume**, which could result in errors.

Use the **report_dft -test_assume** command to list the **test_assume** attributes on a design.

To remove selected or all **test_assume** attributes from a design, use the **remove_attributes** or **reset_design** command.

EXAMPLES

The following commands specify a fixed internal state to assume for a register in an on-chip test controller:

```
prompt> set_test_assume 0 my_tap/reg3/Q

prompt> set_test_assume 1 my_tap/reg3/QN
```

The following command specifies that all the data outputs of a RAM cell are fixed throughout testing:

```
prompt> set_test_assume ONE [get_pins h1/ramcell/DOUT*]
```

set_test_point_element

Configures the insertion of force, control, and observe user-defined test points.

SYNTAX

int **set_test_point_element**
list_of_design_objects
[-type control_0 | control_1
| force_0 | force_1 | force_01
| observe]
[-control_signal *control_name*]
[-clock_signal *clock_name*]
[-test_points_per_source_or_sink *n*]

Data Types

list_of_design_objects	list
control_name	string
clock_name	string
n	integer

ARGUMENTS

list_of_design_objects

Specifies the list of design pin or port objects at which the user-defined test point elements will be inserted. Wildcards and collections are supported. This is a required argument.

-type control_0 | **control_1** | **force_0** | **force_1** | **force_01** | **observe**

Specifies the type of test point to insert at each design object in the list. Specify only one type with each invocation of this command.

-control_signal ***control_name***

Specifies the name of the existing pin or port control signal that activates the test point. The signal must have a type of TestMode, ScanEnable, or IbistEnable.

-clock_signal ***clock_name***

Specifies the name of the clock signal used to clock any inserted user-defined test point scan registers. If no clock signal is specified, the tool determines the clock from the surrounding logic.

In all flows, you can specify the name of a scan clock signal that is predefined with the **set_dft_signal -type ScanClock** command.

In a DFT-inserted OCC controller flow, you can specify the name of a PLL output pin that is predefined with the **set_dft_signal -type Oscillator** command. This specification is mapped to the corresponding OCC controller clock during DFT insertion.

In an existing OCC controller flow, you can directly specify the name of an output pin of an existing OCC controller that is predefined with the **set_dft_signal -type Oscillator** command.

-test_points_per_source_or_sink ***n***

Specifies the number of test points that can be shared per source data signal (for control and force test points) or sink observed signal (for observe test points). The source signal can be a source data scan register or a source signal input port. The sink signal can be an observe scan cell or a sink output port.

A range of 1 to 32 can be specified for *n*.

By default, 8 observe test points can share one sink signal and 8 control or force test points can share one source signal.

DESCRIPTION

The **set_test_point_element** command configures the insertion of force, control, and observe user-defined test points. These test points are subsequently inserted by the **compile_fusion** command.

To use this feature, you must enable the **testability** DFT client:

prompt> **set_dft_configuration -testability enable**

This command requires a list of pins or ports where the test points should be inserted.

Force test points are used when a value needs to be forced throughout the entire test session. A force test point is activated when the control signal (normally the TestMode signal) is asserted. The force_0 and force_1 test point types allow a signal to be replaced with a constant 0 or constant 1 value throughout the entire test session. These test point types are useful when a particular signal must be forced to a known value for testability purposes. The force_01 test point type allows a signal to be replaced with a source data value (driven from a scan register, input port, or user-supplied source data signal) throughout the entire test session.

Control test points are used when a hard-to-control signal should be controllable (selectively forced) for some test vectors, but left unaltered for others. This allows the test program to select either the original signal behavior, or the forced behavior, on a vector-by-vector basis. Control test points are typically inserted to increase the fault coverage of the design. A control test point is like a "selectively-activated" force control point. It works the same way, except that an additional test point enable signal, supplied by a scan register, input port, or user-supplied test point enable signal, must also be asserted.

Observe test points are typically inserted at hard-to-observe signals in a design to reduce test data volume or to increase the coverage. An observe test point passively observes a signal, and captures its value in an observe sink data scan register, or a sink data output port. Multiple observed points within a single observe test point definition can share the same sink point by collapsing the observed signals with an XOR observability tree.

Each **set_test_point_element** command describes a unique test point element definition. Signal sharing is not performed between test point element definitions. If test points within a limited geographic region should share the same source, sink, or enable signals, they should all be provided in a single **set_test_point_element** command. If test points across a wide geographic region should not share signals to avoid routing congestion, they should be broken up into localized groups and specified with separate **set_test_point_element** commands.

EXAMPLES

The following example specifies that observe test points be inserted at the specified set of four design pins. Since **-scan_source_or_sink** is enabled by default, **insert_dft** inserts two new observe scan registers to observe the four pins. The first three pins share one observe scan register, and the last pin is observed by a second observe scan register.

```
prompt> set_test_point_element -type observe {U0/Q U1/Q U2/Q U3/Q} \
    -test_points_per_source_or_sink 3 \
    -clock_signal CLK
```

The following example forces the RSTN pin of an analog block to zero during the entire test program, to hold the analog block in a quiet, low-power reset state:

```
prompt> set_test_point_element -type force_0 {U_ANALOG/RSTN}
```

preview_dft(2)

set_testability_configuration

Configures automatic test-point insertion and global test-point insertion parameters.

SYNTAX

status **set_testability_configuration**
[-target *target_type*]
[-test_point_file *file_name*]
[-only_from_file false | true]
[-clock_signal *clock_name*]
[-control_signal *control_name*]
[-test_points_per_scan_cell *n*]
[-include_elements *object_list*]
[-include_fanin_cone *object_list*]
[-include_fanout_cone *object_list*]
[-exclude_elements *object_list*]
[-exclude_fanin_cone *object_list*]
[-exclude_fanout_cone *object_list*]
[-effort low | medium | high]
[-isolate_elements *cell_list*]
[-max_test_points *n*]
[-random_pattern_count *n*]
[-target_test_coverage *coverage_value*]
[-sg_command_file *file_name*]

Data Types

clock_name string
control_name string
n integer
object_list list
cell_list list
coverage_value float
file_name string
threshold_value integer

ARGUMENTS

-target *target_type*

Enables and configures an automatic test point insertion target.

Test points are not inserted for a target until it is enabled by this option. Target lists are supported.

The valid target values are:

- **random_resistant** - inserts **control_0**, **control_1**, and **observe** test points to improve the testability of hard-to-test (random-pattern-resistant) logic.
- **untestable_logic** - inserts **force_01** and **observe** test points to to control uncontrollable nets and observe unobservable logic, respectively.
- **x_blocking** - inserts **force_01** test points at unknown-function output pins, such as the output pins of black boxes.
- **multicycle_paths** - inserts capture-blocking logic at endpoints constrained by multicycle paths.
- **shadow_wrapper** - inserts a shadow wrapper around each cell specified with the **-isolate_elements** option (**observe** test points at input pins, **force_01** test points at output pins).
- **core_wrapper** - inserts test-point-based core wrapping in the design (**force_01** test points at input ports, **observe** test points at output ports).
- **user** - inserts user-supplied test points described in the external file defined by the **-test_point_file** option

If the **-target** option is omitted, the command can only configure the following global (non-target-specific) options:

- **-test_point_file**
- **-clock_signal**
- **-control_signal**
- **-test_points_per_scan_cell**
- **-sg_command_file**

-test_point_file ***file_name***

Specifies a file that describes test points to insert.

Each line contains three whitespace-separated fields: a user-defined label (can be any string), the test point type keyword, and the net where the test point should be inserted. Any text after the '#' comment character is ignored, whether in-line or on a separate line.

If a test point comes from a SpyGlass run (with an in-line SpyGlass comment), it belongs to that target. Otherwise, it belongs to the **user** target.

Note that file-based test points are not implemented unless the target is enabled (just as with analysis-based test points). For more information, see the DESCRIPTION section.

Supported scopes: global

-only_from_file false | **true**

Specifies whether file-based test points should augment or replace analysis-based test points.

When set to **false** (the default) for a target, the tool performs analysis for it, then implements both analysis-based and file-based test points for it.

When set to **true** for a target, the tool does not perform analysis for it; it implements only file-based test points for it. Any options that affect analysis for that target will have no effect.

This option is valid only when the **-test_point_file** option is also set. For more information, see the DESCRIPTION section.

Supported scopes: all targets

-clock_signal ***clock_name***

Specifies the name of a previously defined ScanClock signal to use for DFT-inserted test point registers.

The default is to use the dominant clock of the logic surrounding each test point.

Supported scopes: global, all targets

-control_signal *control_name*

Specifies the name of control signal to use for enabling test points. The signal must have a type of TestMode or lbistEnable.

The default is to use an available TestMode signal.

Supported scopes: global, all targets

-test_points_per_scan_cell *n*

Specifies the number of test points that can be shared by a single test-point register.

The default is 8.

Supported scopes: global, all targets

-include_elements *object_list*

Specifies hierarchical cells that should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **random_resistant**, **untestable_logic**

-include_fanin_cone *object_list*

Specifies ports or pins whose fanin logic should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **random_resistant**, **untestable_logic**

-include_fanout_cone *object_list*

Specifies ports or pins whose fanout logic should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **random_resistant**, **untestable_logic**

-exclude_elements *object_list*

Specifies objects that should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **random_resistant** (hierarchical cells), **untestable_logic** (hierarchical cells), **core_wrapper** (ports)

-exclude_fanin_cone *object_list*

Specifies ports or pins whose fanin logic should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **random_resistant**, **untestable_logic**

-exclude_fanout_cone *object_list*

Specifies ports or pins whose fanout logic should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **random_resistant**, **untestable_logic**

-effort low | **medium** | **high**

Specifies the effort level used to compute the optimal test points for hard-to-test logic. Higher effort levels yield more efficient test points, but at the expense of analysis runtime.

The default is **medium**.

Supported scopes: **random_resistant**

-isolate_elements ***cell_list***

Specifies hierarchical, black-box, or CTL-modeled cells to be isolated with a test-point shadow wrapper. Wildcards and collections are supported.

The default is an empty list.

Supported scopes: **shadow_wrapper**

-max_test_points ***n***

Specifies the maximum number of test points to be inserted.

This limit applies to the **random_resistant** and **untestable_logic** targets. When applied globally, the tool allocates the limit across both targets. You can also apply per-target limits, which takes precedence.

The default is 5% of the register count of the design.

Supported scopes: global, **random_resistant**, **untestable_logic**

-random_pattern_count ***n***

Specifies the number of random patterns to statistically model when performing random-resistant analysis. Coverage values specified with the **-target_test_coverage** option are interpreted according to this value.

The default is 8000.

Supported scopes: **random_resistant**

-target_test_coverage ***coverage_value***

Specifies the random-pattern target test coverage in percentage points that, when reached, prevents further test points from being generated.

The default is 100.

Supported scopes: **random_resistant**

-reuse_threshold ***threshold_value***

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells when wrapping the design with test points.

The default is 0.

Supported scopes: **core_wrapper**

-depth_threshold ***threshold_value***

Specifies the maximum combinational depth of I/O registers that can be reused as shared wrapper cells when wrapping the design with test points.

The default is 1.

Supported scopes: **core_wrapper**

-sg_command_file ***file_name***

Specifies a file of SpyGlass Tcl commands file to be applied to the test-point analysis.

This options file is an unordered list of SpyGlass Tcl commands that you want to apply. The tool automatically applies the Tcl commands at the proper point in the analysis based on their type (design read, setup, goal definitions, etc.).

Supported scopes: global

DESCRIPTION

The **set_testability_configuration** command enables and configures automatic test-point insertion for one or more targets.

To use this feature, you must first enable the testability DFT client:

```
prompt> set_dft_configuration -testability enable
```

Issue this command without the **-target** option to configure global test-point insertion parameters. These global options are noted above.

Issue this command with the **-target** option to configure the specified target(s). Each target supports a particular subset of this command's options, described above. Warning messages are issued if you specify unsupported options for a target.

Specify the global configuration first, followed by the per-target configurations.

The following global options can also be specified per-target, which takes precedence over their global value:

- **-clock_signal**
- **-control_signal**
- **-test_points_per_scan_cell**

By default, analysis-based test points are implemented for a target when it is enabled. If you specify the **-test_point_file** option, any file-based test points are also implemented for that target. To suppress analysis and implement only the file-based test points, set the **-only_from_file** option to **true** for that target.

EXAMPLES

The following example configures three automatic test-point insertion targets:

```
prompt> # global settings
prompt> set_testability_configuration \
        -test_points_per_scan_cell 20 \
        -control_signal TM_TP
```

```
prompt> # target-specific settings
prompt> set_testability_configuration -target random_resistant \
        -random_pattern_count 1000 -target_test_coverage 95

prompt> set_testability_configuration -target {x_blocking core_wrapper}
```

The following example configures insertion of only file-based test points for two targets from a previous SpyGlass run, without rerunning analysis:

```
prompt> # global settings
prompt> set_testability_configuration \
        -control_signal TM_TP \
        -test_point_file spyglass.txt

prompt> # enable targets for file-based insertion only
prompt> set_testability_configuration -only_from_file true \
        -target {random_resistant x_blocking}

prompt> # specifying exclude elements as name
prompt> set_testability_configuration -target random_resistant -exclude_elements { sa_eeprom } \

prompt> # specifying exclude elements as collection
prompt> set_testability_configuration -target random_resistant -exclude_elements [ list $all_cells ]  \

prompt> # specifying include_elements as list of collection, names and name with wildcard
prompt> set_testability_configuration -target random_resistant -include_elements [ list $all_cells sa_int_ctrl sa_reg_access
```

set_threshold_voltage_group_type

This command specifies which threshold voltage group names for library cells are high, normal, or low vt type.

SYNTAX

string **set_threshold_voltage_group_type**
  -type *vth_type*
  group_names

string *vth_type*
list *group_names*

ARGUMENTS

-type *vth_type*

Specifies the threshold voltage type for the specified groups. Must be one of **high_vt**, **normal_vt**, or **low_vt**.

group_names

A list of threshold voltage group names, which are stored as **threshold_voltage_group** attributes on lib_cell objects.

DESCRIPTION

This command specifies which threshold voltage group names for library cells are high, normal, or low vt type.

It is to be noted that threshold voltage group type information is persistent given that the app option 'power.enable_activity_persistency' is set to 'on'.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example specifies that lib_cells with "threshold_voltage_group" attribute equal to "HVT" or "hvt" are considered as "high_vt" type for optimization.

```
prompt> set_threshold_voltage_group_type -type high_vt {HVT hvt}
```

SEE ALSO

set_max_lvth_percentage(2)
power.enable_activity_persistency(3)

set_timing_derate

Sets the delay derating factors for either the current design or a specified list of cells or library cells.

SYNTAX

int **set_timing_derate**
-early | -late
[-rise]
[-fall]
[-clock]
[-data]
[-cell_delay]
[-cell_check]
[-net_delay]
[-static]
[-dynamic]
[-variation]
[-aocvm_guardband | -pocvm_guardband]
[-pocvm_subtract_sigma_factor_from_nominal]
[-pocvm_coefficient_scale_factor]
[-increment]
[-corners *corner_list*]
derate_value
object_list

Data Types

corner_list list
derate_value float
object_list list

ARGUMENTS

-early

Applies the *derate_value* to early delays (shortest paths). This option and the **-late** option are mutually exclusive.

-late

Applies the *derate_value* to late delays (longest paths). This option and the **-early** option are mutually exclusive.

-rise

Applies *derate_value* to rise delays.

-fall

Applies *derate_value* to fall delays.

-clock

Applies the specified derating factor only to clock paths.

-data

Applies the specified derating factors only to data paths.

-cell_delay

Applies the specified derating factor to cell delays. This option cannot be specified together with the **-cell_check** option.

-cell_check

Applies the specified derating factor only to cell timing checks. If this option is specified, then the derate value set with the **-early** option is applied to hold and removal timing checks, and the derate value set with the **-late** option is applied to setup and recovery timing checks. This option cannot be specified together with the **-clock** and **-data** options. This option cannot be specified with the **-cell_delay** and **-net_delay** options.

-net_delay

Applies the specified derating factor only to net delays. This option cannot be specified together with the **-cell_check** option.

-static

Applies the specified derating factor only to the non-delta portion of net delays. This option also requires that you specify the **-net_delay** option.

-dynamic

Applies the specified derating factor only to the dynamic component of delays. This option also requires that you specify the **-net_delay** option.

-variation

Applies the specified derating factor to statistical delays only. This option is currently ignored.

-aocvm_guardband

Applies a delay to a timing arc that is a product of the guardband derate factor and the advanced OCV derate factor. This option is only applicable in an advanced on-chip variation (AOCV) context. This option cannot be specified together with the **-cell_check** option.

-pocvm_guardband

This option is only applicable in a parametric on-chip variation (POCV) context. In a parametric OCV context, the derate factor that is applied to an arc is a product of the guard-band derate factor and the parametric OCV derate factor corresponding to a distance-based parametric OCV table, if specified. The parametric OCV factor applied to the standard deviation is also multiplied by the guardband factor.

-pocvm_subtract_sigma_factor_from_nominal

This option is only applicable in a parametric on-chip variation (POCV) context and requires constraint variation to be enabled. The derate factor is for subtracting the intrinsic standard deviation from the nominal value for constraint arcs. This option can be used only with the **-cell_check** option, which applies the derating to cell timing check constraints. Note that this derate factor is applied prior to **-pocvm_guardband** option and **-pocvm_coefficient_scale_factor** option.

-pocvm_coefficient_scale_factor

This option is only applicable in a parametric on-chip variation (POCV) context. In a parametric OCV context, the coefficient applied to an arc is a product of the parametric on-chip variation (POCV) coefficient and the parametric on-chip variation (POCV) coefficient scale factor.

-increment

Specifies incremental derate factor that is added to the base derate factor to compute the total derate for an object. This option can not be specified with the options, **-aocvm_guardband**, **-pocvm_guardband** or **-pocvm_coefficient_scale_factor**.

-corners *corner_list*

Specifies the corners that the derate value applies to. If this option is not given, the current corner is used.

derate_value

Specifies the timing derate value to apply to the specified delays as a scalar multiplying factor.

object_list

Specifies the current design, or list of cells, library cells, or nets to which the specified derate factor is applied. If no objects are given, the derate factor is applied to the entire design.

DESCRIPTION

This command sets derating factors for either the current design (if no object list is specified) or a set of cells or library cells in the current design.

Timing derating factors affect delay values shown in timing reports. Longest path delays (for example, launching paths for setup checks or capturing paths for hold checks) are multiplied by the derate value set by using the **-late** option. Shortest paths (such as capturing paths for setup checks or launching paths for hold checks) are multiplied by the derate values set by using the **-early** option. If derating factors are not specified, a value of 1.0 is assumed.

Begin by first setting global or default derates on the design. Then, you can use the *object_list* option to set specific derate values for cells or library cells in the design. To set derate values globally on a design, issue this command with no object list specified.

For example, to set an early derate factor of value 0.95 on all cell and net delays in the design, use the following command:

```
set_timing_derate -early 0.95
```

If only the **-net_delay** option is specified, and no *object_list* is specified, then the derate factor supplied is applied to all net delays in the design.

If only the **-cell_delay** option is specified, then the derate factor supplied is applied to either all cell delays in the design (if no *object_list* is specified) or to each delay (apart from timing check delays) on each cell or library cell specified in the *object_list*.

If neither **-net_delay**, **-cell_delay** nor *object_list* are specified with the command, then it is assumed that the derate factor applies to all cell and net delays in the design.

If only the **-clock** option is specified, then the derate factor supplied is only applied to delays that are in clock paths. If only the **-data** option is specified, then the derate factor supplied applies only to delays that are in data paths. If neither of the above options is specified, then it is assumed that the derate factor applies to both clock and data paths.

The **-cell_check** option is the only option not assumed by default. If specified, this option applies the derate factor to either all timing checks in the design (if no *object_list* is specified) or to a specific list of cells or library cells (specified by *object_list*). Note that the following commands sets all derating factors except for constraints:

```
set_timing_derate -late 1.3
```

set_timing_derate -early 0.8

To set derating for constraints, use the following command

set_timing_derate -late 1.3 -cell_check
set_timing_derate -early 0.8 -cell_check

The incremental derate value, specified using the **-increment** option, is applied to both simple derates as well as AOCVM and POCVM derates. For a given object, the base derate is first computed and then the incremental derate value is added to determine the total derate factor. The incremental derate factors follow the same inheritance, precedence and override rules as the base derates. If the total derate factor after addition of incremental derate value is negative, the tool will limit it to 0.0 and a warning message is issued.

With SI enabled, net delays might also include delta delay resulting from crosstalk interaction between nets. Users can specify separate derate factors for static and dynamic(delta delay) net delays by using **-static** and **-dynamic** options. The net derate factors are applied separately to the static and dynamic delays first and then both derated values are summed to give the total derated net delay.

When the options, **-static** and **-dynamic**, are not specified for net delays, both static and dynamic factors are set. Both -static and -dynamic are supported with -increment option. With aocvm and pocvm, the derate factors from aocvm/pocvm are used along with corresponding static or dynamic incremental derate factors. When old format constraints, where dynamic derates were not supported, are loaded into versions with -static/-dynamic support, both static and dynamic values are set. This is same behavior as set_timing_derate with no -static/-dynamic specified.

The *object_list* option can be used to set specific derate factors on instances (cells or library cells) in the design. On each instance, the options **-cell_delay**, **-cell_check**, **-clock** and **-data** can be used in the same fashion as outlined above to specify exactly how the derate factors should be applied to each instance in the object list.

If no options are specified and an object list is given, then it is assumed that **-cell_delay**, **-clock** and **-data** are TRUE.

When applying derate factors, the tool uses the following priority, starting from the highest:

1. Derate factors set on the leaf cell
2. Derate factors set on the library cell
3. Derate factors set on the hierarchical cell
4. Derate factors set on the design

To set derating values to the default (derate factor of 1.0 for every instance in the design), use the **reset_timing_derate** command.

For delays, an early factor less than 1 and late factor more than 1 adds pessimism to the slack calculation. However, constraint derating is applied directly to the value of constraint. For example, a factor of less than 1 for hold decreases the hold time and gives a less conservative slack. A factor greater than 1 for setup makes setup time larger and gives a more conservative slack.

The following equation is used to apply derates to both positive and negative delays.

derated_delay = delay + ((derate_factor - 1.0)*ABS(delay))

This equation ensures that negative delays will be correctly made more conservative by the application of derates.

To report all derate factors set for the design or for any cell, library cell or net in the design, use the **report_timing_derate** command.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

The following example sets an early (shortest path) derate factor of 0.7 and a late (longest path) derate factor of 1.0 globally on all cell and net delays the design.

```
prompt> set_timing_derate -early 0.70
prompt> set_timing_derate -late 1.0
```

The following example sets an early derate factor of 0.8 for the cell delay of cell U1.

```
prompt> set_timing_derate -early 0.8 -cell_delay [get_cells U1]
```

The following example sets a late derate factor of 1.1 on all instances of library cell IV in the library MY_LIB.

```
prompt> set_timing_derate -late 1.1 [get_lib_cells MY_LIB/IV]
```

Assuming that cell, "inv" is a particular instantiation of MY_LIB/IV in the design, the following command overwrites the late derate factor for the instance "inv" only.

```
prompt> set_timing_derate -late 1.05 [get_cells inv]
```

The following example sets a derate factor on all cells within the hierarchy top/H1.

```
prompt> set_timing_derate -cell_delay -late 1.05 [get_cells top/H1]
```

The following example uses incremental derates to set a late derate factor of 1.15 (= 1.11 + 0.04) and early derate factor of 0.88 (= 0.91 + (-0.03)) for the cell delay of cell top/H1/u12.

```
prompt> set_timing_derate -late 1.09
prompt> set_timing_derate -early 0.91
prompt> set_timing_derate -late 1.11 [get_cells top/H1/u12]

prompt> set_timing_derate -increment -late 0.04 [get_cells top/H1/u12]
prompt> set_timing_derate -increment -early -0.03 [get_cells top/H1/u12]
```

The following example sets static and dynamic derates for net delays to 1.11 for late and 0.88 for early.

```
prompt> set_timing_derate -late 1.1 -net_delay
prompt> set_timing_derate -early 0.88 -net_delay
```

The following example sets different static and dynamic late derates for net delays.

```
prompt> set_timing_derate -late 1.1 -net_delay -static
prompt> set_timing_derate -late 0.28 -net_delay -dynamic
```

The following example sets total static and dynamic derates of 1.2 with incremental derates for late net delays.

```
prompt> set_timing_derate -late 1.07 -net_delay -static
prompt> set_timing_derate -late 0.13 -net_delay -static -increment
prompt> set_timing_derate -late 1.18 -net_delay -dynamic
prompt> set_timing_derate -late 0.02 -net_delay -dynamic -increment
```

The following example sets -pocvm_guardBand, -pocvm_coefficient_scale_factor and -pocvm_subtract_sigma_factor_from_nominal of 1.1, 0.8, and 0.2 for late constraint arc. Assume that intrinsic constraint arc delay in POCV analysis is (nominal, sigma) and POCV corner sigma is 3.0. After applying above derating factors, the derated constraint arc delay will be ((nominal - 0.2 * sigma) * 1.1, sigma * 1.1 * 0.8 * 3.0);

```
prompt> set_timing_derate -late -cell_check -pocvm_guardband 1.1
prompt> set_timing_derate -late -cell_check -pocvm_coefficient_scal_factor 0.8
prompt> set_timing_derate -late -pocvm_subtract_sigma_factor_from_nominal 0.2
```

The following command sets an early derating factor of 0.75 on a specific net, n123, overriding the global derating factor for net delays:

```
prompt> set_timing_derate -net_delay -early 0.75 [get_nets n123]
```

set_operating_conditions(2)

set_timing_paths_disabled_blocks

Ignore the internal reg2reg timing paths across subblocks.

SYNTAX

string **set_timing_paths_disabled_blocks**
[-all_sub_blocks]

list *blocks_list*

ARGUMENTS

-all_sub_blocks

When specified, all reg2reg timing paths across subblocks will be ignored.

DESCRIPTION

This command controls whether tool needs to ignore the internal reg2reg timing paths across subblocks.

Sometimes, during top level optimization with subblocks, user might only focus on the top and boundary logic.

With this command, user could ignore block level reg2reg timing paths which has worst timing violations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

prompt> **set_timing_paths_disabled_blocks -all_sub_blocks**

SEE ALSO

remove_timing_paths_disabled_blocks(2)
report_timing(2)
report_qor(2)

set_top_module

Specifies which module to use as top module in the current unlinked block, and links it

SYNTAX

status **set_top_module**
[*module_name*]

Data Types

module_name string

ARGUMENTS

module

Specifies the name of the module to use as top module while linking the current block. The current block must be unlinked.

DESCRIPTION

This command performs a name-based resolution of block references for the current block. The specified module is used as the top module. References are resolved using other modules within this block, top modules of other physical hierarchy blocks, and leaf cells within lib cell libraries.

Auto Link

Many commands automatically link the current block before executing. These automatic links are always incremental, and might not fully rebind block references when the reference library list or view switch list is changed. To force a full relink and rebinding of the block, use the **link_block -force -rebind** command.

EXAMPLES

In the following example, block TOP in library blockLib is linked to the physical hierarchy blocks MID and BOT, and the lib cell library leafCellLib.

```
prompt> set_top_module TOP
Using libraries: designLib leafCellLib
```

```
Linking design TOP
Linking design BOT
Linking design MID
Design 'TOP' was successfully linked.
1
```

SEE ALSO

link_block(2)

set_topology_edge_shapes

Sets the shape layers for selected or specified topology edges in the current design.

SYNTAX

status **set_topology_edge_shapes**
[-shape l_x_first | l_y_first | l_longer_first | z_x_first | z_y_first | z_longer_first]
[-force]
[*object_list*]

Data Types

object_list collection or selection

ARGUMENTS

-shape l_x_first | l_y_first | l_longer_first | z_x_first | z_y_first | z_longer_firs

Specifies the shape layers template for topology edge.

The shape values are:

l_x_first is L-shape with first segment in x direction
l_y_first is L-shape with first segment in y direction
l_longer_first is L-shape with first segment in longer direction
z_x_first is Z-shape with first segment in x direction
z_y_first is Z-shape with first segment in y direction
z_longer_first is Z-shape with first segment in longer direction

-force

Sets shapes for locked or fixed objects. By default, such objects are skipped according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

DESCRIPTION

The **set_topology_edge_shapes** command sets or resets shape layers for selected or specified topology edges.

Note if option **-shape** is not specified the shape template will be chosen automatically with respect to the access direction of the start and end topology nodes.

EXAMPLES

The following example sets L-shape layers with first segment in x direction for selected topology edges.

prompt> **set_topology_edge_shapes -shape l_x_first**

The alternative syntax uses collection to specify objects.

prompt> **set_topology_edge_shapes [get_selection] -shape l_x_first**

get_selection(2)
set_edit_setting(2)

set_trace_option

Set an option value controlling behavior of command tracing and output annotation..

SYNTAX

set_trace_option [-command name
|-profile profile_metric_types
|-memory_threshold threshold
|-cpu_threshold threshold
|-time_treshold threshold]
[-annotate annnotate_type]

string *name*
string *annotate_type*
list rofile_metric_types
integer *threshold*

ARGUMENTS

-command *name*

This option is mutually exclusive with -profile, -memory_threshold, -cpu_threshold, and -time_threshold. The option identifies the command for which annotation option is being set.

-annotate *annotate_type*

This option is meaningful only when given with the -command option. Set the annotation type of the given command with this option. The allowed values are {annotate, omit}.

The *annotate* option value causes the traced command execution to be annotated to the shell output. If the application supports an output log, the annotation is also output to the output log.

The *omit* option value causes the command execution string to be omitted from output annotation.

-profile *profile_metric_types*

This option is mutually exclusive with all others. The option sets the currently enabled profile metrics, or "all" if all metrics are enabled. Allowed values are a list of: memory, cpu, time, or the value all to indicate enabling of all metrics, or the value none to indicate disabling of all metrics. If none is given in a list with any other value, it is ignored. The enabled profile metrics are reported with command annotations in the tool output to shell, and to the output log if supported by the tool.

-memory_threshold *threshold*

This option is mutually exclusive with all others. The option sets the threshold for gathering memory metrics. The profile data annotation will be output at the end of a command inovcation only when the delta memory use for a command invocation

matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in kilobyges. The special value -1 unsets the threshold.

-cpu_threshold *threshold*

This option is mutually exclusive with all others. The option sets the threshold for gathering CPU usage metrics. The profile data annotation will be output at the end of a command inovcation only when the delta CPU usage for a command invocation matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in seconds. The special value -1 unsets the threshold. If cpu threshold isunset, then the default threshold of 1 second is used. To effect no threshold, set the threshold to 0 (zero).

-time_threshold *threshold*

This option is mutually exclusive with all others. The option sets the threshold for gathering elapsed time metrics. The profile data annotation will be output at the end of a command inovcation only when the elapsed time for a command invocation matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in seconds. The special value -1 unsets the threshold. If time threshold is unset, then the threshold for cpu is used.

DESCRIPTION

If a command is given with -annotate option, then the **set_trace_option** command informs the tool on how to behave during command annotation output, which is started with the **annotate_trace** command.

If profile, memory_threshold, cpu_threshold, or time_threshold is given, the the **set_trace_option** configures the behavior of performance profile gathering and the data reported in command annotations to the output.

EXAMPLES

The following example sets profile configurations, turns annotation off for the command *get_attribute*, then starts command annotations to the output.

```
prompt> set_trace_topion -profile all
prompt> set_trace_topion -memory_threshold 10
prompt> set_trace_topion -cpu_threshold 30
prompt> set_trace_topion -command get_attribute -annotate omit
prompt> annotate_trace -start -profile on
```

SEE ALSO

log_trace(2)
annotate_trace(2)
get_trace_option(2)

set_track_constraint

The command defines a set of track constraints on per-layer basis. The constraints describe rules for the structure of track objects in the block to ensure that the generate wire tracks meet manufacturability criteria

SYNTAX

int **set_track_constraint**
[-block *block*]
-grid *grid*
-label *label*
-layer *layer*
[-mask *masks*]
-offset *offset*
-origin block | core_area
[-track_direction horizontal | vertical]

Data Types

block string
grid int
label string
layer string
masks list of masks
offset list of float

ARGUMENTS

-block *block*

The -block argument specifies the block on which to set the track constraints.

-grid *grid*

The -grid argument specifies the length of the window for the allowable track offset pattern.

-label *label*

The -label argument specifies the label assigned to the track constraint definition generated by the command. Labels must be unique, but may apply to muliple track constraint classifications if more than one is covered in the constraints definition.

-layer *layer*

The -layer argument specifies the layer for which the track constraints apply. Only valid interconnect layers may be given.

-mask *masks*

The -mask argument specifies the mask(s) for which the constraint applies. Mask values currently supported are "mask_one" and "mask_two". The constraint will apply only to tracks that exist on the given mask(s). Giving a list with both "mask_one" and "mask_two" means the constraint will apply to tracks on either mask_one or mask_two.

Omitting the -mask argument will assign the constraint to un-colored tracks.

-offset *offset*

The -offset argument specifies the allowable positions for tracks relative to a multiple of the constraint window (grid) value. The list should contain only non-negative floats in increasing order. The list should not contain any values greater than the value given for the -grid argument. The list may contain only one number but should not be empty.

-origin block | core_area

The -origin argument specifies the reference point for the track constraint pattern defined. A value of "block" means the constraint pattern starts from the boundary of the block. A value of "core_area" means the constraint pattern starts from the boundary of the block's core area.

-track_direction horizontal | vertical

The -track_direction argument specifies the track orientation for which the constraint applies. A value of "horizontal" means the constraint applies only to tracks parallel to the X axis. A value of "vertical" means the constraint applies only to tracks parallel to the Y axis. Omitting this argument means the constraint will apply to both horizontal and vertical tracks.

DESCRIPTION

The set_track_constraint command defines valid wire track structures in the given block on a per-layer basis. The constraint itself is comprised of an origin, grid, and offset. The origin describes the reference point from which to start the pattern. The constraint pattern itself is defined as each offset value starting from each multiple of the grid value. In other words, the constraint pattern says that tracks are valid if they exist at a location given by the expression O + n*G + F for any F in the offset list.

The defined constraint applies to the tracks specified by the block, layer, track_direction, and mask arguments.

Lastly, the label serves as an identifier for the given constraint. Labels may not be re-used once they have been applied. The same constraint may, however, be overwritten with a different label. Constraints (and their corresponding labels) may be removed using the remove_track_constraint command. Once a label has been removed (which happend by removing all constraints covered by that label) it may be re-assigned to a new set of constraints.

EXAMPLES

The following command creates a constraint that applies to both vertical and horizontal tracks with a mask color of 1 on layer M1 in block current_block. The constraint says that valid tracks can exist at offset values of 0, 0.2, 0.8, 1, 1.2, 1.8, 2, etc. from the boundary of the block.

```
prompt> set_track_constraint -block [current_block] -layer M1 \
  -label A -grid 1 -offset {0 0.2 0.8} -origin block -mask mask_one
```

SEE ALSO

remove_track_constraint(2)
report_track_constraints(2)

set_ungroup

Either prevent ungrouping or ungroup cells during **compile**.

SYNTAX

int **set_ungroup**
object_list true | false

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cells or modules. Specifying modules is same as specifying all instances of modules.

true | **false**

The value which determines weather to ungroup cells or to prevent their ungrouping. True ungroups cells. False prevents ungrouping. Default is **true**.

DESCRIPTION

set_ungroup is used to either prevent ungrouping of cells or force ungrouping of cells during **compile**. Cells are prevented from ungrouping if **set_ungroup** is specified with false switch. Cells are ungrouped if **set_ungroup** is specified with true switch. Ungrouping of cells is done early in the optimization so that optimization engine sees ungrouped hierarchies.

Specifying modules is same as specifying all instances of modules.

The **compile** command does not ungroup cells with other constraints such as those marked using **set_dont_touch**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, cell U1 is ungrouped during **compile**.

prompt> **set_ungroup [get_cells U1] true**

In the following example, cell U1 is prevented from ungrouping during **compile**.

prompt> **set_ungroup [get_cells U1] false**

In the following example, all instances of module M are prevented from ungrouping during **compile**.

prompt> **set_ungroup [get_modules M] false**

In the following example, all instances of module M are ungrouped during **compile** .

prompt> **set_ungroup [get_modules M] true**

SEE ALSO

compile(2)
ungroup(2)

set_units

This command has no effect. It exists for backwards compatibility when reading SDC files with the **read_sdc** command.

SYNTAX

int **set_units**
[-time *[optional float][optional scale_value]s*]
[-capacitance *[optional float][optional scale_value]F*]
[-resistance *[optional float][optional scale_value]Ohm*]
[-voltage *[optional float][optional scale_value]V*]
[-current *[optional float][optional scale_value]A*]
[-power *[optional float][optional scale_value]W*]

character *scale_value [f|p|n|u|m|k|M]*

ARGUMENTS

-time ***optional floatoptional scale_values***

-capacitance ***optional floatoptional scale_valueF***

-resistance ***optional floatoptional scale_valueOhm***

-voltage ***optional floatoptional scale_valueV***

-current ***optional floatoptional scale_valueA***

-power ***optional floatoptional scale_valueW***

DESCRIPTION

This command has no effect. It exists for backwards compatibility when reading SDC files with the **read_sdc** command. **read_sdc** will parse the **set_units** command, but since the command has no effect, the **set_user_units** may need to be executed before **read_sdc** if the SDC file's units are not the same as the current user input units. **write_sdc** and **write_script** will write the **set_units** command as the first command at their output, based on the output units currently in effect.

The units used by commands and reports can be set at any time with the **set_user_units** command. All input and output units can be reported by **report_units** command.

SEE ALSO

set_user_units(2)
report_units(2)

set(2)
setenv(2)
sh(2)
unset(2)

set_unloaded_register_removal

Sets the **remove_unloaded_register** attribute on the specified cells or modules, allowing removing of the unloaded registers.

SYNTAX

status **set_unloaded_register_removal**
obj_list
[true | false]

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of cell or module names for which to remove unloaded registers. Cell names in *obj_list* must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true | false

Specifies the value with which to set the **remove_unloaded_register** attribute. When this option is set to true (the default), unloaded register removal is enabled on the specified objects (cells or modules). Unloaded register removal is performed on the specified objects provided that the application option **compile.seqmap.remove_unloaded_registers** is set to true.

A setting of false on a module do not remove unloaded registers for the whole module. A setting of false on an instance do not remove unloaded registers for the whole instance.

DESCRIPTION

The **set_unloaded_register_removal** command sets the **remove_unloaded_register** attribute on the specified *obj_list*. This attribute is used to specify that the cells or modules are to be remove unloaded registers.

If a cell with a specified name is found in the current design, the **remove_unloaded_register** attribute is set to the specified value on the cell. If no cell with a specified name is found, the tool searches for a module and the attribute set on the module.

EXAMPLES

The following example shows how to enable register removal during optimization for the sequential cells named U0 and U1 and how to disable register removal for the U2 cell:

```
prompt> set_unloaded_register_removal {U0 U1} true
prompt> set_unloaded_register_removal U2 false
```

SEE ALSO

compile(2)
get_attribute(2)

set_user_units

This command sets the units that are used for user input and/or output.

SYNTAX

string **set_user_units**
  [-input]
  [-output]
  -type *unit_type*
  -value *unit_value*

string *unit_type*
string *unit_value*

ARGUMENTS

-input

Set the units for data input such as source and read_sdc.

-output

Set the units for data output such as reports and attributes.

-type *unit_type*

Specifies the type of unit to set. This is one of "capacitance", "current", "length", "power", "resistance", "time" or "voltage".

-value *unit_value*

Specifies the unit value. For time, equivalent examples would include "1ps", "1.0ps", "1e-12".

DESCRIPTION

This command sets the units that are used for data input and/or output. The tool maintains separate units for input and input. There are unit values for time, resistance, capacitance, power, voltage and current.

EXAMPLES

The following example sets input and output units to 10ps, 1kOhm, 1pF, 1V and 1mA.

```
prompt> set_user_units -type time -value 10ps
prompt> set_user_units -type resistance -value 1kOhm
prompt> set_user_units -type capacitance -value 1pF
prompt> set_user_units -type voltage -value 1V
prompt> set_user_units -type current -value 1mA
```

The following example sets input time units to 1ps.

```
prompt> set_user_units -input -type time -value 1ps
```

SEE ALSO

get_user_units(2)
report_user_units(2)

set_variation

Applies absolute voltages values of the allowed overshoot(positive threshold) or undershoot(negtive threshold) in the voltage unit of the library.

SYNTAX

status **set_variation**
[-supply *supply_net*]
[-tolerance *tolerance_value*]

Data Types

supply collection
tolerance float

ARGUMENTS

-supply *supply_net*

This option is optional for specifying supply nets.

-tolerance *tolerance_value*

This option is required to specify one tolerance value or two tolerance values. If one only tolerance value specified, it will be applied to both overshoot and undershoot. if two tolerance values specified, the first will be applied to undershoot and the second will be applied to overshoot.

DESCRIPTION

Defines the overshoot and undershoot tolerance for voltage reconciliation on the supply nets and their corresponding netgroup.

EXAMPLES

The following example sets global tolerance value that will be applied to all supplies, only one value specified, both overshoot and undershoot will take the value, means both postive and negative threshold of 0.2 units around the nominal value on all supplies will be considered during voltage reconciliation.

```
prompt> set_variation -tolerance {0.2}
```

The following example sets global tolerance value that will be applied to all supplies. Two values specified as {0.4 0.2}, 0.4 will be set as negative threshold units, 0.2 will be set as positive threshold units.

```
prompt> set_variation -tolerance {0.4 0.2}
```

The following example sets tolerance value for certain supply nets. The value(s) will be applied to all supply nets of the corresponding netgroup.

```
prompt> set_variation -tolerance {0.2} -supply {BLK/VDD}
prompt> set_variation -tolerance {0.4 0.2} -supply {VDDSS}
```

SEE ALSO

connect_supply_net(2)
-reconcile(2)

set_vclp_options

Used to set VCLP related options if users invoke VCLP using check_vclp_design.

SYNTAX

status **set_vclp_options**
[-vclp_exec]
[-work_dir]
[-search_path]
[-link_library]
[-vc_static_home]
[-reset]

Data Types

-vclp_exec string
-work_dir string
-search_path string
-link_library string
-vc_static_home string
-reset boolean

ARGUMENTS

-vclp_exec ***Path to 'vc_static_shell' or the VCLP executable to be used***

Specifies the path to the VCLP executable to be used. The path must be enclosed in double quotes. This argument is optional.

-work_dir ***path to VCLP Working directory***

Specifies the path to the VCLP working directory. This argument is optional. The path must be enclosed in double quotes.

-search_path ***VCLP search path***

Specifies VCLP search path to be used. This argument is optional. The path must be enclosed in double quotes.

-link_library ***VCLP link library***

Specifies VCLP link libraries. This argument is optional. The path must be enclosed in double quotes.

-vc_static_home ***VC_STATIC_HOME environment variable***

This option can be used to set the VC_STATIC_HOME environment variable. This argument is optional. The path must be enclosed in double quotes.

-reset ***Resets all options***

This option can be used to reset all VCLP related options. This argument is optional.

DESCRIPTION

The **set_vclp_options** command is used to set all the VCLP related options is users invoke VCLP in ICC2/FC using **check_vclp_design**.

EXAMPLES

prompt> **set_vclp_options -vc_static_home "/remote/path/example/Release"**

SEE ALSO

check_vclp_design(2)

set_verification_checkpoints

Enables or disables checkpointing within compile.

SYNTAX

status **set_verification_checkpoints**
[-show]
[-off]
[-version *version_name*]
[checkpoints]

Data Types

checkpoints list
version_name string

ARGUMENTS

-show

Lists each checkpoint and whether it is on or off.

-off

Disables all checkpoints. Note that the preRetiming checkpoint is independent of this command and is enabled in the flow if needed.

checkpoints

Specifies a list of checkpoints to enable.

If this argument is provided, then the specified checkpoints will be enabled and all other checkpoints will be disabled. If this argument is not provided, then all supported checkpoints are enabled.

-version *version_name*

Release version supporting compatible ndm lib to use while writing checkpoints. Current default is to use the version of the binary. To find the list of release versions run command report_versions. Allowed values are <version string> and "latest".

DESCRIPTION

This command allows the user to turn on checkpointing within compile. The use of checkpoints can help aid formal verification.

The supported checkpoints are:

ckpt_pre_map ckpt_logic_opt

EXAMPLES

In the following example, the **set_verification_checkpoints** command is used to enable all supported checkpoints.

```
prompt> set_verification_checkpoints
Enabling checkpoint "ckpt_pre_map".
Enabling checkpoint "ckpt_logic_opt".
1
```

In the following example, the **set_verification_checkpoints** commands is used to enable "ckpt_logic_opt" and disable all other supported checkpoints.

```
prompt> set_verification_checkpoints {ckpt_logic_opt}
Disabling checkpoint "ckpt_pre_map".
Enabling checkpoint "ckpt_logic_opt".
1
```

The -show option can be used to display which checkpoints are enabled.

```
prompt> set_verification_checkpoints -show
ckpt_pre_map: off
ckpt_logic_opt: on
Release version: latest
1
```

The -version option can be used to change the library version. Below usage will enable ckpt_pre_map and ckpt_logic_opt checkpoints and also set the version used for writing the library.

```
prompt> set_verification_checkpoints -version O-2018.06
Enabling checkpoint "ckpt_logic_opt".
Enabling checkpoint "ckpt_pre_map".
1
```

To set only the version without enabling ckpt_pre_map and ckpt_logic_opt checkpoits

```
prompt> set_verification_checkpoints -version O-2018.06 -off
Disabling checkpoint "ckpt_logic_opt".
Disabling checkpoint "ckpt_pre_map".
1
```

SEE ALSO

report_versions(2)

set_verification_priority

Sets the **verification_priority** attribute on specified modules or cells.

SYNTAX

status **set_verification_priority**
-all
[-high]
object_list

Data Types

object_list list

ARGUMENTS

-all

Sets the attribute on all modules (equivalent to **[get_modules *]**).

-high

Sets the verification priority to high level. At this level, datapath extraction will be turned off; and high level datapath optimzations are turned off.

object_list

Specifies a list of cells or modules on which the attribute is to be set. If the specified cell is a leaf level cell that is not unmapped DesignWare, the command will skip it.

DESCRIPTION

This command sets the **verification_priority(SVP)** attribute on the specified objects. During **compile**, the optimizations of the design with the attribute are adjusted, some optimization features will be disabled. The disabled optimization features are: ungrouping will be disabled for the cells with SVP, or the cells reference to modules with SVP; Ungrouping of DesignWare components in the design with the attribute is disabled. Some datapath optimizations will be disabled, including extraction of select operators; mutually exclusive resource sharing, etc.

When the attribute is set on a synthetic operator, such as an adder or a multiplier, the resource sharing and the datapath extraction is not performed on the operator. The DesignWare hierarchy of the operator is preserved, except that the size of the DesignWare is small.

The attribute is not transitive to its subdesigns. However, if a design with no SVP attribute is ungrouped into the parent design that has SVP setting, the ungrouped design will honor the parent's SVP setting.

You can use the **remove_verification_priority** command to remove the **verification_priority** attribute.

EXAMPLES

In the following example, the **verification_priority** attribute is set on the *U1* cell:

```
prompt> set_verification_priority [get_cells U1]
```

If the **verification_priority** attribute is specified on a module object, cells using that module are not ungrouped. In this example, all instances of ADDER in the current module are not ungrouped:

```
prompt> set_verification_priority [get_module ADDER]
```

SEE ALSO

compile(2)
remove_verification_priority(2)

set_via_def

Set via def of input vias.

SYNTAX

collection **set_via_def**
[-vias *via_list* | -cells *cell_list*]
[-via_def *via definition*
[-pitch {*horizontal vertical*}]
[-size {*rows columns*}]

Data Types

via_list	collection
cell_list	collection
via definition	string
orientation	string
horizontal	float
vertical	float
rows	integer
columns	integer

ARGUMENTS

-vias *via_list*

Specifies a list of vias to update via definition. This list may contain via collections specified using the get_vias command.

This argument is mutually exclusive with *-cells*.

-cells *cell_list*

Specifies a list of cells to update via definition. This argument only applies to through-silicon via ("TSV") cells, which may be associated with via_defs of type "through_silicon_via_def". TSV cells are identified by their *is_tsv* attribute being true. If any non-TSV cells are specified in this argument, they will be ignored and a warning message issued.

This argument is mutually exclusive with *-vias*.

-via_def *via definition*

Specifies the via definition.

-pitch {*horizontal vertical*}

Specifies the horizontal and vertical pitch values between cuts of a simple array via. The values must be non-negative.

-size {*rows columns*}

Specifies the number of rows and columns (i.e., cut array size) in a simple array via. The values must be 1 or greater. When not specified, the default cut array size is 1x1. When the size is 1x1, simple array via is to change into a simple via.

DESCRIPTION

This command changes via definition of input vias or through-silicon ("TSV") cells.

This command can be used to update simple vias', simple array vias', or custom vias' via definitions. By changing via def and/or size/pitch, a new via with different via definition type might be created. For example, changing via def of a simple via to a custom via def will create a custom via. No custom array via will be created.

This command can also be used to specify the via_def to be associated with TSV cells, which are identified by their *is_tsv* attribute being true. TSV cells may be associated with via_defs of type "through_silicon_via_def", which can be set using this command. TSV cells may also be set to reference user-specifed designs (using the *set_reference* command) with design type "tsv", which is mutually exclusive to referencing a via_def.

EXAMPLES

The following example changes simple via 'VIA_S_1' into a simple array via with via definition 'VIA12'.

```
prompt> set_via_def -vias [get_vias VIA_S_1] -via_def VIA12 -pitch {0.8 0.6} -size {2 18}
```

SEE ALSO

get_vias(2)

set_via_ladder_candidate

Sets via ladder candidates for the specified library-pin.

SYNTAX

status **set_via_ladder_candidate**
lib_pin
-ladder_name via_ladder_name

Data Types

lib_pin pin name or collection
via_ladder_name string

ARGUMENTS

lib_pin

Specifies the library-pin for which via ladder candidate will be set.

-ladder_name *via_ladder_name*

Specifies the via ladder template name present in technology file.

DESCRIPTION

This command sets the via ladder name as via ladder candidate for specified library-pin. This command is additive and should be called once per pair of via ladder candidate and library-pin combination. Each invocation adds another candidate for the specified library-pin. This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following example set the via ladder candidate for the library-pin.

```
prompt> set_via_ladder_candidate [get_lib_pin tcbn90ghvt/AN2HVTD0/A1] -ladder_name "VL1"
1
```

The following examples add via ladder candidates for the same library-pin.

```
prompt> set_via_ladder_candidate [get_lib_pin tcbn90ghvt/AN2HVTD0/A1] -ladder_name "VL2"
1
prompt> set_via_ladder_candidate [get_lib_pin tcbn90ghvt/AN2HVTD0/A1] -ladder_name "VL3"
1
```

SEE ALSO

set_via_ladder_constraints

Sets via ladder constraints for specified pins.

SYNTAX

status **set_via_ladder_constraints**
-pins *pins*
via_ladder_list

Data Types

pins	pin names or collection
via_ladder_list	string

ARGUMENTS

-pins *pins*

Specifies pins for which via ladder constraints will be set. Pins must have block context and should belong to current block.

via_ladder_list

Specifies space-separated ordered-list of via ladder template names present in technology file.

DESCRIPTION

This command sets the list of via ladder names as via ladder constraints for specified pins. If invalid via ladder name is specified, error message is printing out with list of valid template names present in technology file. Constraints set with this command will be read by Zroute to insert via ladders in pins before routing. From the ordered list, first appropriate via ladder will be inserted in the pin.

This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following examples set the specified constraints for the pins

```
prompt> set_via_ladder_constraints -pins "u1/i1 u2/i2" "VL1 VL2 VL3"
1

prompt> set_via_ladder_constraints -pins [get_pins u2/i3] "VL2 VL3"
1
```

SEE ALSO

report_via_ladder_candidates(2)
report_via_ladder_constraints(2)
reset_via_ladder_candidates(2)
set_via_ladder_candidate(2)

set_via_ladder_rules

Sets via ladder rules for the block.

SYNTAX

status **set_via_ladder_rules**
-master_pin_map *masterpin_ladders_list*
-master_pin_map_file *file*
-default_ladders *via_ladders_list*
-all_instances_of *cell_master_pin_list*
-all_clock_outputs true | false
-all_clock_inputs true | false
-all_pins_driving *port_list*
-remove_all_rules

Data Types

masterpin_ladders_list string
file string
via_ladder_list string
cell_master_pin_list string
port_list collection

ARGUMENTS

-master_pin_map *masterpin_ladders_list*

Specifies what type of ladder(s) should be used on an instance of given cell_master/pin if it is to get a ladder. Format of masterpin_ladders_list is {{cell_master/pin {via_ladder_list}}...}. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a warning.

-master_pin_map_file *file*

Specifies file name to provide entries for -master_pin_map option. Format of file entry is same as needed in option -master_pin_map. master_pin_map entries can be provided with both the options together. In case of clash, entry in file will be given priority. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a warning.

-default_ladders *via_ladders_list*

Specifies what ladder to use if a cell/pin requires a ladder based on a rule, but it is not defined in the master_pin_map list. Format of via_ladders_list is {VL1 VL2 ...}.

-all_instances_of *cell_master_pin_list*

Specifies that anytime an instance of this cell master/pin is used, a ladder is to be created automatically. Format of cell_master_pin_list is {cell_master1/pin1 cell_master2/pin2 ...}. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a warning.

-all_clock_outputs true | false

Specifies that all output pins on clock nets get a ladder. Default values is false.

-all_clock_inputs true | false

Specifies that all input pins on clock nets get a ladder. Default values is false.

-all_pins_driving *port_list*

Specifies that all pins driving one of the ports in the collection gets a ladder.

-remove_all_rules

If this option is specified, all the rules will be removed.

DESCRIPTION

This command sets via ladder rules for the block. These rules will be used by zroute to automatically update via ladders as the design changes. Instance/pin specifications set with via ladders constraints commands will remain, and can/should still be used for fixed/non-changing cells. These rules are more valuable for dynamically changing cells. If both an instance specific constraint and a rule exist, the instance constraint should apply.

This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following examples set the specified constraints for the pins

```
prompt> set_via_ladder_rules -all_pins_driving [get_ports Clk] \
  -all_instances_of {mRegister/Ck mAlu/PC[30]}
1
```

set_via_ladder_spacing

Specify the placement spacing constraints to accommodate via ladders among a collection of instances or library cells.

SYNTAX

status **set_via_ladder_spacing**
-cells *cell_list*
-lib_cells *lib_cell_list*
-distance *margin_spec*

Data Types

cell_list collection of cell instances
lib_cell_list collection of library cells
margin_spec list

ARGUMENTS

-cells *cell_list*

Specifies a collection of cell instances on which to apply this spacing constraint.

-lib_cells *lib_cell_list*

Specifies the collection of library cells on which to apply this spacing constraint.

-side *margin_spec*

Specifies the spacing requirement in horizontal and vertical dimension in um. Use the following syntax to specify the margins:

{*distance_x distance_y*}

DESCRIPTION

This command adds placement constraint on a collection of library cells or instances which prevent other cells with any such constraint (which can be of different dimension) to be placed within the distance specified by the argument to this command. This rule is satisfied while searching for legal placement.

EXAMPLES

The following example puts via ladder spacing constraint on a collection of 3 instances requiring no other via ladder spacing constrained cell to be placed within 0.3um in horizontal and 0.4um in vertical dimensions.

```
prompt> set_via_ladder_spacing -cells [ get_cells {U1/A U2/D XYZ} ] -distance {0.3 0.4}
```

SEE ALSO

legalize_placement(2)

set_view_switch_list

Sets the value of the switch list for the specified design, library, or global view.

SYNTAX

status **set_view_switch_list**
[-design *design* | -library *library* | -global]
views

Data Types

design	string
library	string
views	list

ARGUMENTS

-design *design*

Specifies the design for which to set the view switch list. This option is mutually exclusive with the **-library** and **-global** options.

-library *library*

Specifies the library for which to set the view switch list. This option is mutually exclusive with the **-design** and **-global** options.

-global

Sets the global, session-wide view switch list. This option is mutually exclusive with the **-design** and **-library** options.

views

Sets the value for the specified entity's view switch list. Specify *views* as a space-delimited list of view names, enclosed within curly brackets. Note that view switch lists are order dependent. Specifying an empty view switch list value clears the view switch list setting on the entity, and the view switch list value becomes the owning library's view switch list if the entity is a design, or the global view switch list if the entity is a library.

DESCRIPTION

This command sets the view switch list of a design, library, or global session.

The view switch list is a precedence-ordered list of design views that is applied when binding a design. If a design has its view switch list explicitly set, then that view switch list is used. If not, then the design's owning library's view switch list is used. If the

owning library does not have a view switch list explicitly set, then the global view switch list is used. The view switch list attribute is persistent for designs and libraries, but not for the global session.

It is an error to specify more than one of the **-global**, **-library**, or **-design** options. If none of these options are specified, the command sets the global view switch list. Use "{}" to specify an empty view switch list. Setting an entity's view switch list to the empty value clears its view switch list setting, resulting in no explicitly set view switch list on the entity. In that case, its effective view switch list becomes that of its owning entity.

EXAMPLES

The following example sets the view switch list of design "mydesign":

prompt> **set_view_switch_list -design mydesign {abstract outline}**

The following example clears the view switch list of design "mydesign":

prompt> **set_view_switch_list -design mydesign {}**

The following example sets the view switch list of library "mylib":

prompt> **set_view_switch_list -library mylib {frame abstract design}**

Each of the following examples have the same effect of setting the global view switch list:

prompt> **set_view_switch_list {design frame abstract outline}**

prompt> **set_view_switch_list -global {design frame abstract outline}**

SEE ALSO

get_view_switch_list(2)
change_view(2)

set_virtual_pad

Creates a virtual power or ground pad as a voltage source for power network analysis.

SYNTAX

status **set_virtual_pad**
-net *net*
-coordinate {*x y*}
[-layer *layer_name*]

Data Types

net collection
x float
y float
layer_name collection

ARGUMENTS

-net *net*

Specifies the net to which to add the power tap. This is a required option.

-coordinate *coordinate*

Specifies the coordinate of the virtual pad. This is a required option.

-layer *layer_name*

Specifies the layer name on which to create the virtual pad.

DESCRIPTION

This command creates a virtual pad for power network analysis.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example adds a virtual pad.

```
prompt> set_virtual_pad -net VDD -coordinate {1033.275 1860.740}
```

The following example adds a virtual pad on the M6 layer.

```
prompt> set_virtual_pad -net VDD -coordinate {1035.000 1890.850} -layer M6
```

SEE ALSO

remove_virtual_pads(2)
report_virtual_pads(2)
write_virtual_pad_file(2)

set_voltage

Applies an operating voltage to a list of supply nets, supply ports, cells or ports, or to the current design.

SYNTAX

status **set_voltage**
max_voltage
[-min *min_voltage*]
[-dynamic *dynamic_voltage*]
[-min_dynamic *min_dynamic_voltage*]
[-corners *corner_list*]
[-object_list *objects*]
[-cell *cell*]
[-pg_pin_name *pg_pin*]

Data Types

max_voltage float
min_voltage float
dynamic_voltage float
min_dynamic_voltage float
corner_list collection
objects collection
cell string
pg_pin string

ARGUMENTS

max_voltage

Specifies the operating voltage for the maximum delay (slowest) case. This is typically a smaller voltage value. If the **-min** option is not given, this value will also be used for the minimum delay (fastest) case.

-min *min_voltage*

Specifies the operating voltage for the minimum delay (fastest) case. This is typically a larger voltage value.

-dynamic *dynamic_voltage*

Specifies the dynamic voltage for the maximum delay case. The dynamic portion is considered during pessimism removal. The dynamic component of voltage is provided as a negative value in this case. The static voltage is determined by subtracting the dynamic component from the regular voltage

-min_dynamic *min_dynamic_voltage*

Specifies the dynamic voltage for the minimum delay case.

-corners ***corner_list***

Specifies the corners that will use the given voltages. If this option is not given, the current corner will be used.

-object_list ***supply_objects***

Specifies the supply nets, supply ports, cells, or ports that have the operating voltages specified in this command. If this option is not given, the voltages will be applied to the top level of the current design.

-cell ***cell***

This option exists only for script compatibility, and is ignored.

-pg_pin_name ***pg_pin***

This option exists only for script compatibility, and is ignored.

DESCRIPTION

Defines the operating voltage on the supply nets and their corresponding power nets so that the parts of the design powered by these supply nets or power nets are timed and optimized at the specified voltage. If a voltage is set on a supply net that is part of a connected supply net network, the voltage value will be propagated over the entire network.

Primary voltages may also be set on individual cells or ports, or on the top level of the design. However, the preferred methodology is to assign voltages to the supply nets.

If you do not specify an operating voltage for a supply net, the part of the design connected by this supply net continues to be timed and optimized based on the available operating condition settings.

To see the operating voltages of the supply nets, use the **report_supply_nets** command.

To see the operating voltages of the power pins of a particular cell, use the **report_cells -power** command.

The operating voltage of a power net, once defined, can only be overridden with another **set_voltage** command. It can also be cleared by using the **reset_design** command.

Do not forget that the min (BC) voltage is typically *larger* than the max (WC) voltage!

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

The following example sets max (worst-case) and min (best-case) voltage values of 1.05 and 1.2 on the supply net VDD1, for the corner corner3:

prompt> **set_voltage 1.05 -min 1.2 -corner corner3 -object_list [get_supply_net VDD1]**

The following example sets the max and min top-level default primary voltage to 1.05 volts for the current corner. This value will be used for any cells that are not powered by supply nets.

```
prompt> set_voltage 1.05
```

SEE ALSO

connect_supply_net(2)

report_supply_nets(2)
set_domain_supply_net(2)

set_voltage_area

Updates a voltage_area in the current design.

SYNTAX

int **set_voltage_area**
[-add_power_domains *domain_list*]
[-remove_power_domains *domain_list*]
[-power supply_net]
[-ground supply_net]
[-nwell supply_net]
[-pwell supply_net]
[-add_cells cell_list]
[-remove_cells cell_list]
[-remove_all_cells]
[-is_fixed]
[-merge_regions]
[-name voltage_area_name]
voltage_area_object

Data Types

domain_list name or collection of one or more power_domain objects
supply_net name or collection of a single supply net object
cell_list name or collection of one or more cell objects.
voltage_area_name string
voltage_area_object name or collection of a single voltage_area object.

ARGUMENTS

-add_power_domains *domain_list*

Specifies a list of power domains to be added to this voltage_area. All power domains must be associated with the current design and have the same primary supply net. If a power domain already associated with this voltage_area is specified, it is a no-op and a warning message is printed.

-remove_power_domains *domain_list*

Specifies a list of power domains to be removed from this voltage_area. It is an error if the power domain(s) aren't associated with this voltage_area. If the voltage_area contains explicitly associated cells that belong to the power domains to be removed, the voltage_area becomes invalid. When the last power domain is removed, the use_power_domain_cells attribute is reset to false.

-power

Specifies the power supply net for voltage_area. The net must match one of the available power supply nets on the power

domains. Note that you can only use this option on gas-station type voltage_area.

-ground

Specifies the ground supply net for the voltage_area. The net must match one of the available ground supply nets on the power domains. Note that you can only use this option on gas-station type voltage_area.

-nwell

Specifies the nwell supply net for voltage_area. The net must match one of the available power supply nets on the power domains. Note that you can only use this option on gas-station type voltage_area.

-pwell

Specifies the pwell supply net for voltage_area. The net must match one of the available ground supply nets on the power domains. Note that you can only use this option on gas-station type voltage_area.

-add_cells

Specifies a list of cells to be added to the voltage_area. This option can only be used on gas-station type voltage_area. All cells must be at the same physical hierarchy as the current design, and belong to one of voltage_area's associated power domains. Cells can be physical (leaf) or hierarchical. When specifying hierarchical cells, the cells will be expanded into a set of physical cells that reside under them. If cells are later added or removed from this hierarchical cell, the cell membership in the voltage_area is not automatically updated. Note that one hierarchical cell can expand into multiple physical cells. In (the unlikely) case that the hierarchical cell is purely logical (when it corresponds to a local module that has no physical representation), the cell will map to an empty set of physical cells, and a warning message will be printed. The specified cells cannot already be explicitly or implicitly associated with another voltage_area. When used with the -add_power_domains option, the specified cells must also belong to one of the power domains. If any of the power domains already have an associated voltage_area with implicit cell membership (whose use_power_domain_cells attribute is true) created, the cells will be excluded from the implicit cell list. This is important for ensuring that each cell can associate with only one voltage_area.

-remove_cells

Specifies a list of cells to be removed from the voltage_area. All cells must be already explicitly associated with the voltage_area, not merely implicitly associated with the voltage_area via the -use_power_domain_cells option, or it will be an error. Note that this option can be used along with the -user_power_domain_cells option to remove all explicitly associated cells first, and then creates an implicit cell association using the cell memberships from the associated power domains.

-remove_all_cells

Removes all explicitly added cells from this voltage_area.This option is exclusive with the -remove_cells and -add_cells option. If the voltage_area does not have any explicitly associated cells, this option does nothing, and a warning message will be printed.

-is_fixed

Specifies if the voltage_area is at a fixed location. When using this option, the voltage_area must have at least one shape, or it is an error.

-merge_regions

Merge all abutted and overlapping shapes within this voltage_area into a minimum set of disjoint shapes. The merged shape in each resulting disjoint shape is assigned to the shape with the highest stacking order within the group. The rest of the lower stacking order shapes are removed. This option is only valid when there are at least two shapes in the voltage_area. Note that if a shape has explicit cell assignment, that shape will remain discrete and it will not be merged with other shapes in the same voltage_area even if they touch or overlap. For the same reason, this option cannot be used with the -cells option.

-name

Changes the name of the voltage_area. The name cannot conflict with any existing voltage_areas in this design. Note that the name "DEFAULT_VA" is reserved for the auto-generated default voltage_area, and cannot be used.

DESCRIPTION

This command can update the parameters of a voltage_area. You can add or remove cells (if they are being explicitly specified). You can change the power, ground, and isolation power and ground supply nets. You can specify whether or not the voltage_area is fixed. You can specify or update whether or not the voltage_area is fixed. Finally, you can change the name of the voltage_area.

EXAMPLES

The following example adds a cell "uMid1" to the voltage_area VA1:

prompt> **set_voltage_area VA1 -add_cells uMid1 1**

The following example update the voltage_area to add additional power domains

prompt> **set_voltage_area -add_power_domains {INST1} VA1** 1

prompt> **set_voltage_area -add_power_domains {INST2 INST3} VA2** 1

SEE ALSO

get_voltage_area_shapes(2)

set_voltage_area_shape

Updates a voltage_area shape

SYNTAX

collection **set_voltage_area_shape**
[-add_cells *cell_list*]
[-remove_cells *cell_list*]
[-remove_all_cells]
[-lower | -raise |
-top | -bottom |
-above *voltage_area_shape* | -below *voltage_area_shape*]
voltage_area_shape_object

Data Types

cell_list string or collection
voltage_area_shape string or collection
voltage_area_shape_object string or collection

ARGUMENTS

-add_cells *cell_list*

Specifies a list of cells to be added to this voltage_area shape. All cells must be at the same physical hierarchy as the current design. Cells can be physical (leaf) or hierarchical. When a hierarchical cell is specified, the cells will be expanded into a set of physical cells that reside under them. If cells are later added or removed from this hierarchical cell, the cell membership of the voltage_area shape is not automatically updated. Note that one hierarchical cell can expand into multiple physical cells. In (the unlikely) case that the hierarchical cell is purely logical (when it instantiates to a local module that has no physical representation), the cell will map to an empty set of physical cells, and a warning message will be printed. The specified cells cannot already be explicitly or implicitly associated with another voltage_area or explicitly associated with another voltage_area shape of this same voltage_area.

-remove_cells *cell_list*

Specifies a list of cells to be removed from this voltage_area shape. All cells must be already explicitly associated with this shape, or it will be an error.

-remove_all_cells

Removes all cells from this voltage_area shape. This option is mutually exclusive with the **-remove_cells** and **-add_cells** options. If the voltage_area shape does not have any explicitly associated cells, this option does nothing, and a warning message will be printed.

-lower

Places the voltage_area shape one position lower in the voltage_area shape stack.

-raise

Places the voltage_area shape one position higher in the voltage_area shape stack.

-top

Places the voltage_area shape to the top of the voltage_area shape stack.

-bottom

Places the voltage_area shape to the bottom of the voltage_area shape stack, right above the first shape of the default voltage_area.

-above *voltage_area_shape*

Places the voltage_area shape above the given *voltage_area_shape*.

-below *voltage_area_shape*

Places the voltage_area shape below the given *voltage_area_shape*.

DESCRIPTION

The **set_voltage_area_shape** command updates the parameters of a voltage_area shape. You can add or remove cells (if they are being explicitly specified in the owning voltage_area). You can also raise or lower a voltage_area shape in the shape position stack with the **-raise** and **-lower** options, or bring the voltage_area shape to the top (**-top**) or push it to the bottom (**-bottom**) of the position stack. You can also position it below (**-below**) or above (**-above**) another voltage_area shape in the same design.

The command returns a collection of newly created voltage_area_shape if the command succeeded. Otherwise, the command returns "" if it failed, or TCL_ERROR if there was a command syntax error.

The **-top**, **-bottom**, **-above**, and **-below** options are mutually exclusive. It is a syntax error to specify more than one of these options at a time. It is an error to place a shape above or below a shape from a different design.

EXAMPLES

The following example adds a cell to the voltage_area shape:

```
prompt> set_voltage_area_shape -add_cells {uMid1} VOLTAGE_AREA_SHAPE_1
1
```

This example moves a voltage_area_shape one position up.

```
prompt> set_voltage_area_shape -raise VOLTAGE_AREA_SHAPE_1
1
```

This example moves a voltage_area_shape one position down.

```
prompt> set_voltage_area_shape -lower VOLTAGE_AREA_SHAPE_1
1
```

This example brings the voltage_area_shape to the top of the shape stack.

```
prompt> set_voltage_area_shape -top VOLTAGE_AREA_SHAPE_1
1
```

This example moves the VOLTAGE_AREA_SHAPE_2 below VOLTAGE_AREA_SHAPE_1

```
prompt> set_voltage_area_shape -below VOLTAGE_AREA_SHAPE_1 VOLTAGE_AREA_SHAPE_2
1
```

SEE ALSO

set_vsdc

Generates a setup information file in VSDC format for efficient compare point matching in formal verification tools.

SYNTAX

boolean **set_vsdc**
[file_name]
[-append]
[-replace]
[-off]

Data Types

file_name string

ARGUMENTS

file_name

Specifies the file name that the tool should use for recording VSDC setup information. If this command is not issued, the VSDC file is not created. The path can be absolute or relative to the tool's current working directory. If the file exists, an error will result unless *-append* or *-replace* is specified. You must specify the file name unless *-off* is specified.

-append

Append the setup information to an existing file instead of creating a new one. If another VSDC file is already open, it is closed before opening the specified file. If the specified file does not exist, this option is ignored.

-replace

Overwrite the specified file, if it exists, with the new one.

-off

Close the VSDC file and stop recording setup information. No other options can be combined with *-off*.

DESCRIPTION

This command causes the tool to start recording setup information for formal verification tools. (If you are using Formality, the Synopsys formal verification product, you should use the **set_svf** command, instead.) The VSDC file that is produced can be used by some verification tools during the matching step to facilitate the alignment of compare points.

The VSDC file is a series of Tcl commands stored in plain-text format.

The VSDC file is used to account for changes to the hierarchy or to netlist object names that occur during synthesis. Certain operations performed by the compile command perform transformations that are also recorded in the VSDC file.

Because the VSDC output is buffered internally, the file might not be complete until recording is stopped. You can stop recording by running **set_vsdc** *-off* or by exiting from the tool. Running **set_vsdc** with a new file name will write out and close the original VSDC file before starting the new one.

This command returns a Boolean value indicating whether **set_vsdc** succeeded (true) or not (false).

EXAMPLES

In this example, we query the name of the VSDC file and find out that it has not been opened yet. Then we specify the file name and repeat the query.

```
prompt> get_vsdc
VSDC guidance is not enabled.
1
prompt> set_vsdc cache_ctrl.vsdc
1
prompt> get_vsdc
The current VSDC file is /project/chip/cache_ctrl/cache_ctrl.vsdc.
1
```

Formality User Guide

set_vt_filler_rule

Specifies which filler cells should be inserted by the **create_vtcell_fillers** command depending on the cells on the left and right of the gap being filled.

SYNTAX

status **set_vt_filler_rule**
-filler_cells *lib_cells*
-vt_type {*vt_type1 vt_type2*}
[-quiet]

Data Types

lib_cells	collection
vt_type1	string
vt_type2	string

ARGUMENTS

-lib_cells *lib_cells*

Specifies the list of filler cells to be used between the specified vt_types. When the **create_vtcell_fillers** command is issued the tool adds the filler cells in the order that you specify. Filler cells must be specified from the largest to smallest.

-vt_type {*vt_type1 vt_type2*}

Specifies the vt_types to insert cells between. The cells specified with the **-filler_cells** option will be inserted when the **create_vtcell_fillers** command is called. The string default is a keyword and is used to designate cells that have no vt_type assigned.

-quiet

Reduces the information written out by the command. When you specify this option, the command prints minimal information about the current VT settings.

DESCRIPTION

This command specifies which filler cells should be inserted by the **create_vtcell_fillers** command depending on the cells on the left and right of the gap being filled.

EXAMPLES

The following example shows how specify inserted A type filler cells between gaps that are bordered by vtA type cells.

```
prompt> set_vt_filler_rule \
  -filler_cells {myLib/filler2x  myLib/filler1x} \
  -vt_type { default default }

prompt> set_vt_filler_rule \
  -filler_cells {myLib/fillerA2x  myLib/fillerA1x} \
  -vt_type { vtA vtA }
```

create_stdcell_fillers(2)

set_working_design

Sets the current working design.

SYNTAX

status **set_working_design**
-push *cell*
| -pop
[-level *level*]

Data Types

cell collection of one cell
level integer >= 0

ARGUMENTS

-push *cell*

Specifies a cell whose referenced design is pushed onto the stack. You can specify the cell by using either a cell name or a collection that contains one cell object.

This option is mutually exclusive with the **-pop** option. You must use one of them.

-pop

Pops the current working design out of the stack.

This option is mutually exclusive with the **-push** option. You must use one of them.

-level *cell*

Level to pop design stack.

This option works only with the **-pop** option.

DESCRIPTION

This command sets the working design by using a push or pop operation.

The command returns a status value that indicates success or failure.

When you run the **set_working_design** command, the tool maintains a stack of working designs. You can use the

get_working_design_stack command to check this stack and use the **set_working_design_stack** command to switch between different stacks.

The **current_design** command can also set the working design stack. However, it clears the destination stack. For more information, see the **current_design** man page.

When pushing to a child design, this command implicitly opens the child design if it is not yet opened. If you specify a soft macro cell, the open mode is edit if library is opened in edit mode. Otherwise, the open mode is read.

After you finish editing the child design, you can run the **set_working_design -pop** command to pop the child design from the stack and return to its parent design. The changes to the child design are automatically reflected in its ancestor designs.

EXAMPLES

The following example sets the current working design to a child design, BLENDER_2, which is instantiated by the I_ORCA_TOP/I_BLENDER_4 soft macro cell. After performing some operations, the example pops the child design from the stack and returns to the parent design, ORCA.

```
prompt> set_working_design -push I_ORCA_TOP/I_BLENDER_4
1
prompt> current_design
{BLENDER_2}
(some operations performed ...)
prompt> set_working_design -pop
1
prompt> current_design
{ORCA}
```

SEE ALSO

close_blocks(2)
current_design(2)
get_working_design_stack(2)
set_working_design_stack(2)
save_block(2)

set_working_design_stack

Sets the current working design stack.

SYNTAX

collection **set_working_design_stack**
design

Data Types

design collection

ARGUMENTS

design

Specifies the design whose stack is set as the current design stack. You can specify the design by name, name pattern, or a collection. If you specify a collection, the collection must contain only one design.

This is a required argument.

DESCRIPTION

This command sets the current working design stack by specifying a top-level design. The command returns a collection that contains the current working design stack.

The current working design is set to the top of target stack, which is the latest design pushed onto that stack. If the stack contains more than one design, the current working design is not the top-level design.

See the **current_design** man page for information about how to switch to the target top-level design and clear the stack.

EXAMPLES

The following example shows that the **set_working_design_stack** command sets the working design stack without clearing it.

```
prompt> current_design
{TOP}
prompt> set_working_design_stack ORCA
```

```
{ORCA BLENDER_2}
prompt> current_design
{BLENDER_2}
```

SEE ALSO

set_working_design(2)
get_working_design_stack(2)
current_design(2)

set_wrapper_configuration

Sets the default wrapper configuration for the design.

SYNTAX

status **set_wrapper_configuration**
[-reuse_threshold **threshold_value**]
[-chain_count **integer**]
[-test_mode *mode_name*]
[-hier_wrapping enable | disable]
[-mix_cells true | false]
[-mix_with_scan_cells true | false]
[-add_wrapper_cells_to_power_domains enable | disable]
[-use_system_clock_for_dedicated_wrp_cells enable | disable]
[-depth_threshold *threshold_value*]
[-gate_cells none | existing_cg | all]
[-feedthrough_chains disable | enable]
[-input_wrapper_cells *cell_list*]
[-output_wrapper_cells *cell_list*]
[-hold_mux_for_shared_wrapper_cells enable | disable]
[-safe_state 0 | 1 | none]

Data Types

threshold_value integer
mode_name string
cell_list string

ARGUMENTS

-reuse_threshold *threshold_value*

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells.

When the number of I/O registers detected for a port exceeds the specified threshold value, a dedicated wrapper cell is added to the port.

The default value is 0.

If the option is set to 0, tool will use the maximized reuse flow and all I/O registers associated with a port are reused as shared wrapper cells.

If the option is set to -1, tool will use dedicated wrapper flow for all the ports in the design.

-chain_count *chain_count*

Specifies the maximum number of wrp_of chains.

When you do not use the **-chain_count** option, the number of wrp_of chains are determined by the lowest value of either -inputs or -outputs option of set_scan_compression_configuration command.

-test_mode ***mode_name***

Specifies the test mode to which the specification applies.

Only the following options can be specified with this option when the value of the option is not **all**:

-chain_count
-mix_cells

The values of all other options are taken from the wrapper configuration specification for the **all** mode.

The default is **all** (the specification applies to all modes).

-hier_wrapping enable | **disable**

Enables or disables hierarchical wrapping.

Hierarchical wrapping is supported only when there is only one scan mode synthesized in DFT insertion.

When hierarchical wrapping is enabled, the following core wrapping functionality is used:

All input wrapper cells are stitched into one or more input wrapper chains, controlled by an input shift-enable signal.

All output wrapper cells are stitched into one or more output wrapper chains, controlled by an output shift-enable signal.

Separate input and output control signals are used for the following wrapper control signal types:

- Wrapper shift signal
- Wrapper capture signal (if the input or output wrapper chains include a dedicated wrapper cell)
- SAFE mode enable signal (if the input or output wrapper chains include a wrapper cell that drives a SAFE value)

There is no wrapper mode logic added to the design.

The default is **disable**.

-mix_cells true | **false**

Specifies if wrapper cells for input or output ports can be mixed in a wrapper chain.

If this option is set to **false**, all wrapper cells in a wrapper chain are either associated with input ports or output ports but not both.

If this option is set to **true**, input and output wrapper cells can be mixed in the same wrapper chain.

The default is **false**.

-mix_with_scan_cells true | **false**

Controls whether scan cells can be mixed with wrapper cells on the same scan chain.

-add_wrapper_cells_to_power_domains enable | **disable**

Enables or disables the addition of dedicated wrapper cells to associated power domain hierarchies.

This option has no effect if there are no power domains in the design or no dedicated wrapper cells are added during wrapper insertion.

When this option is enabled, the tool identifies the hierarchy in which a dedicated wrapper cell is added by using the following

method.

If the port of the dedicated wrapper cell is connected to an I/O register, the top-level hierarchy of the power domain of the I/O register is used as the location for the dedicated wrapper cell.

If no I/O register is found for the port of the dedicated wrapper cell, the tool checks if the port is connected to a CTL modeled instance. If so, the top-level hierarchy of the power domain of the CTL modeled instance is used as the location for the dedicated wrapper cell.

If neither I/O register nor CTL modeled instance is found to be connected to the port of the dedicated wrapper cell, the top-level hierarchy of the first connected gate is used as the location for the dedicated wrapper cell.

If the I/O register or CTL modeled instance or the gate connected to the port of the dedicated wrapper cell does not have a power domain, the dedicated wrapper cell is added to the top-level hierarchy.

When this option is enabled, no additional hierarchy is created for dedicated wrapper cells added to the design.

When this option is enabled, any user-specified wrapper logic location (**set_dft_location ...**) is ignored.

The default is **disable** so that dedicated wrapper cells are added to the user-specified wrapper logic location if specified (**set_dft_location ...**) or to the top-level hierarchy.

-use_system_clock_for_dedicated_wrp_cells enable | disable

Controls whether the tool uses the system clock of I/O registers of the port as the clock for the dedicated wrapper cell.

When a dedicated wrapper cell is added to a port and this option is enabled, the tool uses the system clock of I/O registers of the port as the clock for the dedicated wrapper cell.

If the port is connected to a single I/O register and the tool adds a dedicated wrapper cell to the port, the clock of the associated I/O register is used as the clock for the dedicated wrapper cell.

The default wrapper clock is used for a dedicated wrapper cell if the associated port is not connected to any I/O registers.

The tool issue an error if more than one I/O register is found for a port and all of these I/O registers do not use the same clock domain and you did not specify any clock for the port. The command is terminated in such a case.

If you specify a clock for such a port, the tool treats the error as a warning and uses the specified clock as the clock for the dedicated wrapper cell.

The default is **enable**.

-depth_threshold *threshold_value*

Specifies the maximum combinational depth of I/O registers that can be reused as shared wrapper cells for a port.

The combinational logic depth is defined as the maximum number of combinational logic levels, including buffers and inverters, between a port and an associated I/O register. For a given port, if the combinational logic depth of any associated I/O register exceeds this value, a dedicated wrapper cell is added to the port.

There is no default for this option. When not specified, the check is not performed and all I/O registers associated with a port are reused as shared wrapper cells, subjective to other checks.

-gate_cells none | existing_cg | all

Controls whether clock-gating logic is inserted or modified to reduce power consumption in core wrapping modes.

This feature implements the following behavior for integrated clock-gating cells:

- In EXTEST (outward-facing) modes, clocks to core register cells are disabled.
- In SAFE mode, clocks to both core register cells and wrapper cells are disabled.

When this option is set to **existing_cg**, the tool modifies only existing integrated clock-gating cells. Both the functional and test enable pin connections are modified.

When this option is set to **all**, the tool modifies existing integrated clock-gating cells, and it also inserts integrated clock-gating cells for more aggressive power reduction. (You must set the **dft.test_icg_p_ref_for_dft** application option to specify the rising-edge ICG library cell to insert.)

The default is **none**, which disables the feature.

-feedthrough_chains enable | **disable**

Specifies whether feedthrough chains are created in transparent modes.

When this option is set to **enable, feedthrough chains with dummy registers are created in inward-facing test modes. No extra test mode is required or created to enable the support. This ensures that the core can be integrated in top-level designs that have a top-level codec.**

The default is **disable**, such that feedthrough chains are not created in inward-facing test modes. In this case, you no longer need to use dedicated wrapper-mode scan I/Os for the core's outward-facing modes. The resulting core contains no feedthrough chains, and it can be integrated in top-level designs that do not have a top-level codec.

-input_wrapper_cells ***cell_list***

Specifies additional scan cells to be classified as output-related registers to include in the input wrapper chain. The input is accepted as a simple list. Wildcards and collections are not supported.

This option is not cumulative; new specifications overwrite previous specifications. Specify an empty list to remove a previous specification.

-output_wrapper_cells ***cell_list***

Specifies additional scan cells to be classified as input-related registers to include in the output wrapper chain. The input is accepted as a simple list. Wildcards and collections are not supported.

This option is not cumulative; new specifications overwrite previous specifications. Specify an empty list to remove a previous specification.

-hold_mux_for_shared_wrapper_cells enable | **disable**

Enables or disables a hold MUX for shared wrapper cells.

When a hold MUX is added, shared wrapper cells hold the state when the cell is not in shift mode in test operation.

The default is not to add a hold MUX to shared wrapper cells.

-safe_state 0 | **1** | **none**

Specifies the safe state value to be used for wrapper cells added by core wrapping.

The default is **none**.

DESCRIPTION

This command sets the default wrapper configuration for the design.

EXAMPLES

```
set_wrapper_configuration -reuse_threshold 4 -chain_count 6
```

SEE ALSO

setenv

Sets the value of a system environment variable.

SYNTAX

string **setenv** *variable_name new_value*

string *variable_name*

string *new_value*

ARGUMENTS

variable_name

Names of the system environment variable to set.

new_value

Specifies the new value for the system environment variable.

DESCRIPTION

The **setenv** command sets the specified system environment *variable_name* to the *new_value* within the application. If the variable is not defined in the environment, the environment variable is created. The **setenv** command returns the new value of *variable_name*. To develop scripts that interact with the invoking shell, use **getenv** and **setenv**.

Environment variables are stored in the Tcl array variable **env**. The environment commands **getenv**, **setenv**, and **printenv** are convenience functions to interact with this array.

The **setenv** command sets the value of a variable only within the process of your current application. Child processes initiated from the application using the **exec** command after a usage of **setenv** inherit the new variable value. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the **exec** command, that value is not reflected in the current application.

EXAMPLES

The following example changes the default printer.

```
shell> getenv PRINTER
laser1
shell> setenv PRINTER "laser3"
laser3
shell> getenv PRINTER
laser3
```

SEE ALSO

exec(2)

printenv(2)
printvar(2)
set(2)
sh(2)
unset(2)

setup_performance_via_ladder

Setup for automatic performance via ladder flow. Generate via rules based on the analysis of layers and associate via rules on lib_pins.

SYNTAX

status **setup_performance_via_ladder**
-max_layer layer_name
-lib_pins lib_pin_names
-association_file association_file_name
-rule_file rule_file_name
-effort low|medium|high|ultra
-stack_via none|alone|composite
-reset
-ignore_dont_use
-stagger
-smaller

Data Types

layer_name string
lib_pin_names string or collection of lib_pins
association_file_name string
rule_file_name string

ARGUMENTS

-max_layes *layer_name*

Specifies max_layer of via ladders. This should not be higher layer than the max_layer in the routing rule.

-lip_pins *lib_pin_names*

Specifies lib_pin_names which need performance via ladder candidates.

-association_file *association_file_name*

Specifies output via ladder association file name. (Default: auto_perf_via_ladder_association.tcl)

-rule_file *rule_file_name*

Specifies output via rule file name. (Default: auto_perf_via_ladder_rule.tcl)

-effort *low*|*medium*|*high*|*ultra*

Specifies effort level. Higher effort will generate more via ladder associations to more lib pins. (Default: low)

-stack_via *none*|*alone*|*composite*

Generate stack via rules and association files. (Default: none)

-reset

Reset existing via ladder candidates from lib_pins.

-ignore_dont_use

Allow via_ladder candidates on lib_cells with dont_use attribute.

-stagger

Generate stagger table.

-smaller

Associate smaller via ladders first.

DESCRIPTION

This command sets automatic performance via ladder flow. It generates via rules based on the analysis of layers and associates via rules on each lib_pin. This command returns 1 if succeeded, 0 otherwise.

When -lip_pins option is not used, the tool searches for all lib cells to select the lip pins to associate. It associates max 2 via ladder candidates per pin, by default. You can increase the number of the candidates with -effort option. With the increased effort level, more candidates are associated to more lib cells. With -effort ultra, almost every lib cells will have the candidates.

When -lip_pins option is used, all those lib pins will have the candidates. The effort level will decide the number of candidates per pin.

If a lib cell already have via ladder candidates before running this command, those candidates will be preserved in the association file. If you want to remove existing candidates, use -reset option.

This command associates bigger via ladder candidates first, by default, out of many possible candidates. This may hurt via ladder insert success ratio in congested design where smaller via ladder may be desirable. With -smaller option, the tool associates smaller via ladder candidates first.

This command can generate stack vias. When -stack_via alone option is used, the tool generates stack via rules and association files, where generic via ladder rules are not generated. -effort and -reset option will be ignored in this mode. -stack_via composite will generate stack via rules and association files using both via ladders and stack vias.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following is the usage examples.

```
prompt> setup_performance_via_ladder
1

prompt> setup_performance_via_ladder -effort ultra -reset
1

prompt> setup_performance_via_ladder -effort high -smaller
1

prompt> setup_performance_via_ladder -reset -stack_via alone
1

prompt> setup_performance_via_ladder -reset -stack_via composite -effort ultra
1

prompt> setup_performance_via_ladder -max_layer M10 -lib_pins [get_lib_pins */*D12*/Z]
1
```

SEE ALSO

reset_via_ladder_candidates(2)
report_via_ladder_candidates(2)

sh

Executes a command in a child process.

SYNTAX

string **sh** [*args*]

string *args*

ARGUMENTS

args

Command and arguments that you want to execute in the child process.

DESCRIPTION

This is very similar to the **exec** command. However, file name expansion is performed on the arguments. Remember that quoting and grouping is in terms of Tcl. Arguments which contain spaces will need to be grouped with double quotes or curly braces. Tcl special characters which are being passed to system commands will need to be quoted and/or escaped for Tcl. See the examples below.

EXAMPLES

This example shows how you can remove files with a wildcard.

```
prompt> ls aaa*
aaa1    aaa2    aaa3
prompt> sh rm aaa*
prompt> ls aaa*
Error: aaa*: No such file or directory
    Use error_info for more info. (CMD-013)
```

This example shows how to grep some files for a regular expression which contains spaces and Tcl special characters:

```
prompt> exec cat test3.out
blah blah blah
```

```
blah blah blah c blah
input [1:0] A;
output [2:0] B;
prompt>
prompt> sh egrep -v {[ ]+c[ ]+} test3.out
blah blah blah
prompt>
prompt> sh egrep {t[ ]+\[} test3.out
input [1:0] A;
output [2:0] B;
```

SEE ALSO

exec(2)

shape_blocks

Shapes and places the shaping objects (physical blocks, power domains or voltage areas, and move bounds) with respect to constraints and utilization requirements. If no utilization constraint is set on the shaping object, the design's utilization will be used. The command uses macro packing to place the top-level macros. If the block grid is created for the block before shaping, it will also align the block shape to the specified block grid. If the placement abstracts of blocks have not been created before this command, shape_blocks will automatically create them.

SYNTAX

int **shape_blocks**
[-channels true | false]
[-constraint_file *file_name*]
[-incremental congestion_driven | target_utilization_driven]
[-pg_strategy *pg_strategy_name*]
[-host_options *host_options_name*]

Data Types

file_name string
pg_strategy_name string
host_options_name string

ARGUMENTS

-channels true | false

Specifies whether channels are created between blocks. Channels can be inserted between blocks or between blocks and the core boundary. By default, the option is true and the command inserts channels.

If channels are required, the channel size is automatically calculated based on the required routing resources among hierarchies and the allowed utilization of each physical hierarchy.

You can also specify the required minimal channel size with the **set_shaping_options -min_channel_size** command. The larger value of user-specified channel size and automatically calculated channel size is used to create channels. When **-min_channel_size** is specified, the automatically calculated channel size is based only on the required routing resources, not on the allowed utilization.

-constraint_file *file_name*

Specifies the file that contains user constraints to control the channel sizes, aspect ratio, utilization, fixed shapes, and relative placement. The supported constraint formats are as follows.

- *Constraint types*

The following keywords define shaping constraints:

- block related keywords
- *allowed_orientation*
- *aspect_ratio*
- *utilization*
- *boundary*
- edge related keywords
- *boundary_channel_size*
- *channel_size*
- *guard_band*
- grouping related keywords
- *define_group*
- relative placement related keywords
- *arrange_in_box*
- *arrange_in_array*

Constraints can take parameters, which is illustrated in the following example of defining channels around a block CPU instantiated within block B:

```
block B {
  channel_size {
    // This constraint only applies to sub-block CPU.
    block_inst CPU;

      // Default: any channel surrounding CPU should be 20u wide.
      // Except left and right size of CPU // which are between 30u
      and 50u.  min = 20, max = 20; left, right: min = 30, max = 50;
      } // Other constraints within the scope of block B go here }
```

- *Scoping and grouping rules*

Global constraints applied to any block are defined at the global scope. These constraints do not have an encompassing block scope. The only constraints that can be defined in global scope are: boundary_channel_size, channel_size, guard_band and utilization. For example

```
  utilization { target: 0.3; }
```

specifies a target utilization of 30% for any shapeable region in this design, unless it is overridden by any later constraint.

guard_band and channel_size can also be specified in the global scope. For example

```
  guard_band { width: 2; height: 3; }
  channel_size { size = 5; }
  block TOP {
    // define constraints in block scope
    ......
  }
```

specifies a guard_band for any voltage area of 2u in width and 3u in height. It also specifies the channel size of 5u between any blocks/VAs.

The default guard band size is zero. For non-abutted floorplan (i.e., option **-channels true** is applied), the default channel size is calculated to minimize the channel routing congestion.

The space between two neighboring blocks is sum of the outer keepouts and channel size for the blocks. The space between two neighboring voltage areas is sum of guard band sizes and channel size.

The constraints defined in the global scope can be overwritten by the constraints defined in the block scope, as shown in the following

example.

Constraints applicable to objects within a particular block are defined inside a block scope:

```
block <reference_name> {
   constraint { }
   constraint { }
   ......
}
```

The reference name identifies the block being constrained. The constraints defined within the block scope can only refer to objects visible in the physical block, or to the physical block itself using the keyword current_block. The constraints cannot refer to objects of another physical block.

Constraints specific to a voltage area in a given block are specified using a voltage area scope. For example

```
guard_band { width: 1; height: 1; }
block BLK1 {
   voltage_area VAS1 {
      contents: voltage_area VAS2, block_inst BLK2;

      // VAS1 and nested voltage areas, like VAS2 get 40u guard band
      // even though the global guard band is 1u. This constraint is
      // limited to voltage areas of this block, BLK1.
      guard_band { width: 40; height: 40; }

      ...
   }
   guard_band {
     voltage_area VA1;
     width: 20; height: 20;
   }
}
```

Specifies the following:

- The voltage area VAS2 and block BLK2 are to be shaped inside VAS1
- A guard band of 40u for VAS1 and any voltage area nested inside (but within the current block)
- A guard band of 20u for voltage area VA1
- A guard band of 1u for other voltage areas

You can define new groups of objects like block instances, voltage areas and other groups with the define_group constraint.

```
block BLK1 {
   define_group GRP1 {
      // E, F, MB1, and VA3 make up group GRP1
      contents: block_inst E, block_inst F,
            move_bound MB1,
            voltage_area VA3;

   }

   arrange_in_array {
      // Refers to the group defined above
      contents: group GRP1,
            block_inst J;
      direction: east;
   }
```

```
}
```

Groups cannot have partial overlap, but nesting is allowed. For example, the following constraint specifies that two blocks, E and F, must be arranged from top to bottom, and shaped along VA3:

```
block BLK1 {
   define_group GRP1 {
      contents: block_inst E, block_inst F,
            voltage_area VA3;

      define_group GRP2 {
         contents: block_inst E, block_inst F;
         arrange_in_array {
            contents: block_inst E, block_inst F;
            direction: south;      // from top to bottom
         }
      }
   }
   // GRP1 shadows E, F and VA3. Constraints at this point
   // can refer to GRP1, (not to E, F and VA3) Those have
   // to be defined inside GRP1 or GRP2.
}
```

In the scope where a group is defined, the group will shadow the objects it contains to prevent inadvertent group overlap. In the example above, GRP1 will shadow E, F and VA3.

- *Constraints*

- Boundary channel constraint

The boundary_channel_size constraint reserves a space between a block or voltage area and its nested regions. The boundary_channel_size and channel_size constraints applying to the same channel are combined by taking the maximum of the two. When a boundary_channel_size constraint is defined inside the global scope, it applies to the boundary inside any block or voltage area. Alternatively, the boundary_channel_size is defined within a block scope, and is applied to the current_block or to a voltage area, specifying the boundary channel's size along the inside of that region's boundary. For example,

```
block CPU {
   boundary_channel_size {
     current_block;
     left: min = 3, max = 5;
     right, bottom: min = 5, max = 99;
   }
}
```

specifies that any voltage area or block instance shaped within CPU is to stay at least 3u to 5u from the left side of the boundary, and 5u to 99u from the right and bottom side of the boundary.

- Utilization constraint

Utilization constraints specify a minimum, target or maximum cell utilization of a shapeable region. For example, requesting a 53% target utilization and setting an upper limit of 70% and a lower limit of 40% is achieved by:

```
utilization {
   target: 0.53;
   max: 0.7;
   min: 0.4;
}
```

Utilization of block instances cannot be specified individually, because multiple instantiations (MIB's) must follow the same constraint.

Instead, you define the constraint for the reference design, say X:

```
block X {
   utilization { target: 0.4; }
}
```

A utilization constraint that does not explicitly name any objects will be applied to the shapeable regions in the current scope (limited to the current block). In the next example a 60% utilization target is set for VA1, VA2 and VA3 (as both are part of G2), but not to block_inst B.

```
define_group G2 { contents: voltage_area VA2, voltage_area VA3; }
define_group G1 {
  contents: voltage_area VA1, group G2, block_inst B;
  utilization { target: 0.6; }
}
```

The above is equivalent to:

```
define_group G2 { contents: voltage_area VA2, voltage_area VA3; }
define_group G1 { contents: voltage_area VA1, group G2, block_inst B; }
utilization { group G1; target: 0.6; }
```

- Aspect ratio constraint

The target aspect ratio of a region can be specified for blocks that are placed with an arrange_in_box constraint:

```
  block RESET {
    aspect_ratio {
       current_block;
       target: width = 3, height = 4;
    }
  }
```

- Guard band constraint

Guard band constraints only affect shapeable voltage areas, and control the width and height of their guard bands. If you specify a voltage area, the constraint will apply to that voltage area only (not recursively). If you specify a group, the constraint will apply to the voltage areas of that group (not recursively). In the example below, a guard band of 20 is assigned to VA3 and VA6.

```
  block CPU1 {
    define_group GRP1 { contents: voltage_area VA6, block_inst L; }
    guard_band { voltage_area VA3, group GRP1; width: 20; height: 20; }
  }
```

If you leave out a list of regions, the constraint will be applied recursively to any voltage area within the encompassing scope and current block. If the encompassing scope is a voltage area, it is included as well. The example below, shows how a guard band of 10u is assigned to all the voltage areas within GRP2 and below (within the same block): VA1, VA2, VA4 and VA5. It also shows how nesting between voltage areas and between move bounds.

```
  block CPU1 {
    // define nesting between voltage areas
    voltage_area VA1 {
      contents: voltage_area VA4, voltage_area VA5;
    }
    // define nesting between move bounds
    move_bound mb1 {
     contents: move_bound mb2;
    }
    define GRP2 {
```

```
    contents: voltage_area VA1, voltage_area VA2, block_inst K;
    guard_band { width: 10; height: 10; }
  }
}
```

- Channel size constraint

A channel_size constraint specifies the size of a channel between regions.

```
channel_size {
  // Primary objects.
  block_inst CPU1, block_inst CPU2;

  // Secondary (neighboring) objects.
  neighbors: current_block;

  // Any channel between block (CPU1 or CPU2) and current_block is 10.
  // For the channel along the left, right side of CPU1 (or CPU2) and
  // neighboring the boundary of current_block,
  // limit the size of the channel to [3, 5].
  size=10;
  left, right: min=3, max=5;
}
```

A channel_size constraint contains an object specifier followed by one or more range specifiers. Object specifiers can be:

- empty, the channel size constraint applies to any object in the current scope.
- a single list, specifying primary objects:
- block_inst followed by an identifier
- voltage_area followed by an identifier
- move_bound followed by an identifier
- group followed by an identifier
- current_block identifying the boundary of the encompassing block
- between a primary object and its neighbor: two lists specified similarly as above. Applies to all possible pairs formed by an object from the primary list and an object from the secondary list.

A range specifier is an edge specifier followed by a limit specifier. They can be:

- empty, in which case the channel size constraint applies to any edge.
- side specific: any of left, right, bottom, top to identify the sides of the primary object.

A limit specifier defines the size range of the constrained channel. It can be one of the following three:

- min = <IDENTIFIER> : specifies a minimum size, maximum unconstrained.
- max = <IDENTIFIER> : specifies a maximum size, minimum is bounded by default (0).
- min = <IDENTIFIER>, max = <IDENTIFIER> : limits the minimum and maximum size of this channel.
- size = <IDENTIFIER> : specifies an exact size.

The channel_size constraint specified last overwrites any previously defined channel_size constraints with equal object specifier. A more specific constraint takes precedence over less specific constraints. Channel size constraints defined inside a block scope are more specialized than channel size constraints defined at the global scope. Specialization is next determined by the object specifier, defined to have increasing order of precedence as follows: empty, object list, object list with neighbor list.

- Relative placement constraint

The arrange_in_array and arrange_in_box constraints instruct the shaper to generate a specific region layout.

The arrange_in_array constraint has the contents list and a direction. The shaper places the regions in the contents list in an array following the specified order, growing the array in the specified direction. Valid directions are: north, west, south, east.

```
block B {
  arrange_in_array {
    contents: block_inst A, voltage_area VA1, group G2;
    direction: west;
  }
}
```

In above example, group A, VA1, and G2 are placed right-to-left in a horizontal array. Change the order to left-to-right by setting the direction to east.

The arrange_in_box constraint places the contents at the specific location. Optionally, the arrange_in_box constraint carries an alignment point (default at center). When an alignment point is specified, the shaper tries to align that point with the target location.

```
voltage_area VA1 {
   arrange_in_box {
      block_inst A;
      // Optional alignment point, default is center.
      alignment_point: x = 1, y = 0;
      location: x = 0.5, y = 0.5;
   }
}
```

In above example, block instance A is placed within VA1's shape. A's lower right corner (1, 0) is to be aligned with VA1's center.

In the following example, the shaper first shapes block C (if it does not already have a given shape) and then applies the arrange_in_box constraints in their order of specification. Finally, the arrange_in_array constraints are applied. In the example above, the shaper places A, GRP1 (= D, E, F, G, VA2). This leaves H and X to be shaped into the cavity defined by C minus the area assigned to A and GRP1. The shaper then arranges H on the left of X. The region layout within group GRP1 is also predetermined. A subgroup GRP2 consisting of block instances D and E is defined, and given a center location. The coordinates define a location within the encompassing region's bounding box, here GRP1, and range from (0, 0), the lower left corner, to (1,1), the upper right corner. Again, the arrange_in_box constraint takes precedence over the arrange_in_array constraint. Note that VA2 is left unconstrained. Finally, within group GRP2, the block instances D and E are arranged from top to bottom. This constraint is applied once GRP2 has been assigned a shape.

```
// Block C contains the following regions for shaping: [A, D, E,
// F, G, H, X, VA2]. Blocks D, E, F, G and VA2 should be kept together,
// other blocks can be placed without restriction
block C {

   define_group GRP1 {
   // The following regions make up group GRP1
   // They must be within C's scope.

      contents: block_inst D, block_inst E, block_inst F,
            block_inst G, voltage_area VA2;

      define_group GRP2 {
         arrange_in_array {
           contents:  block_inst D, block_inst E;
           direction: south;
         }
```

```
        }

        // Order is important. First apply the arrange_in_box,
        // then apply the arrange_in_array constraint
        arrange_in_box {
           // Referring to D and E is not allowed here, because
           // they are grouped into GRP2
           group GRP2;
           location: x = 0.5, y = 0.5; // place in the middle
        }

        // Note: this implicitly defines an unnamed group of F and G.
        arrange_in_array {
           contents: block_inst F, block_inst G;
           direction: east;
        }
     }

     arrange_in_box { block_inst A; location: x = 1, y = 0.5; }
     arrange_in_box { group GRP1; location: x = 1, y = 0.5; }
     arrange_in_array {
        contents: block_inst H, block_inst X;
        direction: east;
     }
  }
```

- Boundary constraint

To consider the current boundary of a region as rigid, define the boundary as rigid within that scope, and provide a shape. Rigid regions will still be moved to a suitable location, but their shapes will not be changed.

For example,

```
  voltage_area VA1 {
     // Only move boundary of VA1, do not change shape
     boundary {
        type: rigid;
        shape: {{0 0} {300 600}};
        // or rectilinear shape as follows
        // shape: {{0 0} {{600 0} {600 1100}
        // {300 1100} {300 500} {0 500} {0 0}};
     }
  }
```

- Allowed orientation constraint

With this constraint, the orientation of individual MIB instances can be restricted to a set of allowed orientations. The specified orientations can be R0, R180, MX and MY.

The specified values are expected to be a subset of the allowed orientations of the reference designs of the given block instances. If a reference design has an associated block grid, the allowed orientations follow from that grid. Otherwise, they follow from the design's allowable_orientations attribute.

If the specified set of orientations is not a subset, it will be ignored silently.

Here's an example restricting the orientation of MIB instances B1, B2, B3 and B4.

```
  block Top {
     // Only move boundary of VA1, do not change shape
```

```
    allowed_orientation {
      block_inst B1, block_inst B2;  // MIB block instances being constrained.
      { R0 R180 };                   // Allowed orientations are R0 and R180.
    }
    allowed_orientation {
      block_inst B3, block_inst B4;
      { MY };
    }
  }
```

-incremental congestion_driven | target_utilization_driven

Specifies that congestion-driven or target utilization-driven incremental shaping is applied. By default, neither shaping strategy is used.

If you specify **-incremental congestion_driven**, routing-based congestion information must be available for the incremental shaping to get the initial channel congestion. You must run global routing before using this option. For the congestion driven incremental shaping, all MIBs will not be moved. Only channel congestion between blocks are considered in the incremental shaping.

If you specify **-incremental target_utilization_driven**, the tool incrementally changes the block shapes to achieve the target utilization specified for each block. If no target utilization is specified, the command uses the design utilization as the target for all blocks with respect to the utilization slack specified by **set_shaping_options -utilization_slack**. For the target area driven incremental shaping, option **-channel false** is not supported.

This option and option **-constraint_file** are mutually exclusive. Only one of them can be specified.

-pg_strategy *pg_strategy_name*

Specifies the PG (power-ground) strategy that the **shape_blocks** command should respect so that the shape boundaries are not collinear with PG meshes.

If a mesh pattern, for example my_pattern, is created using **create_pg_mesh_pattern**, the PG strategy named smesh can be created with the following command:

set_pg_strategy smesh -pattern {{name: my_pattern}{nets: VDD VSS}} -core

When you run the **shape_blocks** command as follows and specify the smesh PG strategy:

shape_blocks -pg_strategy {smesh}

the tool creates shapes which are not collinear with the specified PG meshes. You must specify **-core** with the **set_pg_strategy** command for shaping to create the same PG meshes for the whole design.

-host_options

Specifies that the given host option should be used for distributed processing. Note that only creating the appropriate block views (if needed) will use distributed processing in this command.

DESCRIPTION

This command shapes and places physical blocks, power domains or voltage areas, and move bounds with respect to constraints and utilization requirements. The command also applies optimization to minimize feedthrough counts and interface wirelengths. If there is a power domain which has no corresponding voltage area, this command will create its associated voltage area. If the block grid is created for the block before shaping, it will also align the block shape to the specified block grid.

The **set_editability** command can be used to allow or prevent shaping on specific blocks. Use the **set_shaping_options** command to specify additional constraints for shaping, such as minimum channel size, channel blockages, and so on.

The tool automatically infers the nesting of move bound inside voltage area based on the contents such that voltage area gets the higher priority. If the elements of voltage area are top/hier1 and the elements of move bound are top/hier1/hier2, the move bound will be nested inside the voltage area based on the hierarchy tree such that all elements of the voltage area are in the same voltage area region. For this reason, it is not supported that the same element is used to define voltage area and move bound, i.e., both use top/hier1. In case that the contents are really the same, use top/hier1/* to define the elements of move bound.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example creates an abutted floorplan.

```
prompt> shape_blocks -channels false
```

The following example creates a floorplan with channels and also respects the constraints specified in the **user_constraints** file.

```
prompt> shape_blocks -constraint_file user_constraints
```

Example of making manual adjustments to boundaries after automatic block shaping.

```
set_attribute [get_cells BLK1] -name boundary -value {{0 0} {1000 1000}}
set_attribute [get_voltage_area_shapes -of_objects VA2] -name boundary -value {{0 0} {1000 1000}}
set_attribute [get_bound_shapes -of_objects MB3] -name boundary -value {{0 0} {1000 1000}}
```

shell_is_in_cv_mode

Determines if the shell was invoked in concurrent verification mode.

SYNTAX

status **shell_is_in_cv_mode**

ARGUMENTS

The **shell_is_in_cv_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in concurrent verification mode; the shell was launched from cv_shell.

The command returns 1 if the shell is in concurrent verification mode, or a 0 otherwise.

EXAMPLES

The following example shows how to check the mode in which the shell has been invoked:

```
prompt> if { [shell_is_in_cv_mode] } { \
          echo "Running cv_shell" \
          enable_concurrent_verification -run_dir formality
        } else { \
          echo "Not in cv_shell mode" \
        }
```

signoff_calculate_hier_antenna_property

Calculates the hierarchical antenna properties of a hard macro.

SYNTAX

status **signoff_calculate_hier_antenna_property**
-diffusion_layers {*list_of_layers*}
[-top_cell_pin_only true | false]
[-treat_source_drain_as_diodes true | false]
[-report_diodes true | false]
[-poly_layers {*list_of_layers*}]
[-contact_layers {*list_of_layers*} |
[-v0_layers_between_m1_m0 {*list_of_layers*}]
[-m0_layers_for_poly_connection {*list_of_layers*}]
[-m0_layers_for_diffusion_connection {*list_of_layers*}]
[-contact_layers_between_m0_diffusion {*list_of_layers*}]]
[-gate_class1_marking_layers {*list_of_layers*}]
[-gate_class2_marking_layers {*list_of_layers*}]
[-gate_class3_marking_layers {*list_of_layers*}]

Data Types

list_of_layers list

ARGUMENTS

-diffusion_layers {*list_of_layers*}

Specifies the diffusion layers. Specify the layers by using the layer names or layer numbers from the technology file.

This option is required.

-top_cell_pin_only true | false

Controls how hierarchical nets are handled during antenna property extraction.

By default (true), only properties for nets that are connected to pins in the top level of the hard macro are considered.

If this option is set to false, properties for nets that are connected to pins in the child cells contained in the hard macro are also considered.

-treat_source_drain_as_diodes true | false

Controls how the tool treats the MOS source and drain.

By default (true), the MOS source and drain regions are treated as protection diodes and the MOS source and drain regions that

are connected to a net to be a part of the diode protection area available to that net.

If this option is set to false, they are not treated as protection diodes.

-report_diodes true | false

Controls whether or not the tool reports the location of generated protection diodes.

By default (true), the locations will be reported.

If this option is set to false, the locations will not be reported.

-poly_layers {*list_of_layers*}

Specifies the polysilicon layers. Specify the layers by using the layer names or layer numbers from the technology file.

-contact_layers {*list_of_layers*}

Specifies the contact layers (contact layers are the layers that connect polysilicon to metal1). Specify the layers by using the layer names or layer numbers from the technology file.

-v0_layers_between_m1_m0 {*list_of_layers*}

Specifies the v0 layers (v0 layers are the layers that connect metal1 to metal0). Specify the layers by using the layer names or layer numbers from the technology file.

The **-v0_layers_between_m1_m0** and **-contact_layers** options are mutually exclusive; specify only one.

-m0_layers_for_poly_connection *list_of_layers*

Specifies the m0 layers for poly connection. Specify the layers by using the layer names or layer numbers from the technology file.

The **-m0_layers_for_poly_connection** and **-contact_layers** options are mutually exclusive; specify only one.

-m0_layers_for_diffusion_connection *list_of_layers*

Specifies the m0 layers for diffusion connection. Specify the layers by using the layer names or layer numbers from the technology file.

The **-m0_layers_for_diffusion_connection** and **-contact_layers** options are mutually exclusive; specify only one.

-contact_layers_between_m0_diffusion *list_of_layers*

Specifies the contact layers (contact layers are the layers that connect metal0 to diffusion). Specify the layers by using the layer names or layer numbers from the technology file.

The **-contact_layers_between_m0_diffusion** and **-contact_layers** options are mutually exclusive; specify only one.

-gate_class1_marking_layers {*list_of_layers*}

Specifies the marking layers for gate thickness class 1. Specify the layers by using the layer names or layer numbers from the technology file.

-gate_class2_marking_layers {*list_of_layers*}

Specifies the marking layers for gate thickness class 2. Specify the layers by using the layer names or layer numbers from the technology file.

-gate_class3_marking_layers {*list_of_layers*}

Specifies the marking layers for gate thickness class 3. Specify the layers by using the layer names or layer numbers from the technology file.

DESCRIPTION

This command invokes the IC Validator tool using an automatically generated runset to calculate the hierarchical antenna properties of the current design (hard macro) and stores the values in the database.

The hierarchical antenna properties include gate size, routing area, and diode protection for all the ports of the macros. These properties are used by the router to check antenna rules on nets connected to the macro pins.

Before you use this command, you must open the design library and DESIGN view. The hierarchical antenna properties are stored in the FRAME view of the design. Both the DESIGN and FRAME views of the cell must exist before you run this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the command to extract the hierarchical antenna properties of a hard macro with gate class 1 and gate class 2 marking layers.

```
prompt> signoff_calculate_hier_antenna_property \
  -diffusion_layers { 2 5 } -poly_layers { 7 } \
  -contact_layers  { 14 }  \
  -gate_class1_marking_layers { 12:12 } \
  -gate_class2_marking_layers { 24:12 }
```

The following example runs the command to extract the hierarchical antenna properties of a hard macro with a v0 layer between m1 and m0, an m0 layer for poly connection, and an m0 layer for diffusion connection.

```
prompt> signoff_calculate_hier_antenna_property \
  -diffusion_layers { 6 } -poly_layers { 17 } \
  -v0_layers_between_m1_m0 { 159 } \
  -m0_layers_for_poly_connection { 28 } \
  -m0_layers_for_diffusion_connection { 84 }
```

The following example runs the command to extract the hierarchical antenna properties of a hard macro with a v0 layer between m1 and m0, an m0 layer for poly connection, an m0 layer for diffusion connection, and a contact layer between m0 and diffusion.

```
prompt> signoff_calculate_hier_antenna_property \
  -diffusion_layers { 2 } -poly_layers { 7 } \
  -v0_layers_between_m1_m0 { 35 } \
  -m0_layers_for_poly_connection { 176 } \
  -m0_layers_for_diffusion_connection { 14 } \
  -contact_layers_between_m0_diffusion { 101 }
```

derive_hier_antenna_property(2)

signoff_check_design

Command to do different checks such as metal fill shorts.

SYNTAX

status **signoff_check_design**
[-short_with_metal_fill *true* | *false*]
[-read_frame_view {*list of blocks*}]

Data Types

list of blocks string

ARGUMENTS

-short_with_metal_fill *true* | *false*

Specifies to check for the shorts with metal fill shapes.

-read_frame_view {*list of blocks*}

Specifies the list of blocks for which frames are to be read. By default, the design view of all macros are used if available then the frame view. Wildcards are acceptable.

DESCRIPTION

This command launches the IC Validator tool with a runset created on the fly to do basic checks. The currently supported one is to check shorts with metal fill.

The command creates runset on the fly, launches ICV with the runset and creates an error data for violations.

Before running this command, you must setup the environment settings for the IC Validator tool. For more details about the IC Validator tool, see the *IC Validator Reference Manual*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs design rule checking with maximum number of errors per rule set to 6000.

```
prompt> set_app_options -name signoff.check_design.max_errors_per_rule -value 6000
prompt> signoff_check_design
```

The following example runs IC Validator under the working directory named **my_signoff_run**.

```
prompt> set_app_options -name signoff.check_design.run_dir -value "my_signoff_run"
prompt> signoff_check_design
```

The following example runs IC Validator with user-defined option named **-turbo** and user given runset.

```
prompt> set_app_options -name signoff.check_design.user_defined_options -value "-turbo"
prompt> set_app_options -name signoff.check_design.runset -value "short_finder.rs"
prompt> signoff_check_design
```

SEE ALSO

signoff_check_drc(2)
signoff_create_metal_fill(2)

signoff_check_drc

Performs design rule checking on the current block using a foundry runset.

SYNTAX

status **signoff_check_drc**
[-error_data *errdata_name*]
[-check_all_runset_layers true | false]
[-select_layers *collection_of_layers*]
[-select_rules *list_of_rule_names*]
[-unselect_rules *list_of_rule_names*]
[-coordinates *region_spec*]
[-excluded_coordinates *region_spec*]
[-auto_eco true | false]
[-pre_eco_design *block_name*]

Data Types

errdata_name	string
collection_of_layers	collection
list_of_rule_names	list
region_spec	list
block_name	string

ARGUMENTS

-error_data *errdata_name*

Specifies the name of the error data file.

If you do not specify this option, the error data file is named signoff_check_drc.err.

-check_all_runset_layers true | false

Controls the layers on which to perform design rule checking.

By default (**false**), the command checks the design rules only on the routing layers (metal and via layers).

If **true**, the command checks the design rules on all layers defined in the runset, such as routing layers and device layers. When you set this option to **true**, the command uses the design view instead of the frame view for all cells by automatically setting the **signoff.check_drc.read_design_views** application option to **{*}**. If the cell libraries do not contain design views, the command fails.

The **-check_all_runset_layers** and **-select_layers** options are mutually exclusive; you can specify only one.

-select_layers *collection_of_layers*

Specifies the routing layers (metal or via layers) on which to perform design rule checking. The layer names must be the names defined in the technology file.

By default, the command checks the design rules on all routing layers (metal and via layers).

The **-check_all_runset_layers** and **-select_layers** options are mutually exclusive; you can specify only one.

-select_rules ***list_of_rule_names***

Specifies the rules to check. You can specify either the rule name or number. You can specify wildcards. The rule names are declared in the COMMENT option of the foundry runset.

By default, all design rules are checked.

If you specify both the **-select_rules** and **-unselect_rules** options, the **-unselect_rules** option unselects rules from the selected ones.

-unselect_rules ***list_of_rule_names***

Specifies the rules that are not checked. You can specify either the rule name or number. You can specify wildcards. The rule names are declared in the COMMENT option of the foundry runset.

By default, all design rules are checked (no rules are excluded).

If you specify both the **-select_rules** and **-unselect_rules** options, the **-unselect_rules** option unselects rules from the selected ones.

-coordinates ***region_spec***

Specifies the rectangular or rectilinear regions in which to perform design rule checking. You can specify one or more regions.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you do not specify this option or the **-excluded_coordinates** option, the command performs design rule checking on the entire block.

If you specify both the **-coordinates** and **-excluded_coordinates** options, the **-excluded_coordinates** option excludes regions from design rule checking based on the selected regions.

This option is mutually exclusive with the **-auto_eco true** option.

-excluded_coordinates ***region_spec***

Specifies the rectangular or rectilinear regions to exclude from design rule checking. You can specify one or more regions.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you do not specify this option or the **-coordinates** option, the command performs design rule checking on the entire block.

If you specify both the **-coordinates** and **-excluded_coordinates** options, the **-excluded_coordinates** option excludes regions from design rule checking based on the selected regions.

This option is mutually exclusive with the **-auto_eco true** option.

-auto_eco true | **false**

Controls whether design rule checking is performed only for the automatically detected ECO change area.

By default (**false**), the command performs design rule checking on the entire block.

If **true**, the command compares the block against the version used for the previous run of the **signoff_check_drc** command and detects any physical object changes between them. Design rule checking is performed only for the changed area.

You can use this option only if you have previously run the **signoff_check_drc** command for the current block (or the block specified by the **-pre_eco_design** option).

When you use this option, you cannot use the **-error_data** option. The results of the incremental DRC run are always stored in an error data file named signoff_check_drc_incremental.err. If the **signoff.check_drc.merge_incremental_error_data** application option is set to **true**, the command creates an additional error data file named signoff_check_drc_incremental_merged.err.

The command returns a value of -1 if the incremental DRC run is successful, or if there is no change in the block. If the changes to a block are more than a fixed threshold, the command returns the actual percent change in the block. The default threshold is 20 percent. To specify the threshold value, set the **signoff.check_drc.auto_eco_threshold_value** application option.

This option is mutually exclusive with the **-coordinates** and **-excluded_coordinates** options.

-pre_eco_design ***block_name***

Specifies the block to compare to the current block to determine the ECO change area. You must have previously run a full **signoff_check_drc** command on the specified block.

If you do not specify this option, the tool compares the current block to the version that was used for the previous run of the **signoff_check_drc** command.

This option is valid only with the **-auto_eco true** option.

DESCRIPTION

This command launches the IC Validator tool with a foundry runset to check for DRC violations in the current block. When you use the **signoff_check_drc** command for DRC checking, you must provide cell libraries that contain the child cell data and do not have any DRC violations.

Before running this command, you must set up the environment for the IC Validator tool. For more details about the IC Validator tool, see the *IC Validator Reference Manual*.

The error data generated by the command is not persistent and will be lost if you close the block without saving it.

To reduce the runtime for design rule checking with the IC Validator tool, you can enable multicore processing by using the **set_host_options** command. The IC Validator tool determines the multithreading setting automatically. The **set_host_options** settings are not persistent. You must set them in each session. In addition, the settings are cumulative so that you can define different numbers of jobs on different machines.

After you complete design rule checking on the routing layers, you can perform a quick design rule check on the current block by rerunning the **signoff_check_drc** command with the **-check_all_runset_layers** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the drc.rs runset to perform IC Validator design rule checking. The IC Validator tool reads the design view for the top-level block and all library cell instances and pins only from the frame view for all macro cell instances.

```
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> signoff_check_drc
```

The following example uses the drc.rs runset to perform IC Validator design rule checking. The IC Validator tool reads the design view for the top-level block, all library cell instances, and all instances of the M1 macro; it reads the frame views with blockages and pins for all other macro cell instances.

```
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> set_app_options \
  -name signoff.check_drc.read_design_views -value {M1}
prompt> set_app_options \
  -name signoff.ignore_blockages_from_cell -value false
prompt> signoff_check_drc
```

The following example uses the drc.rs runset to perform IC Validator design rule checking. The IC Validator tool reads the design view for the top-level block and all cell instances. The command reports a maximum of 6000 errors per rule.

```
prompt> set_app_options \
  -name signoff.check_drc.read_design_views -value {*}
prompt> set_app_options \
  -name signoff.check_drc.max_errors_per_rule -value 6000
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> signoff_check_drc
```

The following example skips the DRC violations inside all library cell instances and runs the IC Validator tool in the working directory named **my_signoff_run**.

```
prompt> set_app_options \
  -name signoff.check_drc.ignore_child_cell_errors -value true
prompt> set_app_options -name signoff.check_drc.run_dir \
  -value "my_signoff_run"
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> signoff_check_drc
```

The following example always reads the fill data. The default behavior is to read the fill data only if its timestamp is newer than the timestamp of the design view.

```
prompt> set_app_options -name signoff.check_drc.fill_view_data \
  -value read
```

```
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> signoff_check_drc
```

The following example excludes standard cells, macro cells, I/O pad cells, and filler cells from design rule checking, and runs the IC Validator tool with a user-defined option named **-turbo**.

```
prompt> set_app_options \
  -name signoff.check_drc.excluded_cell_types \
  -value {lib_cell macro pad filler}
prompt> set_app_options \
  -name signoff.check_drc.user_defined_options -value "-turbo"
prompt> set_app_options -name signoff.check_drc.runset \
  -value "drc.rs"
prompt> signoff_check_drc
```

The following example runs design rule checking with a customized error data file, **my_error.err**.

```
prompt> signoff_check_drc -error_data {my_error}
```

The following example runs design rule checking on the M1 and M3 layers of the current block.

```
prompt> signoff_check_drc -select_layers { M1 M3 }
```

The following example runs design rule checking for the rules whose names and descriptions match the M*.W.1 or M*.W.3 patterns:

```
prompt> signoff_check_drc -select_rules { M*.W.1*  M*.W.3* }
```

The following example runs design rule checking for all rules in the specified runset, except those whose names and descriptions match the VIA*.S pattern.

```
prompt> signoff_check_drc -unselect_rules { VIA*.S* }
```

The following example runs design rule checking for the rules whose names and descriptions match the M2.A.2 or M4.S.2 patterns:

```
prompt> signoff_check_drc -select_rules { M2.A.2*  M4.S.2* }
```

The following example runs design rule checking for the rules whose names and descriptions match the *.EN.3 pattern:

```
prompt> signoff_check_drc -select_rules { *.EN.3* }
```

The following example runs design rule checking for all rules in the specified runset, except those whose names and descriptions match the *2.EN.*.1 pattern.

```
prompt> signoff_check_drc -unselect_rules { *2.EN.*.1* }
```

The following example runs design rule checking within the rectangle whose lower-left corner is at (22.47, 98.85) and upper-right corner is at (175.39, 187.35).

```
prompt> signoff_check_drc \
  -coordinates { { {22.47 98.85} {175.39 187.35} } }
```

The following example runs design rule checking within the rectilinear region with the following coordinates: (0, 0), (100, 0), (100, 100), (50, 100), (50, 50), and (0, 50).

```
prompt> signoff_check_drc \
  -coordinates {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}}
```

The following example excludes the rectangular region with its lower-left corner at (50.12, 78.85) and its upper-right corner at (135.43, 157.36) from design rule checking.

```
prompt> signoff_check_drc \
```

-excluded_coordinates { { {50.12 78.85} {135.43 157.36} } }

The following example runs IC Validator using distributed processing on multiple cores of the local machine by starting the IC Validator run with the **-dp4** option.

```
prompt> set_host_options -num_processes 4 {localhost}
prompt> signoff_check_drc
```

The following example runs IC Validator using distributed processing on machine_A and machine_B by starting the IC Validator run with the **-dp -dphosts machine_A machine_A machine_B** options.

```
prompt> set_host_options -num_processes 2 {machine_A}
prompt> set_host_options -num_processes 1 {machine_B}
prompt> signoff_check_drc
```

The following example runs design rule checking for the automatically detected ECO change area.

```
prompt> signoff_check_drc -auto_eco true
```

The following example runs design rule checking for the ECO change area determined by comparing the current block to the block named TOPA.

```
prompt> signoff_check_drc -auto_eco true -pre_eco_design TOPA
```

The following example runs design rule checking for the ECO change area and merges the result from a previous **signoff_check_drc -error_data "pre_eco_drc"** run. The resulting error data file is called signoff_check_drc_incremental_merged.err.

```
prompt> set_app_options \
  -name signoff.check_drc.merge_incremental_data -value true
prompt> set_app_options \
  -name signoff.check_drc.merge_base_error_name \
  -value "pre_eco_drc.err"
prompt> signoff_check_drc -auto_eco true
```

The following example specifies stream files with layout data that replace the layout in the cell libraries for the **signoff_check_drc** run.

```
prompt> set_app_options -name signoff.physical.merge_stream_files \
  -value {stream_file1.gds stream_files2.oas}
prompt> signoff_check_drc
```

signoff_check_drc_icv_live

Run ICV-Live to performs design rule checking on the current block using a foundry runset.

SYNTAX

signoff_check_drc_icv_live
-rect *{{lx ly} {ux uy}}*
[-layers *layers*]
[-child_depth *number*]

Data Types

lx float
ly float
ux float
uy float
layers list of layer names
number integer

ARGUMENTS

-rect *{{lx ly} {ux uy}}*

Specifies the rectangle area to check.

-layers *layers*

Specifies the layers on which to perform design rule checking. The layer names must be the names defined in the technology file. Default is all routing layers (metal and via layers).

-child_depth *number*

Specifies the maximum hierarchical block depth to process. Default is 0.

DESCRIPTION

This command launches the ICV-Live tool with a foundry runset to check for DRC violations in the current block specified rectangle area.

EXAMPLES

The following example uses the drc.rs runset and layer_map.map file to perform ICV-Live design rule checking.

```
prompt> set_app_options -name signoff.check_drc_live.runset -value "drc.rs"
prompt> set_app_options -name signoff.physical.layer_map_file -value "layer_map.map"
prompt> signoff_check_drc_icv_live -rect {{26.257 24.928} {31.932 21.200}} -layers { M1 VIA1 M2 VIA2 }
```

list_of_points	list
nets	collection
threshold	float
design_name	string
foundry_node	string
prefix	string
track_fill_parameter_file_path	string
rules	list

ARGUMENTS

-mode overwrite | add | remove | replace

Specifies the mode of the metal fill operation.

The valid values are

- **overwrite** (the default)
  Replaces the existing metal fill in the current block with new metal fill.

  This mode is supported in both the pattern-based (foundry-qualified runset) and track-based fill flows.

- **add**
  Appends metal fill to the existing metal fill in the current block. The existing fill data is not modified.

  This mode is supported for both pattern-based and track-based fill flows. You can add pattern-based fill on top of pattern-based fill, track-based fill on top of track-based fill, or track-based fill on top of pattern-based fill.

  The main purpose of this mode is to add fill in empty regions. If you run the timing-driven fill flow without fix-density mode enabled, the command removes fill shapes near timing-critical nets, which could create low density pockets. You can use add mode to add fill in these low-density pockets. By default, the command inserts fill to the maximum extent that is allowed. For example, in the track-based fill flow, if you use the sparse fill mode by using the **-fill_all_tracks false** option, the command ensures that the new fill maintains one-track spacing from signal shapes. To limit fill insertion to the low-density pockets, set the **signoff.create_metal_fill.fix_density_errors** application option to **true**. Limiting fill insertion to low-density pockets is supported only when using the track-based fill flow. The density rules must be specified in the technology file or user parameter file. The command uses the density rules to find the density-violating windows.

  You can also use add mode to insert fill in selected regions by using the **-coordinates** option. Use the area-based add mode to insert fill in limited areas, where the combined area is less than 20 percent of the overall chip area. This flow runs on the sparse view of the block and should run at least three times faster than a full-chip run. Because of the limited visibility of data in the sparse view, dense track fill cannot be generated for layers that have double-patterning rules; therefore, the command ignores the **-fill_all_tracks true** option for such layers.

  The command ignores the following application options for track-based fill insertion in add mode:

  - **signoff.create_metal_fill.flat**
  - **signoff.create_metal_fill.max_density_threshold**

- **remove**
  Removes metal fill from the current block.

  By default, the IC Validator tool removes all metal fill from the current block, including the typical critical dimension (TCD) structures. To restrict the metal fill removal, use one or more of the following options:

  - **-select_layers**, which enables layer-based fill removal
  - **-coordinates**, which enables area-based fill removal
  - **-nets**, which removes the metal fill around the shapes of the specified nets based on the spacing requirements specified by the **signoff.create_metal_fill.space_to_nets**, **signoff.create_metal_fill.space_to_clock_nets**, and **signoff.create_metal_fill.space_to_nets_on_adjacent_layer** application options
  - **-timing_preserve_setup_slack_threshold**, which removes the metal fill around the shapes of the nets with a slack less than the specified value based on the spacing requirements specified by the **signoff.create_metal_fill.space_to_nets** and **signoff.create_metal_fill.space_to_nets_on_adjacent_layer** application options
    Note that the tool uses the existing fill when calculating the slack values for pattern-based fill, but not for track-based fill.
  - **-remove_by_rule**, which removes the metal fill based on the specified rules

  This mode is supported in both the pattern-based and track-based flows.

- **replace**
  Replaces the existing metal fill in specific regions of the current block with new metal fill. When you use this mode, you must specify the ECO regions by using at least one of the following options: **-select_layers**, **-coordinates**, **-**

excluded_coordinates, **-nets**, and **-timing_preserve_setup_slack_threshold**.

This mode is supported in both the pattern-based and track-based flows.

-select_layers *layers*

Specifies the routing layers (metal or via layers) on which to perform the metal fill operation. The layer names must be the names defined in the technology file.

If you do not specify this option, the command performs the metal fill operation on all routing layers.

The **-all_runset_layers** and **-select_layers** options are mutually exclusive; you can specify only one.

-all_runset_layers true | false

If **true**, the command inserts fill for all output fill layers defined in the runset. By default (**false**), the command inserts fill only for the routing layers (metal and via layers).

This option is mutually exclusive with the following options: **-select_layers**, **-coordinates**, and **-excluded_coordinates**.

-coordinates *list_of_points*

Specifies the rectangular or rectilinear regions in which to perform the metal fill operation. You can specify one or more regions.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you do not specify this option or the **-excluded_coordinates** option, the command performs the metal fill operation on the entire block.

If you specify both the **-coordinates** and **-excluded_coordinates** options, the **-excluded_coordinates** option excludes regions from the metal fill operation based on the selected regions.

This option is mutually exclusive with the **-auto_eco true** option.

-excluded_coordinates *list_of_points*

Specifies the rectangular or rectilinear regions to exclude from the metal fill operation.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you do not specify this option or the **-coordinates** option, the command performs the metal fill operation on the entire block.

If you specify both the **-coordinates** and **-excluded_coordinates** options, the **-excluded_coordinates** option excludes regions from the metal fill operation based on the selected regions.

This option is mutually exclusive with the **-auto_eco true** option.

-nets *nets*

Specifies the critical nets around which to preserve timing by preventing fill shapes within the minimum spacing of the net shapes associated with the specified nets.

By default, the minimum spacing between the critical net shapes and the fill shapes is based on the minimum spacing specified in the technology file.

- For fill on the same layer as the net shape, the default minimum spacing is two times the minimum spacing value specified for the layer in the technology file.

  To explicitly specify the same layer minimum spacing requirements, set the **signoff.create_metal_fill.space_to_nets** application option.

  To explicitly specify the same layer minimum spacing requirements for clock nets, set the **signoff.create_metal_fill.space_to_clock_nets** application option.

  To add the fill shapes till the clock net shields, set the **signoff.create_metal_fill.fill_shielded_clock** application option.

- For fill in the vertical extension of the net shape on the adjacent layers, the default minimum spacing is the minimum spacing value specified for the layer in the technology file.

  To explicitly specify the adjacent layer minimum spacing requirements, set the **signoff.create_metal_fill.space_to_nets_on_adjacent_layer** application option.

  To explicitly specify the adjacent layer minimum spacing requirements for clock nets, set the **signoff.create_metal_fill.space_to_clock_nets_on_adjacent_layer** application option.

  To allow metal fill in the vertical extension of the net shape on the adjacent layers, set the **signoff.create_metal_fill.fill_over_net_on_adjacent_layer** application option to **true**. In this case, the command does not use the adjacent-layer minimum spacing value.

-timing_preserve_setup_slack_threshold *threshold*

Specifies the setup slack threshold in library time units. The command considers all nets with slack less than the specified threshold as critical nets and preserves the timing for these nets by preventing fill shapes within the minimum spacing of the net shapes associated with these critical nets.

By default, the minimum spacing between the critical net shapes and the fill shapes is based on the minimum spacing specified in the technology file.

- For fill on the same layer as the net shape, the default minimum spacing is two times the minimum spacing value specified for the layer in the technology file.

  To explicitly specify the same layer minimum spacing requirements, set the **signoff.create_metal_fill.space_to_nets** application option.

- For fill in the vertical extension of the net shape on the adjacent layers, the default minimum spacing is the minimum spacing value specified for the layer in the technology file.

  To explicitly specify the adjacent layer minimum spacing requirements, set the **signoff.create_metal_fill.space_to_nets_on_adjacent_layer** application option.

  To allow metal fill in the vertical extension of the net shape on the adjacent layers, set the **signoff.create_metal_fill.fill_over_net_on_adjacent_layer** application option to **true**. In this case, the command does not use the adjacent-layer minimum spacing value.

The default threshold is null, which means that the tool does not automatically determine the critical nets.

You cannot use this option with the **-select_layers** option.

-auto_eco true | **false**

Performs fill removal and refill in the automatically detected ECO change areas. You can use this option only if you have previously run the **signoff_create_metal_fill** command.

By default, when you use the **-auto_eco true** option, the tool compares the current block against the version used for the previous run of the **signoff_create_metal_fill** command and detects any physical object changes between them. To compare the current block to a different block, use the **-pre_eco_design** option to specify the comparison block.

You can run this command immediately after an ECO change to remove overlapped metal fill and keep the density consistent by refilling empty areas created during the ECO change. The command performs fill removal and refill only on the layers with automatically detected changes. If a cell instance changes, the command takes a conservative approach and considers changes on all layers. You can use this option multiple times after every ECO change to do a fast refill in the ECO areas.

Note that a change on a metal layer also triggers fill removal and refill on the adjacent via layers to ensure that no floating or hanging vias remain after the metal shapes are removed from the ECO area.

You can use this option with the **-nets** and **-timing_preserve_setup_slack_threshold** options to ensure that timing is preserved in the ECO area during refill.

If you use the **-select_layers** option, the specified layers must be a subset of the automatically detected changed layers. Any extra layers are ignored. For example, if the automatically detected changed layers are M2, M3, and V2, you can choose to make changes only the M2 layer by using the **-select_layers {M2}** option.

This option is mutually exclusive with the **-mode**, **-all_runset_layers**, **-coordinates**, and **-excluded_coordinates** options.

If the run is successful or there are no changes in the block, the command returns a value of 1. If the percentage of change in the block is greater than the change threshold, the command does not perform metal fill insertion and returns the percentage of change in the design. The default change threshold is 20 percent; to modify the change threshold, set the **signoff.create_metal_fill.auto_eco_threshold_value** application option.

-pre_eco_design ***design_name***

Specifies the block to compare to the current block to determine the ECO change area. You must have previously run a full **signoff_create_metal_fill** command on the specified block.

If you do not specify this option, the tool compares the current block to the version that was used for the previous run of the **signoff_create_metal_fill** command.

This option is valid only with the **-auto_eco** option.

-track_fill off | **generic** | ***foundry_node***

Controls whether the command uses the pattern-based or track-based flow.

By default (**off**), the command uses the pattern-based flow with a user-specified runset.

If you enable the track-based flow by setting this option to **generic** or a *foundry_node* keyword, the tool inserts track-based fill with an automatically generated runset. The track-based flow does not use a user-specified runset.

The *foundry_node* keywords correspond to specific foundries and technology nodes. To see a list of the valid values, use the **-track_fill list** option. For an example, see the EXAMPLES section.

By default, track-based metal fill insertion uses sparse mode, and skips one track between signal shapes and fill shapes. To use dense mode, which does not skip tracks, set the **-fill_all_tracks** option to **true**.

If you are using generic track-based metal fill insertion on a design with double-patterning technology, you must use sparse mode unless the design is precolored.

-fill_all_tracks true | false

Controls whether track-based metal fill insertion uses sparse mode or dense mode.

By default (**false**), track-based metal fill insertion uses sparse mode and skips a track between the signal shapes and the fill shapes.

If **true**, track-based metal fill insertion uses dense mode and does not skip tracks between the signal shapes and the fill shapes. If you enable dense mode and the block uses double-patterning technology, the tool considers the mask constraints during metal fill insertion and colors the fill shapes to avoid double-patterning violations. If the block is not precolored, runtime increases because the IC Validator tool must first color the block.

This option is valid only for the track-based flow.

-report_density on | off | *prefix*

Controls whether the command creates a detailed density and density gradient report.

By default (**off**), the command does not generate density reports.

When set to **on**, the command generates density reports with the following names:
track_fill_color_balance_and_density_report.txt and track_fill_density_gradient_report.txt.

To replace "track_fill" with a user-specified string, specify the string as the *prefix* argument. In this case, the command generates the following reports: *prefix*_color_balance_and_density_report.txt and *prefix*_density_gradient_report.txt.

This option is valid only for the track-based flow.

-output_colored_fill true | false

Controls whether the command sets mask constraints on the fill shapes inserted on double-patterning layers.

By default (**false**), the command does not set mask constraints on the fill shapes.

When **true**, the command assigns a data type of 235 for fill shapes with a **mask_one** mask constraint and 236 for fill shapes with a **mask_two** mask constraint. To assign different data types for the colored fill, set the following parameters in the IC Validator parameter file: **mx_fill_datatype_color1**, **viax_fill_datatype_color1**, **mx_fill_datatype_color2**, and **viax_fill_datatype_color2**.

This option is valid only for the track-based flow.

-track_fill_parameter_file auto | generate_file_only | *track_fill_parameter_file_path*

Specifies behavior related to the IC Validator parameter file. Valid values are

- **auto** (the default)
  The tool generates a parameter file with default values. It uses this file for the metal fill operation and saves it in the fill run directory as track_fill_params.rh.
- **generate_file_only**
  The tool generates a parameter file with default values and saves it in the fill run directory as track_fill_params.rh. When you specify this value, the command quits after generating the parameter file and does not perform the metal fill operation.
- *track_fill_parameter_file_path*
  Specifies the parameter file to use for the metal fill operation.

  To generate the parameter file, you can start with the automatically generated parameter file and customize the settings as needed.

This option is valid only for the track-based flow.

-remove_by_rule {*rules*}

Specifies the type of rule-based fill removal.

By default (**off**), the command does not perform rule-based fill removal.

To enable rule-based fill removal, specify one or more of the following values:

- **max_density_threshold**
  Fill removal honors the maximum density rules specified by the **signoff.create_metal_fill.max_density_threshold** application option.

  This rule is supported only in the track-based flow.

- **ndr**
  Fill removal honors the nondefault routing rules set on the nets.

  This rule is supported in both the pattern-based and track-based flows.

-foundry_fill_type both | feol | beol

Specifies the type of fill to be done using **signoff_create_metal_fill** command on metal layers or base metal layers.

By default, the command does foundry fill on metal layers.

When the option is set to \fboth, the command does the subsequent foundry fill on metal layers and then on base metal layers.

When the option is set to \fbeol, the command does the foundry fill only on metal layers.

When the option is set to \ffeol, the command does the foundry fill only on base metal layers.

-foundry_for_feol_fill off | list | *foundry_node*

Controls whether the command uses the marker layers for base metal layers. The marker layers are chose based on foundry node.

By default (**off**), the command uses no marker layers for base metal layers.

The *foundry_node* keywords correspond to specific foundries and technology nodes. To see a list of the valid values, use the **-foundry_for_feol_fill list** option. For an example, see the EXAMPLES section.

DESCRIPTION

This command invokes the IC Validator tool to perform metal fill operations on the current block. You can use this command to

- Insert metal fill to meet the metal density requirements
- Perform post ECO metal fill removal and re-fill
- Remove metal fill

  The command can use either a pattern-based flow with a user-specified runset or a track-based flow with an automatically generated runset.

  After performing the metal fill operation, the command saves the block. The metal fill data is stored as an internal fill design that consists of the area-fill objects.

  Before using this command,

  - The block must be fully routed design with little or no DRC violations.

- You must save the block to disk (the IC Validator tool reads the design from disk).
- You must define the environment settings for the IC Validator tool.
  For details about the IC Validator tool, see the *IC Validator Reference Manual*.

  To reduce the runtime of the IC Validator tool, you can enable multicore processing by using the **set_host_options** command. The IC Validator tool determines the multithreading setting automatically. Note that the **set_host_options** settings are not persistent. They must be set in each session. In addition, the setting is cumulative so that different numbers of jobs can be defined on different machines.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs pattern-based fill insertion on the entire block using a runset named fill.rs.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> signoff_create_metal_fill
```

The following example fills all empty regions with flattened metal fill.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> set_app_options \
  -name signoff.create_metal_fill.flat -value true
prompt> signoff_create_metal_fill
```

The following example fills all empty regions on the metal1 layer outside the region {{100 150} {300 200}}.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> signoff_create_metal_fill -select_layers {metal1} \
  -excluded_coordinates {{{100 150} {300 200}}}
```

The following example removes the internal fill design from the current block.

```
prompt> signoff_create_metal_fill -mode remove
```

The following example removes the fill from the metal1 and metal3 layers in the internal fill design of the current block.

```
prompt> signoff_create_metal_fill -mode remove \
  -select_layers {metal1 metal3}
```

The following example removes track fill around the n1 and n2 nets.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode remove -nets {n1 n2}
```

The following example removes all metal fill on the metal1 and metal3 layers, and then refills those two metal layers. The existing metal fill on other metal layers remains unchanged.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
```

```
prompt> signoff_create_metal_fill -mode replace \
  -select_layers {metal1 metal3}
```

The following example fills all empty regions in {{100 150} {300 200}} without overwriting the existing metal fill.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> signoff_create_metal_fill -mode add \
  -coordinates {{{100 150} {300 200}}}
```

The following example re-creates track fill for layer M4. Timing and density-based rules are honored during fill replacement. Because M4 is replaced, VIA3 and VIA4 are automatically replaced.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.space_to_nets \
  -value {{M2 4x} {M3 4x} {M4 4x} {M5 5x}}
prompt> set_app_options \
  -name signoff.create_metal_fill.fix_density_errors -value true
prompt> set_app_options \
  -name signoff.create_metal_fill.max_density_threshold \
  -value {{M4 30}}
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode replace -select_layers {M4} \
  -timing_preserve_setup_slack_threshold 0.5
```

The following example uses the track-based flow to re-create the via fill for the VIA1, VIA2, VIA3, VIA4, and VIA5 via layers.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode replace -select_layers {VIA1 VIA2 VIA3 VIA4 VIA5}
```

The following example fills all empty regions in the rectilinear polygon {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}} without overwriting the existing metal fill.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> signoff_create_metal_fill -mode add -track_fill foundryNode \
  -coordinates {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}}
```

The following example adds fill in empty regions without modifying the existing fill and maintains sufficient spacing from the critical nets n1, n2, and n3.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode add -nets "n1 n2 n3"
```

The following example adds track fill only in density-violation windows without modifying existing fill.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.fix_density_errors -value true
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode add -fill_all_tracks true
```

The following example adds track fill only in density-violation windows without modifying existing fill. Within the density-violating windows, the command tries to add fill shapes away from the critical nets n1, n2, and n3.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.fix_density_errors -value true
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode add -fill_all_tracks true -nets "n1 n2 n3"
```

The following example invokes IC Validator with user-defined options named **-turbo** and **-vue**.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.runset -value "fill.rs"
prompt> set_app_options \
  -name signoff.create_metal_fill.user_defined_options \
  -value "-turbo -vue"
prompt> signoff_create_metal_fill
```

The following example lists all supported foundry nodes for the track-based fill flow.

```
prompt> signoff_create_metal_fill -track_fill list
```

The following example creates track-based fill for foundryNode by creating sparse fill to overwrite the existing metal fill.

```
prompt> signoff_create_metal_fill -track_fill foundryNode
```

The following example creates track-based fill for the generic process node by creating sparse fill to overwrite the existing metal fill.

```
prompt> signoff_create_metal_fill -track_fill generic
```

The following example creates track-based fill for foundryNode by creating dense fill to overwrite the existing metal fill.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -fill_all_tracks true
```

The following example creates dense track-based fill for foundryNode. It attaches mask attributes to the fill shapes and outputs the colored fill using datatype 235 for color1 and 236 for color2.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -fill_all_tracks true -output_colored_fill true
```

The following example creates sparse track-based fill for foundryNode and generates density reports with the following names: sparse_fill_color_balance_and_density_report.txt and sparse_fill_density_gradient_report.txt.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -report_density "sparse_fill"
```

The following example creates sparse track-based fill for foundryNode node using a customized track fill parameter file named custom_params.rh.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -track_fill_parameter_file ./custom_params.rh
```

The following example honors the nondefault routing rules during fill removal.

```
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode remove -remove_by_rule {ndr}
```

The following example honors the maximum density rules during fill removal, so it reduces the metal density of the M2 and M3 layers to close to 30 percent.

```
prompt> set_app_options \
  -name signoff.create_metal_fill.max_density_threshold \
  -value {{M2 30} {M3 30}}
prompt> signoff_create_metal_fill -track_fill foundryNode \
  -mode remove -remove_by_rule {max_density_threshold}
```

The following example runs the IC Validator tool using distributed processing on multiple cores of the local machine by starting the IC Validator run with the **-dp4** option.

```
prompt> set_host_options -num_processes 4 {localhost}
prompt> set_app_options \
```

```
    -name signoff.create_metal_fill.runset -value "fill.rs"
  prompt> signoff_create_metal_fill
```

The following example runs the IC Validator tool using distributed processing on machine_A and machine_B by starting the IC Validator run with the **-dp -dphosts machine_A machine_A machine_B** options.

```
  prompt> set_host_options -num_processes 2 {machine_A}
  prompt> set_host_options -num_processes 1 {machine_B}
  prompt> set_app_options \
    -name signoff.create_metal_fill.runset -value "fill.rs"
  prompt> signoff_create_metal_fill
```

The following example performs fill removal and refill for the automatically detected ECO change area. It also makes sure that the newly created fill in the ECO region maintains four times the minimum spacing away from the net1 and net2 nets for the M2 and M3 metal layers.

```
  prompt> set_app_options \
    -name signoff.create_metal_fill.runset -value "fill.rs"
  prompt> set_app_options \
    -name signoff.create_metal_fill.space_to_nets \
    -value {{M2 4x} {M3 4x}}
  prompt> signoff_create_metal_fill -nets "net1 net2" -auto_eco true
```

The following example runs incremental fill for the ECO change area determined by comparing the current block to the block named TOPA.

```
  prompt> set_app_options \
    -name signoff.create_metal_fill.runset -value "fill.rs"
  prompt> signoff_create_metal_fill -auto_eco true \
    -pre_eco_design TOPA
```

The following example specifies stream files with layout data that replace the layout in the cell libraries for the **signoff_create_metal_fill** run.

```
  prompt> set_app_options \
    -name signoff.create_metal_fill.runset -value "fill.rs"
  prompt> set_app_options \
    -name signoff.physical.merge_stream_files \
    -value {stream_file1.gds stream_files2.oas}
  prompt> signoff_create_metal_fill
```

The following example fills all empty regions on poly and diffusion layers.

```
  prompt> set_app_options \
    -name signoff.create_metal_fill.base_metal_layers \
    -value {base_metal_fill.rs}
  prompt> signoff_create_metal_fill -foundry_fill_type feol
```

The following example fills all empty regions on poly and diffusion layers with marker layer fills on particular foundry.

```
  prompt> set_app_options \
    -name signoff.create_metal_fill.base_metal_layers \
    -value {base_metal_fill.rs}
  prompt> signoff_create_metal_fill -foundry_fill_type feol \
  -foundry_for_feol_fill <foundry_node>
```

signoff_create_pg_augmentation

Invokes the IC Validator tool to augment existing PG structure for improving IR drop.

SYNTAX

status **signoff_create_pg_augmentation**
[-node tsmc7 | tsmc16 | samsung7 | samsung10]
[-mode add | remove]
[-nets *nets*]
[-timing_preserve_setup_slack_threshold *threshold*]
[-coordinates_ground *list_of_points*]
[-excluded_coordinates_ground *list_of_points*]
[-coordinates_power *list_of_points*]
[-excluded_coordinates_power *list_of_points*]
[-parameter_file auto | *pga_parameter_file_path*]

Data Types

list_of_points	list
nets	collection
pga_parameter_file_path	string

ARGUMENTS

-node tsmc7 | tsmc16 | samsung7 | samsung10

Specifies the node for which PG-Augmentation flow should be run.

The supported nodes are:

- **tsmc7**
- **tsmc16**
- **samsung7**
- **samsung10**

-mode add | remove

Specifies the mode of the pg augmentation operation.

The valid values are

- **add**
  Appends pg augmentation to the existing pg augmentation in the current block. The existing data is not modified.

The main purpose of this mode is to add PGA in empty regions OR for different power nets.

- **remove**
  Removes pg augmentation from the current block.

  By default, the tool removes all pg augmentation from the current block.

-coordinates_ground *list_of_points*

Specifies the rectangular or rectilinear regions in which to perform the pg augmentation operation for ground net. You can specify one or more regions.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you specify both the **-coordinates_ground** and **-excluded_coordinates_ground** options, the **-excluded_coordinates_ground** option excludes regions from the pg augmentation operation based on the selected regions.

-excluded_coordinates_ground *list_of_points*

Specifies the rectangular or rectilinear regions to exclude from the pg augmentation operation.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you specify both the **-coordinates_ground** and **-excluded_coordinates_ground** options, the **-excluded_coordinates_ground** option excludes regions from the pg augmentation operation based on the selected regions.

-coordinates_power *list_of_points*

Specifies the rectangular or rectilinear regions in which to perform the pg augmentation operation for power net. You can specify one or more regions.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you specify both the **-coordinates_power** and **-excluded_coordinates_power** options, the **-excluded_coordinates_power** option excludes regions from the pg augmentation operation based on the selected regions.

-excluded_coordinates_power *list_of_points*

Specifies the rectangular or rectilinear regions to exclude from the pg augmentation operation.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

The coordinates are floating point numbers in main library units.

If you specify both the **-coordinates_power** and **-excluded_coordinates_power** options, the **-excluded_coordinates_power** option excludes regions from the pg augmentation operation based on the selected regions.

-nets *nets*

Specifies the critical nets around which to preserve timing by preventing PGA shapes within the minimum spacing of the net shapes associated with the specified nets.

-timing_preserve_setup_slack_threshold *threshold*

Specifies the setup slack threshold in library time units. The command considers all nets with slack less than the specified threshold as critical nets and preserves the timing for these nets by preventing PGA shapes within the minimum spacing of the net shapes associated with these critical nets.

-parameter_file auto | *pga_parameter_file_path*

Specifies behavior related to the IC Validator parameter file. Valid values are

- **auto** (the default)
  The tool generates a parameter file with default values. It uses this file for the pg augmentation operation.
- *pga_parameter_file_path*
  Specifies the parameter file to use for the pg augmentation operation.

  To generate the parameter file, you can start with the automatically generated parameter file and customize the settings as needed.

DESCRIPTION

This command invokes the IC Validator tool to perform pg augmentation operations on the current block. You can use this command to

- Insert pg augmentation to improve IR drop
- Remove pg augmentation

  After performing the pg augmentation operation, the command saves the block.

  Before using this command,

  - The block must be fully routed design with little or no DRC violations.
  - You must save the block to disk (the IC Validator tool reads the design from disk).

- You must define the environment settings for the IC Validator tool.
  For details about the IC Validator tool, see the *IC Validator Reference Manual*.

  To reduce the runtime of the IC Validator tool, you can enable multicore processing by using the **set_host_options** command. The IC Validator tool determines the multithreading setting automatically. Note that the **set_host_options** settings are not persistent. They must be set in each session. In addition, the setting is cumulative so that different numbers of jobs can be defined on different machines.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs pg augmentation insertion on the entire block.

```
prompt> set_app_options \
  -name signoff.create_pg_augmentation.ground_net_name -value "VSS"
prompt> set_app_options \
  -name signoff.create_pg_augmentation.power_net_name -value "VDD"
prompt> signoff_create_pg_augmentation -node tsmc7
```

options(3)

signoff_fix_drc

Invokes router to fix selected signoff DRC violations based on the results from a prior IC Validator run and then reruns IC Validator signoff DRC checking.

SYNTAX

status **signoff_fix_drc**
[-start_repair_loop *start_loop*]
[-max_number_repair_loop *max_loops*]
[-select_rules {*list_of_rule_names*}]
[-unselect_rules {*list_of_rule_names*}]
[-coordinates {*list of bounding box(es)*}]
[-excluded_coordinates {*list of exclude bounding box(es)*}]
[-nets {*timing critical nets*}]
[-timing_preserve_setup_slack_threshold {*float value*}]

Data Types

start_loop integer
end_loop integer
list_of_rule_names list

ARGUMENTS

-start_repair_loop *start_loop*

Specifies the starting repair loop. The repair loops are run from the starting repair loop to the maximum number of repair loop specified by the **-max_number_repair_loop** option.

The range is from 1 to 10. The starting repair loop must be less than or equal to the maximum number repair loop.

The default value is 1.

For example, you can run with the default flow (loops 1 and 2) and then follow up with additional "unique" repair loops, such as 3 and 4, by running the command again with a new starting and maximum number repair loop.

-max_number_repair_loop *max_loops*

Specifies the maximum number of repair loop. DRC fixing ends after the maximum number repair loop or when it detects that there are no more signoff DRC violations left, whichever occurs first.

The range is from 1 to 10. The maximum number repair loop must be greater than or equal to the starting repair loop.

The default value is 2.

For example, you can run with the default flow (loops 1 and 2) and then follow up with additional "unique" repair loops, such as 3

and 4, by running the command again with a new starting and maximum number repair loop.

-select_rules {*list_of_rule_names*}

Specifies the rules to check. You can specify either the rule name or number. You can specify wildcards. The rule names are declared in the COMMENT option of the foundry runset.

By default, all design rules are checked.

If you specify both the **-select_rules** option and the **-unselect_rules** option, the **-unselect_rules** option unselects rules from the selected ones.

-unselect_rules {*list_of_rule_names*}

Specifies the rules that are not checked. You can specify either the rule name or number. You can specify wildcards. The rule names are declared in the COMMENT option of the foundry runset.

By default, all design rules are checked (no rules are excluded).

If you specify both the **-select_rules** option and the **-unselect_rules** option, the **-unselect_rules** option unselects rules from the selected ones.

-coordinates {*list of bounding box(es) from where DRC errors will be fixed*}

Specifies the list of bounding box(es) from where DRC errors will be fixed. The following is the syntax:

{{{llx1 lly1} {urx1 ury1}} ...}

The following example shows the rectilinear area (22.47 98.85) (175.39 187.35) where DRC errors will be fixed prompt> signoff_fix_drc -coordinates { { {22.47 98.85} {175.39 187.35} } }

The following example shows the rectilinear area {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}} where DRC errors will be fixed. prompt> signoff_fix_drc -coordinates {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}}

-excluded_coordinates {*list of bounding box(es) from where DRC errors will not be fixed*}

Specifies the list of bounding box(es) from where DRC errors will not be fixed. The following is the syntax:

{{{llx1 lly1} {urx1 ury1}} ...}

The following example shows the rectilinear area (22.47 98.85) (175.39 187.35) where DRC errors will not be fixed. prompt> signoff_fix_drc -excluded_coordinates { { {22.47 98.85} {175.39 187.35} } }

-nets {*list of timing critical nets*}

Specifies the list of timing critical nets that would be protected during fixing flow.

The following example treats nets n1 and n2 as critical during the fixing flow. prompt> signoff_fix_drc -nets {n1, n2}

-timing_preserve_setup_slack_threshold {*float value representing setup slack threshold*}

Specifies the setup slack threshold value for identification of critical nets. The option finds all the paths that have less slack than the specified value and collects the nets that are part of the paths. These timing critical nets are protected during fixing flow.

The following example shows timing will be honored during the fixing flow. Paths that have slack values less than 0.5 are treated as critical prompt> signoff_fix_drc -timing_preserve_setup_slack_threshold 0.5

DESCRIPTION

This command provides tight integration between the Fusion Compiler tool and the IC Validator tool for postroute signoff DRC fixing. It assumes that the current block is near timing closure and there are only a small number of DRC violations left unfixed after the place and route stage.

The command invokes router to fix selected signoff DRC violations based on the results from a prior IC Validator run and then reruns IC Validator signoff DRC checking.

Before you run this command, you must provide the environment settings for IC Validator by using the **set_app_options** command and run the **signoff_check_drc** command or otherwise generate the required IC Validator database. If no database is specified **signoff_fix_drc** will run the signoff_check_drc internally to generate the IC Validator database.

The **set_app_options** for the **signoff_check_drc** command will be applied during the **signoff_fix_drc** command.

Note: When the option "signoff.fix_drc.target_clock_nets" is set to false, the router does NOT have big routing topology changes on clock nets, but it does allow minor shape changes in local area for fixing DRC violations.

To reduce the runtime for signoff autofix DRC flow , you can enable multicore processing by using the **set_host_options** command. router supports multithreading on a multicore machine. IC Validator supports the following types of multicore processing: job submission by a user-specified distributed processing script, job submission by using the Load Sharing Facility (LSF) or Oracle Grid Engine, and distributed processing on the specified hosts. IC Validator determines the multithreading setting automatically. Note that the **set_host_options** settings are not persistent. They must be set in each session. In addition, the setting is cumulative so that different numbers of jobs can be defined on different machines.

Warning

The signoff autofix DRC flow does not address DRC violations within PG nets, clock nets, shielded nets, and frozen nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the signoff autofix DRC flow:

```
prompt> signoff_check_drc
prompt> set_app_options -name signoff.fix_drc.init_drc_error_db \
  -value signoff_check_drc_run
prompt> signoff_fix_drc
```

The following example shows the signoff autofix DRC flow using the design views of all child cells in **signoff_check_drc**:

```
prompt> set_app_options -name signoff.check_drc.read_design_views \
  -value {*}
prompt> signoff_check_drc
prompt> set_app_options -name signoff.fix_drc.init_drc_error_db \
  -value signoff_check_drc_run
prompt> signoff_fix_drc
```

The following example runs router with 4 threads and runs IC Validator using distributed processing on 8 cores of the local machine by starting the IC Validator run with the **-dp32** option.

```
prompt> set_host_options -max_cores 4 -num_process 8
prompt> set_app_options -name signoff.fix_drc.init_drc_error_db \
  -value signoff_check_drc_run
```

```
prompt> signoff_fix_drc
```

The following example runs router with 4 threads and runs IC Validator using distributed processing on 4 cores of the local machine by starting the IC Validator run with the **-dp4** option.

```
prompt> set_host_options -max_cores 4
prompt> set_app_options -name signoff.fix_drc.init_drc_error_db \
  -value signoff_check_drc_run
prompt> signoff_fix_drc
```

Note that the command uses the **-max_cores** setting for both router multithreading and the IC Validator **-dp** setting if and only if the **-max_cores** option is specified alone. The **-max_cores** option has no effect on the IC Validator **-dp** option when it is specified with any other options.

The following example runs the router with one thread and runs IC Validator using distributed processing on eight cores of the local machine by starting the IC Validator run with the **-dp8** option.

```
prompt> set_host_options -num_process 8
prompt> set_app_options -name signoff.fix_drc.init_drc_error_db \
  -value signoff_check_drc_run
prompt> signoff_fix_drc
```

report_host_options(2)
remove_host_options(2)
signoff_check_drc(2)

signoff_fix_isolated_via

Identifies and fixes isolated vias in a design by inserting additional vias in the isolated via region.

SYNTAX

status **signoff_fix_isolated_via**
[-check_only true | false]
[-error_data *errdata_name*]
[-save_design true | false]
[-update_track_fill true | false]
[-track_fill_runset_include_file track_fill_runset_include_file_path]

ARGUMENTS

-check_only true | false

Controls whether to check for isolated via violations only or to check and also fix the violations. By default, this command checks for isolated via violations and fixes the violations.

The default is **false**.

-error_data *errdata_name*

Specifies the name of the error data.

If you do not specify this option, the error data is called *signoff_fix_isolated_via*.err.

-save_design true | false

Specifies to save the design with isolated via fixes automatically. By default, the user needs to run "save_block" after command execution to save the design with the isolated via fixes.

The default is **false**.

-update_track_fill true | false

Specifies to run isolated via fixing after track fill. When this option is set to true, signoff_fix_isolated_via will read existing track fill design, identify isolated vias. Isolated via fixes will only be made in the existing track fill design. The main design will not be touched. By default, the signoff_fix_isolated_via flow will ignore the fill design completely and will make fixes in main design.

You must also specify the track_fill_runset_include_file option when the -update_track_fill is specified.

The default is **false**.

-track_fill_runset_include_file track_fill_runset_include_file_path

Specifies the track fill runset include file. The user can find the track_fill_runset_include_file in track fill run directory. This option is

required when the -update_track_fill is specified.

DESCRIPTION

This command invokes the IC Validator tool using an automatically generated runset to identify and fix isolated vias in a design by inserting additional vias in the isolated via region.

Before you use this command, you must open the design library and design view. By default, the opened design view will be chosen to create isolated via fixes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the command to only check isolated vias in the design view.

```
prompt> signoff_fix_isolated_via \
  -check_only true
```

The following example runs the command to check and fix isolated vias and will save design view with isolated via fixes during the execution of signoff_fix_isolated_via.

```
prompt> signoff_fix_isolated_via \
  -save_design true
```

The following example runs the command to check and fix isolated vias. Furthermore, the command will read track fill design, will identify isolated vias and will create isolated via fixes in track fill design. Please note that with these settings, the main design will not be touched. Also, when you specify -update_track_fill true, you must to specify track_fill_runset_include_file.

```
prompt> signoff_fix_isolated_via \
  -update_track_fill true
  -track_fill_runset_include_file ./user_defined_params.rh
```

signoff_report_metal_density

Reports the metal density and density gradient values.

SYNTAX

status **signoff_report_metal_density**
[-select_layers {*layers*}]
[-coordinates {*list_of_points*}]
[-output {*filename*}]
[-starting_point {*list_of_points*}]

Data Types

layers	collection
list_of_points	list
filename	string

ARGUMENTS

-select_layers {*layers*}

Specifies the routing layers (metal layers) for which to calculate the density and gradient values. The layer names must be the names defined in the technology file.

If you do not specify this option, the command will calculate the density and density gradient values for routing layers in min/max range.

-coordinates {*list_of_points*}

Specifies the rectangular or rectilinear regions in which to calculate the density and gradient values.

To specify each rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

To specify each rectilinear region, use the following syntax to specify the coordinates of the region:

{ {*x y*} {*x y*} {*x y*} {*x y*} ... }

The units of the coordinates are the same as the main library units.

If you do not specify this option, the command calculate the density and gradient values for the entire block.

-output {*filename*}

To specify the name of density and gradient report output in text format. To specify name of the output file, use the following

syntax:

-output filename.txt

If you do not specify this option, the default filename for density value will be "report_metal_density.txt", and for density gradient "gradient_density_report.txt".

-starting_point {*list_of_points*}

By default, starting point is taken as the lower left corner of bounding box of chip-boundary, from where density and gradient window are created. This option is provided so that user can override the starting point.

DESCRIPTION

This command invokes the IC Validator tool with an automatically gener- ated runset to calculate the metal density and density gradient values of the current design. Density calculated is for metal layers only.

EXAMPLES

The following example calculates the metal density and density gradient values for M1 and M3 layers.

```
prompt> set_app_options -name signoff.report_metal_density.run_dir \
  -value my_report_run
prompt> signoff_report_metal_density -select_layers {M1 M3}
```

The following example calculates the metal density and density gradient values for all regions in the rectilinear polygon {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}} .

```
prompt> set_app_options -name signoff.report_metal_density.min_density \
  -value {{M1 20} {M2 15}}
prompt> signoff_report_metal_density \
  -coordinates {{0 0} {100 0} {100 100} {50 100} {50 50} {0 50}}
```

The following example will generate the output density report as "filename.txt" and density gradient report as "filename.txt.gradient".

```
prompt> set_app_options \
  -name signoff.report_metal_density.density_window \
  -value {{M2 30} {M3 40}}
prompt> signoff_report_metal_density -output filename.txt
```

The following example will calculate the metal density and density gradient values from starting point (0, 5).

```
prompt> set_app_options \
  -name signoff.report_metal_density.density_window_step \
  -value {{M3 10} {M4 20}}
prompt> signoff_report_metal_density -starting_point {0 5}
```

sim_assertion_control

Control the behavior of assertions during low power verification.

SYNTAX

status **sim_assertion_control**
[-elements *element_list*]
[-exclude_elements *exclude_list*]
[-domain *domain_name*]
[-model *model_name*]
[-controlling_domain *domain* | -control_expr *boolean_expression*]
[-type *<reset | suspend | kill>*]
[-transitive *[<TRUE | FALSE>]*]

Data Types

element_list list
exclude_list list
model_name string
domain_name string
boolean_expression string

ARGUMENTS

-elements *element_list*

The list of instances or assertions.

-exclude_elements {*exclude_list*}

The list of design elements to which the command does not apply.

-domain *domain_name*

The domain in which to search for assrtions for this command.

-model *model_name*

The model in which to search for assertions.

-controlling_domain *domain_name*

The domain whose primary supply sets simstate controls when the assertion control is active. The DEFAULT controllling domain for each assertion is the domian in which that assertion is contained.

-type *<reset|suspend|kill>*

Specifies the type of assertion control. The default is reset.

-transitive *<TRUE | FALSE>*

Specifies if the command applies to the specified scope or the specified scope and all dependent subtrees.

If *-transitive* is not specified at all or if *-transitive* is specified without a value, the default is *-transitive TRUE*.

DESCRIPTION

The *sim_assertion_control* command provides a mechanism to disable assertions during low power verification. This enables the use of non-power-aware assertions in a power-aware environment. An example is assertions that check against X are typically not valid during power shutoff.

This command is for functional verification only does not have any impact on the implementation tools.

Implementation tool will not parse and check the options and it will not preserve this command in save_upf.

EXAMPLES

The following example selects all assertions in module modA.

```
prompt> sim_assertion_control -model modA  \
     -controlling_domain PD1
```

The following example selects all assertions labeled InstX/Assert1 in the module modA.

```
prompt> sim_assertion_control -model modA  \
     -elements InstX/Assert1
```

SEE ALSO

sim_corruption_control(2)

sim_corruption_control

Provides the ability to disable the corruptions of a specific set of design elements or types of design elements.

SYNTAX

status **sim_corruption_control**
-type <real | integer | seq | comb | port | process>
[-elements *element_list*]
[-exclude_elements *exclude_list*]
[-model *model_name*]
[-domain *domain_name*]
[-transitive *[<TRUE | FALSE>]*]

Data Types

element_list list
exclude_list list
model_name string
domain_name string

ARGUMENTS

-type <real | integer | seq | comb | port | process>

Specifies the type of design elements to which this command applies.

-elements *element_list*

The list of design elements to which the corruption control applies.

-exclude_elements {*exclude_list*}

The list of design elements to which the command does not apply.

-domain *domain_name*

The domain in which the command will apply.

-model *model_name*

The hdl model to which the command will apply.

-transitive *<TRUE | FALSE>*

Specifies if the command applies to the specified scope or the specified scope and all dependent subtrees.

If *-transitive* is not specified at all or if *-transitive* is specified without a value, the default is -transitive TRUE.

DESCRIPTION

This command turns off corruption semantics for specific set of design elements or type of design elements. The intent of this command is to allow behavioral modules to operate properly in a low power environment. For example, many real number modules require special corruption behavior to operate correctly.

This command is for functional verification only does not have any impact on the implementation tools.

Implementation tool will not parse and check the options and it will not preserve this command in save_upf.

EXAMPLES

The following example selects all real nets that start with L but excludes those that start with L1.

```
prompt> sim_corruption_control -type real \
     -elements [find_objects . -pattern "L*" -object_type net]
     -exclude_elements [find_objects . -pattern "L1*" -object_type net]
```

The following example selects integers in modules that belong to domain PD1.

```
prompt> sim_corruption_control -type integer \
     -domain PD1
```

SEE ALSO

set_simstate_behavior(2)

sim_replay_control

Specify initial blocks to be replayed when a domain powers up.

SYNTAX

status **sim_replay_control**
[-elements *element_list*]
[-exclude_elements *exclude_list*]
[-model *model_name*]
[-domain *domain_name*]
[-controlling_domain *domain*]
[-transitive *[<TRUE | FALSE>]*]

Data Types

element_list list
exclude_list list
model_name string
domain_name string

ARGUMENTS

-elements *element_list*

The list of intial blocks and hierarchical instances to which the command applies.

-exclude_elements {*exclude_list*}

The list of design elements to which the command does not apply.

-model *model_name*

The module in which to search for initial blocks.

-domain *domain_name*

The domain in which to search for initial blocks.

-controlling_domain *domain_name*

The domain whose primary supply set's simstate controls when the initial blocks is replayed. The DEFAULT controllling domain for each initial block is the domian in which that initial block is contained.

-transitive *<TRUE | FALSE>*

Specifies if the command applies to the specified scope or the specified scope and all dependent subtrees.

If *-transitive* is not specified at all or if *-transitive* is specified without a value, the default is *-transitive TRUE*.

DESCRIPTION

The *sim_replay_control* command specifies the action to be taken on the selected elements during simulation or formal verification when the simstate of the related supply set transitions from *CORRUPT* to *NORMAL* after time 0. The *sim_replay_control* allows specific initial blocks to be replayed when a domain powers up. Each initial block targeted by this command will be replayed when the primary supply set of the domain that contains the initial block transitions into the *NORMAL* state.

This command is for functional verification only does not have any impact on the implementation tools.

Implementation tool will not parse and check the options and it will not preserve this command in save_upf.

EXAMPLES

The following example selects all initial blocks whose label starts with L but excludes those blocks whose label starts with L1.

```
prompt> sim_replay_control \
     -elements [find_objects . -pattern "L*" -object_type process] \
     -exclude_elements [find_objects . -pattern "L1*" -object_type process]
```

The following example selects all initial blocks inside the modules that belongs to domain PD1.

```
prompt> sim_replay_control -domain PD1
```

SEE ALSO

sim_corruption_control(2)
sim_assertion_control(2)

size_cell

Rebinds leaf cells to a new library cell that has the required drive strength (or other properties).

SYNTAX

collection **size_cell**
cell_list
-lib_cell *lib_cell* | *lib_cell*
[-max_distance_to_spare_cell *length* | -not_spare_cell_aware]

Data Types

cell_list	list
lib_cell	collection
length	float

ARGUMENTS

cell_list

Specifies the leaf cell to be rebound. Each cell must be in scope (at or below the current instance).

-lib_cell *lib_cell*

Specifies the library cell objects to which the specified cell is to be bound. In this case, the object is either a named library cell or a library cell collection. This is a required opton. The library cells specified must be logical equivalent to the library cell which will be rebound.

lib_cell

This positional option is exactly equivalent to **-lib_cell**. And it is mutual exclusive with **-lib_cell**.

-max_distance_to_spare_cell *length*

Specifies the maximum distance between eco cell and spare cell in freeze-silicon mode. If option is not specified, command will use the default value (5x site heights). If there is no valid spare cell found within this distance, command will not do the cell sizing and report a error message to user. The resized eco cell will be placed to overlap the matched spare cell and a new attribute "fs_mapped_cell_name" will be used to record the mapping relationship in both eco cell and spare cell. The feature of spare cell aware only works in freeze-silicon mode currently. This option is mutually exclusive with **-not_spare_cell_aware**.

-not_spare_cell_aware

Disable the feature of spare cell aware in freeze-silicon mode. By default, this option is off. The feature of spare cell aware only works in freeze-silicon mode. This option is mutually exclusive with **-max_distance_to_spare_cell**.

DESCRIPTION

The **size_cell** command changes the drive strength (or other properties) of a leaf cell by rebinding it to a new library cell that has the required properties. Like all other netlist editing commands, for **size_cell** to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. **size_cell** returns the collection of cells sized if successful and a NULL string if unsuccessful. Each cell in *cell_list* must be in scope; that is, at or below the current instance.

The **size_cell** command also supports the spare cell aware feature in freeze-silicon mode.

The *lib_cell* that is being swapped in must conform to the following restrictions:

- *lib_cell* must be functionally compatible with the current library cell to which the cells in *cell_list* are bound.
- *lib_cell* cannot be the same as the current library cell of any of the cells in *cell_list*.
- *lib_cell* must have the same pin count and pin directions as the current library cell of the cells in *cell_list*. **size_cell** will match *lib_cell* by its pin numbers.

  The **size_cell** command is for leaf cells only. **size_cell** is optimized for incremental timing and does not cause a full timing update.

  This command support editing a verilog module in the module aspect, through **edit_module**.

  This command honors design.eco_freeze_silicon_mode. When this app option is true, cell to size will be marked as spare cell and renamed by adding _Spare post-fix, while a new cell of the specified lib cell will be created with attribute is_fs_eco_add being true. This new cell will inherit the name and connection of the cell to size.

Don't touch cells and don't use library cells

When app option *eco.size_cell.honor_dont_touch* is set to true, cells with dont_touch attribute are skipped. When app option *eco.size_cell.honor_dont_use* is set to true, **size_cell** checks if the new library cell has true value in dont_use attriute. **size_cell** errors out if the library cell has dont_use attribute set to true.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, an attempt to size a cell by a funtionally compatible library cell with the same pin count.

```
prompt> size_cell o_reg1 -lib_cell class/FD2P
Information: Sizing cell 'o_reg1' with lib cell 'class/FD2P'
{o_req1}
```

Editing a verilog module in the module aspect:

```
prompt> edit_module h1m {size_cell -lib_cell tcbn90ghvt/BUFFHVTD0 u1}
```

SEE ALSO

get_libs(2)
get_lib_cells(2)

eco.size_cell.honor_dont_touch(3)
eco.size_cell.honor_dont_use(3)

sizeof_collection

Returns the number of objects in a collection.

SYNTAX

int **sizeof_collection** [-categorize]
collection1

Data Types

collection1 collection

ARGUMENTS

collection1

Specifies the collection for which to get the number of objects. If the empty collection (empty string) is used for the *collection1* argument, the command returns 0.

-categorize

Return 0, 1, 2 indicating if the collection has 1, or or more than 1 item.

DESCRIPTION

The **sizeof_collection** command is an efficient mechanism for determining the number of objects in a collection.

EXAMPLES

The following example from PrimeTime shows a simple way to find out how many objects matched a particular pattern and filter in the **get_cells** command.

```
pt_shell> echo "Number of hierarchical cells: \
?           [sizeof_collection \
?             [filter_collection [get_cells * -hier \
?               "is_hierarchical == true"]]]"
Number of hierarchical cells is: 10
```

The following example from PrimeTime shows what happens when the argument for the **sizeof_collection** command results in an empty collection.

```
pt_shell> set s1 [get_cells *]
{"u1", "u2", "u3"}
pt_shell> set ssize [filter_collection $s1 "area < 0"]
pt_shell> echo "Cells with area < 0: [sizeof_collection $ssize]"
Cells with area < 0: 0
pt_shell> unset s1
```

SEE ALSO

collections(2)
filter_collection(2)

snap_cells_to_block_grid

Snaps the specified block cell instances to the block grid.

SYNTAX

status **snap_cells_to_block_grid**
-designs *design_list* |
-grid *grid* |
-cells *cell_list*

Data Types

design_list collection
grid block_grid_object
cell_list collection

ARGUMENTS

-designs *design_list*

Specifies the list of block reference designs whose instances are to be snapped to the associated block grid. This option is mutually exclusive with the **-grid** and **-cells** options, however, you must specify at least one of **-designs**, **-grid**, or **-cells**.

-grid *grid*

Specifies the block grid.

If this option is specified together with the **-cells** option, the user-specified cell instances are snapped to the specified block grid, regardless of which block grid the cells are associated with.

If this option is specified without **-cells**, all block cell instances whose reference design is associated with this block grid are snapped to the block grid. This option is mutually exclusive with the **-designs** option.

You must specify at least one of **-designs**, **-grid**, or **-cells**.

-cells *cell_list*

Specifies the cell instances to be snapped.

If this option is specified together with the **-grid** option, the cell instances are snapped to the specified block grid, regardless of which block grid the cells are actually associated with. If the specified block grid is not associated with a cell, the cell's origin is snapped to the grid. If the specified grid is the one that the cell is associated with, the snap-point setting on the cell's reference design would be honored.

If this option is specified without **-grid**, the cell instances are snapped to their associated block grids, respectively. And the snap-point setting on the cell's reference design would be honored.

You must specify at least one of **-designs**, **-grid**, or **-cells**.

DESCRIPTION

This command snaps the specified block cell instances to the block grid.

If you specify certain cell instances to snap to a block grid that are different from the block grid that the cell is associated with, you might see an error when running the *report_grids* command.

EXAMPLES

The following example finds all instances of the design BLK1 in the current design and snap them to the block grid associated with BLK1.

```
prompt> snap_cells_to_block_grid -designs BLK1
```

The following example uses the *grid* argument. The tool finds all the block reference designs associated with the specified block grid, then finds all the instantiations of the block references in the current design and snap them to the block grid.

```
prompt> snap_cells_to_block_grid -grid [get_grids gr1]
```

The following example uses the **-cells** argument. The tool snaps all the specified cell instances to their respective block grids if the cell has an associated block grid.

```
prompt> snap_cells_to_block_grid -cells [get_cells A1/U1]
```

The following example uses both the **-cells** and **-grid** options. The tool snaps all the specified cell instances' origin to the given block grid.

```
prompt> snap_cells_to_block_grid -cells [get_cells B1/M1] -grid gr1
```

snap_object_shapes

Snap the edges if specified object to given grid. retained.

SYNTAX

status **snap_object_shapes**
-grid *grid*
[-left *left_mode*]
[-right *right_mode*]
[-bottom *bottom_mode*]
[-top *top_mode*]
[-edge_number *integer*]
[-edge_policy keep | increase | decrease | nearest]
[*object_list*]

Data Types

grid string
left_mode string
right_mode string
bottom__mode string
top_mode string
object_list collection

ARGUMENTS

object_list

Collection or selection set containing objects to snap. If this option is not specified, the global selection set is used.

-grid *grid*

Specifies the block or user grid to snap object edges.

-left *left_mode*

Specifies snapping policy for all left edges. Valid values are **keep**, **increase**, **decrease**, **nearest**, **keep_width**, **increase_width**, **decrease_width**, **nearest_width**. The X value of left edges could either be preserved, increase, decreased or rounded to nearest grid. Alternatively the X value of left edges might be set to preserve, increase, decrease or round the width to nearest grid.

-right *right_mode*

Specifies snapping policy for all right edges. Valid values are **keep**, **increase**, **decrease**, **nearest**, **keep_width**, **increase_width**, **decrease_width**, **nearest_width**. The X value of right edges could either be preserved, increase, decreased, rounded to nearest grid. Alternatively the X value of right edges might be set to preserve, increase, decrease or round the width to nearest grid.

-bottom ***bottom_mode***

Specifies snapping policy for all bottom edges. Valid values are **keep**, **increase**, **decrease**, **nearest**, **keep_width**, **increase_width**, **decrease_width**, **nearest_width**. The Y value of bottom edges could either be preserved, increase, decreased or rounded to nearest grid. Alternatively the Y value of bottom edges might be set to preserve, increase, decrease or round the height to nearest grid.

-top ***top_mode***

Specifies snapping policy for all top edges. Valid values are **keep**, **increase**, **decrease**, **nearest**, **keep_width**, **increase_width**, **decrease_width**, **nearest_width**. The Y value of top edges could either be preserved, increase, decreased, rounded to nearest grid. Alternatively the Y value of top edges might be set to preserve, increase, decrease or round the height to nearest grid.

-edge_number ***integer***

Specifies edge number to snap. The edge numbering starts with 1 (left edge) and going clockwise. The option is mutually exclusive with -left, -right, -bottom and -top.

-edge_policy keep | increase | decrease | nearest

Specifies snapping policy for given edge number.

DESCRIPTION

This command snaps object's sides to given grid by specified snapping policies.

Snapping is not performed if object is locked and global settings -ignore_locked is not enabled. Please see **set_edit_setting** for details.

EXAMPLES

The following example modifies currently selected object so that left/bottom edges are snapped to nearest grid and the width/height are preserved.

```
prompt> snap_object_shapes -grid my_grid -left nearest \
  -bottom nearest -right keep_width -top keep_height

prompt> snap_object_shapes -grid my_grid -edge_number 3 \
  -edge_policy nearest
```

The alternative syntax uses collection to specify objects.

```
prompt> snap_object_shapes [get_selection] -grid my_grid -left nearest
```

SEE ALSO

snap_objects

Snaps specified objects to the default snap type. An object is snapped onto the nearest position that satisfies the snapping constraint.

SYNTAX

status **snap_objects**
[*object_list*]

Data Types

object_list collection or selection

ARGUMENTS

object_list

Specifies the collection or selection set containing objects to snap. If this option is not specified, the global selection set is used.

DESCRIPTION

This command snaps the specified objects to the default snap types according to the object types of individual arguments.

The default snap type can be retrieved with the *get_snap_setting* command. Set the snap settings with the *set_snap_setting* command.

EXAMPLES

The following example snaps the cell "abc" to the nearest site row slot.

```
prompt> get_snap_setting -class std_cell
row_site
prompt> change_selection [get_cells "abc"]
prompt> snap_objects
```

The alternative syntax uses collection to specify objects.

```
prompt> snap_objects [get_cells "abc"]
```

get_edit_setting(2)

sort_collection

Sorts a collection based on one or more attributes, resulting in a new, sorted collection. The sort is ascending by default.

SYNTAX

collection **sort_collection**
  [-descending]
  [-dictionary]
  [-limit *value_count*]
  collection
  criteria

int *value_count*
string *collection*
list *criteria*

ARGUMENTS

-descending

Indicates that the collection is to be sorted in reverse order. By default, the sort proceeds in ascending order.

-dictionary

Sort strings dictionary order. For example "a30" would come after "a4".

-limit *value_count*

Only return the first unique values from the primary sort key.

collection

Specifies the collection to be sorted.

criteria

Specifies a list of one or more application or user-defined attributes to use as sort keys.

DESCRIPTION

You can use the **sort_collection** command to order the objects in a collection based on one or more attributes. For example, to get a collection of leaf cells increasing alphabetically, followed by hierarchical cells increasing alphabetically, sort the collection of cells using the *is_hierarchical* and *full_name* attributes as *criteria*.

The *criteria* can specify an attribute on another object. The other object must be available as an attribute on this object. For example, if you had a collection of net shapes, you can sort the objects by net using *owner_net.name* for instance.

In an ascending sort, Boolean attributes are sorted with those objects first that have the attribute set to *false*, followed by the objects that have the attribute set to *true*. In the case of a sparse attribute, objects that have the attribute come first, followed by the objects that do not have the attribute.

Sorts are ascending by default. You can specify ascending or descending order on a per attribute basis. You do this by adding a suffix to the attribute name in the sort criteria. The '-' means sort descending and '+' means sort ascending. If no suffix is specified than the default order ascending unless the *-descending* option is used.

The *-limit* option limits the size of the returned collection by choosing the first unique values from the primary sort criteria. For example using a limit of 1 will return all the objects with the smallest (or biggest if descending) value according to the primary sort key.

EXAMPLES

The following example from PrimeTime sorts a collection of cells based on hierarchy, and adds a second key to list them alphabetically. In this example, cells i1, i2 and i10 are hierarchical, and o1 and o2 are leaf cells. Because the *is_hierarchical* attribute is a Boolean attribute, those objects with the attribute set to *false* are listed first in the sorted collection.

```
pt_shell> set zc [get_cells {o2 i2 o1 i1 i10}]
{"o1" "i2" "o1" "i1" "i10"}
pt_shell> set zsort [sort_collection $zc {is_hierarchical full_name}]
{"o1" "o2","i1" "i10" "i2"}
pt_shell> set zsort [sort_collection -dictionary $zc {is_hierarchical full_name}]
{"o1" "o2" "i1" "i2", "i10"}
pt_shell> set zsort [sort_collection -dictionary $zc {area- full_name}]
{"i10" "o1" "o2" "i1" "i2" "i10"}
pt_shell> set zsort [sort_collection -dictionary $zc {area- full_name} -limit 1]
{"i10" "o1"}
```

SEE ALSO

collections(2)

source

Read a file and evaluate it as a Tcl script.

SYNTAX

string **source** [-echo] [-verbose] [-continue_on_error] *file*

string *file*

ARGUMENTS

-echo

Echoes each command as it is executed. Note that this option is a non-standard extension to Tcl.

-verbose

Displays the result of each command executed. Note that error messages are displayed regardless. Also note that this option is a non-standard extension to Tcl.

-continue_on_error

Don't stop script on errors. Similar to setting the shell variable sh_continue_on_error to true, but only applies to this particular script.

file

Script file to read.

DESCRIPTION

The **source** command takes the contents of the specified *file* and passes it to the command interpreter as a text script. The result of the source command is the result of the last command executed from the file. If an error occurs in evaluating the contents of the script, then the **source** command returns that error. If a return command is invoked from within the file, the remainder of the file is skipped and the source command returns normally with the result from the return command.

By default, source works quietly, like UNIX. It is possible to get various other intermediate information from the source command using the **-echo** and **-verbose** options. The **-echo** option echoes each command as it appears in the script. The **-verbose** option echoes the result of each command after execution.

NOTE: To emulate the behavior of the dc_shell **include** command, use both of these options.

The file name can be a fully expanded file name and can begin with a tilde. Under normal circumstances, the file is searched for

based only on what you typed. However, if the system variable sh_source_uses_search_path is set to "true", the file is searched for based on the path established with the search_path variable.

The **source** command supports several file formats. The *file* can be a simple ascii script file, an ascii script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler. The **-echo** and **-verbose** options are ignored for gzip formatted files.

EXAMPLES

This example reads in a script of aliases:

```
prompt> source -echo aliases.tcl
alias q quit
alias hv {help -verbose}
alias include {source -echo -verbose}
prompt>
```

split_clock_cells

Splits cells in the clock tree to fix DRC violations.

SYNTAX

status **split_clock_cells**
-cells *cell_list*
-loads *pin_port_list*

Data Types

cell_list collection
pin_port_list collection

ARGUMENTS

-cells *cell_list*

This option defines the list of cells that should get split in case their outputs on the clock network violate one of the DRC types. Either this option or the **-loads** option needs to be specified but they cannot be used together.

-loads *pin_port_list*

This option takes a list of pin or port collections and allows to define an explicit splitting of clock cells. All provided pins or ports in a collection need to have the same leaf driver. Each collection of pins or ports will get its own driver by splittingg the original driver. Either this option or the **-cells** option needs to be specified but they cannot be used together.

DESCRIPTION

This command can be used in two different modes. If the **-cells** option is specified then the command is used to split cells in the clock tree whose outputs violate DRC constraints. A typical application is to split integrated clock gates that drive a large amount of cells. Supported DRC constraints are: max transition, max capacitance, max net length, and max fanout. To fix max transition violations on the cell outputs and to avoid over-splitting of cells the input transition times of the cell are bounded by any given max transition constraint (coming either from the library or is set using the *set_max_transition* command).

The second mode of operation is enabled when the **-loads** option is given. Each collection of the given list of collections defines the fanout of a new or the original cell. If the common driving cell has a larger fanout than the specified collections, the remaining pins or ports of the fanout will become the fanout of one exclusive cell.

The cloned cells are named according to the following scheme: <old cell name>_split_<unique number>.

Splitting honors **set_dont_touch** constraints, **set_size_only** constraints, and fixed placement attributes on cells. Splitting is not

performed in case ports would have to be punched on power domain boundaries or frozen cells as defined by the **set_freeze_ports** command. Level-shifters and isolation cells are not split.

Splitting copies timing constraints, UPF constraints, user attributes, and clock balance points on cells as needed. For example, if a false path is defined through some of the split clock logic, the false path constraint is duplicated to all of the split cells as well. Net-based NDRs will get copied on the newly created output nets. The cloned cells are placed in the same logical hierarchy and voltage area as the original cell.

This command can be run before or after the *synthesize_clock_trees* command. In order to get a reasonable estimate of the fanout load of a cell all output nets of the specified cells are globally routed in case the nets have not been routed yet.

Additional verbosity output like assumed input transition times or detected constraints can be enabled by setting the app option *cts.common.verbose* to 1 or 5.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example splits two cells in case their outputs violate DRC constraints.

```
prompt> split_clock_cells -cells [get_cells {u1 u2}]
```

The following example explicitly splits the driver of the given collections of pins. Assume the output Y of cell c1 drives the load pins a1, a2, a3, and a4. Similarly, output Y of cell c2 drives the load pins b1, b2, b3, and b4. Then the following command execution results in two new clones of cell c1. One clone drives only a1, the second clone drives a2, and the original cell c1 drives a3 and a4. Similarly, it will result one new clone of cell c2. New clone drives b1 and b2, and the original cell c2 drives b3 and b4, for example:

```
prompt> set p1 [get_pins a1]
prompt> set p2 [get_pins a2]
prompt> set p3 [get_pins {a3 a4}]
prompt> set p4 [get_pins {b1 b2}]
prompt> set p5 [get_pins {b3 b4}]
prompt> split_clock_cells -loads [list $p1 $p2 $p3 $p4 $p5]
```

split_constraints

Partitions chip-level constraints into separate top-level and block-level constraints.

SYNTAX

int **split_constraints**
[-modes *mode_list*]
[-corners *corner_list*]
[-design_subblocks *block_module_names*]
[-hier_abstract_subblocks *block_module_names*]
[-output *dir_name*]
[-force]
[-nosplit]
[-compress gzip | none]
[-sdc_only | -upf_only]
[-internal_percent *percent_list*]
[-feedthrough_percent *percent_list*]
[-logic_depth]
[-ignore_repeaters]

Data Types

mode_list list
corner_list list
block_module_names list
dir_name string
percent_list\P *list*

ARGUMENTS

-modes *mode_list*

Specifies the modes to write. If this option is not specified, the command writes all modes.

-corners *corner_list*

Specifies the corners to write. If this option is not specified, the command writes all corners.

-design_subblocks *block_module_names*

Retain all the internal constraints of subblocks in the budget. By default, when generating split constraints, the tool assumes that any subblock of a block will be represented by a single-level abstract. So the budget will "cut out" constraints that are not visible on the boundary of the abstract.

You can use the **plan.budget.all_design_subblocks** application option to automatically set this option for all blocks.

-hier_abstract_subblocks *block_module_names*

Retain some extra internal constraints of subblocks in the budget. By default, when generating split constraints, the tool assumes that any subblock of a block will be represented by a single-level abstract. So the budget will "cut out" constraints that are not visible on the boundary of the abstract. With this option, additional block-internal constraints will be kept in places that are necessary for correctly timing hierarchical abstracts.

-output *dir_name*

Specifies the name of the directory in which to write the constraint files and scripts. If this option is not specified, the command writes the files to the *./split* directory.

-force

Overwrites the output directory if it exists. The output directory is specified by the **-output** option. If this option is not specified and the output directory already exists, the command issues an error message and exits.

-nosplit

Writes out long constraint command lines, even if the line length is greater than 80 columns. Use this option to simplify post-processing of the output constraint files or when comparing the constraint files by using the UNIX **diff** command. If this option is not specified, the command breaks long constraint command lines near column 80 and inserts a line continuation character (\).

-compress gzip | none

Specifies the type of compression to use on the output file. If this option is not specified, the command skips compression and writes plain text files.

-sdc_only

Splits only the SDC file. If this option is not specified, the command splits both the SDC and UPF files.

-upf_only

Splits only the UPF file. If this option is not specified, the command splits both the SDC and UPF files.

-internal_percent *percent_list*

Specifies the input and output delay percentage which will serve as the internal block delay percentage and used to calculate the delay for the boundary pins of the block.

-feedthrough_percent *percent_list*

Specifies the input and output delay percentage which will be used to calculate the delay value for feedthrough pins of the block. If this option is not specified the feedthrough pins will be budgetted at 50% of the available clock cycle.

-logic_depth

Specifies that the delay for the boundary pins of the block will be calculated according to logic depth.

-ignore_repeaters

Specifies that the delay for the boundary pins of the block will be calculated accordng to logic depth by considering odd or even number of buffers and inverters if any. This option should only be specified along with -logic_depth option.

DESCRIPTION

This command converts full-chip constraints into top-level and block-level constraints for a hierarchical design. Do the following steps to prepare your design before running the **split_constraints** command.

- Load the full chip netlist without abstracts
- For multivoltage designs, load the full chip UPF and run **commit_upf**
- Load the full-chip SDC
- Declare the blocks with **set_budget_options -add_blocks**
- Run **split_constraints**

For each block specified with **set_budget_options -add_blocks**, the **split_constraints** command creates a separate subdirectory under the directory specified by the **-output** option. The name of the subdirectory corresponds to the name of a block. Additionally, the command creates a directory that corresponds to the top-level design with the name *{design_name}*.

The **split_constraints** command writes constraint files in each block directory, similar to those generated by the **write_script** command. The *{design_name}* directory contains the constraints for the top-level, with the block constraints stripped out.

Inside the directory, mode-specific information is written to files named mode*_{mode_name}*.tcl, and corner-specific information is written to files named corner*_{corner_name}*.tcl. Mode- and corner-independent information is written to the design.tcl file. The top.tcl file sources all other constraint files. You can source the top.tcl file to load all necessary constraints for a block or top-level.

Memory Considerations

The **split_constraints** command requires the full netlist view of your chip. You cannot use abstracts to generate constraints with the **split_constraints** command. For large chips, the full netlist view can consume a significant amount of memory. The **split_constraints** command is specifically designed to use less memory than other commands that process design constraints. In particular, **split_constraints** processes constraints without calculating or propagating delay values and significantly reduces memory overhead.

To preserve the memory advantage of **split_constraints**, you should not trigger a timing update with the **report_timing**, **report_constraint**, or **report_qor** commands while the full-chip netlist is loaded. After the **split_constraints** command completes, you can control memory usage by using abstracts in your design.

Multiply Instantiated Blocks (MIB)

The **split_constraints** command has a limited capacity to handle multiply-instantiated blocks, and creates a single combined set of constraints for each block. Here is a summary of how conflicts are handled when the top-level constraints differ across instances:

- If constant values propagate from the top level to the boundary of the block, and the same constant feeds every block instance, then the constant is applied in the split constraints for the block. This process is repeated in the **write_budgets** command.
- If constant values propagate from the top level to the boundary of the block, but the same constant is not present for every block instance, then a warning is issued and the constant is not applied in the split constraints for the block.
- If timing exceptions such as **set_false_path** or **set_multicycle_path** straddle the boundary of a multiply-instantiated instance, the exceptions are pushed down using dedicated virtual clocks on the block ports. The virtual clocks keep the timing paths and corresponding constraints separate from each other when the block is timed. This process is repeated in the **write_budgets** command.
- All other block constraints, including the clocks and internal timing exceptions, will be pushed down to the block based on the first instance of the MIB. The other instances will be ignored. So you should be careful to constrain the "core" of all of your blocks in the same way.

Based on the restrictions above, it is required that the core of every instance of an MIB operate identically. The instances should be driven by the identical clocks in identical places. And internal constraints of the block should be identical. If they are not, the

split constraints will not faithfully reproduce the behavior of all of your MIB instances. Note that the top-level clocks which feed the blocks do not need to have identical names, only identical waveform. Later in the flow, the **set_block_to_top_map** command can be used to adapt to the mismatch of names.

There might be cases where you want instances of an MIB block to work in differing modes. For example, one MIB instance might be clocked with a fast clock and another with a slower clock. Or perhaps you want the instances to have different constant values to configure the block inputs. You can accomplish this by using the **set_block_to_top_map** command before running **split_constraints**. The syntax would look something like the following:

```
prompt> set_block_to_top_map -block inst1 -mode {fast_clock func}
prompt> set_block_to_top_map -block inst2 -mode {slow_clock func}
```

By default, **split_constraints** creates block constraints with a mode setting that matches the top level. But in this case, the block constraints will be generated with two modes (fast_clock and slow_clock). And the constraints for inst1 and inst2 will be kept completely separate in the block. No merging will occur.

Hierarchical Splitting

The **split_constraints** and **write_budgets** commands have advanced options that allow you control how the boundaries between a logical or physical hierarchy are handled for timing. This section first describes the default behavior of **split_constraints**, then discusses the variants of that behavior. For the purpose of discussion, assume a design with three block levels: top, mid, and bot. Everything except the top must be declared as budget blocks by using:

```
prompt> set_budget_options -add_blocks {mid mid/bot}
```

The **split_constraints** works on each block declared in the **set_budget_options** statement. Constraints are written to characterize the timing paths and clocks contained in the block, and constraints are written to characterize timing paths the enter or pass through any nested blocks.

Constraints are not written for timing paths that are fully contained in the "core" of nested blocks. For example, the constraints written for block "mid" will include everything that applies to mid itself *and* constraints for all timing paths that cross between mid and bot. But by default, constraints that apply to paths in the core of bot are not included in the split constraints for mid. Boundary constraints for the input and output ports for mid (for paths that cross from top to mid) are also *not* included by **split_constraints**. The boundary constraints come for paths at input and output ports of a block come from the **write_budgets** command.

There are two command line options of the **split_constraints** command that you might need to specify to modify which constraints are kept for a block. As the previous paragraph describes, constraints are not written for timing paths that are fully contained in the "core" of nested blocks. But you can override this default.

- You can use the *-design_subblocks* option to specify that nested modules in a design hierarchy will not be abstracted when they are used in their parent context. For example, if you specify "mid" as a design_sublock, then the split constraints written for "top" will also include *all* of the constraints for mid.
- You can use the *-hier_abstract_subblocks* option to specify that nested modules will be represented as a hierarchical abstract. When creating split constraints for a hierarchical abstract all constraints which apply to the boundary of that abstract will be included. Additionally constraints are also maintained along any timing paths that connect to hierarchically nested abstracts in the levels below. For example, if you specify "mid" as a hier_abstract_subblock, then the split constraints written for "top" will also include all of the boundary constraints for mid *and* all of the boundary constraints for bot.

In a multilevel hierarchy, the *-design_subblocks* and *-hier_abstract_subblocks* options may force constraints to cover many levels at one time. For example, if you are generating constraints for "top", and block "mid" is labeled as a design_subblock, then the constraints for top must include boundary constraints for "bot". In the following example, the generated constraints for the top level include all paths at the top, all paths in mid, and the boundary paths of bot.

```
prompt> split_constraints -design_subblocks mid
```

Splitting Clock Latencies

By default, the **split_constraints** command does not attempt to apportion clock latencies across blocks. Clock latencies are

pushed from the chip level down to each block, without change. For example, if the source clock latency of clock CLK1 is 2 at the top level, the source clock latency will still be 2 at the port boundary in the split constraints for each block.

You can use the **plan.budget.split_latencies** app option to cause the **split_constraints** command to reapportion and/or redefine clock latencies at block boundaries. This way you can adjust both the source latency and network latency seen during the synthesis of individual blocks.

Use the **-early_latency**, **-late_latency**, **-source**, **-early_dynamic**, and **-late_dynamic** options of **set_latency_budget_constraints** to control how latencies will be split.

For more details, see the **plan.budget.split_latencies** man page.

Multicorner-Multimode Support

By default, this command works on all scenarios. To specify different scenarios, use the **-corners** and **-modes** options.

EXAMPLES

The following example writes constraints for all blocks to the split_cons directory.

```
prompt> split_constraints -output split_cons
```

The following example selects values for splitting clock latencies to be used by split_constraints.

```
prompt> set_latency_budget_constraints -clock CLK1 \
        -early_latency 0.50 -late_latency 0.60 -default
prompt> set_latency_budget_constraints -clock CLK1:B1 -source \
        -early_latency 0.42 -late_latency 0.50 -default
prompt> set_app_options -name plan.budget.split_latencies -value prects
prompt> split_constraints
```

split_fanout

Reduces the load on a net by inserting repeater cells. The command supports two modes: add a repeater cell on the subset of loads crossing different hierarchy, or insert a repeater cell to maintain the fanout count of driven loads is equal to or less than the maximum specified fanout.

SYNTAX

status **split_fanout**
[-driver *pin_port* | -net *net*]
[-hierarchy *hierarchy* | -on_route]
[-loads *pin_ports* | -max_fanout *number*]
-lib_cell *repeater_lib_cell*
[-respect_blockages]
[-max_distance_for_incomplete_route *length*]
[-net_prefix *prefix*]
[-cell_prefix *prefix*]

Data Types

pin_port	list
net	list
hierarchy	string
pin_ports	list
number	integer
repeater_lib_cell	string
length	float
prefix	string

ARGUMENTS

-driver *pin_port*

Specifies the driver on which to insert a repeater cell.

-net *net*

Specifies the net on which to insert a repeater cell. The **-net** option is mutually exclusive with the **-driver** option, only one of them can be specified.

-on_route

Enables on-route buffering by inserting buffers based on routing topology instead of logical connectivity. The **-hierarchy** option is mutually exclusive with the **-on_route** option, only one of them can be specified. Neither option is required. If the **-on_route** and **-loads** are used, all the loads must share the same net through the entire logical hierarchy and the buffer is added at the first common branch of routes. All the specified loads must have the same common branch of route data and no other loads can exist

under the same common branch. If **-on_route** is used, either **-driver** or -net can be used.

-loads ***pin_ports***

Specifies the loads on which to add repeater cells. The **-loads** option is required if the **-max_fanout** option is not used.

-max_fanout ***number***

Enables manual maximum fanout violation fixing based on input number. The number must be equal or greater than 2. If **-on_route** is used, the repeater is added based on the route data. Otherwise, the repeater is added based on the logical connectivity. The **-max_fanout** option is mutually exclusive with **-loads**, only one of them can be specified.

-max_distance_for_incomplete_route ***length***

Specifies a search distance for incomplete routes from the pin's terminal. This option is used to support the incompletely route nets. The default length value of **-max_distance_for_incomplete_route** is one repeater height. The net can be routed incompletely, but all route segments must be fully interconnected and only one wire within search distance can exist from each untouched load pin.

-hierarchy ***hierarchy***

Specifies the hierarchy to use when inserting repeater cells. This option can be used only when **-loads** is used. The **-hierarchy** option is mutually exclusive with **-on_route**, only one of them can be specified, but neither of them is required.

If **-hierarchy** is not specified, all specified loads must be connected to the same connection. Otherwise, the tool issues an error message.

-respect_blockages

Specifies that no repeater should be added inside a placement blockage, soft macro or hard macro. If the repeater is inside the blockage, the location to use when adding repeater cells will be moved to the new location toward the driver direction without overlapping the blockage. If the new location cannot be meet this requirement, an error message will be issued. You must specify the **-respect_blockages** together with the **-on_route** option.

-lib_cell ***repeater_lib_cell***

Specifies the library cell object to use as a buffer. If the specified library cell is inverting, an inverter pair is inserted instead of a buffer. Inverter pair cannot be used with the **-on_route** or **-max_fanout** option. This option is required.

-net_prefix ***prefix***

Specifies the prefix to use for new nets that are created when repeaters are inserted in the netlist.

By default, the command uses "eco_net" as the prefix.

-cell_prefix ***prefix***

Specifies the prefix to use for new repeater cells that are inserted in the netlist.

By default, the command uses "eco_cell" as the prefix.

DESCRIPTION

The **split_fanout** command has two features. The **-loads** option provides a way to add repeater on the subset of loads crossing different hierarchy. The **-max_fanout count** option inserts repeater cells to maintain the fanout count of driven loads is equal to or less than count. Port punching might be needed if the given loads are in a different logic hierarchy if **-loads** is used. If **-max_fanout** is used, the port punching might be needed if the physical topology and logical hierarchy are inconsistent.

If **-loads** is used without **-on_route**, the buffer is added at the center of the given loads. If both **-loads** and **-on_route** are specified, the buffer is added at the first common branch of routes.

If an inverting library cell is specified by **-lib_cell**, the **-on_route** and **-max_fanout** options cannot be used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example inserts a buffer at the top level, and connects the driver dc1/ZN to the input pin of buffer. Port h3/enet and net h3/enet are created to connect the output pin of buffer to the loads {h3/lc1_2/I lc1_1/I}.

```
prompt> all_connected -leaf [get_nets -of dc1/ZN]
{dc1/ZN lc1_1/I h3/lc1_4/I h3/lc1_3/I h3/lc1_2/I}

prompt> split_fanout -driver dc1/ZN -loads {h3/lc1_2/I lc1_1/I} \
  -net_prefix enet -cell_prefix ecell
```

The following example inserts buffers using on-route buffering. In addition to the previous example, the buffer is added at the first branch of the existing route and the net data is split into two different nets.

```
prompt> split_fanout -on_route -loads {h3/lc1_2/I lc1_1/I} \
  -net_prefix enet -cell_prefix ecell -lib_cell lib/BUF
```

The following example inserts a buffer to ensure that max_fanout is equal to or less than 8. The grouping of loads is based on the order of the route data from loads to driver. Port punching might be required.

```
prompt> split_fanout -max_fanout 8 -net n7 -on_route \
  -net_prefix enet -cell_prefix ecell -lib_cell lib/BUF
```

The following example inserts a buffer to ensure that max_fanout is equal to or less than 8. Moreover, the buffer will be added in the location without overlapping any blockages.

```
prompt> split_fanout -respect_blockages -max_fanout 8 -net n7 -on_route \
  -net_prefix enet -cell_prefix ecell -lib_cell lib/BUF
```

SEE ALSO

all_connected(2)

split_macro_group

Split macro groups.

SYNTAX

collection_of_macro_groups **split_macro_group**
object object_list

Data Types

object collection of objects

ARGUMENTS

object collection_of_macro_group

Specifies macro groups to split.

DESCRIPTION

This command splits the macro group based on connectivity. It returns the collection of macro groups after splitting.

EXAMPLES

The following command splits macro group G1.

prompt> **split_macro_groups** G1

SEE ALSO

create_macro_group(2)

split_multibit

Splits a multibit cell into smaller multibit cells or single-bit cells.

SYNTAX

status **split_multibit**
cell_name
-lib_cells *list_of_lib_cells*
-path_groups *list_of_string*
-slack_threshold *float*
-cells *list_of_cells*
-exclude_instance *exclude_cells*
-verbose_file *file_name*

Data Types

cell_name string
list_of_lib_cells list
list_of_cells list or collection
exclude_cells list or collection

ARGUMENTS

cell_name

Specifies the name of the multibit cell that needs to be split. If neither "cell_name" or "-path_groups" is specified, tool will split all the multibit cells whose slack is less than threshold. If no option is specified, tool will split all the multibit cells with negative slack. This option is mutually exclusive with "-path_groups".

-lib_cells *list_of_lib_cells*

Specifies the list of smaller multibit cells or single-bit cells used to replace the multibit cell.

-slack_threshold *float*

Specifies the value of slack threshold. Tool will split multibit cells on the critical path whose slack is less than threshold. The default value of threshold is 0. This option is mutually exclusive with "cell_name" and "-lib_cells".

-path_groups *list_of_string*

Specifies the list of path_group names. Tool will split multibit cells belongs to path group list. If "-slack_threshold" is not specified, the multibit cells with negative slack will be split. If "-slack_threshold" is specified, the multibit cells with less slack than threshold will be split. This option is mutually exclusive with "cell_name" and "-lib_cells".

-cells *list_of_cells*

Specifies the list of multibit cells to be considered for splitting.

-exclude_instance *exclude_cells*

Specifies the list of multibit cells to be ignored for splitting.

-verbose_file *file_name*

Specifies the file name in which verbose messages and summary related to de-banking is dumped.

DESCRIPTION

The **split_multibit** command splits a multibit cell into smaller multibit cells or single-bit cells. The original cell is removed from the netlist and replaced by smaller multibit cells or single-bit cells.

The order of the library cells specified by using the **-lib_cells** option determines the pin connection order of the split cells.

The total bit-width of all the listed split library cells should equal the bit-width of the original multibit cell. If the total bit-width is too large, some bits of the split library cells are not used, then the pins of the unused bits are left dangling.

If a pin in the original multibit cell does not have a corresponding pin in the split library cell, the tool disconnects the pin and issues a warning message.

The new cells' name is derived from "single_bit_list" attribute of original multibit cell. If the 'single_bit_list' attribute is missing, the command will derive new cell's name based on original multibit cell's name and bit width.

EXAMPLES

The following example splits a 6-bit multibit cell into two smaller 3-bit cells:

```
prompt> split_multibit reg_6_bit_inst \
  -lib_cells { mylib/REG_3_BIT mylib/REG_3_BIT }
```

The following example splits a 2-bit multibit cell into two single-bit cells. If the 'single_bit_list' attribute of original multibit cell is "reg1 reg2", then the newly created single-bit cells are named by "reg1" and "reg2". If the 'single_bit_list' attribute is missing, then the new cells will be named as "reg_orig_inst_bank[0]" and "reg_inst_bank[1]"

```
prompt> split_multibit reg_orig_inst \
  -lib_cells { mylib/REG mylib/REG }
```

EXAMPLES

The following example splits multibit cells with negative slack and belongs to path group.

```
prompt> split_multibit -path_groups clk1_path
```

SEE ALSO

identify_multibit(2)
create_multibit(2)

split_objects

Splits a collection of net shapes and returns the collection of net shapes after the split.

SYNTAX

collection **split_objects**
[-line *line*]
[-rect *rectangle*]
[-ignore_end_cap]
[-gap *distance*]
[-gap_min_spacing]
[-force]
[-simple]
[*object_list*]

Data Types

object_list collection or selection
line string
rectangle string
distance float

ARGUMENTS

object_list

Collection or selection set containing objects to split. If this option is not specified, the global selection set is used.

-line *line*

Specifies the line to split objects by.

-rect *rectangle*

Specifies the rectangle to split objects by.

-ignore_end_cap

Ignores end caps when splitting wires.

-gap *distance*

Specifies the cut gap distance between resulting object edges.

-gap_min_spacing

Uses minimum spacing as the split gap.

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

DESCRIPTION

This command splits one or more specified objects skipping all fixed objects. The following objects are supported: movebound shapes, voltage area shapes, corridor shapes, net shapes, and pin shapes.

Snapping is performed only on the cut line or rectangle according to global snap settings. It is assumed that the original shapes are already correct.

The command returns a collection of the split objects if *object_list* is a collection of objects. Otherwise it splits objects in specified selection set and returns status.

EXAMPLES

The example splits the currently selected objects object along the line ((100,100) (200, 100)).

prompt> **split_objects -line {{100 100} {200 100}}**

The alternative syntax uses collection to specify the objects to split.

prompt> **split_objects [get_selection] -line {{100 100} {200 100}}**

SEE ALSO

change_selection(2)
create_shape(2)
get_selection(2)
get_shapes(2)
get_snap_setting(2)
merge_objects(2)
set_snap_setting(2)

split_polygons

Decomposes geometric objects into trapezoids, creating a collection of geo_mask or poly_rect objects.

SYNTAX

collection **split_polygons**
[-objects *object_list*]
[*pos_object_list*]
[-output poly_rect | geo_mask]
[-split horizontal | vertical]

Data Types

object_list collection
pos_object_list collection

ARGUMENTS

-objects *object_list*

Specifies the objects to be used to define the geometric region to be split. The object list can be a heterogeneous collection of poly_rect, geo_mask, shape, layer, and other physical objects.

If you specify a layer, the generated object includes the area of every shape in that layer. For other types of geometric objects, the generated object includes the area of each object in the list.

pos_object_list

Specifies the objects to be used to define the geometric region to be split. This positional option is provided for compatibility with other tools.

You must use either the **-objects** *object_list* option or the *pos_object_list* option; you cannot use both of these options together.

-output *poly_rect* | *geo_mask*

Specifies the type of object to return as a result, either **poly_rect** or **geo_mask**. The default is **geo_mask**.

-split *horizontal* | *vertical*

Specifies the direction of the fracture lines used for splitting the polygon, either **horizontal** or **vertical**. The default it horizontal.

DESCRIPTION

This command decomposes a specified region or list of regions into trapezoidal regions. If a fully trapezoidal decomposition is not possible, the result is a mixed set of trapezoidal and triangular regions. If the region is manhattan-angled (has no diagonal segments), the result is a set of rectangles.

By default, the command returns a geo_mask object. To return a poly_rect object instead, use the **-output poly_rect** option. A poly_rect object is a single geometric shape consisting of a set of coordinate points. A geo_mask object is a collection of poly_rect objects.

EXAMPLES

The following example returns a collection of geo_mask objects with trapezoidal regions, a decomposition of all the shapes on layer M1.

```
prompt> split_polygons -objects [get_layers M1]
```

resize_polygons(2)
compute_area(2)
transform_polygons(2)

split_rdl_routes

Splits the redistribution layer (RDL) route into parallel routes and optionally copies the RDL route to the specified adjacent layer.

SYNTAX

status **split_rdl_routes**
[-nets *collection_of_nets* | -nets_in_file *nets_file*]
[-objects *collection_of_objects*]
[-mode same_layer | adjacent_layer]
[-widths {*layer_widths_list*}]
[-spacings {*layer_spacings_list*}]
[-number_of_routes {*layer_number_list*}]
[-from_layers {*layer_list*}
-to_layers {*layer_list*}
-via_interval *distance*]

Data Types

collection_of_nets collection
nets_file string
collection_of_objects collection
layer_widths_list list of string and float numbers pairs
layer_spacings_list list of string and float numbers pairs
layer_number_list list of string and integer pairs
layer_list list of string
distance float

ARGUMENTS

-nets *collection_of_nets*

Specifies the RDL nets to split.

-nets_in_file *nets_file*

Specifies the name of the file that contains the list of RDL nets to split.

-nets has higher priority than **-nets_in_file**.

-objects *collection_of_objects*

Specifies the RDL nets (see **-nets**) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option **flip_chip.route.routing_style** is **spanning_tree**, the whole nets of the cells or pins are regarded as involved.

If neither **-nets**, **-nets_in_file**, nor **-objects** option is specified, all RDL nets are split.

-mode same_layer | adjacent_layer

Specifies the mode used to split RDL nets. Valid mode values are

- **same_layer** (the default)
  In this mode, the command splits the original RDL routes into several parallel, thinner routes on the same layer. You can use the **-widths**, **-spacings**, and **-number_of_routes** options to control how the routes are split. You can either split the original RDL route or copy it, but you cannot combine both operations. By default, **same_layer** mode is used to split the RDL nets.

- **adjacent_layer**
  In this mode, the command copies the RDL nets from the source layers specified by the **-from_layers** option to the target layers specified by the **-to_layers** option. If the copied routes create DRC violations with other shapes in the target layers, the tool automatically trims the violating piece of the route. If a blockage or metal shape exists on the destination layer, the tool creates a route around the blockage or metal shape. If the tool cannot create the shape, the tool issues an error message.

  After copying the routes, the command inserts vias between the source layers and the target layers along the target nets using the spacing specified by the **-via_interval** option.

  The **-from_layers**, **-to_layers**, and **-via_interval** options are required when you use the **adjacent_layer** mode. You can either split the original RDL route or copy it, but you cannot combine both operations.

-widths {*layer_widths_list*}

Specifies the width values after split for each given metal layer. The list format is:

{*layer_name1* {*width11 width12 width13* ...}
layer_name2 {*width21 width22 width23* ...}
layer_name3 {*width31 width32 width33* ...}
...}

The layer name is as specified in the technology file. The tool splits the routes into thinner routes based on the ordering of the width values. If only one width value is given, the tool splits the routes into thinner routes of equal widths. The units are microns.

The tool must maintain at least minimum spacing between each thin route. For each layer, the width of the original route shape should be greater than or equal to the summation of widths + minSpacing * (number_of_route-1).

If this option is omitted, the tool automatically calculates the width by dividing the original route width by the value specified by **-number_of_routes**. If the **-number_of_routes** option is omitted, the tool adjusts the value so that the split width is less than or equal to the maxWidth of the layer and the number of routes is at least two. The tool maintains at least minSpacing in between the split routes.

This option is valid only for the *same_layer* mode.

-spacings {*layer_spacings_list*}

Specifies the spacing values between the routes after split for each given metal layer. The list format is:

{*layer_name1* {*spacing11 spacing12 spacing13* ...}
layer_name2 {*spacing21 spacing22 spacing23* ...}
layer_name3 {*spacing31 spacing32 spacing33* ...}
...}

The layer name is as specified in the technology file. The tool maintains spacing between the split routes based on the ordering of the spacing values. If only one spacing value is given, the tool maintains equal spacing between according to the spacing value. The units are microns.

If the summation of the widths + summation of the spacing does not equal the original width, the tool does not perform the split operation.

If this option is omitted, tool automatically maintains equal spacing between the routes. The tool must maintain at least minimum spacing between each thin route. For each layer, the width of the original route shape should be larger or equal to summation of widths + minSpacing * (number_of_route-1).

This option is valid only for the *same_layer* mode.

-number_of_routes {*layer_number_list*}

Specifies the number of routes after split for each given metal layer. The list format is:

{*layer_name1 number1*
layer_name2 number2
layer_name3 number3 ...}

You must specify the layer name by using the layer name from the technology file.

If either the **-widths** or **-spacings** options are given in a list form, the value of **-number_of_routes** should be equal to the length of the **-widths** list or the length of **-spacings** list + 1.

If this option is omitted, the tool automatically calculates the number of routes by dividing the original route width by the **-widths** value. If the **-width** option is omitted, the tool adjusts the width value so that the split width is less than or equal to the maxWidth and the number of routes is at least two. The tool adjusts the value so that at least minSpacing is maintained between the split routes.

This option is valid only for *same_layer* mode.

-from_layers {*layer_list*}

Specifies the source layer names from which you want to split the RDL nets. The routed pattern for the target nets is copied from these layers. The number of layers specified in the **-from_layers** option should match the number of layers specified in the **-to_layers** option. The layers specified by the **-to_layers** and **-from_layers** options should be adjacent.

This option is valid for *adjacent_layer* mode only.

-to_layers {*layer_list*}

Specifies the destination layer names to which you want to split the RDL nets. The routed pattern for the target nets is copied to these layers. The number of layers specified in the **-to_layers** option should match the number of layers specified in the **-from_layers** option. The layers specified by the **-to_layers** and **-from_layers** options should be adjacent.

This option is valid for *adjacent_layer* mode only.

-via_interval *distance*

Specifies the interval distance to use when inserting vias along the target nets. The interval should be no smaller than via enclosure size. If the interval distance is too small, the tool skips the crowded via and inserts via until next valid location. The tool inserts vias between the layers specified by the **-from_layers** and **-to_layers** options.

This option is valid only for *adjacent_layer* mode.

DESCRIPTION

This command splits the route shapes of routed RDL nets into parallel routes.

In *same_layer* (default) mode, the routes are split into thinner routes according to the specified width, spacing and number of routes. The thinner routes are on the same layer as the original route.

In *adjacent_layer* mode, the routes are copied from the original layer to an adjacent target layer. The tool inserts vias between the layers.

RDL nets are nets in flip-chip or 3DIC designs which are routed on the redistribution layer. In a flip-chip design, RDL nets connect a bump cell to driver I/O cells. In a 3DIC or interposer design, RDL nets can connect the following elements:

- A micro-bump cell and a micro-bump cell
- A micro-bump cell and a through silicon via (TSV) cell
- A micro-bump cell and driver I/O cell

Micro-bump cells are also called flip-chip pads.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example routes "NET1" with the RDL router using the given NDR rule. The tool splits the route into 3 thin routes with a width of 3 on the M8 layer and 2 thin routes with a width of 5 on the M9 layer.

```
prompt> create_routing_rule rdlRule \
      -spacings {M8 5 M9 5} -widths {M8 12 M9 12}
prompt> set_routing_rule NET1 -rule rdlRule
prompt> route_rdl_flip_chip -nets NET1 -layers {M8 M9}
prompt> split_rdl_routes -nets NET1 -widths {M8 3 M9 5} -number_of_routes {M8 3 M9 2}
```

The following example splits the route into 5 thin routes with widths of 4, 3, 4, 3, and 4 and a spacing of 1 between them. The original RDL net was routed with an NDR width of 22 on the M9 layer.

```
prompt> split_rdl_routes -widths {M9 {4 3 4 3 4}} \
  -spacings {M9 {1 1 1 1}} -number_of_routes {M9 5}
```

The following example splits the route into 2 thin routes with the width of 10. The original RDL net was routed with NDR width of 22 on M9 layer, a maxWidth of 10 and a minSpacing of 0.4.

```
prompt> split_rdl_routes
```

The following example routes a net with the RDL router, splits the route, and move the routes to lower metal layers.

```
prompt> route_rdl_flip_chip -layers {M9 M8}
prompt> split_rdl_routes -mode adjacent_layer \
  -from_layers {M9 M8} -to_layers {M8 M7} -via_interval 10
```

SEE ALSO

route_rdl_flip_chip(2)

spread_objects

Spreads specified objects between anchor objects or the specified objects parent.

SYNTAX

status **spread_objects**
[*object_list*]
[-anchor *object_list*]
[-parent]
[-from {*x y*}]
[-to {*x y*}]
[-margin]
[-vertical]

Data Types

object_list collection or selection
x float
y float

ARGUMENTS

object_list

Collection or selection set containing objects to spread. If this option is not specified, global selection set is used.

-anchor *object_list*

Specifies the objects which should target objects are spread between.

-parent

Specifies that objects are spread within parent bounding rectangle.

For terminals and I/O pads the parent object will be the die. For soft macro pins the parent object will be the soft macro. For all other objects the parent will be the core.

-from *value_point_rect*

Specifies that the objects are spread between two positions. The first position is specified by this argument and the second position is specified by the **-to** argument.

-to *value_point_rect*

Specifies that the objects are spread between two positions. The first position is specified by the **-from** argument and the second position is specified by this argument.

-margin

Uses extended objects boundaries. The block boundaries are extended with keepout margins. The voltage areas boundaries are extended with guard bands. To exclude certain block keepout margins from consideration, use the following command:

```
prompt> win_set_filter -class cell \
  -filter {hard_macro_margin hard_margin route_blockage_margin soft_margin}
```

-vertical

Spreads the specified objects vertically rather than horizontally when using the **-to**, **-from**, or **-parent** options.

DESCRIPTION

The command spreads the specified objects horizontally between the leftmost and rightmost anchors or fixed objects. If no fixed objects are specified, the leftmost and rightmost objects are used. To spread objects vertically, specify the **-vertical** option.

The anchor object or anchor position and to position mark a range over which the objects are spread. The objects are then evenly spaced (moved) over this range.

Note that snapping is done automatically global using the snap settings.

EXAMPLES

The following example moves the currently selected objects so that they are spread equally in the horizontal direction between parent edges.

```
prompt> spread_objects -parent
```

The alternative syntax uses a collection to specify objects.

```
prompt> spread_objects [get_selection] -parent
```

The following example moves the currently selected objects so that they are spread equally in the vertical direction between parent edges.

```
prompt> spread_objects -parent -vertical
```

snap_objects(2)

spread_spare_cells

Spreads spare cells evenly throughout a rectilinear region. The spare cells usually come through Verilog ECO or manual netlist editing commands.

SYNTAX

status **spread_spare_cells**
[-cells *cell_objects*]
| [-voltage_areas *voltage_area_list*]
[-boundary *{ {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }*]
[-ignore_blockage_types *blockage_type_list*]
[-density_aware_ratio *percentage*]
[-random_distribution]

Data Types

cell_objects collection
voltage_area_list list
llx float
lly float
urx float
ury float
x1 float
y1 float
x2 float
y2 float
blockage_type_list list
percentage integer

ARGUMENTS

-cells *cell_objects*

Specifies a collection of spare cells to spread. The cells in the collection must be marked as spare cells. The command issues an error if any specified cell is not a spare cell. The option is mutually exclusive with **-voltage_areas**. By default, the command spreads all spare cells in the design.

-voltage_areas *voltage_area_list*

Specifies a list of voltage areas. The command spreads the spare cells that belong to specified voltage areas. This option is mutually exclusive with **-cells**. By default, the command spreads all spare cells in the design.

-boundary *{ {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }*

Specifies the rectangular or rectilinear region in which to spread spare cells. The command does voltage area-aware spreading

in the user-specified region. A rectangle is specified by its lower-left and upper-right coordinates, that is, {llx lly} and {urx ury}. A polygon is specified by its points, that is, {x1 y1} {x2 y2} {x3 y3}, and so on. The unit is micron. The command issues an error if any spare cell to be spread does not belong to any voltage area within the user specified region. By default, the command performs wire spreading in the core area.

-ignore_blockage_types ***blockage_type_list***

Specifies a list of blockage types. The command allows spare cells to be placed inside the blockage if blockage type is specified by the option. The command supports all blockage types same as create_placement_blockage, but does not honor any placement constraint that the blockage has. If the option is not used, the spare cells can not be placed inside any placement blockage.

-density_aware_ratio ***percentage***

Specifies the percentage of spare cells to be spread with density aware. This option allows user to control the percentage of density aware for spare cell spreading. The percentage means the percentage of spare cells will be spread considering density of existing cells, and the rest will be spread evenly. The two spreading ways are both blockage aware.

- The default percentage is 100, that means all spare cells are spread with considering cell density;
- 20 means 20% spare cells will be spread based on cell density and 80% spare cells will be spread evenly across the design;
- 0 means all spare cells are spread evenly without considering cell density.

-random_distribution

Spreads spare cells randomly. The *-random_distribution* and *-density_aware_ratio* options are mutually exclusive. When the option is used, the tool will ignore the current cell density and spare cells are spread with random distribution.

DESCRIPTION

This command spreads spare cells evenly in rectilinear regions. The command spreads all spare cells by default, or based on the spare cells specified by the **-cells** or **-voltage_areas** option. The command spreads spare cells in the core area by default, or in the user-specified rectilinear region specified by the **-boundary** option. The command is blockage-aware, and does not place spare cells with a blockage or macro. The command is voltage area-aware and spreads the spare cells within the associated voltage area for the cell. The command automatically derives the region in which to spread the cells from the voltage area boundaries for the specified spare cells. For voltage areas with multiple regions, such as disjoint voltage areas, the spare cells are placed according to the available area ratio and the reference name.

The command supports both legalized and non-legalized designs. If there is insufficient space to spread the spare cells that belong to the voltage area, the command issues a warning and skips cell spreading in this voltage area.

The placement of spare cells is not guaranteed to be legal. You should run the **place_eco_cells -cells -legalize_only** command or the **legalize_placement** command to generate a legal placement as needed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example spreads all spare cells within its associated voltage area.

```
prompt> spread_spare_cells
```

The following example spreads only the spare cells specified with the **-cells** option.

```
prompt> spread_spare_cells -cells [get_cells $spareCells]
```

The following example uses the **-voltage_areas** option to spread only the spare cells that belong to the VA1 and VA2 voltage areas.

```
prompt> spread_spare_cells -voltage_areas {VA1 VA2}
```

The following examples use the **-boundary** option to spread only the spare cells in specified rectilinear regions.

```
prompt> spread_spare_cells -boundary {{10.8 20.3} {40.4 50.1}} \
  -cells [get_cells $spareCells]

prompt> spread_spare_cells -boundary {{10.8 20.3} {40.4 50.1}} \
  -voltage_areas {VA1}

prompt> spread_spare_cells -boundary {{10.8 20.3} {40.4 20.3} {40.4 50.1} \
  {25.0 50.1} {25.0 30.3} {10.8 30.3} {10.8 20.3}} \
  -cells [get_cells $spareCells]

prompt> spread_spare_cells -boundary {{10.8 20.3} {40.4 20.3} {40.4 50.1} \
  {25.0 50.1} {25.0 30.3} {10.8 30.3} {10.8 20.3}}
```

The following example uses the **-ignore_blockage_types** option to allow spare cells to be placed inside the blockage with user-specified type.

```
prompt> spread_spare_cells -ignore_blockage_types {soft partial}
```

The following example uses the **-density_aware_ratio** option to allow user to control the percentage of spare cells to be spread with density aware.

```
prompt> spread_spare_cells -density_aware_ratio 100
prompt> spread_spare_cells -density_aware_ratio 80
```

The following example uses the **-random_distribution** option.

```
prompt> spread_spare_cells -random_distribution
```

SEE ALSO

add_spare_cells(2)
get_attribute(2)
get_voltage_areas(2)
report_voltage_areas(2)
create_placement_blockage(2)

spread_wires

Spreads the wires in the current design to improve the total short critical area.

SYNTAX

status **spread_wires**
[-min_jog_length *min_ratio*]
[-min_jog_spacing_by_layer_name {*list_of_layer_value_pairs*}]
[-pitch *number_of_pitches*]
[-timing_preserve_nets {*collection_of_nets*}]
[-timing_preserve_setup_slack_threshold *slack_value*]
[-timing_preserve_hold_slack_threshold *slack_value*]

Data Types

count integer
min_ratio integer
number_of_pitches float
collection_of_nets collection
slack_value float
list_of_layer_value_pairs collection

ARGUMENTS

-min_jog_spacing_by_layer_name *list_of_layer_value_pairs*

Sets the minimum jog spacing value for each layer. You must specify the layers by using the layer names in the technology file.

Use the following format to specify the minimum jog spacing for each layer:

{*layerName value*}

For example, to specify a minimum jog spacing of 0.07 for metal2 and 0.08 for metal3, specify {{metal2 0.07} {metal3 0.08}}.

By default, this value is set to the minimum spacing for the layer plus a half layer pitch.

-min_jog_length

Sets the minimum value of the ratio of jog length to layer pitch.

By default, the *min_ratio* value is 2.

-pitch *num_of_pitches*

Sets the spread value in terms of number of pitches.

By default, the *num_of_pitches* value is 0.5.

-timing_preserve_nets {*collection_of_nets*}

Specifies the nets to preserve timing on.

If you specify this option, the command considers the specified nets as timing critical and skips wire spreading on these nets and the adjacent nets on the same layer within two routing pitches.

-timing_preserve_setup_slack_threshold *slack_value*

Specifies the setup slack threshold for timing critical nets.

If you specify this option, the command skips wire spreading on all nets with a worst setup slack less than or equal to this value and the adjacent nets on the same layer within two routing pitches.

-timing_preserve_hold_slack_threshold *slack_value*

Specifies the hold slack threshold for timing critical nets.

If you specify this option, the command skips wire spreading on all nets with a worst hold slack less than or equal to this value and the adjacent nets on the same layer within two routing pitches.

DESCRIPTION

This command spreads the wires in the current design to reduce the total short critical area. When spreading, a piece of the original wire is broken and pushed away and jog wires are created at both ends to maintain a connection.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example spreads the wires 0.5 pitches.

prompt> **spread_wires -pitch 0.5**

SEE ALSO

route_detail(2)
widen_wires(2)

start_auto_save

Starts auto-saving in the current session.

SYNTAX

status **start_auto_save**
-frequency *time_interval*
[-location *disk_location*]
[-allowed_disk_space *space_limit*]
[-environment_settings include | exclude]
[-action_on_exit clear | keep]

Data Types

time_interval	integer
disk_location	string
space_limit	integer

ARGUMENTS

-frequency *time_interval*

Specifies the minimum time interval(in seconds) after which auto-save is triggered. The frequency specified must be greater than 1800 seconds. If a frequency is not specified, the default value of 1800 seconds will be used.

-location *disk_location*

Specifies the location where the auto-save data is to be stored. By default, disk location is current working directory.

-allowed_disk_space *space_limit*

Specifies the amount of disk space(in gigabytes or megabytes) that can be consumed by auto-save data. Specify disk space with the following tags: G, g, GB, Gb, gb, M, m, MB, Mb or mb. When this option is not specified, there is no limit on the space used by the auto-saved data.

-environment_settings *include* | *exclude*

Specifies whether to include or exclude the session-specific app options and Tcl variables when auto-save is triggered.

By default, session environment settings are included in the auto-saved library.

-action_on_exit *clear* | *keep*

Specifies whether to clear or keep auto_saved data when you exit the tool.

By default, auto-saved data will be kept.

DESCRIPTION

This command controls the auto-saving of the library data in the current session. Auto-saving must be initialized by specifying its frequency and can be stopped later as required by using the stop_auto_save command.

Frequency, location, allowed_disk_space, action_on_user_tool_exit and environment_settings can be configured when initialized or resumed.

Auto-saving in the current session is not enabled by default.

EXAMPLES

The following example starts auto-saving library data regularly after an interval of 2000 seconds.

```
prompt> start_auto_save -frequency 2000
Information: Auto-saving started for the current session. (NDMUI-877)
```

The following example starts auto-saving library data regularly after an interval of 1800 seconds at location /u/temp

```
prompt> start_auto_save -frequency 1800 -location /u/temp
Information: Auto-saving started for the current session. (NDMUI-877)
```

remove_auto_save(2)
report_auto_save(2)

start_busplan_gui

Start the busplan register planning GUI dialog.

SYNTAX

int **start_busplan_gui**

DESCRIPTION

Starts the busplan register planning GUI dialog. If the dialog is already open, it will first be closed and then re-started. If the main GUI has not already been started, it will be started first.

EXAMPLES

prompt> **start_busplan_gui**

SEE ALSO

create_busplans(2)
gui_start(2)
start_gui(2)

start_gui

Starts the application GUI.

SYNTAX

string **start_gui**
[-file *script*]
[-no_windows]
[-offscreen 1|0]
[-- x_args ...]

string *script*

ARGUMENTS

-file "*script*"

The given script file is sourced before the GUI starts.

-no_windows

The GUI starts without showing the default window.

-offscreen

If the specified value is 1 then the GUI starts in offscreen mode.

If the specified value is 0 then the GUI starts in normal (X Display) mode.

-- x_args ...

X11-specific arguments to pass to the X connection.

DESCRIPTION

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. This is an alias for the gui_start command.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful start_gui command has no effect.

EXAMPLES

The following example starts the application GUI.

shell> **start_gui**

SEE ALSO

stop_gui(2)
gui_start(2)
gui_stop(2)

stop_auto_save

Stops auto-saving in the current session.

SYNTAX

status **stop_auto_save**

DESCRIPTION

This command stops auto-saving library data in the current session. Auto-saving can be resumed later by using the start_auto_save command.

Auto-saving in the current session is not enabled by default.

EXAMPLES

The following example stops auto-saving of library data:

```
prompt> stop_auto_save
Information: Auto-saving stopped for the current session. (NDMUI-879)
```

SEE ALSO

start_auto_save(2)
recover_auto_save(2)
remove_auto_save(2)
report_auto_save(2)

stop_gui

Stops the application GUI.

SYNTAX

string **stop_gui**

ARGUMENTS

None.

DESCRIPTION

This command stops the application GUI and returns to the shell prompt. It is ignored if the application GUI has not been started or has been stopped. This is an alias for the gui_stop command.

EXAMPLES

The following example stops the application GUI and returns to the shell prompt.

shell> **stop_gui**

SEE ALSO

start_gui(2)
gui_start(2)
gui_stop(2)

suppress_message

Disables printing of one or more informational or warning messages.

SYNTAX

string **suppress_message** [*message_list*]

list *message_list*

ARGUMENTS

message_list

A list of messages to suppress.

DESCRIPTION

The **suppress_message** command provides a mechanism to disable the printing of messages. You can suppress only informational and warning messages. The result of **suppress_message** is always the empty string.

A given message can be suppressed more than once. So, a message must be unsuppressed (using **unsuppress_message**) as many times as it was suppressed in order for it to be enabled. The **print_suppressed_messages** command displays the currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to suppress the CMD-029 message:

```
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
prompt> suppress_message CMD-029
prompt> unalias q*
prompt>
```

SEE ALSO

print_suppressed_messages(2)
unsuppress_message(2)
get_message_ids(2)
set_message_info(2)

swap_objects

Swaps two cells in the GUI.

SYNTAX

status **swap_objects**
[*object_list*]

Data Types

object_list collection

ARGUMENTS

object_list

Specifies a collection or selection set that contains the objects to swap. If this option is not specified, the global selection set is used.

DESCRIPTION

This command swaps two selected cells. This command only swaps two cells of same geometry. Upon completion of swap, the two cells should swap location as well as orientation.

You should use this command only for supported cell types such as standard cells, I/O pads, soft macros, hard macros, and so on. The swap action is not performed in the following scenarios.

- One or both cells are marked as fixed
- Width or height of the cells does not match

EXAMPLES

The following example swaps the two selected cells.

```
prompt> swap_objects
```

The alternative syntax uses a collection to specify the objects.

prompt> **swap_objects [get_selection]**

SEE ALSO

get_selection(2)
change_selection(2)

synthesize_clock_trees

Builds and optimizes clock trees based on the clock definition.

SYNTAX

status **synthesize_clock_trees**
[-clocks *clock_list*]
[-propagate_only]
[-postroute]
[-routed_clock_stage detail | detail_with_signal_routes]

Data Types

clock_list collection

ARGUMENTS

-clocks *clock_list*

Specifies the clocks to compile. Without this option the command synthesizes all currently defined clocks in all active modes.

-propagate_only

Propagates all clocks in all active scenarios. Ideal clock related settings such as ideal clock network latencies on pins are also purged. Clock uncertainty is not purged. This option should be used when more modes/scenarios are activated after CTS is done. It does not synthesize the clocks but only propagates the clocks.

-postroute

Runs post-route clock tree optimization. This option should be used after clock tree is synthesized and routed.

-routed_clock_stage detail | detail_with_signal_routes

Specifies the route stage of the design for post-route clock tree optimization. Possible values of this option are **detail** and **detail_with_signal_routes**. **detail** means only clock nets are detail routed; signal nets are not routed. **detail_with_signal_routes** means both clock nets and signal nets are detail routed. This option must be used together with **-postroute** option.

DESCRIPTION

This command synthesizes clock trees and updates the design database with the compiled clock trees. The compilation of the clock tree is skew driven. Optionally, this command can optimize compiled clock tree for slack metric.

The command will work on clocks in active scenarios. It will have clocks balanced if either setup or hold analysis is active. It will fix the transition violations on clock pins if max_transition analysis is active, and fix the capacitance violation on clock nets if max_capacitance analysis is active. At the end of this command it will invoke **mark_clock_trees** to mark clock synthesized attributes on clock objects.

Before running the **synthesize_clock_trees** command, the **set_lib_cell_purpose** command can be applied to select buffers or inverters which used during clock tree synthesis.

EXAMPLES

The following example shows that the lib_cells matching 'buf*' in the 'tech_lib' library should not be inserted for clock tree synthesis:

```
prompt> set_lib_cell_purpose -exclude cts {tech_lib/buf*}
```

The following example shows a command that performs clock tree synthesis for clocks 'CLK1' and 'CLK2':

```
prompt> synthesize_clock_trees -clocks {CLK1 CLK2}
```

The following example shows a command that reports the summary and timing characteristics of the compiled clock trees:

```
prompt> report_clock_qor -clocks {CLK1 CLK2}
```

The following example shows a command that performs clock tree synthesis for clocks from modes 'fun.mode' and 'bist.mode':

```
prompt> set cts_clocks [get_clocks -clocks {CK1 CK2} -mode fun.mode]
prompt> append_to_collection cts_clocks [get_clocks -clocks {BCLK1 BCLK2} -mode bist.mode]
prompt> synthesize_clock_trees -clocks cts_clocks
```

SEE ALSO

set_scenario_status(2)

synthesize_clock_trunk_endpoints

Run block level clock trunk planning (CTP).

SYNTAX

status **synthesize_clock_trunk_endpoints**
[-blocks *block_designs*]
[-clocks *clock_list*]
[-estimate_timing]
[-host_options host_option_name]
[-work_dir path]
[-auto_clock connected | local | all]

Data Types

block_designs list
clock_list collection

ARGUMENTS

-blocks *block_designs*

Specifies the list of child blocks for which clock trunk planning needs to be done. Block designs may reference to either design views or abstract views. If this option is not specified, then clock trunk planning is done for all child blocks at all hierarchy levels.

In a multi-level physical hierarchy design, clock trunk planning is done in bottom-up manner and the order is automatically inferred.

This option cannot over-ride the abstract generation behavior of the command, which is to generate abstracts - after doing clock trunk planning - only for the blocks referencing to abstract views.

-clocks *clock_list*

Specifies the clocks for which clock trunk planning is to be done. The *clock_list* can contain master clocks at the top-level as well as clocks at the block-level. The command creates a mapping between clock definitions at top-level and clock definitions at block level. The mapped clocks are then passed to option **"-clock"** of **synthesize_clock_trunks**, which is executed for individual blocks.

By default, all clocks are synthesized. All virtual clocks are skipped. So a block level clock whose master can not be traced to top-level clock is ignored.

-estimate_timing

This boolean option invokes VIPO on blocks referecing to abstract views - after block-level CTP is done. This will not invoke VIPO at top-level.

-host_options ***host_option_name***

Specifies that the given host option should be used for distributed processing. If not specified, the tool will look for the global host option and use the global host option if it has distributed processing settings.

Depending on the design hierarchy, the command might need to run clock trunk planning for more than one block. Some of the blocks can run at the same time, depending on the hierarchy nesting.

-work_dir ***path***

Specifies the directory to put all generated scripts and log files. The command needs to run clock trunk planning for one or more child blocks of the current block. Scripts and log files would be genereated for CTP and subsequent abstract view creation at the child blocks' level.

If this option is not specified, the *work_dir* setting for the specified host option would be used. If no **-host_options** is specified, the *work_dir* of the global host option would be used. If there is no global host option and no **-host_options** is specified, the default is *./work_dir*.

-auto_clock connected | **local** | **all**

Associates clocks at the block level with clocks at the top level. For example, your top-level clock might be called "SYS_CLK", and the same clock in the block might be called "CLK". You can set the association between block clock and top clock by using the **set_block_to_top_map** command, or by using **synthesize_clock_trunk_endpoints -auto_clock** and specifying the same rule. See the **set_block_to_top_map** man page for more details. Note that the **-clocks** and **-auto_clock** options are mutually exclusive.

You can select one of three rules for auto-clock mapping:

- **connected** - The "connected" rule associates block-level clocks with top-level clocks under the following conditions: If a block clock has its source at a block port (a boundary clock), it can be associated to a top-level clock that propagates to that port. If a block clock has its source on an internal pin sources (a local clock), the top-level clock source must be declared at the same pin.
- **local** - The "local" rule maps connected clocks. In addition, if a block clock has its source on an internal pin sources (a local clock) and has no associated top-level clock, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock.
- **all** - The "all" rule maps clocks as in the "local" rule. In addition, if a block clock has its source at a block port (a boundary clock) and no top-level clock propagates to that port, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock. The top-level boundary clock will allow timing analysis to be done, but it is not necessarily correct for signoff. You should consider removing or replacing this clock before signoff.

Note that if two block-level clocks are declared at the same boundary port, the "all" rule cannot resolve both of them. This is because it will not automatically declare two conflicting clocks in the top-level block. You must manually declare two top-level clocks, with the appropriate waveforms. After the top clocks exist, **-auto_clock** mapping can associate them with the block clocks.

DESCRIPTION

This command runs block-level clock trunk planning (CTP) for all or specified child blocks - based on option **"-blocks"**. A run script is generated for each child block. In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and run the block scripts in a bottom-up order.

The tool gets the constraint files from the constraint mapping file. See the man page for **set_constraint_mapping_file** for details of how to set up the constraint mapping file.

SDC constraints are loaded through command **source**. Operations **remove_modes -all** and **remove_corners -all** are performed before loading the SDC constraints for a block.

CTS_CONSTRAINT constraints are loaded through command **source**. Then **"synthesize_clock_trunks -create_anchors -clock <clock_list>"** is performed on the block. Block-level CTP will not be triggered for blocks for which CTS_CONSTRAINT file is not specified in set_constraint_mapping_file.

For the blocks referencing to abstract views, the command generates abstract views after running CTP. If the abstract view with timing information exists for a block, the same type of abstract is re-created. For others, abstract views are generated with timing_level set to "compact". Abstract views are not generated for blocks referencing design views.

The command automatically sources top level SDC constraints, after block-level clock trunk planning is done.

This command also saves the current block to disk.

EXAMPLES

The following example runs block-level CTP on all child blocks across all hierarchies.

```
prompt> synthesize_clock_trunk_endpoints
```

The following example runs block-level CTP on child blocks GPU0 and GPU1

```
prompt> synthesize_clock_trunk_endpoints -blocks {GPU0 GPU1}
```

The following example runs block-level CTP only for clock CLK in all the child blocks

```
prompt> synthesize_clock_trunk_endpoints -clocks {CLK}
```

synthesize_clock_trunk_setup_hier_context

Prepare/Update hierarchical designs for clock trunk planning.

SYNTAX

status **synthesize_clock_trunk_setup_hier_context**
[-init]
[-commit]
[-host_option host_option_name]

Data Types

-init Boolean
-uninit Boolean
-host_option String

ARGUMENTS

-init

When this argument is specified, optimizable abstracts will be created for sub-blocks linked with abstracts. This argument is mutually exclusive with argument "-commit".

-commit

When this argument is specified, regular abstract will be created for sub-blocks linked with abstracts. This argument is mutually exclusive with argument "-init".

-host_option host_option_name

Specifies that the given host option should be used for distributed processing. If not specified, the tool will run in serial mode.

DESCRIPTION

This commans performs preparation (with argument "-init") or updation (with argument "-commit") for sub-blocks for clock trunk planning flow. With argument "-host_option", it can run the operations in distributed fashion.

EXAMPLES

The following example creates optimizable abstracts serially for sub-blocks linked with abstracts.

```
prompt> synthesize_clock_trunk_setup_hier_context -init
```

The following example creates regular abstracts for sub-blocks linked with abstracts. Here tool will distribute the jobs according to specified host options.

```
prompt> synthesize_clock_trunk_setup_hier_context -commit -host_option grdOptions
```

SEE ALSO

synthesize_clock_trunks(2)
set_host_options(2)

synthesize_clock_trunks

Performs automatic clock trunk planning for the specified clock or clocks.

SYNTAX

status **synthesize_clock_trunks**
[-clock *clocks*]
[-from *startStage*]
[-to *endStage*]
[-list_only]

Data Types

clocks collection of clocks
startStage string
endStage string

ARGUMENTS

-clock *clocks*

Specifies the clocks for which automatic planning is to be performed.

-list_only

Prints out the major stages that constitute the default flow for the **synthesize_clock_trunks** command in THO mode.

These stages are: **pin_constr_generation**, **read_pin_constr_and_place_pins**, **clock_trunk_synthesis**.

This option cannot be used with the **-from** or **-to** options.

-from *startStage*

Specifies the starting stage for the **synthesize_clock_trunks** command. Valid values are **pin_constr_generation**, **read_pin_constr_and_place_pins**, **clock_trunk_synthesis**.

The default is **pin_constr_generation**.

If you specify both the **-to** and **-from** options, the *startStage* stage cannot be preceded by the *endStage* stage in the order specified by the **-list_only** option.

-to *endStage*

Specifies the final stage for the **synthesize_clock_trunks** command. Valid values are **pin_constr_generation**, **read_pin_constr_and_place_pins**, **clock_trunk_synthesis**.

The default is **clock_trunk_synthesis**.

If you specify both the **-to** and **-from** options, the *startStage* stage cannot be preceded by the *endStage* stage in the order specified by the **-list_only** option.

DESCRIPTION

This command performs automatic clock trunk planning on the specified clocks, or on all clocks.

The following prerequisites must be completed before running the **synthesize_clock_trunks** command. This can be achieved by running **synthesize_clock_trunk_endpoints** command before **synthesize_clock_trunks**.

- Blocks must be shaped
- Block clock ports must be placed.
- Top-level flip-flops must be placed.
- Clock trunk endpoints must have been identified with **set_clock_trunk_endpoints** and appropriate phase delays must have been set.

The command performs following tasks:

- Uses CTS engine to synthesize physical clock tree topology at top level.
- Compensates for the phase delays in the block level clock trunk endpoints.
- Maximize the common clock path between blocks communicates with each other.

The command supports two flavors:

- Pushdown mode: Enabled when app-option plan.clock_trunk.flow_control is set to push_down before executing the command. In this mode, the tool will consider the blocks as read-only. Hence CTS will place the clock trunk cells on top of the block. Use **push_down_clock_trunks** command (after synthesize_clock_trunks) to commit the physical topology of the clock trunk. Options -from and -to of synthesize_clock_trunks are not applicable for CTP-Pushdown mode.

- THO mode: Enabled when app-option plan.clock_trunk.flow_control is set to optimize_subblocks before executing the command. In this mode the tool will consider the blocks as editable. pin_constr_generation stage generates topological pin constraints for clock-nets. read_pin_constr_and_place_pins stage read these pin-constraints and execute place_pins for all these synthesized clock nets.

In order to check if the design is ready for synthesize_clock_trunks command, please run the command check_design_for_clock_trunk_planning command.

EXAMPLES

The following example performs automatic clock trunk planning for the clock CLK in CTP-Pushdown mode.

```
prompt> set_app_options -name plan.clock_trunk.flow_control -value push_down
prompt> synthesize_clock_trunks -clock CLK
```

The following example performs automatic clock trunk planning in CTP-THO mode for all clocks in the current mode. Here, it only runs pin_constr_generation step

```
prompt> set_app_options -name plan.clock_trunk.flow_control -value optimize_subblocks
```

prompt> **synthesize_clock_trunks -clock [all_clocks] -from pin_constr_generation -to pin_constr_generation**

The following example performs automatic clock trunk planning for all clocks in all active modes.

prompt> **synthesize_clock_trunks**

synthesize_multisource_clock_subtrees

Synthesizes the subtrees in a structural multisource clock tree synthesis (CTS) flow.

SYNTAX

status **synthesize_multisource_clock_subtrees**
[-clocks *clock_list*]
[-list_only]
[-from preprocess | merge | optimize | route_clock | refine]
[-to preprocess | merge | optimize | route_clock | refine]

Data Types

clock_list collection

ARGUMENTS

-clocks *clock_list*

Specifies which clocks to synthesize. The subtree options are defined by the **set_multisource_clock_subtree_options** command. By default, all multisource clocks are synthesized.

-list_only

Lists the available steps for the subtree synthesis command. These steps are **preprocess**, **merge**, **optimize**, **route_clock**, and **refine**. By default, all five steps are run when the **synthesize_multisource_clock_subtrees** command is used. But, the *-from* and *-to* options can be used to limit the command to execute only the specified range of steps. *-list_only* simply lists the valid steps that can be passed to the *-from* and *-to* options.

-from preprocess | **merge** | **optimize** | **route_clock** | **refine**

Specifies that multisource subtree synthesis should start from the specified step. By default, all the steps are run in order: **preprocess**, **merge**, **optimize**, **route_clock**, and **refine**. This option can be used to start from a later step. For example, **synthesize_multisource_clock_subtrees -from optimize** skips the preprocess and merge steps and only execute the optimize, route_clock, and refine steps.

The *-from* and *-to* options can be used together or separately to run only certain steps of subtree synthesis, mainly for analysis purposes. Regardless of the usage of these options, all five steps should eventually be run, and run in the correct order.

-to preprocess | **merge** | **optimize** | **route_clock** | **refine**

Specifies that multisource subtree synthesis should end at the specified step. By default, all the steps are run in order: **preprocess**, **merge**, **optimize**, **route_clock**, and **refine**. This option can be used to end before completing all steps. For example, **synthesize_multisource_clock_subtrees -to optimize** runs the preprocess, merge, and optimize steps, but skips the route_clock and refine steps. The **-from** and **-to** options can be used together or alone to run only certain steps of subtree synthesis, mainly for analysis purposes. Regardless of the usage of these options, all five steps should eventually be run, and run

in the correct order.

DESCRIPTION

Structural multisource clock trees are clock trees where the user specifies the structure of the clock paths in the incoming netlist. The tool is not allowed to modify the sequence of clock cells types on any path from the multisource roots to the clock sinks. This means that structural multisource clock tree construction is restricted to merging, splitting (cloning), sizing and relocation of cells in the incoming netlist. No restructuring or (un)buffering of the clock nets is allowed, since this would modify the sequence of cell types on a path from multisource root to clock sink.

A multisource CTS tree has several components, including the pre-mesh tree driving the mesh, the mesh itself, the driver objects which are driven by the mesh, and the subtrees driven by those driver objects. The **synthesize_multisource_clock_subtrees** command is used to structurally synthesize the subtrees driven by the mesh.

Structural synthesis of multisource subtrees involves several steps, the end goal being a set of DRC-free subtrees that are built to meet your latency and skew targets.

Specifying Structural Subtree Synthesis Options and Constraints

Synthesis constraints should first be defined by using the **set_multisource_clock_subtree_options** command. This command performs four main functions:

- Defines driver objects for subtrees of a clock for balancing and sink assignment
- Defines which clock to balance in each subtree set
- Defines synthesis constraints like total maximum wire delays
- Enables level balancing and defines the target level number

A subtree set indicates that a set of clock fanouts and sinks are equivalent. Equivalent fanouts and sinks can be freely assigned to any driver object for the subtree set, and that they should be skew balanced together. This is done by specifying the driver objects that fan out to the sinks of that subtree set.

Each subtree set can be synthesized for only one clock. The clock needs to be specified with the **set_multisource_clock_subtree_options** command.

The synthesis style disallows buffer insertion or removal for opimization. Only the existing logic in the subtrees can be used, and that logic is sized, merged, split, and placed to meet the CTS goals. This structural approach requires a netlist that has been prepared specifically for this synthesis style, since no buffer insertion or removal can be done.

Buffers can only be inserted to balance the number of levels in the subtrees. This level balancing step is executed in the preprocess step and needs to be enabled by the **set_multisource_clock_subtree_options** command.

Default command tries to balance all the subtrees to same level. You can specify different target_level for the sinks using set_multisource_clock_subtree_constraints command.

Using structural mode is the only way to guarantee a certain number of clock levels to each sink. Since no buffer insertion or removal is performed (except for level balancing), the number of levels to each sink remain the same before and after subtree synthesis.

The netlist needs to have enough clock levels to allow sufficient splitting of logic to drive the clock trees. If not enough levels exist in the pre-CTS structural tree, this can create a very large pin load driven by the driver objects after subtree synthesis, since many split buffers or gates will have to connect to that driver stage.

You can also optionally enable ICG re-ordering feature with set_multisource_clock_subtree_options. ICG re-ordering is performed only if it saves power. You can prevent specific ICGs from re-ordering using set_multisource_clock_subtree_constraints command.

This is useful for designs where impact of dynamic power due to net switching activity is higher and clock gating is employed to address the same.

You can also optionally enable power aware subtree synthesis to allow optimization of subtrees for DRC and latency with focus to total clock tree power. This feature is false by default, and can be enabled using the app_option cts.multisource.subtree_synthesis_enable_power_optimization.

In addition to the constraints defined by **set_multisource_clock_subtree_options**, subtree synthesis also honors:

- **set_max_transition** DRC limits
- **set_max_capacitance** DRC limits
- Fanout limits set by the app option **cts.common.max_fanout**
- Latency targets set by **set_clock_tree_options -target_latency**
- Float and stop exceptions set by **set_clock_balance_points**
- Ignore exceptions set by **set_clock_balance_points -consider_for_balancing false**
- **set_placement_status**, **set_dont_touch**, and **set_size_only** constraints on cells in the clock tree
- Clock cell spacing rules set by **set_clock_cell_spacing**

Constraints that are not honored by subtree synthesis include:

- Skew targets set by **set_clock_tree_options -target_skew**
- Skew groups created by **create_clock_skew_group**
- Balance groups created by **create_clock_balance_group**
- Max net length limits set by the app option **cts.common.max_net_length**

Executing Structural Subtree Synthesis

Structural subtree synthesis is performed with the **synthesize_multisource_clock_subtrees** command. By default, this command operates on all clocks that have subtrees defined by the **set_multisource_clock_subtree_options** command.

Structural subtree synthesis consists of five main steps. First, level balancing is executed in the preprocess step, if enabled. Without a given target level, level balancing inserts buffers such that all sinks of an option set are at the same logic level in the clock tree. The command minimizes the number of inserted buffers by inserting them as early as possible in the subtrees. Constraints like don't-touches on nets or frozen hierarchy ports are honored during this process. If a target level is specified with the **set_multisource_clock_subtree_options** command, then buffers are inserted such that all sinks are at the given target level. Clock paths to sinks which are already at a higher level than the specified target, are not modified. The type of buffer will be selected from the available list of buffers enabled for CTS. Sizing and possibly splitting of these inserted buffers will happen at later optimization stages.

Next, all clock logic in the subtree group is merged as much as possible and assigned to a single driver object of that group. Merging all clock logic helps ensure that the subsequent splitting of clock tree logic is done optimally, based on the locations of the driver objects and the clock sinks.

Merging is done for all equivalent clock cells. The cells need to share common driver nets on each input pin to be considered equivalent for merging. Any timing constraints on the cells need to be the same for merging to occur.

Merging can occur across logical hierarchy boundaries, and merging honors any frozen ports defined by the **set_freeze_ports** command. **dont_touch** constraints on cells and nets in the clock tree can restrict merging. Any cells set as **size_only** or **fixed** are not be merged. Merging can only occur across cells that belong to the same library cells subset and that are within the same power domain, voltage area, and move bound.

Merging of certain cells can be disabled using the **-dont_merge_cells** option of the **set_multisource_clock_subtree_options**

command. Note, however, that cells specified with this option can still be split (see the next optimization step below). This means that a second execution of this command cannot merge these cells again unless the option set definition is altered and the cells are removed from the **-dont_merge_cells** list.

The naming convention for the merged cells can be configured through the following app options: cts.multisource.subtree_merge_cell_name_prefix, cts.multisource.subtree_merge_cell_name_suffix, and cts.multisource.subtree_merge_concatenate_length_threshold

After merging is complete, the next step in subtree synthesis occurs, which is splitting and optimization. As the clock trees are clustered and built, all clock logic is assigned to the appropriate subtrees based on nearest location, and splitting of clock logic is done as needed in order to divide and assign the sinks and clock fanouts to their subtrees. This optimization is intertwined with sizing and relocation of the clock logic.

Splitting and optimization honors frozen ports set with the **set_freeze_ports** command, **set_dont_touch** constraints, **set_size_only** constraints, and fixed placement attributes on cells. Splitting is not performed in case ports would have to be punched on power domain boundaries.

Splitting copies timing constraints, UPF constraints, and user attributes on cells as needed. For example, if a false path is defined through some of the split clock logic, the false path constraint is duplicated to all of the split cells as well. The cloned cells are placed in the same logical hierarchy and voltage area as the original cell.

After this splitting and optimization step, all logic is assigned to the appropriate subtrees, and the trees have been optimized to be DRC-free and to meet your latency targets.

The naming convention for the cells and nets created during splitting can be configured through the following app options:

cts.multisource.subtree_split_cell_name_prefix,
cts.multisource.subtree_split_cell_name_suffix,
cts.multisource.subtree_split_net_name_prefix, and
cts.multisource.subtree_split_net_name_suffix.

The next step in subtree synthesis is clock routing. All clock nets are routed in this stage. The routing approach is controlled by the **cts.multisource.subtree_routing_mode** app option, which can be set to **none** to do virtual routing of clock nets in the subtrees, **global** to do global routing of those nets, or **fishbone** to do fishbone routing. Fishbone routing creates a mix of detail routed fishbone trunks and fingers, and global comb routes to connect the net loads to the fishbone fingers.

The final step is incremental refinement. This step performs cell sizing and cell relocation based on global/fishbone routing. Relocation does not happen on cells connected to clock straps/fishbone routing. The refinement timing is based on extracted clock routes to have the most accurate timing and DRC picture available.

By default, **synthesize_multisource_clock_subtrees** runs these five steps when building subtrees. By using the **-from** and/or the **-to** options to this command, it can be restricted to only run certain steps. The valid step names are **preprocess**, **merge**, **optimize**, **route_clock**, and **refine**. Typically, these options are used to run only one component of the subtree synthesis and analyze results before continuing to the next step. In the end, all five steps should be run to fully synthesize the subtree.

Subtree synthesis generates logfile output, which gives basic guidance about what the command is doing and any problems encountered during execution. You can generate additional, verbose output by setting the **cts.multisource.verbose** application option to 1. This setting is intended for advanced users doing more detailed investigation of the multisource subtree synthesis results.

Driver Objects

In a structural multisource CTS flow, the subtrees can optionally connect to the mesh through a layer of cells i.e. driver objects. These cells are specified by the **set_multisource_clock_subtree_options -driver_objects** command and option. The driver object acts as the driver or root of a particular multisource CTS subtree. If the driver objects connect to subtrees through clock straps, the placement of first-level cells in the subtree is snapped to the driver object's routing geometries, to ensure efficient connection of the subtree to the clock straps.

Typically, a driver object is a clock buffer, but the multisource CTS flow allows a lot of flexibility in the driver object concept. The following are supported approaches for driver objects of subtrees:

(1) A standard cell, with its clock output pin defined as the driver object. The first-level cells in the subtree are snapped to the driver cell output pin geometry.

(2) The driver object is a standard cell output pin, which is connected to a net which has prerouted geometries. The first-level cells in the subtree are snapped to the prerouted geometries on the driver's net.

(3) There is nodriver cell, instead, the clock port terminals are used as driver objects. For example, there are eight driver objects associated with eight clock ports, clk[0:7]. Each port has different terminal shapes. The first-level cells in the subtree are snapped to the terminals.

(4) There is no driver cell, instead, the driver objects are clock ports that have prerouted net geometries. This differs from the previous example where each port had just the terminal shapes. In this case, there are also prerouted nets connecting to those terminals. The first-level cells in the subtree are snapped to the prerouted nets attached to the port terminals.

Based on the previous four examples, a driver object can be either a physical cell output or an input port of the block. If no prerouted net geometries exist, then the cell output pin or the port terminal shapes are used for snapping the first-level cells in the subtrees. If instead there are net shapes with the *shape_use==stripe* or *shape_use==user_route* properties set, those net shapes are used as snapping points for the first-level cells in the subtrees.

If a driver object net has preroute shapes with both *shape_use==stripe* and *shape_use==user_route* properties, the *stripes* setting take precedence over the *user_routes* setting and only those stripe shapes are used for snapping and routing to the first level in the subtrees. This distinction can be useful to define a preroute structure where the subtrees can only connect to certain shapes.

You can use the app option **cts.multisource.ignore_drc_on_subtree_driver** to specify that max_capacitance and/or max_anout constraints are to be ignored on the driver object pin or ports.

Latency and Skew Targets

The skew balancing behavior of multisource subtree synthesis is very similar to that of standard CTS. Subtree synthesis honors latency targets as specified by the **set_clock_tree_options -target_latency** command. If no target latency is set, then subtree synthesis works toward a minimum latency solution for the subtree group.

Subtree synthesis also honors stop, float, and ignore clock exceptions specified by the **set_clock_balance_points** and **set_clock_balance_points** commands. When using structural style subtree synthesis, no optimization is done beyond clock exceptions that are intermediate in the clock tree. It is safer to only use exceptions on sinks when doing structural subtree synthesis.

The **set_clock_tree_options -target_skew** command is not currently honored by multisource subtree synthesis. Skew is always minimized towards zero clock skew in a subtree group.

Skew groups and balance groups as specified by the create_clock_skew_group and create_clock_balance_group commands are not honored by multisource subtree synthesis.

Structural multisource subtree synthesis supports one additional approach to latency targeting that is not available in regular CTS, called *latency mode*. This mode is activated by specifying **set_clock_tree_options -target_latency 0** on the clock object being balanced for the multisource subtree group. In latency mode, the latency target for every clock sink is explicitly specified as a **set_clock_balance_points** float constraint. This differs from ordinary treatment of float constraints, which are normally considered offsets rather than absolute targets.

For example, typically if a balance point is specified on a sink with downstream_latency 200ps using the **set_clock_balance_points** command, that is meant to model 200ps of downstream latency from the balance point, which tells CTS to tap that sink 200ps earlier in the clock tree. But in latency mode, that 200ps constraint is instead treated as an absolute latency target to be achieved at that sink.

This mode of latency targeting and skew balancing is typically achieved using the **derive_clock_balance_points -reference_latency 0.0** command. If this command is run before **synthesize_multisource_clock_subtrees**, then the ideal latency at every sink is converted to a **set_clock_balance_points** float pin constraint. Note that this value includes both source and network **set_clock_latency** constraints seen at each sink in ideal mode.

For example, if sink A has an ideal network latency of 180ps set by the set_clock_latency command, this is translated to a **set_clock_balance_points -consider_for_balancing true -delay -0.180** constraint on that sink. Note that the polarity of the

constraint is reversed, as a negative balance point downstream_latency indicates that a sink should be delayed in the clock network by that amount.

All of this enables a flow where you explicitly specify the desired latency to every sink in ideal mode using **set_clock_latency** constraints. Then, by converting those ideal latencies to balance point constraints, and specifying a target latency of 0 on the clock to enable *latency mode*, multisource subtree synthesis can build the trees while targeting the ideal latencies.

Given all this, you can use one of two use models:

The standard approach, where a target latency is set with **set_clock_tree_options**, otherwise minimum latency clock trees are targeted. Optionally, balance point and ignore point constraints can also be applied to affect the skew balancing, just as with standard CTS.

The alternate *latency mode* approach, where achievable ideal mode latencies are specified for every sink by using **set_clock_latency** constraints. By setting a target latency of 0 and using the **derive_clock_balance_points -reference_latency 0.0** command, these latencies are converted to balance point constraints and targeted as absolute latency goals at each sink.

Fishbone Routing

Fishbone routing is one of the available routing approaches for subtree synthesis, configured by setting the **cts.multisource.subtree_routing_mode** app option to *fishbone*. Fishbone routing is a structured routing topology where the net driver feeds a central fishbone trunk that spans the cluster of net loads being driven. Fishbone routing is only done for a net if the trunk is at least five gcells in length.

Several fishbone fingers can extend from the central trunk. The net loads connect directly to the fishbone fingers by way of comb routes, typically one comb route for each net load. The frequency of these fingers is controlled by the **cts.routing.fishbone_max_tie_distance** app option, which specifies a maximum distance from a net load to its nearest fishbone finger.

Optionally, you can use an additional level of fishbone routing, called sub-fingers. The sub-fingers connect to the fingers, and then the comb routes can instead connect the net loads to the sub-fingers. This can reduce wire length, especially in the case that a large **fishbone_max_tie_distance** is used. The behavior of sub-fingers is controlled by the **cts.routing.fishbone_max_sub_tie_distance** app option.

After the subtree synthesis command completes, the trunk, fingers and sub-fingers are detail routed, and defined as preroutes, using the *shape_use==stripe* attribute. The comb routes connecting the net loads to either the fingers or sub-fingers are global routes.

The fishbone trunk and fingers are routed on the two highest layers configured for the net. If sub-fingers are used, they are routed on the layer directly below the finger layer. The comb routes can use any available routing layer for the net.

Fishbone trunks can optionally be biased toward power or ground nets to act as a shield on one side of the trunk, to improve signal integrity on the fishbone trunks. Biasing is enabled separately for horizontal and vertical trunks by setting a spacing rule between the trunk and the power or ground net using the **cts.routing.fishbone_horizontal_bias_spacing** and/or **cts.routing.fishbone_vertical_bias_spacing** app options.

When biasing is enabled, two additional controls are available. The **cts.routing.fishbone_bias_threshold** app option specifies a minimum trunk length before biasing is attempted. The **cts.routing.fishbone_bias_window** app option specifies a maximum displacement from the preferred trunk location to the biased trunk location, above which biasing is not attempted.

Library Cell Subsets

Multisource subtree synthesis honors library cell subsets, if defined. Subsets can be defined in the library manager or the implementation tool by using the **subset_name** attribute, for example:

```
set_attribute [get_lib_cells */INV1*] subset_name INV1
set_attribute [get_lib_cells */INV2*] subset_name INV2
```

Library cells can be resized only within their subset. In the previous example, the */INV1* library cells can be resized to other */INV1* library cells and the */INV2* library cells can be resized to other */INV2* library cells. All inverters that do not belong to one of these subsets can be resized among each other.

Merging is restricted to subsets, so if two cells would otherwise be merge candidates but their library cells belong to different subsets, they are not merged.

Splitting is not affected by subsets, as the split cells all initially get the same library cell as the unsplit reference cell.

Multicorner-Multimode Support

This command works on all the active corners for the given clock mode under an app option cts.multisource.enable_multi_corner_support if set to true. This feature is false by default which means this command works on primary corner of the given clock mode.

EXAMPLES

The following example uses multisource subtree synthesis on all defined clocks with driver objects defined on them.

```
prompt> synthesize_multisource_clock_subtrees
```

The following example calls multisource subtree synthesis on only clocks clk1 and clk2.

```
prompt> synthesize_multisource_clock_subtrees -clocks [get_clocks {clk1 clk2}]
```

The following example calls only the optimize step of subtree synthesis on clock clk.

```
prompt> synthesize_multisource_clock_subtrees -clocks clk -from optimize \
  -to optimize
```

The following example lists the valid steps that make up the multisource subtree synthesis command.

```
prompt> synthesize_multisource_clock_subtrees -list_only
```

synthesize_multisource_clock_taps

Performs multisource CTS tap assignment.

SYNTAX

status **synthesize_multisource_clock_taps**
[-clocks *clock_list*]

Data Types

clock_list collection

ARGUMENTS

-clocks *clock_list*

Specifies for which clocks tap assignment should be performed. The tap assignment options are defined by the **set_multisource_clock_tap_options** command. By default, all clocks which have tap assignment options defined will be considered.

DESCRIPTION

Regular multisource CTS is an alternative CTS approach which is a hybrid between a traditional automated CTS solution and a more manual full clock mesh implementation (structural multisource). Regular multisource CTS provides benefits such as better OCV tolerance than traditional CTS, and better power than a full mesh flow. Compared to a structural mesh approach, regular multisource trees typically have a less dense mesh structure with fewer tap points from the mesh to the driven taps. Also, the subtrees below the tap drivers can be deeper; structural mesh flows typically have no more than two to three levels beyond the mesh, whereas a regular multisource flow has no restriction on the levels beyond the mesh.

A regular multisource CTS tree has several components, including the pre-mesh tree driving the mesh, the mesh itself, the tap drivers which are driven by the mesh, and the subtrees driven by those tap drivers. The **synthesize_multisource_clock_taps** command is used to assign clock sinks to tap drivers by cloning intermediate clock cells.

Once tap assignment has been done, regular clock tree synthesis and optimization using the **synthesize_clock_trees** or **clock_opt** command is used to synthesize clock subtrees below the tap drivers.

Specifying Tap Assignment Options

Tap assignment options should first be defined by using the **set_multisource_clock_tap_options** command. This command performs two main functions:

- Defines tap driver objects for sink assignment

- Defines a clock to be used for sink identification

A tap assignment driver object set indicates that a set of clock fanouts and sinks are equivalent. Equivalent fanouts and sinks can be freely assigned to any tap driver from the set.

Each tap driver can be synthesized for only one clock. The clock needs to be specified with the **set_multisource_clock_tap_options** command.

Executing Tap Assignment

Tap assignment is performed with the **synthesize_multisource_clock_taps** command. By default, this command operates on all clocks that have tap assignment options defined by the **set_multisource_clock_tap_options** command.

Tap assignment consists of two main steps. First, all clock logic in the fanout of the tap drivers is merged as much as possible and assigned to a single tap driver of that group. Merging all clock logic helps ensure that the subsequent splitting of clock tree logic is done optimally, based on the locations of the tap drivers and the clock sinks.

Merging is done for all equivalent clock cells. The cells need to share common driver nets on each input pin to be considered equivalent for merging. Any timing constraints on the cells need to be the same for merging to occur.

Merging can occur across logical hierarchy boundaries, and merging honors any frozen ports defined by the **set_freeze_ports** command. **dont_touch** constraints on cells and nets in the clock tree can restrict merging. Any cells set as **size_only** or **fixed** are not be merged. Merging can only occur across cells belonging to the same *lib_cell subset* and which are within the same power domain, voltage area, and move bound.

You can prevent merging of cells by specifying them with the **-dont_merge_cells** option of the **set_multisource_clock_tap_options** command. Note, however, that cells specified with this option can still be split (see next step below). This means that a second execution of this command cannot merge these cells again unless the option set definition is altered and the cells are removed from the **-dont_merge_cells** list.

You can allow splitting of cells with user_dont_touch/user_size_only by specifying them with the **-relax_split_restrictions_for_cells** option of the **set_multisource_clock_tap_options** command. These cells will be split for optimization during tap assignment as required, similar to any other cell without user_dont_touch/user_size_only. Note, these cells once split, will not be merged back if **synthesize_multisource_clock_taps** is called consecutively. Hence, user needs to ensure to use a pre-tap assignment block when exploring tap driver locations using multiple calls to **synthesize_multisource_clock_taps**.

The naming convention for the merged cells can be configured through the following app options: cts.multisource.tap_merge_cell_name_prefix, cts.multisource.tap_merge_cell_name_suffix, and cts.multisource.tap_merge_concatenate_length_threshold

After merging is complete, the next step in tap assignment occurs, which is splitting of clock cells to reassign clock sinks to tap drivers. Sinks are assigned and reconnected to the closest tap driver. By default, the distance between a sink and a tap driver is computed by estimating the path length considering the placeable standard cell area. Macros and placement blockages will cause detouring estimations in this mode. By setting the application option **cts.multisource.tap_synthesis_route_based_estimation** to *true* tap assignment will use a buffer-aware global route based distance estimation. This mode uses more runtime but might deliver better assignments in terms of final clock tree synthesis QoR.

The tap drivers need to have a fixed location and placed legally. Placement blockages are honored and macros taken into account while computing the shortest distance to make sure that buffers or other clock logic can be placed along the path from the tap driver to the sink.

Splitting honors frozen ports set with the **set_freeze_ports** command, **set_dont_touch** constraints, **set_size_only** constraints, and fixed placement attributes on cells. Splitting is not performed in case ports would have to be punched on power domain boundaries.

Splitting copies timing constraints, UPF constraints, and user attributes on cells as needed. For example, if a false path is defined through some of the split clock logic, the false path constraint is duplicated to all of the split cells as well. The cloned cells are placed in the same logical hierarchy and voltage area as the original cell.

The naming convention for the cells and nets created during splitting can be configured through the following app options: **cts.multisource.subtree_split_cell_name_prefix**, **cts.multisource.subtree_split_cell_name_suffix**,

cts.multisource.subtree_split_net_name_prefix, and **cts.multisource.subtree_split_net_name_suffix**.

Tap assignment generates logfile output, which gives basic guidance about what the command is doing and any problems encountered during execution. You can generate additional, verbose output by setting the **cts.multisource.verbose** application option to 1. This setting is intended for advanced users doing more detailed investigation of the multisource subtree synthesis results.

Tap Drivers

In a regular multisource CTS flow, the subtrees connect to the mesh through tap drivers. These are specified by the **set_multisource_clock_tap_options -driver_objects** command. The tap driver acts as the driver or root of a particular multisource CTS subtree.

Typically, a tap driver is a clock buffer, but the multisource CTS flow allows a lot of flexibility in the tap driver concept. A tap driver can be an ICG output pin or a clock input port. It is required that tap drivers have a legal and fixed location.

lib_cell Subsets

Multisource tap assignment honors *lib_cell subsets*, if defined. Subsets can be defined in the library manager or an implementation tool by setting the *subset_name* attribute, for example:

```
set_attribute [get_lib_cells */INV1*] subset_name INV1
set_attribute [get_lib_cells */INV2*] subset_name INV2
```

lib_cells can only be resized within their subset. In the above example, **/INV1** lib_cells can be resized to other **/INV1** lib_cells, **/INV2** lib_cells can be resized to other **/INV2** lib_cells, and all inverters not belonging to one of those subsets can be resized among each other.

Merging is restricted to subsets, so if two cells would otherwise be merge candidates but their lib_cells belong to different subsets, they are not merged.

Splitting is not affected by subsets, as the split cells all initially get the same lib_cell as the unsplit master cell.

Sink Groups

Multisource tap assignment allows the user to control individual sink to tap driver assignment using sink groups. Sink groups can be defined using the **create_multisource_clock_sink_group** command. A sink group contains a set of sink pins which should be assigned together to one particular tap driver. A sink group can be either exclusive or non-exclusive. Exclusive means that no other sink which is not in that sink group can be assigned to the tap driver of that sink group. A non-exclusive sink group allows other sinks to get assigned to the tap driver of the sink group as well.

Multivoltage support

By default, tap assignment does not punch ports on power domain boundaries while splitting cells. It also does not split power management cells such as isolation and level shifter cells by default. When the app option **cts.multisource.enable_full_mv_support** is set to *true* then port punching on power domain boundaries and cloning of power management cells is allowed. UPF constraints are honored and copied as required during this. In this case the command also considers the drivability of the tap drivers from an MV point of view. If for example, a tap driver which is geometrically closer to the sinks is less always-on than a given first-level clock cell, then this clock cell cannot be reassigned to that tap driver. In such a case the closest tap driver which can electrically drive the loads is selected. The warning message CTS-741 is printed in case a sink cannot be assigned to its closest tap driver due to this MV check.

Integrated tap assignment in place_opt

When **place_opt.flow.enable_multisource_clock_trees** options is set to *true* during place_opt, **place_opt** will run tap assignment internally and user need not run **synthesize_multisource_clock_taps** explicitly before **clock_opt**. While using this feature, care must be taken that all multisource CTS related setup such as global clock tree (Htree) creation, clock mesh creation, definition of options for tap assignment, tap driver insertion, removing constraints like user_dont_touch, fixed, etc. to allow cell cloning and required CTS related settings are provided before place_opt. With this **place_opt integrated tap_assignment** feature, place_opt can see the clock structure changes done as part of tap assignment, especially ICG clones, and perform improved placement and

optimization. This feature supports all the features currently honored by **synthesize_multisource_clock_taps**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example performs tap assignment on all defined clocks with tap driver objects defined on them.

```
prompt> synthesize_multisource_clock_taps
```

The following example calls multisource tap assignment on only clocks clk1 and clk2.

```
prompt> synthesize_multisource_clock_taps -clocks [get_clocks {clk1 clk2}]
```

synthesize_multisource_global_clock_trees

Performs synthesis and detail routing on specified nets to build H-tree style global clock tree with minimum skew between the endpoints of the net; which is essential in multisource clock tree structure.

SYNTAX

status **synthesize_multisource_global_clock_trees**
[-nets *net_list*]
[-lib_cells *libcell_list*]
[-prefix *name*]
[-roots *pin_port_list*]
[-leaves *pin_list*]
[-skip_pin_connections]
[-use_zroute_for_pin_connections]

Data Types

net_list collection
libcell_list collection
name string
pin_port_list collection
pin_list collection

ARGUMENTS

-nets *net_list*

Specifies the nets for which synthesis and detail routing should be performed. Each specified net is synthesized individually. It is assumed that the leaf pins of each net are regulary distributed such that a symmetric H-tree can be constructed. This option is mutually exclusive to the options *-roots* and *-leaves*. It requires option *-lib_cells*.

-lib_cells *libcell_list*

Specifies a list of library cells of type buffer or inverter which are allowed to be used during synthesis. They need not have any purpose assigned but should not be marked dont_touch. In case multi voltage support is required (which is given when app option *cts.multisource.enable_full_mv_support* is set to *true*) and single and dual rail versions of the repeaters are given the order of the given library cells play a role. The first, second etc. occurrence of a single rail buffer/inverter is matched with first, second etc. occurrence of a dual rail buffer/inverter. It is assumed that these pairs of repeaters are electrical equivalent in terms of input capacitance and delay. Any single or dual rail repeater which is not matched with a counterpart is dropped. This option is mutually exclusive to the options -roots and -leaves. It requires option -nets.

-prefix *name*

Specifies a string which is used as a name prefix for newly created instances during synthesis. This option is mutually exclusive to the options *-roots* and *-leaves*. It requires option *-nets*.

-roots *pin_port_list*

Specifies a list of starting pins or ports in the netlist for which the nets should be detailed routed in H-tree style. It requires option *-leaves*. This option is mutually exclusive to the options *-nets* and *-lib_cells*.

-leaves *pin_list*

Specifies a list of pins in the netlist up to which the nets should be detail routed in H-tree style. It requires option *-roots*. This option is mutually exclusive to the options *-nets* and *-lib_cells*.

-skip_pin_connections

If specified the routing engine will not finish the connection down to the pin shape. It will stop at the highest available metal layer close to the pin shape. By default the routing engine connects all the way down to the pin shapes. However, it is recommended to use the Zroute engine for pin connections.

-use_zroute_for_pin_connections

If specified the Zroute engine is used to finish the connection down to the pin shape. By default, the Custom Router engine is used to do the routing all the way down to the pin shapes. This option will have no effect if *-skip_pin_connections* is specified. It is recommended to use the Zroute engine for pin connections.

DESCRIPTION

The *synthesize_multisource_global_clock_trees* command can be called in two flavors. When called with options *-nets* and *-lib_cells* it will insert repeaters instantiated from library cells specified with option *-lib_cells* on the nets specified with option *-nets* such that the given design constraints are fulfilled. Each net behind the inserted repeaters will be detail routed using the Custom Router. The repeaters are inserted in such a way that the detail routing will have H-tree style. This requires that the sink pins in the nets specified with option *-nets* are distributed regularly in the design area for example by using the **create_clock_drivers** command.

When command *synthesize_multisource_global_clock_trees* is called with options *-roots* and *-leaves* all nets in the netlist between the specified root pins and leaf pins are routed in H-tree style if possible. It is required that each root pin drives the same number of leaf pins and that each such path from root pin to leaf pin has the same number of gate levels. Every net at the same gate level is handled in such a way that the resulting detail routing is as symmetric as possible against the other nets in the same gate level. The Multi-Level Physical Hierarchy Flow (MLPH Flow) is also supported in this mode. Using this flow the H-tree routing can also be done inside the physical hierarchy blocks. MLPH flow can be enabled by setting the application option *cts.multisource.enable_mlph_flow* to true.

In the MLPH flow, the physical blocks must have a fixed placement status, should be editable and port-punching should also be enabled. The optimization of physical blocks must be enabled using the application option *top_level.optimize_subblocks*. In addition, the MSCTS full MV flow should also be turned ON using the application option *cts.multisource.enable_full_mv_support*. To enable the routing to take place inside physical hierarchy blocks, the application option *custom.route.block_soft_macros* must be set to false for the current block.

The router called from command *synthesize_multisource_global_clock_trees* to create the long distance routing is constraint to use the highest two metal layers available for the nets passed with option *-nets* or connecting the cells derived from the cones spanned by the elements of the options *-roots* and *-leaves*. These layers can be controlled by using the commands *set_clock_routing_rules*/*set_routing_rule* in conjecture with an explicit non-default routing rule created with command *create_routing_rule*. The layers should be within global min/max layers specified with *set_ignored_layers*.

The command *synthesize_multisource_global_clock_trees* is making use of application option *cts.multisource.enable_pin_accessibility_for_global_clock_trees* to control the placement of inserted cells such that they are accessible from the selected Htree routing layers. This ensures good global clock tree (Htree) routing topology and hence the QoR. This can be contra productive in case the specified library cells through option *-lib_cells* are multi-row height cells. In such a case

the application option should set to false.

If the command *synthesize_multisource_global_clock_trees* is used on a design with multi voltage (MV) setup it is required to set the application option *cts.multisource.enable_full_mv_support* to *true*. This enables additional code to ensure that a MV clean input is still clean after adding repeaters in the design.

Use the command *remove_multisource_global_clock_trees* to undo the logical and physical changes of command *synthesize_multisource_global_clock_trees*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example buffers the root net clk and routes all nets driven by the inserted buffers in H-tree style.

```
prompt> synthesize_multisource_global_clock_trees -nets [get_nets clk] \
   -lib_cells [get_lib_cells */CKBUF*]
```

The following example determines all nets between primary input clk and leaf pins clk_leaf_*/A and detail route them in H-tree style. All nets at the same gate level as being equivalent and the resulting detail routing should be as symmetric as possible.

```
prompt> synthesize_multisource_global_clock_trees -roots [get_pins clk] \
   -leaves [get_pins clk_leaf_*/A]
```

The following example inserts a 4 level buffer tree in a multi-physical hierarchy design and creates H-tree style routing using the MLPH flow.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] \
                        -lib_cells $bufs \
                        -configuration [list [list -level 1 -prefix TAP1 -boxes {1 1}] \
                                             [list -level 2 -prefix TAP2 -boxes {2 1}] \
                                             [list -level 3 -prefix TAP3  -boxes {2 2}] \
                                             [list -level 4 -prefix TAP4 -boxes {4 4}] \
                                       ]

prompt> set_app_options -block [current_block] -name custom.route.block_soft_macros -value false
prompt> synthesize_multisource_global_clock_trees -roots B1/y -leaves [get_pins -hier TAP4*/a] -use_zroute_for_pin_connections
```

synthesize_regular_multisource_clock_trees

Performs auto tap synthesis and global clock tree synthesis for regular multisource clock trees. It includes auto tap insertion and buffering global clock tree (Htree) as well as detail routing of the global clock tree (Htree). It takes input from set_regular_multisource_clock_tree_options to guide the synthesis specified by the user.

SYNTAX

status **synthesize_regular_multisource_clock_trees**
[-from tap_synthesis | htree_synthesis]
[-to tap_synthesis | htree_synthesis]
[-clocks *clock_list*]
[-list_only]

Data Types

clock_list collection

ARGUMENTS

-from tap_synthesis | htree_synthesis

Specifies that regular multisource clock tree synthesis should start from the specified step. By default, all the steps are run in order: **tap_synthesis**, and **htree_synthesis**. This option can be used to start from a specific step. For example, **synthesize_regular_multisource_clock_trees -from htree_synthesis** skips the tap synthesis step.

The *-from* and *-to* options can be used together or separately to run only certain steps of the regular multisource synthesis.

-to tap_synthesis | htree_synthesis

Specifies that regular multisource clock tree synthesis should end at the specified step. By default, all the steps are run in order: **tap_synthesis**, and **htree_synthesis**. This option can be used to end at a specific step. For example, **synthesize_regular_multisource_clock_trees -to tap_synthesis** skips the Htree synthesis step.

-clocks *clock_list*

Specifies for which clocks auto tap synthesis should be performed. By default, clocks or nets defined through set_regular_multisource_clock_tree_options will be considered.

-list_only

Lists the available steps for the regular multisource clock tree synthesis command. These steps are **tap_synthesis**, and **htree_synthesis**. By default, all steps are run when the **synthesize_regular_multisource_clock_trees** command is used. But, the *-from* and *-to* options can be used to limit the command to execute only the specified steps. *-list_only* simply lists the valid steps that can be passed to the *-from* and *-to* options.

DESCRIPTION

The *synthesize_regular_multisource_clock_trees* command performs regular multisource clock tree synthesis, from auto tap synthesis to Htree synthesis. It takes input from option command set_regular_multisource_clock_tree_options. The feature aims at automatically creating Htree friendly tap drivers using configuration (tap_boxes) from user as guidance. This helps user to arrive at suitable tap driver configuartion easily.

In auto tap synthesis, it inserts tap drivers based on *-tap_boxes* and library cells from the option *-tap_lib_cells* in the options command and select the locations based on clock sinks distribution. When *-tap_template_cells* is given in the options command, it will split the template cell as tap drivers instead of inserting repeaters. The tap locations are optimized to form a regular grid and also a Htree build feasibility is performed at this step to help find a set of taps that will likely be accepted at global clock tree synthesis step. You can use additional switches -max_displacement, -keepout and -tap_boundary to control max_displacement of tap drivers from referred locations and region allowed for tap driver insertion.

After auto tap synthesis, the command will do the global clock tree synthesis. It will insert repeaters instantiated from library cells specified through the option command on option *-htree_lib_cells* on the nets specified with option *-nets* such that the given design constraints are fulfilled similar to synthesize_multisource_global_clock_trees. Each net in the global clock tree will be detail routed using Custom Router for balanced routing and use zroute for final pin connections. The repeaters are inserted in such a way that the detail routing will have Htree style.

The tap drivers and Htree repeaters by default have "clk_drv" and "msgts" as prefix. You can specify desired naming convention using -prefix switch.

The command synthesize_regular_multisource_clock_trees picks up the Htree NDR and layer list specified through the option command on option -htree_routing_rule and -htree_layer_list. If these are not specified then same are picked up from the clock tree settings specified with set_routing_rule and set_clock_routing_rules. The layers should be within global min/max layers specified with set_ignored_layers.

The command synthesize_regular_multisource_clock_trees makes use of applictaion option cts.multisource.enable_pin_accessibility_for_global_clock_trees to control the placement of inserted cells such that they are accessibe from the selected Htree routing layers. This ensures good global clock tree (Htree) routing topology and hence the QoR.

If the command synthesize_regular_multisource_clock_trees is used on a design with multi voltage (MV) setup it is required to set the application option cts.multisource.enable_full_mv_support to true. This enables additional code to ensure that a MV clean input is still clean after adding repeaters in the design.

Commands report_regular_multisource_clock_tree_options and remove_regular_multisource_clock_tree_options can be used to report and remove the options as required.

Use commands remove_multisource_global_clock_trees and remove_clock_drivers to remove htree and tap drivers as required. These are useful when exploring different tap driver configurations.

For detailed messaging you can cts.multisource.verbose application option during debug.

Once tap drivers are inserted and Htree is built you can define tap assignment settings using set_multisource_clock_tap_options and run tap assignment using synthesize_multisource_clock_taps. If using tap assignment at place_opt then only set_multisource_clock_tap_options is sufficent. Please refer to place_opt.flow.enable_multisource_clock_trees for more details.

To do multiple clock synthesis using this command, the order of the synthesis will follow the order of the clocks under -clocks. If -clocks is not given, the synthesis will follow the order of the set_regular_multisource_clock_tree_options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example inserts tap drivers in 4 columns and 2 rows for clock **clk** ensuring Htree compatibility and builds Htree automatically to drive the tap drivers using specified library cells, NDR and layer list.

```
prompt> set_regular_multisource_clock_tree_options -clock clk -topology htree_only -prefix MSCTS \
 -tap_boxes {4 2} -tap_lib_cells [get_lib_cells LIB1/BUF1] \
 -htree_lib_cells [get_lib_cells LIB1/BUF2] -htree_layers "m9 m10" -htree_routing_rule "htree_ndr"

prompt> synthesize_regular_multisource_clock_trees
```

Similar to the above example, the following example performs auto tap synthesis and htree synthesis with successive command calls for debug.

```
prompt> set_regular_multisource_clock_tree_options -clock clk -topology htree_only -prefix MSCTS \
 -tap_boxes {4 2} -tap_lib_cells [get_lib_cells */CKBUF*] \
 -htree_lib_cells [get_lib_cells */CKINV*] -htree_layers "m9 m10" -htree_routing_rule "htree_ndr"

prompt> synthesize_regular_multisource_clock_trees -from tap_synthesis  -to tap_synthesis
prompt> synthesize_regular_multisource_clock_trees -from htree_synthesis  -to htree_synthesis
```

train_pg_ml_model

Create ML training files based on created ML training data in memory, and then train the ML model for fixability prediction.

SYNTAX

status **train_pg_ml_model**
[-input_directory *directory_name*]

Data Types

directory_name string

ARGUMENTS

-input_directory *directory_name*

Specify directory name of created ML training file. If the option is not specified, the command creates ML training files in the default directory ./pg_model based on ML training data in memory.

DESCRIPTION

This command creates ML training files based on created ML training data in memory, and then train the ML model for fixability prediction. The trained model is stored in the directory ./pg_model

EXAMPLES

The following example creates ML training data in memory, output training data to files in directory ./pg_model, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

prompt> **compile_pg -create_ml_data**
prompt> **train_pg_ml_model**

The following example creates ML training data in memory, output training data to files in directory pg_data_1, and train ML model on the training files in the directory pg_data_1. The trained ML model is stored in the directory ./pg_model.

prompt> **compile_pg -create_ml_data**
prompt> **create_pg_ml_data -output_directory pg_data_1**

```
prompt> train_pg_ml_model -input_directory {pg_data_1}
```

transform_polygons

Performs translation and rotation of a geometric region and returns the result as a geo_mask.

SYNTAX

collection **transform_polygons**
[-objects *object_list*]
[*pos_object_list*]
[-orientation *orientation*]
[-coordinate {*x y*}]
[-inverse]

Data Types

object_list collection
pos_object_list collection
orientation string
x float
y float

ARGUMENTS

-objects *object_list*

Specifies the objects to be used to define the geometric region to be transfomed. Objects can be a heterogeneous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

This is a required option.

-orientation *orientation*

Specifies the orientation to which the geometric region should be rotated. Rotation is counterclockwise about the origin ({0 0}). Valid value for the orientation are: R0, R90, R180, R270, MX, MXR90, MY, MYR90.

-coordinate *coordinate*

Specifies the relative coordinate to translate (shift) the geometric region by. If the *-orientation* option is also specified, the translation will happen after the rotation.

-inverse

This argument when provided with transform_polygons command, inverts the desired transformation.

DESCRIPTION

This command performs translation and/or rotation of a geometric region specified by *objects* and returns the result as a geo_mask object. The objects in *objects* are not modified, rather the result of the transformation of the region specified by *objects* is returned.

EXAMPLES

The following example returns a geo_mask with a rectangle rotated 90 degrees counterclockwise and moved up by 10 units.

```
prompt> transform_polygons -coordinate {0 10} -orientation R90 \
  -objects [create_poly_rect -boundary {{100 100} {130 110}}]
```

trim_pg_mesh

Trims dangling wires of PG nets after the PG mesh is created.

SYNTAX

status **trim_pg_mesh**
[-nets *netname_list*]
[-types *type_list*]
[-layers *layer_list*]
[-trim_to *trim_to_opt*]
[-drc *drc_opt*]
[-verbose *verbose_opt*]
[-shapes *shape_list*]
[-undo]

Data Types

netname_list list
type_list list
layer_list list
trim_to_opt specification
drc_opt specification
verbose_opt specification
shape_list list

ARGUMENTS

-nets *net_list*

Specifies a list of PG nets on which to trim wires. By default, all PG nets are processed.

-types *type_list*

Specifies a list of PG object types. The PG types should include one or more of the following keywords: **ring**, **stripe**, **lib_cell_pin_connect**, **macro_pin_connect**, and **macro_conn**. These types are for PG rings, PG straps, standard cell pin connections, macro pin connections. By default, all of these types are considered for wire trimming.

-layers *layer_list*

Specifies metal layer names for the PG objects. *layer_list* is a list containing layer names. By default, objects on all metal layers are considered for wire trimming.

-trim_to target_wire | via

Specifies the stop criteria for wire trimming. If **via** is specified, then wire ends are trimmed to the closest same net and same layer

via metal enclosure. By default, wire ends are trimmed to closest target of another same net PG wires, pins, or terminals.

-drc no_check | **check_but_no_fix**

Specifies the DRC option for PG wire trimming. The argument following **-drc** must be either no_check or check_but_no_fix. no_check means that no DRC check is performed. check_but_no_fix means that DRC check is performed, DRC errors are reported, but no DRC fixing is performed. By default, DRC is checked and fixed for the PG wire trimming. If wire has DRC and the tool cannot fix it, the wire is restored to an original shape.

-verbose none | **{dangling drc}**

Writes out extra information to the log file. The argument following **-verbose** must be either **none** or one of: **dangling**, **drc** or **{dangling drc}**. If **dangling** is specified, **gui_add_annotation** commands are written to the log file with the original shape bounding box of the deleted dangling wire. If **drc** is specified, **gui_add_annotation** commands are output into log file with original shape bounding box of restored due to DRC wire in addition to DRC violation report. Default is **none**

-shapes ***shape_list***

Specifies a list of PG shapes for which to trim wires. By default, all feasible wires of PG nets will be trimmed.

-undo

Restores trimmed shapes to their original dimensions, and restores deleted dangling wires and vias, trimmed by most recent **trim_pg_mesh** command. Only one level of undo is supported; the **trim_pg_mesh -undo** command clears the undo command stack.

DESCRIPTION

This command performs PG wire trimming after the PG mesh is created for the whole design. This command is used to remove dangling wire ends and trim them to the closest target of other same net PG wires or pins or terminals. If **trim_to via** is specified, the wire ends are trimmed to the closest same net and same layer via metal enclosure. If the tool finds dangling wires, the wire and connecting vias are removed. The criteria for dangling wire is a wire, connecting to just one same or different layer target with via or via stack with one or both wire ends dangling (not connected). The tool may leave some dangling wires to avoid creating a DRC violation if the wire may have been routed as a patch to cover a minimum edge length, minimum width, minimum area, or other DRC violation.

The **trim_pg_mesh** command can be run several times to further trim wires after dangling shapes are removed. Note that you can only restore shapes to the state before most recent **trim_pg_mesh** command; only one level of undo is supported. Floating wire shapes and vias, which represent a disconnected component of any number of wires and vias, should be removed using the **check_pg_connectivity** PG command. This command returns a collection of floating vias and wires. You can easily remove floating objects reported by **check_pg_connectivity** with the **remove_objects command**. You should remove any floating PG objects before running **trim_pg_mesh**.

EXAMPLES

The following example performs PG wire trimming on PG nets VDD and VSS after PG mesh is created with one of PG creation commands.

```
prompt> compile_pg
prompt> trim_pg_mesh \
   -nets {VDD VSS}
```

The following example performs PG wire trimming on all PG nets, only for stripes and standard cell connections on layer M5. DRC is checked but not fixed, and DRC report and bounding boxes of wires with DRC and dangling wires are output into log.

```
prompt> compile_pg
prompt> trim_pg_mesh \
   -types {stripe lib_cell_pin_connect} \
   -layers M5 \
   -drc check_but_no_fix \
   -verbose {dangling drc}
```

trim_shapes

This command symmetrically trims line-ends of shapes according to specified line-end spacing values per layer.

SYNTAX

status **trim_shapes**
-line_end_spacings {*list_of_layer_value_pairs*}

Data Types

list_of_layer_value_pairs list

ARGUMENTS

-line_end_spacings {*list_of_layer_value_pairs*}

Specifies the desired line-end spacing per layer.

{*layerName value*}

DESCRIPTION

This command symmetrically trims line-ends of shapes according to specified line-end spacing values per layer. For line-end spacings greater or equal to the specified layer value, nothing is done. For line-end spacings smaller than the specified value, both line-ends are trimmed symmetrically such that the specified spacing is accomplished between the new line-ends. For line-ends which are defined by a via surround, the via might be replaced by one with a smaller surround to accomplish the desired spacing. Please note that vias which are excluded from signal routing (excludedForSignalRoute = 1) are also used for replacement.

Only wires and vias can be trimmed (signal, PG and clock nets), other situations remain unchanged. All situations which could not be fixed are flagged as DRC violations. Other DRC types are not checked or reported.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

prompt> **trim_shapes -line_end_spacings {{M1 0.02} {M2 0.03}}**

unalias

Removes one or more aliases.

SYNTAX

string **unalias**
patterns

ARGUMENTS

patterns

Specifies the patterns to be matched. This argument can contain more than one pattern. Each pattern can be the name of a specific alias to be removed or a pattern containing the wildcard characters ***** and **%**, which match one or more aliases to be removed.

DESCRIPTION

The **unalias** command removes aliases created by the **alias** command.

EXAMPLES

The following command removes all aliases.

prompt> **unalias ***

The following command removes all aliases beginning with f, and the alias rt100.

prompt> **unalias f* rt100**

SEE ALSO

alias(2)

uncommit_block

Merges the contents of a physical block into the parent design and updates the reference of the instance, and removes the design for the block if specified.

SYNTAX

collection **uncommit_block**
-design *reference_design*
-type *cell_hierarchy_type*
[-remove_design]
[-verbose]

Data Types

reference_design string or collection
cell_hierarchy_type string

ARGUMENTS

-design *reference_design*

Specifies the name of the cell reference design to be uncommitted. This is a required option.

-type *cell_hierarchy_type*

Specifies the cell hierarchy type after uncommit. Valid types are **module_boundary** and **module**. By default, the type is **module_boundary**.

-remove_design

Removes the design referenced by cell.

-verbose

Displays additional debugging information.

DESCRIPTION

This command removes the physical hierarchy for the specified design and converts the reference into a logical hierarchy cell. The command fails if the given cell path name or object does not exist or is already a logical hierarchy cell.

If the **-remove_design** option is used, the command removes the reference design for the specified cell.

As part of the uncommit process, certain physical elements within the block are propagated to the parent cell. Among these elements are routing, route guides, placement blockages, move bounds and relative placement groups.

Also, logical group bounds are propagated automatically to the top block during uncommit_block.

If there is name conflict for relative placement group then its name is prefixed with name of the uncommitted block.

If the block to be uncommitted has site arrays, they are propagated up to the parent if they are non-default site arrays and they have no conflicts with existing non-default site arrays in the parent.

Default site arrays are not propagated up. But the command does check block default site arrays and confirms that if the block has a default site array, the command asserts that the parent must have a default site array also. If it doesn't the command will issue an error and reject the block for uncommit. If a default site array exists in both the block and the parent, the command asserts that they must be identical in definition and that the default rows in the block are aligned with the ones in the parent. If there is any type of incompatibility between the default site array in the block and in the parent, the command rejects the block for uncommit. There is, however, an exception to this rule. If a block being uncommitted is specified to be uncommitted to a module (no hier boundary) AND the reference block has no cells that are placed, then the checking rule is relaxed for default site arrays consistency with the top.

The changes to the netlist, as a result of uncommitting blocks to modules, are dramatic, and structural. Because of this, it is necessary to purge ALL existing timing constraints before uncommitting the blocks. This is done automatically inside of uncommit_block. This will affect all top-level timing constraints, including attributes such as "dont_touch" and other timing-based attributes. It is necessary for the user to re-apply timing constraints after running this command.

Please note, also, that if uncommit_block is performed in a "bottom-up" approach (where a mid-level block of a MPH design is opened as the current block), that the automatic purging of timing constraints in the current block will result in linking problems when the top block is subsequently opened.

EXAMPLES

This example uncommits the block instances of design A:

```
prompt> uncommit_block -design A
```

SEE ALSO

commit_block(2)
get_cells(2)
set_cell_hierarchy_type(2)

undefine_user_attribute

Removes the specified user-defined attribute from all open libraries.

SYNTAX

status **undefine_user_attribute**
-classes *class_list*
[-quiet]
[-force]
-name *attribute_name*
pos_attribute_name

Data Types

class_list list
attribute_name string
pos_attribute_name string

ARGUMENTS

-classes *class_list*

Specifies the classes from which to remove the user-defined attribute. Valid classes are design, port, cell, net, clock, and so on.

-quiet

Turns off the warning message that would otherwise be issued if the attribute or classes are incorrectly specified.

-force

Forces removal of the user-defined attribute, even if the attribute is set for some objects.

-name *attribute_name*

Specifies the name of the attribute. This option is mutually exclusive with *pos_attribute_name*. Specify either **-name** or *pos_attribute_name*, but not both.

pos_attribute_name

Specifies the name of the attribute. This positional option is provided for compatibility with other tools. This option is mutually exclusive with **-name**. Specify either **-name** or *pos_attribute_name*, but not both.

DESCRIPTION

This command removes the user-defined attribute from all the libraries opened in the session. The attribute is removed from the classes that support user-defined attributes.

The command issues an error message and exits under the following conditions:

- The specified attribute is an application attribute (not a user-defined attribute) in any of the class specified by the **-classes** option.
- The class list contains a class where the specified attribute is set for at least one object in any design.

Use the **list_attributes** command to confirm that the attributes you undefined are removed from the design.

EXAMPLES

The following example sets a user-defined attribute named *attr_1* and undefines it using **-name** option. The attribute is removed from the track class.

```
prompt> define_user_attribute -classes {track} -type double \
  -range_min 2.0 -range_max 3.2 -name attr_1

prompt> undefine_user_attribute -name attr_1 -classes track
1
```

The following example undefines a user-defined attribute named *attr_1* by specifying it as a positional attribute.

```
prompt> undefine_user_attribute attr_1 -classes track
1
```

The following example tries to undefine an application attribute name named *layer* from the track class by using the **-name** option. The command issues an error message and exits because layer is an application attribute, not a user-defined attribute.

```
prompt> undefine_user_attribute -name layer -classes track
Error: Attribute 'layer' is not user-defined for class(es) 'track'.
Cannot undefine it. (ATR-016)
```

The following example tries to undefine a user-defined attribute named *attr_1* by using the **-name** option. The command issues an error message and exits because the attribute is set for at least one object in a design for the track class.

```
prompt> undefine_user_attribute -name attr_1 -classes track
Error: Attribute 'attr-1' has been set for at least one of the object of
following class(es) 'track'. Cannot undefine it. (ATR-018)
```

The following example undefines a user-defined attribute named *attr_1* by using the **-name** option. The first command fails because the attribute is set for at least one object in a design for the track class. The second command uses the **-force** option to force removal of the attribute.

```
prompt> undefine_user_attribute -name attr_t -classes track
Error: Attribute 'attr_t' has been set for object(s) of following
class(es): 'track'. Cannot undefine it. (ATR-018)
```

```
prompt> undefine_user_attribute -name attr_1 -classes track -force

undo

Undo the effects of one or more commands.

SYNTAX

int **undo**
[-levels *num_levels* | -marker *marker_name*]
[-check_only]
[-silent]

Data Types

num_levels int
marker_name string

ARGUMENTS

-levels *num_levels*

Undoes the effects of the specified number of command levels.

-marker *marker_name*

Reverts the system state to the point of creation of the marker with the specified user or system name.

-check_only

Causes the command to return the same status and messages it would otherwise return without actually performing the undo or changing anything.

-silent

Surpresses messages and a TCL error in the event of an error.

DESCRIPTION

This command undoes the effects of one or more previous database-changing commands, or "command levels". If the *-levels* option is used, then the specified number of command levels will be undone. It is an error to specify more levels than there are in the command undo history.

Note that a command level refers to a command that explicitly changes the system state, so the undoing of one level may revert the state back several commands, such that only the earliest command was a database-changing command, the other more recent commands being ignored. Some commands that change environmental parameters but not the database are also exempt and are not considered as command levels. Use the *get_undo_info* command to determine what the command corresponding to the next undoable command level is.

If the *-marker* option is used, then the system state will be reverted to that of when the specified marker was created. *marker_name* may be the user assigned or system generated name of the marker. This option would typically be used to revert back to a user marker, which would have been created using the *create_undo_marker* command. It is an error to specify a marker that was created later than the current point in the command history - for that case use the *redo* command instead.

If neither the *-levels* or *-marker* option is used, then this command will undo one command level.

The command returns the actual number of command levels undone or, if the *-check_only* option was used, that would have been undone without the *-check_only* option.

Not all commands are undoable. If a non-undoable command is executed, the undo history will be cleared. Use the *get_undo_info* command to determine which commands are undoable.

To preserve system resources and minimize the impact on performance, the undo system limits the size of the undo history it maintains. These limits can be adjusted via the following app options: *undo.max_levels* - the maximum number of command levels to save, and *undo.max_memory* - the maximum amount of memory (in bytes) the undo system may use.

EXAMPLES

The following undoes one command level:

```
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> set_attribute $inst origin {100 300}
{U368}
prompt> get_attribute $inst origin
100.0000 300.0000
prompt> undo
1
prompt> get_attribute $inst origin
0.0000 0.0000
```

The following undoes back to a user marker:

```
prompt> create_undo_marker my_mrk
my_mrk
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> set_attribute $inst origin {200 400}
{U368}
prompt> set_attribute $inst origin {300 600}
{U368}
prompt> get_attribute $inst origin
300.0000 600.0000
prompt> undo -marker my_mrk
2
prompt> get_attribute $inst origin
0.0000 0.0000
```

ungroup_cells

Removes one level of hierarchy.

SYNTAX

status **ungroup_cells**
cell_list | -all
[-flatten]
[-simple_names]
[-prefix *prefix_name*]
[-start_level *n*]
[-force]

Data Types

cell_list list
prefix_name string
n integer

ARGUMENTS

cell_list

Specifies a list of hierarchical cells whose hierarchies will be ungrouped. If more than one cell is specified, the list must be enclosed in braces ({}). You must specify either *cell_list* or the -all keyword, but not both.

-all

Indicates that all hierarchical cells in the current block (or current instance if set) are to be ungrouped. You must specify the *-all* keyword or *cell_list*, but not both.

-flatten

Indicates that the specified cells are to be ungrouped recursively until all levels of hierarchy are removed.

-simple_names

Indicates that simple and nonhierarchical names are to be used for cells that are ungrouped. When this option is not specified, cells are given the default hierarchical names. With this option, cells maintain their original names.

-prefix prefix_name

Specifies the prefix to use in naming ungrouped cells. The default naming style is as follows:

cell_being_ungrouped/*old_cell_name*{*number*}

-start_level n

Causes all hierarchical cells that are at the level specified by n to be flattened. This option implies the **-flatten** option. The level value can be 1, 2, 3, and so on. Specifying a value of 1 flattens the cells from the current design. Specifying a value of 2 maintains the top-level hierarchy and all cells in each of the top-level hierarchy to be flattened.

-force

Causes all dont_touch hierarchical cells to be flattened. The dont_touch attribute is inherited by their leaf cells. This option can only be used when either the **-all** keyword or *cell_list* is specified.

DESCRIPTION

This command removes a single level of hierarchy by dissolving the specified hierarchical cell and absorbing its internal cells and nets into the parent cell. Nets that were connected to ports in the cell that was ungrouped are deleted, and the corresponding nets in the parent cells are extended to connect to the newly promoted cells' pins.

Nets and cells from the dissolved hierarchies are renamed to preserve their original path names from the top block. The new names are formed by joining the instance name of the dissolved cell with the original net or cell name separated by the hierarchical separator character (default '/'). For example, if ungrouping cell mid1 causes cell U8 to be moved to mid1's parent cell, the command renames cell U8 to be mid1/U8. This renaming allows power and timing constraint files to work correctly with the ungrouped objects.

The **ungroup_cells** command does not collapse block boundaries, so the specified cells might not directly instantiate a block. If the *-flatten* option is specified, the submodule recursion will stop at any block boundaries.

Cells marked with the **dont_touch** attribute cannot be ungrouped.

No constraints are moved or deleted by this command. If a specified cell has timing or power constraints on itself or its pins, it cannot be ungrouped.

This command operates on a single instance of the parent module that contains the cell being ungrouped. If that module is multiply instantiated, a separate and unique module will be created for this instance and the cell will be ungrouped only in this instance module.

EXAMPLES

The following example dissolves the hierarchical cells mid1/bot1 and mid1/bot2 and group their cells into module mid1:

```
prompt> get_cells mid1/*
{mid1/bot1 mid1/bot2}
prompt> ungroup_cells [get_cells mid1/*]
1
prompt> get_cells mid1/*
{mid1/bot2/c1 mid1/bot1/c1 mid1/bot1/c2 mid1/bot2/c2}
```

The following example dissolves all hierarchy below the current instance:

```
prompt> ungroup_cells -flatten -all
1
```

SEE ALSO

group_cells(2)
set_dont_touch(2)

uniquify

Creates individual reference copies for cells that have logic module references in the current design.

SYNTAX

collection **uniquify**
[cell_list]
[-verbose]
[-uniquify_children]
[-force]
[-base_name *base_name*]
[-new_name *new_name*]

Data Types

cell_list list
base_name string
new_name string

ARGUMENTS

cell_list

Specifies a list of hierarchical cells to be bound to unique reference copies. Each cell must be in the scope of the current instance, that is, in the hierarchy. Each cell must have a logic module reference.

-verbose

Prints additional messages.

-uniquify_children

Includes child hierarchical instances for the uniquify process. Instances with references of type block or lib_cell are stopping points.

-force

Uniquifies even if they are already unique or are marked with the dont_touch attribute. The top-level design and the ILMs are not renamed.

-base_name *base_name*

Specifies the base name to be used instead of the original module name for the new module.

-new_name *new_name*

Specifies the module name to use for a single cell specified using cell_list. If **new_name** conflicts with an existing module name, **design.uniquify_naming_style** is used to create new module name. This option can not be used with -force or -uniquify_children.

DESCRIPTION

The **uniquify** command takes the reference module of each cell in the current design and creates a unique copy. Then, all cells point to their individual reference modules. If the dont_touch attribute is set on a cell or a module, a new module is not created for that cell or any cell with that reference module. If a list of hierarchical cells is specified, the **uniquify** command works on the complete paths to these specified cells. A unique reference module is generated for each cell in the specified list even if the dont_touch attribute is set on the cell or its reference module. All the parent cells of the specified cells are also uniquified if they are not uniquified already.

A cell list might include cells that have different references. When a cell list is provided by the **get_cells** command, it automatically uses instances that have logic module references and prints out warnings for instances that do not have logic module references. The name of the new reference copy is determined by the value of the **design.uniquify_naming_style** application option that is set for the parent design. The default is "%s_%d".

Note: Empty modules are uniquified by default; these can be skipped by setting the **design.uniquify_skip_empty_modules** application option to true.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates uniquely named reference modules for all cells in the current design, but not for cells or their reference modules marked with the dont_touch attribute:

```
prompt> uniquify
```

In the following example, the **uniquify** command creates unique reference copies for the specified cells:

```
prompt> uniquify {u2 u3}
2
```

In the following example, u1 and u2 are instances of unique references mid1 and mid2. Executing the uniquify -force or uniquify {u1 u2} command renames the reference copies:

```
prompt> uniquify {u1 u2}
2
prompt> get_modules
{mid1_0 mid2_0}
```

In the following example, a new module "ADDER1" is created for cell u4 in the current design.

```
prompt> uniquify {u4} -new_name ADDER1
1
```

uniquify_block

Create individual reference copies for specified cells having block references.

SYNTAX

collection **uniquify_block**
[-library library]
cell_list

Data Types

cell_list list
library library name

ARGUMENTS

cell_list

Specifies the list of hierarchical cells to be bound to unique reference copies. Each cell must be in scope (at or below the current instance). Each cell must have block reference.

-library

Specifies the library name in which to create the copy of the block reference. Library provided should be an existing one. If this option is not specified, new copy will be created in library of existing reference.

DESCRIPTION

The **uniquify_block** command creates individual copies of block references for each specified cell. While making copy of block reference, all views are copied. Cells are then bounded to their respective views. The existing reference could only be a block in the current design. Cell list may include cells having difference references. When cell list is provided through **get_cells**, command automatically picks up instances that have block reference and print out warning for instances not having block reference. Name of the new reference copy will be determined using value of app option "design.uniquify_naming_style" set for the parent design. Default value is "%s_%d". This command shall implicitly retain the editability of the old reference by propagating the hierarchical edit-control to the new reference.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, uniquify_block is used to create unique reference copies for cells provided. New reference copies of blocks are created in library lib1.

```
prompt> uniquify_block -library lib1 {u2 u3}
2
```

unplace_group_repeaters

Unplace the previous placement of the repeaters.

SYNTAX

status **unplace_group_repeaters**
-cells *cell_list* |
-repeater_groups *group_id_list*
[-lib_cell_input *pin_name*]
[-lib_cell_output *pin_name*]

Data Types

cell_list	collection
group_id_list	list
pin_name	string

ARGUMENTS

-cells *cell_list*

Specifies the list of repeaters to be unplaced in the pipeline repeater paths. The two options -cells and -repeater_groups are mutually exclusive, and one of them is required.

-repeater_groups *group_id_list*

Specifies the list of repeater group ids. The two options -cells and -repeater_groups are mutually exclusive, and one of them is required.

-lib_cell_input *pin_name*

Specifies the pin name when lib cell has multiple input pins. The default value is D.

-lib_cell_output *pin_name*

Specifies the pin name when lib cell has multiple output pins. The default value is Q.

DESCRIPTION

This command unplaces the previous placement of the repeaters on route. The routes of the connected nets of the unplaced registers will be merged to complete route recovery.

This command unplaces only those repeaters that were added using add_group_repeaters or placed using place_group_repeaters.

However, for the virtual connections (that is, for the cells between groups that may not be connected directly), you need to set the app option eco.placement.eco_enable_virtual_connection to true.

EXAMPLES

The following examples show the usages of command.

The following examples show the usages of -cells.

```
prompt> unplace_group_repeaters -cells $ecoCells -lib_cell_input D -lib_cell_output Q
```

The following examples show the usages of -repeater_groups.

```
prompt> set_repeater_group -group_id 1 -cells [get_cells {eco_cell_3 eco_cell_7}] -cutline {{720 366} {720 386}}
prompt> set_repeater_group -group_id 2 -cells [get_cells {eco_cell_2 eco_cell_6}] -cutline {{920 366} {920 386}}
prompt> set_repeater_group -group_id 3 -cells [get_cells {eco_cell_1 eco_cell_5}] -cutline {{1230 330} {1230 350}}
prompt> set_repeater_group -group_id 4 -cells [get_cells {eco_cell_0 eco_cell_4}] -cutline {{1430 330} {1430 350}}
prompt> unplace_group_repeaters -repeater_groups {1 2 3 4} -lib_cell_input D -lib_cell_output Q
```

SEE ALSO

add_group_repeaters(2)
place_group_repeaters(2)

unsetenv

Removes a system environment variable.

SYNTAX

string **getenv**
variable_name

Data Types

variable_name string

ARGUMENTS

variable_name

Specifies the name of the environment variable to be unset.

DESCRIPTION

The **unsetenv** command searches the system environment for the specified *variable_name* and removes variable from the environment. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the **env** Tcl array variable. The **unsetenv**, commands is a convenience function to interact with this array. It is equivalent to 'unset ::env(*variable_name*)'

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you unset the variable using the **unsetenv** command, you remove the variable value in the application and in any new child processes you initiate from the application using the **exec** command. However, the variable is still set in the parent process.

See the **set** and **unset** commands for information about working with non-environment variables.

EXAMPLES

In the following example, **unsetenv** remove the DISPLAY varible from the environment:

prompt> **getenv DISPLAY**

```
host:0
prompt> unsetenv DISPLAY
prompt> getenv DISPLAY
Error: can't read "::env(DISPLAY)": no such variable
    Use error_info for more info. (CMD-013)
```

SEE ALSO

catch(2)
exec(2)
printenv(2)
set(2)
unset(2)
setenv(2)
getenv(2)

unsuppress_message

Enables printing of one or more suppressed informational or suppressed warning messages.

SYNTAX

string **unsuppress_message** [*messages*]

list *messages*

ARGUMENTS

messages

A list of messages to enable.

DESCRIPTION

The **unsuppress_message** command provides a mechanism to re-enable the printing of messages which have been suppressed using **suppress_message**. You can suppress only informational and warning messages, so the **unsuppress_message** command is only useful for informational and warning messages. The result of **unsuppress_message** is always the empty string.

You can suppress a given message more than once. So, you must unsuppress a message as many times as it was suppressed in order to enable it. The **print_suppressed_messages** command displays currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to re-enable the suppressed CMD-029 message. Assume that there are no aliases beginning with 'q'.

```
prompt> unalias q*
prompt> unsuppress_message CMD-029
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
```

SEE ALSO

print_suppressed_messages(2)
suppress_message(2)

update_block_views

This command detects any boundary change for readonly abstract blocks and incrementally updates the physical data for these blocks.

SYNTAX

int **update_block_views**
[-blocks *reference_names*]
[-verbose]

Data Types

reference_names list

ARGUMENTS

-blocks *reference_names*

Specifies a list of block references. When nothing is specified, command works on all the blocks.

-verbose

Specifies the verbosity of the command. By default verbose messaging is turned off.

DESCRIPTION

The **update_block_views** command updates the physical objects of a readonly abstract in case there is a boundary change for the abstract block. Prior to running this command, user is expected to reshape the block using GUI stretching utility.

This command works only on readonly abstract blocks.

This command will move/trim/remove the physical objects of that readonly abstract to honor the new block boundary. Additionally, this command will update locations information in the para file associated with the abstract. Also, new frame view will be created for this abstract. If there is an existing frame view, then new frame view will be created with same value of '-block_all' of the old abstract. If there isn't an existing frame view, then '-block_all true' will be used for frame creation. .

EXAMPLES

The following example updates the readonly abstract view for block reference "blk".

prompt> **update_block_views -blocks blk**

The following example checks for boundary changes for all the blocks and then updates them with verbosity turned on.

prompt> **update_block_views -verbose**

SEE ALSO

create_abstract(3)

update_constraint_mapping_file

Removes the specified constraint types for certain blocks in the mapping file.

SYNTAX

status **update_constraint_mapping_file**
[-remove_all]
[-remove_blocks *blocks*]
[-remove_types *constraint_types*]

Data Types

blocks collection
constraint_types collection

ARGUMENTS

-remove_all

Remove all constraint references for all blocks specified in the constraint mapping file. The **-remove_all** argument cannot be used together with the **-remove_blocks** or **-remove_types** arguments.

-remove_blocks *blocks*

Specifies a list of blocks for constraint removal, for all blocks specified in the constraint mapping file. All constraint mapping file references for the specified blocks are removed. If the **-remove_types** argument is not also specified, the tool removes all constraint mapping file references for all constraint types for the specified blocks. This argument is mutually exclusive with the **-remove_all** argument.

-remove_types *constraint_types*

Specifies a list of constraint types for removal. The *constraint_types* must be one or more of **DEF**, **UPF**, **ETM_UPF**, **SDC**, **BUDGET**, **CLKNET**, **PG_COSNTRAINT**, **COMPILE_PG**, **CTS_CONSTRAINT**, **BTM**, **FLOORPLAN** or **SCANDEF**. When no block is specified with the **-remove_blocks** argument, the tool removes the specified mapping file references for all blocks specified in the constraint mapping file. This argument is mutually exclusive with **-remove_all** argument.

DESCRIPTION

This command updates the current mapping between constraint mapping files and blocks. The current mapping is defined when you run the **set_constraint_mapping_file** command and specify a constraint mapping file. The constraint mapping file contains lines which specify a block name, constraint type, and corresponding constraint file name for each constraint. The supported

constraint types are DEF, UPF, ETM_UPF, SDC, BUDGET, CLKNET, PG_CONSTRAINT, COMPILE_PG, CTS_CONSTRAINT, BTM, FLOORPLAN and SCANDEF. After setting the constraint mapping file, the *update_constraint_mapping_file* command can be used to remove specified constraint type references for certain blocks, or remove all entries for all blocks in the map. Use the **report_constraint_mapping_file** command to verify the new mapping.

This command has three arguments: **-remove_all**, **-remove_types**, and **-remove_blocks**. At least one argument must be specified. To remove all constraint type entries for all blocks in the map, use the **-remove_all** argument. To remove all constraint map file entries for specified blocks, use the **-remove_blocks** argument. To remove the entries for specified types of constraints for all blocks in the map, use the **-remove_types** argument. To remove specific types of constraints for certain blocks, use both the **-remove_blocks** and **-remove_types** arguments.

EXAMPLES

The following constraint mapping file example specifies DEF, UPF and BTM constraint files for the blocks in the design. The files are used in the hierarchical flow from Verilog input to block shaping. The design has a top-level and two child blocks: BLK_A and BLK_B. The content of the constraint mapping file *./map_file.1* is:

```
BLK_A  DEF ./constraints/BLK_A.def
BLK_A  UPF ./constraints/BLK_A.upf
BLK_B  BTM ./constraints/BLK_B.btm
BLK_B  DEF ./constraints/BLK_B.def
BLK_B  UPF ./constraints/BLK_B.upf
TOP    DEF ./constraints/TOP.def
TOP    UPF ./constraints/TOP.upf
```

The following example sets the constraint mapping file using the preceding file, removes all constraint type entries for BLK_A, and reports the modified settings with the *report_constraint_mapping_file* command. Note that block BLK_A does not appear in output from the **report_constraint_mapping_file** command.

```
prompt> set_constraint_mapping_file ./map_file.1
prompt> update_constraint_mapping_file -remove_blocks BLK_A
prompt> report_constraint_mapping_file
BLK_B BTM ./constraints/BLK_B.btm
BLK_B DEF /disk1/constraints/BLK_B.def
BLK_B UPF /disk1/constraints/BLK_B.upf
TOP DEF /disk1/constraints/TOP.def
TOP UPF /disk1/constraints/TOP.upf
```

The following example removes the DEF constraint type for all blocks in the map. Note that constraint type DEF does not appear in output from the **report_constraint_mapping_file** command.

```
prompt> set_constraint_mapping_file ./map_file.1
prompt> update_constraint_mapping_file -remove_types DEF
prompt> report_constraint_mapping_file
BLK_A UPF ./constraints/BLK_A.upf
BLK_B BTM ./constraints/BLK_B.btm
BLK_B UPF /disk1/constraints/BLK_B.upf
TOP UPF /disk1/constraints/TOP.upf
```

The following example removes the UPF and BTM constraint types for block BLK_B and TOP.

```
prompt> set_constraint_mapping_file ./map_file.1
prompt> update_constraint_mapping_file -remove_types {UPF BTM} -remove_blocks {BLK_B TOP}
prompt> report_constraint_mapping_file
BLK_A DEF ./constraints/BLK_A.def
```

```
BLK_A UPF /disk1/constraints/BLK_A.upf
BLK_B DEF ./constraints/BLK_B.def
TOP DEF /disk1/constraints/TOP.def
```

SEE ALSO

report_constraint_mapping_file(2)
set_constraint_mapping_file(2)

update_cross_probing_files

Updates the paths of the cross-probed files.

SYNTAX

status **update_cross_probing_files**
[-search_path *paths*]
[-original_file *file1*]
[-new_file *file2*]
[-write_script_only *output_file*]
[-force]
[-verbose]

Data Types

paths list
output_file string
file1 string
file2 string

ARGUMENTS

-search_path *paths*

By default, the **search_path** variable is used to search for files when the tool updates the cross-probed files. If this option is specified, the tool uses the *paths* specified with this option instead.

When search paths are used, the first matching file found will be used as the replacement file. In general, a file is considered a match if its basename matches the original file and the file content is identical as determined by the tool.

-original_file *file1* / -new_file *file2*

Updates only one cross-probed file. The **-original_file** and **-new_file** options must be used together. The existing cross-probed file, *file1*, in the cross-probing database will be updated to the new file specified by *file2*. For the update to be successful,

- The *file1* argument needs to be an existing file in the set of cross-probed files as listed by the **report_cross_probing_files** command.
- The basename of the file in *file1* and *file2* need to match unless the **-force** option is used.
- The calculated checksum value of *file2* needs to match the one stored in the database for *file1*.

-write_script_only *output_file*

Specifies not to update the paths of the cross-probed files but writes the commands to a file. The file can be examined, modified if necessary, and then sourced as a Tcl script.

-force

Updates all cross-probed files (even the file paths are fine) if you specify this option without the **-original_file** and **-new_file** options. Without this option, the command updates files that do not have an OK status as reported by the **report_cross_probing_files** command.

When you specify the **-original_file** and **-new_file** options, the **-force** option allows the command to update the cross-probed file paths even if the basenames are different.

-verbose

Specifies to use verbose mode. The command prints out additional information messages.

DESCRIPTION

In order for GUI cross-probing functionality to work, the files that are stored in the database must be valid. If the design has been moved to a different location or cross-probed files have been moved to a different disk location, the paths that are stored in the database need to be updated accordingly. Running this command updates these paths.

To get a list of all cross-probed files and each file status, run the **report_cross_probing_files** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **-search_path** option with the **update_cross_probing_files** command:

```
prompt> report_cross_probing_files

update_timing

Updates timing information on the current design.

SYNTAX

string **update_timing**
[-full]

ARGUMENTS

-full

Indicates that the entire timing analysis is to be performed from the beginning. The default is to perform an incremental analysis, which updates only out-of-date information and runs more quickly.

DESCRIPTION

Updates timing for the current design. Timing is also automatically updated by commands that need the information, such as the **report_timing** command. This command explicitly prepares the design for further analysis.

By default, the **update_timing** command uses an efficient timing analysis algorithm that requires minimal computation effort and updates existing timing analysis information only where needed. You can override this default behavior using the **-full** option, which causes the entire timing update to be performed from the beginning. To avoid unnecessarily long run times, use the **-full** option only when you need to override incremental timing analysis. If the design is not timed, the **update_timing** command has the same runtime independent of the **-full** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example updates timing information for the current design.

prompt> **update_timing**

prompt> **update_timing -full**

SEE ALSO

report_timing(2)

update_topology_node

Updates multiple topology node attributes in a single command.

SYNTAX

collection **update_topology_node**
[*topology_node_list*]
[-name *topology_node_name*]
[-objects *object_list*]
[-constrained_objects *object_list*]
[-origin *coord*]
[-constraint_type edge | side | bbox | tap]
[-edge *edge_list*]
[-start *dist_or_pct*]
[-end *dist_or_pct*]
[-range *dist_or_pct*]
[-offset *distance*]
[-side *side_list*]
[-alignment left | right]
[-bbox_percentage *float_single_or_pair*]
[-corner_type auto | cross | default | river]
[-constraint_source user | application]
[-halo *distance*]

Data Types

topology_node_list collection
topology_node_name string
object_list collection
coord float_pair
edge_list integer_list
dist_or_pct float [+ "%"]
distance float
side_list string

ARGUMENTS

-name *topology_node_name*

Specifies the name of the topology_node. The name may not contain the special character '/'. If unspecified, the node's name will remain unchanged.

-objects *object_list*

Specifies the set of objects to be associated with the topology_node. The objects may be hierarchical. Allowed object types are pins, ports, cells, voltage_areas, voltage_area_shapes, shapes, placement_blockages, routing_blockages, bounds, and bound_shapes.

-constrained_objects *object_list*

Specifies the set of constrained objects to be associated with the topology_node. The objects may be hierarchical. Allowed object types are pins and ports.

-origin *coord*

Specifies the origin of the topology_node. If unspecified, the origin will be auto-computed based on the other specified options if possible.

-constraint_type edge | side | bbox | tap

Specifies the constraint type of the topology_node.

-edge *edge_list*

Specifies the constraint edge list of the topology_node. Value must be a list of integer values.

-start *dist_or_pct*

Specifies the constraint start of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-end *dist_or_pct*

Specifies the constraint end of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-range *dist_or_pct*

Specifies the constraint range of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-offset *distance*

Specifies the constraint offset of the topolology_node.

-side *side_list*

Specifies the constraint sides of the topolology_node. Value may be a single instance or list of the following: W, N, E, or S.

-alignment left | right

Specifies the constraint alignment of the topolology_node.

-bbox_percentage *float_single_or_pair*

Specifies the bbox_percentage of the topology_node. Specify a single value for linear regions, and a float pair for 2D regions.

-corner_type auto | cross | default | river

Specifies the corner_type of the topology_node.

-constraint_source user | application

Specifies the constraint_source of the topology_node.

-halo *distance*

Specifies the halo of the topology_node. May only be specified when the *-origin* argument is specified.

DESCRIPTION

The **update_topology_node** command allows the user to modify several topology_node attributes at once, instead of incrementally using the *set_attribute* command.

EXAMPLES

The following example sets a topology_node to constraint_type "origin":

```
prompt> update_topology_node [get_topology_nodes TOPOLOGY_NODE0] -constraint_type origin -origin {1.0 2.4}
{curplan/TOPOLOGY_NODE0}
```

upf_version

Displays the version of UPF currently being used to interpret UPF commands.

SYNTAX

string **upf_version**
[*version*]

Data Types

version String

ARGUMENTS

version

Documents the UPF version for which the UPF commands that follow were written.

DESCRIPTION

This command returns a string value representing the version of UPF used by the tool to interpret other UPF commands.

An optional **version** argument can be given to the command; it will be ignored and won't have any impact on the syntax or semantics of any of the UPF commands, as its only purpose is to document the intended version that should be used to interpret the commands that follow.

Any instance of usage will be preserved as part of the UPF file that can be retrieved using the **save_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example makes use of the command using the optional argument.

```
prompt> upf_version 2.1
IEEE-1801
```

SEE ALSO

save_upf(2)

use_interface_cell

Specifies how to map the isolation, level-shifter, and enable level-shifter cells belonging to the specified isolation and/or level-shifter strategy.

SYNTAX

status **use_interface_cell**
interface_implementation_name
-strategy *list_of_isolation_level_shifter_strategies*
-domain *power_domain*
-lib_cells *lib_cells*

Data Types

interface_implementation_name string
list_of_isolation_level_shifter_strategies list
power_domain string
lib_cells list

ARGUMENTS

interface_implementation_name

Specify the name of the interface cell implementation strategy.

list_of_isolation_level_shifter_strategies

Specify one of the following: - one isolation strategy, or - one level shifter strategy, or - a pair of isolation and level shifter strategies No more than one isolation or level shifter strategy is allowed in one command.

-domain *power_domain*

Specifies the name of the power domain name to which the strategy/strategies belongs.

-lib_cells *lib_cells*

Specifies a list of the target library cells to be used for the isolation mapping.

DESCRIPTION

This command defines how the **compile** command performs the mapping of isolation, level-shifter, or enable level-shifter cells.

EXAMPLES

In the following example, the isolation cells belonging to the strategy named ISO1 will be mapped to the isocell1 library cell with the highest priority, and level-shifter cells belonging to the strategy LS1 will be mapped to the levshicell1 library cell with the highest priority:

```
prompt> use_interface_cell my_interface -domain PD1 -strategy {ISO1 LS1} \
 -lib_cells {isocell1 levshicell1} \
 -port_map {{VDD sn1} {VSS gnd}}
```

SEE ALSO

vclp_stop

Used to terminate vclp if vclp was invoked by the user by running check_vclp_design.

SYNTAX

status **vclp_stop**

DESCRIPTION

The **vclp_stop** command terminates vclp, if vclp was invoked by the user within this tool.

SEE ALSO

check_vclp_design(2)

vclp_zoom_highlight

This command is used to highlight the instance that is selected in verdi GUI in ICC2/FC GUI.

SYNTAX

status **vclp_zoom_highlight**

DESCRIPTION

If users have invoked VCLP with **check_vclp_design** and are interacting with the Verdi GUI, they can use the **vclp_zoom_highlight** command to highlight the instance that was selected in Verdi GUI in ICC2/FC GUI.

SEE ALSO

check_vclp_design(2)

verify_via_ladders

Verifies the via ladders in a design to confirm that the via ladders match user-specified via ladder constraints and that the via ladders are properly connected to pins.

SYNTAX

status **verify_via_ladders**
[-nets {*collection_of_nets*}]
[-shift_vias_on_transition_layers true | false]
[-report_all_via_ladders true | false]

Data Types

{*collection_of_nets*} collection

ARGUMENTS

-nets {*collection_of_nets*}

Specifies the nets on which to verify via ladders.

Via ladders will be verified only on the specified nets.

If you do not specify this option, all via ladders will be verified.

-shift_vias_on_transition_layers true | false

Specifies whether the command should expect that via ladder cuts on transition layers have been shifted off the routing tracks.

The default is false.

If via ladders were inserted using insert_via_ladders -shift_vias_on_transition_layers true, the via ladders should be verified using verify_via_ladders -shift_vias_on_transition_layers true.

If via ladders were inserted using insert_via_ladders -shift_vias_on_transition_layers false, the via ladders should be verified using verify_via_ladders -shift_vias_on_transition_layers false.

If false (the default), via ladder cuts must be centered at the intersection of routing tracks to be considered correctly placed.

If true, via ladder cuts are allowed to be shifted off track on transition layers.

-report_all_via_ladders true | false

Species whether to print all the entries of via ladder verification report.

The default is true.

If false, the report only prints the first 40 entries for each category.

DESCRIPTION

The **verify_via_ladders** command verifies the via ladders in the layout of a design.

This command does not perform conventional design rule checking on via ladders. The command checks that via ladders in the design are properly connected to pins and that the via ladders in the layout match the via ladder constraints on the corresponding pins.

The command reports all via ladders in the layout, and the matching tech file ViaRule template. A "Misplaced via ladder" DRC is reported if a via ladder is dangling or floating or not properly connected to a pin. A "Misplaced via ladder" DRC is reported if a via ladder is connected to a pin but does not match the via ladder constraints for that pin. A "Needs via ladder" DRC is reported for any pin that has a via ladder constraint but does not have a matching physical via ladder in the layout.

EXAMPLES

The following example verifies all via ladders in the design.

```
prompt> verify_via_ladders
```

The following example will verify all via ladders in the design and assumes that these were inserted using insert_via_ladders -shift_vias_on_transition_layers true.

```
prompt> verify_via_ladders -shift_vias_on_transition_layers true
```

which

Locates a file and displays its pathname.

SYNTAX

string **which** *filename_list*

list *filename_list*

ARGUMENTS

filename_list

List of files to locate.

DESCRIPTION

Displays the location of the specified files. This command uses the search_path to find the location of the files. This command can be a useful prelude to read_db or link_design, because it shows how these commands expand filenames. The **which** command can be used to verify that a file exists in the system.

If an absolute pathname is given, the command searches for the file in the given path and returns the full pathname of the file.

EXAMPLES

The following examples are based on the following search_path.

prompt> **set search_path "/u/foo /u/foo/test"**

The following command searches for the file name foo1 in the search_path.

prompt> **which foo1**
/u/foo/foo1

The following command searches for files foo2, foo3.

prompt> **which {foo2 foo3}**
/u/foo/test/foo2 /u/foo/test/foo3

The following command returns the full pathname.

```
prompt> which ~/test/designs/sub_design.db
/u/foo/test/designs/sub_design.db
```

SEE ALSO

link_design(2)
read_db(2)
search_path(3)

widen_wires

Performs wire widening on the current design and reduces the open critical area to improve the yield.

SYNTAX

status **widen_wires**
[-spreading_widening_relative_weight *ratio_value*]
[-widen_widths_by_layer_name {*list_of_layer_value_lists*}]
[-timing_preserve_nets {*collection_of_nets*}]
[-timing_preserve_setup_slack_threshold *slack_value*]
[-timing_preserve_hold_slack_threshold *slack_value*]

Data Types

count integer
collection_of_nets collection
slack_value float
ratio_value float
list_of_layer_value_lists collection

ARGUMENTS

-spreading_widening_relative_weight *ratio_value*

Controls the relative preference for wire spreading versus wire widening.

During wire widening, Zroute increases the wire width to reduce open critical area. Due to the limited routing resources, this decreases the spacing to the neighboring wires and can reduce the improvement in critical area shorts that occurred during wire spreading.

If there are conflicts between the desired width and the desired spacing, you can use this option to alter the weight on either spacing or width according to your preference. If the value is set to 0.5, it means spacing and width have equal weight. If the value is less than 0.5, more weight is put on width. If the value is greater than 0.5, more weight is put on spacing. The greater the weight on width, the greater the expected improvement for open critical area. The greater the weight on spacing, the greater the expected improvement for critical area shorts.

You can specify an floating-point number between 0.0 and 1.0. The default is 0.5.

-widen_widths_by_layer_name {*list_of_layer_value_lists*}

Specifies a list of desired wire widths on each layer for the router to try. You can specify a maximum of five wire widths for each layer. You must specify the layers by using the layer names in the technology file.

Use the following format to specify the allowed wire widths for each layer:

{*layerName value1* [*value2* [*value3* [*value4* [*value5*]]]]}

For example, {{metal2 0.07 0.06} {metal3 0.08}}.

The wire width values should be between the default wire width and the maximum width that does not trigger any fat wire rules. The tool validates the input wire widths and skips them if they are not valid. If none of the wire widths specified for a layer is valid, the default wire width values will be used for such layer.

The default value for the maximum wire width for a layer is about 1.5 times the layer default width.

-timing_preserve_nets {*collection_of_nets*}

Specifies the nets to preserve timing on.

If you specify this option, the command considers the specified nets as timing critical and skips wire widening on these nets and the neighboring nets.

-timing_preserve_setup_slack_threshold *slack_value*

Specifies the setup slack threshold for timing critical nets.

If you specify this option, the command skips wire widening on all nets with a worst setup slack less than or equal to this value and the neighboring nets.

-timing_preserve_hold_slack_threshold *slack_value*

Specifies the hold slack threshold for timing critical nets.

If you specify this option, the command skips wire widening on all nets with a worst hold slack less than or equal to this value and the neighboring nets.

DESCRIPTION

The **widen_wires** command performs wire widening to reduce the total open critical area. It attempts to widen every wire in the design. The options control the maximum number of search and repair iterations performed after wire widening to resolve any violations.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command performs wire widening.

```
prompt> widen_wires
```

SEE ALSO

route_detail(2)
spread_wires(2)

win_select_objects

Creates a collection of objects equivalent to a graphical selection operation.

SYNTAX

string **win_select_objects**
[-slct_targets *slct_bus*]
[-slct_targets_operation *operation*]
[-create_slct_buses]
[-root *instance*]
[-within *rectangle* | -line *line* |-at *point* |
-radius *r* | -again_at]
[-intersect]
[-index *i*]
[-visible]

string *slct_bus*
string *operation*
string *instance*

ARGUMENTS

-slct_targets *slct_bus*

Specifies the name of a selection bus to store the result in. By default the result of this command is returned in a collection. If this option is specified selection bus *slct_bus* is used instead. *slct_bus* is also returned as result of the command.

-slct_targets_operation *operation*

Specifies which operation should be used when storing the result in selection bus *slct_bus*. This is only allowed if you specify the -slct_targets option. Legal operations are clear, add and remove.

-create_slct_buses

Specifies that a new selection bus is created and used to store the result in. Using this option is equivalent to first creating a selection bus using the create_selection_bus command and then providing the created selection bus to option -slct_targets.

-root *instance*

Specifies a string for the instance whose component design objects and hierarchy are to be examined against the specified region criteria.

-within "*rectangle*"

Collects design objects lying within the specified rectangle.

-line "*line*"

Collects design objects intersected by specified line.

-at "*point*"

Collects design objects whose bounding box contains the specified point.

-radius *r*

Specifies a radius for points specified by the **-at** option. It is applicable only for **_pins** and **_ports**.

-again_at

Reapplies the previous **-at** option, but returns a previously-matched design object.

-index *i*

For point select (-at option) specifies a specific object index to select. Similar to running -again_at.

-intersect

Collects design objects intersecting with specified rectangle. Without this option, the command collects design objects contained in the specified rectangle.

-visible

Select objects marked as visible with win_set_select_class command.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

win_set_select_class(2)
win_set_filter(2)

win_set_filter

Sets a filter to apply to objects selected by the **win_select_objects** command.

SYNTAX

int **win_set_filter**
-class *class_name*
[-stop_level *level*]
[-start_level *level*]
[-z_level *level*]
[-filter *expression*]
[-layer *list*]
[-user_filter *true*|*false*]
[-user_filter_cmd *tcl_cmd*]
[-highlighted_only *true*|*false*]
[-expand_cell_types *list*]
[-visible]

ARGUMENTS

-class "*class_name*"

Specifies a single class name for which the filter is to apply.

-stop_level "*level*"

Specifies the hierarchy level, up to which **win_select_objects** searches for design objects down the hierarchy. This has no effect on objects that are not collectable.

-start_level "*level*"

Specifies the hierarchy level, from which **win_select_objects** begins searching for design objects down the hierarchy. This has no effect on objects that are not collectable.

-z_level "*level*"

Specifies the interesting Z levels in a 3dic design. The 0 value means all chips in the current 3dic design. Other values mean only the chips on this level and the level below. For example 1 means chips on level 0 and level 1.

-filter "*expression*"

Specifies a filter expression that an object must satisfy to be returned by the **win_select_objects** command. The expression argument must be a Boolean expression based on attributes of the specified class. If this option is not specified, the filter is cleared.

-layer "*list*"

Specifies a layer number list that an object must satisfy to be returned by the **win_select_objects** command. If this option is not specified, the layer filter is cleared.

-user_filter "*true*|*false*"

Enables user supplied filter command.

-user_filter_cmd "*tcl_cmd*"

Specifies a tcl command for filtering.

-highlighted_only "*true*|*false*"

Specifies that only highlighted objects can be selected.

-expand_cell_types "*list*"

Specifies cell types for searching design objects down the hierarchy when the search level is greater than 0. This has no effect on types that is not supported or objects that are not collectable.

-visible

Specified filters are for visible objects. By default the filters are for selectable objects.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

win_select_objects(2)
win_set_select_class(2)

win_set_select_class

Sets the design objects to be collected by the **win_select_objects** command.

SYNTAX

string **win_set_select_class**
{-all | *class_names*}
[-visible]

ARGUMENTS

-all

Selects all classes. The **-all** option and the *class_names* option are mutually exclusive.

class_names

Specifies a list of design objects. The **-all** option and the *class_names* option are mutually exclusive.

-visible

Specified classes are for visible objects. By default the classes are for selectable objects.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

win_select_objects(2)
win_set_filter(2)

win_snap_point

Snaps a point to a grid or to the nearest object. The result of this command is returned as a point. If the point cannot be snapped the result point is equal to the given point.

SYNTAX

string **win_snap_point**
-point *point*
[-snap_type *snap_type*]
[-radius *r*]

string *snap_type*

ARGUMENTS

-snap_type *snap_type*

Specifies the type of snapping to use. It is one of these values [litho (default), site, wiretrack, user, objects]. In case of snapping to the nereast objects, the objects will be chosen based on filters set by previous calls of *win_set_select_class -visible* and *win_set_filter -visible* commands.

-point "*point*"

Specifies a point to snap.

-radius *r*

Specifies a radius for point specified by the **-point** option. It is applicable only for snapping to objects.

DESCRIPTION

This command is for use by the graphics window(s) while editing. You are advised not to use this command directly.

EXAMPLES

icc_shell> **win_snap_point -snap_type litho -point {123.456 456.123}**
123.460 456.120

SEE ALSO

win_set_select_class(2)
win_set_filter(2)

write_aif

Writes bump locations and connected nets or ports to an Advanced Input Format (AIF) file.

SYNTAX

status **write_aif**
[-use_port_name]
[-hierarchy]
[-bumps *bump_cell_collection*]
aif_file_name

Data Types

bump_cell_collection collection
aif_file_name string
bump_objects_collection collection

ARGUMENTS

-use_port_name

Writes the associated port name for each bump to the AIF file. If a bump does not have an associated port, the command writes the associated net name.

By default, the command writes the associated net name for each bump.

-hierarchy

Writes information for bumps within child cells of the current block. If a bump connects to a port or net within the hierarchy, use its top-level port or net and top-level location.

When you use this option, the generated AIF file contains the following note at the beginning of the file:

;It was written by write_aif with option -hierarchy

By default, only the top-level bump instances are reported in the AIF file.

-bumps *bump_cell_collection*

Specifies the bump instances to write to the AIF file.

This option by itself specifies bump instances at the top level. If you include bump instances in child cells, you must also specify the **-hierarchy** option.

By default, all top-level bump instances are written to the AIF file.

-bump_objects *bump_objects_collection*

Specifies the bump pins or pin shapes to write to the AIF file in NETLIST section. You can specify a mixture of pin and pin shapes

This option by itself specifies bump pins or pin shapes that are not in bump cells. These pins or pin shapes are not written to the AIF file by default.

aif_file_name

Specifies the name of the generated AIF file.

DESCRIPTION

The **write_aif** command writes information about the specified bump instances to the specified AIF file. You can specify the file with a relative or absolute path.

The AIF file includes the following information for the bump instances:

- Connectivity

  By default, the connectivity is the name of the net connected to the bump instance. To use the connected port name instead, use the **-use_port_name** option.

- Reference bump cell
- Orientation
- Location

  The location represents the center of the bump instance. The coordinates of the bump center reference the center of the die, which is defined as the center of die area object in the block and are specified in the [DIE] section of the AIF file. The command uses the following formula to calculate the coordinates of the center of the bump instance:

  ```
  Pad_center_x = AIF_Pad_x + die_width/2 + die_offset_x
  Pad_center_y = AIF_Pad_y + die_height/2 + die_offset_y
  ```

The following is an example AIF file.

```

```

The following list describes the file sections in the AIF file:

- [DATABASE]

  Identifies the file as an AIF file and contains the version and units of the coordinates.

- [DIE]

  Describes the die width, height, and die name. Width is measured along the horizontal x-axis and height is measured along the vertical y-axis. The width and height are defined per the die nominally described dimensions.

- [PADS]

  The PADS section defines all pad types needed for the die.

- [NETLIST]

  Defines each net and the coordinates of each die pad. Each column requires an entry. If a particular data item is not present, you must use a hyphen as a placeholder.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples writes all top-level bump instances to an AIF file named my.aif.

```
prompt> write_aif my.aif
1
```

The following example writes the specified bump instance to an AIF file named my.aif. The connectivity column of the AIF file reports the ports connected to the bump instances.

```
prompt> write_aif my.aif -use_port_name -bumps [get_cells iBump_*]
1
```

SEE ALSO

read_aif(2)

write_app_options

Writes application option data to a binary data file for later reporting by the **report_app_options** command and comparison by the **compare_app_options** command.

SYNTAX

integer **write_app_options**
-output *data_file*
[-non_default]

Data Types

data_file string

ARGUMENTS

-output *data_file*

Specifies the output file name to contain the application option settings and metadata. The *data_file* argument can be a local file name or a full path name to the file.

-non_default

Writes out data only for application options with nondefault values.

DESCRIPTION

This command generates an encoded binary data file that contains information on all application options and their current values and metadata.

If application option values were set with the **set_app_options** command, the source location of the call to **set_app_options** will be recorded.

If an internal application options has a non-default value, the tool issues the following message:

"There are additional internal differences with no available TBC source."

Or...

"There are additional internal differences."

This message indicates that the design contains Synopsys internal application options that were possibly set from a .tbc file or by

using some other method.

The **-non_default** option specifies that only application options with nondefault values are written to the data file. Otherwise, all application option values are written to the data file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a encoded binary data file that contains all application options with non-default values. Use the **report_app_options** and **compare_app_options** commands to examine the data.

prompt> **write_app_options -output app_option.data -non_default**

The following example creates a encoded binary data file that contains all application options. The **-non_default** option is omitted to allow a comprehensive comparison between two tool sessions for all application options using this data, including application option withs default values, allowed values, block scope vs. global scope, and so on.

prompt> **write_app_options -output SP1.data**

reset_app_options(2)
set_app_options(2)

write_app_var

Writes a script to set the current variable values.

SYNTAX

string **write_app_var**
-output *file*
[-all | -only_changed_vars]
[*pattern*]

Data Types

file string
pattern string

ARGUMENTS

-output *file*

Specifies the file to which to write the script.

-all

Writes the default values in addition to the current values of the variables.

-only_changed_vars

Writes only the changed variables. This is the default when no options are specified.

pattern

Writes the variables that match the specified *pattern*. The default is "*".

DESCRIPTION

The **write_app_var** command generates a Tcl script to set all application variables to their current values. By default, variables set to their default values are not included in the script. You can force the default values to be included by specifying the **-all** option.

EXAMPLES

The following is an example of the **write_app_var** command:

```
prompt> write_app_var -output sh_settings.tcl sh*
```

SEE ALSO

get_app_var(2)
report_app_var(2)
set_app_var(2)

write_ascii_files

Writes the design data and shell commands for the current design so that the settings are saved when you load the design back into the tool.

SYNTAX

status **write_ascii_files**
-output *dir_name*
[-modes *mode_list*]
[-corners *corner_list*]
[-include *include_list*]
[-exclude *exclude_list*]
[-golden_upf_file *upf_file*]
[-golden_floorplan]
[-no_library_creation]
[-multicore]
[-force]
[-def_units 100 | 200 | 1000 | 2000 | 10000 | 20000]
[-def_version *version*]
[-compress gzip]

Data Types

mode_list	list
corner_list	list
include_list	list
exclude_list	list
dir_name	string
upf_file	string

ARGUMENTS

-modes *mode_list*

Specifies the modes to write.

By default, all modes are written.

-corners *corner_list*

Specifies the corners to write.

By default, all corners are written.

-include *include_list*

Specifies a list of constructs and objects to include in the output. When this option is used, the Verilog netlist contains the basic logic netlist and only the types of constructs and objects specified with this option. The valid values are:

all
all_physical_cells
analog_pg
corner_cells
cover_cells
diode_cells
empty_modules
end_cap_cells
feedthrough_cells
filler_cells
flip_chip_driver_cells
flip_chip_pad_cells
leaf_module_declarations
pad_cells
pad_spacer_cells
pg_netlist
pg_objects
physical_only_cells
scalar_wire_declarations
shadow_netlist
spare_cells
supply_statements
unconnected_ports
user_pg
well_tap_cells

For a description of each construct and object type, see the DESCRIPTION section. The default behavior is to include everything except for scalar wire declarations, leaf module declarations, PG objects, and connections to unconnected ports.

-exclude *exclude_list*

Specifies a list of constructs and objects to exclude from the output. When this option is used, the Verilog netlist contains everything except for the types of constructs and objects specified with this option.

The valid values are:

all_physical_cells
analog_pg
corner_cells
cover_cells
diode_cells
empty_modules
end_cap_cells
feedthrough_cells
filler_cells
flip_chip_driver_cells
flip_chip_pad_cells
leaf_module_declarations
pad_cells
pad_spacer_cells
pg_netlist
pg_objects
physical_only_cells
scalar_wire_declarations
shadow_netlist

spare_cells
supply_statements
unconnected_ports
well_tap_cells

-output *dir_name*

Specifies the name of the directory in which to write the script files.

-no_library_creation

Exclude library creation and library setup

-multicore

Enable multicore support

-force

Overwrites the existing script files. By default, the command fails if the script file already exists.

-golden_floorplan

Specifies to use the golden floorplan.

-golden_upf_file *upf_file*

Specifies the golden UPF file.

-def_units 100 | 200 | 1000 | 2000 | 10000 | 20000

Specifies the number of units per micron in the DEF file. All database length units are scaled accordingly in the output DEF. If units are not specified, the units per micron is obtained from the technology length precision. Valid values are 100, 200, 1000, 2000, 10000, and 20000. This option is passed to the DEF writer and the behavior is identical to the **-units** option of the *write_def* command.

-def_version *version*

Specifies the DEF syntax version used to create floorplan.def file. Valid values are 5.7 and 5.8. The default version is 5.7.

-compress gzip

Specifies the method used to compress the generated script files.

By default, the command writes the script files as simple text files and does not compress them.

DESCRIPTION

The **write_ascii_files** command writes the design files and Tcl scripts for the current design to load the design data into back into the tool.

Files are written into the directory specified by the -output option. The written files include the following, if the data is present:

Netlist in Verilog format
SAIF name mapping
Tcl floorplan and DEF files
Design's power intent as a UPF command script
Scan chain information in SCANDEF format

Constraints in SDC format
Timing contexts (scenarios)
Cell expansion data
RP groups

In addition, the write_ascii_files command writes the following:

Tool application option settings
The top-level script to load the generated data back into the tool
Library setup information

The write_ascii_files command saves the design data for the current design and names the output files with the design name. The top-level script, **<design_name>**.fc_script.tcl, loads all the design data in the correct order. By default the tool includes a script, **<design_name>**.library_setup.tcl, to create a design library. In the golden UPF mode, the command writes out the supplemental UPF file and the name mapping file, and the top-level script includes load_upf commands to load the golden files specified by the -golden_upf option.

The top-level script does not include the commit_upf or update_timing commands after loading the design.

The -include and -exclude options are passed directly to the write_verilog command. For more information about the behavior of this option please review the write_verilog man page.

The **write_ascii_files** command includes an execution log file that can be reviewed to check the messages issued by the tool when writing out the various files.

Multicorner-Multimode Support

By default, this command uses information from all modes and all corners.

You can specify the modes and corners to write by using the **-modes** and **-corners** options.

EXAMPLES

The following example writes the settings on the current design to the test_scr directory.

```
prompt> write_ascii_files -output test_scr
```

write_blackbox_timing_script

Writes a script that contains the black box timing information for the design.

SYNTAX

status **write_blackbox_timing_script**
output_file_name | -qtm_format [-qtm_directory *directory_name*]

Data Types

output_file_name string
directory_name string

ARGUMENTS

output_file_name

Specifies the name of the black box timing file to write to. This option is mutually exclusive with **-qtm_format** and you must specify one of them.

-qtm_format

Writes out black box timing data in Quick Timing Model (QTM) format. This option is mutually exclusive with *output_file_name* and you must specify one of them.

-qtm_directory *directory_name*

Specifies the directory in which to write the QTM files. The tool writes out one QTM file for each scenario. Depending on the number of scenarios in the design, the tool might need to write out more than one QTM file. The default directory is *bbt_qtm_dir*. This option can only be specified together with **-qtm_format**.

DESCRIPTION

This command writes out black box timing information to either a file in black box timing (BBT) format or a set of files in QTM format. If it writes out a file in BBT format, the file contains the commands to regenerate the black box timing data for the current design in this tool. If it writes out one or more QTM files, the files would contain QTM commands and can be used to generate .db files to model the black box design's timing. These files can also be used in the PrimeTime tool.

The design must already have black box timing defined.

EXAMPLES

The following example sources a file that creates black box timing for the current design, then writes out a script that contains the defined black box timing.

```
prompt> source block.bbt.tcl
prompt> write_blackbox_timing_script bbt_new.tcl
```

The following example sources a file that creates black box timing for the current design, then writes out QTM for the defined black box timing.

```
prompt> source block.bbt.tcl
prompt> write_blackbox_timing_script -qtm_format -qtm_directory qtm_files
```

commit_blackbox_timing(2)

write_budgets

Writes SDC I/O constraints for budgeted blocks to disk.

SYNTAX

int **write_budgets**
[-blocks *block_cells*]
[-top]
[-full_budget_blocks *block_module_names*]
[-design_subblocks *block_module_names*]
[-hier_abstract_subblocks *block_module_names*]
[-shell_subblocks *block_module_names*]
[-output *dir_name*]
[-force]
[-verbose]
[-nosplit]
[-compress gzip]
[-format dc | icc2]

Data Types

block_cells collection
block_module_names collection
dir_name string

ARGUMENTS

-blocks *block_cells*

Writes block budgets for only the named cell instances. It is an error to include instances which were not previously declared with the **-add_blocks** option of the **set_budget_options** command.

-top

Writes a budget for the top level.

-full_budget_blocks *block_module_names*

Writes "full" budgets for the specified blocks, instead of the default incremental budget. See the section on "Budget Constraint Styles" for more information.

You can set the **plan.budget.all_full_budgets** application option to true to automatically set this option for all blocks. The tool always writes a full budget for the top module.

-design_subblocks *block_module_names*

Keeps internal constraints for subblocks in the budget. Note that this option has no effect unless you also select the **-full_budget_blocks** option for the parent of the subblock. Please refer to the man page for **split_constraints** for a full description of this option. You can use the **plan.budget.all_design_subblocks** application option to automatically set this option for all blocks.

-hier_abstract_subblocks ***block_module_names***

Retain some extra internal constraints of subblocks in the budget. Note that this option has no effect unless you also select the **-full_budget_blocks** option for the parent of the subblock. Please refer to the man page for **split_constraints** for a full description of this option.

-shell_subblocks ***block_module_names***

Creates timing budgets as a "budget shell" for each specified block. When you use a budget shell, the contexts of your block is ignored, and the boundary timing of your block is based only on your budget constraints. Note that budget shells require you to relink your design using shell libraries instead of a netlist or an abstract. See "hierarchical budgeting" below for details.

Note that using **-shell_subblocks** automatic adds the parent of the subblock to the list of blocks for **-full_budget_blocks**. Parent blocks of shell blocks cannot have incremental budgets.

-output ***dir_name***

Specifies the name of the directory under which the scripts are written. By default, the directory is "./budgets". For each budgeted block, a subdirectory is added under your specified directory. The subdirectory has the same name as the block.

-force

Forces the output directory to be overwritten, if it already exists.

-verbose

Prints detailed warning messages about pins with missing budget specifications. By default, only a summary is printed. You can use the **report_budget** command to show the verbose feedback at any time.

-nosplit

Writes out long constraint command lines, even if the line length is greater than 80 columns. Use this option to simplify post-processing of the output constraint files or when comparing the constraint files by using the UNIX **diff** command. If this option is not specified, the command breaks long constraint command lines near column 80 and inserts a line continuation character (\).

-compress gzip

Specifies the method used to compress the generated script files. By default, the command writes the script files as simple text files and does not compress them.

-format dc | icc2

Specifies the tool in which the budget shells created by the command will be used.

Valid values are:

- icc2 (the default)
  The budget shells generated can be used by ICC2
- dc
  Besides the budget shells db files, other files are created to facilitate the ICC2->DC flow. The tool outputs timing constraints that can be read in Design Compiler as well as Milkyway libraries to be used as reference libraries in DC.

This option can only be used together with the **-shell_subblocks** option.

DESCRIPTION

This command writes SDC constraints for your budgets to disk. For each budgeted subblock, a separate subdirectory is written under the directory specified by the **-output** option. The name of the subdirectory will correspond to the module name of a budgeted block. The command writes multiple files within each subdirectory, similar to those created by the **write_script** command.

You are responsible for applying the budget constraints to your lower-level blocks. This is done by sourcing the file called "top.tcl" from the **write_budgets** output. For example, if your module name is MY_BLOCK, and you have written your budgets to a directory called "budgets", you should use the following command to apply budget constraints to your lower-level blocks:

```
source budgets/MY_BLOCK/top.tcl
```

The **source top.tcl** command loads other files corresponding to constraints for block modes and corners. The number of mode and corner files written depends on what modes and corners are currently defined at the top level, and on any mode and corner settings you declared with the **set_block_to_top_map** command.

Using write_budgets in the Flow

In a typical design flow, the lowest level blocks in your design are represented by block abstracts. Block abstracts save significant memory and CPU. When processing block abstracts, the **write_budgets** command only writes constraints that apply to the boundary of a subblock. The output of **write_budgets** is *not* a complete set of constraints for a block. Rather, the output is intended to be "layered" incrementally on top of your existing block constraints. To use the budget file from **write_budgets**, you need to perform the following steps:

- Load your block
- Apply your regular block constraints that constrain the internal parts of your block.
- At the top level, obtain budget constraints automatically by using **compute_budget_constraints** or manually using**set_pin_budget_constraints** and other related commands. If you want to generate hold constraints as well as setup, then set the **plan.budget.write_hold_budgets** app option to true.
- Write budget SDC with **write_budgets**
- Overlay the output from **write_budgets** into your block to set boundary constraints for the block.

It is only necessary to apply your internal block constraints one time. After applying the constraints, you can incrementally apply new boundary constraints whenever your budget is updated. If you do not have internal block constraints, consider using the **split_constraints** command to derive block-level constraints based on chip-level constraints.

You can make **write_budgets** create "full" budgets, which include constraints for both the boundary of the block and internal constraints. To write full budgets, specify the **-full_budget_blocks** option. In general, it is not recommended to use full budget constraints, because there might be a large runtime and memory impact. Also, applying full budgets is disruptive because it overwrites any existing constraints for your block. Incremental budgets allow the existing internal constraints of your block to be maintained. See the section on "Budget Constraint Styles" for more information.

The budget constraints written by **write_budgets** include clock latency adjustments to account for partially implemented clock networks. Different latency adjustments should be chosen at different stages of the design flow. See the details in the description of the **-adjust_latency** option of the **set_budget_options** command. Also, you should read the description of the **-latency_target** and **-balance** options of the **compute_budget_constraints** command.

Clock Name Mapping

It is possible that clocks defined in your blocks have names that do not match connected top-level clock names. For example, a top-level clock named "SYS_CLK" may be connected to a block-level clock named "CLK". The **write_budgets** command understands that names may not match, and automatically derives the mapping between top-level and block-level clocks. This allows **write_budgets** to generate the proper constraints for the block.

If there is insufficient information to automatically derive a mapping between top-level clocks and block-level clocks, you can manually specify a mapping with the **set_block_to_top_map** command. If no mapping is specified, **write_budgets** assumes that the block-level clock name matches the top-level clock name.

Budget shells

The **write_budgets** command supports a construct called "budget shell", which is a special library cell without a netlist. In a design hierarchy, a budget shell can be used to replace a lower-level block. After the lower level block is replaced by a shell, you can no longer examine timing for paths inside of the block or paths that pass between the block and its parent block. Instead, the boundary ports of a "budget shell" are budgeted: paths that originally went from the parent hierarchy into child hierarchy are replaced with new budgeted paths that go from parent hierarchy to the ports of the shell. The timing of the new paths is adjusted to match the budget constraints that you set for the replaced block.

Budget shells are useful for separating the higher levels of your design from the lower levels of your design. If you use a budget shell for a lower level design, you can optimize the higher level design independently. The timing of the top-level design only depends on the lower level's budget constraints, not on the actual timing in the lower level.

Note that budget shells do not eliminate the need to optimize the top level along with the full (non-shell) block. Because the shell only follows a budget, it is inherently pessimistic. Using the actual timing of a lower-level block might let you see additional slack along a path that the budget did not see. In particular, it is not advisable to use budget shells when doing hold fixing on paths between top level and block level. The budget pessimism potentially causes over-buffering.

Hierarchical budgeting

The **write_budgets** command has advanced options to control how the boundaries between a logical or physical hierarchy are handled for timing. This section first describes the default behavior of **write_budgets** and then discusses the variants of that behavior. For the purpose of discussion, assume a design with three block levels: top, mid, and bot. Everything except the top must be declared as budget blocks by using:

```
prompt> set_budget_options -add_blocks {mid mid/bot}
```

By default, **write_budgets** works on all block hierarchy instances declared with **set_budget_options**. For each block in the hierarchy, constraints are written to characterize the timing paths and clocks that enter at the block's inputs or leave at the block's outputs. For example, block mid will get boundary constraints for inputs and outputs coming down from or going up to block top. And block bot will get boundary constraints for inputs and outputs coming down from or going up to block mid. No boundary constraints will be written for block top.

You can specify "budget shell" blocks with the **-shell_subblocks** option of **write_budgets**. See the section on "budget shells" for more information. Because no logic in a budget shell hierarchy is exposed to its parent block, different constraints are needed for that parent block. For example, if "bot" was listed as a shell block, the constraints for "mid" would not include full paths that pass between mid and bot. Instead, constraints are added that constrain the partial paths from mid to the ports of bot. The timing constraint will be created based on your current budget constraints, not the current timing of the full path. Also, the budgeted paths between "top" and "mid" will also be constrained -- as they were in the default behavior of **write_budgets**. In summary, "mid" sees both budgeted path constraints passing from/to "top" and budgeted path constraints passing from/to "bot".

You can specify that nested blocks in a design hierarchy will not be abstracted when optimized in their parent context with the **-design_subblocks** option of **write_budget**. This allows a child block and its parent block to be optimized together in a "virtual flat" manner. Because all of the logic of the child block is exposed to its parent block, different constraints are needed for that parent block. For example, if "bot" was listed as a flat block, the constraints for "mid" would need to cover not only all of the paths of mid, but also all the paths of bot.

In a multilevel hierarchy, the **-design_subblocks** options can force constraints to cover many levels at the same time. For example, if you are generating constraints for "top", and block "mid" is labeled as a design_subblock, then the constraints for top will need to consider boundary constraints for "bot". In the following example, the generated constraints for the top level include all paths at the top, all paths in mid, and the boundary paths of bot.

```
prompt> write_budgets -top design_subblocks mid
```

Budget Constraint Styles

For each budgeted block in your design, the **write_budgets** command can generate budgets in one of two styles. Budgets can include "full constraints" or budgets can include "incremental constraints". Full constraints are a complete set of constraints for a block. Incremental constraints preserve a block's internal constraints but updates the constraints on the block interface. The budget style is controlled by the **-full_budget_blocks** option.

"Incremental" constraints apply only to the interface timing paths of a budgeted block. These constraints are intended to be overlaid on top of the existing internal constraints of the block. Using these constraints, you can incrementally change the block's interface boundary constraints without disturbing the internal constraints. If you do not have existing internal constraints for your block, you can generate them by using the **split_constraints** command. These constraints are generated by default.

"Full" constraints include constraints for both the interface of the budgeted block *and* the internal block paths. If you use these constraints, any existing constraints on the block will be removed and replaced. These constraints are used for the top-level block budget, for modules selected by the **-full_budget_blocks** option and for parent blocks of modules listed in the **-shell_subblocks** option.

When calculating "full" constraints, the **write_budgets** command examines the timing of all internal paths for each budgeted block. If you are using abstracts to represent some of your blocks, timing the internal paths of the block is not possible. In this case, "full" constraints cannot be generated for abstracted blocks. If you want to generate "full" constraints, you must also use a full design view (not an abstract) for the block.

Memory Considerations

When you generate full constraints, you are required to change the selected blocks to a full design views. For large designs, this could require significant memory and runtime. To reduce the resource requirements, consider using the **split_constraints** command to generate the internal constraints of your budgeted block. The **split_constraints** command is specifically designed to use much less memory and runtime. After you have the results of **split_constraints**, you run **write_budgets** its default incremental setting.

This command returns 1 on success, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example creates block budget scripts for all declared budget blocks. The output is written to a directory called "budgets". If the directory already exists, it is overwritten.

```
prompt> write_budgets -force
```

The following examples creates budget scripts for the instance i_cpu in all modes. The output is written to a directory called "cpu_budget".

```
prompt> write_budgets -block i_cpu -output cpu_budget
```

The following example assumes a pre-CTS design. The commands automatically create a budget that assumes clock latency targets should be balanced across all blocks. Make sure you are using "prects" latency adjustment for your blocks. Then write the budget budgets along with the necessary clock latency adjustments to implement the balancing.

```
prompt> compute_budget_constraints -latency_targets estimated -balance true
prompt> set_budget_options -adjust_latency prects -all
prompt> write_budgets
```

The following example assumes a design where CTS has been run in the blocks but not yet balanced at the top. The commands automatically create a budget that assumes clock latency targets should be balanced across all blocks. Make sure you are using "target" latency adjustment for your blocks. Then write the budget budgets along with the necessary clock latency adjustments to implement the balancing.

```
prompt> compute_budget_constraints -latency_targets actual -balance true
prompt> set_budget_options -adjust_latency target -all
prompt> write_budgets
```

The following example assumes a design that has the final block and top clock trees. The commands create a budget that uses the actual current latencies (with no rebalancing). Make sure you are using "actual" latency adjustment for your blocks. Then write the budget budgets along with the necessary clock latency adjustments at block inputs.

```
prompt> compute_budget_constraints -latency_targets actual -balance false
prompt> set_budget_options -adjust_latency actual -all
prompt> write_budgets
```

write_busplans

Writes various files and scripts for busplans.

SYNTAX

int **write_busplans**
[-implementation_script *filename*]
[-multi_cycle_script *filename*]
[-xml_file *filename*]
[buses]

Data Types

filename string
buses collection of busnames

ARGUMENTS

-implementation_script filename

Specifies the name for the implementation script. This script contains constraints, such as movebounds and route corridors, that are used to create the busplan in the design.

-multi_cycle_script filename

Specifies the name for the multi cycle path script. This script sets multi cycle path constraint on paths that have virtual registers.

-xml_file filename

Specifies the name for an XML data file. This saves all current bus planning information (for the specified busplans) into an XML document. These XML documents can be loaded into the tool with the *load_busplans* command.

buses

Specifies the names of the buses to consider. If no buses are specified, the default is all buses in the busplan.

DESCRIPTION

Creates various files and scripts regarding the busplan. Use options to create the bus plan representation in different formats.

SEE ALSO

create_busplans(2)
get_busplans(2)
get_net_estimation_rules(2)
load_busplans(2)
modify_busplan(2)
report_busplans(2)
set_net_estimation_rule(2)

write_cell_expansion

Writes the cell expansion data to a file to support ASCII flow.

SYNTAX

int **write_cell_expansion**
[-output *output_file_name*]
[-scale_factor *unit_scale*]

Data Types

output_file_name string
unit_scale float

ARGUMENTS

-output *output_file_name*

Specifies the name of the output expansion data file. This is a required argument.

-scale_factor *unit_scale*

Specifies the scale factor between tools. This is optional.

DESCRIPTION

The **write_cell_expansion** command writes the cell expansion data to a file.

EXAMPLES

The following example writes out a cell expansion file from the existing design.

prompt> **write_cell_expansion -output out.exp**

SEE ALSO

read_cell_expansion(2)

write_checksum

This utility is for generating checksums.

SYNTAX

status **write_checksum**
[-output_directory *output_directory_path*]
[-type *checksum_type_list*]
[-scenario *scenario_name*]

Data Types

output_directory_path string
checksum_type_list list
scenario_name list

ARGUMENTS

-output_directory *output_directory_path*

Directory in which checksum will be generated.

If this option is not specified, current directory is utilized.

-type *checksum_type_list*

Specifies the list of checksums to be generated.

Valid values it can take are **all**, **library**, **design**, **parasitics**, and **constraints**.

If this option is not specified, all checksums are generated.

-scenario *scenario_name*

Specifies the scenario for which checksum needs to be generated.

If this option is not specified, the tool uses the current scenario.

DESCRIPTION

The **write_checksum** command generates checksums for input consistency checker.

The **write_checksum** command generates the checksums. If the **-output_directory** option is not specified, the checksums are

generated in the current directory. The checksum is generated into a subdirectory with the name of the scenario inside output_directory. If scenario option is not specified then the current_scenario is utilized.

If the **-type** option is not specified, all the checksums are generated. The values it can take are **all**, **library**, **design**, **parasitics**, and **constraints**.

EXAMPLES

The following example generates checksums on the current design to the checksum_out directory.

```
prompt> write_checksum -output_directory checksum_out
```

SEE ALSO

compare_checksum(2)

write_clock_trunks

Writes a Tcl script to re-create the specified clock trunk or for all clock trunks. The script includes clock trunk guide buffers.

SYNTAX

write_clock_trunks
[-clock *clock_list*]
[-file *file_name*]

Data Types

clock_list list or collection
file_name string

ARGUMENTS

-clock *clock_list*

Writes the clock trunk only for the specified clocks. By default, clock trunks for all clocks in the design are written.

Use this option to save a planned clock trunk for a specific clock, then re-create the clock trunk in a newly modified netlist to handle ECOs.

-file *file_name*

Specifies the name of the Tcl file to write. By default, the Tcl file is written to the terminal and to the logfile.

DESCRIPTION

This command writes a Tcl script you can use to re-create the current clock trunk.

This command does the following:

- The clock trunk for the given clocks is determined following the rules as for the **gui_load_clock_trunk_planning** command.
- For any buffers in the clock trunk, Tcl code is generated which re-creates the buffer if not present, and sets the location and placement status to its current value.
- For other cells in the clock trunk, Tcl code is generated which sets the location and placement status of the cell to its current value, if the cell exists.

EXAMPLES

The following example writes a script that can be used to re-create the clock trunk for the clock named CLK.

prompt> **write_clock_trunks -clock CLK -file CLK_trunk.tcl**

SEE ALSO

gui_load_clock_trunk_planning(2)
remove_clock_trunk_endpoints(2)
report_clock_trunk_endpoints(2)
set_clock_trunk_endpoints(2)

write_collection

Output a machine readable report of attribute values for elements in a collection.

SYNTAX

write_collection
collection
-file *filename*]
[-format *format*]
[-max_rows *value_count*]
[-columns *attribute_list*]
[-metadata]

string *collection*
string *filename*
string *format*
int *value_count*
list *attribute_list*

ARGUMENTS

collection

Specifies the collection on which to report. The collection may be homogeneous or heterogeneous. If the collection is very large, you may want to use the **-max_rows** option to limit the size of your output.

-file *filename*

This option indicates the name of the file to which the data is written.

-format *format*

This option accepts one of the following valid argument values: "csv" | "tsv". If the option is omitted, the default format is "csv", or command separated values. The argument "tsv" produces a tab separated values formatted data.

-max_rows *value_count*

This option indicates how many rows of data to include in the output. This number indicates the number of collection elements on which data is output.

-columns *attribute_list*

Indicates the set of attributes for which to output values, and their order in the output.

The special attribute name "object_class" may be used to include the element object class names, such as "cell" or "net", in the output.

If the option is omitted, then the object names and object class (or type) names are output by default.

-metadata

This option indicates that a meta data section should be included in the output.

DESCRIPTION

This command outputs tabular data of attribute values for elements of the given collection. The attribute values in the output are determined by the list of attributes given to the **-columns** option. The columns in the tabular report will be ordered by the order of attributes in the list. The command **list_attributes** may be called to view a list of attributes defined for an object class.

If the collection is large, the output size may be limited by indicating a **-max_rows** value. The commands **filter_collection** and **sort_collection** may be called to filter and sort a collection based on some criteria prior to creating a report for the collection elements.

By default, the output file omits the meta data section. If **-metadata** option is present, the output initiates with the meta data section which contains information such as the file generation timestamp, the product name and version and column data types. Some consumers of csv/tsv files benefit from the extra information in the meta data while other consumers do not handle it well.

EXAMPLES

The following example from IC Compiler II writes the full_name and area values of cells in a collection to a comma separated values (CSV) file named "cell_area.db".

```
icc2_shell> set cells [get_cells U*]
icc2_shell> write_collection $cells -columns {full_name area} \
        -file cell_area_pins.db
```

The next example outputs the same values to a tab separated values (TSV) file.

```
icc2_shell> write_collection $cells -columns {full_name area} \
        -format "tsv" -file cell_area_pins.db
```

The next examples limits the output to a CSV file to the first 10 objects in the collection.

```
icc2_shell> write_collection $cells -columns {full_name area} \
        -file cell_area_pins.db -max_rows 10
```

The next example first sorts the original collection of cells by the area attribute value in descending order, limiting the resulting collection to the top 10 area values. The example then outputs the full_name and area values to a CSV file named top_10_areas.db.

```
icc2_shell set sorted_cells [sort_collection -dictionary \
        $cells {area- full_name} -limit 10]
icc2_shell> write_collection $cells -columns {full_name area} \
        -file top_10_areas.db
```

The next example writes a sorted collection as in the above example but further limits the output to the first 10 objects in the collection. Note that this command may produce an output that is different from the above example. Limiting the sort to the first 10 values may produce a collection with more than 10 objects since multiple objects may share the same area value.

```
icc2_shell set sorted_cells [sort_collection -dictionary \
        $cells {area- full_name} -limit 10]
icc2_shell> write_collection $sorted_cells -columns {full_name area} \
        -file first_10_objects_by_area.db -max_rows 10
```

The next example outputs to a CSV file which will include the meta data section.

```
icc2_shell> write_collection $cells -columns {full_name area} \
         -format "csv" -file cell_area_pins.db -metadata
```

SEE ALSO

report_collection(2)

write_def

Writes a DEF file from a given design.

SYNTAX

string **write_def**
[-compress *method*]
[-units *units_per_micron*]
[-include *include_list*]
[-exclude *exclude_list*]
[-objects *objects*]
[-version *version*]
[-convert_sites { {*from_site to_site*} ... }
[-include_tech_via_definitions]
[-via_as_fixed]
[-routed_nets]
[-self_contained]
[-bus_delimiters *bus_bit_chars*]
[-traverse_physical_hierarchy]
[-no_marker_layer]
def_file_name
[-include_physical_status *include_physical_status_list*]
[-exclude_physical_status *exclude_physical_status_list*]
[-only_master_variant]
[-cell_types *cell_types_list*]
[-net_types *net_types_list*]
[-include_pad_owned_terminals]
[-design *design*]

Data Types

design	string
method	string
units_per_micron	int
include_list	list
exclude_list	list
objects	collection
version	string
from_site	string
to_site	string
bus_bit_chars	string
def_file_name	string
include_physical_status_list	list
exclude_physical_status_list	list
cell_types_list	list
net_types_list	list

ARGUMENTS

-compress ***method***

Specifies file compression format. The only format currently supported is **gzip**. A .gz extension is appended to the file name if no extension is specified. By default, DEF files are written in uncompressed text format.

-units ***units_per_micron***

Specifies the number of units per micron in the DEF file. All database length units are scaled accordingly in the output DEF file. If not specified, the units per micron is obtained from the technology length precision. Valid values are 100, 200, 1000, 2000, 10000, and 20000.

-include ***include_list***

Specifies which optional constructs and object types to include in the output DEF file. The output DEF file always contains the basic DEF items: version, divider character, bus bit characters, design name, units, and die area. When you use the **-include** option, only the listed optional constructs and object types are included in the generated DEF file. These are the optional constructs and object types:

blockages
bounds
cells
fills
nets
pg_metal_fills
ports
routing_rules
rows_tracks
scanchains
specialnets
vias
cut_metal

-exclude ***exclude_list***

Specifies which optional constructs and object types to exclude from the output DEF file. When you use this option, all of the optional constructs and object types are included in the generated DEF file except for those specified in the exclusion list.

When you use neither the **-include** nor **-exclude** option, the default behavior is to write out all the optional constructs and object types.

-objects ***objects***

Specifies a collection of objects to write out to the DEF file. The objects can be physical cells, physical nets, physical ports, routing_blockage (non-reserved), placement_blockage (hard, soft, partial), move bounds, rows, net shapes and vias. The output DEF file contains only the objects specified by this option, unless you also use the **-include** or **-exclude** option.

- If cells are specified, they are written to the COMPONENTS section, and all other cells are omitted.
- If nets are specified, they are written to the SPECIALNETS and/or NETS sections, and all other nets are omitted.
- If ports are specified, they are written to the PINS section, and all other ports are omitted.
- If blockages are specified, they are written to the BLOCKAGES section, and all other blockages are omitted.
- If move bounds are specified, they are written to the REGIONS and GROUPS sections, and all other move bounds are

omitted.

- If net shapes and/or vias are specified, they are written to the SPECIALNETS and/or NETS sections, and all other shapes and/or vias and the net connections are omitted. You can use the **set_app_options -name file.def.skip_connection_of_incomplete_net -value false** command before write_def command to write the net connections.
- If you specify the lower left via of a via ladder to the **-objects** option, the via ladder is written out. If you specify other vias or shapes of a via ladder to the -objects option, the via ladder is excluded from the generated DEF file, and only the corresponding net will be written out.

-version *version*

Specifies the DEF syntax version. Valid values are 5.7 and 5.8. The default is DEF version 5.8.

-convert_sites { {*from_site to_site*} ... }

Specifies a list of site name pairs, with each pair representing a map from one site name to another site name. All rows of site *from_site* are written as rows of *to_site*.

-include_tech_via_definitions

Includes all via definitions in the technology file, including those not used in the design, in the output DEF file. By default, only via definitions present in the design are written out to the DEF VIAS section.

-self_contained

Indicates that the output DEF must be self-contained. A self-contained DEF should not reference any objects which are not defined in the same DEF file. Please note that this option supports cell and move bound objects only.

-via_as_fixed

Indicates that all the via definitions are written out as fixed vias in the output DEF file.

-routed_nets

Indicates that all the nets written out in the output DEF file are routed nets i.e. has atleast one shape associated it.

-bus_delimiters *bus_bit_chars*

Specifies the bus bit characters to use in the output DEF. Valid values are "[]", "{}", "()", and "<>". When specified, the DEF BUSBITCHARS statement and bus names are written out using these bus bit characters.

-traverse_physical_hierarchy

Indicates writing the design information across all levels of the physical hierarchy to DEF file.

nets
: If the net crosses physical hierarchy, the sub-block nets are not written out, but all their wiring shapes are superimposed onto the net and written out. All the nets, which does not cross physical hierarchy, can be written out.

pins
: Sub-block pins are not written out, but all their shapes can be superimposed onto the connected net and written out.

via definitions and bounds
: If there is a name collision between top and sub block objects, the sub block objects are written out with block name prefix.

routing rules If a routing rule exists in the sub block and matches a routing rule that already exists in the top block, the sub block routing rule is not written out. If two routing rules have the same name but they are different in fact, the sub block routing rule is written out with the block name prefix.

cells, rows, blockages and tracks
They can be written out from each level of the physical hierarchy.

-no_marker_layer

Indicates disabling the writing of marker layers.

def_file_name

Specifies the name of the DEF file to be written. If the file already exists, it is overwritten. If the name ends with the .gz extension, it is compressed using the gzip format.

-include_physical_status *include_physical_status_list*

Specifies which cells to include in the output DEF file based on their physical status. When you use this option, all of the specified cells are excluded in the generated DEF file except for those whose physical status is specified in the *include_physical_status_list*. These are the optional physical status:

unplaced
placed
legalize_only
application_fixed
fixed
locked
all

-exclude_physical_status *exclude_physical_status_list*

Specifies which cells to exclude in the output DEF file based on their physical status. When you use this option, all of the specified cell are included in the generated DEF file except for those whose physical status is specified in the *exclude_physical_status_list*.

-include_physical_status and *-exclude_physical_status* are mutually exclusive.

-only_master_variant

Indicates that all the instances of variants are replaced by instances of the masters.

-cell_types *cell_types_list*

Specifies which cells to include in the output DEF file based on their types. When you use this option, all of the specified cells are excluded in the generated DEF file except for those whose cell types is specified in the *cell_types_list*. These are the specifiable cell types:

corner
end_cap
pad
flip_chip_pad
flip_chip_driver
pad_spacer
macro
lib_cell

This option provides additional level of filtering when used along with *-include_physical_status* and *-exclude_physical_status*.

-net_types *net_types_list*

Specifies which nets to include in the output DEF file based on their types. When you use this option, all of the specified nets are excluded in the generated DEF file except for those whose net types is specified in the *net_types_list*. These are the specifiable net types:

signal
power
ground
clock

-include_pad_owned_terminals

Includes port terminals having **is_owned_by_pad** attribute values of true. If the port **preferred_pin** attribute is set, then the preferred pin terminal is output. Otherwise if the port **die_side** attribute is set, then terminals on the die side are output. Otherwise all such terminals are output. Without this option, such terminals are output if and only if their **is_def_duplicate** attribute values are true.

-design *design*

Specifies the design (block) to be written as a DEF format. The default is the current block.

DESCRIPTION

This command writes the current or given design to a DEF file, including the physical layout, netlist, and design constraints. If the current design is not linked, it is automatically linked and then written out.

For the shapes which have no nets association, only when they are cut metal, or special wire extension, or metal fill they will be written out, otherwise, they will not.

The **-include** and **-exclude** options are mutually exclusive. When you use the **-include** option, the DEF contains the basic DEF items (version, divider character, bus bit characters, design name, units, and die area) and the objects specified with this option. When you use the **-exclude** option, the DEF contains everything except for the objects specified with this option.

When neither the **-include** nor **-exclude** option is used, the default behavior is to write out everything. However, if you use the **-objects** option, the output includes only the objects specified in the **-objects** argument.

These are the valid values for the *include_list* and *exclude_list*:

blockages Routing and placement blockage definitions defined in the DEF BLOCKAGES section.

bounds Move bound definitions defined in the DEF REGIONS and GROUPS sections.

cells Cell definitions defined in the DEF COMPONENTS section.

fills Floating metal fills defined in the DEF FILLS section.

nets Regular net definitions defined in the DEF NETS section.

pg_metal_fills Special net power and ground net fill shapes defined in the DEF SPECIALNETS section.

ports Port definitions defined in the DEF PINS section.

routing_rules Nondefault routing rule definitions in the DEF NONDEFAULTRULES section.

rows_tracks Row and track definitions defined with the DEF ROW and TRACKS statements.

scanchains Scan chain definitions in the DEF SCANCHAINS section.

specialnets Special net definitions, except power and ground net fill shapes, in the DEF SPECIALNETS section. Power and ground net fill shapes are specified by the option value, pg_metal_fills.

vias Via definitions defined in the DEF VIAS section.

cut_metal Shapes on the cut-metal layers, and metal shapes under cut-metal shapes.

These are the valid value only for the *exclude_list*:

non_mask_purpose Shapes of LayerDataType with nonMask=1 will be excluded from the DEF.

EXAMPLES

The following example writes a compressed DEF file using 1000 units per micron:

prompt> **write_def -compress gzip -units 1000 top.def**

The following example writes a DEF file that includes the floorplan data and excludes all other optional constructs and object types.

prompt> **write_def -include {rows_tracks bounds cells blockages} fp.def**

The following example writes a DEF file that excludes all special wiring but includes all other optional constructs and object types.

prompt> **write_def -exclude {specialnets pg_metal_fills} no_special.def**

SEE ALSO

read_def(2)

set_app_options(2)

write_default_pg_pattern

Writes out the default **create_pg_*_pattern** commands to describe the default PG patterns for the current design. Supported patterns are PG ring, mesh, macro connection, standard cell connection, and special patterns.

SYNTAX

status **write_default_pg_pattern**
[-type {*pattern_types*}]
[-output_filename *file_name*]

Data Types

pattern_types list
file_name string

ARGUMENTS

-type {*pattern_types*}

Specifies a list of one or more PG pattern types to write out. Supported types are: **ring**, **mesh**, **macro_conn**, **std_conn**, and **special**. By default, the command outputs all PG pattern types.

-output_filename *file_name*

Specifies the file name to use to write out the patterns. By default, the command writes the output to the terminal.

DESCRIPTION

This command writes out the appropriate **create_pg_*_pattern** commands to describe the default PG ring, mesh, macro connection, standard cell connection and special patterns. The command writes the output to the terminal and saves the output to the file specified by the **-output_filename** option.

EXAMPLES

The following example writes out the default mesh and ring patterns to *default.tcl* and to the terminal.

```
prompt> write_default_pg_pattern -type {mesh ring} \
            -output_filename default.tcl
```

SEE ALSO

create_pg_macro_conn_pattern(2)
create_pg_mesh_pattern(2)
create_pg_ring_pattern(2)
create_pg_special_pattern(2)
create_pg_std_cell_conn_pattern(2)

write_design_io

Writes out a text file containing information for I/O elements present in the design.

SYNTAX

string **write_design_io**
-file_name *file_name*
[-contents *object_type*]
[-columns_file *file_name*]
[-map_file *file_name*]
[-delimiter_char *char*]
[-cell_origin_type *string*]
[-within *bbox*]
[-objects *collection*]
[-units *units_per_micron*]

Data Types

file_name string
object_type string
char string of one character
bbox list of coordinates
units_per_micron integer

ARGUMENTS

-file_name *file_name*

Specifies the name of the output file to write the I/O design data. The file is an ASCII file that uses comma-separated value (CSV) format. A different field separator can be specified with the **-delimiter_char** option.

-contents *object_type*

Specifies the I/O object types to write to the output file. Supported object types are "c4", "ubump", "tsv", and "all". If not specified, the command writes out all I/O object types.

-columns_file *file_name*

Specifies a file that contains the column names to write out. Use this file to specify the column order and limit the data that is written to the output file.

For example, the following columns file specifies that only X origin, Y origin, C4 instance name, TSV instance name, and reference name information are written to the output file.

```
X_origin,Y_origin,C4_inst,TSV_inst,Reference_name
```

-map_file *file_name*

Specifies a CSV file that maps custom column names in the output CSV file to standard Synopsys column names. Custom column names are specified in the first field, and standard Synopsys column names are specified in the second field, separated by a comma.

For example, the following map file maps four custom column names to their corresponding Synopsys column names.

```
IO_driver name,C4_inst
Ref_Cell,Reference_name
X_COORD,X_origin
Y_COORD,Y_origin
```

-delimiter_char *char*

Specifies a single character to be used as the field delimiter in the output files. If not specified, comma is the field delimiter.

-cell_origin_type *string*

Specifies what point of the cell should be considered as its origin in order to do its placement. The allowed values are *lower_left* or *center*. The bounding box of the cell will be used to calculate its center. This option is optional. If not specified, the lower left corner of the cell will be considered.

-within *bbox*

When this option is specified, the writer will select only those I/O objects which are contained within the given bbox and write them out. This option can also be specified along with the *-contents* option.

-objects *collection*

When this option is specified, the writer will write out only those I/O objects which are a part of the collection. If the collection contains objects which are not C4 bumps, ubumps or TSVs, then such objects will be skipped, and the writer will continue to write the remaining objects. This option cannot be specified with *-within* option or with *-contents* option.

-units *units_per_micron*

If the length unit used in the output CSV file needs to be different from that of the design library, this option can be used to specify the custom unit for length. When specified, the distance values (of X/Y coordinates) in microns will be multiplied by this number and written out in the CSV file. The value must be an integer >=1. This is an optional option. If not specified, the distance values will be assumed to be in the same unit as the current library.

DESCRIPTION

The **write_design_io** command writes out the I/O information for to a CSV file. The file can be read directly by the **read_design_io** command. The command will write the following data into the output file:

- C4 bump cells

- Microbump cells

- Through-Silicon Vias (TSVs)

Each row in the output file contains information for one I/O object. By default, each row contains the name of the object, its reference name, X/Y location, orientation, net, and port name if it is connected. By default, the following standard columns are written to the output file.

- Reference_name

- C4_inst
- Ubump_inst
- TSV_inst
- X_origin
- Y_origin
- Orientation
- Port_name
- Net_name
- Comments

The columns and column order written to the file can be specified in a file and referenced by the **-columns_file** option. Custom column names can be specified by creating a mapping file and referencing the file with the **-map_file** option. The default field delimiter is a comma and can be changed by specifying the **-delimiter_char** option.

Field Map File Details

If the output file should contain custom names for fields instead of the Synopsys standard names, a mapping file can be provided via the **-map_file** option. Use the mapping file to create a map between your custom name and the corresponding Synopsys standard name for the field.

Each line in the map file contains exactly two strings separated by a comma. The first string is a user-defined field string and the second string is a Synopsys keyword. The order of lines does not matter. If the second string is not recognized, the line is ignored with a warning message.

The following map file maps the standard C4_inst field name to "IO_driver", and maps the standard Reference_name field name to "Ref_Cell".

```
IO_driver,C4_inst
Ref_Cell,Reference_name
```

The custom field names should not be same as the standard field names. Also, they must not contain any wildcard or special characters.

EXAMPLES

The following example writes all I/O design objects at the top level to a CSV file named out1.csv. All standard fields all written to the output file.

```
prompt> write_design_io -file_name out1.csv
1
```

The following example writes out a colon-separated file with custom column names, specifies a map file for the column names, specifies what columns to write out. Only TSVs are written out.

```
prompt> write_design_io -delimiter_char ":" \
  -map_file map.txt -contents "tsv" -columns_file cols.txt \
  -file_name out2.csv
Warning: Ignoring entry as number of columns in map file should be exactly 2.
 (map.txt line 3) (TLNL-014)
```

```
Warning: Unrecognized column name 'DUMMY' in map file, ignoring it.
  (map.txt line 4) (TLNL-018)
Parsing columns file cols.txt
1
```

write_dff_trace_filters

Writes the current trace filter pattern set to a file.

SYNTAX

status **write_dff_trace_filters**
-type pin | net
-filename *filename*
[-overwrite]

Data Types

filename string

ARGUMENTS

-type pin | **net**

Specifies the type of filter set to save to a file, either pin or net.

-filename ***filename***

Specifies the filename to use when saving the indicated filter set type.

-overwrite

Overwrites the file if it already exists.

DESCRIPTION

This command writes out trace filter patterns created by the **compute_dff_connections** command. Trace filter patterns are written to the filename specified by the **-filename** option. This file can be read by the **create_dff_trace_filters** command to restore the list of filters in another session.

EXAMPLES

The following example saves pin filters to a file called pinFilters.txt, and reads the filters with the **create_dff_trace_filters** command.

```
prompt> write_dff_trace_filters -type pin -filename pinFilters.txt
1
prompt> create_dff_trace_filters -type pin -filename pinFilters.txt
1
```

SEE ALSO

write_drc_error_data

Writes a DRC error data object associated with a block to file on disk and returns a collection that contains the DRC error data object.

SYNTAX

collection **write_drc_error_data**
  -error_data *drc_error_data*
  -file_name *file_name*
  [-overwrite]

Data Types

drc_error_data collection
file_name string

ARGUMENTS

-error_data *drc_error_data*

Specifies the DRC error data object to export to a file.

-file_name *file_name*

Specifies the name of the error data file to create.

The naming convention for an error data file is to append an underscore, the checker name, and the ".err" suffix to the design name. For example, for a design named "my_design" and a checker named "test", the error data file name is named "my_design_test.err".

-overwrite

Overwrites an existing file with the same name as the specified output file.

By default, the command fails is a file exists with the same name.

DESCRIPTION

The **write_drc_error_data** command writes an error data object to an external error data file with the specified file name. The command fails if the specified error data file already exists.

The original error data object remains open and in memory. The external error data file is not opened.

The command returns 1 if successful; 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example exports the physical DRC error data file that is named "dppinassgn.err". Although the output looks like a list, it is not. The output is a display of the name of the object in the returned collection.

```
prompt> write_drc_error_data -file_name my_design_dppinassgn.err -overwrite
1
```

write_ems_rules

Saves commands used to create user-defined rules as a script.

SYNTAX

write_ems_rules
[-rule *ems_rule_name*]
[-all]
[-overwrite]
output_file

Data Types

ems_rule_name string
output_file string

ARGUMENTS

-rule *ems_rule_name*

Specifies the rule name for an EMS rule. The option takes name of a rule or a pattern capturing names of multiple rules as argument. The *ems_rule_name* should be already available in EMS memory, otherwise the command will fail with an error message. The **-rule** option is optional, and the **-all** and **-rule** options are mutually exclusive.

output_file

Specifies the output file name. The command writes out a set of Tcl commands to create one or more EMS rules to the specified file, and the file can be used as a Tcl script to source commands to create user-defined EMS rules in a new session. If the file name already exists, the tool issues an error message. To overwrite the contents of an existing file, use the **-overwrite** option. The *output_file* argument is a mandatory argument.

-all

This option saves the commands to create all user-defined rules in EMS memory into the user-provided file as a Tcl script. If command is not provided with either **-all** or **-rule** options then the default behavior is as if **-all** option is provided. The option **-all** is an optional option and is mutually exclusive with the **-rule** option.

-overwrite

Forces overwrite of the output file if the file already exists. By default, if the file exists, an error message is issued and the command exits. This is an option is optional.

DESCRIPTION

This command is used to write out a Tcl script file that contains commands to create user-defined rules. This script can be sourced in a different session to create the user-defined rules again; this is needed since user-defined rules are not persistent across sessions.

EXAMPLES

The following example creates, edits, writes out, and reads in EMS rules in a two sessions.

```
# In session 1
prompt> create_ems_rule -name "TEMP-001" \
  -severity "Info" -message "Pin:%pin has capacitance:%cap"
prompt> edit_ems_rule -name "TEMP-001" \
  -parameters "name:pin type:string command:get_pins"
prompt> edit_ems_rule -name "TEMP-001" \
  -parameters "name:cap type:double"
prompt> create_ems_rule -name "TMP-002" \
  -severity "Error" -message "Cell %cell is not placed"
prompt> edit_ems_rule -name "TMP-002" -severity "Info"
prompt> edit_ems_rule -name "TMP-002" \
  -message "The Cell %cell is not placed."
prompt> edit_ems_rule -name "TMP-002" \
  -parameters "name:cell type:string command:get_cells"
prompt> write_ems_rules -overwrite -all ems_rules.tcl
prompt> quit

# In session 2
prompt> source ems_rules.tcl
prompt> report_ems_rules -all

Rule: TEMP-001
  Severity: Info
  Message: Pin:%pin has capacitance:%cap
  Parameter name: cap type: double command: NA
  Parameter name: pin type: string command: get_pins

Rule: TMP-002
  Severity: Info
  Message: The Cell %cell is not placed.
  Parameter name: cell type: string command: get_cells
```

SEE ALSO

create_ems_rule(2)
report_ems_rules(2)

write_feasibility_constraints

Writes timing constraints for the current design to make paths feasible by using a slack threshold value.

SYNTAX

status **write_feasibility_constraints**
-output *dir_name*
[-feasibility_factor *feasibility_factor_value*]
[-method multicycle_path | false_path | path_margin]
[-type setup | hold | both]
[-effort medium | high]
[-apply]
[-compress none | gzip]

Data Types

dir_name string
feasibility_factor_value float

ARGUMENTS

-output *dir_name*

Specifies the name of the directory **dir_name** in which to write the timing constraint files for the current design.

-feasibility_factor *feasibility_factor_value*

Specifies the value used to determine the feasible paths. By default, the value is set to 2.0. A timing path having negative slack, at the data-pin of an endpoint is said to be an infeasible timing path. This slack threshold value is determined by the user such that the absolute slack value for an endpoint should be lesser than the product of **feasibility_factor_value** and the capture clock period. If the endpoint belongs to an IO bound path, then the threshold is adjusted by subtracting the product of IO constraint value and the feasibility factor.

-method multicycle_path | **false_path** | **path_margin**

Specifies the technique based on which paths will be made feasible. By default, **set_multicycle_path** technique is used. Other available techniques to make the paths feasible are **path_margin** and **false_path**.

-type setup | **hold** | **both**

Specifies the type of constraints to be written into the timing constraint files. By default, the **setup** constraints are written into these files. Other available options include writing only the **hold** or writing **both** setup and hold constraints into these files. Note that the setup and hold constraints are written only if the respective flags are set true for the scenarios.

-effort medium | **high**

Specifies the effort to be applied to generate the constraints. By default, the effort is **medium** which will generate the constraints of open-ended type. This is very fast, but less accurate. A more accurate effort type is **high** which will generate a more specific close-ended timing constraint. Note that the **high** effort is more runtime intensive but is more accurate.

-apply

Applies the timing constraints to the current design to make the timing paths feasible. If this option is not specified, the command only generates the timing constraint files.

-compress none | **gzip**

Specifies the compression type to use when generating the timing constraint files. By default, no compression is performed.

DESCRIPTION

The **write_feasibility_constraints** command generates constraint files. The constraints can be applied to the current design by using the *-apply* option to convert infeasible timing paths to feasible paths. A timing path having negative slack at the data-pin of an endpoint is said to be an infeasible timing path. The number of constraint files generated is dependent on the total number of modes present in the design.

The **-output** option is required to specify the directory in which to write the constraints. By default, **setup** constraints are generated using **multicycle_path** technique with a feasibility factor of 2.0. Only hold or both type of constraints can be generated using other techniques like **path_margin** and **false_path**; you must specify an appropriate value for *feasibility_factor*.

The actual value of the *feasibility_factor* is calculated based on the clock period and can be selected by the user. If slack of an endpoint is **SLACK** and the capture clock period which reaches the same endpoint is **CLOCK_PERIOD**, the tool considers this endpoint as infeasible if and only if

abs(SLACK) > (feasibility_factor * CLOCK_PERIOD)

If the endpoint is from an IO bound path, then an additional adjustment is made to compute the slack threshold. If the IO constraint value is **IO_CONSTRAINT**, then the tool considers this endpoint as infeasible if and only if

abs(SLACK) > (feasibility_factor * (CLOCK_PERIOD - IO_CONSTRAINT))

The changes made by applying the feasibility constraints can be reverted by using the *remove_feasibility_constraints* command and mentioning the **output** as its input directory.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example generates Tcl files with timing constraints by using the multicycle_path method and a feasibility factor of 2.0.

```
prompt> write_feasibility_constraints -output Multicycle_Path_2
prompt> all_modes
{Mode_1 Mode_2}
```

The following example writes files with the names Mode_1.tcl and Mode_2.tcl into the MultiCycle_Path_2 directory. The constraints are applied to the current design by the **-apply** switch.

```
prompt> write_feasibility_constraints -output Multicycle_Path_2 -apply
```

The following example generates Tcl files with hold timing constraints by using the false_path method and a feasibility factor of 1.5. The tool writes the files named Mode_1.tcl and Mode_2.tcl to the False_Path_1.5 directory. The **-apply** option can be used to set the constraints for the current design.

```
prompt> write_feasibility_constraints -output False_Path_1.5 \
  -method false_path -feasibility_factor 1.5 -type hold
```

set_false_path(2)
set_multicycle_path(2)
set_path_margin(2)

write_floorplan

Writes floorplan information to files.

SYNTAX

status **write_floorplan**
[-include *include_list*]
[-exclude *exclude_list*]
[-output *dir_name*]
[-force]
[-nosplit]
[-format icc | icc2]
[-objects *objects_list*]
[-blocks *blocks_list*]
[-def_units 100 | 200 | 1000 | 2000 | 10000 | 20000]
[-compress gzip | none]
[-add_def_dependencies true | false]
[-via_as_fixed]
[-routed_nets]
[-include_physical_status *include_physical_status_list*]
[-exclude_physical_status *exclude_physical_status_list*]
[-cell_types *cell_types_list*]
[-net_types *net_types_list*]
[-read_def_options *option_string*]
[-def_version *version*]

Data Types

include_list	list
exclude_list	list
dir_name	string
objects_list	collection
blocks_list	collection
include_physical_status_list	list
exclude_physical_status_list	list
cell_types_list	list
net_types_list	list
option_string	string
version	string

ARGUMENTS

-include *include_list*

Specifies the types of data to include in the output. This option cannot be specified together with the **-exclude** or **-objects** options. If this option is not specified, all types are included by default.

The supported types are:

- blockages
- bounds
- cells
- corridors
- die_area
- edit_groups
- io_guides
- macros
- module_boundaries
- nets
- pin_guides
- pins
- route_guides
- rows
- tracks
- vias
- scan_chains
- routing_directions
- voltage_areas
- fills
- pg_metal_fills
- routing_rules
- pg_regions

Specify **-include macros** to output only macro cells and skip standard cells. Specify **-include cells** to output all cells. If you specify **-include {macros cells}**, the command issues a warning message that macros will be ignored.

-exclude *exclude_list*

Specifies the types of data to exclude from the output. This option cannot be specified with the **-include** option or **-objects** options. If this option is specified, the command writes all types, except the types specified in *exclude_list*. The allowed data types are the same as for the **-include** option.

-output *dir_name*

Specifies the name of the directory in which to write the floorplan files. The default is *./floorplan*. If the directory already exists, the

command issues an error message, unless **-force** is also specified.

-force

Overwrites floorplan files in the ./floorplan directory, or in the directory specified by the **-output dir_name** option. By default, the command issues an error message and exits if the directory exists.

-nosplit

Writes out long lines, even if the line length is greater than 80 columns. Use this option to simplify post-processing of the output constraint files or when comparing the constraint files by using the UNIX **diff** command. If this option is not specified, the command breaks long lines near column 80 and inserts a line continuation character (\).

-format icc | icc2

Specifies the target tool for which to write the floorplan. Valid values are **icc** and **icc2**. By default, the value is **icc2**.

To take floorplan information to the Design Compiler tool (in topographical mode) for RTL resynthesis with floorplan information such as macro placement), use the **-format icc** option. The EXAMPLES section contains an example of this flow.

-objects *objects_list*

Specifies the objects to include in the output. Supported object types are cells, ports, blockages, voltage areas, bounds, edit groups, routing corridors, module boundaries, PG regions, site rows, and site arrays. Objects of other types are ignored.

This option cannot be specified with the **-include**, **-exclude**, or **-blocks** options.

-blocks *blocks_list*

Specifies the blocks to output hierarchically. If this option is not specified, only the top-level block is written. This option cannot be combined with the **-objects** option.

-def_units 100 | 200 | 1000 | 2000 | 10000 | 20000

Specifies the number of units per micron in the DEF file. All database length units are scaled accordingly in the output DEF. If not specified, the units per micron is obtained from the technology length precision. Valid values are 100, 200, 1000, 2000, 10000, and 20000. This option is passed to the DEF writer and the behavior is identical to the **-units** option of the *write_def* command.

-compress gzip | none

Specifies the compression type to use when writing the .DEF file. By default, no compression is performed.

-add_def_dependencies true | false

Specifies whether to add dependencies (sections not requested) to the .DEF file to make it self-sufficient. For example, if this option is set to true, if nets are in the **-include** list but vias are not, the VIAS section will be added anyway; if the option is set to false, it will not be added. The default is true.

-via_as_fixed

Indicates that all the via definitions are written out as fixed vias in the output file.

-routed_nets

Indicates that all the nets written out in the output are routed nets, that is, each net has at least one shape associated it.

-include_physical_status *include_physical_status_list*

Specifies which cells to include in the output based on their physical status. When you use this option, all of the specified cells are included in the generated DEF file. The physical status can be one or more of the following:

all

application_fixed
fixed
legalize_only
locked
placed
unplaced

-exclude_physical_status *exclude_physical_status_list*

Specifies which cells to exclude in the output file based on their physical status. When you use this option, all of the specified cell are included in the generated DEF file except for those whose physical status is specified in the *exclude_physical_status_list*.

-include_physical_status and *-exclude_physical_status* are mutually exclusive.

-cell_types *cell_types_list*

Specifies which cells to include in the output DEF file based on their types. When you use this option, all of the specified cells are excluded in the generated file except for those whose cell types is specified in the *cell_types_list*. These are the specifiable cell types:

corner
end_cap
pad
flip_chip_pad
flip_chip_driver
pad_spacer
macro
lib_cell

-net_types *net_types_list*

Specifies which nets to include in the output DEF file based on their types. When you use this option, all of the specified nets are excluded in the generated file except for those whose net types is specified in the *net_types_list*. The net types can be one or more of the following:

clock
ground
power
signal

-read_def_options *option_string*

Specifies options to include with the **read_def** command that is written to the floorplan file.

-def_version *version*

Specifies the DEF syntax version used to create floorplan.def file. Valid values are 5.7 and 5.8. The default is DEF version 5.7.

DESCRIPTION

The **write_floorplan** command writes the *floorplan.tcl* Tcl script and *floorplan.def* DEF file. The *floorplan.def* file generally includes the objects that are numerous, as sourcing the corresponding Tcl would be time-consuming. The *floorplan.tcl* contains the remaining floorplan constructs and a **read_def** command to load the *floorplan.def* file. To restore the floorplan, source the *floorplan.tcl* Tcl script.

By default, the floorplan files are written to a directory named *./floorplan*. The destination can be changed by using the **-output**

option. The command also writes a third file, *floorplan_compare_data.txt*, that contains information to use when comparing the output with a new design by using the **compare_floorplans** command. If the **-blocks** option is used, the command creates subdirectories with names corresponding to the list of blocks.

The **write_floorplan** command writes out user attributes associated with objects to the Tcl script. In the IC Compiler tool, there is no shape or via object associated with a terminal. In this case, the script sets user attributes from the terminal and shape or via object on the terminal for the IC Compiler tool. If there is a conflict between values of the same attribute, a higher precedence is given to the value set on the terminal.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example writes floorplan files to the script directory.

```
prompt> write_floorplan -output script
```

The following example writes only cells and blockages.

```
prompt> write_floorplan -include {cells blockages}
```

The following example writes macros hierarchically for all blocks.

```
prompt> write_floorplan -include {macros} -blocks [get_blocks *:*]
```

The following example writes the selected objects and ignores objects that belong to unsupported types.

```
prompt> write_floorplan -objects [get_selection]
```

The following example writes floorplan information in icc format. This could be used to export the floorplan information to the Design Compiler tool (in topographical mode) where the RTL is resynthesized with this floorplan information. Non-PG nets and non-fixed cells are not needed for re-synthesis and so they can be filtered out of the DEF file by using post-processing.

```
prompt> write_floorplan -format icc
```

The following example writes out the floorplan file for all blocks. To load back floorplan file for each block, one method is source the floorplan.tcl Tcl script, the other method is use **set_constraint_mapping_file floorplan/mapfile** and **load_block_constraints -type FLOORPLAN -all_blocks**.

```
prompt> write_floorplan -output floorplan -blocks [lsort -unique \
  [get_attribute [get_cells -hierarchical -filter is_soft_macro] ref_name]
```

The following example writes out the floorplan file and includes the **-add_def_only_objects {cells}** and **-no_incremental** options to the **read_def** command written to the floorplan file.

```
prompt> write_floorplan -output "dirName" -nosplit -verbosity low \
  -def_version 5.8 -read_def_options {-add_def_only_objects {cells} -no_incremental}
```

SEE ALSO

compare_floorplans(2)
read_def(2)
write_def(2)

write_frame_options

Writes a Tcl script that sets the frame view generation options.

SYNTAX

status **write_frame_options**
-library *lib_name*
[-block *block_name*]
[-output *file_name*]
[-format lm_shell | icc2_shell]

Data Types

lib_name string
block_name string
file_name string

ARGUMENTS

-library *lib_name*

Specifies the library for which to output the frame view generation options.

This is a required option.

-block *block_name*

Specifies the blocks for which to output the frame view generation options.

By default, the command writes the frame view generation options for all blocks in the specified reference library.

-output *file_name*

Specifies the output file name.

By default, the frame view generation options are output to the console.

-format lm_shell | icc2_shell

Specifies the output format, lm_shell or icc2_shell.

The default is lm_shell.

DESCRIPTION

This command outputs the original frame view generation options. By default, the command writes the option settings to the console. To save the option settings in a Tcl file, use the **-output** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example outputs the frame view generation options for every frame view in the library.

```
prompt> write_frame_options -library testLib \
  -output allOption.tcl
```

The following example outputs the frame view generation options for the specified block in the library.

```
prompt> write_frame_options -library testLib \
  -block testLib/block1/frame \
  -output block1Option.tcl
```

units_per_micron integer
report_file_name string
verbose_report_file_name string
cell_renaming_files string
layer_collection collection
output_file string
views string
cell_type_list list
depth integer

ARGUMENTS

-bus_delimiters *delimiters*

Specifies the bus delimiters to be used in port, pin, and net names to denote bus subscripts. Valid values are "[]", "{}", "()", and "<>".

-block_map *block_map_file_name*

Specifies the name of a block mapping file, a text file containing a list of blocks to ignore (not write out), in the following format:

```
; This is a block mapping file
 myBlockA:ignore     ; ignores myBlockA
 myBlockB:ignore     ; ignores myBlockB
```

-compress

Writes out the GDSII file in gzip (.gz) compressed format to save disk space. A .gz extension is appended to the file name if no extension is specified. By default, the output is uncompressed.

-connect_below_cut_metal

Generates metal layers below the cut metal. For generating metal, it is assumed that two pieces of metal of same size and mask color abut with the cut metal. By default, this action is not performed.

-design *design_name*

Specifies the name of the top design (block) to be written as a GDSII stream. The default is the current block.

-disable_output_mask_layers *mask_layers*

Specifies the layers for which the geometry and text information corresponding to a color-mask configuration are written without considering the color-mask configuration. The color-mask information of the objects is not considered while writing them.

-fill include | exclude | fill_only

Writes or omits fill data according to the specified mode:

- **include**: Writes all geometries, including fill data (default)
- **exclude**: Omits all fill data
- **fill_only**: Writes only the fill data

-flat_vias

Flattens via shapes when writing the GDSII file. By default, vias are written as instances of via masters and are not flattened.

When **-output_net_text** is on and **-net_text_on** is all_shapes_and_vias with this option, the valid text is outputted once, otherwise the text isn't outputted

-force

Writes out the GDSII file, even if the design or library has mismatches; by default, the command issues an error message and stops. This option is deprecated in favor of the **-allow_design_mismatch** option.

-foreign

Uses the LEF foreign cell name as the structure name and instance name. This option affects the STRNAME structure name and the SREF structure element reference name in GDSII. By default, the command ignores the LEF FOREIGN statements and uses the original cell name.

-hierarchy top | design | design_lib | all_design_libs | all

Specifies the parts of the design hierarchy to write out:

- **top**: Writes only the top module in the design, excluding the contents of lower-level modules of the netlist.
- **design**: Writes the design, including lower-level submodules (soft macros), stopping at the design boundary.
- **design_lib**: Writes the design, stopping at its design library boundary.
- **all_design_libs**: Writes the designs in all design libraries but excluding the reference libraries; stops at all design library boundaries.
- **all**: Writes the entire design, including modules in reference libraries.

  The default is "*design_lib*".

-ignore_cut_datatype_tbl_mapping

Ignores the mapping of datatype, based on the via dimensions, from the cutDataTypeTbl entry in the technology file. By default, the command writes cuts of different sizes as different data types as defined by the cut data table in the technology file.

-instance_property ***instance_property_value***

Writes out instance names as a property attribute with the given attribute number in the GDSII stream. By default, no instance property attribute is written.

-keep_data_type

Keeps the data type for each object as defined in the design library (when run in an implementation tool) or the cell library (when run in the library manager). By default, the command converts the data type to 0.

When the **-layer_map** option is used, the layer data type specified in the layer mapping file overrides the data type in the database, and the **-keep_data_type** option setting is ignored. For objects on layers not defined in the layer mapping file, the **-keep_data_type** option still applies.

-layer_map ***layer_map_file_name***

Specifies a layer mapping file that customizes the translation of layer, data type, and purpose between the tool's data model and the GDSII file. For details, see "Layer Mapping File" in the DESCRIPTION section.

-layer_map_format icc2 | icc_default | icc_extended

Specifies the format of the layer mapping file. This option allows the command to accept an IC Compiler layer mapping file. These are the allowed settings:

- **icc_default**: IC Compiler default layer mode, system layers 188-255
- **icc_extended**: IC Compiler extended layer mode, system layers 4001-4095
- **icc2**: IC Compiler II layer mapping file format (default)

-layers ***layers***

Writes only the specified layers of the technology; all other layers are excluded. By default, the command writes all layers to the GDSII file.

-lib_cell_view frame | layout | design

Specifies the name of the view used for writing leaf-level reference library cells to the GDSII file. If the user-specified view is not available for a particular reference library cell, the command skips writing the library cell definition. The default is **layout**.

-library ***name***

Specifies the name of the source library. The default is the current library.

-long_names

Writes out names longer than 32 characters. Use this option to write long hierarchical names without modification. By default, the command limits each name string to 32 characters.

-mask_shifted_suffix ***suffix_string***

Specifies the suffix string used to generate cell master names when the tool performs double-patterning mask swapping. For details, see "Double-Patterning Cell-Level Mask Swapping" in the DESCRIPTION section. This option is mutually exclusive with the **-mask_shifted_suffix_without_constraint** option.

-mask_shifted_suffix_without_constraint ***suffix_string***

Specifies the suffix string used to generate cell master names when the tool performs double-patterning mask swapping. This option differs from the *mask_shifted_suffix* option because the instance-specific mask information is not added to the cell master

names. For details, see "Double-Patterning Cell-Level Mask Swapping" in the DESCRIPTION section.

-merge_conflict_suffix *suffix_string*

Specifies the suffix string to be used to generate new names for resolving merge conflicts that occur with the **-merge_files** option.

-merge_files *merge_files*

Specifies the names of the input stream files to be merged. You can specify both GDSII and OASIS files as input that are to be merged with the newly generated GDSII stream. The command first merges the specified files into an intermediate GDSII file. Then it merges the newly generated GDSII stream with this intermediate file to produce the final GDSII file.

-merge_gds_top_cell *top_cell*

Specifies the top cell to be considered for the merge flow. When this option is specified only the cells in it's hierarchy are considered for merge operation. All remaining cells are removed from the resultant GDSII file.

-merge_cell_shapes

Specifies that the shapes from identically named cells in different source files are to be merged into a single cell in the output file.

-merge_overwrite_conflicting_cell

Writes out the last conflicting cell, only if there are conflicting cells in GDSII files to be merged.

-net_property *net_property_value*

Writes out net names as a property attribute with the given attribute number in the GDSII stream. A property attribute number is an integer from 0 to 127. By default, no net property attribute is written.

-net_text_on all_shapes_and_vias | all_shapes | each_layer | single_shape

Writes or omits net text according to the specified mode:

- **all_shapes_and_vias**: Writes net text on all shapes and vias per net
- **all_shapes**: Writes net text on all shapes (excluding via shapes) per net
- **each_layer**: Writes net text on one shape per layer (excluding via layers) per net
- **single_shape**: Writes net text on one shape per net (default)

  This option require **-output_net_text** to be specified.

-output_net_text

Writes out TEXT objects for net shapes. By default, no TEXT objects are written out for net shapes.

-output_pin text | geometry | all | none

Specifies the manner in which pin objects are written into the GDSII file. Allowed values are:

- "**text**": Writes the name of each pin as a TEXT object associated with the pin.
- "**geometry**": Writes the geometry of each pin as a POLYGON or BOUNDARY object associated with the pin.
- "**all**": Writes both the text and geometry of each pin.
- "**none**": Prevents the writing of pin data.

  The default is "*all*"

-pin_property *pin_property_value*

Writes out pin names as a property attribute with the given attribute number in the GDSII stream. By default, no pin property attribute is written.

-via_property *via_property_value*

Generates the via and via matrix property with the specified attribute number in the GDSII stream. By default, no via or via matrix property is written into GDSII file.

-propagate_pin_mask_to_via_metal

Propagates the double-patterning mask property of each metal1 pin shape, as specified by the pin shape's mask_constraint attribute, to the corresponding metal1 layer of a via dropped on the pin. This modifies the lower_mask_constraint attribute setting of the via from no_mask to match the attribute setting on the pin shape. (An existing setting other than no_mask is not modified).

This option affects only the data written to the GDSII file.

-rename_cell *cell_renaming_files*

Specifies the mapping files which contain pairs of original and new cell names. Each line in the mapping file specifies the name mapping for a single cell.

OldCellName NewCellName

The following example maps ADDFHX1_A to ADDFHX1_B, NOR to NOR2 and XOR to XOR2X4.

#mapfile
ADDFHX1_A ADDFHX1_B
NOR NOR2
XOR XOR2X4

Mask-shifted cells, however, are represented differently in the mapping file. The name mapping comprises three sections: MASKSHIFTLAYER, MASKSHIFTPATTERN and CELLMAP.

For example, to rename the cell A with mask shifting on layer M1 or/and M2, enter the following:

<MASKSHIFTLAYER>
M1 M2
</MASKSHIFTLAYER>
<MASKSHIFTPATTERN>
00 01 10 11
</MASKSHIFTPATTERN>
<CELLMAP>
A AM2B NONE AM1BM2B
</CELLMAP>

MASKSHIFTLAYER specifies the relevant metal layers, in order, on a single row.

MASKSHIFTPATTERN specifies the mask shift combinations to apply to the metal layers. The digits in each combination correspond to the metal layers listed in MASKSHIFTLAYER, respectively. For example, the 00 combination represents a shift value of 0 on layers M1 and M2; the 01 combination represents a shift value of 0 on layer M1 and 1 on layer M2; the 10 combination represents a shift value of 1 on layer M1 and 0 on layer M2; and so on.

The number of mask shift combinations is less than or equal to pow(m, n), where n is the number of layers specified in MASKSHIFTLAYER and m is the count of the shift values. For 2-mask layers, valid shift values are 0 and 1, so m is 2. In the example above, two metal layers are specified (M1 M2), so there are four mask shift combinations (00 01 10 11).

CELLMAP specifies the cell mappings that correspond to each mask shift pattern for a given cell. (Each row specifies the mappings for a single cell, so the number of mappings in each row corresponds to the number of MASKSHIFTPATTERN combinations.) The **write_gds** command renames a cell based on the cell's mask_shift attribute and the mapping file content.

In the example above, cell A is mapped to A, AM2B, NONE, and AM1BM2B when its mask_shift attribute is set to 0 on both layers

(00), set to 1 on layer M2 (01), set to 1 on layer M1 (10), and set to 1 on both layers (11), respectively. When a mask-shifted cell is not expected for a particular mask shift combination, the cell name is mapped to NONE and **write_gds** errors out. When a mask-shifted cell is undefined, the mapping file does not contain the corresponding name mappings and **write_gds** errors out.

By default, the original cell name is preserved in the output GDSII file.

-units ***units_per_micron***

Specifies the resolution to use for writing the GDSII, expressed as the number of units per micron. The default is 10000 (Angstrom units, 1e-10 m).

-report_cell_source ***report_file_name***

Specifies the name of the summary report file in which the physical data of a top-level design is written corresponding to GDSII stream file in plain ascii format. By default, this option writes out the design view of the current block in the current library.For available data, it reports for all the unique libraries used to export cells and one instance from each library which gives user a capability to validate that the exported data come from the right versions of the instantiations be it std cells,IP and blocks. It will write five columns:

- **Path**: The source path or reference location of every reported ndmInstance.
- **Type**: The type of instance whether it is macro_cell,lib_cell,std_cell etc.
- **Reference Name**: The name of the Reference design of that instance.
- **Instance Name**: The name of ndmInst.
- **Physical Hierarchy**: The reference module is present in which all other physical blocks.

-verbose_report_cell_source ***verbose_report_file_name***

Specifies the name of the summary report file.It will report same data as in report_cell_source option but for available data,it reports for all libraries and all physical instances which are exported from them and which are not part of hierarchy of a macro_cell.

-use_block_name

Uses the block name (and user label, if any) instead of the module name for the top structure in the GDSII file. By default, the name used for each structure name is the module name in the data model. In cases where the module name and block name for the top module are different, this option causes the block name to be used; if the block has a user label, the resulting name is *block_user_label*.

-view frame | **abstract** | **timing** | **layout** | **design**

Specifies the name of the view to be written. The default is the **design** view.

-write_default_layers ***layer_collection***

Specifies the layers for which the geometry and text information corresponding to a color-mask configuration is written into the default base. When this option is used with layer-mapping information for the color-masks, all the geometry and text information corresponding to the layers in the input collection are written twice: first into the layer-datatype pair obtained from the layer-map by considering the color-mask configuration, and then again without considering the color-mask configuration.

-write_instance_shape_mask

Writes instance-specific shape masks to the GDSII file as overlapping shapes in the parent structure. For a lib cell instance, the shape mask in bound view will be output, if the value specified by "-lib_cell_view" is different from its bound view. By default, instance-specific shape masks are not written.

-write_instance_via_mask

Writes instance-specific via masks to the GDSII file as overlapping shapes in the parent structure. For a lib cell instance, the via

mask in bound view will be output, if the value specified by "-lib_cell_view" is different from its bound view. By default, instance-specific via masks are not written.

-write_instance_blockage_mask

Writes instance-specific blockage masks to the GDSII file as overlapping shapes in the parent structure. By default, instance-specific blockage masks are not written.

-write_instance_mask_on_layers *layers*

Writes instance-specific mask to the GDSII file on the specified layers only. By default, it is enabled for all the layers.

-allow_design_mismatch

Writes out the GDSII file, even if the design or library has mismatches; by default, the command issues an error message and stops.

-exclude_empty_block

Exclude the empty structure defintions and instances in the GDSII file for each empty block or library cell. By default, the empty block or library-cell defintions are included in the output.

-no_marker_layer

Doesnot generates the marker layer data.

-switch_view_list

Specifies the reference block views for hierarchical block instances to be opened. The view at the head of the list is in higher priority.

-cell_types *cell_type_list*

Writes out only the specified types of cells. By default, the **write_gds** command writes out all types of cells. These are the cell types that you can specify in the *cell_type_list*:

lib_cell
macro
corner
cover
end_cap
filler
flip_chip_driver
flip_chip_pad
pad
pad_spacer
tsv
vib
well_tap

If you use the **-child_depth** option, the **write_gds** command writes out only the types of cells specified by the **-cell_types** option at the current block and their children (including all types of cells in the children) through the specified child depth. It does not write out any other types of cells at the current block nor any of their children.

-child_depth

Specifies the maximum hierarchical block depth to be output. The default value is to output all hierarchical blocks in the hierarchical scope specified by option "-hierarchy". The hierarchical depth is 0 for top block, the depth is increased 1 for child blocks to which instances referred in current block.

-verbose

Prints the details of the hierarchical blocks to be output, and warning messages for those which reference design and view cannot be found.

output_file

Specifies the name of the output GDSII file. If the name ends with the .gz extension, it is compressed using the gzip format.

DESCRIPTION

This command writes out the physical data of a top-level design in a GDSII stream file for tapeout or for export to third-party tools. By default, the command writes out the design view of the current block in the current library and maintains the original layer numbers as it converts the data to GDSII format.

The command offers the following options:

- The name of the library, design, and view to be written out
- The mapping of the database layers to GDSII layers
- The mapping of net, instance, and pin names in the conversion to GDSII format
- The manner of writing out pin objects (text or geometry)
- The handling of mask-shifted multiple-patterning data
- The layers, hierarchical blocks, and fill data to be included in the GDSII output
- The merging of design data with existing GDSII files

To locate files that have relative pathnames, the command uses the **search_path** variable and searches for each file in each directory listed in the **search_path**. Files that have absolute pathnames are loaded as though there were no **search_path**. To determine the file that **write_gds** loads, use the **which** command.

Layer Mapping File

By default, the **write_gds** command maintains the original layer numbers when it writes out the GDSII file.

When there is explicit mapping of system purpose (-1, -2, -3 and -4) in layer mapping file, the tool will use that mapping; for example, with the mapping "all 32:-1 32:55", the tool maps database layer "32:-1" to GDS layer 32:55; if no mapping for these system purposes, the tool will follow the mapping of the purpose 0 of the same layer. For example, if the mapping has "all 32:0 32:70", system purpose "-1" will be mapped to GDS layer 32:70. Please note that GDS datatype can't be any data less than 0, the usage like "all 32:-1 132:-1" is invalid for GDS language, and the datatype will be taken as 0 like "A 32:-1 132 0"

You can optionally provide a layer mapping file to specify the mapping of layers and data types between the database and the GDSII layers. You can use the same mapping file for both the **write_gds** and **read_gds** commands. This is the mapping file format:

```
; single line comment
[read_always { true | false [-mapped_only | -ignore_missing_layers ] } ]
[blockage_as_zero_spacing {true|false}]
[cell_prop_attribute attribute_number]
[net_prop_attribute  attribute_number]
[pin_prop_attribute  attribute_number]
[via_prop_attribute  attribute_number]
[object_type] tool_layer_number[:tool_purpose][:use_type][:mask_type] \
  gdsii_layer_num[:gdsii_data_type]
```

For example,

```
; This is my layer mapping file
                ;
    84      92    ; ICC2 layer 84 = GDSII layer 92
                ;
    59      69:3  ; ICC2 layer 59 = GDSII layer 69, data type 3
                ;
    17:1    117:3  ; ICC2 layer 17, purpose 1 = GDSII layer 117, data type 3
                ;
data 33:0:*:*  1:2  ; ICC2 data on layer 33, purpose 0, any use type,
                ;  any mask type = GDSII layer 1, data type 2
text 33:0:*:*  1:4  ; ICC2 text on layer 33, purpose 0, any use type,
                ;  any mask type = GDSII layer 1, data type 4
                ;
; all other layers and data types match between ICC2 and GDSII
```

In each line, any text after a semicolon "*;*" is a comment.

The **read_always** statement determines how the **read_gds** command handles differences between GDSII layers and database layers. The **blockage_as_zero_spacing** statement determines how the **read_gds** command interprets GDSII blockage layers, as either zero-spacing or design-rule-spacing guides. For details, see the man page for the **read_gds** command.

The **cell_prop_attribute**, **net_prop_attribute**, **pin_prop_attribute**, and **via_prop_attribute** statements specify the property attribute numbers used for storing cell instance, net, pin names, via attribute in the GDSII file. The specified value for the properties should be distinct. For example, the statement "net_prop_attribute 5" causes the **write_gds** command to write out net names of objects as property attribute 5 in the GDSII file. These statements in the layer mapping file have higher priority than the corresponding **write_gds** command options, **-instance_property**, **-net_property**, **-pin_property**, and **-via_property**.

After you write a GDSII file with these properties, when you read the file back into the tool with the **read_gds** command, the original cell names are restored, and the pins and nets are properly identified without the tool spending time on connectivity tracing.

Each field of the layer mapping line is separated by a colon "**:**". Each field can be an explicit value, an asterisk "*****" wildcard character, or left blank. An asterisk or black space indicates any value.

A more specific rule priority than a more general rule. For example, the rule "5:3 8", has higher priority than "5 7". If conflicting rules are specified in different lines (for example, first "6:2 4" and then "6:2 7"), the last one in the file is used and the earlier one is ignored.

The optional *object_type* keyword at the beginning of a layer mapping line restricts the mapping rule to only the specified object types:

- **data**: Mapping applies only to non-text objects
- **text**: Mapping applies only to text objects
- **all**: Mapping applies to both text and non-text objects (default)

tool_layer_number is the layer number in the database, an integer.

tool_purpose is the purpose number in the database, an integer.

use_type is the usage type in the database, which is one of the following.
"route_guide,single_row_via_ladder_pattern_must_join_allowed" requires the relative "tool_layer_number" is any layer number(*), and the format of the layer mapping file is specified as icc_default with -layer_map_format option.
"instance_specific_mask" is to copy the instance-specific mask constraints data (via cut-shapes, shapes, and blockages) to a layer, it is effective when at least one of three options(-write_instance_via_mask, -write_instance_shape_mask and -write_instance_blockage_mask) is specified. Please note, this is "copy" operation, which means the instance specific mask will be written onto original layer still at the same time. By default "power" is to map all power data. "power,net", "power,port", "power,

pin" are to distinguish net, port, pin respectively. The same rules apply to "ground", "clock", "signal" and their corresponding net, port, pin use_types. "same_net_feedthrough_tsv" can be used to create special marking layers in GDS for qualified TSV. Any shape whose mask_name is 'tsv' in design database is duplicated as a marking layer shape in GDS only when "same_net_feedthrough_tsv" is defined in the layer map. The qualified TSV should have a pin. This pin should have a net. The net should have ports of shapes with layer mask_names on backside and front-side both. "hi_voltage" is to index write_gds to output net voltage_range_max as a text. "lo_voltage" is to index write_gds to output net voltage_range_min as a text. The net can be signal, clock, power or ground.

mask_type is the mask type of the shape in a multiple-patterning technology. For a metal layer, the following mask types are supported:

mask_one
mask_two
mask_three
same_mask

For a VIA cut layer, the following additional mask types are supported:

MASK_FOUR
MASK_FIVE
MASK_SIX
...
MASK_FIFTEEN

gdsii_layer_num is the layer number of the geometry or TEXT in the GDSII file, an integer.

gdsii_data_type is the data type number of the geometry or TEXT in the GDSII file, an integer.

Double-Patterning Cell-Level Mask Swapping

In a double-patterning technology, a layer is decomposed into two different masks, with physically adjacent geometries assigned alternately to the two masks. The physical layer is fabricated on the chip using two separate photolithography steps, minimizing optical proximity degradation between adjacent geometries. Double-patterning technology is typically used only for the finest, densest, lowest-level interconnection layers such as M1, VIA1, and M2 layers.

The assignment of adjacent geometries to one mask or the other is called "coloring" and each geometry assigned to a mask is said to have "color" such as mask_one or mask_two. In the cell library, the **mask_constraint** attribute specifies the coloring of each shape in the library cell.

Two shapes of different colors are allowed to be closer to each other than two shapes of the same color. When the spacing between two shapes of the same color is small enough to violate the same-color spacing requirement (but not the different-color spacing requirement), it is called a color violation.

In a "correct-by-construction" standard cell library, the double-patterning shapes are far enough inside the cell boundary to prevent color violations from occurring, even when two cells are placed edge-to-edge. In that case, the tool performs placement and legalization without considering the coloring inside the cells.

On the other hand, for a "precolored" standard cell library, colored shapes are close enough to the cell boundary that color violations can occur between shapes of the same color in two different cells, if the cells are placed edge-to-edge. The placer or legalizer can fix such violations by moving the cells apart in the row, leaving a gap; or possibly by flipping one of the cells in place.

Another way to fix a color violation is to swap the color assignments in the cell instance, without moving or flipping the cell. To do this, the placer sets a cell attribute called mask_shift at the instance level. This attribute is a text string that specifies whether to swap the color assignments within each layer.

For example, when a cell's mask_shift attribute is set to the following string, it swaps the coloring assignments of the shapes in the M1 layer, but not in the VIA1 and M2 layers:

{{M1 1} {VIA1 0} {M2 0}}

Based on the mask_shift attribute setting, the **write_gds** command performs color modification of each cell during stream-out to GDSII format. In this example, the **write_gds** command swaps the coloring assignments in layer M1. For that layer only, it writes out the shapes with the mask_one attribute to the mask_two mask, and conversely, writes out the shapes with the mask_two attribute to the mask_one mask.

The **write_gds** command carries out the modification by writing out an instance of a new master cell master having the switched mask assignments. In effect, the command copies the original cell, modifies the mask assignments as specified by the mask_shift attribute, creates a new master cell having the switched masks, and writes out one or more instances of the new cell.

The **write_gds** command creates a name for the new cell master by joining the following items with underscore characters:

The original cell master name
The suffix string set by the -mask_shifted_suffix option ("SHIFT" by default)
The layer number of first swapped layer
The number 1, indicating the amount to shift the mask for the layer
The layer number of next swapped layer
The number 1, indicating the amount to shift the mask for the layer
...

For example, suppose that the name of the original cell master is INV1, the default suffix string "SHIFT" is being used, and the mask_shift attribute of an INV1 cell instance is set as follows:

{{M1 1} {VIA1 0} {M2 1}}

In that case, the swap occurs in layer M1 (layer 15) and in layer M2 (layer number 17), so the name of the newly generated cell master is "INV1_SHIFT_15_1_17_1".

The tool does not add the new reference cell to the database. It only streams out the new reference cell to the GDSII file.

EXAMPLES

The following command writes out the current block as a GDSII stream file named myDesign.gds:

```
prompt> write_gds -units 1000 myDesign.gds
```

The following command writes out the block myLib:BlockA.design as a GDSII stream file named myBlockA.gds, using a database unit size of 1 nanometer:

```
prompt> write_gds -library myLib -design BlockA -units 1000 myBlockA.gds
```

The following command writes out the current block as a GDSII stream file using a layer mapping file to modify the layers and datatypes, a block mapping file that specifies some blocks to skip, and a cell renaming file to rename some of the blocks before writing:

```
prompt> write_gds -layer_map myLayerMap -block_map myBlockMap \
  -rename_cell myRenamingFile myDesign.gds
```

The following command writes out the current block as a GDSII stream file, including only layers M1, V1, M2, V2, and M3:

```
prompt> write_gds -layers {M1 V1 M2 V2 M3} myDesign.gds
```

write_io_constraints

Writes signal I/O constraints based on IO placement results to the specified file.

SYNTAX

status **write_io_constraints**
-filename *file_name*
[-format order_only | spacing | pitch | fixed]
[-block]

Data Types

file_name string

ARGUMENTS

-filename *file_name*

Specifies the name of the file to use to write the I/O constraints.

-format order_only | spacing | pitch | fixed

Specifies the I/O constraint format. The default is **order_only**. The **order_only** argument writes only pad order information to the file. The **spacing** argument writes the spacing values between pads and the pad cell names to the file. The **pitch** argument, writes pad cell locations by using cell pitch instead of spacing values. All pad cells must be placed evenly in the IO guide before using the **pitch** argument. The **fixed** argument specifies that all pads cell are fixed at their current locations. The default is **order_only**.

-block

Writes out I/O constraints with respect to the reference blocks in the design. By default, I/O constraints are written from the top level with the hierarchical path to the I/O pad cell.

DESCRIPTION

This command generates signal I/O constraints based on the current IO pad placement. Only pad cells that are legally placed within IO guides are considered. The legal placement is defined as pads that are aligned with IO guides and are in the correct orientation. Pads placed illegally are not included in the constraint file.

The **-filename** option is required. If the **-format** option is not specified, this command generates result by using the **-format order_only** format.

EXAMPLES

The following example writes the IO placement result to the file named io_constraint_file.

```
prompt> write_io_constraints -filename io_constraint_file
```

SEE ALSO

place_io(2)
set_signal_io_constraints(2)

write_ivm

Reads via variation file(.ivm) for current desgin.

SYNTAX

status **write_ivm**
file_name
[-corners *corners*]

Data Types

file_name string
corners list

ARGUMENTS

file_name

Specifies the via variation file name to write.

-corners *corners*

Specifies the list of corners for which to apply the extraction options. If corners are not specified then the ivm file will be applied to all corners.

DESCRIPTION

This command writes .ivm file for via variation analysis for the current design.

EXAMPLES

The following example writes new.ivm file for specified two corners.

prompt> **write_ivm new.ivm -corners {FuncMode_max.SS.081v.125c_FuncCmax.corner FuncMode_min.FF.099v.125c_Func(**

SEE ALSO

report_ivm(2)
remove_ivm(2)

write_parasitics(2)

write_lef

Writes out the data from a library in LEF format.

SYNTAX

string **write_lef**
[-library *library*]
[-design *design*]
[-include *include_list*]
[-properties *property_list*]
[-slice_polygon]
[-write_additional_viarule]
[-version *version_number*]
lef_file_name

Data Types

library	string
design	string
include_list	list
property_list	list
lef_file_name	string
version_number	string

ARGUMENTS

-library *library*

Specifies the library. The default is the current library. This option is mutual exclusive with **-design**.

-design *design*

Specifies the design from which the LEF file will be written. If it has a frame view, it will be written. Otherwise, if it has a design view, all reference designs instanced in it as frame view will be written. This option is mutual exclusive with **-library**.

-include *include_list*

Specifies which sections to include in the LEF output file. By default, all sections are included. The valid settings are:

- **cell**: includes the version, bus bit characters, divider character, macros, and extensions sections
- **tech**: includes all sections except for macros

-properties *property_list*

Specifies which PROPERTY statements to write. Only the properties in the specified list are written; all others are omitted. By

default, all properties are written.

-slice_polygon

Slices the polygons into rectangles for output to the LEF file.

-write_additional_viarule

Specifies the option to write simple via_def as VIARULE.

-version *version_number*

Specifies the version number for the output LEF file. Valid values are 5.6, 5.7 or 5.8. The default is 5.8.

lef_file_name

Specifies the name of the LEF file to be written. If this file already exists, it is overwritten.

DESCRIPTION

This command writes out the data from a library in Library Exchange Format (LEF). By default, the command writes out both the technology information and library cell information.

You can optionally restrict the output to only cell information or only technology information by using the **-include** option. To restrict the types of properties written, use the **-properties** option. To slice polygons into rectangles, use the **-slice_polygon** option.

EXAMPLES

The following example writes a LEF file for library lib_A, including both the technology and library cell information:

```
prompt> write_lef -library lib_A lib_A.lef
```

The following example writes a LEF file from design routed:

```
prompt> write_lef -design design design.lef
```

SEE ALSO

read_lef(2)
read_tech_lef(2)

write_lib_package

Stores a library, its reference libraries, and current application option settings into a package file.

SYNTAX

status **write_lib_package**
[-library *library*]
[-blocks *blocks*]
[-exclude_ref_libs *ref_libs*]
[-exclude_design_view *ref_libs*]
[-verbose]
[-include_all_blocks]
[-include_view *views*]
[-exclude_view *views*]
[-include_label *labels*]
[-exclude_label *labels*]
[-auto_saved_data include | exclude]
[-exclude_dir_path]
file_name

Data Types

library collection
blocks collection
ref_libs collection
file_name string
include_view collection
exclude_view collection
include_label collection
exclude_label collection

ARGUMENTS

-library *library*

The library to store as a package. This can either be a name or a collection of a single library. The default is the current library.

-blocks *blocks*

The collection of blocks to be packed; all other blocks are excluded from the library package.

-include_all_blocks

If this option is used, all blocks in the library are included in the library package. This option is mutually exclusive to **-blocks** option.

-include_view *views*

The views provided with include_view option will be packed in the library package. This option is mutually exclusive to **-include_all_blocks**.

-exclude_view *views*

The views provided with exclude_view option will not be packed in the library package.

-include_label *labels*

The labels provided with include_label option will be packed in the library package. This option is mutually exclusive to **-include_all_blocks**.

-exclude_label *labels*

The labels provided with exclude_label options will not be packed in the library package.

-exclude_ref_libs *ref_libs*

Excludes the specified reference libraries from the library package; only the specified design library (or current library) is included in the package.

Without this option, the **write_lib_package** command includes the reference libraries of the specified (or current) library in the package, and the **read_lib_package** command restores the reference libraries to a new location under the directory of the restored design library.

-exclude_design_view *ref_libs*

Excludes the design views of all the lib_cells from the specified reference libraries. This option does not apply to hierarchical-sub-design design libraries.

-verbose

Reports the command progress and the application options being saved in the package.

-auto_saved_data include | exclude

Specifies whether to include or exclude auto_saved data of the library in the lib_package. By default, auto-saved data will be included.

-exclude_dir_path

If this option is used, all the local directory paths in app-options, ref_libs will be removed before packing.

file_name

The name of the file in which to store the library package.

DESCRIPTION

This command stores a design library, its linked reference libraries, the current application option settings, and the current Tcl variable settings into a library package file.

You can later unpack the file into a self-contained library and restore the tool settings by using the **read_lib_package** command. By default, the reference libraries are restored to a subdirectory below the restored library directory.

To store the design library and exclude one or more reference libraries from the library package file, use the **-exclude_ref_libs**

option of the **write_lib_package** command.

By default, lib_package will be compressed. To disable compression of lib_package, set the app_option **lib.setting.compress_lib_package** to false.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example the packs the current library and its reference libraries into a single file, mylib.pkg.

```
prompt> write_lib_package mylib.pkg
1
```

The following example packs the library named "mylib" into a single file, mylib.pkg. The **-verbose** option reports the progress of the command and the application options and Tcl variables being saved.

```
prompt> write_lib_package -library mylib -verbose mylib.pkg
Packing library mylib...
 App Options
 ...
 Tcl Variables
 ...
Packed 10 app options and 30 tcl variables
Library mylib packed successfully
1
```

The following example packs a specified library into a single file, mylib.pkg. The library is specified as a collection. The library package includes only the "MID" and "BOT" blocks and excludes all reference libraries.

```
prompt> write_lib_package -library [get_libs libA] \
  -blocks [get_blocks {MID BOT}] -exclude_ref_libs * mylib.pkg
1
```

read_lib_package(2)
lib.setting.compress_lib_package(3)

write_macro_relative_location

Writes the previously set constraints which place hard macros or macro array relative to anchor objects to file

SYNTAX

status **write_macro_relative_location**
[*target_list*]
[-file *file_name*]
[-hierarchical]

Data Types

target_list list
file_name string

ARGUMENTS

target_list

Specifies the list of hard macros or macro arrays on which to write relative location constraints to file. By default is writing constraints on all hard macros and macro arrays.

-file *file_name*

The file name of macro relative location constraints output. The default is macro_relative_location_constraints.tcl

-hierarchical

This option supports MPH designs to write out macro relative location constraints for hard macros hierarchically.

DESCRIPTION

This command writes hard macro or macro array relative location constraints set by the **set_macro_relative_location** command to file.

EXAMPLES

The following command writes the relative location constraint to file A.tcl.

```
prompt> write_macro_relative_location -file A.tcl
```

SEE ALSO

set_macro_relative_location(2)
remove_macro_relative_location(2)
report_macro_relative_location(2)
derive_macro_relative_location(2)
create_placement(2)
create_macro_relative_location_placement(2)

write_matching_types

Writes out existing assignment of bumps and flip_chip_drivers or user-specified matching types.

SYNTAX

status **write_matching_types**
-file_name *file_name_string*
[-from_existing_assignment]

Data Types

file_name_string string

ARGUMENTS

-file_name *file_name_string*

Specifies the name of the output file with *file_name_string*. This option is required.

-from_existing_assignment

Writes out existing assignment of bumps and flip_chip_drivers, which is the bump assignment results of the **place_io** command. If this option is not specified, the command writes out user-specified matching types.

DESCRIPTION

This command writes out the existing assignment of bumps and flip_chip_drivers, or user-specified matching type assignments, to an output file. Use the output of this command to capture the current assignments; modify and reload the output assignment file as needed.

If you do not specify the **-from_existing_assignment** option, user-defined matching types will retain the names that were assigned by the user.

If you specify the **-from_existing_assignment** option:

a. If only one assignment-based matching type is associated with one user-defined matching type, the new matching type will be named $USER_MATCH_NAME_assignBased, where $USER_MATCH_NAME is the name specified by you and _assignBased is a suffix string.

b. If multiple assignment based matching types are associated with a user matching type, the new matching types will be named $USER_MATCH_NAME_assignBased_$index, where $index is a integer starting from 0.

c. If the assignment-based matching type is not associated with any user matching type, its name will be existing_assignment_$index, where index is a integer starting from 0.

The file name is a required option and can be customized with the **-file_name file_name_string** option.

EXAMPLES

The following example writes out existing assignment to a file named matching_types.tcl.

```
prompt> write_matching_types -file_name matching_types.tcl -from_existing_assignment
```

write_name_map

Writes a name map file from the current design.

SYNTAX

string **write_name_map**
name_map_file

Data Types

name_map_file string

ARGUMENTS

name_map_file

Specifies the name of the output name map file. If the file already exists, it is overwritten.

DESCRIPTION

This command writes the name map data from the current block to the specified name map file.

Name map data is loaded into the design using the **read_name_map** command. Note that this data is not automatically modified by netlist editing commands. So this **write_name_map** command can only write out what was originally loaded by the **read_name_map** command.

EXAMPLES

The following example writes a name map file:

prompt> **write_name_map top.nmf**

SEE ALSO

read_name_map(2)

write_net_estimation_rules

Writes a Tcl script that can be used to re-create the net estimation rules.

SYNTAX

int **write_net_estimation_rules**
[-script *script_name*]
[-format tcl | xml]
[-net_estimation_rule *pattern*]
[-cell *cell*]
[-as_cell *cell_name*]
[-include_cell \inc_type]
[rules]

Data Types

script_name string
pattern string
cell collection
cell_name string
inc_type true | false | auto (default)

ARGUMENTS

-script *script_name*

Specifies the name of the script to write. If no script is specified, then the script will be named net_estimation_rules.tcl

-format tcl | xml

Specifies the format of the output script. Valid values are *tcl* or *xml*. The *tcl* format writes a Tcl script that can be sourced by the tool. The *xml* format writes an XML document that can be loaded with the **read_net_estimation_rules** command. If not specified, the default format is *tcl*.

-net_estimation_rule *pattern*

Specifies the net estimation rule to write out.

-cell *cell*

Specifies the physical cell from which to write the net estimation rule.

By default, the current block is searched for the specified net estimation rule(s)..

-as_cell *string*

Specifies the physical cell name to write into the script using -cell. This allows for a quick "copy" of rules from one cell to another. It can take rules from one cell and write them as if they belonged to another. This script can then be read (XML) or sourced (TCL) to put those rules into the new cell.

-include_cell *inc_type*

auto - only include "cell" attribute in script if rule is not in "top" true - always include "cell" attribute in script file false - never include "cell" attribute in script file

rules

Specifies the name of a net estimation rule or rules to report. Net estimation rules are defined with the **set_net_estimation_rule** command. If no rule is specified, then all the rules are written.

DESCRIPTION

This command writes a script that contains rules created with the **set_net_estimation_rule** command.

NET ESTIMATION RULES AND HIERARCHY

Net estimation rules can be created in any physical block at any level of the hierarchy and multiple blocks can have different rules with the same name. However, rules are often stored/retrieved by name, and doing this can cause confusion as to which rule is being used by a given command. Generally, the "current" (top) block's list of rules is searched by commands such as *estimate_timing*. This means that if you define rule R1 in "top" and rule R1 in block "B1", if you make block B1 the current block, commands will use B1's R1. When you go back to top, top's R1 is used. To avoid confusion, use globally unique rule names and define them at the top - they will be propagated to child blocks during distributed commands as necessary. Rules in child blocks that have the same name as rules in top may also be overwritten during distributed commands.

EXAMPLES

The following example creates one non-default rule and write out the script.

```
prompt> set_net_estimation_rule -parameter register_spacing -value 20 myrule
prompt> write_net_estimation_rules
(info) 1 net estimation rules written.
1
```

The following example creates one non-default rule and writes out the rule as an XML document. The output file name is rules.xml.

```
prompt> set_net_estimation_rule -parameter register_spacing -value 20 myrule
prompt> write_net_estimation_rules -script rules.xml -format xml
(info) 1 net estimation rules written.
1
```

The following examples writes rules from cell TOP_CELL/B1 and saves them to an XML file using the "cell" attribute of TOP_CELL/C1.

```
prompt> write_net_estimation_rules -script rules.xml -cell TOP_CELL/B1 -as_cell TOP_CELL/C1 -format xml (info) 1 net estimation rules written.
```

output_file

Data Types

delimiters string
name string
design_name string
layer_map_file_name string
block_map_file_name string
units_per_micron integer
net_property_value integer
instance_property_value integer
pin_property_value integer
via_property_value integer
compression_level integer
report_file_name string
verbose_report_file_name string
layer_collection collection
suffix_string string
layers collection
merge_files string
top_cell string
cell_renaming_file string
views string
output_file string
cell_type_list list
depth integer

ARGUMENTS

-bus_delimiters *delimiters*

Specifies the bus delimiters to be used in port, pin, and net names to denote bus subscripts. Valid values are "[]", "{}", "()", and "<>".

-library *name*

Specifies the name of the source library. The default is the current library.

-design *design_name*

Specifies the name of the top design (block) to be written as an OASIS stream. The default is the current block.

-view frame | **abstract** | **timing** | **layout** | **design**

Specifies the name of the view to be written. The default is the **design** view.

-lib_cell_view frame | **layout** | **design**

Specifies the name of the view used for writing leaf-level reference library cells to the OASIS file. If the user-specified view is not available for a particular reference library cell, the command skips writing the library cell definition. The default is **layout**.

-fill include | exclude | fill_only

Writes or omits fill data according to the specified mode:

- **include**: Writes all geometries, including fill data (default)
- **exclude**: Omits all fill data
- **fill_only**: Writes only the fill data

-layer_map *layer_map_file_name*

Specifies a layer mapping file that customizes the translation of layer, data type, and purpose between the tool's data model and the OASIS file. For details, see "Layer Mapping File" in the DESCRIPTION section.

-layer_map_format icc2 | icc_default | icc_extended

Specifies the format of the layer mapping file. This option allows the command to accept an IC Compiler layer mapping file. These are the allowed settings:

- **icc_default**: IC Compiler default layer mode, system layers 188-255
- **icc_extended**: IC Compiler extended layer mode, system layers 4001-4095
- **icc2**: IC Compiler II layer mapping file format (default)

-block_map *block_map_file_name*

Specifies the name of a block mapping file, a text file containing a list of blocks to ignore (not write out), in the following format:

```
; This is a block mapping file
 myBlockA:ignore     ; ignores myBlockA
 myBlockB:ignore     ; ignores myBlockB
```

-hierarchy top | design | design_lib | all_design_libs | all

Specifies the parts of the design hierarchy to write out:

- **top**: Writes only the top module in the design, excluding the contents of lower-level modules of the netlist.
- **design**: Writes the design, including lower-level submodules (soft macros), stopping at the design boundary.
- **design_lib**: Writes the design, stopping at its design library boundary.
- **all_design_libs**: Writes the designs in all design libraries but excluding the reference libraries; stops at all design library boundaries.
- **all**: Writes the entire design, including modules in reference libraries.

The default is "*design_lib*".

-units *units_per_micron*

Specifies the resolution to use for writing the OASIS data, expressed as the number of units per micron. The default is 10000 (Angstrom units, 1e-10 m).

-net_property *net_property_value*

Writes out net names as a property attribute with the given attribute number in the OASIS stream. A property attribute number is an integer from 0 to 127. By default, no net property attribute is written.

-instance_property ***instance_property_value***

Writes out instance names as a property attribute with the given attribute number in the OASIS stream. By default, no instance property attribute is written.

-pin_property ***pin_property_value***

Writes out pin names as a property attribute with the given attribute number in the OASIS stream. By default, no pin property attribute is written.

-via_property ***via_property_value***

Generates the via and via matrix property with the specified attribute number in the OASIS stream. By default, no via or via matrix property is written into OASIS file.

-keep_data_type

Keeps the data type for each object as defined in the database. By default, the command converts the data type to 0.

When the **-layer_map** option is used, the layer data type specified in the layer mapping file overrides the data type in the database, and the **-keep_data_type** option setting is ignored. For objects on layers not defined in the layer mapping file, the **-keep_data_type** option still applies.

-compress ***compression_level***

Writes out the OASIS file in compressed format to save disk space, using the specified compression level, an integer from 1 to 9. Using a higher number results in greater compression (a smaller file) but slower saving and reading. Using a value of 6 results in a good trade-off between compression and speed. By default, the output is not compressed.

-output_pin text | **geometry** | **all** | **none**

Specifies the manner in which pin objects are written into the OASIS file. Allowed values are:

- "**text**": Writes the name of each pin as a TEXT object associated with the pin.
- "**geometry**": Writes the geometry of each pin as a POLYGON or BOUNDARY object associated with the pin.
- "**all**": Writes both the text and geometry of each pin.
- "**none**": Prevents the writing of pin data.

The default is "*all*"

-output_net_text

Writes out TEXT objects for net shapes. By default, no TEXT objects are written out for net shapes.

-net_text_on all_shapes_and_vias | **all_shapes** | **each_layer** | **single_shape**

Writes or omits net text according to the specified mode:

- **all_shapes_and_vias**: Writes net text on all shapes and vias per net
- **all_shapes**: Writes net text on all shapes (excluding via shapes) per net
- **each_layer**: Writes net text on one shape per layer (excluding via layers) per net
- **single_shape**: Writes net text on one shape per net (default)

  This option require **-output_net_text** to be specified.

-flat_vias

Flattens via shapes when writing the OASIS file. By default, vias are written as instances of via masters and are not flattened.

When **-output_net_text** is on and **-net_text_on** is all_shapes_and_vias with this option, the valid text is outputted once, otherwise the text isn't outputted.

-report_cell_source ***report_file_name***

Specifies the name of the summary report file in which the physical data of a top-level design is written corresponding to GDSII stream file in plain ascii format. By default, this option writes out the design view of the current block in the current library.For available data, it reports for all the unique libraries used to export cells and all instances which gives user a capability to validate that the exported data come from the right versions of the instantiations be it std cells,IP and blocks. It will write five columns:

- **Path**: The source path or reference location of every reported ndmInstance.
- **Type**: The type of instance whether it is macro_cell,lib_cell,std_cell etc.
- **Reference Name**: The name of the Reference design of that instance.
- **Instance Name**: The name of ndmInst.
- **Physical Hierarchy**: The reference module is present in which all other physical blocks.

-verbose_report_cell_source ***verbose_report_file_name***

Specifies the name of the summary report file.It will report same data as in report_cell_source option but for available data,it reports for all libraries and all instances which are exported from them.

-foreign

Uses the LEF foreign cell name as the structure name and instance name. By default, the command ignores the LEF FOREIGN statements and uses the original cell name.

-ignore_cut_datatype_tbl_mapping

Ignores the mapping of datatype, based on the via dimensions, from the cutDataTypeTbl entry in the technology file. By default, the command writes cuts of different sizes as different data types as defined by the cut data table in the technology file.

-propagate_pin_mask_to_via_metal

Propagates the double-patterning mask property of each metal1 pin shape, as specified by the pin shape's mask_constraint attribute, to the corresponding metal1 layer of a via dropped on the pin. This modifies the lower_mask_constraint attribute setting of the via from no_mask to match the attribute setting on the pin shape. (An existing setting other than no_mask is not modified).

This option affects only the data written to the OASIS file, not the vias stored in the database.

-write_default_layers ***layer_collection***

Specifies the layers for which the geometry and text information corresponding to a color-mask configuration is written into the default base. When this option is used with layer-mapping information for the color-masks, all the geometry and text information corresponding to the layers in the input collection are written twice: first into the layer-datatype pair obtained from the layer-map by considering the color-mask configuration, and then again without considering the color-mask configuration.

-mask_shifted_suffix ***suffix_string***

Specifies the suffix string used to generate cell master names when the tool performs double-patterning mask swapping. For details, see "Double-Patterning Cell-Level Mask Swapping" in the DESCRIPTION section. This option is mutually exclusive with the **-mask_shifted_suffix_without_constraint** option.

-mask_shifted_suffix_without_constraint ***suffix_string***

Specifies the suffix string used to generate cell master names when the tool performs double-patterning mask swapping. This option differs from the *mask_shifted_suffix* option because the instance-specific mask information is not added to the cell master

names. For details, see "Double-Patterning Cell-Level Mask Swapping" in the DESCRIPTION section.

-use_block_name

Uses the block name (and user label, if any) instead of the module name for the top structure in the OASIS file. By default, the name used for each structure name is the module name in the data model. In cases where the module name and block name for the top module are different, this option causes the block name to be used; if the block has a user label, the resulting name is *block-name_user-label*.

-layers *layers*

Writes only the specified layers of the technology; all other layers are excluded. By default, the command writes all layers to the OASIS file.

-write_instance_shape_mask

Writes instance-specific shape masks to the OASIS file as overlapping shapes in the parent structure. For a lib cell instance, the shape mask in bound view will be output, if the value specified by "-lib_cell_view" is different from its bound view. By default, instance-specific shape masks are not written.

-write_instance_via_mask

Writes instance-specific via masks to the OASIS file as overlapping shapes in the parent structure. For a lib cell instance, the via mask in bound view will be output, if the value specified by "-lib_cell_view" is different from its bound view. By default, instance-specific via masks are not written.

-connect_below_cut_metal

Generates metal layers below the cut metal. For generating metal, it is assumed that two pieces of metal of same size and mask color abut with the cut metal. By default, this action is not performed.

-force

Writes out the OASIS file, even if the design or library has mismatches; by default, the command issues an error message and stops. This option is deprecated in favor of the **-allow_design_mismatch** option.

-merge_files *merge_files*

Specifies the names of the input stream files to be merged. You can specify both GDSII and OASIS files as input that are to be merged with the newly generated OASIS stream. The command first merges the specified OASIS files into an intermediate OASIS file. Then it merges the newly generated OASIS stream with this intermediate file to produce the final OASIS file.

-merge_conflict_suffix *suffix_string*

Specifies the suffix string to be used to generate new names for resolving merge conflicts that occur with the **-merge_files** option.

-merge_oasis_top_cell *top_cell*

Specifies the top cell to be considered for the merge flow. When this option is specified only the cells in it's hierarchy are considered for merge operation. All remaining cells are removed from the resultant OASIS file.

-merge_cell_shapes

Specifies that the shapes from identically named cells in different source files are to be merged into a single cell in the output file.

-merge_overwrite_conflicting_cell

Writes out the last conflicting cell, only if there are conflicting cells in OASIS files to be merged.

-rename_cell *cell_renaming_file*

Specifies a file that contains the mapping from original cell names to new cell names. The renaming works for both reference

library cells and design blocks. Each line in the file specifies the name mapping for a cell:

OldCellName NewCellName

For example, to map TOP to NEWTOP, enter the following line into the file:

TOP NEWTOP

If only mask shifted cell needs to be renamed, comments with keywords "mask shifted" and "end" need to be added to start and end lines. For example, to map mask shifted cell A to ASHIFT, enter the following lines into the file:

```
; mask shifted cell mapping
A  ASHIFT
; end mask shifted cell mapping
```

By default, the original cell names are written.

-write_instance_blockage_mask

Writes instance-specific blockage masks to the OASIS file as overlapping shapes in the parent structure. By default, instance-specific blockage masks are not written.

-write_instance_mask_on_layers *layers*

Writes instance-specific mask to the OASIS file on the specified layers only. By default, it is enabled for all the layers.

-allow_design_mismatch

Writes out the OASIS file, even if the design or library has mismatches; by default, the command issues an error message and stops. T

-no_marker_layers

Doesnot generates the marker layer data.

-switch_view_list

Specifies the reference block views for hierarchical block instances to be opened. The view at the head of the list is in higher priority.

-cell_types *cell_type_list*

Writes out only the specified types of cells. By default, the **write_oasis** command writes out all types of cells. There are the cell types that you can specify in the *cell_type_list*:

```
lib_cell
macro
corner
cover
end_cap
filler
flip_chip_driver
flip_chip_pad
pad
pad_spacer
tsv
vib
well_tap
```

If you use the **-child_depth** option, the **write_oasis** command writes out only the types of cells specified by the **-cell_types** option at the current block and their children (including all types of cells in the children) through the specified child depth. It does not

write out any other types of cells at the current block nor any of their children.

-child_depth

Specifies the maximum hierarchical block depth to be output. The default value is to output all hierarchical blocks in the hierarchical scope specified by option "-hierarchy". The hierarchical depth is 0 for top block, the depth is increased 1 for child blocks to which instances referred in current block.

-verbose

Prints the details of the hierarchical blocks to be output, and warning messages for those which reference design and view cannot be found

output_file

Specifies the name of the output OASIS file.

DESCRIPTION

This command writes out the physical data of a top-level design in as an OASIS (Open Artwork System Interchange Standard) stream file for tapeout or for export to third-party tools. By default, the command writes out the design view of the current block in the current library and maintains the original layer numbers as it converts the data to OASIS format.

The command offers the following options:

- The name of the library, design, and view to be written out
- The mapping of database layers to OASIS layers
- The mapping of net, instance, and pin names in the conversion to OASIS format
- The manner of writing out pin objects (text or geometry)
- The handling of mask-shifted multiple-patterning data
- The layers, hierarchical blocks, and fill data to be included in the OASIS output
- The merging of design data with existing OASIS files

To locate files that have relative pathnames, the command uses the **search_path** variable and searches for each file in each directory listed in the **search_path**. Files that have absolute pathnames are loaded as though there were no **search_path**. To determine the file that **write_oasis** loads, use the **which** command.

Layer Mapping File

By default, the **write_oasis** command maintains the original layer numbers of the database when it writes out the OASIS file.

When there is explicit mapping of system purpose (-1, -2, -3 and -4) in layer mapping file, the tool will use that mapping; for example, with the mapping "all 32:-1 32:55", the tool maps database layer "32:-1" to oasis layer 32:55; if no mapping for these system purposes, the tool will follow the mapping of the purpose 0 of the same layer. For example, if the mapping has "all 32:0 32:70", system purpose "-1" will be mapped to oasis layer 32:70. Please note that oasis datatype can't be any data less than 0, the usage like "all 32:-1 132:-1" is invalid for oasis language, and the datatype will be taken as 0 like "A 32:-1 132 0"

You can optionally provide a layer mapping file to specify the mapping of layers and data types between the database and the OASIS layers. You can use the same mapping file for both the **write_oasis** and **read_oasis** commands. This is the mapping file format:

```
; single line comment
[read_always { true | false [-mapped_only | -ignore_missing_layers ] } ]
[blockage_as_zero_spacing {true|false}]
[cell_prop_attribute attribute_number]
[net_prop_attribute  attribute_number]
[pin_prop_attribute  attribute_number]
[via_prop_attribute  attribute_number]
[object_type] tool_layer_number[:tool_purpose][:use_type][:mask_type] \
  oasis_layer_num[:oasis_data_type]
```

For example,

```
; This is my layer mapping file
                ;
    84      92    ; ICC2 layer 84 = OASIS layer 92
                ;
    59      69:3  ; ICC2 layer 59 = OASIS layer 69, data type 3
                ;
    17:1    117:3  ; ICC2 layer 17, purpose 1 = OASIS layer 117, data type 3
                ;
data 33:0:*:*  1:2  ; ICC2 data on layer 33, purpose 0, any use type,
                ;  any mask type = OASIS layer 1, data type 2
text 33:0:*:*  1:4  ; ICC2 text on layer 33, purpose 0, any use type,
                ;  any mask type = OASIS layer 1, data type 4
                ;
; all other layers and data types match between ICC2 and OASIS
```

In each line, any text after a semicolon "*;*" is a comment.

The **read_always** statement determines how the **read_oasis** command handles differences between OASIS layers and database layers. The **blockage_as_zero_spacing** statement determines how the **read_oasis** command interprets OASIS blockage layers, as either zero-spacing or design-rule-spacing guides. For details, see the man page for the **read_oasis** command.

The **cell_prop_attribute**, **net_prop_attribute**, **pin_prop_attribute**, and **via_prop_attribute** statements specify the property attribute numbers used for storing cell instance, net, pin names, and via attribute in the OASIS file. The specified value for the properties should be distinct. For example, the statement "net_prop_attribute 5" causes the **write_oasis** command to write out net names of objects as property attribute 5 in the OASIS file. These statements in the layer mapping file have higher priority than the corresponding **write_oasis** command options, **-instance_property**, **-net_property**, **-pin_property**, and **-via_property**.

After you write an OASIS file with these properties, when you read the file back into the tool with the **read_oasis** command, the original cell names are restored, and the pins and nets are properly identified without the tool spending time on connectivity tracing.

Each field of the layer mapping line is separated by a colon "**:**". Each field can be an explicit value, an asterisk "*" wildcard character, or left blank. An asterisk or black space indicates any value.

A more specific rule priority than a more general rule. For example, the rule "5:3 8", has higher priority than "5 7". If conflicting rules are specified in different lines (for example, first "6:2 4" and then "6:2 7"), the last one in the file is used and the earlier one is ignored.

The optional *object_type* keyword at the beginning of a layer mapping line restricts the mapping rule to only the specified object types:

- **data**: Mapping applies only to non-text objects
- **text**: Mapping applies only to text objects
- **all**: Mapping applies to both text and non-text objects (default)

tool_layer_number is the layer number in the database, an integer.

tool_purpose is the purpose number in the database, an integer.

use_type is the usage type in the database, which is one of the following.
"route_guide,single_row_via_ladder_pattern_must_join_allowed" requires the relative "tool_layer_number" is any layer number(*), and the format of the layer mapping file is specified as icc_default with -layer_map_format option.
"instance_specific_mask" is to copy the instance-specific mask constraints data (via cut-shapes, shapes, and blockages) to a layer, it is effective when at least one of three options(-write_instance_via_mask, -write_instance_shape_mask and -write_instance_blockage_mask) is specified. Please note, this is "copy" operation, which means the instance specific mask will be written onto original layer still at the same time. By default "power" is to map all power data. "power,net", "power,port", "power, pin" are to distinguish net, port, pin respectively. The same rules apply to "ground", "clock", "signal" and their corresponding net, port, pin use_types. "same_net_feedthrough_tsv" can be used to create special marking layers in GDS for qualified TSV. Any shape whose mask_name is 'tsv' in design database is duplicated as a marking layer shape in GDS when "same_net_feedthrough_tsv" is defined in the layer map. The qualified TSV should have a pin. This pin should have a net. The net should have ports of shapes with layer mask_names on backside and front-side both. "hi_voltage" is to index write_gds to output net voltage_range_max as a text. "lo_voltage" is to index write_gds to output net voltage_range_min as a text. The net can be signal, clock, power or ground.

mask_type is the mask type of the shape in a multiple-patterning technology. For a metal layer, the following mask types are supported:

mask_one
mask_two
mask_three
same_mask

For a VIA cut layer, the following additional mask types are supported:

MASK_FOUR
MASK_FIVE
MASK_SIX
...
MASK_FIFTEEN

oasis_layer_num is the layer number of the geometry or TEXT in the OASIS file, an integer.

oasis_data_type is the data type number of the geometry or TEXT in the OASIS file, an integer.

Double-Patterning Cell-Level Mask Swapping

In a double-patterning technology, a layer is decomposed into two different masks, with physically adjacent geometries assigned alternately to the two masks. The physical layer is fabricated on the chip using two separate photolithography steps, minimizing optical proximity degradation between adjacent geometries. Double-patterning technology is typically used only for the finest, densest, lowest-level interconnection layers such as M1, VIA1, and M2 layers.

The assignment of adjacent geometries to one mask or the other is called *coloring* and each geometry assigned to a mask is said to have a *color*, such as **mask_one** or **mask_two**. In the database, the **mask_constraint** attribute specifies the coloring of each shape in the library cell.

Two shapes of different colors are allowed to be closer to each other than two shapes of the same color. When the spacing between two shapes of the same color is small enough to violate the same-color spacing requirement (but not the different-color spacing requirement), it is called a color violation.

In a "correct-by-construction" standard cell library, the double-patterning shapes are far enough inside the cell boundary to prevent color violations from occurring, even when two cells are placed edge-to-edge. In that case, the tool performs placement and legalization without considering the coloring inside the cells.

On the other hand, for a "precolored" standard cell library, colored shapes are close enough to the cell boundary that color violations can occur between shapes of the same color in two different cells, if the cells are placed edge-to-edge. The placer or legalizer can fix such violations by moving the cells apart in the row, leaving a gap; or possibly by flipping one of the cells in place.

Another way to fix a color violation is to swap the color assignments in the cell instance, without moving or flipping the cell. To do this, the placer sets a cell attribute called mask_shift at the instance level. This attribute is a text string that specifies whether to swap the color assignments within each layer.

For example, when a cell's mask_shift attribute is set to the following string, it swaps the coloring assignments of the shapes in the M1 layer, but not in the VIA1 and M2 layers:

{{M1 1} {VIA1 0} {M2 0}}

Based on the mask_shift attribute setting, the **write_oasis** command performs color modification of each cell during stream-out to OASIS format. In this example, the **write_oasis** command swaps the coloring assignments in layer M1. For that layer only, it writes out the shapes with the mask_one attribute to the mask_two mask, and conversely, writes out the shapes with the mask_two attribute to the mask_one mask.

The **write_oasis** command carries out the modification by writing out an instance of a new master cell master having the switched mask assignments. In effect, the command copies the original cell, modifies the mask assignments as specified by the mask_shift attribute, creates a new master cell having the switched masks, and writes out one or more instances of the new cell.

The **write_oasis** command creates a name for the new cell master by joining the following items with underscore characters:

The original cell master name
The suffix string set by the -mask_shifted_suffix option ("SHIFT" by default)
The layer number of first swapped layer
The number 1, indicating the amount to shift the mask for the layer
The layer number of next swapped layer

The number 1, indicating the amount to shift the mask for the layer
...

For example, suppose that the name of the original cell master is INV1, the default suffix string "SHIFT" is being used, and the mask_shift attribute of an INV1 cell instance is set as follows:

{{M1 1} {VIA1 0} {M2 1}}

In that case, the swap occurs in layer M1 (layer 15) and in layer M2 (layer number 17), so the name of the newly generated cell master is "INV1_SHIFT_15_1_17_1".

The tool does not add the new reference cell to the database. It only streams out the new reference cell to the OASIS file.

EXAMPLES

The following command writes out the current block as an OASIS stream file named myDesign.oasis:

```
prompt> write_oasis -units 1000 myDesign.oasis
```

The following command writes out the block myLib:BlockA.design as a OASIS stream file named myBlockA.oasis, using a database unit size of 1 nanometer:

```
prompt> write_oasis -library myLib -design BlockA -units 1000 myBlockA.oasis
```

The following command writes out the current block as an OASIS stream file using a layer mapping file to modify the layers and datatypes, a block mapping file that specifies some blocks to skip, and a cell renaming file to rename some of the blocks before writing:

```
prompt> write_oasis -layer_map myLayerMap -block_map myBlockMap \
  -rename_cell myRenamingFile myDesign.oasis
```

The following command writes out the current block as an OASIS stream file, including only layers M1, V1, M2, V2, and M3:

```
prompt> write_oasis -layers {M1 V1 M2 V2 M3} myDesign.oasis
```

read_gds(2)
merge_stream(2)

write_optimization_history

Write design optimization history from saved file.

SYNTAX

status **write_optimization_history**
[-file *file_name*]

DESCRIPTION

This command saves the history of the optimization steps applied to the design to a file.

SEE ALSO

read_compile_history(2)
write_compile_history(2)
report_optimization_history(2)

write_parasitics

Writes parasitics to SPEF files for current design.

SYNTAX

status **write_parasitics**
-output <file_name>
[-no_name_mapping]
[-hierarchical]
[-compress]
[-format spef|gpd|attach_gpd]
[-corner <corner_name>]
[-rde_corr]
[-via_area]

Data Types

<file_name> string

ARGUMENTS

-output <file_name>

Specifies the name of the output file to which parasitics for the current design are written.

All corners are written to SPEF files with the following format:

<file_name>.<parasitic_tech_name>_<temperature>[_<user_scaling>].spef

The user scaling is in the following format:

VR: <horizontal_res_scale>_<vertical_res_scale>_<horizontal_cap_scale>_<vertical_cap_sclae>_<via_res_scale>

RDE: <res_scale>_<cap_scale>_<rde_res_scale>_<rde_cap_scale>

Mix-mode/DR: <res_scale>_<cap_scale>_<ccap_scale>

-no_name_mapping

Specifies that the net name is used directly in the file. With no name mapping, the actual net names are used in the SPEF file.

By default, the net names are mapped to numbers that are later used when writing RC details.

-hierarchical

To write hierarchical SPEF files. It generates SPEF files for each block. This switch for the time being doesn't invoke extraction. User should run update_timing before using -hier. If sub-blocks have not been extracted, there will have no sub-blocks SPEF file.

-compress

To write gzip SPEF files.

-format

Specifies the data format to output parasitics, spef, gpd or attach_gpd. If it is not specified, the default parasitics output format is SPEF file. attach_gpd format would attach gpd into ndm design.

-corner <corner_name>

Specifies the corner name to write out SPEF file. It supports for a single corner and SPEF file only.

-rde_corr

To enable RDE RC correlation. When current design is a routed design, by using this option it captures RDE footprint internally from a current design and generate RDE spef files. By comparing normal spef files RC correlation can be done. After generating spef files RDE footprint will be gone.

-rde_corr

Specifies to write out via area information in spef file. When PT uses FC/ICC2 a spef file for via variation spef file needs to have via area information. This option enables to write out via area information in the spef file.

DESCRIPTION

This command writes parasitics for the current design to SPEF files. All corners are written to SPEF files. The file XX.spef_scenario is generated when executing the command and this file lists the scenarios associated with the output spef files. Basically, it honors set_user_units but it only accpets Kohm, ohm and F, pF, fF only.

For up-to-date parasitics, it is recommended to do **update_timing** before **write_parasitics**.

Multicorner-Multimode Support

EXAMPLES

The following example writes parasitics for all corners in the current design.

prompt> **write_parasitics -output design**

prompt> **write_parasitics -output design -format gpd**

write_physical_rules

Writes out abstract physical rules/attributes in PRF format from the target library and all its cells.

SYNTAX

int **write_physical_rules**
[-file *output_file*]
[-include *include_list*]
[-library *lib*]

Data Types

output_file string
lib string
include_list list of string

ARGUMENTS

-file *output_file*:

Specify the file name to be written out. If not specified, the data will be written out to screen.

-include *include_list*

Specifies which rules to be written out.

- **library**: Writes out library level rules.
- **cell**: Writes out cell/pin level rules and attributes.
- **instructions**: Writes out stream in instructions.
- **site**: Writes out site and row_pattern and track_pattern under these two groups.
- **layer**: Writes out layer definition under library level.
- **pin_attr**: Writes out pin level attributes such as "direction","port_type", "pg_type" and "is_secondary_pg". This option can only work together with "cell".
- **routing_blockage**: Writes out routing_blockage definition. This option can only work together with "cell".
- **terminal**: Writes out terminal definition. This option can only work together with "cell".
- **shape**: Writes out shape definition. This option can only work together with "cell".
- **all**: Writes out all rules and attributes.

The default value is *{library cell}*.

-library ***lib***

Specifies the target library to write out the rules and attributes. This option is only avaiable in ICC2. If not specified, current library will be used.

In library manager, it's always the current worksapce library.

DESCRIPTION

This command writes out abstract physical rules and attributes from target library and all its cells in PRF format.

EXAMPLES

The following example writes out rules from library and cells to file out.prf.

```
prompt> write_physical_rules -file out.prf
2
```

The following example writes out instructions and cell level rules/attributes to screen.

```
prompt> write_physical_rules -include {instructions cell}
2
```

SEE ALSO

read_physical_rules(2)
remove_physical_rules(2)

write_pin_constraints

Writes topological and physical pin constraints to a file.

SYNTAX

status **write_pin_constraints**
[-from_existing_pins]
[-pins *pins*]
[-nets *nets*]
[-exclude_nets *nets*]
[-ports *ports*]
[-bundles *bundles*]
[-bundle_pin_constraint]
[-cells *cells*]
[-self]
[-exclude_leaf_cells]
[-topological_map *map_constraint*]
[-physical_pin_constraint *pin_constraint*]
-file_name *filename*

Data Types

pins collection
nets collection
ports collection
bundles collection
cells collection
map_constraint string
pin_constraint string
filename string

ARGUMENTS

-from_existing_pins

Writes the pin constraint file based on the actual pin locations and net connections for the pins in the design, instead of the constraints for the pins. If this option is specified without the **-topological_map** and **-physical_pin_constraint** options, the command writes out the physical pin constraints with side, layer, offset, length and width. If this option is not specified, the command writes out pin constraints based on the existing pin constraint settings.

When this option is used together with the **-cells** option, the command writes out the constraints for the pins of the specified cells.

When this option is used together with the **-self** option, the command writes out the constraints for the top-level ports.

-pins *pin*

Specifies which pins to write out to the constraint file. If this option is not specified, the command writes out constraints for all constrained pins.

-nets ***net***

Specifies which nets to write out to the constraint file. If this option is not specified, the command writes out constraints for all constrained nets.

-exclude_nets ***net***

Specifies the nets whose topological and physical constraints will be skipped when writing the constraint file. The physical pin constraints associated with pins and ports on excluded nets will not be skipped.

If used with the **-from_existing_pins** and **-topological_map** options, the command skips the flat nets that the excluded nets belong to.

If used without option **-from_existing_pins**, the command skips the topological constraints that are associated with the excluded nets.

-ports ***port***

Specifies which ports to write out to the constraint file. If this option is not specified, the command writes out constraints for all constrained ports.

-bundles ***bundle***

Specifies which bundles to write out to the constraint file. If this option is not specified, the command writes out constraints for all constrained bundles. Only top-level bundles can be specified.

-bundle_pin_constraint

Writes bundle pin constraints to the constraint file. Only top-level bundles can be written out.

-cells ***cell***

Specifies which block cell pin constraints to write out to the constraint file. This option is mutually exclusive with the **-nets**, **-pins** and **-ports** options. If this option is not specified, the command writes out constraints for all constrained block cells. Only top-level cells can be specified.

-self

Writes out constraints for the top-level pins. This option is mutually exclusive with the **-nets**, **-pins**, **-ports** and **-cells** options. If this option is not specified, the command writes out the constraints for the blocks in the design.

-exclude_leaf_cells

Excludes the topological constraint segment that contains standard cell pins in output file, as long as the other element in that segment is specified within other topological constraint segments, so that no information on physical blocks or physical pins is lost.

For example, when the option is not used, the topological constraints are:

```
start topological map;
{net A}
  {{pin INV1/Y} {{cell UA} {side 1}}}
  {{{cell UA} {side 1}} {{cell UA/UB} {side 1}}}
  {{{cell UA/UB} {side 3}} {{cell UA} {side 3}}}
  {{{cell UA} {side 3}} {pin INV2/A}};
end topological map;
```

With this option, the segments with standard cell pins will be removed and the output is as follows:

```
start topological map;
{net A}
 {{{cell UA} {side 1}} {{cell UA/UB} {side 1}}}
 {{{cell UA/UB} {side 3}} {{cell UA} {side 3}}};
end topological map;
```

This option can only be used together with the **-from_existing_pins** and **-topological_map** options.

-topological_map ***map_constraint***

Writes out the topological map constraints for the design. This option can write out both top-level and block-level topological constraints.

Specify one or more of the following arguments to write these constraints to the file:

- **side**

  The side number is a positive integer that starts from 1. Given any block with a rectangular or rectilinear shape, the left-most edge is side number 1. If there are multiple left-most edges, then edge 1 is the lowest left-most edge. The sides are numbered in consecutive order proceeding clockwise around the shape. Shape refers to the shape of the block instance, not the shape of the reference block.

- **layer**

  The layer constraint specifies the metal layers to use for the pins.

- **offset**

  The offset specifies the distance in microns from the starting point of a given edge to the routing cross-point on that edge in the clockwise direction. The starting point for edge number 1 is the lower vertex, the starting point for edge number 2 is the left vertex, and so on. You must specify the side number when you specify an offset.

- **offset_range** *real*

  When you specify this argument, the command adds the specified value to, and subtracts it from, the current offset position. For example, if the current offset is 20 and you specify **-topological_map {offset offset_range 5}**, the command writes the constraint as {offset {15 25}}. If the specified value is outside of the boundary, the edge boundary endpoint is used.

  The **offset_range** argument must be zero or a positive number.

- layer_range *int*

  When you specify this argument, the command adds layers above and below the current pin layer to create the output constraint. For example, if the current layer for the pin is M4 and you specify **-topological_map {layer layer_range 2}**, the command adds two layers above and two layers below the current pin layer and writes the constraint as {layers {METAL2 METAL3 METAL4 METAL5 METAL6}}.

  The **layer_range** argument must be zero or a positive number.

When you specify multiple arguments, you can separate them with the vertical bar character (|). The **-topological_map {side | layer | offset}** option and **-topological_map {side layer offset}** option specify the same information.

The command writes out the constraints for the specified arguments only when you also specify the **-from_existing_pins** option. If you do not specify the **-from_existing_pins** option, the command writes out all pin constraints associated with the specified objects stored in design database and ignores the arguments to the **-topological_map** option.

If you specify this option without an argument, the command writes only cell information.

If you do not specify this option, the command writes out all options with no offset range or layer range.

Use this option in an incremental pin-placement flow to write the current constraints, edit them, and read them into the tool.

If no argument is passed to this option and also specified together with -from_existing_pins, then the command will print only the cell information.

The following example writes out offsets with range of 2 microns and layers with a range of 2.

```
write_pin_constraints -file_name pinconstraints.txt -from_existing_pins \
  -topological_map {side | layer | offset | offset_range 2.0 | layer_range 2}
```

If net A is connected from block cell B through side 3 at offset 14 and layer M4, and to cell C through side 1 at offset 24 and layer M4, the **write_pin_constraints** command output is as follows:

```
start topological map;
{nets A}
 {{{cell B} {sides 3}
  {offset {12 16}} {layers {METAL2 METAL3 METAL4 METAL5 METAL6}}}
 {{cell C} {sides 1} {offset {22 26}}
  {layers {METAL2 METAL3 METAL4 METAL5 METAL6}}}};
end topological map;
```

-physical_pin_constraint ***pin_constraint***

Writes out the physical pin constraints for the design.

Specify one or more of the following arguments to write these constraints to the file:

- **side**

  The side number is a positive integer that starts from 1. Given any block with a rectangular or rectilinear shape, the left-most edge is side number 1. If there are multiple left-most edges, then edge 1 is the lowest left-most edge. The sides are numbered in consecutive order proceeded clockwise around the shape. The shape here referring to reference block's shape, not the block instance's shape.

- **layer**

- **location**

  If you specify location, the command writes out the coordinate of the center of the pin in the reference block or reference design.

- **offset**

  If you specify offset, the command writes out the offset calculated based on the center of the corresponding pin.

  The offset specifies the distance in microns from the starting point of a given edge to the routing cross-point on that edge in the clockwise direction. The starting point for edge number 1 is the lower vertex, the starting point for edge number 2 is the left vertex, and so on. You must specify the side number when you specify an offset.

- **width**

- **length**

- **order**

  The order specifies the pin constraints start from the pin placed nearest to the starting point of a particular side and sorted based on their distance from the starting point.

- **offset_range** *real*

  When you specify this argument, the command adds the specified value to, and subtracts it from, the current offset position. For example, if the current offset is 20 and you specify **-physical_pin_constraint {offset offset_range 5}**, the command writes the constraint as {offset {15 25}}. If the specified value is outside of the boundary, the edge boundary endpoint is

used.

- **layer_range** *int*

  When you specify this argument, the command writes out the layer range using the layer for the current pin as the middle layer.

When you specify multiple arguments, you can separate them with the vertical bar character (|). The **-physical_pin_constraint {side | layer | offset}** option and **-physical_pin_constraint {side layer offset}** option specify the same information.

The command writes out the constraints for the specified arguments only when you also specify the **-from_existing_pins** option. If you do not specify the **-from_existing_pins** option, the command writes out all pin constraints associated with the specified objects stored in design database and ignores the arguments to the **-physical_pin_constraint** option.

If you do not specify this option, the command writes out all options with no offset range or layer range.

The following example output is written out when you specify the option **-physical_pin_constraints {side | offset | layer}**.

```
start physical pin constraint;
{pins pin_name} {reference ref_block_name} {sides 1} {offset 14} {layers metal1};
.....
end physical pin constraints;
```

-file_name ***filename***

Specifies the file name for the pin constraints output file.

DESCRIPTION

This command writes out the routing topology of nets that are connected to block pins. It can also write out physical information of existing block pins or from existing pin constraints.

The **-pins**, **-nets**, **-ports**, **-cells** and **-self** options are mutually exclusive, you can specify only one of these options with the **write_pin_constraints** command.

If none of the **-topological_map**, **-physical_pin_constraint**, **-cells** and **-self** options are specified, the command writes the topological map section, physical constraints section, pin spacing per edge per layer and block pin constraints sections.

You can run this command multiple times to write out different constraints to different files and specify different objects (nets, pins or cells). The separate files can be concatenated to create a constraint file with multiple topological map sections or multiple physical pin constraint sections. If the same object is written out multiple times with same constraints, the last record takes precedence. If the same object is written out multiple times with different constraints, they are combined together. If the topological map section conflicts with the physical pin constraints section, the topological map section takes precedence. This command only works in design view. If current design is in abstract view, users need to merge data to design view first.

EXAMPLES

The following example writes topological pin constraints to the topo.cstr file based on existing pin placement. The command writes the side, layer, and offset constraints.

```
prompt> write_pin_constraints -from_existing_pins -file_name topo.cstr \
  -topological_map {side | layer | offset}
```

To write all the user-specified individual pin constraints and
topological constraints stored in the design database to pin.cstr file

```
prompt> write_pin_constraints -file_name pins.cstr  -physical_pin_constraint {} \
  -topological_map {}
```

write_pt_checksum

This command is for generating checksums for PT.

SYNTAX

status **write_pt_checksum**
[-pt_exec_path *pt_shell_path*]
[-pt_user_script *pt_user_script*]
[-output_directory *output_directory_path*]
[-type *checksum_type_list*]

Data Types

pt_shell_path string
the_script string
output_directory_path string
checksum_type_list list

ARGUMENTS

-pt_exec_path *pt_shell_path*

The path to the PT executable.

-pt_user_script *the_script*

User specified script for PT session.

-output_directory *output_directory_path*

Directory in which checksums will get generated.

-type *checksum_type_list*

Specifies the list of checksums to be generated.

Valid values it can take are **all**, **library**, **design**, **parasitics**, and **constraints**.

If this option is not specified, all checksums are generated.

DESCRIPTION

The **write_pt_checksum** command generates checksums for a pt session.

The **write_pt_checksum** command generates the checksums for a pt session. The command generates two log files pt_checksum.log and pt_output.log. If -type option is not specified all the checksums are generated. The values it can take are **all**, **library**, **design**, **parasitics**, and **constraints**.

EXAMPLES

The following example generates checksums in checksum_out directory.

```
prompt> write_pt_checksum -pt_exec_path $PT_HOME/bin/pt_shell \
  -pt_user_script pt_user_script.tcl -output_directory checksum_out \
  -type {library design}
```

SEE ALSO

write_checksum(2)
compare_checksum(2)

write_push_down_eco

Generate an eco script that can move down a tree of std-cells, from top physical level to the overlapping blocks on next physical level.

SYNTAX

string **write_push_down_eco**
  [-dir *dir_name*]
  \fcell_list

Data Types

dir_name string
cell_list list

ARGUMENTS

-dir *dir_name*

Specifies the directory to output the eco files. The default directory is *psuh_down_eco_scripts*. One eco file will be generated for each block. User is supposed to source the top block script, which will call the scripts for other blocks.

cell_list

Specifies the cells to be pushded down.

DESCRIPTION

This command will generate an eco script that can move down a tree of std-cells, from top physical level to the overlapping blocks on next physical level.

EXAMPLES

prompt> **write_push_down_eco [get_cells U0]**
prompt> **source ./push_down_eco_scripts/DUT.tcl**

write_rde

Writes RDE model to a encrypted file for current design.

SYNTAX

status **write_rde**
file_name
[-help]

Data Types

file_name string

ARGUMENTS

file_name

Specifies the name of the output file to which a RDE model for the current design are written.

-help

Specifies the usage of write_rde

DESCRIPTION

This command writes RDE model for the current design to an encrypted file. For very large designs, the runtime of the RDE capture step can be reduced by dumping the RDE model from a prior run with "write_rde" and reading it back into a successive run with "read_rde". Once the RDE model information is read in, before either the place_opt or clock_opt flow stages, the subsequent RDE capture step(s) will be skipped subject to the following use model. A RDE model dumped after place_opt (final_opto) may be reused only by the place_opt call of the successive run. An RDE model dumped after clock_opt may be used in both the place_opt and clock_opt stages of the new run (the model need only be read in one time, before either place_opt or clock_opt). The "read_rde" command includes some checking as to whether there have been floorplan changes and, if so, may not allow the RDE model to be read in. In this case, the user should run the default flow and regenerate new RDE model information after the RDE capture stages if desired.

USAGE

run 1 : place_opt -from final_opto write_rde place_opt_RDE ... clock_opt -from final_opto write_rde clock_opt_RDE

run 2 : read_rde place_opt_RDE OR read_rde clock_opt_RDE place_opt -from final_opto ... read_rde clock_opt_RDE clock_opt -from final_opto

EXAMPLES

The following example writes a RDE model for the current design.

```
prompt> write_rde -help
Usage: write_rde    # a RDE stream out command
       [file_name]          (filename to write out)
prompt> write_rde my.rde
```

SEE ALSO

read_rde(2)

write_routes

Writes the routing information to the specified file.

SYNTAX

status **write_routes**
-output *file_name*
[-nets *collection_of_nets*]
[-objects *collection_of_objects*]

Data Types

output string
nets collection
objects collection

ARGUMENTS

-output *file_name*

Specifies the output file name. Routing information is written to *file_name*. This is a required argument.

-nets *collection*

Specifies the collection of nets for which to write out routing information. If you specify more than one net, separate them with a space.

-objects *collection*

Specifies a collection of shapes and/or vias.

The **-nets** and **-objects** are mutually exclusive.

If you do not use **-nets** nor **-objects**, the tool writes out all routing information by default.

DESCRIPTION

The **write_routes** command outputs the routing information as a set of tcl commands to the specified file. Users can source the file back into the tool.

Limitations

Shielding association is not supported.

EXAMPLES

The following examples write the routing information to a file called my_route.txt.

prompt> **write_routes -output my_route.txt**
prompt> **write_routes -objects [get_selection] -output my_route.txt**

SEE ALSO

write_def(2)
create_shape(2)
create_via(2)

write_routing_constraints

Writes routing constraints of the design in a Tcl script.

SYNTAX

status **write_routing_constraints**
file_name
[-significant_digits *digits*]

Data Types

file_name string
significant_digits int

ARGUMENTS

file_name

The generated Tcl script name.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default value depends on the tech precision. Use this option if you want to over-ride the default.

RETURN VALUE

Returns 1 if the Tcl script is successfully write out, and 0 if not.

DESCRIPTION

The **write_routing_constraints** command writes the routing constraints in the current design in form of a Tcl script.

The routing constraints which will be written by the command are create_routing_rule, set_routing_rule, create_wire_matching, create_length_limit, create_differential_group, create_net_shielding, create_net_priority, create_bus_routing_style and set_ignored_layers.

EXAMPLES

The following example writes routing constraints of the current design in **file_name** file.tcl:

```
prompt> write_routing_constraints file
1
```

SEE ALSO

create_routing_rule(2)
set_routing_rule(2)
create_wire_matching(2)
create_length_limit(2)
create_differential_group(2)
create_net_shielding(2)
create_net_priority(2)
create_bus_routing_style(2)
set_ignored_layers(2)

write_rp_groups

Writes out the relative placement constraints for the specified relative placement groups.

SYNTAX

int **write_rp_groups**
rp_group_list [-hierarchical] | -all
[-nosplit]
[-file_name *filename*]
[-create]
[-cell]
[-blockage]
[-rp_group]

Data Types

rp_group_list list or collection
filename string

ARGUMENTS

rp_group_list

Specifies the relative placement groups for which constraints have to be written out.

This option is mutually exclusive with the **-all** option.

-all

Specifies that constraints for all relative placement groups of current block are to be written out. Please note that constraints of relative placement groups of child blocks are not written.

This option cannot be used with either the *rp_group_list* argument or the **-hierarchical** option.

-hierarchical

Specifies that constraints for all relative placement groups within the hierarchy of the groups in *rp_group_list* are to be written out. By default, subgroups are not written out.

This option is mutually exclusive with the **-all** option.

-nosplit

Indicates that lines are not to be split when column fields overflow. This is most useful when comparing previous script files with the UNIX diff command, or for post-processing the script.

-file_name *filename*

Specifies the name of the file to which the relative placement constraints will be written. The default is to write to standard output.

-create

Specifies that **create_rp_group** and **set_rp_group_options** commands should be written out.

-cell

Specifies that **add_to_rp_group -cell** commands should be written out.

-blockage

Specifies that **add_to_rp_group -blockage** commands should be written out.

-rp_group

Specifies that **add_to_rp_group -rp_group** commands should be written out.

DESCRIPTION

The **write_rp_groups** command writes the relative placement constraints for the specified relative placement groups. You can use the generated commands to re-create the relative placement group constrains on the same design. Please note that constraints can be sourced back only from the block they are written from.

When you specify any of the **-create**, **-cell**, **-blockage**, and **-rp_group** options, the generated constraints contains only the commands related to the specified options. If you do not specify any of these options, all commands are written out.

EXAMPLES

The following example uses **write_rp_groups** to re-create relative placement groups after their removal.

```
prompt> get_rp_groups
{grp_mul grp_ripple top_group}

prompt> write_rp_groups -all -file_name my_groups.tcl
1

prompt> remove_rp_groups -all
3

prompt> source my_groups.tcl
{grp_mul grp_ripple top_group}

prompt> get_rp_groups
{grp_mul grp_ripple top_group}
```

SEE ALSO

add_to_rp_group(2)
create_rp_group(2)
remove_rp_groups(2)

write_safety_register_script

Writes a script file for creating safety register rules and groups.

SYNTAX

status **write_safety_register_script**
-output *filename*

Data Types

filename string

ARGUMENTS

-output *filename*

The name of the output text file where the script for generating rules and groups will be written out. If the file already exists, it will be overwritten.

DESCRIPTION

Writes out a Tcl script file containing commands for creating the safety_register_rules and safety_register_groups. This information can be used in tools in downward flow which do not accept the same database format. The file will be written in ASCII text format and will contain the commands like create_safety_register_rule and create_safety_register_group.

EXAMPLES

The following example writes out a script file which can be sourced in another tool to re-create the safety data.

prompt> **write_safety_register_script -output ./create_safety_data.tcl**

SEE ALSO

create_safety_register_rule(2)

set_safety_register_rule(2)
create_safety_register_group(2)

write_saif

Writes a backward Switching Activity Interchange Format (SAIF) file.

SYNTAX

status **write_saif**
file_name
[-duration *duration_value*]
[-cells *cell_list*]
[-no_hierarchy]
[-propagated]
[-switching_activity_types *act_list*]
[-exclude_sdpd]
[-scenarios *scenario_list*]
[-modes *mode_list*]
[-corners *corner_list*]
[-compress gzip | none]

Data Types

file_name string
duration_value float
cell_list list
act_list list
scenario_list list
mode_list list
corner_list list

ARGUMENTS

output_file_name

Specifies the name of the SAIF file to write.

-duration *duration_value*

Specifies the duration value as a floating point number. The reported power numbers depend on the duration value specified. The unit of the duration is always assumed to be in nanosecond. If not specified, the duration is assumed to be 1.0 ns.

-cells *cell_list*

Specifies the cell list for which the SAIF file is written. The SAIF file has the activity information for the top level of the design. It prints out the switching activity of the instances present down the hierarchy ONLY if the cell_list contains the whole hierarchy of the instance.For an instance U1/U2/U3 the cell_list has to be {U1 U1/U2 U1/U2/U3}.

-no_hierarchy

Makes the command write out SAIF information non-hierarchically. If not used, the default behavior is to write out SAIF hierarchically till the leaf cell.

-propagated

Runs the propagation engine before writing out SAIF file. The effort level for propagation is taken from the value specified by the propagation effort app option. The default level of propagation is low. After running the propagation engine the SAIF file is written out.

-switching_activity_types *act_list*

Specifies the switching activity types for which the SAIF file is written out. The list can have values - annotated / simulated / propagated / sta / default. If this option is not used the annotated and simulated information is written out. This option also supports the value 'all'. If 'all' is used with this option then all types of switching activities are written out.

-exclude_sdpd

Inhibits the state-dependent and path-dependent (SDPD) switching activity generation. If you do not specify this option, the **write_saif** command outputs SDPD information by default. When the **write_saif** command is called with the *-propagated* option, nonannotated SDPD information is also propagated and generated in the SAIF file. *-propagated* and *-exclude_sdpd* options can be used together to output the propagated simple switching activity and no SDPD information.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, SAIF file is written for the current scenario in the design.

If the filtered active scenario name is scn1 and the output file name is file1 then the SAIF file written out has the name file1_scn1. Similarly files are written for each scenario if there are more than 1 filtered active scenarios. If there is only 1 scenario then the output SAIF file has name file1.

-modes *mode_list*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*, and is active. The criteria for a scenario to be filtered is only based on the active flag set on a scenario and does not depend on the dynamic/leakage power flags. If this option is not specified, scenarios are not filtered based on modes.

-corners *corner_list*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*, and is active. The criteria for a scenario to be filtered is only based on the active flag set on a scenario and does not depend on the dynamic/leakage power flags. If this option is not specified, scenarios are not filtered based on corners.

-compress gzip | none

This option takes one of the two values 'gzip' or 'none'. 'gzip' compresses the output SAIF file. 'none' does not compress the output SAIF file. If this option is not specified then by default the output SAIF file is not compressed.

DESCRIPTION

The **write_saif** command writes a backward SAIF file. The default behavior is to write out the annotated or simulated switching activity information including state-dependent and path-dependent for the complete design without running the propagation engine. This command only works on the valid active scenarios. Even if the leakage/dynamic power flags for a scenario are enabled/set ,but the active flag for a scenario is false/not-set, the scenario is not considered for write_saif. The **'-scenarios', '-modes', '-corners'**

options filter out the active scenarios from all the scenarios present in the design. If these options are not used, then the current scenario is used **if** it is active. If the current scenario is not active and the **'-scenarios', '-modes', '-corners'** options are not specified, no SAIF is written out.

If there are more than 1 filtered active scenarios, the SAIF file written out for each scenario has the name *ouput_file_name_scn_name*. If there is only one filtered active scenario, SAIF file with name *output_file_name* is written out without any suffix.

Multicorner-Multimode Support

EXAMPLES

The following example writes the SAIF file for the current design.

```
prompt> write_saif test.saif
```

The following example writes out the SAIF for the top design, U1 and U1/U2 instances.

```
prompt> write_saif -cells {U1 U1/U2} test.saif
```

The following example runs the propagation and then writes out the SAIF having propagated or annotated activity information.

```
prompt> write_saif -propagated -switching_activity_types {annotated} test.saif
```

The following example writes out the non state-dependent and path-dependent switching activity information non-hierarchically.

```
prompt> write_saif -no_hierarchy test.saif
```

The following example writes out all the types of switching activity information - annotated,simulated,propagated,sta,default.

```
prompt> write_saif -switching_activity_types {all} test.saif
```

The following example writes out SAIF files test.saif_scn1 and test.saif_scn2 for the active scenarios scn1 and scn2 present in the design.

```
prompt> write_saif -scenarios {scn1 scn2} test.saif
```

The following example writes out SAIF file test.saif in compressed format.

```
prompt> write_saif -compress gzip test.saif
```

write_sanity_check_point

Writes out a sanity check point for the current design.

SYNTAX

status **write_sanity_check_point**
-stage setup | placement
[-output *file_name*]

Data Types

file_name string

ARGUMENTS

-stage setup | placement

Specifies the different design stage for sanity check. For "setup" stage, the command will write out design sanity check points with zero-interconnection delay setting. For "placement" stage, the command will internally run create_placement, then write out design sanity check point with zero-interconnection delay setting.

-output *file_name*

Specifies the name of the generated sanity check point file. For setup stage, tool will generate sanity_setup_qor_log as default output file. For placement stage, tool will generate sanity_placement_qor_log as default output file.

DESCRIPTION

This command writes out sanity check points for the current design. The sanity check points include information such as design area and buffer information, number of dont-touch cells, number of size-only cells, number of fixed placement cells, settings on ignored layers, path groups, design critical path information, QoR (WNS, TNS, NVE), logical DRC violations, number of placement blockages, number of bounds, number of physical-only cells, utilization, and placement wire length.

Note: Due to engine implementation differences, the tool derived size-only and dont-touch numbers might differ between the tools.

EXAMPLES

The following example writes sanity check points for the design.

```
prompt> write_sanity_check_point -stage setup

Writing Sanity Check Point

Finish Sanity Check

1
```

SEE ALSO

report_design(2)
report_qor(2)

write_scan_def

Generates SCANDEF scan chain information for performing scan chain reordering in the physical implementation flow.

SYNTAX

status **write_scan_def**
  [-output *def_file*]
  [-version *def_version*]

Data Types

def_file string
def_version string

ARGUMENTS

-output *def_file*

Specifies the name of the SCANDEF output file to create for the physical implementation tool. The default name is current_design.def, in the current directory.

-version *def_version*

Specifies the DEF version of the output file. Valid values are **5.7** and **5.8**.

DESCRIPTION

The **write_scan_def** command generates scan chain information in SCANDEF format. It is a post-DFT command, intended for use after scan chains are inserted into the design.

EXAMPLES

```
prompt> write_scan_def -output scan.def
```

SEE ALSO

preview_dft(2)
compile(2)
set_scan_configuration(2)
create_test_protocol(2)

write_script

Writes shell commands to save the current settings.

SYNTAX

status **write_script**
[-modes *mode_list*]
[-corners *corner_list*]
[-include *include_list*]
[-exclude *exclude_list*]
[-format dc | icc | icc2| pt]
[-output *dir_name*]
[-force]
[-nosplit]
[-compress gzip]

Data Types

mode_list	list
corner_list	list
include_list	list
exclude_list	list
dir_name	string

ARGUMENTS

-modes *mode_list*

Specifies the modes to write.

By default, all modes are written.

-corners *corner_list*

Specifies the corners to write.

By default, all corners are written.

-include *include_list*

Specifies the types of data to include in the output.

Valid values are **annotation**, **aocvm_coefficient**, **aocvm_coefficient_lib_cell**, **app_options**, **block_to_top_map**, **budget**, **case_analysis**, **cell_mode**, **clock**, **clock_cell_spacing_rule**, **clock_gating_check**, **clock_group**, **clock_jitter**, **clock_latency**, **clock_latency_2**,**clock_max_level_control**,**clock_multisource_options**, **clock_scale_mode_groups**, **clock_sense**, **clock_target_skew_latency**, **clock_transition**, **clock_tree_reference_subset**, **clock_uncertainty**,

By default, all types of data are included in the output.

You cannot specify this option with the **-exclude** option.

-exclude ***exclude_list***

Specifies the types of data to exclude from the output.

Valid values are **annotation**, **aocvm_coefficient**, **aocvm_coefficient_lib_cell**, **app_options**, **block_to_top_map**, **budget**, **case_analysis**, **cell_mode**, **clock**, **clock_cell_spacing_rule**, **clock_gating_check**, **clock_group**, **clock_jitter**, **clock_latency**, **clock_latency_2**,**clock_max_level_control**,**clock_multisource_options**, **clock_scale_mode_groups**, **clock_sense**, **clock_target_skew_latency**, **clock_transition**, **clock_tree_reference_subset**, **clock_uncertainty**, **create_cell_bus**,**crpr_scale_factor**, **cts_balance_point**, **cts_exception**, **cts_extended_constraints**, **cus_clock_arrival**, **data_check**, **data_check_ignore**, **disable_timing**, **dont_touch**, **dont_use**, **drc_disable_flags**, **drc_disable_types**, **drive_info**, **edrc**, **exception**, **file_line_info**, **freeze_ports**, **global_route**, **ideal_network**, **idn_annotation**, **ignored_layers**, **input_delay**, **interclock_balance**, **isolate_ports**, **latch_loop_breaker**, **latency_adjustment**, **lib_pin_noise_margin**, **load**, **max_low_vth**, **max_time_borrow**, **min_pulse_width**, **net_resistance**, **output_delay**, **parasitic_corner**, **parasitic_global**, **path_group**, **path_ignored_block**, **placement_spacing_rule**, **port_pin_noise_margin**, **power_clock_scaling\f, power_derate\f, pvt, pvt_dynamic, routing_rule, scaling_lib_groups, \fscan_chain, size_only, skew_group, target_library_subset,timing_derate, via_ladder_commands and voltage_area_rule.**

By default, all types of data are included in the output.

You cannot specify this option with the **-include** option.

-format dc | icc | icc2| pt

Specifies the format used to write the script files.

Valid values are

- icc2 (the default)
  The script files uses IC Compiler II command syntax.
- dc
  The script files uses Design Compiler command syntax.
- icc
  The script files uses IC Compiler command syntax.
- pt
  The script files use PrimeTime command syntax.

-output ***dir_name***

Specifies the name of the directory in which to write the script files.

The default is ./wscript.

-force

Overwrites the existing script files.

By default, the command fails if the script file already exists.

-nosplit

Prevents the splitting of command lines in the script when column fields overflow. This is most useful for doing comparisons with existing scripts or for post-processing the script.

-compress gzip

Specifies the method used to compress the generated script files.

By default, the command writes the script files as simple text files and does not compress them.

DESCRIPTION

The **write_script** command writes Tcl scripts to recreate the attributes on the current design.

By default, the **write_script** command writes command scripts to a directory named ./wscript.

This command writes multiple files to the specified directory. It writes mode-specific information to files named mode_*{mode_name}*.tcl and corner-specific information to files named corner_*{corner_name}*.tcl. It writes information that is not dependent on the mode or corner to a file named design.tcl. Clock tree synthesis options are written into a file called cts.tcl. It also writes a file named top.tcl that sources all the other script files. You can source the top.tcl script to re-create the data on the current design.

This command does not support user-defined attributes; it supports only the attributes and objects created by the following commands:

create_clock
create_generated_clock
create_routing_rule
create_voltage_area_rule
define_scaling_lib_group

write_sdc

Writes the design constraints in Synopsys Design Constraints (SDC) format.

SYNTAX

status **write_sdc**
-output *file_name*
[-nosplit]
[-version *sdc_version*]
[-mode *mode*]
[-corner *corner*]
[-scenario *scenario*]
[-compress gzip]
[-include *include_list*]
[-exclude *exclude_list*]

Data Types

file_name string
sdc_version string
mode string
corner string
scenario string
include_list list
exclude_list list

ARGUMENTS

-output *file_name*

Specifies the name of the generated SDC file.

-nosplit

Prevents the splitting of command lines in the generated SDC file. This is most useful for doing comparisons with existing SDC files with the UNIX **diff** command or for post-processing the script.

-version *sdc_version*

Specifies the SDC version used for the generated SDC file.

Valid values are 1.7, 1.8, 1.9, 2.0, 2.1, and **latest** (the default).

-mode *mode*

Specifies the mode to write.

By default, the current mode is written.

-corner ***corner***

Specifies the corner to write.

By default, the current corner is written.

-scenario ***scenario***

Specifies the scenario to write.

By default, the scenario (if any) of the specified mode and corner is written. It is an error to use this option with the **-mode** or **-corner** options.

-compress gzip

Specifies the method used to compress the generated SDC file.

By default, the command writes the SDC file as a simple text file and does not compress it.

-include ***include_list***

Specifies the types of data to include in the output.

Valid values are **case_analysis**, **clock**, **clock_gating_check**, **clock_group**, **clock_latency**, **clock_sense**, **clock_transition**, **clock_uncertainty**, **data_check**, **data_check_ignore**, **disable_timing**, **drive_info**, **edrc**, **exception**, **file_line_info**, **ideal_network**, **input_delay**, **load**, **max_time_borrow**, **output_delay**, **path_group**, **pvt**, and **timing_derate**.

By default, all types of data are included.

This option cannot be specified with the **-exclude** option.

-exclude ***exclude_list***

Specifies the types of data to exclude from the output.

Valid values are **case_analysis**, **clock**, **clock_gating_check**, **clock_group**, **clock_latency**, **clock_sense**, **clock_transition**, **clock_uncertainty**, **data_check**, **data_check_ignore**, **disable_timing**, **drive_info**, **edrc**, **exception**, **file_line_info**, **ideal_network**, **input_delay**, **load**, **max_time_borrow**, **output_delay**, **path_group**, **pvt**, and **timing_derate**.

By default, all types of data are included.

This option cannot be specified with the **-include** option.

DESCRIPTION

The **write_sdc** command writes out a script file in Synopsys Design Constraints (SDC) format. This script contains commands that can be used in the Fusion Compiler, IC Compiler II, PrimeTime, Design Compiler, and IC Compiler tools. The SDC format is also licensed by external vendors through the TAP-in program. SDC-formatted script files are read into the Fusion Compiler, IC Compiler II, PrimeTime, Design Compiler, and IC Compiler tools by using the **read_sdc** command.

By default, the script is written as a simple text file in the latest SDC version. To write an earlier SDC version, use the **-version** option. To write a compressed SDC file, use the **-compress** option.

SDC is a subset of the commands already supported by the Fusion Compiler, IC Compiler II, PrimeTime, Design Compiler, and IC Compiler tools. The **write_sdc** command writes the following commands (those added for versions 1.7 and later are noted):

General Purpose Commands:

- expr
- list
- set

Object Access Functions:

- all_clocks
- all_inputs
- all_outputs
- all_registers (1.7)
- current_design
- current_instance
- get_cells
- get_clocks
- get_libs
- get_lib_cells
- get_lib_pins
- get_nets
- get_pins
- get_ports
- set_hierarchy_separator

Basic Timing Assertions:

- create_clock
- create_generated_clock (1.3)
- group_path (1.7)
- set_clock_gating_check
- set_clock_groups (1.7)
- set_clock_latency
- set_clock_sense (1.7)
- set_clock_transition
- set_clock_uncertainty
- set_false_path
- set_ideal_latency (1.7)
- set_ideal_transition (1.7)
- set_input_delay
- set_max_delay
- set_min_delay
- set_multicycle_path
- set_output_delay
- set_propagated_clock

New options to existing supported commands:

- create_clock -add (1.4)
- create_generated_clock -add
- create_generated_clock -master_clock
- create_generated_clock -combinational (1.7)

Secondary Assertions:

- set_disable_timing
- set_max_time_borrow

Environment Assertions:

create_voltage_area
set_case_analysis
set_drive
set_driving_cell
set_fanout_load
set_input_transition
set_ideal_network (1.7)
set_level_shifter_strategy
set_level_shifter_threshold
set_load
set_logic_dc
set_logic_one
set_logic_zero
set_max_area
set_max_capacitance
set_max_dynamic_power
set_max_leakage_power
set_max_transition
set_min_capacitance
set_min_fanout
set_min_porosity
set_operating_conditions
set_port_fanout_number
set_voltage (1.8)
set_wire_load_min_block_size
set_wire_load_mode
set_wire_load_model
set_wire_load_selection_group

Like the **write_script** command, the **write_sdc** command writes out commands relative to the top level of the design, regardless of the current instance. SDC files written by the **write_sdc** command must be read in from the top level of the design.

For a complete guide to using SDC with Synopsys tools, see the *Using the Synopsys Design Constraints Format Application Note*, which is available in SolvNet at https://solvnet.synopsys.com.

The usage of some of the supported commands is restricted when reading SDC. In some cases, some options are not allowed. The **write_sdc** command supports the restricted usage by restricting what is written.

When the hierarchy has been partially flattened, embedded hierarchy separators can make names ambiguous. It is not clear which hierarchy separator characters are part of the name, and which are real separators. You can make hierarchical names unambiguous by using the **set_hierarchy_separator** SDC command or the **-hsc** option, which is available on the **get_cells**, **get_lib_cells**, **get_lib_pins**, **get_nets**, and **get_pins** SDC object access commands. It is considered a best practice to write SDC files that contain names that are not ambiguous.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenario** option or the **-corner** and **-mode** options.

EXAMPLES

The following command writes the SDC file to a file named top.sdc:

```
prompt> write_sdc -output top.sdc
```

1

SEE ALSO

read_sdc(2)
write_script(2)

write_shadow_eco

Writes out one or more Tcl scripts that can be used to re-create feedthroughs created by **place_pins** or **push_down_objects**.

SYNTAX

status **write_shadow_eco**
[-reporting_style design_based | block_based]
[-command_style icc2 | dc]
[-output *path_name*]
[-set_shadow_status]
[-disable_undo]
[-nets *list_of_nets*]
[-cells *list_of_cells*]
[-latest_rounds *list_of_integers*]
[-self]

Data Types

path_name string
list_of_cells list

ARGUMENTS

-reporting_style design_based | block_based

Specifies how the shadow scripts should be created.

- If the style is **design_based**, the tool writes out one script.
- If the style is **block_based**, the tool writes out a set of shadow scripts for the top block and some or all the child physical blocks under top. The script for the top block contains Tcl commands to create feedthrough nets and make the correct netlist update to connect those feedthrough nets to corresponding ports or pins. The scripts for the child physical blocks contain the similar Tcl commands. Each script only makes the netlist update within the corresponding top block or the child block and no netlist update involving upper or lower physical hierarchies.

  The top block is always enabled for the shadow script creation unless the **set_editability** command explicitly disables it.

  The child physical blocks whose shadow scripts are to be created are those child physical blocks that have feedthroughs created, and at the same time specified by the **-cells** option and also enabled by **set_editability** command. If the **-cells** option is not used, then they are decided by the **set_editability** command. By default, all child physical blocks with feedthroughs created have the corresponding shadow scripts created.

The tool writes the scripts under the path specified by the **-output** option.

The default is **design_based**.

-command_style icc2 | dc

Specifies the command style used in the output Tcl script. If the command style is **icc2**, the tool writes IC Compiler II commands. If the command style is **dc**, the tool writes Design Compiler commands.

If the command style is **dc**, note that the Verilog reader tools in the Design Compiler and IC Compiler II tools can behave slightly differently when processing nets that connect to the ports of Verilog modules. In the IC Compiler II tool, the Verilog reader tries to match the net name to the Verilog module port name that the net connects to. However, if the net is declared as a wire with a name other than the name of the port it connects to, the Verilog reader changes the net name to match the port name. For any feedthroughs created on such a net, the **write_shadow_eco** command writes out the changed net name instead of the original net name.

On the other hand, the Design Compiler Verilog reader does not make the net name changes. Therefore, if Design Compiler reads in the original Verilog netlist, then Design Compiler reads in the ECO scripts created by **write_shadow_eco** in IC Compiler II, there might be errors. Design Compiler might report that some nets do not exist because of the net name changes.

To avoid such possible errors, you can either modify the original Verilog netlist to avoid using different names between nets and the module ports they connect to, or in the Design Compiler session, use a Verilog netlist created by IC Compiler II before creating the feedthroughs with the output of the **write_shadow_eco** command.

The default is **icc2**.

-output *path_name*

Specifies the output path in which to write the scripts. If the **-reporting_style** option is omitted or specified as **design_based**, and the *path_name* is an existing directory, the output script name is the same as the current design name with a ".script" extension name. The script is saved under the specified directory.

If the **-reporting_style** option is omitted or specified as **design_based**, and the *path_name* is an existing file, the output script overwrites the existing file.

If the **-reporting_style** option is omitted or specified as **design_based**, and the *path_name* is not an existing file or an existing directory, then *path_name* is treated as the full or relative path to the output script.

If the **-reporting_style** option is specified as **block_based**, and *path_name* is an existing file, then the output scripts are saved under the same directory as the existing file. The file names of the scripts are determined by the **-reporting_style** that is specified.

If the **-reporting_style** option is specified as **block_based**, and *path_name* is not an existing file, it is then treated as the full or relative path to the output directory, under which the output scripts are saved.

If this option is missing, the default output directory is the current working directory.

-set_shadow_status

If the option **-command_style** is specified as **icc2**, then setting shadow status commands are included in the output scripts.

-disable_undo

If the option **-command_style** is specified as **icc2**, then disabling undo commands are included in the output scripts.

-nets *list_of_nets*

Specifies a list of nets for which to create shadow eco scripts.

-cells *list_of_cells*

Specifies a list of cells for which to create shadow eco scripts. This option is in effect only when the option **-reporting_style** is specified as **block_based**. If the **-reporting_style** option is specified as **design_based** or omitted, then this option has no effect and is silently ignored. The child blocks that have corresponding shadow scripts are those have feedthroughs created, and at the same time specified by this option and also enabled by **set_editability** command.

If the **-cells** option is not specified, then the cells whose shadow scripts are to be created are decided by the setting of the command **set_editability**.

Note, the current top block can also be enabled or disabled for shadow script creation by the setting of **set_editability** command.

-latest_rounds ***list_of_integers***

Specifies the latest steps of **place_pins** or **push_down_objects** in which the shadow objects were created. The integers must be equal to or larger than 1. Number 1 means the latest **place_pins** or **push_down_objects** in which shadow objects were created. Number 2 means the latest but 1 (i.e. 2nd from current). And so on and so forth. If this option is used, then only shadow objects created during the specified **place_pins** or **push_down_objects** are regarded as shadow by **write_shadow_eco**. All others are regarded as original objects, even if they have shadow status *pushed_down* or *copied_down*.

In addition, to be able to recognize and honor this option, the app option **plan.pins.enable_feedthrough_timestamps** must be set true when **place_pins** or **push_down_objects** are called.

-self

Specifies that the shadow script is created for the top design.

DESCRIPTION

This command writes out one or more Tcl script that can be used to duplicate the exact same feedthrough pins, ports and nets that are created by the commands **place_pins** or **push_down_objects**, which have pushed_down or copied_down shadow attributes. When the scripts are applied to the netlist before feedthrough creation, the same feedthroughs are re-created.

The input to the command is a feedthrough created design. Additionally, it can also have buffers inserted by **add_buffer_on_route** or **add_buffers**. The command **write_shadow_eco** analyzes the netlist to identify the following objects:

- feedthrough pins, ports and nets
- any standard cells with pushed_down or copied_down shadow status
- buffers with pushed_down or copied_down shadow status
- buffers inserted by **add_buffer_on_route** or **add_buffers** on feedthrough nets
- buffers that can be 100% determined as being inserted on feedthrough nets after feedthrough creation

All of the above objects are regarded as shadow objects. The output shadow ECO scripts should re-create them and connect them correctly when applied to the design before the feedthrough creation.

In addition, the shadow ECO scripts creation can be customized by the following two app options:

- plan.shadow.exclude_non_shadow_buffers
- plan.shadow.exclude_non_hierarchical_objects

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes out the feedthrough creation script.

```
prompt> write_shadow_eco
```

SEE ALSO

place_pins(2)
push_down_objects(2)

plan.shadow.exclude_non_shadow_buffers(3)
plan.shadow.exclude_non_hierarchical_objects(3)

write_spare_ports_eco

generate an script file that will create dummy FT ports

SYNTAX

string **write_spare_ports_eco**
[-dir *dir_name*]
[-name *port_name*]
[-direction *direction*]
[-bits *bits*]
cell_list

Data Types

dir_name string
port_name string
direction string
bits int
cell_list list

ARGUMENTS

-dir *dir_name*

Specifies the directory to output the eco files. The default directory is *create_spare_ports*. One eco file will be generated for each block. User is supposed to source the top block script, which will call the scripts for other blocks.

-name *port_name*

Specifies the names of the ports to be created. The default name is *dummyFT*.

-direction *direction*

Specifies the direction of the ports to be created. The direction contain {in | out | inout}, this is required option.

-bits *bits*

Specifies the sequence number of created ports. Start index and end index, must be non-negative value.

cell_list

Specifies the cells to create FT ports scripts.

DESCRIPTION

The **write_spare_ports_eco** command generates a script that contains the Tcl commands to that will create dummy FT ports base on customer input.

EXAMPLES

The following example writes out script for cell "U*" instances, with name Test_FT.

prompt> **write_spare_ports_eco [get_cells U*] -direction in -dir test_path -bits {0 4} -name Test_FT**

SEE ALSO

write_push_down_eco(2)

write_split_net_eco

Generate an eco script that can move the branch-out of a multi-fanout net up to top level.

SYNTAX

string **write_split_net_eco**
[-filename *file_name*]
[-nets \fnet_collection]

Data Types

file_name string
net_collection list

ARGUMENTS

-filename *file_name*

Specifies the output eco file name. If not file name not specified, the content of the eco file will be returned to the console.

-nets *net_collection*

Specifies the nets to split. If not specified, all the multi-fanout interface nets in the design will be splited. Note that a net must connect to multiple physical block pins to qualify for split. A net not connect to physical block pins will not be split. Once a net qualifies for split, then the branch-out will be moved as up as it can: the branch-out will be continued moved up, if it is driven by a pin of higher level, either it is a physical level or just a logic wrapper.

DESCRIPTION

This command will generate an eco script that can move the branch-out of a multi-fanout net up to top level.

EXAMPLES

prompt> **write_split_net_eco -filename split.tcl**
prompt> **source split.tcl**

write_taps

Writes existing taps into a text file for later reuse.

SYNTAX

status **write_taps**
-file *file_name*
[*taps*]

Data Types

string *file_name*
list *taps*

ARGUMENTS

-file *file_name*

Specifies the name of the file to which the tap points are written.

taps

Specifies the tap points to be written. The tap points can be specified as name patterns or collections of taps.

DESCRIPTION

The command writes a file containing the location and associated supply net for each inserted tap, which can be read into a later session with the **create_taps -import file** command.

The tap points written to the file can be limited to specific types by using the filter option with the **get_taps** command. For example, you can capture the set of tap points that were inserted in *top_pg* type.

The following is the format of the output file:

supply_net_name layer_number X_coordinate Y_coordinate [R(R_value)] [L(L_value)] [C(C_value)]

Lumped RLC values will be written to the tap file if they are specified for the taps. The units are Ohm for resistance, Henry for inductance, and Farad for capacitance. In the following example, no lumped RLC value is written to the tap file:

VDDY 39 746.800 469.400
VDDY 39 0.200 469.400
VDDY 39 0.200 548.600

```
VDDY 39 0.200 627.800
VSS 39 746.800 51.800
VSS 39 0.200 51.800
VSS 39 746.800 131.000
VSS 39 746.800 210.200
VSS 39 746.800 368.600
```

In the following example, the lumped RLC value is written to the tap file:

```
VDDY 39 746.800 469.400 R(0.001) L(1.0e-9) C(2.0e-12)
VDDY 39 0.200 469.400
VDDY 39 0.200 548.600
VDDY 39 0.200 627.800
VSS 39 746.800 51.800
VSS 39 0.200 51.800
VSS 39 746.800 131.000
VSS 39 746.800 210.200
VSS 39 746.800 368.600
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example writes a file containing the taps that were inserted via the lib_cell reference.

```
prompt> write_taps [get_taps -filter type {libcell_pg}] -file ./MyTapFile
```

SEE ALSO

create_taps(2)

write_tech_file

Write a technology file from the current library.

SYNTAX

int **write_tech_file**
[-library *lib_name*]
file_name

ARGUMENTS

-library *lib_name*

Library from which the technology file to be written, default is current lib.

file_name

The output technology file name.

RETURN VALUE

Returns 1 if the technology file is successfully write out, and 0 if not.

DESCRIPTION

The **write_tech_file** command writes out a technology file from the user specified library. If there is no library specified, the default is current library.

EXAMPLES

The following example dump out a technology file "tcb90g.tf" from the current library.

prompt> **write_tech_file tcbn90g.tf**

SEE ALSO

create_lib(2)
read_tech_file(2)

write_test_model

Writes a test model file

SYNTAX

status **write_test_model**
-output *filename*

Data Types

filename string

ARGUMENTS

-output

File name the protocol will be written to

-format ctl | icl | pdl

Specifies the format of the test model file. By default, the model is assumed to be in .ctl format.

When **icl** is specified, the CTL test model information and an interface-only representation of the design are written out to a file. This file describe the ports for connections to Server/Subserver and TDR registers.

DESCRIPTION

The write_test_model command writes test model associated to the current design.

The test model files represent the test behavior of designs. The attributes that are represented include all DFT signals and their purpose, the test timing, and the sequence of events needed to shift test vectors in and out of the design. Test models are read from disk using the read_test_model.

Note that for standard IEEE1838, TAP port specifications inside Internal statment of testmode will adhere the following points.

- **Primary Tap:** User data will contain both "IEEE1149.1" and "IEEE1838" standards to define the port as Primary TAP. Last user data will contain the name of the tap set.

  For example, "tdo" { DataType ScanDataOut User "IEEE1149.1" User "IEEE1838" User "PTAP set name" { ScanDataType Internal; } }

- **Secondary Tap:** User data will contain only "IEEE1838" standard to define the port as secondary TAP. Last user data will contain the name of the die to which the port belongs,

  For example, "myStapTdo" { DataType ScanDataOut User "IEEE1838" User "STAP set name" { ScanDataType Internal; } }

EXAMPLES

prompt> write_test_model -output myModel.ctl

File name: myModel.ctl

1

prompt> write_test_model -format icl -output 1687.icl -test_mode ieee_1687

File name: 1687.icl

Information: ICL file '1687.icl' generated successfully.

1

SEE ALSO

read_test_model(2)

write_test_protocol

Writes a STIL test protocol file.

SYNTAX

status **write_test_protocol**
-output *filename*
[-test_mode *modename*]

Data Types

filename string
modename string

ARGUMENTS

-output

File name the protocol will be written to

-test_mode

test mode the protocol is extracted from

DESCRIPTION

The write_test_protocol command outputs the STIL test protocol from memory to disk in text format. This allows you to customize the test protocol. The scan test protocol formally defines the process by which a design is tested, so the sequence of scan-in vectors, parallel vectors, and scan-out vectors is performed for each test pattern. The protocol defined for a design is used to drive scan test and design rule checking.

EXAMPLES

```
prompt> write_test_protocol -test_mode ScanCompression_mode -output my.spf
```

SEE ALSO

create_test_protocol(2)

write_topology_constraints

Generate Tcl statements to add and/or reset multicycle constraints for topology plan objects

SYNTAX

int **write_topology_constraints**
[-filename *filename*]
[-include_reset]
[-only_reset]
[-overwrite]
[-use_object_lookup]
[topology plans]

Data Types

filename string
topology plans collection of topology plans

ARGUMENTS

-filename filename

Specifies the name for the Tcl output filename to write the multicycle constraints. Use stdout as the filename to write to the console instead.

-include_reset

Include *reset_paths* statements in the output to undo / remove the multicycle path constraints set by this command.

-only_reset

Only include the *reset_paths* statements - do not include any multicycle path statements. This option implies *-include_reset*.

-overwrite

Overwrite any files that may already exist with the given filename.

-use_object_lookup

When specified, include Tcl calls to **get_pins** or **get_ports** (as appropriate) when passing objects to the **set_multicycle_path** or **reset_paths** commands. The default is just to pass the object name and let the command determine the object(s) being referenced.

topology plans

Specifies a collection (or list of names) of topology plans to be included in the report. The default is all topology plans belonging

to the current block.

DESCRIPTION

This command creates Tcl statements of the form: set_multicycle_path -setup <count> -from <object> [-through <object>] -to <object>. and set_multicycle_path -hold <count-1> -from <object> [-through <object>] -to <object>.

for any stages of a given topology crossing through any virtual sequential repeaters (registers) that do not have any netlist implementation or do not have associated netlist objects. Timing paths default to values of "-setup 1" and "-hold 0", which is equivalent to crossing through zero virtual registers, and therefore, if all sequential topology repeaters of a given topology plan have associated std cell objects, then no statements will be generated for that topology plan. That is, statements of the form "-setup 1" and "-hold 0" will not be skipped since they are assumed by default.

The generated statements can then by used to apply suitable multicycle path constraints to the nets / objects of a topology plan when used with **report_timing**.

The reset options generate statements of a similar form, but using "reset_paths" instead of "set_multicycle_path" as the command.

Note: if the first/last object of an applicable multicycle path is a sequential element (register), then the first/last part of the path statement will be -from <clkObject> / -to <clkObject>. However, if the object is a port or block pin (non-sequential object), the first/last parts of the path statement will use "-through" instead of "-from" and "-to".

report_topology_plans(2)

write_topology_plans

Writes topology plan information in Tcl format for the current design.

SYNTAX

int **write_topology_plans**
[-log]
[-include_objects]
[-current_block]
[*topology_plan_list*]
[-filename *filename*]

Data Types

topology_plan_list collection
filename string

ARGUMENTS

-log

Writes out topology plan information to the console and log file.

-include_objects

Includes Tcl commands to create bundles and supernets in the output.

-current_block

Only writes out topology plans for current block.

-filename *filename*

Specifies the file name for the topology plans output file.

topology_plan_list

Specifies a list of topology plans to write out. The list can contain topology plan names, patterns, or collections. A collection can be specified by using the **get_topology_plans** command.

DESCRIPTION

The **write_topology_plans** command generates a script that contains the Tcl commands to re-create the topology plans in the design. The script includes the topology plan name and topology edges and topology nodes. If *topology_plan_list* is specified, the command writes only the specified topology plans. If *topology_plan_list* is not specified, the command writes out all topology plans in the design.

EXAMPLES

The following example writes out information for the topology plan named "topo_5".

```
prompt> write_topology_plans topo_5 -include_objects -log
# icc2 Q-2019.12 Oct 1, 2019
# design: GPU_TOP_DG

write_topology_report

Writes a report summarizing topology repeater status for implementation.

SYNTAX

int **write_topology_report**
[-filename *filename*]
[-compress]
[-no_referenced_plans]
[-overwrite]
[-verbose]
[topology plans]

Data Types

filename string
topology plans collection of topology plans

ARGUMENTS

-filename filename

Specifies the name for the XML report to be written. If not specified, default is to write to the console.

-compress

Produce a .gz compressed filed

-no_referenced_plans

By default, any plans not in the list of specified plans, but referenced by one of the specified plans using a reference node are added to the list of plans included in the report. This option prevents referenced plans from being added to the list of reported plans.

-overwrite

Overwrite any files that may already exist with the given filename

-verbose

Display extra information during processing

topology plans

Specifies a collection (or list of names) of topology plans to be included in the report. The default is all topology plans belonging to the current block.

DESCRIPTION

This command creates a report detailing the specified topology plans, including attributes, node, edge and repeater information. The included information is somewhat redundant, but is intended to make it easy for the user to find any required data to make it easy to implement registers in RTL.

write_verilog

Writes a Verilog description of the current design.

SYNTAX

string **write_verilog**
[-compress *method*]
[-top_module_first]
[-hierarchy *scope*]
[-split_bus]
[-include *include_list*]
[-exclude *exclude_list*]
[-force_reference *blocks_and_lib_cells*]
[-force_no_reference *blocks_and_lib_cells*]
[-switch_view_list *views*]
[-only_master_variant]
[-shell_only]
[-module_list]
[-mask_shifted_suffix_without_constraint *suffix_string*]
[-rename_cell *cell_renaming_files*]
verilog_file_name

Data Types

method string
scope string
include_list list
exclude_list list
blocks_and_lib_cells list
views list
suffix_string string
verilog_file_name string

ARGUMENTS

-compress *method*

Specifies file compression format. The only format currently supported is **gzip**. A .gz extension is appended to the file name if no extension is specified. By default, the Verilog file is not compressed.

-top_module_first

Writes the modules hierarchically top-down, so that the top module appears first in the output file. By default, modules are written hierarchically bottom-up, with the top module last in the file.

-hierarchy *scope*

Writes only the modules in the specified scope. The default *scope* value is **design**. These are the valid settings for the *scope*:

```
top         Writes only the top module in the design.
design      Writes the design, stopping at its design boundary.
design_lib  Writes the design, stopping at its design library boundary.
all         Writes the design, including modules in reference libraries.
```

-split_bus

Writes bus ports and nets as individual bits. The bus port and net names are treated as scalar names and escaped.

For example, if you have the following module definition:

```
module top (out, in);
  output [3:0] out;
  input in;
  wire [3:0] n;
  ...
endmodule
```

It is written as follows:

```
module top(\out[3] , \out[2] , \out[1] , \out[0] , in);
  output \out[3] ;
  output \out[2] ;
  output \out[1] ;
  output \out[0] ;
  input in;
  wire \n[3] ;
  wire \n[2] ;
  wire \n[1] ;
  wire \n[0] ;
  ...
endmodule
```

-include *include_list*

Specifies a list constructs and objects to include in the output. When this option is used, the Verilog contains the basic logic netlist and only the types of constructs and objects specified with this option. The valid values are:

```
all
all_physical_cells
analog_pg
corner_cells
cover_cells
diode_cells
empty_modules
end_cap_cells
feedthrough_cells
filler_cells
flip_chip_driver_cells
flip_chip_pad_cells
leaf_module_declarations
pad_cells
pad_spacer_cells
pg_netlist
pg_objects
```

physical_only_cells
scalar_wire_declarations
shadow_netlist
spare_cells
supply_statements
unconnected_ports
user_pg
well_tap_cells

For a description of each construct and object type, see the DESCRIPTION section. The default behavior is to include everything except for scalar wire declarations, leaf module declarations, PG objects, and connections to unconnected ports.

-exclude *exclude_list*

Specifies a list of constructs and objects to exclude from the output. When this option is used, the Verilog contains everything except for the types of constructs and objects specified with this option.

The valid values are:

all_physical_cells
analog_pg
corner_cells
cover_cells
diode_cells
empty_modules
end_cap_cells
feedthrough_cells
filler_cells
flip_chip_driver_cells
flip_chip_pad_cells
leaf_module_declarations
pad_cells
pad_spacer_cells
pg_netlist
pg_objects
physical_only_cells
scalar_wire_declarations
shadow_netlist
spare_cells
supply_statements
unconnected_ports
well_tap_cells

-force_reference *blocks_and_lib_cells*

Specifies blocks and lib_cells to write to the Verilog file. The *blocks_and_lib_cells* argument is either a collection or a name list of blocks and lib_cells. Instances of the block or lib_cell are written regardless of the design types specified by the **-include** or **-exclude** option. The module declaration of the block is written. The module declaration of the lib_cell is also written if you use the **-include leaf_module_declarations** option.

The forced blocks and lib_cells are not written if they are outside the scope specified by the **-hierarchy** option.

-force_no_reference *blocks_and_lib_cells*

Specifies blocks and lib_cells to omit from the Verilog file. The *block_and_lib_cells* argument is either a collection or name list of blocks and lib_cells. Instances of the block or lib_cell are omitted regardless of the design types specified by the **-include** or **-exclude** option. The module declaration of the block is omitted. The module declaration of the lib_cell is also omitted, even if you use the **-include leaf_module_declarations** option.

The **-force_reference** and **-force_no_reference** options may be used simultaneously. However if a block or lib_cell is listed in both options, it is omitted because the **-force_no_reference** option has precedence.

-switch_view_list

Specifies the reference block views for hierarchical block instances to be opened. The view at the head of the list is in higher priority.

-only_master_variant

Indicates that all the instances of variants are replaced by instances of the masters.

verilog_file_name

Specifies the name of the Verilog file to be written. Any existing file of the same name is overwritten. If the name ends with the .gz extension, it is compressed using the gzip format.

-shell_only

Writes a Verilog shell netlist that contains only the module definitions and ports; it does not include any cell instances. The **-shell_only** option cannot be used with the following options:

-compress
-exclude
-force_reference
-force_no_reference
-include
-module_list
-split_bus
-switch_view_list
-top_module_first

-module_list

Lists the modules to be defined in the output Verilog. Definitions for all other modules are omitted.This option has precedence over all other options in controlling which module definitions appear in the output Verilog. This option does not control the output of the module contents, such as the inclusion or exclusion of module instances.

If the **-module_list** is not specified, all modules within the specified hierarchy scope are written (see **-hierarchy** option).

The **-module_list** option cannot be used with the following options:

-hierarchy
-shell_only

-mask_shifted_suffix_without_constraint *suffix_string*

Specifies the suffix string used to generate reference cell name when double-patterning mask shifting enabled in the flow. If a cell instance has the mask_shift attribute set to none zero value, this option will write the reference name of this instance as <original_reference_name>_<suffix_string>. Without this option, the reference name of the instance with non-zero mask_shift will be the original name.

-rename_cell *cell_renaming_files*

Specifies a file that contains the mapping from original mask shifted cell names to new cell names. The renaming works for both reference library cells and design blocks.

The name mapping comprises three sections: MASKSHIFTLAYER, MASKSHIFTPATTERN and CELLMAP.

For example, to rename the cell A with mask shifting on layer M1 or/and M2, enter the following:

```
<MASKSHIFTLAYER>
M1 M2
</MASKSHIFTLAYER>
<MASKSHIFTPATTERN>
00 01 10 11
</MASKSHIFTPATTERN>
<CELLMAP>
A AM2B NONE AM1BM2B
</CELLMAP>
```

MASKSHIFTLAYER specifies the relevant metal layers, in order, on a single row.

MASKSHIFTPATTERN specifies the mask shift combinations to apply to the metal layers. The digits in each combination correspond to the metal layers listed in MASKSHIFTLAYER, respectively. For example, the 00 combination represents a shift value of 0 on layers M1 and M2; the 01 combination represents a shift value of 0 on layer M1 and 1 on layer M2; the 10 combination represents a shift value of 1 on layer M1 and 0 on layer M2; and so on.

The number of mask shift combinations is less than or equal to pow(m, n), where n is the number of layers specified in MASKSHIFTLAYER and m is the count of the shift values. For 2-mask layers, valid shift values are 0 and 1, so m is 2. In the example above, two metal layers are specified (M1 M2), so there are four mask shift combinations (00 01 10 11).

CELLMAP specifies the cell mappings that correspond to each mask shift pattern for a given cell. (Each row specifies the mappings for a single cell, so the number of mappings in each row corresponds to the number of MASKSHIFTPATTERN combinations.) The **write_verilog** command renames a cell based on the cell's mask_shift attribute and the mapping file content.

In the example above, cell A is mapped to A, AM2B, NONE, and AM1BM2B when its mask_shift attribute is set to 0 on both layers (00), set to 1 on layer M2 (01), set to 1 on layer M1 (10), and set to 1 on both layers (11), respectively. When a mask-shifted cell is not expected for a particular mask shift combination, the cell name is mapped to NONE and **write_verilog** errors out. When a mask-shifted cell is undefined, the mapping file does not contain the corresponding name mappings and **write_verilog** errors out.

By default, the original cell name is preserved in the output verilog file.

DESCRIPTION

This command writes a hierarchical Verilog netlist from the current design. The current design is automatically linked if it is not already linked. The modules are ordered bottom-up by default, or top-down if you use the **-top_module_first** option. If the design is not linked and auto-linking fails, only the modules of the current design are written.

Before you use the **write_verilog** command, to change the names of objects in the design to conform to Verilog naming conventions, use the **change_names -rules verilog** command.

When you use the **-include** option, the command writes out the basic logic netlist and only the objects specified with this option. When you use the **-exclude** option, the command writes out everything except for the objects specified with this option. If you use neither of these options, the output includes everything except scalar wire declarations, leaf module declarations, PG objects, and connections to unconnected ports. This is equivalent to specifying:

```
-exclude { scalar_wire_declarations leaf_module_declarations
        pg_objects unconnected_ports }
}
```

These are the valid values for the *include_list* and *exclude_list*:

```
GENERAL
------------------------------
```

empty_modules Module declarations for hierarchical (non-leaf) cells, which may have port declarations, but no internal module instances and net connections regardless of dangling nets in it. Both the empty module and its cell instances will be included or excluded.
leaf_module_declarations Module declarations for leaf-level cells. These module declarations contain port declarations, but no internal module instances.
scalar_wire_declarations Scalar wire declarations.
shadow_netlist Shadow netlist cells, nets, ports, and pins.
unconnected_ports Connections to unconnected ports on module instances. These connections are written out with a net named "SYNOPSYS_UNCONNECTED_" plus a unique integer.

POWER AND GROUND

analog_pg Analog power and ground nets, ports, and pin connections.
pg_netlist Power and ground nets, ports, and pin connections.
pg_objects All power and ground objects. Specifying this value is equivalent to specifying the analog_pg, pg_netlist, and supply_statements values.
supply_statements Supply1 and Supply0 declarations for power and ground nets.
user_pg Power and ground nets, ports, and pins, along with tie nets, which have **is_user_pg** attribute values of true.

CELL TYPE

all_physical_cells Physical cells in any of the below categories. Specifying this value is equivalent to specifying all of the other individual values below.
corner_cells Physical cells with design_type "corner".
cover_cells Physical cells with design_type "cover".
diode_cells Physical cells with design_type "diode".
end_cap_cells Physical cells with design_type "end_cap".
feedthrough_cells Physical cells with design_type "feedthrough".
filler_cells Physical cells with design_type "filler".
flip_chip_driver_cells Physical cells with design_type "flip_chip_driver".
flip_chip_pad_cells Physical cells with design_type "flip_chip_pad".
pad_cells Physical cells with design_type "pad".
pad_spacer_cells Physical cells with design_type "pad_spacer".
physical_only_cells Physical cells which are physical-only (i.e., cell is_physical_only attribute is true).
spare_cells Physical cells which are unconnected or only connected to constant nets.
well_tap_cells Physical cells with design_type "well_tap".

The *include_list* also allows the following value:

all All of the objects in the other categories

EXAMPLES

The following example writes a Verilog file:

```
prompt> write_verilog my_output.v
```

The following example writes a Verilog file with all constructs and objects:

```
prompt> write_verilog -include {all} my_output.v
```

The following example writes a Verilog file with everything except cover and well tap cells.

```
prompt> write_verilog -exclude {cover_cells well_tap_cells} my_output.v
```

The following example writes a Verilog file with everything except scalar wire declarations and leaf module declarations. It implicitly includes all physical cells, the PG netlist, and supply statements.

```
prompt> write_verilog -exclude \
  { scalar_wire_declarations leaf_module_declarations} my_output.v
```

The following example writes a Verilog file with everything except scalar wire declarations, leaf module declarations, and supply statements. It implicitly includes all physical cells and the PG netlist.

```
prompt> write_verilog -exclude {scalar_wire_declarations \
  leaf_module_declarations supply_statements} my_output.v
```

The following example writes a Verilog file containing the user PG netlist and associated supply statements, but omits the non-user PG netlist.

```
prompt> write_verilog -include {user_pg supply_statements} my_output.v
```

The following example writes a Verilog file containing the modules mid and bot.

```
prompt> write_verilog -module_list {mid bot} my_output.v
```

SEE ALSO

change_names(2)
read_verilog(2)

write_virtual_pad_file

Saves all existing virtual pad locations and layers to a file.

SYNTAX

status **write_virtual_pad_file**
file_name

Data Types

file_name string

ARGUMENTS

file_name

Specifies a file name into which to write all existing virtual pad locations and layers.

DESCRIPTION

This command saves all existing virtual pad locations and layers to a file.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example saves all existing virtual pads to a file name test.vpad.

prompt> **write_virtual_pad_file test.vpad**
