add_array_to_macro_group

Add macro array to macro group.

SYNTAX

status **add_array_to_macro_group**
-group macro_group
-array macro_array

ARGUMENTS

-macro_group macro_group

Specifies macro group.

-macro_array macro_array

Specifies macro array.

DESCRIPTION

This command add macro array to macro group. All macros of the macro array will be added to the macro group. If the macro array belongs to another macro group before this command, it will be removed from that macro group and added to the new macro group. If the macro group contains macros before the command, those macros and macros of the macro group must belong to the same placeable area, i.e, movebound, voltage area, or block.

EXAMPLES

The following command add macro array array1 to micro group group1

prompt> **add_array_to_macro_group** -group group1 -array array1

SEE ALSO

create_macro_group(2)
remove_array_from_macro_group(2)
add_macro_to_group(2)
remove_macros_from_group(2)
create_macro_array(2)

add_attachment

Adds user defined attachments on a library or a design.

SYNTAX

status **add_attachment**
name
-file_name
-object

Data Types

name string

ARGUMENTS

name

Name of the attachment.

-file_name

Name of the file to be attached.

-object

A library or a design object. A cell library should be used only in Library Manager Shell. lib-cells can not have attachments.

DESCRIPTION

This command adds an attachment to the given library or design. The user attachment is always a file and once attached to the given object, a copy of the file is taken into the database and completely managed by the tool.

EXAMPLES

In the following example an attachment is added to the current block.

prompt> **add_attachment -object [current_block] -file_name test_att.txt test_att**

1

SEE ALSO

remove_attachments(2)

add_buffer

Adds buffer cells on the nets that are connected to the specified pins.

SYNTAX

collection **add_buffer**
[-new_net_names *new_net_names*]
[-new_cell_names *new_cell_names*]
[-inverter_pair]
[-no_of_cells *number*]
object_list
[-lib_cell *buffer_lib_cell*]
[*buffer_lib_cell*]

Data Types

new_net_names list
new_cell_names list
number integer
object_list list
buffer_lib_cell collection

ARGUMENTS

-new_net_names *new_net_names*

Specifies the names of the new nets to add. You must specify one net name per buffer when adding buffers, and two net names per inverter pair when adding inverter pairs. If the specified net name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the net name.

Optionally, if you specify only the common base name, the tool generates new net names by adding unique numeric suffixes to the common base name. The specified names can be any valid net names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance. By default, the command uses the base name eco_net.

-new_cell_names *new_cell_names*

Specifies the names of the new cells to be added. You must specify one cell name per buffer when adding buffers, and two cell names per inverter pair when adding inverter pairs. If the specified cell name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the cell name.

Optionally, if you specify only the common base name, the tool generates new cell names by adding unique numeric suffixes to the common base name. These names can be any valid cell names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance.

By default, the command uses *eco_cell* as the common base name.

-inverter_pair

Adds inverter pairs instead of buffer cells. If you specify this option, you must supply a library cell that has an inverting output. You can use this option when the specified library cell or buffer has both inverting and noninverting outputs.

-no_of_cells ***number***

Specifies the number of buffer cells or inverter pairs to be inserted per net. The inserted repeaters are connected back-to-back in series. By default, the command inserts a single buffer cell or inverter pair per net.

object_list

Specifies a list of nets, pins, or ports that must be buffered. The new buffer cells or inverter pairs are placed close to the specified pins or ports if their cells are placed.

If you specify a net, the tool connects the buffers or inverter pairs such that a new buffer cell is the new load of the original net.

If you specify pins, the tool groups all of the specified pins based on the nets to which they are connected. When the grouped pins are load pins, the tool adds the buffers so that the new buffer cells can drive them. When the grouped pins are driver pins, the tool connects the new buffer cells so that they become the load of the specified driver pin.

-lib_cell ***buffer_lib_cell***

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. This is a required option.

If the library cell has both inverting and noninverting outputs, that is, it can act both as buffer and inverter, the **-inverter_pair** option controls which output is used. If the library cell has multiple outputs, the command uses the first noninverting or inverting output.

buffer_lib_cell

This positional option is exactly equivalent to -lib_cell. And it is mutual exclusive with **-lib_cell**.

DESCRIPTION

This command adds buffers or inverter pairs at one or more specified pins or ports. A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

Like all other netlist editing commands, the command arguments to **add_buffer** must be valid for the command to run successfully. If the command succeeds, the result is a collection of the newly-added cells. If the command fails, the command returns an empty collection or an empty string and does not change the netlist.

By default, each newly-created cell has a name beginning with the eco_cell string and ending with a unique numeric suffix. Each newly-created net has a name beginning with the eco_net string and ending with a unique numeric suffix. To override the automatic name generation by the tool, use the **-new_net_names** and **-new_cell_names** options.

You can mimic buffer addition by using other commands, such as **create_cell**, **create_net**, **disconnect_net**, and **connect_net**. The **add_buffer** command provides a more efficient and safe way to add buffers.

This command support editing a Verilog module in the module aspect, through **edit_module**.

This command will check the editability of the block before adding buffer cells.

This command honors the **design.eco_freeze_silicon_mode** application option. When this application option is **true**, the

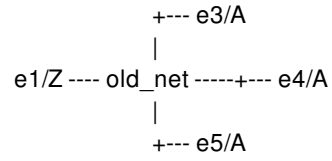
is_fs_eco_add attribute of the added buffers is set to **true**.

The **add_buffer** command uses the following basic rules to check its arguments for validity:

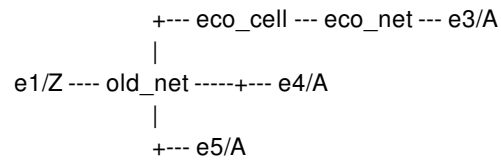
- The pin or port must be in scope; that is, at or below the current instance. For a description of special scoping rules, see the "Buffering Inside Boundary Pins" section.
- The pin or port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The net cannot be either a PG net or a tie net.
- The specified library cell cannot be sequential.
- The specified library cell must be a buffer, as previously defined.
- The *number* argument of the **-no_of_cells** option must be a positive, nonzero integer.
- The library cell must have an inverting output, when you use the **-inverter_pair** option. The command uses the first inverting output and adds two cells so that it preserves the logic of the path.

Adding and Connecting the New Buffer

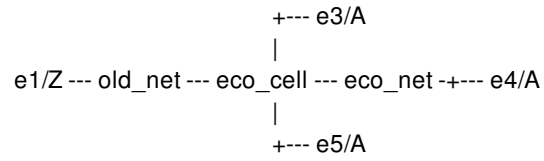
The following figure shows an example network that is used to describe the rules used by the **add_buffer** command to connect the new buffer or inverter pair:



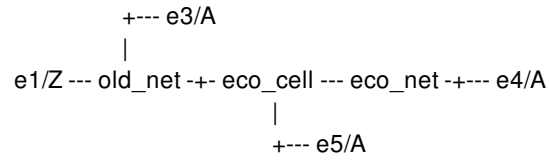
If the specified pin is a load, the load is first disconnected from its old net and then connected to the new net, as shown in the following figure:



If the specified pin is a driver, all loads on that net are disconnected from the old net and are connected to the new net, as shown in the following figure:



If you specify a list of load pins on the same net, these load pins are grouped and the new net drives them, as shown in the following figure:



Note that the tool cannot buffer a net driven by multiple drivers.

Buffering Inside Boundary Pins

When you use this command to add a buffer at a pin on the boundary of a hierarchical block, the command adds the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To add the buffer inside the hierarchical block, set the scope to that block by using the **current_instance** command, and then run the **add_buffer** command. The tool adds the buffer within the block to which the **current_instance** is set.

Don't touch support for nets

When app option *eco.add_buffer.honor_dont_touch* is set to true, nets with dont_touch attribute are skipped.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a library cell that is not a buffer. The command fails and generates an error message.

```
prompt> add_buffer e1/Z -lib_cell class/AN2P
Information: Buffering net old_net. (HFS-701)
Error: library cell 'AN2P' is not a buffer or an inverter. (ECOUI-010)
```

The following example specifies a buffer for the library cell:

```
prompt> add_buffer e1/Z -lib_cell class/B1I
{eco_cell}
```

The following example specifies an inverter for the library cell. The command succeeds and creates the new cells named *eco_cell* and *eco_cell_1*. The new nets are named *eco_net* and *eco_net_1*. The **report_cells** command displays the connections for cell e3.

```
prompt> add_buffer e3/A -lib_cell class/IV -inverter_pair
{eco_cell eco_cell_1}

prompt> report_cells -connections e3
****************************************
Report : cell
 -connections
****************************************

Connections for cell 'e3':

[-verbose]

Data Types

list_of_nets list
buffer_lib_cell string
prefix string
coordinate_list list
user_specified_buffer_list list
length float
user_specified_bus_buffer_list list
bus_cell_prefix_list list
length_ratio float

layer_scale_list list
cell_list list
supply_net string
voltage_area_specific_lib_cell_list list
voltage_areas collection
mv_aware_lib_cell_list list

ARGUMENTS

list_of_nets

Specifies the nets to be buffered. If **-user_specified_buffers** or **-location** is used, this option must specify only a single net name.

-lib_cell ***buffer_lib_cell***

Specifies the library cell object to use as a repeater. The object is either a named library cell or a library cell collection.

The library cell must be either buffer or inverter. The command automatically determines the type of the library cell and inserts buffer or inverter pairs on routes based on the type.

This option cannot be used with the **-user_specified_buffers** or **-user_specified_bus_buffers** options. If **-location**, **-repeater_distance** or **-repeater_distance_length_ratio** is specified, this option must also be specified.

buffer_lib_cell

This positional option is exactly equivalent to the **-lib_cell** option. This option is mutually exclusive with the **-lib_cell** option.

-net_prefix ***prefix***

Specifies the prefix to be used for new nets that are created when buffers are inserted in the netlist. By default, the command uses "eco_net" as the prefix.

-cell_prefix ***prefix***

Specifies the prefix to be used for new buffers that are inserted in the netlist. By default, the command uses "eco_cell" as the prefix. This option cannot be used with the **-user_specified_buffers** option.

-location ***coordinate_list***

Specifies the center point coordinates for the locations of the buffer or inverter pair cells. The format is:

{*x1 y1 layer1 x2 y2 layer2* ...}

You must specify one location per buffer when inserting buffers. You must specify two locations per inverter pair when inserting inverter pairs. These locations can be any valid {x_coordinate y_coordinate layer_name} triplet that is not far away from the placement region of the core area and is relative to the chip origin. These locations must be within a region from the route. The region radius is specified by the **-max_distance_to_route** option. Specify the coordinates in user units. More than one routing shape can overlap the specified location. The layer is used to decide which shape to pick.

- If you specify a valid name for the layer, the location is matched on a routing shape on the specified layer.
- If you specify the **-detect_layer** option, the coordinate_list must use the format {x1 y1 x2 y2}, with no layer name specification. The command tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the command writes out an error message and exits.

For best results, specify the explicit layer instead of using the **-detect_layer** option.

-user_specified_buffers ***user_specified_buffer_list***

Specifies the center point coordinates for the locations of the buffer or inverter pair cells, as well as their names and library cells. The format is:

{*name1 lib_cell1 x1 y1 layer_name1 name2 lib_cell2 x2 y2 layer_name2* ...}

You must specify one five-tuple per buffer when inserting buffers. You must specify two five-tuples per inverter pair when inserting inverter pairs. The names should be valid name strings for buffers or inverters. The library cells should be name strings or collections. They can be all inverters, all buffers or buffers/inverters mixed. When input mixed buffers/inverters, the inverters must be pairs in each branch path. The locations can be any valid coordinates with layers that are not far away from the placement region of the core area and are relative to the chip origin. These locations must be within a region from the route. The region is specified by **-max_distance_to_route**. Specify the coordinates in user units. More than one routing shape can overlap the specified location. The layer is used to decide which shape to pick. This option cannot be used with the **-lib_cell** or **-voltage_area_specific_lib_cells** options.

- If you specify a valid name for the layer, the location is matched on a routing shape on the specified layer.
- If you specify the **-detect_layer** option, the user_specified_buffer_list must use the format { name1 lib_cell1 x1 y1 name2 lib_cell2 x2 y2 }, with no layer name specification. The command tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the command writes out an error message and exits.

For best results, specify the explicit layer instead of using the **-detect_layer** option.

-max_distance_to_route ***length***

Specifies the maximum horizontal or vertical distance in user units between the specified location and route. The default for this option is five times the height of reference cell. You can use this option only if you also use the **-location** or **-user_specified_buffers** option.

-detect_layer

Specifies that the tool detects the layer of location coordinates automatically. The tool tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the tool will error out. When this option is used, the coordinate_list uses the format {x1 y1 x2 y2} or {name1 lib_cell1 x1 y1 name2 lib_cell2 x2 y2}, no layer name specified.

You can use this option only if you also use the **-location** or **-user_specified_buffers** option.

-user_specified_bus_buffers ***user_specified_bus_buffer_list***

Specifies the center point coordinates for the locations of bus buffer or inverter pair cells, as well as their names and library cells, using the format {*bus_buffer_pattern1 lib_cell1 x1 y1 bus_buffer_pattern1 lib_cell2 x2 y2* ...}. You must specify one four-tuple per buffer added on each bit at a location. You must specify two four-tuples per inverter pair when inserting inverter pairs. The *bus_buffer_patterns* should be name strings or collections created by the **create_eco_bus_buffer_pattern** command. The library cells should be name strings or collections. They must be either all inverters or all buffers. The locations can be any valid coordinates that are inside the placement region of the core area and are relative to the chip origin. These locations must be within routes of the bus. Routes of all bits near this point must be parallel and match style (horizontal or vertical) of the specified pattern. For horizontal routes, the center of the bus buffer pattern is located at the x of the specified location. For vertical routes, the center of the bus buffer pattern is located at the y of the specified location. And routes of all bits near this point must be in same situation (e.g. same VA, not over blockage/macro). Specify the coordinates in units of user unit.

This option cannot be used with the **-repeater_distance**, **-repeater_distance_length_ratio**, **-location** or **-user_specified_buffers** options. This option cannot be used with the **-lib_cell** or **-voltage_area_specific_lib_cells** options.

-bus_cell_prefix ***bus_cell_prefix_list***

Specifies the prefix to be used for new buffers that are added by the **-user_specified_bus_buffers** option.

If this option not specified, or the pattern of bus buffers are not listed in *bus_cell_prefix_list*, tool uses the prefix specified by *-cell_prefix*. If *-cell_prefix* is also not specified, default prefix will be name of the bus buffer pattern

You can use this option together with the *-user_specified_bus_buffers* option.

-repeater_distance *length*

Specifies the distance in user units between each buffer to be inserted along the route. This option applies to the entire physical route for the specified nets.

-repeater_distance_length_ratio *length_ratio*

Specifies the distance between each buffer that is inserted along the route as a ratio of the total route length. The value range is between 0.0 and 1.0. This option applies to the entire physical route for the specified nets.

Only one of the **-location**, **-user_specified_buffers**, **-user_specified_bus_buffers**, **-repeater_distance**, or **-repeater_distance_length_ratio** options should be specified.

-first_distance *length*

Specifies the distance in user units between the driver pin and the first buffer introduced along the route. This option must be used together with the **-repeater_distance** or **-repeater_distance_length_ratio** option.

-first_distance_length_ratio *length_ratio*

Specifies the distance between the driver pin and the first buffer introduced along the route as a ratio of the total route length. The value range is between 0.0 and 1.0. This option must be used together with the **-repeater_distance_length_ratio** option.

-scaled_by_layer *layer_scale_list*

Scales the distance between buffers by the scaling factor specified for the layer. Specify the scaling factors by using the following format:

{{*layer1 factor1*} {*layer2 factor2*} ...}

The command scales the distance on each layer with the following formula:

D = d*L_M

d:the repeater distance
D:the repeater scaled distance
L_M:layer scaling factor on metal M

Layers that are not in the list use a default factor of 1. You must specify this option together with the **-repeater_distance** option.

-scaled_by_width

Scales the distance between buffers by the ratio of the default width for the layer and the actual route width. This option is mutually exclusive with the **-only_global_routed_nets** option.

The command scales the distance on each layer with the following formula:

D = d*w_M/w_R

d:the repeater distance
D:the repeater scaled distance
w_M:default route width on metal M
w_R:actual route width

By default, the scaling factor is 1 (w_M=w_R). You must specify this option together with the **-repeater_distance** option.

-only_global_routed_nets

Enable buffer insertion on global routed nets. When this option is used, the specified nets must be only global routed without track assignments or detail routes. This option is mutually exclusive with the **-scaled_by_width** option.

-respect_blockages

Specifies that no buffer should be added within a placement blockage, soft macro, or hard macro.

-allow_insertion_over_cell *cell_list*

Specifies the soft macro or hard macro instances in which the repeaters can be added. This option must be used together with the **-respect_blockages** option.

-dont_allow_insertion_over_cell *cell_list*

Specifies the soft macro or hard macro instances in which the repeaters are not allowed. This option is mutually exclusive with the **-respect_blockages** option.

-max_distance_for_incomplete_route *length*

Defines the maximum search distance for incomplete routes. By default, the search distance is one repeater height.

-snap_to_sites

Snaps the newly added buffers to the nearest sites.

-punch_port

Enables buffer insertion on a route segment, even when the topology is different than the netlist connection in the logical hierarchy. In this situation, the tool creates a hierarchical port to connect the loads of the buffer. This option is mutually exclusive with the **-respect_voltage_areas**, **-voltage_area_specific_lib_cells** and **-respect_gas_station** options.

-respect_gas_station *supply_net*

Buffers will only be added within gas stations (whose is_primary attribute is false) for the specified *supply_net* and along the routes. The buffers that are inserted will belong to the gas station. This option automatically enables the **-respect_voltage_areas** option. This option is mutually exclusive with the **-punch_port** option.

-max_distance_route_to_gas_station *length*

Specifies the distance between the gas station in which the buffer is added the route. If this option is not specified, gas stations must be on the route.

-respect_voltage_areas

Inserts buffers within the hierarchy of the voltage area such that the buffer is physically inside hierarchy in the layout. When this option is specified, buffers cannot be added outside core area. This option is mutually exclusive with the **-punch_port** option.

-voltage_area_specific_lib_cells *voltage_area_specific_lib_cell_list*

Specifies library cell objects to be used in the specified voltage areas. The format is:

{*va1 lib_cell1 va2 lib_cell2* ...}

For the default voltage area, specify DEFAULT_VA as the voltage area name. If a buffer is added within a voltage area that is not specified by this option, the lib cell specified by **-lib_cell** will be used. When the **-voltage_area_specific_lib_cells** is specified, buffers cannot be added outside core area. The **-lib_cell** option is always required when **-voltage_area_specific_lib_cells** is specified. This option will automatically enable the **-respect_voltage_areas** option. This option is mutually exclusive with the **-user_specified_buffers** and **-punch_port** options.

-allow_physical_feedthrough_buffer *voltage_areas*

Specifies voltage areas in which buffers can be added, even if they are physical-only feedthroughs. *voltage_areas* must by a

primary voltage area. This option must be used together with the **-respect_voltage_areas** or **-voltage_area_specific_lib_cells** option.

-on_top_hierarchy

Adds buffers to the net at the highest level of hierarchy. By default, the buffers are added in the lowest common ancestor hierarchy of the pins driven by the buffers.

-max_distance_to_spare_cell ***length***

Specifies the maximum distance between newly added buffers and spare cells in freeze-silicon mode. If this option is not specified, the command uses the default of 5 site heights. For user location based, buffer is inserted at the projected location on the route; there must be a compatible spare cell within the maximum search distance or the command will write out an error message and exit. For repeater distance based, the buffer is added only when there is a compatible spare cell within the maximum search distance. The newly added buffers are placed to overlap the matched spare cells and a new "fs_mapped_cell_name" attribute is added to record the mapping relationship in both buffers and spare cells. The feature of spare cell aware only works in freeze-silicon mode, inverter pair input and some other advanced options. This option is mutually exclusive with the **-not_spare_cell_aware** option.

-not_spare_cell_aware

Disables the spare cell-aware feature in freeze-silicon mode. By default, this option is off. The spare cell-aware feature only works in freeze-silicon mode. This option is mutually exclusive with the **-max_distance_to_spare_cell** option.

-select_mv_buffers ***mv_aware_lib_cell_list***

Specifies single rail and dual rail library cell objects to be used in the specified voltage areas. The format is:

{*va1 single_rail_lib_cell1 dual_rail_lib_cell1 va2 single_rail_lib_cell2 dual_rail_lib_cell2* ...}

When this option is specified, command will enable mv aware features. It will select the mv legal lib cell from the input list to create buffers and update supply net automatically. For the default voltage area, specify DEFAULT_VA as the voltage area name. For the voltage areas not specified by this option, command will use the lib cell specified by **-lib_cell**. This option will automatically enable the **-respect_voltage_areas** option.

-verbose

Shows verbose messages.

DESCRIPTION

This command adds buffers along the route of the specified nets. The new buffers are placed but not legalized, and the original net and the newly created nets are not rerouted.

The new buffers are placed close to the route of the input net. The new nets follow the original route as much as possible. User can query the new buffers by the collection *abor_new_buffers*.

A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

By default, each newly added buffer has a name beginning with the prefix eco_cell and ending with a numeric suffix. To override the automatic name generation by the tool, use the **-net_prefix** and **-cell_prefix** options.

This command also supports spare cell aware feature in freeze-silicon mode.

The **add_buffer_on_route** command uses the following basic rules to validate the command arguments:

- The net cannot be a PG net or a tie net.
- The net can be routed incompletely. But all routing segments must be fully interconnected and there is one and only one wire within search distance from each untouched load pin. The search distance can be specified by the **-max_distance_for_incomplete_route** option.
- The library cell cannot be sequential.
- The library cell must be a buffer or inverter, as previously defined.

This command honors the **design.eco_freeze_silicon_mode** application option. When this application option is true, the is_fs_eco_add attribute is set to true for the inserted buffers.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the command adds buffers on net1 using the lib/BUF library cell. The repeater distance is 100 and the first distance is 80.

```
prompt> add_buffer_on_route -repeater_distance 100 \
  -first_distance 80 net1 -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. One location is specified and let command to detect layer.

```
prompt> add_buffer_on_route -location {100 200} -detect_layer net1 \
  -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. Both location and layer are specified.

```
prompt> add_buffer_on_route -location {100 200 METAL3} net1 \
  -lib_cell lib/BUF
```

The following example adds buffers on net1 by using the **-user_specified_buffers** option.

```
prompt> add_buffer_on_route n1 \
  -user_specified_buffers {eco1 bufbd2 70 10 eco2 bufbd4 140 10} \
  -detect_layer
```

The following example adds buffers on bus data* by using the **-user_specified_bus_buffers** option.

```
prompt> add_buffer_on_route [get_nets data*] \
  -user_specified_bus_buffers "bpuLT bufx8 x1 y1 bpuBR bufx8 x2 y2"
```

The following example adds buffers on net1 using the lib/BUF library cell. Repeater distance is 40 percent of the total route length and a first distance of 20 percent of the total route length is specified.

```
prompt> add_buffer_on_route \
  -repeater_distance_length_ratio 0.4 \
  -first_distance_length_ratio 0.2 \
  net1 -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. A repeater distance of 100 is used. The distance scaling factor for METAL2 is 0.9 and the distance scaling factor for METAL3 is 0.8. The repeat distance is scaled by the route width on each layer.

```
prompt> add_buffer_on_route -repeater_distance 100 \
  -scaled_by_width -scaled_by_layer { {METAL2 0.9} {METAL3 0.8} } \
  net1 -lib_cell lib/BUF
```

The following example snaps the new added buffers to the nearest sites.

```
prompt> add_buffer_on_route -location {100 200 METAL3} net1 \
  -lib_cell lib/BUF -snap_to_sites
```

The following example creates the necessary hierarchical ports after buffer insertion.

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \
  -lib_cell lib/BUF -punch_port
```

The following example inserts buffers while respecting voltage areas.

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \
  -lib_cell lib/BUF -respect_voltage_areas
```

The following example respects voltage areas and adds buffer in physical-only feedthrough voltage areas.

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \
  -lib_cell lib/BUF -respect_voltage_areas \
  -allow_physical_feedthrough_buffer {VA1 VA2}
```

The following example specifies lib cells for voltage areas. Buffers added in va1 will use lib cell BUF1; buffers added in default voltage area will use lib cell buf2; buffers added in all other voltage areas will use lib cell BUF0.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \
  -lib_cell lib/BUF0 \
  -voltage_area_specific_lib_cells {va1 lib/BUF1 DEFAULT_VA lib/BUF2}
```

The following example adds buffers only within 10 user unit of gas stations for net vdd1. The buffers will belong to those gas stations.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \
  -lib_cell lib/BUF -respect_gas_station vdd1 \
  -max_distance_route_to_gas_station 10
```

The following example shows enable mv aware features in add_buffer_on_route.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \
  -lib_cell lib/BUF \
  -select_mv_buffers {VA1 lib/BUFS1 lib/BUFD1 VA2 lib/BUFS2 lib/BUFD2}
```

add_command_hook

Add hook into command execution

SYNTAX

string **add_command_hook** -before *script*
-after *script*
-replace *script*
[-name *name*]
commandName

string *script*
string *script*
string *script*
string *name*
string *commandName*

ARGUMENTS

-before *script*

Hook runs before command.

-after *script*

Hook runs after command.

-replace *script*

Hook runs in place of command.

-name *name*

Name of hook. If no name is specified a name is automatically generated.

commandName

Command to update.

DESCRIPTION

The **add_command_hook** adds a customization point into the execution of an application command. For example, these hooks can

be used to either run a report or gather statistics before and after an application command is run.

Within the body of any hook the get_current_hook_command can be used to query the command and its arguments. For example, a before and after hook may use this information if the hook actions should only happen when specific options are specified. In a replace hook the hook can run the replaced command possibly updating the command options.

This command returns the name of the hook which can be used to remove the hook from the command if desired.

EXAMPLES

Arrange for report timing to be executed every time place_opt_is run.

```
prompt> add_command_hook place_opt -before report_timing
before0
```

Force all report_timing calls to use the -nosplit option.

```
prompt> add_command_hook report_timing -replace {eval [get_current_hook_command] -nosplit}
replace0
```

SEE ALSO

get_command_hooks(2)
remove_command_hook(2)
get_current_hook_command(2)

add_eco_repeater

Adds buffer cells.

SYNTAX

collection **add_eco_repeater**
-cell_name *repeater_name*
-lib_cell *buffer_lib_cell*
-input_net_name *input_net_name*
-output_net_name *output_net_name*
[-load *list_of_pin_or_port_names*]

Data Types

repeater_name	string
buffer_lib_cell	collection
input_net_name	string
output_net_name	string
list_of_pin_or_port_names	list

ARGUMENTS

-cell_name *repeater_name*

Specifies the name of the repeater to add. It should not be same with the name of an existing cell.

-lib_cell *buffer_lib_cell*

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. It must be a buffer or inverter.

-input_net_name *input_net_name*

Specifies the names of the input net. If it is an existing net, it will be connected to the input pin of the repeater; otherwise, a new net will be created as this name and connected to the input pin of the repeater. The net cannot be either a PG net or a tie net.

-output_net_name *output_net_name*

Specifies the names of the output net. If it is an existing net, it will be connected to the output pin of the repeater; otherwise, a new net will be created as this name and connected to the output pin of the repeater. The net cannot be either a PG net or a tie net.

-load *list_of_pin_or_port_names*

The specified loads will be driven by the added repeater. Such pins or ports must be connected with the specified and existing input_net or output_net If this option is not specified, all loads of the existing input_net or output_net will be driven by the added repeater.

DESCRIPTION

This command inserts a repeater in an existing net, to buffer all or part of its loads. You must specify such net as either *input_net_name* or *output_net_name*, while the other net must be specified as a new net.

This command support editing a verilog module in the module aspect, through **edit_module**.

This command will check the editability of the block before adding buffer cells.

This command honors the **design.eco_freeze_silicon_mode** application option. When this application option is **true**, the **is_fs_eco_add** attribute of the added buffers added is set to **true**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies the existing net n1 as *input_net_name* and all of its loads will be buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name n1 \
   -output_net_name newNetName -lib_cell INVLVTD0
```

The following example specifies the existing net n1 as *output_net_name* and all of its loads will be buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name newNetName \
   -output_net_name n1 -lib_cell INVLVTD0
```

The following example specifies the existing net n1 as *output_net_name* and only its loads {U1/A U2/A} will be buffered, other loads connected with n1 will not be buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name newNetName \
   -output_net_name n1 -lib_cell INVLVTD0 -load {U1/A U2/A}
```

The following example shows that this command also support editing a verilog module.

```
prompt> edit_module h1m {add_eco_repeater -cell_name ecoCell \
   -input_net_name newNetName -output_net_name n1 -lib_cell \
   INVLVTD0 -load {U1/A U2/A} }
```

SEE ALSO

edit_module(2)
remove_eco_repeater(2)

add_feedthrough_buffers

Inserts buffers on all feedthrough nets.

SYNTAX

status **add_feedthrough_buffers**
[-type buffer | inverter]
[-buffer_side input | output | both]
[-user_buffer *cell_ref*]
[-nets *nets*]
[-logical]
[-verbose]

Data Types

cell_ref string
nets collection

ARGUMENTS

-type buffer | **inverter**

Specifies the type of cell, buffer or inverter, to use for isolating feedthroughs. By default, a buffer is used.

-buffer_side input | **output** | **both**

Specifies what side of the net should the feedthrough buffer be added. Possible values are "input", "output", or "both". By default, the buffer is added on the output side. This option is honored only for physical feedthroughs, not for logical feedthroughs.

-user_buffer *cell_ref*

Specifies the buffer library cell to use for all feedthroughs.

-nets *nets*

Specifies a collection of nets to work on. Only feedthroughs on ports on those nets will be isolated.

-logical

Inserts logical feedthroughs as well as physical feedthroughs. This option helps to eliminate assign statements in the output Verilog for all nonleaf hierarchical cells.

-verbose

Prints additional debugging information to the terminal.

DESCRIPTION

This command identifies all feedthroughs in the design and buffers them according to command options. By default, the command inserts buffers on a feedthrough net near the output port of the feedthrough.

EXAMPLES

The following example inserts buffers on all physical feedthroughs, with buffers on both input and output ports, with user buffer type "libcell1"

prompt> **add_feedthrough_buffers -buffer_side "both" -user_buffer "libcell1"**

The following example inserts buffers on all physical and logical feedthroughs.

prompt> **add_feedthrough_buffers -logical**

SEE ALSO

remove_feedthroughs(2)

add_group_repeaters

On route repeater planning for a group of nets or bundles.

SYNTAX

collection **add_group_repeaters**
-nets ***collection_of_nets*** | **-bundles** ***collection_of_bundles***
-repeater_distance ***length*** **[-first_distance** ***length*****]** **[-min_distance_repeater_to_load** ***length*****]** **[-tolerance** ***length*****]**
| **-relative_distance** ***distance_list***
| **-number_of_repeater_groups** ***number***
| **-location** ***location_list***
| **-cutlines** ***cutline_list***
[-allow_insertion_over_block]
-lib_cell ***repeater_lib_cell***
[-lib_cell_input ***lib_cell_pin*****]**
[-lib_cell_output ***lib_cell_pin*****]**
[-net_prefix ***prefix*****]**
[-cell_prefix ***prefix*****]**
[-horizontal_repeater_spacing ***spacing*****]**
[-vertical_repeater_spacing ***spacing*****]**
[-snap_pattern ***pattern*****]**
[-preview]
[-layer_cutting_spacing ***list*****]**
[-layer_cutting_distance ***list*****]**
[-honor_special_cell ***collection_of_lib_cells*****]**
[-smart_net_grouping | **-honor_user_net_grouping_id** ***list_of_group_ids*****]**

Data Types

collection_of_bundles	collection
collection_of_nets	collection
length	float
distance_list	list
location_list	list
cutline_list	list
number	integer
lib_cell_pin	string
prefix	string
spacing	integer
pattern	string
layer_cutting_spacing	list
layer_cutting_distance	list
honor_special_cell	collection
list_of_group_ids	list

ARGUMENTS

-nets *collection_of_nets*

Sepcifies multiple nets for adding group repeaters. This option is required.

-bundles *collection_of_bundles*

Sepcifies the multiple bundles for adding group repeaters. This option is required.

-repeater_distance *length* | -relative_distance *distance_list* | -location *location_list*

These three options are mutually exclusive. One of them must be used.

-repeater_distance *length*

Specifies the distance between repeater groups.

-first_distance *length*

Specifies the distance from drivers to the first group of repeaters. Use with -repeater_distance *length*.

-min_distance_repeater_to_load *length*

Specifies the minimum distance from last repeater group to the loads. This is only honored in two-pin nets. Use with -repeater_distance *length*.

-tolerance *length*

Specifies maximum delta distance over repeater distance. Use with -repeater_distance *length*.

-relative_distance *distance_list*

Specifies the distances from drivers to the first group of repeaters, then first group to second group of repeaters, and so on.

-number_of_repeater_groups *number*

Specifies the total number of repeater groups to be inserted. If the lib cell is inverting, the specified number must be even. This option can only be used in two-pin nets.

-location *location_list*

Specifies the center point coordinates for the locations of repeater group centers. The format is:

{*x1 y1 x2 y2 x3 y3* ...}

You must specify one location per repeater group when inserting buffers. You must specify two locations per inverter pair when inserting inverters. These locations can be any valid {x_coordinate y_coordinate} pair that is not far away from the placement region of the core area and is relative to the chip origin. These locations must be within a region from the route. Specify the coordinates in user units.

-cutlines *cutline_list*

Specifies line segments for the locations of repeater group centers. Cutline is a pair of points. It must be orthogonal to the routes. The format is:

{*{{x y1} {x y2}} {{x1 y} {x2 y}}* ...}

You must specify one cutline per repeater group when inserting buffers. You must specify two cutlines per inverter pair when

inserting inverters. These cutlines can be any valid pair of points {{x1 y1} {x2 y2}} that is orthogonal to the routes. Specify the coordinates in user units.

-allow_insertion_over_block

Specified that repeater groups can be inserted on top of blocks. This is optional.

-lib_cell ***lib_cell***

Specifies the library cell object to use as a repeater. The object is either a named library cell or a library cell collection.

The library cell must be either buffer or inverter. The command automatically determines the type of the library cell and inserts buffer or inverter pairs on routes based on the type.

-lib_cell_input ***lib_pin***

Specified the input pin name of the library cell. This is optional.

-lib_cell_output ***lib_pin***

Specified the output pin name of the library cell. This is optional.

-net_prefix ***prefix***

Specifies the prefix to be used for new nets that are created when buffers are inserted in the netlist. By default, the command uses "eco_net" as the prefix.

-cell_prefix ***prefix***

Specifies the prefix to be used for new buffers that are inserted in the netlist. By default, the command uses "eco_cell" as the prefix. This option cannot be used with the **-user_specified_buffers** option.

-horizontal_repeater_spacing ***spacing***

Specified the horizontal spacing between two adjacent repeaters in the horizontal direction in terms of number of site width. For example, when -snap_pattern is checkerboard, if the width of repeater is 9 cell site, then the minimum horizontal spacing is 9. If user specify it less than 9, it will automatically extend the spacing to 9. In order to make the checkerboard pattern, horizontal spacing should be 9,13,17,21... in this case.

-vertical_repeater_spacing ***spacing***

Specified the vertical spacing between repeaters in the vertical direction in terms of number of site height. When -snap_pattern is checkerboard, specified library cell is single site height, the minimum vertical spacing is 1 site height. In order to make a checkerboard pattern, veritcal spacing should be 1,5,9...in this case. When user specify vertical spacing as 4, it will automatically round to 5. For a double site height library cell, user can specify 2,6,10...to ensure checkerboard pattern.

-snap_pattern ***pattern***

Specified repeaters patterns within a group, support pattern: -checkerboard. If user don't specify -snap_pattern, then default snap pattern is checkerboard insertion pattern.

-preview

Display repeaters as gui annotation objects.

-layer_cutting_spacing

Specified the layer cutting spacing list, routes on output side of repeaters are right next to repeaters boundary, routes on input side of repeater can be further away from repeater boundary. Specify the option by using the following format:

{*{layer1 cutting_spacing_1} {layer2 cutting_spacing_2}* ...}

-layer_cutting_distance

Specified the layer cutting distance list, user can define input routes and output routes to cell center distances. Specify the option by using the following format:

{*{layer1 cutting_distance_in_1 cutting_distance_out_1} {layer2 cutting_distance_in_2 cutting_distance_out_2}* ...}

-honor_special_cell *lib_cell_collection*

Specified a collection of lib cells that repeaters will not inserted overlap with these cells.

-smart_net_grouping |-honor_net_group_id *list_of_group_ids*

These two options are mutually exclusive.

-smart_net_grouping

Use smart net grouping algorith to determine repeater locations. Must be used with -cutlines option.

-honor_user_net_grouping_id *list_of_group_ids*

Use existing group id on nets (net attribute eco_net_group_id). User specifies the descending priorities of net groups for repeater insertion.

DESCRIPTION

This command adds repeater groups for given nets or bundles. User specified distances between repeater groups or locations.

This command will creater the following collections: all newly-added repeaters (*agr_new_repeaters*), all the unrouted nets (*agr_unrouted_nets*) and all the nets that failed to insert buffers (*agr_unbuffered_nets*).

EXAMPLES

The following examples show three different usages of command options.

prompt> **add_group_repeaters -bundle {bundle_1 bundle2} -repeater_distance 100**

prompt> **add_group_repeaters -nets pr_nets -relative_distance {70 90 90 60}** \
-lib_cell lib/INV0

prompt> **add_group_repeaters -nets pr_nets -location {200 2500 300 2500 400 2500 500 2500}** \
-lib_cell lib/XOR4 -lib_cell_input "A4" -lib_cell_output "Z"

prompt> **add_group_repeaters -bundles [get_bundles] -lib_cell lib/BUF1 -number_of_repeater_groups 20**

prompt> **add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP -cutlines { {2632 1288} {2632 856} }**

prompt> **add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP -cutlines {{2632 1288} {2632 856}}** \
-smart_net_grouping

prompt> **add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP -cutlines {{2632 1288} {2632 856}}** \
-honor_user_net_grouping_id {3 2 1 6 5 4 0}

SEE ALSO

add_buffer_on_route(2)
create_group_repeaters_guidance(2)

add_macro_to_group

Add macro to macro group.

SYNTAX

status **add_macro_to_group**
-group macro_group
-macros list_of_macros

Data Types

list_of_macros collection of macros

ARGUMENTS

-group macro_group

Specifies macro group.

-macros list_of_macros

Specifies macros.

DESCRIPTION

This command add macros to the macro group. If the macro belongs to another macro group before the command, it will be removed from that macro group and added to the new macro group. If the macro group contains macros before the command, the added macros and existing macros must belong to the same placeable area, i.e, movebound, voltage area, and block. If a macro belongs to a macro array, the array will be added to the macro group.

EXAMPLES

The following command add macros M1, M2 to macro group groups.

prompt> **add_macro_to_groups** -group group1 -macros {M1 M2}

The following command add macro M1 to macro group group1. M1 belongs to a macro array array1. As the result, all macros of the array will be added to the macro group.

```
prompt> create_macro_array -num_rows 2 -num_cols 2 {M1 M2 M3 M4} \
  -name my_edit_group
prompt> add_macro_to_group -group group1 -macros M1
```

SEE ALSO

create_macro_groups(2)
remove_macros_from_group(2)

add_parameter

Define parameters that can be overridden by apply_power_model.

SYNTAX

string **add_parameter**
parameter_name
-default *default_value*
[-type *type_name*]
[-description *description text*]

Data Types

parameter_name	string
default_value	string
type_name	buildtime, runtime, or rate
description text	string

ARGUMENTS

parameter_name

Specifies the name of the parameter to be defined inside a power model.

-default *default_value*

Specifies the default value of the parameter if there is no parameter mapping specified in the **apply_power_model** command.

-type *type_name*

When -type option is specified, the parameter defined is used for system-level IP power model. The parameter scope is within the power model only and power models and power functions cannot access parameters that are defined outside of the power model in which they are used.

Three types of parameters 3 can be defined as follows:

1. Build time - for parameters that remain unchanged during run time
2. Run time - for parameters that can change during run time
3. Rate - for parameters that represent rate-based quantities that can change during run time

-description *text*

Text description of the parameter.

DESCRIPTION

The add_parameter command is used to define parameters for use within a power model. A parameter can be used just like a regular Tcl variable by prepending the parameter name with the $ keyword.

This command can only be defined within the **define_power_model** command and applied to a macro instance through the **apply_power_model** command. It is an error if this command is executed through the **load_upf** command.

The **-parameters** option of the **apply_power_model** command can change the value of a parameter during application of the power model on a macro instance. If the parameter is not found in the **-parameter** option, default value specifed in **add_parameter** will be used.

A power model provides a self-contained environment for variables. Parameters defined outside a power model are not visible inside the power model. Parameters defined within a power model are only visible inside the power model.

EXAMPLES

```
define_power_model MODEL -for {lib_cell} {
  add_parameter PD_NAME -default "PD" -description "power domain in model"
  add_parameter process -type buildtime -default 1.0
  add_parameter cache_miss -type rate -default 0.02
  create_supply_net VDD
  create_supply_net VSS
  create_supply_set SS -function {power VDD} -function {ground VSS}
  create_power_domain $PD_NAME -supply {primary SS} -include_scope
}

apply_power_model MODEL -parameters {{PD_NAME pd_macro}}
```

add_pins_to_virtual_connection

Connects pins or ports to the virtual connection.

SYNTAX

status **add_pins_to_virtual_connection**
-object *virtual_connection*
-pins *pin_port_list*

Data Types

virtual_connection collection
pin_port_list collection

ARGUMENTS

-object *virtual_connection*

Specifies one virtual connection.

-pins *pin_port_list*

Specifies a list of pins and ports to be connected to the virtual connection. The command errors out if any pin is connected to the existing virtual connection.

DESCRIPTION

This command connects pins to the specified virtual connection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples connect pins to the virtual connection.

prompt> **add_pins_to_virtual_connection** \

```
    -object [get_virtual_connections -name SNPS_vc_0] \
    -pins {lh1/ff3/Y U2/A U3/A MemData[0]}

prompt> add_pins_to_virtual_connection \
    -object [get_virtual_connections -name SNPS_vc_0] \
    -pins [get_pins {U2/A U3/A}]

prompt> add_pins_to_virtual_connection \
    -object [get_virtual_connections -name SNPS_vc_0] \
    -pins [get_ports MemData[0]]
```

SEE ALSO

add_port_protection_diodes

Adds diodes around the specified ports to protect them. One diode is added to each specified port.

SYNTAX

status **add_port_protection_diodes**
[-prefix *name*]
[-ignore_dont_touch]
-diode_lib_cell *lib_cell*
-port *ports*

Data Types

name string
lib_cell collection
ports collection

ARGUMENTS

-prefix *name*

Specifies the prefix used to identify the newly added diode cells. By default, no prefix is used and the tool assigns a cell name.

-ignore_dont_touch

Specifies that port protection diodes can be added to nets with the dont_touch attribute.

By default, port protection diodes are not inserted on nets that have the dont_touch attribute.

-diode_lib_cell *lib_cell*

Specifies the name of the library reference cell used for the new diodes. You can specify only a single library cell.

This is a required option.

-port *ports*

Specifies the ports to which to connect protection diodes.

This is a required option.

DESCRIPTION

The **add_port_protection_diodes** command performs the following tasks:

1. Creates the new diodes and adds them into the netlist.
2. Connects the new diodes to the specified ports.
3. Legalizes the diodes.
4. Marks the diodes as fixed.

Use this command in the preroute stage to prevent antenna violations.

Note that if this command succeeds, all of the inserted diodes are located at legal locations and marked as fixed. However, this does not necessarily mean that other movable standard cells are in legal locations. It is possible that some movable standard cells overlap with the inserted diodes. To legalize these standard cells, run the **place_opt**, **clock_opt** command or the **legalize_placement** command.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example runs the **add_port_protection_diodes** command.

```
prompt> add_port_protection_diodes -prefix MY_DIODE \
  -diode_lib_cell [get_lib_cell XXX] -port [all_inputs]
```

SEE ALSO

report_port_protection_diodes(2)
remove_cells(2)
legalize_placement(2)

add_port_state

Defines the names and voltages of the possible states of a supply port for a UPF power state table.

SYNTAX

string **add_port_state**
supply_port_name
-state {*state_name state_value*}

Data Types

supply_port_name string
state_name string
state_value string

ARGUMENTS

supply_port_name

Specifies the name of the supply port. Hierarchical names are allowed. Use only supply port names previously listed in the **create_pst** command.

-state {*state_name state_value*}

Specifies the name and value of a state of the supply port. You can repeat this option in the command to define multiple supply states.

The supply state value can be specified as one of the following:

- A single floating-point number that represents the nominal voltage for the named state:

  -state {sLO 0.88}

- Three floating-point numbers that represent the minimum, nominal, and maximum voltages of the named state:

  -state {sLO 0.88 0.90 0.92}

- The keyword **off**, which represents the inactive state:

  -state {PDOWN off}

DESCRIPTION

The **add_port_state** command adds state information to a supply port for a UPF power state table. The command specifies the name of the supply port and the possible states of the port. Each state is specified as a state name and the voltage level for that state.

State name must meet UPF naming convention. Otherwise tool will issue an error.

You can specify the voltage level as a single nominal value, a set of three values (minimum, nominal, and maximum), or the keyword **off** to indicate the off state. The first state specified is the default state.

A port might be in any of the defined states and can take any voltage within a defined range, so a tool cannot determine the voltage to use from the power state table alone. In most tools, use the **set_voltage** command (a non-UPF command) to specify the operating voltage.

Use the **create_pst** command first, then the **add_port_state** command to specify the names and voltages of the possible states for each supply port, and finally the **add_pst_state** command to specify the allowed combinations of supply states. Here is an example:

```
# Create power state table, specify supply ports for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_port_state PN1     -state {sLO 0.88}
add_port_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_port_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the **create_pst** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the states and voltages of a supply port named VN1:

```
prompt> add_port_state VN1 \
     -state {active_state 0.88 0.90 0.92} \
     -state {off_state off}
```

SEE ALSO

add_pst_state(2)
create_pst(2)
report_pst(2)

add_power_state

Adds power state information to a supply set.

SYNTAX

status **add_power_state**
[-supply]
[-group]
[-domain]
object_name
-state *state_name*
{[-supply_expr {*supply_expression*}]
[-logic_expr {*logic_expression*}]
[-simstate {*simstate*}]
[-illegal]}
[-update]

Data Types

object_name string
state_name string
supply_expression string
logic_expression string
simstate string

ARGUMENTS

-supply | **-group** | **-domain** ***object_name***

Specifies the name of the supply set(-supply) or group(-group) or domain (-domain). The name should be a simple, non-hierarchical name.

-state ***state_name***

Specifies the name of the state of the supply set. The name should be a simple, non-hierarchical name.

-supply_expr {*supply_expression*}

Specifies the net and netstate. The **supply_expression** must use the following syntax if without -supply option

net == *netstate*

The **supply_expression** can use the following syntax if with -supply option

net == *netstate* && *net* == *netstate*

The *net* can be power or ground, and the *netstate* syntax must be one of the following:

status in V2.0 syntax: without -supply option and single == state
`{*status*}
`{*status*, *nom*}
`{*status*, *min*, *max*}
`{*status*, *min*, *nom*, *max*}

status in V3.0 syntax: with -supply option or multiple == state with && supported
{*status*}
{*status nom*}
{*status min max*}
{*status min nom max*}

- *status* can be OFF or FULL_ON
- *min*, *nom*, and *max* are floating-point numbers representing the minimum, nominal, and maximum voltages of the specified state, respectively.
- If the *status* is FULL_ON, at least one voltage must be defined. You can specify one or three voltage values. If three values are specified, they should be in increasing order.

-logic_expr {*logic_expression*} without -group/-domain option

Specifies a SystemVerilog Boolean expression in terms of logic nets and supply nets. The **-logic_expr** option does not affect implementation and is intended to be used by simulation tools, to read and write transparently.

-logic_expr {*logic_expression*} with -group/-domain option

Specifies expression in terms of group/domain state or supply set state. The **logic_expression** can use the following syntax with for group/domain state definition

supplySet/group/PST/domain == state && supplySet/group/PST/domain == state

-simstate {*simstate*}

Specifies a simstate for the power states associated with a supply set, valid values are NORMAL, CORRUPT_ON_ACTIVITY, CORRUPT, NOT_NORMAL, CORRUPT_STATE_ON_CHANGE, CORRUPT_STATE_ON_ACTIVITY, and CORRUPT_ON_CHANGE. The **-simstate** option does not affect implementation and is intended to be used by simulation, so the tool reads and writes the information specified with this option transparently.

-illegal

If specified, the power state is defined as illegal. If not specified (default) the state is legal state.

-update

Indicates this command provides additional information for a previous command with the same object_name and executed in the same scope.

DESCRIPTION

This command defines one or more power states of an object. Power states may be defined for a supply set, a power domain, a group.

If the *object_name* does not already exist as supply set or power state group or power domain, this command issues an error.

For supply set state, -update is supported for new state definition but it's optional.

e.g. prompt > **add_power_state SS1 -state SS1_state1 ...**

To add another SS1_state2, there are three ways to do it:

prompt > **add_power_state SS1 -state SS1_state1 ... -state SS1_state2 ...**
prompt > **add_power_state SS1 -state SS1_state2 ...**
prompt > **add_power_state SS1 -state SS1_state2 ... -update**

For group state, -update is mandatory for new state definition in this release.

prompt > **add_power_state -group GroupA -state A_state1 ...**

To add another A_state2, there are two ways to do it:

prompt > **add_power_state -group GroupA -state A_state1 ... -state A_state2 ...**
prompt > **add_power_state -group GroupA -state SS1_state2 ... -update**

Following without -update is an Error :

prompt > **add_power_state -group GroupA -state SS1_state2 ...**

For supply set state, -update is supported for sub-state conjunctions :

e.g. prompt > **add_power_state SS1 \ -state HPg {-supply_expr {(power == {OFF}) && (ground =={FULL_ON 0})}}**

Or use -update :

prompt > **add_power_state SS1** \
-state HPg {-supply_expr {(power == {OFF})}
prompt > add_power_state SS1 \
-state HPg {-supply_expr {(ground =={FULL_ON 0})}} -update

Following without -update will cause an Error for duplicated definition of state HPg

prompt > **add_power_state SS1** \
-state HPg {-supply_expr {(ground =={FULL_ON 0})}}

For group state, -update is also supported for sub-state conjunctions:

e.g. prompt> **add_power_state -group group_A \ -state lo2 {-logic_expr {SS1 == HPg && SS2 == HVp}**

Or use -update :

prompt > **add_power_state group1** \
-state lo2 {-logic_expr {SS1 == Hpg}}
prompt > **add_power_state group1** \
-state lo2 {-logic_expr {SS2 == HVp}} -update

We even can create an empty power state first, then update it later:

prompt>**add_power_state SS1 -state ON {}** \
prompt>**add_power_state SS1 ON {-supply_expr {power == FULL_ON}} -update**\

The domain state has same usage as group/supply set, with -update option.

prompt > **add_power_state domain1** \
-state hi_state {-logic_expr {SS1 == HPg && primary == HVp}}

```
prompt > add_power_state domain1 \
      -state off_state {-logic_expr {SS1 == HPg && primary == OFF}} -update
prompt > add_power_state group1 -state hi {-logic_expr {domain1 == hi_state}}
```

EXAMPLES

The following example shows the states and voltages of a supply set, SS1:

```
prompt> add_power_state SS1 \
      -state HVp {-supply_expr {power == `{FULL_ON, 0.88, 0.90, 0.92}}}

prompt> add_power_state SS1 \
      -state HPg {-supply_expr {ground == `{OFF}}}

prompt> add_power_state SS1 -supply \
      -state HPg {-supply_expr {(power == {OFF}) && (ground =={FULL_ON 0})}}

prompt> add_power_state -group group_A \
      -state lo2 {-logic_expr {SS1 == HPg && SS1 == HVp}
```

SEE ALSO

add_pst_state(2)
create_pst(2)
create_supply_set(2)
report_pst(2)

add_pst_state

Defines the states of each of the supply ports or nets for one possible state of the design for a UPF power state table.

SYNTAX

status **add_pst_state**
state_name
-pst *table_name*
-state *supply_states*

Data Types

state_name	string
table_name	string
supply_states	list

ARGUMENTS

state_name

Specifies a name for the power state being defined in the command.

-pst *table_name*

Specifies the name of the power state table previously defined by the **create_pst** command. The power state being defined is added to this power state table.

-state *supply_states*

Lists the supply state names in the order corresponding to the **-supplies** option listing in the **create_pst** command. For the power state being defined, the listed supply states are active for the respective supplies. The supply state names in the list must be defined by previous **add_port_state** commands.

DESCRIPTION

The **add_pst_state** command defines the states of each of the supply ports or supply nets for one possible power state configuration of the design for a UPF power state table.

The command specifies a name for the power state, the name of the power state table previously created by the **create_pst** command, and the states of the supply ports in the same order listed in the **create_pst** command. The voltages corresponding to these supply states are defined by the **add_pst_state** command.

The following script demonstrates the power state definition flow:

```
# Create power state table, specify supply ports for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_port_state PN1     -state {sLO 0.88}
add_port_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_port_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the **create_pst** command.

For a group of supply ports and supply nets directly connected together, the allowable supply states are derived from the shared pool of supply states commonly owned by the members of the group.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following script specifies four allowed combinations of supply states for the power state table named MyPST:

```
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
add_pst_state S4 -pst MyPST -state {sHI sLO PDOWN}
```

add_port_state(2)
create_pst(2)
report_pst(2)

add_redundant_vias

Replaces single-cut vias with multiple-cut via arrays. It can also replace a single-cut via with another single-cut via that has a different contact code.

SYNTAX

status **add_redundant_vias**
[-effort low | medium | high]
[-list_only true | false]
[-timing_preserve_nets *collection_of_nets*]
[-timing_preserve_setup_slack_threshold *slack_value*]
[-timing_preserve_hold_slack_threshold *slack_value*]
[-nets *collection_of_nets*]

Data Types

collection_of_nets	collection
slack_value	float

ARGUMENTS

-effort low | **medium** | **high**

Specifies the effort used to perform redundant via insertion.

The default is medium.

-list_only true | **false**

Controls whether the tool performs redundant via insertion or lists the default via mappings to be used for redundant via insertion.

By default (**false**), the tool performs redundant via insertion.

-timing_preserve_nets *collection_of_nets*

Specifies the nets to preserve timing on.

If you specify this option, the command considers the specified nets as timing critical and skips redundant via insertion on them.

-timing_preserve_setup_slack_threshold *slack_value*

Specifies the setup slack threshold for timing critical nets. The unit of the threshold is in library units.

If you specify this option, the command skips redundant via insertion on all nets with a worst setup slack less than or equal to this value.

-timing_preserve_hold_slack_threshold *slack_value*

Specifies the hold slack threshold for timing critical nets. The unit of the threshold is in library units.

If you specify this option, the command skips redundant via insertion on all nets with a worst hold slack less than or equal to this value.

-nets ***collection_of_nets***

Specifies the nets on which to perform redundant via insertion.

By default, redundant via insertion is performed on all nets.

DESCRIPTION

This command replaces one set of vias in the design with another set. By default, all single-cut vias are replaced with 2-cut via arrays. You can change the behavior by using the **add_via_mapping** command to specify the exact via mapping to be used by this command. From a netlist connectivity point of view, using a single-cut via is no different from using a multiple-cut via array, so additional via cuts in a multiple-cut via array are regarded as redundant vias from this point of view. However, redundant vias can increase yield during manufacturing and are an important design-for-manufacturing (DFM) feature.

The command tries to replace vias when the new via or via array does not introduce any design rule violations. However, sometimes new violations are introduced by accident and the command cleans them up later by performing search and repair.

EXAMPLES

The following example replaces all single cut vias by 2-cut via arrays.

```
prompt> add_redundant_vias
```

The following example replaces single-cut vias named VIA23 with 1x3 via arrays named VIA23 and single-cut vias named VIA34 with 5x1 via arrays named VIA34.

```
prompt> add_via_mapping \
  -from {VIA23 1x1} -to {VIA23 1x3}
prompt> add_via_mapping \
  -from {VIA34 1x1} -to {VIA34 5x1}
prompt> add_redundant_vias
```

The following example replaces single-cut vias named VIA23 with 1x2 via arrays named VIA23 on the net named net1.

```
prompt> add_via_mapping \
  -from {VIA23 1x1} -to {VIA23 1x2}
prompt> add_redundant_vias -nets net1
```

SEE ALSO

add_via_mapping(2)

add_shield_association

Associates shielding shapes and vias to shielded nets.

SYNTAX

status **add_shield_association**
-objects *shape_and_via_list*
-nets *net_list*

Data Types

shape_and_via_list collection
net_list collection

ARGUMENTS

-objects *shape_and_via_list*

Specifies a list of shielding shapes and vias to add to shield association.

-nets *net_list*

Specifies a list of shielded nets to add to shield association.

DESCRIPTION

This command associates the specified shielding shapes and vias to the shielded nets.

EXAMPLES

The following example adds shielding shape 'shape1' and shielded net 'net1' to shield association.

prompt> **add_shield_association -objects shape1 -nets net1**
1

The following example adds shielding via 'via1' and shielded net 'net1' to shield association.

prompt> **add_shield_association -objects via1 -nets net1**

1

SEE ALSO

remove_shield_association(2)

add_spare_cells

Inserts spare cells into the current design.

SYNTAX

status **add_spare_cells**
-cell_name *name*
-lib_cell *reference*
[-num_instances *number*]
-num_cells {*reference number reference number* ...}
[-hier_cell *hierarchy_name*]
[-boundary *{ {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }*]
[-voltage_areas *voltage_area_list*]
[-ignore_blockage_types *blockage_type_list*]
[-density_aware_ratio *percentage*]
[-input_pin_connect_type *tie_low* | *tie_high* | *open*]
[-repetitive_window {width height}]
[-random_distribution]

Data Types

name string
reference collection
number integer
hierarchy_name collection
llx float
lly float
urx float
ury float
x1 float
y1 float
x2 float
y2 float
voltage_area_list list
blockage_type_list list
percentage integer

ARGUMENTS

-cell_name *name*

Specifies the name prefix for the spare cells. An integer suffix is automatically appended to the name prefix for each instance. When a name is generated for a spare cell and the name already exists, the tool automatically assigns a unique name for the spare cell.

-lib_cell ***reference***

Specifies the library cells to insert as spare cells. The input can be names or collections. Use this option together with the **-num_instances** option. This option is mutually exclusive with the **-num_cells** option.

-num_instances ***number***

Specifies the number of instances of each library cell to add as spare cells. Use this option together with the **-lib_cell** option. This option is mutually exclusive with the **-num_cells** option.

-num_cells {*reference number reference number ...*}

Specifies library cell names and the number of instances to insert for each unique library cell. The valid format is {*ref1 num1 ref2 num2 ...*}. This option is mutually exclusive with the **-lib_cell** and **-num_instance** options.

-hier_cell ***hierarchy_name***

Specifies the hierarchy in which to insert the spares cells. The **-hier_cell**, **-boundary** and **-voltage_areas** options are mutually exclusive.

-boundary ***{ {{llx lly} {urx ury}} | {{x1 y1} {x2 y2} ...} }***

Specifies the boundary in which to insert the spares cells. Only one rectangle or rectilinear polygon is allowed for this option. When specifying this option, new spare cells are inserted inside voltage areas within the specified boundary. The **-hier_cell**, **-boundary** and **-voltage_areas** options are mutually exclusive.

-voltage_areas ***voltage_area_list***

Specifies the voltage areas in which the spares cells are added. The new spare cells are added to these specified voltage areas. The **-hier_cell**, **-boundary** and **-voltage_areas** options are mutually exclusive.

-ignore_blockage_types ***blockage_type_list***

Specifies a list of blockage types. The command allows spare cells to be added inside the blockage if blockage type is specified by the option. The command supports all blockage types same as create_placement_blockage, but does not honor any placement constraint that the blockage has. If the option is not used, the spare cells can not be added inside any placement blockage.

-density_aware_ratio ***percentage***

Specifies the percentage of spare cells to be added with density aware. This option allows user to control the percentage of density aware for adding spare cells. The percentage means the percentage of spare cells will be added considering density of existing cells, and the rest will be added evenly. The two spreading ways are both blockage aware.

- The default percentage is 100, that means all new spare cells are added with considering cell density;
- 20 means 20% spare cells will be added based on cell density and 80% spare cells will be added evenly across the design;
- 0 means all new spare cells are added evenly without considering cell density.

-input_pin_connect_type ***tie_low*** **|** ***tie_high*** **|** ***open***

Specifies the connection type of input pins of new spare cells. The valid values are **tie_low**, **tie_high** and **open**.

- **tie_low**: input pins are connected to tie low net.
- **tie_high**: input pins are connected to tie high net.
- **open**: input pins are kept open.

If this option is not specified, the default value is **tie_low**.

-repetitive_window *{width height}*

Add and place spare cells through repetitive windows. The *width* and *height* are distance with micron unit. When this option is specified, spare cells with the specified number and types will be added to each window. And the window will apply repetitively start from the low-left of the placement area. The option *-lib_cell* with *-num_instances* or option *-num_cells* can be used to specify the number and types of spare cells to be added within each window. The specified number is considered the number in each window. For windows that cut by blockage or other voltage areas and windows

For windows whose placeable area is not the same as window size, the cell number will be calculated on the area ratio.

- Windows that cut by blockages or other voltage areas.
- Windows that near the boundary edge when the boundary size is not integral multiple of window size.

-random_distribution

Place all newly added spare cells randomly. The *-random_distribution* and *-density_aware_ratio* options are mutually exclusive. When the option is used, the tool will ignore the current cell density and spare cells are placed with random distribution.

DESCRIPTION

This command adds a specified number of instances of the library cell as spare cells in a design. It adds the spare cells to the logical netlist and places them in corresponding physical regions as evenly as possible, and avoids all placement blockages.

Specifying more than one library cell allows you to place the instances of different library cells evenly throughout the regions. The library cell must exist in your link libraries.

The **-lib_cell** and **-num_instances** options are used together to insert spare cells with same number of instances for different library cells. To add spare cells with a different number of instances from different library cells, use the **-num_cells** option. You must use one of the **-lib_cell** and **-num_cells** options to specify library cells. The **-num_cells** option is mutually exclusive with the **-lib_cell** and **-num_instances** options.

This command provides three options to distribute the spare cells in different ways:

- **-hier_cell** : Spare cells are placed around the existing placed cells of the specified hierarchy. And these spare cells are also placed inside the regions of the voltage area of the specified hierarchy.
- **-boundary** : Spare cells are added to the voltage areas evenly within the specified boundary. These new cells are also added to the corresponding hierarchies.
- **-voltage_areas** : Spare cells are added to the specified voltage areas evenly. These new cells are also added to corresponding hierarchies.
- If none of these three options is specified, the default behavior is to distribute new spare cells to all voltage areas including the default voltage area for the design.

The **-hier_cell**, **-boundary** and **-voltage_areas** options are mutually exclusive.

The new spare cells will not be legalized. You can use **place_eco_cells -legalize_only** or **legalize_placement** to legalize these cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example adds 20 instances of a library cell *and2* with the prefix *SpareCell* to the current design.

```
prompt> add_spare_cells -cell_name SpareCell -lib_cell and2 -num_instances 20
```

The following example adds 15 instances of library cells *and2* and *nor2* with the prefix *SpareCell* in the hierarchical cell *I_SUB*.

```
prompt> add_spare_cells -cell_name SpareCell \
  -lib_cell {and2 nor2} -num_instances 15 -hier_cell I_SUB
```

The following example inserts 10 instances of library cell *and1* and 5 instances of library cell *nor1* with the prefix *SpareCell* in the boundary.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell  -boundary {{5.04 2.52} {120.06 80.4}}
```

The following example inserts 10 instances of library cell *and1* and 5 instances of library cell *nor1* with the prefix *SpareCell* in the specified voltage areas.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -voltage_areas pd2
```

The following example uses the **-ignore_blockage_types** option to allow spare cells to be added inside the blockage with user-specified type.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -ignore_blockage_types {soft partial}
```

The following example uses the **-density_aware_ratio** option to allow user to control the percentage of spare cells to be added with density aware.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -voltage_areas pd2 -density_aware_ratio 100
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -voltage_areas pd2 -density_aware_ratio 80
```

The following example uses the **-input_pin_connect_type** option to control the connection type of the input pins of the new spare cells.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -input_pin_connect_type tie_high
```

The following example uses the **-repetitive_window** option to add spare cells by repetitive window.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -repetitive_window {20 20}
```

The following example uses the **-random_distribution** option.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \
  -cell_name SpareCell -random_distribution
```

add_state_transition

Defined named state transitions between power states of an object.

SYNTAX

status **add_state_transition**
[-supply]
[-domain]
[-group]
object_name
-transition {*transition_name*
[-from *from_list* -to *to_list*]
[-paired {*from_state to_state*}]
[-through *through_list*]
[-legal]
[-illegal]}
[-update]

Data Types

object_name string
transition_name string
from_list list
to_list list
through_list list
from_state string
to_state string

ARGUMENTS

-supply | **-domain** | **-group** ***object_name***

Specifies the name of the supply set(-supply) or domain(-domain) or group (-group). If none of the type is specified, it could be any UPF object which contains the power state. The name should be a simple, non-hierarchical name.

transition_name

Specifies the simple name of transition.

-from ***from_list***

Specifies an unordered list of power state names active before a state transition. Empty list expands to all named power states for the specified object.

-to *to_list*

Specifies an unordered list of power state names active after a state transition. Empty list expands to all named power states for the specified object.

-paired {*from_state to_state*}

Specifies a list of from-state name and to-state name pairs.

-through *through_list*

Specifies list of intermediate states. This option is only applicable when -from/-to options are specified. The effective transition sequence is -from, -through, -to.

-legal | -illegal

Specify the legality of the transition being defined as either legal or illegal. The default is -legal.

-update

Indicates this command provides additional information for a previous command withthe same object_name and executed in the same scope.

DESCRIPTION

The add_state_transition command defines named state transitions between power states of an object.

This is a new command added in UPF 3.0, it replaces the describe_state_transition.

EXAMPLES

The following example shows how to add state transitions:

```
prompt> add_state_transition -domain PDA \
 -transition {turn_on -from OFF_MODE -to NORMAL_MODE}
 -transition {suspend -from NORMAL_MODE -to SLEEP_MODE}
 -transition {resume -from SLEEP_MODE -to NORMAL_MODE}
 -transition {turn_off -from NORMAL_MODE -to OFF_MODE}
prompt> add_state_transition -domain PDA -update\
 -transition {error1 -from OFF_MODE -to SLEEP_MODE -illegal}
```

SEE ALSO

add_power_state(2)
describe_state_transition(2)

add_supply_state

Defines the names and voltages of the possible states of a supply object for a UPF power state table.

SYNTAX

string **add_supply_state**
supply_name
-state {*state_name state_value*}

Data Types

supply_name string
state_name string
state_value string

ARGUMENTS

supply_name

Specifies the name of the supply port, supply net or supply set function. Hierarchical names are allowed.

-state {*state_name state_value*}

Specifies the name and value of a state of the supply. You can repeat this option in the command to define multiple supply states.

The supply state value can be specified as one of the following:

- A single floating-point number that represents the nominal voltage for the named state:

  -state {sLO 0.88}

- The keyword **off**, which represents the inactive state:

  -state {PDOWN off}

DESCRIPTION

The **add_supply_state** command adds state information to a supply object for a UPF power state table. The command specifies the name of the supply object and the possible states of the object. Each state is specified as a state name and the voltage level for that state.

You can specify the voltage level as a single nominal value, or the keyword **off** to indicate the off state. The first state specified is the

default state.

A supply object might be in any of the defined states and can take any voltage within a defined range, so a tool cannot determine the voltage to use from the power state table alone. In most tools, use the **set_voltage** command (a non-UPF command) to specify the operating voltage.

Use the **create_pst** command first, then the **add_supply_state** command to specify the names and voltages of the possible states for each supply, and finally the **add_pst_state** command to specify the allowed combinations of supply states. Here is an example:

```
# Create power state table, specify supply ports or nets for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_supply_state PN1     -state {sLO 0.88}
add_supply_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_supply_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the **create_pst** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the states and voltages of a supply set function named ss1.power:

```
prompt> add_supply_state ss1.power \
    -state {active_state1 0.88} \
    -state {active_state2 0.92} \
    -state {off_state off}
```

add_tie_cells

Inserts tie cells into the current design.

SYNTAX

status **add_tie_cells**
[-objects *object_name_or_collection*]
[-tie_high_lib_cells *lib_cells*]
[-tie_low_lib_cells *lib_cells*]

Data Types

object_name_or_collection collection
lib_cells list

ARGUMENTS

-objects *object_name_or_collection*

Specifies the objects for tie cell insertion. Currently supported object types are pin, port, cell and lib_cell. If this option is not used, all constant pins in current design will be considered for tie cell insertion. If the object type is cell, only the constant pins on the cell will be considered. If the object type is lib_cell, only the constant pins of the cells that match the library cells will be considered.

-tie_high_lib_cells *lib_cells*

Limits the tie high cells that can be used for this invocation of the command. When this argument is supplied, tie cell insertion will only use tie cells that are neither don't use nor don't touch, are for optimization purpose and in the library cell list. A library cell in the list that is not a tie cell will not be used.

-tie_low_lib_cells *lib_cells*

Limits the tie low cells that can be used for this invocation of the command. When this argument is supplied, tie cell insertion will only use tie cells that are neither don't use nor don't touch, are for optimization purpose and in the library cell list. A library cell in the list that is not a tie cell will not be used.

DESCRIPTION

This command adds tie cells to drive constant pins in the design, if there are useable tie cells in the library.

SEE ALSO

set_lib_cell_purpose(2)

add_to_bound

Assigns cells, ports, and groups to a bound in the current design.

SYNTAX

integer **add_to_bound**
bound_object
cell_and_port_and_group_list

Data Types

bound_object	list
cell_and_port_and_group_list	list

ARGUMENTS

bound_object

Specifies the name or collection of a single bound. The bound object can be specified by using the **get_bounds** command. However it must return a collection of one and only one bound object.

cell_and_port_and_group_list

Specifies a list of cells, ports, and groups to assign to the bound. The list may contain names, patterns, or collections. It is an error to include a port which has already been assigned to another bound. If the bound is a move bound, it is an error to include a cell which has already been explicitly assigned to another move bound. If this bound is a group bound, it is an error to include a cell which has already been explicitly assigned to another group bound. If a cell is hierarchical, its child cells are also implicitly in the bound, as well as any cells added to its hierarchy in the future, unless the child cell is assigned to another bound. Cells that belong to a relative placement group cannot be individually added to a bound. All cells of a relative placement group must be added to a bound together. Group objects are only valid when adding to a repelling bound. Furthermore, repelling bounds may contain either cells and ports or groups, but not a mix.

DESCRIPTION

The **add_to_bound** command assigns cells, ports, and groups to an existing bound.

You can change the floorplan by assigning cells to the bound. The placer honors the new bound cells during coarse placement.

EXAMPLES

The following example assigns cells to a bound named "movebound1".

```
prompt> add_to_bound movebound1 { inv1 add1 }
1
```

The following example assigns the hierarchical cell "mid" to the bound. The bound implicitly contains all cells within "mid".

```
prompt> add_to_bound movebound1 [get_cells mid]
1
```

The following example assigns all cells of a relative placement group "rp1" to the bound.

```
prompt> add_to_bound movebound1 [get_cells -of_objects rp1]
1
```

The following example assigns all repelling bound groups to the bound

```
prompt> add_to_bound repellingGroupBound1 [get_groups -filter "is_repelling_bound_group==true"]
```

SEE ALSO

create_bound(2)
get_bounds(2)
remove_bounds(2)
remove_from_bound(2)
report_bounds(2)

add_to_bundle

Adds objects to the specified bundle.

SYNTAX

status **add_to_bundle**
-bundle *bundle*
[-prepend | -before_object *before_object*]
objects

Data Types

bundle collection
before_object collection
objects collection

ARGUMENTS

-bundle *bundle*

Specifies the bundle to which to add the objects.

-prepend

Adds the objects as the first objects in the bundle. This option is mutually exclusive with the **-before_object** option. By default, objects are added to the end of the bundle.

-before_object *before_object*

Adds the objects before the specified object in the bundle. This option is mutually exclusive with the **-prepend** option. By default, objects are added to the end of the bundle.

objects

Specifies the objects to add to the bundle. The objects must be nets, bundles or supernets.

The objects are added to the bundle in the order in which they are specified.

DESCRIPTION

This command adds one or more objects to the specified bundle. By default, the objects are added at the end of the bundle. You can insert objects at the start of the bundle with the **-prepend** option, or insert the objects before a specified object in the bundle with the

-before_object option.

A different type of object than the type of bundle can't be added to the bundle.

EXAMPLES

The following example adds an object to the end of a bundle.

```
prompt> add_to_bundle -bundle [get_bundles BUNDLE_5] [get_nets Clk]
1
```

The following example adds an object to the start of a bundle.

```
prompt> add_to_bundle -bundle [get_bundles BUNDLE_5] \
  -prepend [get_nets Reset]
1
```

SEE ALSO

create_bundle(2)
get_bundles(2)
get_nets(2)
remove_bundles(2)
remove_from_bundle(2)
report_bundles(2)

add_to_collection

Adds objects to a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

collection **add_to_collection**
[-unique]
collection1
object_spec

Data Types

collection1	collection
object_spec	list

ARGUMENTS

-unique

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

collection1

Specifies the base collection to which objects are to be added. This collection is copied to the result collection, and objects matching *object_spec* are added to the result collection. The *collection1* option can be the empty collection (empty string), subject to some constraints, as explained in the DESCRIPTION section.

object_spec

Specifies a list of named objects or collections to add.

If the base collection is heterogeneous, only collections can be added to it.

If the base collection is homogeneous, the object class of each element in this list must be the same as in the base collection. If it is not the same class, it is ignored. From heterogeneous collections in the *object_spec*, only objects of the same class of the base collection are added. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

The *object_spec* has some special rules when the base collection is empty, as explained in the DESCRIPTION section.

DESCRIPTION

The **add_to_collection** command allows you to add elements to a collection. The result is a new collection representing the objects in the *object_spec* added to the objects in the base collection.

Elements that exist in both the base collection and the *object_spec*, are duplicated in the resulting collection. Duplicates are not removed unless you use the *-unique* option. If the *object_spec* is empty, the result is a copy of the base collection.

If the base collection is homogeneous, the command searches in the database for any elements of the *object_spec* that are not collections, using the object class of the base collection. If the base collection is heterogeneous, all implicit elements of the *object_spec* are ignored.

When the *collection1* argument is the empty collection, some special rules apply to the *object_spec*. If the *object_spec* is non-empty, there must be at least one homogeneous collection somewhere in the *object_spec* list (its position in the list does not matter). The first homogeneous collection in the *object_spec* list becomes the base collection and sets the object class for the function. The examples show the different errors and warnings that can be generated.

The **append_to_collection** command has similar semantics as the **add_to_collection** command; however, the **append_to_collection** command can be much more efficient in some cases. For more information about the command, see the man page.

For background on collections and querying of objects, see the **collections** man page.

EXAMPLES

The following example from PrimeTime uses the **get_ports** command to get all of the ports beginning with 'mode' and then adds the "CLOCK" port.

```
pt_shell> set xports [get_ports mode*]
{"mode[0]", "mode[1]", "mode[2]"}
pt_shell> add_to_collection $xports [get_ports CLOCK]
{"mode[0]", "mode[1]", "mode[2]", "CLOCK"}
```

The following example from PrimeTime adds the cell u1 to a collection containing the SCANOUT port.

```
pt_shell> set so [get_ports SCANOUT]
{"SCANOUT"}
pt_shell> set u1 [get_cells u1]
{"u1"}
pt_shell> set het [add_to_collection $so $u1]
{"u1"}
pt_shell> query_objects -verbose $het
{"port:SCANOUT", "cell:u1"}
```

The following examples show how the **add_to_collection** command behaves when the base collection is empty. Adding two empty collections yields the empty collection. Adding an implicit list of only strings or heterogeneous collections to the empty collection generates an error message, because no homogeneous collections are present in the *object_spec* list. Finally, as long as one homogeneous collection is present in the *object_spec* list, the command succeeds, even though a warning message is generated. The example uses the variable settings from the previous example.

```
pt_shell> sizeof_collection [add_to_collection "" ""]
0

pt_shell> set A [add_to_collection "" [list a $het c]]
Error: At least one homogeneous collection required for argument 'object_spec'
       to add_to_collection when the 'collection' argument is empty (SEL-014)
```

```
pt_shell> add_to_collection "" [list a $het $sp]]
Warning: Ignored all implicit elements in argument 'object_spec'
        to add_to_collection because the class of the base collection
        could not be determined (SEL-015)
{"SCANOUT", "u1", "SCANOUT"}
```

add_to_edit_group

Adds objects to an edit group in the current design.

SYNTAX

collection **add_to_edit_group**
edit_group_object
object_list

Data Types

edit_group_object list
object_list list

ARGUMENTS

edit_group_object

Specifies the name or collection of a single edit group. The edit group object can be specified by using the **get_edit_groups** command, however it must return a collection of exactly one edit group object.

object_list

Specifies a list of objects to add to the edit group. The list can contain names, patterns, or collections. It is an error to include an object which is already contained within another edit group or one that belongs to a different design.

DESCRIPTION

The **add_to_edit_group** command adds objects to an existing edit group. The command returns a collection containing the modified edit group as the only object, or TCL_ERROR if the command fails.

EXAMPLES

The following example adds objects to an edit group named "edit_group1"

prompt> **add_to_edit_group edit_group1 { U31 voltage_group2 }**
{"edit_group1"}

SEE ALSO

create_edit_group(2)
get_edit_groups(2)
remove_edit_groups(2)
remove_from_edit_group(2)
report_edit_groups(2)

add_to_group

Adds objects to the group in the current design.

SYNTAX

integer **add_to_group**
group
object_list

Data Types

group list
object_list list

ARGUMENTS

group

Specifies the name or collection of groups. The group object can be specified by using the **get_groups** command.

object_list

Specifies a list of objects to add to the group. The list can contain names, patterns, or collections. It is an error to include an object that does not belong to the current design.

Supported object classes are cell, pin, port, net, module, shape, placement_blockage, site_row, via, track, bound, bound_shape, routing_rule, routing_blockage, routing_guide, io_guide, io_ring, voltage_area, voltage_area_shape, pin_blockage, pin_guide, pg_region, edit_group, terminal, routing_corridor, routing_corridor_shape, grid, matching_type, site_array, supernet, shaping_blockage, constraint_group, topological_constraint, via_region, topology_edge, topology_node, overlap_blockage and group.

Supported object classes for repelling bound groups are cell.

DESCRIPTION

The **add_to_group** command adds objects to the group. The command returns the number of objects added into the group. If the command fails, it returns a TCL_ERROR.

EXAMPLES

The following example adds two nets n12, n13 to the group named "group1"

```
prompt> add_to_group group1 [ get_nets { n12 n13} ] }
2
```

SEE ALSO

add_to_io_guide

Adds pads to an I/O guide in the current design.

SYNTAX

int **add_to_io_guide**
[-before *pad_object*]
io_guide_object
pad_cell_list

Data Types

pad_object pad cell
io_guide_object list
pad_cell_list list

ARGUMENTS

-before *pad_object*

Specifies the name or collection of a single library cell. The pads are inserted before the specified pad cell. By default, new cells are added at the end of the list.

io_guide_object

Specifies the name or collection of a single I/O guide. The *io_guide_object* can be specified by using the **get_io_guides** command. However it must return a collection of one and only one io_guide object.

pad_cell_list

Specifies a list of pads to add to the I/O guide. The list can contain names, patterns, or collections. It is an error to include a cell or port which has already been assigned to another io_guide or one that belongs to a different design.

DESCRIPTION

The **add_to_io_guide** command adds pad cells to an existing I/O guide. You can change the floorplan by adding cells to the I/O guide. The I/O placer honors the new io_guide cells during coarse placement.

The command returns 1 if the command succeeds, 0 if it fails, or TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example adds cells to an io_guide named "io_guide1"

```
prompt> add_to_io_guide io_guide1 { bus_4 }
1
```

The following example adds cells to an io_guide named "io_guide1" before pad3.

```
prompt> add_to_io_guide -before bus_4 io_guide1 { bus_2 bus_3 }
1
```

SEE ALSO

remove_from_io_guide(2)
report_io_guides(2)
remove_io_guides(2)

add_to_io_ring

Adds guides to an I/O ring in the current design.

SYNTAX

int **add_to_io_ring**
io_ring_object
guide_list

Data Types

io_ring_object list
guide_list list

ARGUMENTS

io_ring_object

Specifies the name or collection of a single I/O ring. The *io_ring_object* can be specified by using the **get_io_rings** command. However it must return a collection of one and only one io_ring object.

guide_list

Specifies a list of I/O guides to add to the I/O ring. The list can contain I/O guide names, patterns, or collections. It is an error to include a I/O guide which has already been assigned to another I/O ring.

DESCRIPTION

The **add_to_io_ring** command adds I/O guides to an existing I/O ring.

You can change the floorplan by adding I/O guides to the I/O ring. The I/O placer honors the new I/O ring guides during I/O placement.

The command returns 1 if the command succeeds, 0 if it fails, or TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example adds guides to an I/O ring named "io_ring1"

```
prompt> add_to_io_ring io_ring1 { io_guide1 io_guide2 }
1
```

SEE ALSO

remove_io_rings(2)

add_to_matching_type

Assigns cells, pins, and terminals to the matching type.

SYNTAX

int **add_to_matching_type**
matching_type
object_list

Data Types

matching_type list
object_list list

ARGUMENTS

matching_type

Specifies the name or collection of a single matching type. The matching type can be specified by using the **get_matching_types** command. However it must return a collection of one and only one matching type.

object_list

Specifies a list of cells, pins, and terminals to add to the matching type. The list can contain names, patterns, or collections. It is an error to add an object which is already in another matching type. Each object can exist in at most one matching type in the block.

DESCRIPTION

The **add_to_matching_type** command assigns cells, pins, and terminals to an existing matching type.

When I/O placement is performed, objects can be connected only to other objects with the same matching type. The matching type exists only in the block in which it was created, but its containing objects can span into subblocks. As a result, the matching types for the current block can apply to objects in subblocks when performing I/O placement from the current block, but matching types created in other blocks are not visible from the current block.

EXAMPLES

The following example assigns cells to a matching type named "myMatchingType1".

```
prompt> add_to_matching_type myMatchingType1 [get_cells inv1]
1
```

SEE ALSO

create_matching_type(2)
get_matching_types(2)

add_to_multisource_clock_sink_group

Adds clock sinks to a sink group defined for multisource clock tap assignment

SYNTAX

status **add_to_multisource_clock_sink_group**
-name *name*
-sinks *pin_or_port_list*

Data Types

name	string
pin_or_port_list	collection

ARGUMENTS

-name *name*

This required option defines the name of the sink group to which sinks are to be added. Sink groups are defined using the **create_multisource_clock_sink_group** command.

-sinks *pin_or_port_list*

This required option specifies a list of sinks that should get added to the sink list of the sink group given by option **-name**.

DESCRIPTION

The **add_to_multisource_clock_sink_group** command is used to add clock tree sinks to a sink group defined for multisource clock tap assignment.

The list of assigned sinks to a sink group can be obtained by accessing the sink group attribute **sinks**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

This example adds the clock tree sink reg1/CK to sink group sink_group1.

```
prompt> add_to_multisource_clock_sink_group -name sink_group1 -sinks [get_pins reg1/CK]
```

SEE ALSO

add_to_must_join_ports

Combines ports into a new or existing must-join port group.

SYNTAX

integer **add_to_must_join_ports**
port_list

Data Types

port_list collection

ARGUMENTS

port_list

Specifies a port name list or a port collection to form into a must-join group. Ports must be in the current block.

DESCRIPTION

The **add_to_must_join_ports** command combines the specified ports into a must-join port group. The command creates a new must-join port group if none of the ports in port_list are already in a must-join port group. If one of the ports is already in a must-join port group then the other ports will be added to the existing group. If two or more ports are already in must-join port groups then the groups will be merged into a single group and any unassociated ports will be added to the resulting group.

If the port list contains only a single port, the command will remove the port from any must-join port group.

EXAMPLES

The following example creates a must-join port group.

```
prompt> add_to_must_join_ports {A0 A1 A2}
1
```

The following example adds additional ports to the above must-join port group.

```
prompt> add_to_must_join_ports {A0 A3 A4 A5}
1
```

The following example remove a port from its must-join port group.

```
prompt> add_to_must_join_ports {A5}
1
```

add_to_net

Adds shapes, vias and via_matrixes to a net in the current design.

SYNTAX

integer **add_to_net**
net
shape_and_via_list

Data Types

net collection
shape_and_via_list collection

ARGUMENTS

net

Specifies the net to which to add shapes, vias and via_matrixes.

shape_and_via_list

Specifies the shapes, vias and via_matrixes to add to the net. The list may contain names, patterns, or collections. It is an error to include a shape, via or via_matrix which has already been assigned to another net. Text shapes may not be added to a net.

DESCRIPTION

The **add_to_net** command adds shapes, vias and via_matrixes to an existing net. Each shape, via and via_matrix may belong to one and only one net. Rects, polygons, paths, simple vias, simple array vias, and custom vias, via_matrixes may belong to a net. A text shape may not belong to any net.

EXAMPLES

The following example adds path shapes to a net.

```
prompt> add_to_net net1 [get_shapes PATH_16_*]
1
```

The following example adds simple vias to a net.

```
prompt> add_to_net net1 [get_vias VIA_S_*]
1
```

SEE ALSO

get_vias(2)

add_to_net_bus

Adds the specified existing net to the existing net bus in the current design.

SYNTAX

collection **add_to_net_bus**
net_bus
net

Data Types

net_bus collection
net collection

ARGUMENTS

net_bus

Specifies the net bus in which net needs to be added.

net

Specifies the net to add to the net bus. The *net* should have the same base name as the *net_bus*.This net must be existing.

DESCRIPTION

This command adds the existing net to the existing net bus in the current design. Net bus numbering must increment in consecutive order; out-of-order bus nets are not allowed and will cause the tool to issue an error message.

The command returns the updated net bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates a net bus named bus1, then adds net bus1[8] to the net bus named *bus1* having nets from 1 to 7. The third command tries to add an illegal bus net; bus net numbers must increment in consecutive order.

prompt> **create_net_bus -create_nets bus1[0:7]**

{bus1}

prompt> **add_to_net_bus bus1 bus1[8]**
{bus1}

prompt> **add_to_net_bus bus1 bus1[10]**
Error: Net addition will create a hole in the net bus. (NDM-120)

add_to_pin_blockage

Adds pins, nets, or ports to a pin blockage in the current design.

SYNTAX

status **add_to_pin_blockage**
pin_blockages
objects

Data Types

pin_blockages collection
objects collection

ARGUMENTS

pin_blockages

Specifies the pin blockages to which to add the specified objects.

objects

Specifies the physical pins, nets, or ports to add to the pin blockages. The specified objects must have the same type as the objects that already exist in the pin blockage.

DESCRIPTION

The **add_to_pin_blockage** command adds physical pins, nets, or ports to existing pin blockages. The specified objects can be added to multiple pin blockages.

Each pin blockage can contain objects of only one type (either pin, net, or port). It cannot contain a mixture of object types. If a pin blockage already contains pins, it cannot be assigned nets or ports. If a pin blockage already contains nets, it cannot be assigned pins or ports. If a pin blockage already contains ports, it cannot be assigned pins or nets.

EXAMPLES

The following example adds nets to a pin blockage named PIN_BLOCKAGE_1.

```
prompt> add_to_pin_blockage PIN_BLOCKAGE_1 [get_nets net*]
1
```

SEE ALSO

report_pin_blockages(2)
remove_pin_blockages(2)
remove_from_pin_blockage(2)
get_pins(2)
get_ports(2)
get_nets(2)

add_to_pin_guide

Adds pins, nets, or ports to a pin guide in the current design.

SYNTAX

status **add_to_pin_guide**
pin_guides
objects

Data Types

pin_guides collection
objects collection

ARGUMENTS

pin_guides

Specifies the pin guides to which to add the specified objects.

objects

Specifies the physical pins, nets (individual or bundled), or ports to add to the pin guides. The specified objects must have the same type as the objects that already exist in the pin guide. Currently bundles of supernets is not supported. If bundle of supernets is specified then it will be skipped with a warning message.

DESCRIPTION

The **add_to_pin_guide** command adds physical pins, nets, bundles of nets, or ports to existing pin guides. If the parent of a pin guide is the current design, ports or nets can be added to the pin guide. If the parent of a pin guide is a hierarchical cell, pins or nets can be added to the pin guide. Pins, nets, or ports can be added to multiple pin guides.

Each pin guide can contain objects of only one type, either pin, net, or port. It cannot contain a mixture of object types. If a pin guide already contains pins, it cannot be assigned nets or ports. If a pin guide already contains nets, it cannot be assigned pins or ports. If a pin guide already contains ports, it cannot be assigned pins or nets.

EXAMPLES

The following example adds nets to a pin guide named PIN_GUIDE_1.

```
prompt> add_to_pin_guide PIN_GUIDE_1 [get_nets net*]
1
```

add_to_placement_attraction

Assigns cells to a placement_attraction in the current design.

SYNTAX

integer **add_to_placement_attraction**
placement_attraction_object
cell_list

Data Types

placement_attraction_object list
cell_list list

ARGUMENTS

placement_attraction_object

Specifies the name or collection of a single placement_attraction. The placement_attraction object can be specified by using the **get_placement_attractions** command. However it must return a collection of one and only one placement_attraction object.

cell_list

Specifies a list of cells to assign to the placement_attraction. The list may contain names, patterns, or collections. If a cell is hierarchical, its child cells are also implicitly in the placement_attraction, as well as any cells added to its hierarchy in the future. Cells that belong to a relative placement group cannot be individually added to a placement_attraction. All cells of a relative placement group must be added to a placement_attraction together.

DESCRIPTION

The **add_to_placement_attraction** command assigns cells to an existing placement_attraction.

You can change the floorplan by assigning cells to the placement_attraction. The placer honors the new placement_attraction cells during coarse placement.

EXAMPLES

The following example assigns cells to a placement_attraction named "placement_attraction1".

```
prompt> add_to_placement_attraction placement_attraction1 { inv1 add1 }
1
```

The following example assigns the hierarchical cell "mid" to the placement_attraction. The placement_attraction implicitly contains all cells within "mid".

```
prompt> add_to_placement_attraction placement_attraction1 [get_cells mid]
1
```

The following example assigns all cells of a relative placement group "rp1" to the placement_attraction.

```
prompt> add_to_placement_attraction placement_attraction1 [get_cells -of_objects rp1]
1
```

add_to_port_bus

Adds the specified existing port to the existing port bus in the current design.

SYNTAX

collection **add_to_port_bus**
port_bus
port

Data Types

port_bus collection
port collection

ARGUMENTS

port_bus

Specifies the port bus in which port needs to be added.

port

Specifies the port to add to the port bus. The *port* should have the same base name as the *port_bus*.This port must be existing.

DESCRIPTION

This command adds the existing port to the existing port bus in the current design. Port bus numbering must increment in consecutive order; out-of-order bus ports are not allowed and will cause the tool to issue an error message.

The command returns the updated port bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates a port bus named bus1, then adds port bus1[8] to the port bus named *bus1* having ports from 1 to 7. The third command tries to add an illegal bus port; bus port numbers must increment in consecutive order.

prompt> **create_port_bus -create_ports bus1[0:7]**

{bus1}

prompt> **add_to_port_bus bus1 bus1[8]**
{bus1}

prompt> **add_to_port_bus bus1 bus1[10]**
Error: Port addition will create a hole in the port bus. (NDM-115)

add_to_routing_corridor

Associates nets, supernets, and their bundles with a routing corridor.

SYNTAX

status **add_to_routing_corridor**
routing_corridor
object_list

Data Types

routing_corridor list
object_list list

ARGUMENTS

routing_corridor

Specifies the routing corridor with which to associate the specified nets.

This is a required option.

object_list

Specifies the nets and supernets (individual or bundled) to associate with the routing corridor.

This is a required option.

DESCRIPTION

This command associates nets, supernets, and their bundles with a routing corridor.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example associates the nets named net_a and net_b with the routing corridor named corridor_a.

```
prompt> add_to_routing_corridor \
  corridor_a [get_nets [list net_a net_b]]
```

The following example associates the supernet named supernet_1 with the routing corridor named corridor_a

```
prompt> add_to_routing_corridor \
  corridor_a supernet_1
```

add_to_rp_group

Adds cell, relative placement group or relative placement blockage to a relative placement group in the current design.

SYNTAX

integer **add_to_rp_group**
rp_group_object
[-row *row_number*]
[-column *column_number*]
[-override_alignment *left* | *right*]
-cells *cell_list*
[-num_rows *number_of_rows*]
[-num_columns *number_of_columns*]
[-pin_name *pin_name*]
[-orientation *direction*]
[-free_placement]
[-height *object_height*]
[-width *object_width*]|
-rp_group *rp_group_object* |
-blockage *blockage_name*
[-width *object_width*]
[-height *object_height*]
[-allow_overlap]

Data Types

rp_group_object collection
row_number integer
column_number integer
left string
right string
cell_list list
number_of_rows integer
number_of_columns integer
pin_name string
direction list
object_height integer
object_width integer
blockage_name string

ARGUMENTS

rp_group_object

Specifies the name or collection of a single relative placement group, to which the objects will be added. The relative placement object can be specified by using the **get_rp_groups** command. However it must return a collection of one and only one relative placement group.

-row ***row_number***

Specifies the row position in which to add the object. If you do not specify the row position, the default is zero.

-column ***column_number***

Specifies the column position in which to add the object. If you do not specify the column position, the default is zero.

-override_alignment ***left*** | ***right***

Specifies the type of the override alignment for the specified relative placement object in its column. The specified override alignment will override the alignment type that was inherited from its parent relative placement group. The right override alignment is not supported for the multi column relative placement cell.

-cells ***cell_list***

Specifies a list of cells to add to the relative placement group. If this command option is used with *free_placement* command option then all the cells specified in the list will be added otherwise, only the first cell of the list will be added to the RP group location. The list may contain names, patterns, or collections. It is an error to include a cell, which has already been assigned to another relative placement group. The hard macro cells can also be added to RP group.

-num_rows ***number_of_rows***

Specifies the number of rows to which you add the cell(s). The default is 1 if you do not specify this option. This option can also be used with *-free_placement* for adding free placement cells.

-num_columns ***number_of_columns***

Specifies the number of columns to which you add the cell(s). The default is 1 if you do not specify this option. The pin alignment is not supported for a cell that occupies multiple columns. This option can also be used with *-free_placement* for adding free placement cells.

-pin_name ***pin_name***

Specifies the name of the pin to use for pin alignment of this cell with other cells in a group. This overrides the default pin name specified for the relative placement group into which it is being added. This option can only be used when adding a leaf cell with the **-cells** option. The option is not applicable on hard macro cells.

-orientation ***direction***

Specifies the placement orientation of the cell, with respect to the group in which the cell is being added. You can specify a list of possible orientations, and the tool chooses the first legal orientation for the cell. The option is not applicable on hard macro cells.

-free_placement

Specifies that the given cells will not have a fixed relative location inside the relative placement group. The default value is false and it can be used only with the -cells option. This option is used along with *-num_rows*, *-num_columns*, *-height* and *-width* options. The *-num_rows* and *-num_columns* options will specify number of rows and columns to which free placement cells will be added. The *-height* and *-width* options will specify the height and width of the free placement region.

-height ***object_height***

Specifies the height of the blockage being added when used with the **-blockage** option or the height of the free placement region when used with **-free_placement**. option. The unit for height is the height of the site row for a particular library. If you do not specify the height, it defaults to the site row height.

-width ***object_width***

Specifies the width of the blockage being added when used with **-blockage** or the width of the free placement region when used with **-free_placement**. The unit for width is the width of the site row for a particular library. If you do not specify the width, it defaults to the width of the site for horizontal_compression **tiling_type** and for other tiling types it is the width of the column into which the blockage is being added. If you do not specify the width with **-free_placement** option, the width of free placement region defaults to the width of the site row.

-rp_group ***hier_rp_group_object***

Specifies the relative placement group name or collection to add to the relative placement group. It is an error to include a relative placement group, which has already been added.

-blockage ***blockage_name***

Specifies the name of the blockage to add to the relative placement group. It is an error to provide a *blockage_name*, which has already been used for some other relative placement blockage.

-allow_overlap

Specifies that the blockage can be placed over fixed objects. It can also overlap with relative placement blockages, but cannot overlap with the relative placement cells. The blockage cannot overlap with fixed objects if the option is not given.

DESCRIPTION

The **add_to_rp_group** command adds cells, relative placement group or relative placement blockage to existing relative placement group. The added object is placed in a particular lattice position of the group as specified by a **row** and **column** options. The hard macro cells also can be added to the relative placement group. The user has to follow a flow when hard macros are present in the relative placement group. Please refer to user guide for more details.

EXAMPLES

The following example uses **add_to_rp_group** to add a cell to an existing relative placement group and then adds that group hierarchically to another existing group.

```
prompt> get_rp_groups grp_ripple
{grp_ripple}

prompt> add_to_rp_group grp_ripple -cells carry_in_1 -row 1 -column 2
1

prompt> add_to_rp_group top_group -rp_group grp_ripple -row 2 -column 2
1
```

The following example uses **add_to_rp_group** to add a blockage to an existing relative placement group.

```
prompt> add_to_rp_group grp_ripple -blockage grp_ripple_blkg2 \
  -row 2 -column 2 -allow_overlap
1
```

The following example uses **add_to_rp_group** to add free placement cells to an existing relative placement group.

```
prompt> add_to_rp_group grp_ripple \
  -cells {carry_in_1 carry_in_2 carry_out_1} -free_placement \
```

-row 1 -column 1 -height 2 -width 5 -num_rows 2 -num_columns 2

add_to_scan_chain

Adds the specified existing stub_chains to the existing scan_chain in the current design.

SYNTAX

collection **add_to_scan_chain**
[-at *index*]
scan_chain
stub_chains

Data Types

index int
scan_chain collection
stub_chains collection

ARGUMENTS

index

Specifies the position within the scan_chain to add the stub_chains.

scan_chain

Specifies the name or collection of the scan chain to which to add stub_chains.

stub_chains

Specifies the name or collection of the stub chains to add into the *scan_chain*.

DESCRIPTION

This command adds the existing *stub_chains* into the existing *scan_chain*. The index value can range from 0 to the number of stub chains in the *scan_chain* minus 1. If *index* is not specified, default position is the end of *scan_chain*.

The command returns 1 if the command succeeds, 0 if it fails, or TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates a stub_chain named stub1, a scan_chain named scan1 and then adds the stub_chain stub1 to the scan_chain scan1 at the default index.

```
prompt> create_stub_chain -name stub1
{stub1}

prompt> create_scan_chain -name scan1
{scan1}

prompt> add_to_scan_chain scan1 stub1
1
```

The following example creates 3 stub_chains {stub1, stub2, stub3}, a scan_chain named scan1 having stub_chains {stub1, stub3} and then adds stub_chain stub3 at index 1 into the scan_chain.

```
prompt> create_stub_chain -name stub1
{stub1}

prompt> create_stub_chain -name stub1
{stub2}

prompt> create_stub_chain -name stub1
{stub3}

prompt> create_scan_chain -name scan1 {stub1 stub3}
{scan1}

prompt> add_to_scan_chain -at 1 scan1 stub2
1
```

remove_scan_chains(2)
report_scan_chains(2)

add_via_mapping

Adds via mapping options for redundant via insertion.

SYNTAX

status **add_via_mapping**
-from *via_pattern*
-to *list_of_destination_vias*
[-weight *weight*]
[-transform all | flip | none | rotate]
[-force]
| -from_icc_file *script*

Data Types

via_pattern	string
list_of_destination_vias	list
weight	integer
script	string

ARGUMENTS

-from *via_pattern*

Specifies the vias to be replaced during redundant via insertion.

A via pattern has two parts: viaDefName and site_spec mxn. viaDefName is via definition name. MxN specifies the number of contacts in the horizontal (M) and vertical (N) directions.

This option supports simple vias.

This is a required option and must be specified.

-to *list_of_destination_vias*

Specifies the list of vias to insert during redundant via insertion. This is a required option and must be specified.

This option supports simple vias and custom vias. If a custom via is specified, the target MxN dimension must be 1x1.

-weight *weight*

Specifies the weight of contacts for the vias inserted during redundant via insertion. The weight is an integer between 1 and 30 (inclusive). Via mappings with a higher weight are preferred over via mappings with a lower weight.

The default is 1 for all via mappings.

-transform all | **flip** | **none** | **rotate**

Specifies the types of rotated via arrays that can be used during signal routing and redundant via insertion.

The definition for each mode is:

- **none** : Do not rotate or swap via arrays.
- **flip** : Use 1 x N and N x 1 via arrays as rotated equivalent vias.
- **rotate** : Rotate line via arrays instead of flipping (swapping row and column numbers).
- **all** : Use all four possible via arrays. This option is the default.

-force

Overwrites via mappings with the same "from" and "to" via patterns, if it already exists.

-from_icc_file ***script***

Specifies the script file that contains via mapping settings from IC Compiler **define_zrt_redundant_vias** command.

Before apply the via mapping settings in the script file, all existing via mappings will be removed first.

This option is exclusive with all other options.

DESCRIPTION

This command sets options for redundant via insertion. The redundant via definitions are saved in the design.

This command can also accept a script file that contains the **define_zrt_redundant_vias** command from IC Compiler.

EXAMPLES

The following example sets the options for via replacement with double vias:

```
prompt> add_via_mapping  -from {VIA12 1x1} \
  -to { VIA12 1x2}
```

The following example sets the options for via replacement with weight of 2:

```
prompt> add_via_mapping -from {VIA23_r90 1x1}  \
  -to { VIA23 2x1} -weight 2
```

The following example sets the options for via replacement by a script file:

```
prompt> add_via_mapping -from_icc_file RVI.tcl
```

The RVI.tcl has following content:

```
set VIA_OPT_LIST {
  {"VIA23"         "VIA23"       2     1      2}
  {"VIA23_VV"      "VIA23_VV"    2     1      2}
  {"VIA23"         "VIA23_FBD"   1     1      9}
```

```
    {"VIA23"         "VIA23_FBS"    1     1      8}
    {"VIA23"         "VIA23_PBD"    1     1      7}
    {"VIA23_LONG_V"    "VIA23_PBD"    1     1      8}
    {"VIA23_LONG_H"    "VIA23_FBD"    1     1      9}
}
set _from_list ""
set _to_list ""
set _xfactor_list ""
set _yfactor_list ""
set _to_via_weight_list ""

foreach {_from _to _xfactor _yfactor _to_via_weight} [join $VIA_OPT_LIST] {
    set _from_list           "$_from_list          $_from"
    set _to_list             "$_to_list            $_to"
    set _xfactor_list        "$_xfactor_list       $_xfactor"
    set _yfactor_list        "$_yfactor_list       $_yfactor"
    set _to_via_weight_list    "$_to_via_weight_list   $_to_via_weight"
}
define_zrt_redundant_vias \
-from_via      $_from_list \
-to_via        $_to_list \
-to_via_x_size  $_xfactor_list \
-to_via_y_size  $_yfactor_list \
-to_via_weights $_to_via_weight_list
```

SEE ALSO

remove_via_mappings(2)
report_via_mapping(2)

alias

Creates a pseudo-command that expands to one or more words, or lists current alias definitions.

SYNTAX

string **alias**
[*name*]
[*def*]

Data Types

name string
def string

ARGUMENTS

name

Specifies a name of the alias to define or display. The name must begin with a letter, and can contain letters, underscores, and numbers.

def

Expands the alias. That is, the replacement text for the alias name.

DESCRIPTION

The **alias** command defines or displays command aliases. With no arguments, the **alias** command displays all currently defined aliases and their expansions. With a single argument, the **alias** command displays the expansion for the given alias name. With more than one argument, an alias is created that is named by the first argument and expanding to the remaining arguments.

You cannot create an alias using the name of any existing command or procedure. Thus, you cannot use **alias** to redefine existing commands.

Aliases can refer to other aliases.

Aliases are only expanded when they are the first word in a command.

EXAMPLES

Although commands can be abbreviated, sometimes there is a conflict with another command. The following example shows how to use **alias** to get around the conflict:

```
prompt> alias q quit
```

The following example shows how to use **alias** to create a shortcut for commonly-used command invocations:

```
prompt> alias include {source -echo -verbose}

prompt> alias rt100 {report_timing -max_paths 100}
```

After the previous commands, the command **include script.tcl** is replaced with **source -echo -verbose script.tcl** before the command is interpreted.

The following examples show how to display aliases using **alias**. Note that when displaying all aliases, they are in alphabetical order.

```
prompt> alias rt100
rt100  report_timing -max_paths 100

prompt> alias
include  source -echo -verbose
q  quit
rt100  report_timing -max_paths 100
```

SEE ALSO

unalias(2)

align_objects

Aligns specified objects.

SYNTAX

status **align_objects**
[-anchor *object_list*]
[-parent]
[-to *point*]
[-to_box *box*]
[-side *alignment_side*]
[-anchor_side *anchor_side*]
[-offset *offset*]
[-skip_anchor]
[-group]
[-margin]
[-force]
[-simple]
[*object_list*]

Data Types

object_list collection
point float
box list
alignment_side string
anchor_side string
offset float

ARGUMENTS

object_list

Collection or selection set containing objects to align. If this option is not specified, the global selection set is used.

-anchor *object_list*

Specifies the objects to which other objects are aligned.

-parent

Aligns objects to the parent edge.

For terminals and I/O pads, the parent object is the die. For soft macro pins, the parent object is the soft macro. For all other objects, the parent is the core.

-to *point*

Specifies a point with which to align the objects.

-to_box *box*

Specifies a box with which to align the objects.

-side *alignment_side*

Specifies the side of the object to be aligned. The valid value is one of **left**, **right**, **hcenter**, **bottom**, **top**, **vcenter**.

The description of the valid values are as follows:

left - align to the left side
right - align to the right side
top - align to the top side
bottom - align to the bottom side
hcenter - align to the horizontal center
vcenter - align to the vertical center

The default is **left**.

-anchor_side *anchor_side*

Specifies the anchor object side to use when aligning objects. Valid values are **auto**, **ll**, **ur**, or **center**.

auto - determine anchor side automatically
ll - align to the lower-left side of the anchor object
ur - align to the upper-right side of the anchor object
center - align to the center of the anchor object

The default is auto.

-offset *offset*

Specifies the offset from the specified anchor object's side. The default is **0.0**.

-skip_anchor

When **-offset** is specified and anchor is not given explicitly with -anchor/-parent/-to/-to_box options then this option allows to skip implicit anchor object when applying offset. This option is not compatible with -anchor, -parent, -to or -to_box options and requires -offset option be specified.

-group

Treat the objects as a single object. If you specify **-group**, the tool maintains the relative position between the specified objects. Be default, objects are treated individually.

-margin

Use extended objects boundaries. When you specify **-margin**, the block boundaries are extended with keepout margins and voltage area boundaries are extended with guard bands. To exclude certain block keepout margins from consideration, use the following command:

```
prompt> win_set_filter -class cell \
  -filter {hard_macro_margin hard_margin route_blockage_margin soft_margin}
```

-force

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using **get_edit_setting**.

-simple

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using **get_snap_setting**.

DESCRIPTION

This command aligns a list of unfixed objects so that their left, right, top, or bottom edges are coincident with, or at a specified offset from, an anchor object or anchor position.

You can specify an anchor object or anchor position, or allow the command to automatically determine the anchor object from the supplied list of objects by using the following algorithm:

- If any objects are marked as fixed, the anchor object is selected from the set of fixed objects. The rightmost fixed object is used for right alignment, the topmost fixed object is used for top alignment, and so on.
- If no objects are marked as fixed, then the anchor object is the leftmost, rightmost, topmost, or bottommost object for alignment of left, right, top, and bottom, respectively.

NOTE:Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example moves the currently selected objects so that their left edges are *20* units from the left edge of the core.

```
prompt> align_objects -parent -offset 20
```

The alternative syntax uses a collection to specify the objects.

```
prompt> align_objects [get_selection] -parent -offset 20
```

align_pins

Aligns the specified block pins with their connected pins. If no block pins are specified, the command aligns the currently selected block pins.

SYNTAX

status **align_pins**
[*object_list*]
[-change_layer_width]
[-change_layer_height]

Data Types

object_list collection

ARGUMENTS

object_list

Specifies a collection or selection list that contains pins to align. If this option is not specified, the global selection list is used.

-change_layer_width

Changes the pins' layer and width to match the layer and width of the connected pin.

-change_layer_height

Changes the pins' layer and height to match the layer and width of the connected pin.

DESCRIPTION

This command aligns pins specified in *object_list* or the currently selected pins. Pins are aligned with the pins to which they connect based on the current snapping constraints. For each pin to align, the tool finds another pin that connects to the same net and uses the connected pin as an anchor object. After the command completes, the center points for both the selected pin and the anchor pin should be on the same horizontal or vertical lines if both pins satisfy the current snapping constraints.

Note that the **align_pins** command does not consider side, layer, offset, and other pin constraints specified by the **set_individual_pin_constraints**, **set_block_pin_constraints**, or **read_pin_constraints** commands. To place pins while honoring constraints set by these commands, use the **place_pins** command.

You should only use the **align_pins** command when the connected pins are physically close and have no obstacles between them. This command does not perform overlap checking or blockage avoidance. Alignment is not performed and the pin is not moved if

any of the following are true:

- Pins are marked as fixed
- Selected objects are not of type pin, port, or terminal
- Pins belong to a power or ground net
- Pins have multiple terminals that do not intersect

Note that snapping is done automatically based on global snap settings.

EXAMPLES

The following example moves the currently selected pins so that the pins align either horizontally or vertically with their connected pins.

```
prompt> align_pins
```

The following example aligns the currently selected pin and changes the layer and width of the selected pin to match the layer and width of the connected pin.

```
prompt> align_pins -change_layer_width
```

The following example uses an alternative syntax to specify a collection of objects.

```
prompt> align_pins [get_pins I_ALU/OUT[2]]
```

all_clocks

Creates a collection of all clocks in the specified design.

SYNTAX

collection **all_clocks**
[-design *design*]
[-mode *mode*]

Data Types

design collection
mode collection

ARGUMENTS

-design *design*

Specifies the design for which to return the clocks. You can specify only a single design.

If you do not specify this option, the command returns all clocks in the current design.

-mode *mode*

Specifies the mode for which to return the clocks. You can specify only a single mode.

If you do not specify this option, the command returns all clocks in the current mode.

DESCRIPTION

The **all_clocks** command creates a collection of all clocks in the specifed design. If you did not define any clocks, the empty collection (empty string) is returned.

If you want only certain clocks, use the **get_clocks** command to create a collection of clocks that match a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following example applies the **set_propagated_clock** command to all clocks in the design.

```
prompt> set_propagated_clock [all_clocks]
```

SEE ALSO

collections(2)
create_clock(2)
get_clocks(2)
set_propagated_clock(2)

all_connected

Creates a collection of objects connected to nets, scalar nets of net_bus, pins, ports or scalar ports of port_bus.

SYNTAX

collection **all_connected**
[-leaf]
[-physical_context]
objects

Data Types

objects list

ARGUMENTS

-leaf

Specifies that only leaf pins are returned for a hierarchical net.

For nonhierarchical nets, there is no difference in output.

-physical_context

Searches physical objects rather than logical objects.

When specified for nets, the command returns physical pins or ports. For pins and ports, the command returns the physical net, which might be in a different hierarchy and connected to the pin through hierarchical pins or ports.

objects

Specifies the objects whose connections are returned. You must specify objects that are nets, net_bus, pins, ports or port_bus.

This is a required argument.

DESCRIPTION

The **all_connected** command creates a collection of objects connected to the specified nets, net_buses, pins, ports or port_buses. The collection can contain nets, ports, pins, or a combination of ports and pins. In the latter case, the ports are first, followed by the pins.

When issued from the command prompt, the **all_connected** command behaves as though the **query_objects** command has been

called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the **shell.common.collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example shows all objects connected to the net named CLOCK.

```
prompt> query_objects -verbose [all_connected [get_nets CLOCK]]
{{port CLOCK} {pin U1/CP} {pin U2/CP} {pin U3/CP} {pin U4/CP}}
```

The following example shows all objects connected to the net_bus N.

```
prompt> all_connected N
{{P[7]} {P[6]} {P[5]} {P[4]} {P[3]} {P[2]} {P[1]} {P[0]}}
```

SEE ALSO

collections(2)
get_nets(2)
get_pins(2)
get_ports(2)
query_objects(2)
shell.common.collection_result_display_limit(3)

all_corners

Creates a collection of all corners in the current design. You can assign these corners to a variable or pass them into another command.

SYNTAX

collection **all_corners**
[-design *design*]

Data Types

design collection

ARGUMENTS

-design *design*

Name of the top design. The default is the current design.

DESCRIPTION

The **all_corners** command creates a collection of all corners in the current design. If you do not define any corners, a collection containing the default corner is returned.

If you want only certain corners, use **get_corners** to create a collection of corners matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all corners.

SEE ALSO

collections(2)
create_corner(2)
current_corner(2)
get_corners(2)

all_exceptions

Creates a collection of all timing exceptions in the current design.

SYNTAX

collection **all_exceptions**
[-design *design*]
[-mode *mode*]

Data Types

design	collection
mode	collection

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-mode *mode*

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

DESCRIPTION

The **all_exceptions** command creates a collection of all timing exceptions in the current scenario. If no timing exceptions exist, the empty string is returned. You can assign these exceptions to a variable or pass them into another command. Timing exceptions are created by **set_false_path**, **set_multicycle_path**, **set_max_delay** or **set_min_delay**.

If you want only certain exceptions, use **get_exceptions** to create a collection of exceptions matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

This example sets the variable allExcepts to a collection of all timing exceptions in the design.

```
prompt> set allExcepts [all_exceptions]
```

SEE ALSO

collections(2)
set_false_path(2)
set_multicycle_path(2)
set_max_delay(2)
set_min_delay(2)
get_exceptions(2)
shell.common.collection_result_display_limit(3)

all_fanin

Creates a collection of pins, ports, or cells in the fanin of the specified sinks.

SYNTAX

collection **all_fanin**
[-from *from_list*]
[-through *through_list*]
-to *to_list*
[-flat] [-only_cells]
[-quiet]
[-startpoints_only]
[-levels *level_count*]
[-pin_levels *pin_count*]
[-step_into_hierarchy]
[-trace_arcs timing | enabled | all]
[-continue_trace *pin_types*]

Data Types

from_list list
through_list list
to_list list
level_count integer
pin_count integer

ARGUMENTS

-from *from_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanin of each object in *to_list* becomes part of the resulting collection only if it is in the fanout cone of at least one object in *from_list*. If a net is specified, the effect is the same as listing all load pins on the net.

-through *through_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified the fanin of each object in *to_list* is restricted to objects on paths through the pins, ports or nets in *through_list*.

-to *to_list*

Specifies a list of sink pins, ports, or nets to trace. Each object is a named pin, port, or net or a collection of pins, ports, or nets. The timing fanin of each sink becomes part of the resulting collection. If a net is specified, the effect is the same as listing all driver pins on the net.

This option is required.

-flat

Includes objects throughout the design hierarchy in the result. This means that the only non-leaf objects in the result are hierarchical sink pins.

If you do not specify this option, the result includes only objects within the same hierarchical level as the current sink.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-only_cells

Includes only cells in the timing fanin of the specified sinks in the result and not pins or ports.

-startpoints_only

Includes only the timing startpoints in the result.

-levels ***level_count***

Stops the traversal when it reaches the specified cell depth, where the counting is performed over the layers of cells of the same distance from the sink. This option cannot be used together with **-pin_levels**.

-pin_levels ***pin_count***

Stops the traversal when it reaches the specified pin depth, where the counting is performed over the layers of pins of the same distance from the sink. This option cannot be used together with **-levels**.

-step_into_hierarchy

Performs counting as though the design is flat. Although pins inside the hierarchy are not returned, they determine the depth of the related output pins.

If you do not specify this switch, a hierarchical block at the same level of hierarchy as the current sink is considered to be a cell; the input pins are considered a single level away from the related output pins, regardless of what is inside the block.

This option cannot be used with the **-flat** option and only has effect with either the **-levels** or **-pin_levels** option.

-trace_arcs timing | enabled | all

Specifies the type of combinational arcs to trace during the traversal.

Allowed values are **timing** (the default), which permits tracing only of valid timing arcs (that is, arcs which are neither disabled nor invalid due to case analysis); **enabled**, which permits the tracing of all enabled arcs and disregards case analysis values; and **all**, which permits the tracing of all combinational arcs regardless of either case analysis or arc disabling.

-continue_trace ***pin_types***

This option permits the user to override the default behavior of the traversal which is to stop at all timing startpoints. When used, the travsal is permitted through startpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- **generated_clock_source** - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

DESCRIPTION

The **all_fanin** command creates a collection of objects in the timing fanin of the specified sink pins, ports, or nets in the design. A pin is considered to be in the timing fanin of a sink if there is a timing path through combinational logic from the pin to that sink (see also the **-trace_arcs** option). The fanin stops at the clock pins of registers (sequential cells).

If the current instance in the design is not the top level of hierarchy, only objects within the current instance are returned.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

This example shows the timing fanin of a port in the design. The fanin includes a register, reg1.

```
prompt> query_objects [all_fanin -to out_1]
{"out_1", "reg1/Q", "reg1/CP"}
```

This example shows the flat mode of **all_fanin**. The sink is an input pin of a hierarchical cell, H1, which is connected to an output pin of another hierarchical cell, H2. H2 contains additional hierarchy and eventually, a leaf cell with two inputs, each of which has a top-level register in its fanin.

```
prompt> query_objects [all_fanin -to H1/a -flat]
{"H1/a", "H2/U1/n1/Z", "H2/U1/n1/A", "H2/U1/n1/B",
 "reg1/Q", "reg2/Q", "reg1/CP", "reg2/CP"}
```

This example shows the timing fanin of an output port that passes through pin u1/z or pin u2/z.

```
prompt> query_objects [all_fanin -to out -through {u1/z u2/z}]
{"out", "u3/z", "u3/a", "u3/b", "u1/z", "u1/a", "u2/z", "u2/z",
 "reg1/q", "reg2/q", "reg1/cp", "reg2/cp"}
```

This example shows the timing fanin of an output port the passes through pin u1/z and pin u3/a.

```
prompt> query_objects [all_fanin -to out -through u1/z -through u3/a]
{"out", "u3/z", "u3/a", "u1/z", "u1/a", "reg1/q", "reg1/cp"}
```

SEE ALSO

all_fanout(2)
report_transitive_fanin(2)
current_instance(2)

all_fanout

Creates a collection of pins/ports or cells in the fanout of the specified sources.

SYNTAX

collection **all_fanout**
-from *from_list*
[-through *through_list*]
[-to *to_list*]
[-clock_tree]
[-flat]
[-quiet]
[-only_cells]
[-endpoints_only]
[-levels *level_count*]
[-pin_levels *pin_count*]
[-trace_arcs *arc_types*]
[-step_into_hierarchy]
[-continue_trace *pin_types*]

Data Types

from_list list
through_list list
to_list list
level_count integer
pin_count integer
arc_types string
pin_types string

ARGUMENTS

-from *from_list*

Specifies a list of source pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each source in *from_list* becomes part of the resulting collection. If a net is specified, the effect is the same as listing all load pins on the net. This option is exclusive with the **-clock_tree** option.

-through *through_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified the fanout of each object in *from_list* is restricted to pins on paths through the pins, ports or nets in *through_list*.

-to *to_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each object in *from_list* becomes part of the resulting collection if it is in the fanin cone of at least one object in *to_list*. If a net is specified, the effect is the same as listing all driver pins on the net.

-clock_tree

Indicates that all clock source pins or ports in the design are to be used as the list of sources. Clock sources are specified using **create_clock**. If there are no clocks, or if the clocks have no sources, the result is the empty collection. This option is exclusive with the **-from** option.

-flat

There are two major modes in which **all_fanout** functions: hierarchical (the default) and flat. When in hierarchical mode, only objects within the same hierarchical level as the current source are included in the result. In flat mode, the only non-leaf objects in the result will be hierarchical source pins.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-only_cells

The result will include only cells in the timing fanout of the *from_list* and not pins or ports.

-endpoints_only

When this option is specified, only the timing endpoints will be included in the result.

-levels *level_count*

The traversal will stop when reaching a depth of search of *cell_count* hops, where the counting is performed over the layers of cells of same distance from the source. This option cannot be used together with **-pin_levels**.

-pin_levels *pin_count*

The traversal will stop when reaching a depth of search of *pin_count* hops, where the counting is performed over the layers of pins of same distance from the source. This option cannot be used together with **-levels**.

-trace_arcs *arc_types*

Specifies the type of combinational arcs to trace during the traversal. Allowed values are **timing** (the default), which permits tracing only of valid timing arcs (that is, arcs which are neither disabled nor invalid due to case analysis); **enabled**, which permits the tracing of all enabled arcs and disregards case analysis values; and **all**, which permits the tracing of all combinational arcs regardless of either case analysis or arc disabling.

-step_into_hierarchy

This option may only be used in hierarchical mode and only has effect with either **-levels** or **-pin_levels**. Without the switch, a hierarchical block at the same level of hierarchy as the current sink is considered to be a cell; the output pins are considered a single level away from the related input pins, regardless of what is inside the block. With the switch enabled, the counting is performed as though the design were flat, and although pins inside the hierarchy are not returned, they determine the depth of the related input pins.

-continue_trace *pin_types*

This option permits the user to override the default behavior of the traversal which is to stop at all timing endpoints. When used, the travsal is permitted through endpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- **generated_clock_source** - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

DESCRIPTION

The **all_fanout** command creates a collection of objects in the timing fanout of specified source pins/ports or nets in the design. A pin is considered to be in the timing fanout of a source if there is a timing path through combinational logic from that source to the pin (please also see the **-trace_arcs** option). The fanout stops at the inputs to registers (sequential cells). The sources are specified using either **-clock_tree** or **-from** *from_list*.

If current instance in the design is not the top level of hierarchy, only objects within the current instance will be returned.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

This example shows the timing fanout of a port in the design. The fanout includes a register, reg3.

```
prompt> query_objects [all_fanout -from in1]
{"in1", "reg3/D"}
```

This example shows the difference between the hierarchical and flat modes of **all_fanout**. The source is an output pin of a hierarchical cell, H3/z1, which is connected to an input pin of another hierarchical cell, H4/a. H4 contains a leaf cell U1 with input A and output Z. The first command is hierarchical mode, and shows that hierarchical pins are included in the result. The second command is in leaf mode, and leaf pins from the lower level are included.

```
prompt> query_objects [all_fanout -from H3/z1]
{"H3/z1", "H4/a", "H4/z", "reg2/D"}

prompt> query_objects [all_fanout -from H3/z1 -flat]
{"H3/z1", "H4/U1/A", "H4/U1/Z", "reg2/D"}
```

This example shows how to get the fanout of reg1/CP on paths passing through u1/Z and U3/Z.

```
prompt> query_objects [all_fanout -from reg1/CP -through U1/Z \
        -through U3/A]
{"out", "U3/Z", "U3/A", "U1/Z", "U1/A", "reg1/Q", "reg1/CP"}
```

SEE ALSO

all_fanin(2)
current_instance(2)
report_transitive_fanin(2)

all_high_transitive_fanout

Returns a collection of high-fanout nets from the current design or from the specified input collection. A tie net will be filtered out in the collection.

SYNTAX

collection **all_high_transitive_fanout**
-nets
[-threshold *value*]
[*input_coll*]
[-through_buf_inv]

Data Types

value float
input_coll collection

ARGUMENTS

-nets

Returns the collection of high-fanout nets.

-threshold *value*

Specifies a threshold value used to determine if a net is a high-fanout net. The *value* is a user-specified value. If the value is less than 1, a default value will be the threshold. By default, the value of the **design.high_fanout_net_threshold** application option is used to determine if a net is a high-fanout net.

input_coll

Searches the specified input collection for high-fanout nets. Objects are to be searched only from the contents of the specified input collection, rather than from the design.

-through_buf_inv

Indicates to treat a buffer tree as transparent. The leaf loads of the buffer tree are treated as the fanouts of the net.

DESCRIPTION

The **all_high_transitive_fanout** command returns a collection of all high-fanout nets in the design. The tool searches the entire design hierarchy. It returns nets from the entire design, not just from the top level.

To determine if a net is a high-fanout net, use the **design.high_fanout_net_threshold** option value as the threshold value. The command returns all nets with a fanout count not less than this threshold as high-fanout nets. You can also specify the threshold by using the **-threshold** option.

If you specify a value for *input_coll*, the command searches for high-fanout objects only from the specified collection, rather than from the entire design.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection handle.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the collection of all high-fanout nets from the design:

```
prompt> all_high_transitive_fanout -nets
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from an existing collection stored in $COLL:

```
prompt> all_high_transitive_fanout -nets $COLL
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from the design having a fanout count of more than 100:

```
prompt> all_high_transitive_fanout -nets -threshold 100
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

SEE ALSO

all_transitive_fanin(2)
all_transitive_fanout(2)
foreach_in_collection(2)
sizeof_collection(2)

all_inputs

Creates a collection of all input ports in the current design. You can assign these ports to a variable or pass them into another command.

SYNTAX

collection **all_inputs**
[-level_sensitive]
[-exclude_clock_ports]
[-edge_triggered]
[-clock *clock_name*]

Data Types

clock_name list

ARGUMENTS

-level_sensitive

Only considers ports with level-sensitive input delay. This is specified by **set_input_delay 2 -clock CLK -level_sensitive IN1**. This option cannot be used together with **-edge_triggered**.

-exclude_clock_ports

Excludes input ports which serve as clock sources.

-edge_triggered

Only considers ports with edge-triggered input delay. This is specified by **set_input_delay 2 -clock CLK IN2**. This option cannot be used together with **-level_sensitive**.

-clock *clock_name*

Only considers ports with input delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

DESCRIPTION

The **all_inputs** command creates a collection of all input or inout ports in the current design. You can limit the contents of the collection by specifying the type of input delay that must be on a port.

You can remove clock source ports from the resulting collection by specifying *-exclude_clock_ports* option.

If you want only certain ports, use **get_ports** to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, **all_inputs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable **collection_result_display_limit**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example specifies a driving cell for all input ports.

prompt> **set_driving_cell -lib_cell FFD3 -pin Q [all_inputs]**

SEE ALSO

get_ports(2)
query_objects(2)
report_ports(2)
set_driving_cell(2)
set_input_delay(2)
shell.common.collection_result_display_limit(3)

all_modes

Creates a collection of all modes in the current design. You can assign these modes to a variable or pass them into another command.

SYNTAX

collection **all_modes**
[-design *design_name*]

Data Types

design_name string

ARGUMENTS

-design *design_name*

Name of the top design. The default is the current design.

DESCRIPTION

The **all_modes** command creates a collection of all modes in the current design. If you do not define any modes, a collection containing the default mode is returned.

If you want only certain modes, use **get_modes** to create a collection of modes matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all modes.

EXAMPLES

This script uses the **all_modes** command to perform **report_clocks** one time for each defined mode.

```
foreach_in_collection mode [all_modes] {
  current_mode $mode
  report_clocks
```

```
}
```

SEE ALSO

collections(2)
create_mode(2)
current_mode(2)
get_modes(2)
report_clocks(2)

all_outputs

Creates a collection of all output ports in the current design. You can assign these ports to a variable or pass them into another command.

SYNTAX

collection **all_outputs**
[-level_sensitive]
[-edge_triggered]
[-clock *clock_name*]

Data Types

clock_name list

ARGUMENTS

-level_sensitive

Only considers ports with level-sensitive output delay. This is specified by **set_output_delay 2 -clock CLK -level_sensitive IN1**. This option cannot be used together with **-edge_triggered**.

-edge_triggered

Only considers ports with edge-triggered output delay. This is specified by **set_output_delay 2 -clock CLK IN2**. This option cannot be used together with **-level_sensitive**.

-clock *clock_name*

Only considers ports with output delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

DESCRIPTION

The **all_outputs** command creates a collection of all output or inout ports in the current design. You can limit the contents of the collection by specifying the type of output delay that must be on a port.

If you want only certain ports, use **get_ports** to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, **all_outputs** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable

collection_result_display_limit.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example specifies a pin capacitance for all output ports.

```
prompt> set_load 4.56 [all_outputs]
```

The following example shows the names all of the output ports with output delay relative to PHI1.

```
prompt> all_outputs -clock PHI1
```

SEE ALSO

collections(2)
get_ports(2)
report_ports(2)
query_objects(2)
set_output_delay(2)
shell.common.collection_result_display_limit(3)

all_registers

Creates a collection of register cells or pins. You can assign the resulting collection to a variable or pass it into another command.

SYNTAX

collection **all_registers**
[-clock *clock_name*]
[-rise_clock *rise_clock_name*]
[-fall_clock *fall_clock_name*]
[-cells]
[-data_pins]
[-clock_pins]
[-async_pins]
[-output_pins]
[-level_sensitive]
[-edge_triggered]

Data Types

clock_name list
rise_clock_name list
fall_clock_name list

ARGUMENTS

-clock *clock_name*

Considers all registers clocked by *clock_name*. This is either the name of a clock or a collection containing a clock. For example, all registers whose clock pins are in the fan out of the specified clock.

-rise_clock *rise_clock_name*

Considers all registers clocked by *rise_clock_name* and having open edge effectively the rising clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops without any inversion on the clock path or falling edge triggered flip-flops with inversion on the clock path.

-fall_clock *fall_clock_name*

Considers all registers clocked by *fall_clock_name* and having open edge effectively falling the clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops with inversion on the clock path or falling edge triggered flip-flops without any inversion on the clock path.

-cells

Creates a collection of cells (default). The cells are registers and are further limited by other command options.

-data_pins

Creates a collection of register data pins. The collection can be limited by other command options.

-clock_pins

Creates a collection of register clock pins. The collection can be limited by other command options.

-async_pins

Creates a collection of asynchronous preset or clear pins.

-output_pins

Creates a collection of register output pins.

-level_sensitive

Limits search to level-sensitive latches.

-edge_triggered

Limits search to edge-triggered flip-flops.

DESCRIPTION

The **all_registers** command creates a collection of pins or cells related to registers.

When issued from the command prompt, **all_registers** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum using the variable **collection_result_display_limit**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following command returns all registers in the current design.

```
prompt> all_registers
```

SEE ALSO

collections(2)
get_cells(2)
get_pins(2)

shell.common.collection_result_display_limit(3)

all_scenarios

Creates a collection of all scenarios in the current design.

SYNTAX

collection **all_scenarios**
[-design *design*]

Data Types

design collection

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

DESCRIPTION

The **all_scenarios** command creates a collection of all scenarios in the current design, or the design specified by the **-design** option.

If you want only certain scenarios, use **get_scenarios** to create a collection of scenarios matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all scenarios.

all_transitive_fanin

Reports pins, ports, or cells in the fanin of specified sinks.

SYNTAX

list **all_transitive_fanin**
-to *sink_list*
[-startpoints_only]
[-only_cells]
[-flat]
[-levels *count*]

Data Types

sink_list list
count int

ARGUMENTS

-to *sink_list*

Reports a list of sink pins, ports, or nets in the design and connectivity based fanin of each sink in the *sink_list*. If you specify a net, the effect is the same as listing all driver pins on the net.

-startpoints_only

Returns only the connectivity startpoints.

-only_cells

Results in a set of all the cells in the connectivity fanin of the *sink_list*.

-flat

Specifies to function in the flat mode of operation. The two major modes in which **all_transitive_fanin** functions are hierarchical (default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current sink are returned. Thus, pins within a level of hierarchy lower than that of the sink are used for traversal but they will not be reported.

-levels *count*

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are of equidistant from the sink.

DESCRIPTION

This command reports the connectivity fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the connectivity fanin of a sink if there is a path through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells).

NOTE: This command reports results except the cases

1. *false paths* do not have an impact on this commands ability to trace logic

2. manually created clocks are not treated as paths start points

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show the connectivity fanin of a port in the design. The design comprises three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_transitive_fanin -to tout
{"ii2/hin", "iv3/in", "iv3/out", "tin", "ii2/hout", "tout"}

prompt>  all_transitive_fanin -to tout -flat

{"ii2/iv1/U1/a", "ii2/iv2/U1/z", "tin", "iv3/U1/a", "ii2/iv1/U1/z",
"ii2/iv2/U1/a", "iv3/U1/z", "tout"}
```

all_fanin(2)
all_fanout(2)
report_transitive_fanin(2)

all_transitive_fanout

Returns a set of pins, ports, or cells in the fanout of the specified sources.

SYNTAX

list **all_transitive_fanout**
-from *source_list*
[-endpoints_only]
[-only_cells]
[-flat]
[-levels *count*]

Data Types

source_list list
count int

ARGUMENTS

-from *source_list*

Specifies a list of source pins, ports, or nets in the design. The connectivity fanout of each source in *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net.

-endpoints_only

Returns only connectivity endpoints as a result.

-only_cells

Results in a set of all cells in the connectivity fanout of the *source_list*, rather than a set of pins or ports.

-flat

Specifies to function in the flat mode of operation. The two major modes in which **all_transitive_fanout** functions are hierarchical (default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current source are returned. Thus, pins within a level of hierarchy lower than that of the source are used for traversal but are not reported.

-levels *count*

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are of equidistant from the source.

DESCRIPTION

This command reports the connectivity fanout of specified source pins, ports, or nets in the design. A pin is considered to be in the connectivity fanout of a sink if there is a path through combinational logic from that source to the pin. The fanout report stops at the inputs to registers (sequential cells).

NOTE: This command reports results except the cases

1.**false paths** do not have an impact on this commands ability to trace logic 2.Manually created clocks are not treated as paths start points

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the connectivity fanout of a port in the design. The design comprises three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_transitive_fanout -from tin
{"iv3/out", "tout", "iv3/in", "ii2/hin", "ii2/hout", "tin"}

prompt> all_transitive_fanout -from tin -flat
{"tout", "ii2/iv2/U1/z", "ii2/iv1/U1/a", "iv3/U1/z", "iv3/U1/a",
"ii2/iv2/U1/a", "ii2/iv1/U1/z", "tin"}

prompt> all_transitive_fanout -from tin -levels 1 -only_cells
{"iv3", "ii2"}
```

analyze

Analyzes the specified HDL source files and stores the resulting templates into the specified library in a format ready to specialize and elaborate to form linkable cells of a full design.

SYNTAX

status **analyze**
[-format verilog | sverilog | vhdl]
[-standard 1987 | 1993 | 1995 | 2001 | 2005 | 2008 | 2009 | 2012]
[-define *define_list*]
[-hdl_library *hdl_library_name*]
[-uses *design_libs_list*]
[-vcs *vcs_opts*]
[-update]
[-recursive]
[-autoread]
[-rebuild]
[-output_script *output_string*]
[-exclude *exclude_list*]
[-verbose]
[-top *top_design_name*]
file_list

Data Types

file_list list
hdl_library_name string
design_libs_list string
define_list string
vcs_opts string
output_string string
top_design_name string
exclude_list list

ARGUMENTS

-hdl_library *hdl_library_name*

Specifies the template library where analyzed output files are stored. When the -hdl_library option is not used, the hdl_library_name is taken from **hdlin.hdl_library.default_name**. If the directory for the hdl_library_name is not defined, then **define_hdl_library** is automatically called to do so.

-uses *design_libs_list*

This option is not available with the **-format vhdl** or **-autoread** option.

SystemVerilog and Verilog designs might contain unresolved references to unelaborated design templates without indication of where those template definitions are located.

The compiler and linker always search for these templates first in the home directory of the parent design. By default, they then continue each template search by visiting every design library defined by the **define_hdl_library** command. The **-uses** option overrides this last step. It stores a design library search order within each design being analyzed. Later, elaboration or linking will follow this prescribed order rather than visiting every known library. An empty list argument limits the search to just the home library of the parent design. You do not need to repeat the **-hdl_library** setting, and you cannot override a search of the work directory.

-standard 1987 | 1993 | 1995 | 2001 | 2005 | 2008 | 2009 | 2012

Specifies the revision year of the IEEE standard that governs the selected language's syntax and semantics. The default revision years are IEEE Std 1076-2008 for VHDL, IEEE Std 1800-2012 for SystemVerilog, and IEEE Std 1364-2005 for Verilog.

-format verilog | sverilog | vhdl

Specifies the format of the files to be analyzed. The supported formats are Verilog, SystemVerilog, and VHDL.

Specifies that the **-autoread** option should look for files in the specified language whose extensions match the extensions in the list identified by the **hdlin.autoread.verilog_extensions**, **hdlin.autoread.sverilog_extensions**, or **hdlin.autoread.vhdl_extensions** application option. The **-autoread** option supports Verilog, SystemVerilog, and VHDL formats. By default, **-autoread** reads in all the files it finds that have Verilog, SystemVerilog, and VHDL extensions. You can use the **-autoread** option to specify file names in the *file_list* that do not have one of the language-specific extensions.

-vcs *vcs_opts*

Specifies all VCS-specific command-line options. The options must be specified as a single string, such as enclosed within braces ({}) or double quotation marks (""). Options specified by the **-vcs** option follow the VCS command-line syntax:

[-sverilog | -verilog] Specifies the format of the files to be analyzed.

[-y *directory_path*] Specifies the directories that contain the library files to be searched for unresolved module instantiations in the design.

[+libext+.*extension1*+...] Specifies the extension to consider during a file search in the -y library directories. The default is no extension.

[-v *library_file*] Holds several module definitions to be used during the search for unresolved modules.

[-f *command_file*] Specifies a command file.

[+define+*macro_name*+...] Defines a macro.

[+incdir+*dir1*+...] Includes directories in the search list.

src_file1 Specifies the files that are to be analyzed.

This option is not available with the **-autoread** option.

-define *defines_list*

Specifies a list of constant macros to be defined for the session of the **analyze** command. This is useful for the inclusion of Verilog or SystemVerilog code enclosed by `ifdef/`endif constructs. For details, see the documentation.

file_list

Specifies the files to be analyzed.

To analyze multiple files, list them by using curly braces, {}. Note: Source files in a list are effectively concatenated into a single

source stream in the listed order.

In **-autoread** mode only, the *file_list* argument can also specify directory names. All HDL source files located in those directories are prescanned. For more information about prescanning, see the descriptions for the **-autoread** and **-recursive** options.

-autoread

Specifies to use the **-autoread** mode for script-free analysis of whole HDL source directories or directory trees. All HDL source files located in those directories are prescanned, grouped, and then ordered into distinct source code streams based on their mutual inclusion and package-reference dependences. Some or all source streams are finally analyzed using the basic command.

By default, the **-autoread** option creates or replaces only a subset of analyzed result files; it works in an incremental-update mode that resembles the Unix make command. If an HDL source file does not exist or is newer than the intermediate files it should produce, only that file and the source streams that require it are reanalyzed.

For more information, see the description for the **-rebuild** option.

-top *design_name*

Identifies the top-level component of a hierarchical design specified within the **-autoread** HDL source directories.

The **analyze -autoread -top** *design name* command selects a subset of the indicated HDL source streams to analyze. Its goal is to analyze into intermediate form precisely those source files required for a later elaboration and linking of *design_name*. Files in the indicated directories that are not required to elaborate the design hierarchy descending from *design_name* are prescanned but the design templates they would produce are not created or replaced.

If the **-top** option is not provided, all HDL source streams indicated by the **file_list** argument are analyzed.

This option can be used only with the **-autoread** option.

-recursive

Specifies that the **analyze -autoread** command must recursively scan the directory trees below those specified in the *file_list* list. By default, the **-autoread** option looks only in the specified directories.

This option can be used only with the **-autoread** option.

-exclude *exclude_list*

Specifies a list of files and directories that are not to be analyzed. An **analyze -autoread [...] file_list** command checks each HDL source path against all elements of the *exclude_list*; it ignores a file if it or any of its directory paths matches any excluded path.

This option can be used only with the **-autoread** option.

-rebuild

Replaces any result files regardless of their timestamp. It analyzes all the indicated HDL source streams as if the result library was empty.

This option can be used only with the **-autoread** option.

-verbose

Prints out more messages for the **-autoread** option.

This option can be used only with the **-autoread** option.

-output_script *file_name*

Creates a Tcl script that is compatible with Design Compiler, Fusion Compiler, and Formality.

The file reading order for third-party tools and a DOT language file dependency graph are embedded in the script as comments.

This option is available only with the **-autoread** option.

DESCRIPTION

This command translates the specified HDL files and stores the intermediate format in the specified hdl_library.

The following paragraphs describe the support for the **-autoread** option:

The **-autoread** option reads in the files from file_list, determines the dependencies between them, and analyzes them in the right order to prevent errors due to missed or misplaced files.

The dependencies are calculated only from the files or directories present in *file_list*. If *file_list* changes between consecutive calls with the **-autoread** option, the dependency inference is performed over the latest set of files provided. Based on this, all required sources must be present in *file_list* option or be available if the **-recursive** option is used on each call with the **-autoread** option.

If the top design name is provided by the **-top** option, only the source files required for elaborating that top design are analyzed. This filtering is based on file dependencies previously inferred. If the **-top** option is not provided, all sources are ordered, grouped, and analyzed per the dependency inferred between them.

To locate the source files, the command expands each item in the *file_list* list with the **search_path** variable. Then, it determines whether the result is excluded by the **-exclude** option or the **hdlin.autoread.exclude_extensions** application option. If it is not excluded and a file ends with one of the extensions in the **hdlin.autoread.vhdl_extensions** application option list, it is considered a VHDL source file. If the file ends with one of the extensions in the **hdlin.autoread.verilog_extensions** application option list, it is considered a Verilog source file. If the file ends with one of the extensions in the **hdlin.autoread.sverilog_extensions** application option list, it is considered a SystemVerilog source file.

When expanding a directory, the command collects the files from the directory, and from its subdirectories and theirs recursively if the **-recursive** option is set. The command then performs all extension checks on these files. If the **-format** option is set, only files with Verilog, SystemVerilog, or VHDL extensions are collected based on the value of the option.

After the **-autoread** option collects all of the source files, it performs the following dependency checks:

- Detects analyze dependencies: List RTL files in the right order for analyzing. For example, analyze the file that contains a VHDL entity before analyzing files that defines architectures of that entity, or analyze the file that contains a SystemVerilog package declaration before the files that import that package.
- Detects Verilog and SystemVerilog compilation unit dependencies: Determine if a file needs to be analyzed in the same compilation unit with other files. For example, if a file defines macros, SystemVerilog local parameter, and SystemVerilog enumerated values, and the file is not explicitly included by the file that requires that definitions, the **-autoread** option groups them in the same compilation unit in the correct order. This might not always be possible, such as when a macro is defined several times in different files and the **-autoread** option cannot determine which of those alternatives is the right choice.
- Detects link dependencies: Schedule the analyze stage for files required for elaboration of the design hierarchy. For example, if a Verilog or SystemVerilog design that is instantiated in one source file is declared on a different source file provided in the *file_list*, the second file also requires to be analyzed for a complete top-down design elaboration.
- Detects include dependencies: If a Verilog or SystemVerilog file is included in another source and the file changes between two consecutive calls of the **-autoread** option (in the same synthesis session), the **analyze** command includes this file and all files that include them to update the design.
- Infers the target library for VHDL files. However, if the **-library** option is specified, this step is skipped and VHDL files provided in the *file_list* are analyzed into the specified design library.

After the dependency check, all the required HDL files specified by the *file_list* option (regarding its dependencies and the **-top**

design option if defined) are analyzed.

When the **-autoread** option is used again (with the same *file_list* setting) after a file is changed, only the updated source files are analyzed.

The **-autoread** option executes the dependency analysis based only on the current *file_list* information. All HDL source files that might have relevant dependency relationships should be passed together in one **analyze -autoread** command.

EXAMPLES

The following example analyzes the packages.vhd file and stores the results in the MY_LIB HDL library:

```
prompt> analyze -format vhdl -hdl_library my_lib packages.vhd
```

The following example analyzes two SystemVerilog clients of two libraries:

```
prompt> define_hdl_library BUSDEFN -path /remote/IP/metra/big_bus
prompt> define_hdl_library NClib   -path ../../NCD/libNC
prompt> analyze -format sverilog -uses { BUSDEFN  NClib }  { senderAlice.sv receiverBob.sv }
```

The following example assumes that the current directory is the source directory. It specifies the source file list early in the command line and gives options, including the name of the top-level entity later.

```
prompt> analyze {.} -autoread -recursive -top E1
```

The next example specifies extensions for Verilog files that are different from the default ({.v}), sets the source list and the exclude list, and calls the command with the name of the top-level module name, forcing it to only collect files with Verilog extensions:

```
prompt> set_app_options -name hdlin.autoread.sverilog_extensions -value {.ve .VE}
prompt> set my_sources {mod1/src mod2/src}
prompt> set my_excludes {mod1/src/incl mod2/src/incl}
prompt> analyze $my_sources -exclude $my_excludes -autoread \
  -format verilog
```

Note that excluding include directories explicitly is only necessary if include files have the same extensions as source files and not all include files are included in the source.

analyze_datapath_extraction

Analyzes DesignWare datapath extraction.

SYNTAX

status **analyze_datapath_extraction**
[-html_file file]
[-max_msgs *max_num_msgs*]
[-no_autoungroup]
[-no_report]
[-nosplit]
[module_list]

ARGUMENTS

-html_file *file*

Redirect the output of the report to specified files in HTML format.

-max_msgs *max_num_msgs*

Specifies the maximum number of messages of each type to display in each module.

-no_autoungroup

Specifies that automatic ungrouping is disabled. All hierarchies are preserved unless otherwise specified. The **-no_autoungroup** option in **analyze_datapath_extraction** behaves the same way as the **-no_autoungroup** option in **compile**. If you plan to specify the **-no_autoungroup** option in **compile**, you should also specify the **-no_autoungroup** option in **analyze_datapath_extraction**.

-no_report

Specifies not to report contained resources at the end of the analysis.

-nosplit

Does not split lines if column overflows.

module_list

Specifies list of modules to run datapath extraction analysis. If it's not specified, the whole current design will be analyzed.

DESCRIPTION

This command analyzes the datapath extraction of the current design.

When a DesignWare operator is not extracted, it analyzes the reason why it is not extracted. If it is due to the RTL coding, the tool issues a message about the RTL coding style that interferes with datapath extraction.

After the analysis, a report shows the contained resources in the design. This report helps to find the resources in the design source code.

The messages are sorted based on the priority. From high to low, the message types are "HDL-120", "HDL_132", "HDL-129", "HDL-133", "HDL-122", "HDL-125", "HDL-126", and "HDL-121". Within the same type, the messages are also sorted based on their potential impact.

For big designs, there could be a large number of messages. To make the output more readable, besides the **-max_msgs** option, the **set_msg** command can also be used in advance to control the desired number of each message in total to show, or just filter out some of the messages.

For more information about RTL coding styles that help improve datapath extraction, see the coding guidelines documented in "Coding Guidelines for Datapath Synthesis" on SolvNet (https://solvnet.synopsys.com/retrieve/015771.html).

Here are examples of possible warning messages issued by the **analyze_datapath_extraction** command:

"HDL-120": Issued when a DesignWare operator is breaking the datapath due to leakage on its fanout or the fanout of its driver. This DesignWare operator can be the boundary node of an extracted datapath block.

Datapath leakage occurs when an internal operand is not wide enough to store the result of an operation but the full result is required later. Operands with leakage must be binary and must be at the boundary of a datapath block. Therefore, operands with leakage will break a potentially larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

Example 1: module test(a, b, c, d, e, f, o1, o2, o3); input [10:0] a, b; input [5:0] c, d, e, f; output [8:0] o1; output [9:0] o2; output [7:0] o3; assign o1 = a + b + c; (add_9, add_9_2) assign o2 = f + o1; (add_10) assign o3 = e + o1; (add_11) endmodule

In this design, the input 'o1' of 'add_10' is truncated. Therefore, the following message is issued:

Information: Operator associated with resources 'add_10' in design 'test' breaks the datapath extraction because there is leakage due to truncation on the fanout of its driver 'add_9 add_9_2'. (HDL-120)

On the other hand, the width of 'o3' is smaller than the width of 'o1'. Therefore, there is no leakage on the input of 'add_11".

Example 2: module leakage_a (a, b, c, z); input signed [7:0] a, b; input [7:0] c; output [9:0] z; wire signed [8:0] t; assign t = a + b; //add_6 // leakage: signed result used in wider unsigned expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(signed) and fanout(unsigned) of add_6:

Information: Operator associated with resources 'add_6' in design 'leakage_a' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Example 3: module leakage_b (a, b, c, z); input [7:0] a, b; input signed [7:0] c; output signed [10:0] z; wire signed [8:0] t;

assign t = a + b; // add_7 // leakage: unsigned result used in wider signed expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(unsigned) and fanout(signed) of add_7:

Information: Operator associated with resources 'add_7' in design 'leakage_b' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Subtraction can give negative results that cannot be represented with an unsigned operand of limited width. It is recommended to declare the operands as signed. Note that constants used in signed operations need to be marked signed as well.

Example 4: It is recommended to change the following RTL code: input [13:0] a ; input [13:0] b ; wire [15:0] o = a - 14'd4 - b ;

to

input signed [13:0] a ; input signed [13:0] b ; wire signed [15:0] o = a - 14'sd4 - b;

The "HDL-120" message is associated with coding guideline 19. (https://solvnet.synopsys.com/retrieve/015771.html#leakage).

"HDL-121": There is a sequential cell that breaks the datapath extraction.

Example: module test (clk, en, a, b, c, z); input clk, en; input [7:0] a, b; input [15:0] c; output [15:0] z; reg [15:0] prod;

always @ (posedge clk) begin if (en) begin prod <= a * b; end end assign z = prod + c; endmodule

There is a register between the multiplier and the adder. The following message will be issued:

Information: There is sequential cell in between operator associated with 'mult_11' and 'add_15' in design 'test'. (HDL-121)

The extracted datapath block cannot contain sequential cells (for example, registers). The register in between operators will break a potential larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

The "HDL-121" message is associated with coding guideline 12. (https://solvnet.synopsys.com/retrieve/015771.html#pipelining).

"HDL-125": Design contains instantiated DW. If the instantiated DW is replaced with an inferred DW OP, it could be extracted.

Example: module test(a,b,c,z); parameter wl = 5; input [wl-1:0] a,b,c; output [2*wl-1:0] z;

wire [wl-1:0] sum; assign sum = (b+a); DW02_mult #(wl, wl)U_mult(sum, c, 1'b0, z); endmodule

The instantiated DW02_mult can be replaced by an inferred multiplier. The following message will be issued:

Information: Cell 'U_mult' in design 'test' can not be extracted because it instantiates 'DW02_mult', which could be inferred with operator '*' instead. (HDL-125)

The instantiated DesignWare component cannot be extracted into datapath blocks. If the RTL design uses inferred the DesignWare operation instead of instantiated DesignWare components, the inferred DesignWare operator might be extracted into a datapath block.

The "HDL-125" message is associated with coding guideline 11. (https://solvnet.synopsys.com/retrieve/015771.html#component_instantiation).

EXAMPLES

The following example shows the analysis report that the datapath extraction is broken due to a number of reasons.

```
prompt > analyze_datapath_extraction -no_report

analyze_datapath_library_cell

Displays function, area and power characteristics of cells from the technology libraries used in datapath generation.

SYNTAX

status **analyze_datapath_library_cell**
[-html_file file]

ARGUMENTS

-html_file

Redirect the output of the report to specified files in HTML format.

DESCRIPTION

This command displays function, area and power characteristics of cells of the library that are used in datapath generation. It also checks for cells or combinations of cells that can improve power QoR during datapath generation.

EXAMPLES

The following examples use the demo class.nlib library. The **analyze_datapath_library_cell** command prints some general attributes of the library.

```
-----------------
 Library(s) Used
-----------------

  class (File: /u/test/class.nlib)
  Library units: time=1.00ns voltage=1.00V capacitance=1.00pF dynamic_power=1.00pW leakage_power=1.00pW
```

This description is followed by four tables. The first table lists significant cells used in datapath generation.

```

The third table lists characteristics for the lowest area and power versions of the library cells. The area, power, and drive-strength characteristics are checked for potential problems and get listed in the fourth table.

The cell characterization table contains the following information for each cell type:

```
Smallest Cell    : The smallest cell that is found in the library
Total # Drives   : Number of different drive strengths for this cell
Min Area # Drives : Number of different drive strengths for the minimum area version of this cell
Estim Size       : Estimated size of the cell based on the estimated grid size
Actual Size      : Cell size from the library data
Dynamic Power    : Dynamic power from the library data
Min # Trans      : Estimated minimum number of transistors required to implement the cell
Estim # Grids    : Estimated number of grids required to implement the cell
Actual # Grids   : Calculated number of grids for the cell based on the area of the smallest inverter in the library
```

When a potential problem in the cell is detected, an asterisk (*) is added to the value in the characterization table.

```

SEE ALSO

report_power_library(2)

analyze_design_violations

Analyzes the specific violations in current design, identifies unfixable violations, and generates a summary report.

SYNTAX

status **analyze_design_violations**
[-type max_trans | static_noise | setup | hold | only_lib]
[-fanout *hfn_threshold*]
[-slack *small_violation_threshold*]
[-output *output_prefix*]
[-stage preroute | postroute]
[-drc_nets *nets*]
[-endpoints *pins*]
[-max_slack *slack_value*]
[-min_slack *slack_value*]

Data Types

hfn_threshold	integer
small_violation_threshold	float
output_prefix	string
nets	collection
pins	collection
slack_value	float

ARGUMENTS

-type max_trans | static_noise | setup | hold | only_lib

Specifies the type of violation to analyze. Only one type can be specified at each time. By default, the maximum transition violations (**max_trans**) are analyzed.

When type is **static_noise**, static noise violations are analyzed.

When type is **setup**, setup violations are analyzed. For each end point, only the worst path is picked up.

When type is **hold**, hold violations are analyzed. For each end point, only the worst path is picked up too.

When type is **only_lib**, only the library settings that affect optimization are checked. Some messages are reported when buffers or inverters are missing for entire design, for a particular voltage and for a particular site-row. Note that this checking also happens for other types.

-fanout *hfn_threshold*

Specifies the threshold which is used for high fanout net check. The default value at pre-route stage is the value from

opt.common.max_fanout, and the default value at post-route stage is the value from extrat.high_fanout_threshold.

-slack *small_violation_threshold*

Specifies the slack threshold in picoseconds which is used for checking of a small violation. A positive value is required. By default, any slack violation less than 5 ps (**-slack 0.005**) is considered a small violation.

-output *output_prefix*

Specifies the output file name. The command appends "$type.txt" to the prefix and overwrites the file if there has been one. The output contains a summary of analysis, followed by a list of detailed violations, printed one-by-one in descending order. Violations are also grouped by category. By default, the output file is analyze_design_violations.max_trans.txt.

-stage preroute | **postroute**

Specifies the routing stage used for analysis. Default is **preroute**. The fanout threshold is different at either stage.

-drc_nets *nets*

Specifies the nets with LDRC violation. Tool only performs analysis on these nets.

-endpoints *pins*

Specifies the endpoint pins with timing violation. Tool only performs analysis on these nets.

-max_slack *slack_value*

Specifies the maximum slack of violations that will be analyzed. The violations larger than the value are filtered. It can work with "-min_slack". When "-drc_nets" or "-endpoints" is used, this option is ignored.

-min_slack *slack_value*

Specifies the minimum slack of violations that will be analyzed. The violations larger than the value are filtered. It can work with "-max_slack". When "-drc_nets" or "-endpoints" is used, this option is ignored.

DESCRIPTION

This command analyzes the specified violations in current design and generates a summary report for them. The violations to be analyzed is specified by -type option. The analyzed result is summarized in log file and is elaborated in a standalone output file. It is important to understand the output.

The outputs for LDRC and timing are different. LDRC violations are net based and the result are categories of nets. Timing violations are path based and its result are paths grouped by timing constraints.

First, the output of LDRC is introduced, which is made by 7 parts.

1. Summary of total violations

   It presents the global view of violations, including violation count, worst and total slack.

2. Categories which causes or may cause LDRC violations unfixable.

   Categories of Reasons are listed one by one. The abbreviation of reason is in "()". Then the violation number, worst/total cost in the category and the percentage in total are listed. After the separator "|", it is pin info. If there is just "0" after the string of reason, it means no violation belongs to the category.

   Note that a violation can match different categories, but it will be put into one. There is internal priority of categories.

"Entire net is dont_touch(D)": All the net segments are dont_touch, no buffer can be added for fixing.

"Net between pad cell and port(PAD)": Such kind of nets are not touched by optimization.

"Tristate nets(TR)": Tristate nets are not touched by optimization.

"Nets with multiple drivers(MD)": Multi-driven nets are not touched by optimization.

"Nets in read-only sub blocks(RO)": Nets in read-only blocks are all dont_touch.

"Nets are highly blocked(BLK)": This means the net's bounding box are highly blocked (blockage ratio > 95%). The buffering will be very difficult, though detouring may solve it.

"Nets with port far from the core area(FP)": Port location is set far from core area. New buffer could not be added outside core area for fixing.

"Large input transition of driver(LI)": It checks the max_trans violation on the input side of driver cell. If there has been large max_trans violation (> 10 * *small_violation_threshold*) on them, current net is grouped here. It is used for max_trans analysis only.

3. Categories about the clock nets.

   Usually nets on clock network are not touched by signal nets optimization. But if they drive data pins, optimization should also make a fix.

   "Clock is used as clock only(COC)": Net is on clock network and drives only clock pins.

   "Clock is used as data path only(COD)": Net is on clock network and drives only data pins.

   "Clock is used as clock and data(CAD)": Net is on clock network and drives both clock pins and data pins.

   "Clock is used as others(CO)": Other definition about the clock nets.

4. Categories which help understanding of fixable violations.

   They are some properties which are not the unfixed reasons but give tips on what remaining violations are. Violations listed here are usually fixable.

   "Net is crossing high density area(DEN)": High-density can be a reason to drop a buffering solution. Here the density check is not so identical with optimization. It catches a net here when the density of net's bounding box is over 0.95.

   "Net is partially blocked(PB)": This category means there is high-density around any of the pins in the net.

   "Connect to excluded cell of XMB(XME)": The excluded cells of a module-based exclusive move bounds are allowed to place outside of the bounds. Once buffering happens, new buffer belongs to the bound and can only be placed inside bound. So, if excluded cells are far away from the bound, no buffering can fix the violation.

   "Connect to excluded cell of HMB(HME)": This is the same as "XME", the difference is that the type of move bound is module-based hard move bound. However, Hard move bounds are suggested to remove during optimization, since hard move bounds are not honored by optimization.

   "Nets across different exclusive MBs(DXM)": Violation on nets which are crossing boundaries of exclusive move bounds may be unfixed due to unknown limitation. User can pay attention to them.

   "Nets across different hard MBs(DHM)": Violation on nets which are crossing boundaries of exclusive move bounds may be unfixed due to unknown limitation. User can pay attention to them. However, Hard move bounds are suggested to remove during optimization, since hard move bounds are not honored by optimization.

   "Some segments of net are dont_touch(PD)": Some net segments of the net are dont_touch. Though there are still bufferable net segments, it is not sure whether buffering can happen.

   "High fanout nets(> $Threshold)(HF)": The nets whose fanout number is larger than $Threshold are grouped here. For pre-route

stage, the value comes from opt.common.max_fanout, and for post-route stage, the value comes from extrat.high_fanout_threshold. The threshold value is present here.

"Nets crossing different voltage areas(MV)": The nets crossing multiple voltage areas are quite complicated. They are grouped here but lack of sufficient analysis. User can refer to "check_bufferability" commands.

"Nets with small violation(> $Threshold)(S)": Small violations are not analyzed but it does not mean optimization does not work on them. The threshold value is listed here and can be changed by "-slack" option.

"Nets are too short(TS)": If the net length is smaller than a threshold, the net is grouped here. The threshold is decided by internal grid size. If a net has been short, buffering does not help for LDRC and setup. It is necessary to find other reason.

"Nets are long(> 400.0um)(LN)": The nets whose length is over 400 um are grouped here. It is not reasonable to leave so long nets. User needs to check out real reasons.

"Other violations(OV)": Those violations which could not be grouped to above categories are all here.

5. Distributions of fixable violations.

   For LDRC violations, there are four distributions, including slack, fanout, net length and constraint. The distributed violations are those fixable ones. Now the boundaries of distribution cannot be changed.

6. Top 10 Violations and their category given by abbreviation.

7. Guidance to find detailed report.

   The report file is $prefix.$type.txt, e.g. analyze_design_violations.max_trans.txt. In the report file, the info in the regular log is also printed. And following that, there is elaboration of violations. The elaboration is also grouped by category. This means violations with the same reason are shown together. In each category, the violations are printed in descending order. For each violation, there are net name, worst pin name, constraint, slack and scenario. For static noise violation, worst pin is always the net driver. This is an example of a violation.

```
ropt_net_329531
  Worst Pin: PMB_inst/rst_n                    0.200,  -0.006,  ta_test_ss28_0.75V_m0.60VS_0.60GS_m40C_SigC
```

For timing analysis, the output format is similar, but the context is quite different since timing is path-based. This is the introduction.

1. Summary of total violations

   This is similar to LDRC analysis. The summary includes violated path count, worst and total slack.

2. Categories listed by timing constraints that may be over-set.

   There are some descriptions with the word "large" in the categories. The reference is 10% of the clock period. "large" means that the checked thing is greater than the reference value. However, this does not mean the violation is unfixable due to the too "large" setting. It is just a potential reason. A path may match different categories, but it can only be grouped to the worst category. In the detailed log file, all categories are listed for top 10 paths.

   "Large clock skew(LCS)": clock skew is the gap between delay to clock pin of launch register and clock pin to capture register. For setup, it is clock delay of launch register minus clock delay of capture register. For hold, it is opposite. The larger clock skew is, the less room for either setup or hold fixing.

   "Large external input delay(LID)": External Input delay occupies arrive time. The larger it is, the less room for setup fixing.

   "Large driver adjustment(LDA)": Driver adjustment occupies arrive time. The larger it is, the less room for setup fixing.

   "Large clock uncertainty(LCU)": For setup, clock uncertainty tightens require time. The larger it is, the less room for setup fixing. For hold, clock uncertainty increases require time. The larger it is, the more delay at path should be added.

   "Large setup time of end point(LLS)": Setup time tightens require time. The larger it is, the less room for setup fixing.

   "Large external output delay(LOD)": For setup, external output delay tightens require time. The larger it is, the less room for setup

fixing. For hold, external output delay increases require time. The larger it is, the more delay at path should be added.

"Large hold time of end point(LLH)": Hold time increases require time of hold. The larger it is, the more delay on path should be added.

"Delay setting is illegal(ID)": Delay is set as negative value.

"Conflict with setup at endpoint(CSE)": This is for hold analysis only. When setup is also violated, fixing hold will degrade setup.

"Path ends up at scan in pin(SIP)": End point of path is scan in pin of register.

"Small violations(SM)": Small violations are not analyzed but it does not mean optimization does not work on them. The threshold is 5 ps and can be changed by "-slack" option.

"Remaining violating paths(OT)": It contains all violations which are not grouped to any of above categories.

3. Distribution of uncategorized violations by slack

   Distributed violations are from "Remaining violating paths". Now the boundaries of distribution cannot be changed.

4. Top 10 Violations and their category given by abbreviation.

5. Guidance to find detailed report.

   In the file of timing analysis report, it also prints the summary first and then the elaboration of paths. The elaboration is different from LDRC analysis. It does not follow the category. The paths are printed in the descending order of slack. Besides some timing info, the path analysis result is listed. There could be more than one category. For top 10 violations, the buffering capability of nets along the path is also analyzed, which uses the same way as max_trans analysis.

EXAMPLES

The following examples show different analysis:

prompt> **analyze_design_violations**

The command analyzes "max_trans" violations by default and generates the following report.

```
    Start analyzing max_trans violations.

    Detect 29 violating nets.
      Worst: -0.028     Total: -0.316     Average: -0.011
  1 violating nets are categorized.
      Worst: -0.013     Total: -0.013     Average: -0.013
  28 violating nets are uncategorized.
      Worst: -0.028     Total: -0.303     Average: -0.011

    Detect 252 violating pins.
      Worst: -0.028     Total: -2.622     Average: -0.010
  14 violating pins are categorized.
      Worst: -0.013     Total: -0.167     Average: -0.012
  238 violating pins are uncategorized.
      Worst: -0.028     Total: -2.455     Average: -0.010

analyze_lib_cell_placement

Analyze a collection of library cells for their ability to be placed in the current design.

SYNTAX

status **analyze_lib_cell_placement**
-lib_cells *cells*
[-trials *num_trials*]
[-region {{*llx lly*} {*urx ury*} }]
[-no_pg_drc]
[-no-adv]
[-max_cells *rpt_max*]
[-threshold *pass_thresh*]
[-directory *drc__directory*]
[-drc_limit *num_drcs*]

Data Types

cells collection
num_trials integer
llx float
lly float
urx float
ury float
rpt_max integer
pass_thresh float
drc_directory string
num_drcs integer

ARGUMENTS

-lib_cells *cells*

Specifies the library cells to analyze for placeability. This is a required option.

-trials *num_trials*

Specifies the number of random sites at which to test the legality of each cell. The default is 1000. A value of 0 will force an exhaustive search of all free sites in the design.

-region { {*llx lly*} {*urx ury*} }

Specifies a bounding box in which to search for legal sites. Library cells will be considered legal for sites in the region only if they remain wholly withing the region.

-no_pg_drc

This option disables pnet checking (the "pg_drc" rule in the Advanced Legalizer).

-no-adv

No advanced rule checking will be performed if this option is specifed.

-max_cells *rpt_max*

Specifies the maximum number of cells to list in the report. The default is 100. The true limit is the minimum of *rpt_max* and the number of lib cells specified.

-threshold *pass_thresh*

Specifies the threshold pass rate. Only cells whose pass rate is less than this will be reported. The default is 1.0, that is, 100%.

-directory *drc__directory*

Specify a directory for DRC violation files. The default is the current directory.

-drc_limit *num_drcs*

Specify a limit for how many DRC violations are written to each DRC file. The default is 100.

DESCRIPTION

This command tests a collection of library cells for their ability to be placed in a the current design. For each library cell in the collection, *num_trials* free sites are selected at random. If a region is specified, then the list of random sites is limited to free sites within that area. If the cell can be placed at that site in any orientation, then it is considered to pass at that site. If it cannot, it is considered to fail at that site. The pass rate for the cell is the number of passing sites divided by the number of sites tested.

After all of the cells have been analyzed, a report is produced listing cells in order of increasing pass rate. The length of this report is limited by the *rpt_max* argument. It is also limited by the *pass_thresh* argument. No cells whose pass rate is above this will be reported.

With DRC enabled (without using the -no_pg_drc option), when a lib cell has DRC violations, a file is created containing the violations. The file is named *analyze.libCellName.drc*. By default these files are written to the current directory. You can specify a directory using the *-directory drc_directory* option. By default, up to 100 DRC violations will be written into the file. You can change the limit using the *-drc_limit num_drcs* option. Setting *num_drcs* to zero means to write all violations. Also note that whatever directory you choose, existing drc files will be overwritten.

Multi threading is available when using the advanced legalizer. The maximum number of threads is obtained from the value set with the **set_host_options** command, but may be lowered based on the size of the site map.

EXAMPLES

The following example analyzes all opened designs.

prompt> **analyze_lib_cell_placement -lib_cells [get_lib_cells -filter is_open==true]**

analyze_mv_design

Analyzes multivoltage design connections

SYNTAX

status **analyze_mv_design**
-level_shifter
[-through]
[-global_report]
[-output <output_file>]
[-html]
[-csv]
[-nosplit]
[-verbose]
[-example]

Data Types

through list
output_file string

ARGUMENT

-level_shifter

Enables level-shifter analysis. Required option, must be used with either [-global_report] or with [-through].

-through

Specifies a net or pin, and will report the global net containing that pin/net.

-global_report

Make an analysis of level-shifter insertion on the whole design, and counts one error for each driver-load pair.

-priority

The errors for global_report are picked based on a priority list, with this command you can change the order in which an error is selected in a driver-load pair.

The available priorities are:

1.

Missing or Problem with UPF constraint (MPC).

An error will be classified as MPC if:

a.

There is no domain boundary

b.

There is a Missing strategy (LS or ISO)

c.

Strategy cannot be fulfilled because there is a problem that prevent LS insertion.

2.

Problems that result in the maximum number of violations for that global net (FO).

This counts the number of loads that a specific error is affecting, so the one that is affecting more loads is going to have more priority.

3.

Library violation (LV).

An error will be classified as LV if it is related to missing library cell, for example: problem with map command (LS or ISO), main rail violation or no library cell matches the operating conditions.

4.

Supply violation (SV).

An error will be classified as SV if there is any problem with supplies availability.

5.

Dont touch (DT).

Net has dont touch.

6.

Closer to load (CL) Last resource to avoid ties. This counts the number of power domain (PD) boundaries are between the error and the load, the one with less PD boundaries between the error and the load is going to be chosen if all other categories are the same.

The command will receive a list with the priority order, if this is not given the default priority will be used {MPC FO LV SV DT CL}

-verbose

Generates detailed information in the report. For -through, add the list of supplies and list of lib cells. And for -global_report add the list of drivers for each error.

-output <*output_file*>

Print report into <*output_file*>.

-html

Print report in HTML format.

-csv

Print report in CSV (Comma-Separated Value) format. *-output* option is required when using this option and cannot be used in conjuntion with the *-html* option

-nosplit

Most of the reported data is listed in fixed-width columns. If the data for a given column exceeds the column width, the next field begins on a new line, starting in the right column. The *-nosplit* option prevents this behavior, allowing all the data to be written on a single line.

-example

Show example of different usages for analyze_mv_design.

DESCRIPTION

The analyze_mv_design command performs multivoltage analysis and reports design details that can help understand why level-shifter insertion failed. You can perform level-shifter analysis by using the -level_shifter with -global_report or with -through. The level-shifter analysis through a global net lists variable settings, driver and load information, signal connections, library availability information, and errors and warning collected from create_mv_cells.

EXAMPLES

The following examples are for -level_shifter -global_report and -level_shifter -through:

```
prompt> analyze_mv_design -level_shifter -global_report

analyze_power_plan

Analyzes a complete or partial power network for voltage (IR) drop and electromigration on the specified power and ground nets. This command also calculate track utilization by P/G in each layer.

SYNTAX

status **analyze_power_plan**
[-nets *net_list*]
[-power_budget *power_budget*]
[-voltage *voltage*]
[-read_power_file *power_file_name*]
[-analyze_power]
[-pad_references *power_pad_reference_name*]
[-use_terminals_as_pads]
[-report_track_utilization_only]

Data Types

net_list	collection or list
power_budget	float
voltage	float
power_file_name	string
power_pad_reference_name	string

ARGUMENTS

-nets *net_list*

Specifies the power or ground nets on which to perform power network analysis. This is a required option if the **-report_track_utilization_only** option is not specified.

-power_budget *power_budget*

Specifies a total power budget for the design on which to perform power network analysis. The power budget is divided among the instances according to the cell area. For hard macros or standard cells, the power budget is computed based on the percentage of the total area. For hierarchical blocks, the power is computed based on the total area of all their child cells and blocks inside. The unit is in mW.

For example, if the power budget for the entire design is 500 mW, the total area of the top-level blocks is 500,000 square microns, and one of the blocks has an area of 25,000 square microns, power network analysis allocates the power for that 25,000-square-micron block as follows:

500mW * (25,000/500,000) = 25mW

Either **-power_budget** or **-read_power_file** should be specified to provide power data.

-voltage *voltage*

Specifies the voltage of the net to be analyzed. The voltage is applied at the power pad. The voltage unit is volts. The default is 1.5.

-read_power_file *power_file_name*

Obtains the power calculation source from a side file. By default, this option is off. The supported power files are PT-PX power output file, and default power file. The format of the default power file is as follows. Instance *instance_name power_value*

-analyze_power

Specifies the option to get power consumption as report_power. The option will use it for IR-drop calculation.

-pad_references *pad_references*

Specifies the pad references and the associated net as follows

net_name:*pad_reference_name*

If net name is not specified, the pad reference is used for all the analyzed nets. By default, PNA will assume all the pads logically connected to signal **1** or **0** as power pads.

-use_terminals_as_pads

Use terminals of top block as power/ground pads. By default, the option is off. This option treats terminals as additional power/ground pads. They can exist while using virtual pads. PNA will not make virtual connection if no P/G wires connect to them.

-report_track_utilization_only

If the option is used, all the other options are not required. This option will report the percentage of track resource is occupied by P/G wires but skip calculating IR drop. If the option is not used, PNA will still calculate track utilization percentage and perform IR-drop and EM calculation.

DESCRIPTION

This command performs a power network analysis (PNA) in a complete or partial power/ground network during the design planning stage. If the power ports in standard cells and hard macros are not connected to the power and ground network, PNA creates virtual connections to those unconnected power ports. PNA then analyzes the IR drop and electromigration in the power network based on user-specified power budget and voltage supply. This command requires that at least one cell in the design is logically connected to the power or ground net being analyzed. If not, you should use the **connect_pg_net** command to create the logic connection first. If there are any power switches that are connected to the analyzed net, you should set up a suitable resistance to power switches before you use this command. If not, PNA will assign a very small resistance to all unspecified power switches. To set up resistance of power switches, you can use **set_attribute** to set power_switch_resistance or **plan.pna.power_switch_resistance** application option as follows:

set_app_options -name plan.pna.power_switch_resistance

This command also calculates track utilization. Power, ground and secondary nets are taken into account. Only preferred routing direction defined in tech file is considered as routing resource. The resource of each routing layer that P/G wires utilize is displayed in the log.

EXAMPLES

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW.

```
prompt> analyze_power_plan -nets VDD -power_budget 1000
```

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW using pad reference VDD_NS

```
prompt> analyze_power_plan -nets VDD -power_budget 1000 -pad_references "VDD_NS"
```

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW using pad reference VDD_NS for VDD and VSS_NS for VSS.

```
prompt> analyze_power_plan -nets {VDD VSS} -power_budget 1000 \
  -pad_references "VDD:VDD_NS VSS:VSS_NS"
```

The following example analyze the IR drop on the *VDD* net with a total power budget of *1000* mW with power switch cell (50 Ohm)

```
prompt> set_attribute [get_cells power_switch_cell_name] power_switch_resistance 50
prompt> analyze_power_plan -nets {VDD} -power_budget 1000
```

or

```
prompt> set_app_options -name plan.pna.power_switch_resistance -value \
  {{power_switch_lib_cell_name1 50}}
prompt> analyze_power_plan -nets {VDD} -power_budget 1000
```

SEE ALSO

connect_pg_net(2)

plan.pna.power_switch_resistance(3)

analyze_rail

Performs the targeted rail analysis on the specified nets. This command generates the data needed to run the RedHawk tool and runs the RedHawk tool within the current tool session. This command enables several target analyses, such as power and ground network voltage drop analysis, electromigration analysis, and minimum path resistance analysis. A previously generated RedHawk command script can also be used to perform the analyses.

SYNTAX

status **analyze_rail**
[-redhawk_script_file *redhawk_script* | -nets *net_list*]
[-voltage_drop *static* | *dynamic* | *dynamic_vcd* | *dynamic_vectorless*]
[-switching_activity {*file_format* [*file_name*] [*strip_path*] [*time_window*]} | -power_analysis icc2]
[-electromigration]
[-min_path_resistance]
[-effective_resistance]
[-result_name *result_name*]
[-check_missing_via]
[-extra_gsr_option_file]
[-script_only]
[-submit_to_other_machines]
[-multiple_script_files {{*result_name script_file*}...}]
[-bg]
[-step_size *time*]
[-stop_time *time*]

Data Types

file_format	string
file_name	string
nets	collection or list
redhawk_script	string
result_name	string
strip_path	string
time	string

ARGUMENTS

-redhawk_script_file *redhawk_script*

Specifies and uses an existing RedHawk script to perform the RedHawk run.

This script is usually generated from an earlier **analyze_rail** run.

When a user-specified script file is used, all other currently enabled options are ignored. For example, if you run the **analyze_rail**

-voltage_drop static -redhawk_script_file myscript.tcl command, the -voltage_drop option is ignored.

This option and the -nets option are mutually exclusive.

-nets *net_list*

Specifies the power and ground supply nets to be analyzed. This option is required if the -redhawk_script_file option is not set.

The tool considers all the switched or internal power nets of the specified power nets in the analysis. You do not need to explicitly specify the internal power nets.

If the -nets option is selected, you need to specify at least one of the following options: *-min_path_resistance* or *-voltage_drop*.

This generates extra VDD_NETS and GND_NETS blocks in the GSR file.

Each specified power net must have a corresponding *supply_net* defined with its *voltage_min* attribute set. The *voltage_min* attribute may be set using the **set_voltage** command.

-voltage_drop *static* | *dynamic* | *dynamic_vcd* | *dynamic_vectorless*

Performs voltage drop analysis on the specified power and ground nets.

When this option is selected, the tool checks for voltage drop violations on the specified power and ground supply nets. The results are saved under the current rail database directory, set by the rail application option rail.database, or the RAIL_DATABASE directory (the default). After the /fBanalyze_rail/fP command completes operation, the **open_rail_result** command is automatically invoked so users can view results in the GUI. It generates a voltage drop map, a parasitics map, and a power map. In addition, it reports voltage drop violations in a text file and in an error view.

-switching_activity {*file_format file_name strip_path time_window*}

Specifies an optional switching activity file. The *file_format* argument can be *VCD* (a VCD file generated from a gate-level simulation), *FSDB*, *SAIF*, or *ICC_ACTIVITY*.

A VCD or SAIF file can reference a top-level design in a different hierarchy than the one used in the current session. The *strip_path* argument removes the specified string from the beginning of the object name. Using this option modifies the object names in the VCD or SAIF file to make them compatible with the object names in the design library.

For example, use the following option to load a VCD file and strip the /top_design/cup_module prefix from all object names.

```
-switching_activity {VCD top_design.vcd /top_design/cup_module}
```

For example, use the following option to load a VCD file without a strip path.

```
-switching_activity {VCD top_design.vcd}
```

If you have annotated switching activity on the design in the IC Compiler II environment, set the *file_format* argument to *ICC_ACTIVITY*. When you specify this format, the tool creates a temporary SAIF file that contains the user-annotated switching activity and passes it to the RedHawk tool. The *file_name* argument does not apply to this format.

When the *file_format* arguement is set to *VCD* or *SAIF*, the tool generates a VCD_FILE or SAIF_FILE block in the GSR file, respectively.

When the *strip_path* argument is specified, the tool generates the *FRONT_PATH* component in the VCD_FILE block, or the *ROOT_INSTANCE* component in the SAIF_FILE block. Both VCD_FILE and SAIF_FILE blocks are in the GSR file.

When the *time_window* argument is specified, the tool generates the *SELECT_RANGE* component in the VCD_FILE block in the GSR file.

-electromigration

Performs electromigration analysis on the specified power and ground nets.

When enabled, the tool analyzes the current density on the specified nets and identifies the segments with potential

electromigration issues. It also calculates current violations based on the default rules that are loaded in the design library. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the **analyze_rail** command completes, the **open_rail_result** command is automatically invoked, so you can view the results in the GUI. It generates a electromigration map and reports the current violations in an error view.

The -electromigration option must to specified with the -voltage_drop option.

When analysis run is complete, the tool adds the RedHawk "perform emcheck" command in the run script.

-min_path_resistance

Performs minimum path resistance analysis on the specified power and ground nets. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the **analyze_rail** command completes, the **open_rail_result** command is automatically invoked so you can view the results in the GUI. It generates a minimum path resistance map.

If you want to perform minimum path resistance analysis only, do not use the -voltage_drop option.

When analysis run is complete, the tool adds the RedHawk "perform gridcheck -limit -1 -fullchip" command to the run script.

-effective_resistance

Performs effective resistance analysis on the specified power and ground nets. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the **analyze_rail** command completes, the **open_rail_result** command is automatically invoked so you can view the results in the GUI. It generates an effective resistance map.

When analysis run is complete, the tool adds the RedHawk "perform res_calc" command in the run script.

-power_analysis *icc2*

When *icc2* is selected, the native power analysis is used to generate necessary power data for rail analysis.

See the **report_power** command man page for more information.

-result_name *result_name*

Specifies the directory name for saving the rail analysis results. The results are saved in {design_name}/rail/{result_name} directory under the current rail database directory, set by the rail application option rail.database, or by default under the RAIL_DATABASE directory.

The default result name is REDHAWK_RESULT.

Subsequent analyses overwrite the previous analyses results.

This generates an INSTANCE_POWER_FILES block in the GSR file.

-check_missing_via

Performs missing via check.

When checking is complete, the tool adds the RedHawk "mesh vias -report_missing" command in the run script.

"-check_missing_via" requires "-voltage_drop".

-extra_gsr_option_file

Specifies an external GSR file to include at the tail of the generated GSR file.

This generates extra INCLUDE statements at the end of the GSR file, and overrides the application option settings.

-script_only

Generates the RedHawk script and the input data for the target analysis, such as voltage drop, minimum path resistance or electromigration, without actually executing the analysis run.

This allows you to modify and reuse the run script as desired.

-submit_to_other_machines

Launches RedHawk on a separate machine. This option should be used with the **set_host_options** command to set a specific machine or farm.

-multiple_script_files {{*result_name script_file*}...}

Launches multiple RedHawk jobs using multiple script files provided in the option. When analysis is finished, each result is saved with the result_name specified. This option has to be used with the -submit_to_other_machines option, and the **set_host_options** option where a farm machine system has to be set.

The number of licenses required is equal to the number of script files provided. If there are not enough licenses available, the **analyze_rail** command aborts with an error message. If you want to run **analyze_rail** when the number of available licenses is less than the number of scripts, use **set_app_options -name rail.license_checkout_mode -value wait** before invoking the **analyze_rail** command. The tool launches scripts based on the number of the available licenses, and puts other scripts waiting for an available license. A license is released from other sessions or from the same session when a script finishes the job. With this application option set to *wait*, the license checking is performed dynamically when scripts are running during the **analyze_rail** command run.

-bg

Launches RedHawk in the background process and returns shell to the user. Use the **report_background_jobs** command to check if a previous background job has completed. Below restrictions apply: - Recursive -bg is not allowed. - Overlapping background jobs is not allowed. - RAIL_DATABASE related commands and license-related commands are not allowed in the background jobs.

-step_size

For RedHawk-SC flow, generates the *step_size* argument used by **create_analysis_view** command in analyze_rail.py file generated by the **analyze_rail** command.

The default value: For technology 5nm or below, use 5ps as the step size. For technology above 5nm, use 10ps as the step size. If technology is not specified, by default technology is set to 7nm. Use the application option *rail.technology* to specify the technology.

-stop_time

For RedHawk-SC flow, generates the *max_duration* argument used by the **create_analysis_view** command in the analyze_rail.py file generated by the analyze_rail command.

The default value: Always use 4x dominant clock period as the maximum duration. If the calculated max duration is smaller than step size, then the maximum duration is equal to 10x step size.

DESCRIPTION

This command prepares the data needed for RedHawk rail analyses, and then calls RedHawk or RedHawk-SC to perform the specified rail analysis run. The supported rail analyses are voltage drop analysis, electromigration analysis, minimum path resistance analysis, and effective resistance analysis.

The results are saved under the current rail database directory, set by the rail application option rail.database, or the RAIL_DATABASE directory (the default). After the **analyze_rail** command completes, the **open_rail_result** command is

automatically invoked, so you can view the results in the GUI. The command generates error views that capture violations found during the analysis. You can display the generated errors in the error browser, depending on the analysis options you chose.

You can perform multiple analyses, such as voltage drop and electromigration, in a single run.

The generated analysis results include the following information:

- Average voltage drop values in a map file
- Average electromigration values in a map file
- An error cell with average electromigration values

There are several rail application options that are used by the **analyze_rail** command:

- rail.redhawk_path to specify the RedHawk executable path For example:

  ```
  prompt> set_app_options -name rail.redhawk_path \
    -value /release/latest/Testing/bin
  ```

- rail.database to specify where to save the RedHawk analysis results (the default is RAIL_DATABASE) For example:

  ```
  prompt> set_app_options -name rail.database -value my_rail_output
  ```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs static voltage drop analysis for the nets {VDD VDDV} using native power analysis:

```
prompt> create_taps -import my.tap
prompt> analyze_rail -nets {VDD VDDV} -voltage_drop static \
  -power_analysis icc2
```

The following example performs minimum path resistance analysis for the net VDD:

```
prompt> create_taps -import my.tap
prompt> analyze_rail -nets VDD -min_path_resistance
```

The following example specifies a time window for the VCD file which is used to run dynamic rail analysis on the net VDD.

```
prompt> analyze_rail -voltage_drop dynamic_vcd -nets vdd \
  -switching_activity {VCD top_design.vcd /top_design/cup_module \
    {start_time end_time}}
```

The following example specifies a time window for the FSDB file which is used to run dynamic rail analysis on the net VDD.

```
prompt> analyze_rail -voltage_drop dynamic_vcd -nets vdd \
  -switching_activity {FSDB top_design.fsdb /top_design/cup_module \
    {start_time end_time}}
```

The following example submits a RedHawk job to an LSF farm.

```
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P bnormal}
prompt> analyze_rail -voltage_drop dynamic -submit_to_other_machines
```

The following example launches multiple RedHawk jobs to farm machines to have both static and dynamic rail analyses running at the same time. Two SNPS_INDESIGN_RH_RAIL licenses will be checked out.

```
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P bnormal}
prompt> analyze_rail -multiple_script_files {{static static.tcl} {dynamic dynamic.tcl}} -submit_to_other_machines
```

The following example assumes only 2 licenses are available, but needs to launch 4 RedHawk script files in the same analysis run. Since **set_app_options -name rail.license_checkout_mode -value wait** is set, the **analyze_rail** command launches 2 scripts first and puts other 2 scripts waiting for a license to be available.

```
prompt> set_app_options -name rail.license_checkout_mode -value wait
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P bnormal}
prompt> analyze_rail -multiple_script_files {{result1 result1.tcl} {result2 resilt2.tcl} {result3 result3.tcl} {result4 result4.tcl}} -
```

The following example launches RedHawk in background process and shell is returned to user.

```
prompt> analyze_rail ... -bg
prompt>
```

analyze_subcircuit

Invokes circuit simulation on a subcircuit of the current design. This command is suitable for analyzing clock mesh nets.

SYNTAX

status **analyze_subcircuit**
[-name *string*]
[-from *pins*]
[-to *pins*]
[-net *net*]
[-simulator *name_of_simulator*]
[-spice_header_files *list_of_files*]
[-driver_subckt_files *list_of_files*]
[-configuration *list_of_scenario_configurations*]
[-clock *clock_name*]
[-spef_input_file_suffix *string*]
[-rc_include_file_suffix *string*]
[-num_simulation_cycles *inf*]
[-extraction]
[-create_spice_deck]
[-run_simulation]
[-write_annotation]
[-apply_annotation]
[-include_power_analysis]
[-verbose]

Data Types

pins collection of pins
net collection of one net
list_of_files list
list_of_scenario_configurations list
clock_name string
name_of_simulator string

ARGUMENTS

-name *string*

Specifies the name of this subcircuit, which is used to distinguish it from other subcircuits in the same design. The string is used to construct both circuit elements and file names, so it must only contain alphanumeric characters and underscores. With that restriction, you can use any name, but if a clock is being analyzed you should use the name of the clock (if this is unique). Many files are generated based on this name. The name is also given to the output directory, to be created in the current working

directory. If no directory by this name exists, one is created. Because many files are created in this directory, you must specify a directory with write permissions and sufficient disk space.

-clock *clock_name*

Specifies for which clock domain the analysis should be done. This especially helps to select the appropriate clock path when multiple clocks arrive at pins of a cell in the clock tree.

-from *pins*

Specifies the startpoint or startpoints to analyze a circuit. This can be a single driving point of the clock tree, such as the clock source pin, or it can be a set of driver pins in the pre-mesh clock tree.

-to *pins*

Specifies a collection of load pins that are driven by the circuit. These define the endpoints of the clock tree paths to be analyzed.

-net *net*

Specifies a single net, whose load pins will be used instead of -to as the endpoints of the clock tree paths to be analyzed. Typically this would be a multidriver clock mesh net. Either -to or -net must be specified.

-simulator *name_of_simulator*

Specifies which SPICE simulator to use. Only finesim, hspice, and nanosim simulators are supported. The default is nanosim. The simulator you want to use must be available as a working and properly licensed Linux command in your shell path. You may need to adjust the path in your .cshrc or .login file.

-spice_header_files *list_of_files*

Specifies the locations of the SPICE device models of the transistors. SPICE device models are needed for all the transistors. You specify the device models with the file path, and the file paths are copied into the simulator input. If you specify multiple files, they are included in the order specified. Note that file locations are relative to the current working directory (not relative to the new working directory defined by -name.) Absolute file paths may also be used.

-driver_subckt_files *list_of_files*

Specifies the locations of the subcircuit models of the buffers in the clock mesh tree. The circuit simulator requires a subcircuit model for all the buffers in the clock mesh tree. You specify the subcircuit models with the file path, and the file paths are copied into the simulator input. If you specify multiple files, they are included in the order specified. Note that file locations are relative to the current working directory. Absolute file paths may also be used.

-configuration *list_of_scenario_configurations*

Customizes the SPICE settings for each scenario and max/min setting to be analyzed. The list can be of any length. Single curly braces are recommended. If Tcl variable substitution is desired, the list can be defined using "..." rather than {...}. Each -scenario_name that is specified is followed by the custom file settings for that scenario. Any or all of the four types of custom file settings may be supplied. For any combinations not specified, the general settings from the **-spice_header_files** and **-driver_subckt_files** options will be used.

The format of the *list_of_scenario_configurations* argument is:

```
-configuration {
  -scenario_name scenario
   [-max_driver_subckt_files max_files]
   [-max_spice_header_files header_max]
   [-min_driver_subckt_files min_files]
   [-min_spice_header_files header_min]
  [-scenario_name scenario]
   [-max_driver_subckt_files max_files]
   [-max_spice_header_files header_max]
```

```
    [-min_driver_subckt_files min_files]
    [-min_spice_header_files header_min]
    ...
}
```

-spef_input_file_suffix *string*

This option can be used to customize the flow for -create_spice_deck, by replacing the default SPEF parasitics file name with an alternate user-provided SPEF file. For example, this could be used if an external extraction tool is being called rather than native extraction and SPEF generation. The external SPEF file should be generated without a name mapping table: in the IC Compiler tool, use the **write_parasitics -no_name_mapping** command. For each scenario and max/min simulation, the custom SPEF file names should follow this pattern:

<subcircuit_name>.<scenario_name>.<max/min>.<suffix_name>

-rc_include_file_suffix *string*

This option can be used to customize the flow for -create_spice_deck, by replacing the default include file name, for the net parasitics RC data, with the given custom suffix. The default suffix is \'rc.sp\', so for example, \'rc_custom.sp\' could be specified here instead. Users running external extraction tools instead of -extraction can then generate a customized RC parasitics input file for SPICE, and include it in the top-level SPICE deck file with this option, instead of the default.

-num_simulation_cycles *int*

This option can be used to extend the SPICE simulation duration for the given number of clock periods. This is very useful for insuring that the simulated circuit voltages have stabilized after circuit startup. By default only a single clock period is simulated. A typical value might be 3.

-extraction

Controls whether the analysis performs native extraction of RC parasitics and writes its own SPEF files for use by the **-create_spice_deck** option. This is Step 1 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

-create_spice_deck

Controls whether the analysis will create the top-level SPICE deck files whose names end with *.top.sp, *.rc.sp, and *.meas.cmd. The *.rc.sp file describes the net RC parasitics in native SPICE format, and is by default created here by reading in the SPEF files generated by the -extraction step. The *.top.sp file is the top-level SPICE command file. The *.meas.cmd file defines to SPICE how to measure arrival and transition times at the pins of the clock tree. This is Step 2 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

-run_simulation

Controls whether the analysis will run the SPICE simulation for each active scenario and max/min setting. The -simulator option specifies which SPICE tool is to be used. The SPICE measurement output files from this step are inputs to the -write_annotation step. This is Step 3 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

-write_annotation

Controls whether the analysis will create *.tcl timing annotation files for the clock tree, based on reading in the SPICE measurement output files from -run_simulation. These files define annotated transition time and arc delay for the analyzed portions of the clock tree. For multidriver clock mesh nets, they also apply set_disable_timing to disable all except one of those drivers. The annotated net arc delays are then defined from the one remaining driver only. This is Step 4 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

-apply_annotation

Controls whether the analysis will source the *.tcl annotation files from -write_annotation, causing the set_disable_timing, set_annotated_delay, and set_annotated_transition constraints to be applied to the clock tree. This is Step 5 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

-include_power_analysis

Annotates power measurement from spice simulation into the design. If this option is specified, it appends .meas statements to the *.meas.cmd files which measure the average power of each cell instance in the spice netlist. It also appends set_annotated_power command in the *.tcl annotation files from -write_annotation. These commands annotate the measured power back into the design.

-verbose

Displays the extraction and circuit simulation messages to the console. By default, these messages are redirected into log files in the output directory.

DESCRIPTION

In general, the tool performs timing prediction with static timing analysis. But for some purposes, such as clock meshes, it is necessary or desirable to use circuit simulation. This command generates the necessary files to run a SPICE circuit simulator, invokes the simulator, and reads the output of simulation back into your design as annotation constraints for delay and transition times. The annotation constraints are Tcl files which can be reused in later sessions, as long as the clock tree netlist is unchanged.

Files

Inputs required:

You must have a circuit-level model for each of the buffer gates in your clock tree, and a transistor model for each of the transistors in the circuit models.

Files generated:

This command creates a directory named using the -name string, if it is not already present, and populates it with files for simulation and annotation. These include the circuit files, command files, and measurement files. One of these files is a shell script that is used to invoke the circuit simulator. Simulation produces many output and log files, which also populate the directory. This command then processes those output files and generates an annotation file. This file can be sourced into your design, to update the delays and transition times of your subcircuit to match the circuit simulation results.

Limitations

The subcircuit to be is analyzed is modeled as being driven by a single clock waveform signal. That signal is applied at the pin or pins named by -from. A typical usage is to name the clock source pin using -from.

If you want to analyze a set of mesh drivers whose inputs are not yet connected, you can do this using the **-from** option by listing all the mesh driver input pins. For the purpose of simulation, these are all driven in parallel, with no skew among them. This type of simulation is only for early exploration, before the clock tree in the fanin of the mesh drivers has been designed.

Buffers that are "shorted together" in a mesh or other structure are supported. The resistance and capacitance of the mesh is determined by extraction, and is expressed in a SPEF parasitic data file. The SPEF file is generated natively by default, but manual use of external extraction tools such as StarRC is supported by the customized-flow options, which allow users to call an external tool with their own scripting, and then bring the resulting SPEF or other parasitic model files into the SPICE simulation flow.

The underlying circuit simulator is not case-sensitive, so elements "buff_27" and "BUFF_27" are indistinguishable, and the design

must not contain both names. For similar reasons, circuit elements should not contain the dot character ".".

The loads of the clock tree endpoints (flip-flops or latches) are modeled by lump capacitance, not by active transistor models, since the outputs of those gates are not part of the simulation. If this operation is done before the signal nets have been routed, which would normally be the case, then final gate placement, routing geometry and detailed placement might not match the geometry in the final chip. There is no modeling of IR drop in the power or ground wires. The actual VSS and VDD used for each buffer gate is assumed to be static and is determined before simulation starts.

For more information on simulation see the documentation for Hspice, Finesim, and Nanosim.

Multicorner-Multimode Support

This command works on all active scenarios.

EXAMPLES

In the following example, a clock tree called clk1 has been implemented with a set of specified library references to be used as buffers, driving a clock mesh net called mesh_net. This causes a new directory named clk1 to be created, containing the simulation and annotation files for the specified clock tree. The endpoints of the analyzed tree are the load pins of mesh_net.

After this command has been run, the **report_timing** command reflects the delays and transitions observed in the circuit simulation, if the -path_type full_clock_expanded reporting option is used to show the annotated arc delays and transitions in the clock tree. This example uses hspice as the simulator.

```
prompt> analyze_subcircuit -name clk1 \
  -from clk1_source_pin -net mesh_net \
  -simulator hspice \
  -spice_header_files original/models.sp \
  -driver_subckt_files {original/drivers.sp extra_cells.sp}
```

analyze_timing_correlation

Analyzes timing correlation with the PrimeTime tool.

SYNTAX

status **analyze_timing_correlation**
-work_dir *dir_name*
-pt_exec_path *filename*
[-scenarios *scenarios_list*]
[-delay_calculation_style zero_interconnect | auto]
[-si_enable_analysis true | false]
[-waveform_analysis_mode disabled | full_design]
[-enable_ccs_rcv_cap true | false]
[-pba_mode *pba_mode*]
[-overwrite_work_dir]
[-clear_work_dir]
[-save_pt_session]
[-use_pt_save_session]
[-disable_compatibility_settings]
[-enable_compatibility_settings]
[-pass_rate_threshold *integer*]
[-pt_search_path *paths_list*]
[-script_only]
[-pt_pre_link_script *filename*]
[-pt_post_link_script *filename*]
[-pt_user_script *filename*]
[-verbose]
[-nworst integer]

Data Types

dir_name string
filename string
scenarios_list list
pba_mode string
paths_list list

ARGUMENTS

-work_dir *dir_name*

Specifies working directory used to store all intermediate files which could be generated by analyze_timing_correlation. The files includes the design-files like netlist/constraints/parasitics, per-scenario Tcl-scripts and timing-data.

-pt_exec_path *executable_path*

Specify the PrimeTime executable image used for correlation. For example, /global/apps/pt_2015.06/bin/pt_shell

-scenarios *scenarios_list*

Specify which scenarios to analyze. By default, all scenarios are analyzed.

-delay_calculation_style zero_interconnect | auto

Controls the type of delay calculation performed during timing correlation analysis. When not specified, the tool uses the value of the **time.delay_calculation_style** application option.

Valid values are **zero_interconnect** and **auto**. When specifying **zero_interconnect** the tool infers that both signal integrity and waveform analysis are to be disabled, unless explicitly specified.

-si_enable_analysis true | false

Controls whether signal integrity is considered during timing correlation analysis. When not specified, the tool uses the value of the **time.si_enable_analysis** application option. Setting this value to true implies that timing windows are enabled.

Valid values are **true** and **false**.

-waveform_analysis_mode disabled | full_design

When not specified, the tool uses the value of the **time.delay_calc_waveform_analysis_mode** application option.

Valid values are **disabled** and **full_design**.

-enable_ccs_rcv_cap true | false

Specifies whether or not the Composite Current Source (CCS) receiver capacitance model is enabled. When not specified the tool uses the value of the **time.enable_ccs_rcv_cap** application option.

Valid values are **true** and **false**.

-pba_mode pba_mode

Specifies whether to perform path-based analysis or graph-based analysis The default is to perform graph-based analysis.

Valid values are **none**, **path** and **exhaustive**.

-overwrite_work_dir

Initially overwrite the existing work_dir directory.

-clear_work_dir

Overwrite existing work_dir upon command completion.

-save_pt_session

Save PrimeTime-Sessions and store it under '-work_dir' for later use.

-use_pt_save_session

Reuse existing PrimeTime-save-session stored under '-work_dir'.

-disable_compatibility_settings

Disables correlation changes to timer settings.

When you use this option, the command uses the current tool timing context during correlation analysis. This is not recommended

for the best alignment with the PrimeTime tool.

-enable_compatibility_settings

Enables correlation changes to tool timer settings.

When you use this option, the command modifies the timing context during correlation analysis to provide the best alignment. This is recommended for the best alignment with the PrimeTime tool.

-pass_rate_threshold *integer*

threshold criteria for correlation measurement, the default is 3. By default, 0.5 is used when delay_calculation_style equals 'zero_interconnect'.

-pt_search_path *paths_list*

Additional search_path used to resolve linked-libraries in PrimeTime. For example, '-pt_search_path {path1 path2 path3...}'.

-script_only

Write the design collateral and setup Tcl script files only.

-pt_pre_link_script *script_path*

Tcl script file to be sourced before design has been linked in PrimeTime.

-pt_post_link_script *script_path*

Tcl script file to be sourced after design has been linked in PrimeTime.

-pt_user_script *script_path*

Specifies a user-defined PrimeTime script for correlation.

By default, the command generates the design files for the PrimeTime runs based on the current tool settings.

If you use this option, the command uses the specified PrimeTime script for the correlation report.

The command ignores this option if you use the **-pt_pre_link_script** or **-pt_post_link_script** option.

-verbose

Show more detail information.

-nworst integer

Specifies how many timing endpoints to report in verbose analysis. By default, 5 endpoints are reported.

DESCRIPTION

The **analyze_timing_correlation** command generates a correlation report between this tool and the PrimeTime tool.

By default, the command performs the following tasks:

1. Generates QoR-compatible design files for the PrimeTime tool based on the current tool settings for each scenario.
2. Invokes the PrimeTime tool to collect the PrimeTime timing data.
3. Collects the timing data from this tool.

4. Generates the correlation report.

Multicorner-Multimode Support

By default, this command applies to all scenarios.

EXAMPLES

The following example uses the PrimeTime image located at /bin/pt_shell to generate a correlation report. The intermediate data is stored in a subdirectory named tmp.

```
prompt> analyze_timing_correlation -work_dir tmp \
  -pt_exec_path /bin/pt_shell -overwrite_work_dir -save_pt_session
```

SEE ALSO

save_upf(2)
write_parasitics(2)
write_script(2)
write_verilog(2)

annotate_trace

Control annotation of traced command execution to the shell output.

SYNTAX

annotate_trace [-start|-stop]
[-profile profile_annotation_type]
[-log log_string]
[-quiet]

string *log_string*
string *profile_annotation_type*

ARGUMENTS

-start

This option is mutually exclusive with -stop. The option starts the annotation of traced command execution to the shell output. Each executed command string is annotated to the output prepended with ";## ".

-stop

This option is mutually exclusive with -start. This option stops annotation of traced command execution to the shell output.

-profile *profile_annotation_type*

This option selects the profile data output behavior for command annotation. This option is only meaningful when given with the -start option. The argument is one of: on, with_start, off. The /flon/fP value starts annotation with profile data output enabled in the default mode which is to output the data only at the end of a command invocation. The data is output only if the delta values from the beginning of the command invocation meet or exceed the thresholds set for each of the reported metrics. The /flwith_start/fP value starts annotation with profile data output both at the beginning and at the end of a command invocation. The profile data is output at the beginning irregardless of any thresholds since delta values cannot be calculated at the beginning of the invocation. The profile data output at the end of command invocation is controlled by thresholds. The /floff/fP value disables profile data output. If profile data annotation is enabled but profile metric gathering has not been enabled with set_trace_option, all profile metrics are auto-enabled. If omitted, annotation is started without profile data output.

-log *log_string*

This option outputs the given log_string to the shell output prepended with ";## ". If the given string contains newline characters, each line is prendended with ";## ".

-quiet

If given, this option causes the command to ignore error conditions such as an attempt to log a comment string before annotation is started. The command will exit quietly when it encounters an error condition.

DESCRIPTION

The **annotate_trace** command performs operations related to annotating traced command execution to the shell output. If the application creates an output log, the annotation is made also to the output log. The command strings which are annotated to the output are those that are traced for creating a traced command replay log.

The **annotate_trace** with no options will report on the current status of annotation: on or off.

EXAMPLES

The following example starts annotation of executed commands to the output. Then the command is invoked again with no options to report on the status.

```
prompt> annoate_trace -start
prompt> annoate_trace
on
```

The following example configures profile metrids, then starts annotation of executed commands to the output along with the profile data.

```
prompt> set_trace_topion -profile all
prompt> set_trace_topion -memory_threshold 10
prompt> set_trace_topion -cpu_threshold 0
prompt> annotate_trace -start -profile with_start
```

SEE ALSO

set_trace_option(2)
get_trace_option(2)
log_trace(2)

append_to_collection

Adds objects to a collection and modifies a variable.

SYNTAX

collection **append_to_collection**
[-unique]
var_name
object_spec

Data Types

var_name	collection
object_spec	list

ARGUMENTS

-unique

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

var_name

Specifies a variable name. The objects matching *object_spec* are added into the collection referenced by this variable.

object_spec

Specifies a list of named objects or collections to add.

DESCRIPTION

The **append_to_collection** command allows you to add elements to a collection. This command treats the variable name given by the *var_name* option as a collection, and it appends all of the elements in *object_spec* to that collection. If the variable does not exist, it is created as a collection with elements from the *object_spec* as its value. If the variable does exist and it does not contain a collection, it is an error.

The result of the command is the collection that was initially referenced by the *var_name* option, or the collection created if the variable did not exist.

The **append_to_collection** command provides the same semantics as the common use of the **add_to_collection** command; however, this command shows significant improvements in performance.

An example of replacing the **add_to_collection** command with the **append_to_collection** command is provided below. For example,

```
set var_name [add_to_collection $var_name $objs]
```

Using the **append_to_collection** command, the command becomes:

```
append_to_collection var_name $objs
```

The **append_to_collection** command can be much more efficient than the **add_to_collection** command if you are building up a collection in a loop. The arguments of the command have the same restrictions as the **add_to_collection** command. For more information about these restrictions, see the **add_to_collection** man page.

EXAMPLES

The following example from PrimeTime shows how a collection can be built up using the **append_to_collection** command:

```
pt_shell> set xports
Error: can't read "xports": no such variable
    Use error_info for more info. (CMD-013)
pt_shell> append_to_collection xports [get_ports in*]
{"in0", "in1", "in2"}
pt_shell> append_to_collection xports CLOCK
{"in0", "in1", "in2", "CLOCK"}
```

apply_clock_gate_latency

Annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the **set_clock_gate_latency** command.

SYNTAX

status **apply_clock_gate_latency**

ARGUMENTS

The **apply_clock_gate_latency** command has no arguments.

DESCRIPTION

The **apply_clock_gate_latency** command annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the **set_clock_gate_latency** command.

Use this command to manually annotate clock-latency values specified by the **set_clock_gate_latency** command to existing clock-gating cells.

The tool only annotates the latency value on the clock pin of a cell (clock gate or register) whose stage is N and whose clock domain is *clk*, if the **set_clock_gate_latency -stage N** was explicitly used for the clock domain. The tool never overwrites latency values on pin objects that are annotated by the **set_clock_latency command**, but it can overwrite values that were annotated due to the **set_clock_gate_latency** command or by optimizations that were enabled by the application option **compile.clockgate.physically_aware**. Latency annotation is only supported for flip-flops and clock gates. The tool does not annotate macro cell pins.

To remove annotated latencies that were specified using the **set_clock_gate_latency** command, use the **reset_clock_gate_latency** command.

To remove the clock gate latency settings that were specified by the **set_clock_gate_latency** command in the current scenario, use the **set_clock_gate_latency -reset** command.

To report the clock gate latency settings that were specified by the **set_clock_gate_latency** command, use the **report_clock_gate_latency** command.

Multicorner-Multimode Support

The actual clock latency annotation performed during the execution of **compile** or **apply_clock_gate_latency** commands is done for all the scenarios for which a clock latency value is available.

apply_power_model

Apply a power model which describes the power intent of a reference library cell to instances.

SYNTAX

string **apply_power_model**
[*power_model_name*]
[-elements *instance_names*]
[-supply_map *supply_map_list*]
[-port_map *port_map_list*]
[-parameters *param_map_list*]
[-all_hard_macros]

Data Types

power_model_name string
instance_names list of instances
supply_map_list list of {power_model_supply_set current_scope_supply_set}
port_map_list list of {power_model_supply/logic_port current_scope_supply/logic_net}
param_map_list list of {power_model_parameter parameter_value}

ARGUMENTS

power_model_name

Specifies the name of the power model to be applied. The name should be a simple (non-hierarchical) name.

The applied power model is searched in this descending order of preference:

1. Power models defined in the current scope.
2. Power models defined in any direct ancestor scope: the closest the better.
3. Power models defined in user power model library. Please see app options mv.upf.power_model_search_path(3) and mv.upf.power_model_library(3).
4. Power models defined in any scope.

-elements *instance_names*

Specifies a collection of cells that this power model should be applied to.

If this option is not specified, the power model will be applied to all cells in and under the current scope whose reference library cells match those specified in the power model (i.e. library cells listed in **-for** option of the **define_power_model** command).

-supply_map *supply_map_list*

Specifies the mapping of supply sets in the power model to supply sets in the current scope. For example:

-supply_map {{model_vdd top_vdd} {model_vss top_vss}}

-port_map ***port_map_list***

Specifies the mapping of supply/logic ports in the power model to supply/logic nets in the current scope. For example:

-port_map {{model_supply_port top_supply_net} {model_logic_port top_logic_net}}

-parameters ***param_map_list***

Specifies the mapping of parameters in the power model to actual parameter values. For example:

-parameters {{model_param1 "value_1"} {model_param2 "value_2"}}

-all_hard_macros

Apply power models to all hard macro cells under the current scope with matching power model, i.e., the macro lib cell is included in the **-for** option of the **define_power_model** command, or the power model name is the lib cell name.

power_model_name must not be provided and no other options can be specified.

DESCRIPTION

The apply_power_model command binds the power_model_name to the cell instances specified by the -elements option. The associated parameter binding specified via the -parameters option allows objects within the environment to be bound to parameters defined within the power model. Not all parameters within the power model need to be bound to objects in the environment and parameters that are not bound shall retain their default values during run time.

The apply_power_model command sets the scope to each of the specified set of instances, referred to as the instance scope, and then executes the set of UPF commands in the power model power_model_name. Upon return, the current scope is restored to the scope in which the command was invoked.

EXAMPLES

The following example applies a power model to two macro cells:

```
prompt> define_power_model MODEL -for {macro_lib_cell} {
  create_supply_set SS_macro
  create_supply_set SS_macro_ao
  create_supply_port VDD_macro
  create_supply_port VSS_macro
}
prompt> create_supply_set SS_top
prompt> create_supply_set SS_top_ao
prompt> create_supply_net VDD_top
prompt> create_supply_net VSS_top
prompt> apply_power_model MODEL -elements {u1/macro u2/macro}
                        -supply_map {{SS_macro SS_top} {SS_macro_ao SS_top_ao}}
                        -port_map {{VDD_macro VDD_top} {VSS_macro VSS_top}}
```

The following example applies a power model to all instanced cells of lib_cell in or under the current scope. Power domain

PD_macro will be created in each of the macro cells:

```
prompt> define_power_model MODEL -for {lib_cell} {
  add_parameter DOMAIN -default domain -description "top power domain in model"
  create_supply_net VDD
  create_supply_net VSS
  create_supply_set SS -function {power VDD} -function {ground VSS}
  create_power_domain PD_$DOMAIN -supply {primary SS} -include_scope
}
prompt> apply_power_model MODEL -parameters {{DOMAIN macro}}
```

The following example applies power model MODEL_A to all instantiated cells of lib_cell_A and applies power model lib_cell_B to all instantiated cells of lib_cell_B in or under the current scope:

```
prompt> sh cat ./power_model.upf
define_power_model MODEL_A -for {lib_cell_A} { create_power_domain PD_A }
prompt> sh cat ./lib_cell_B.upf
define_power_model lib_cell_B { create_power_domain PD_B }
prompt> set_app_options -as_user_default \
   -name mv.upf.power_model_search_path -value "."
prompt> set_app_options -as_user_default \
   -name mv.upf.power_model_library -value "power_model.upf lib_cell_B.upf"
prompt> apply_power_model -all_hard_macros
```

apropos

Searches the command database for a pattern.

SYNTAX

string **apropos**
  [-symbols_only]
  pattern

Data Types

pattern string

ARGUMENTS

-symbols_only

Searches only command and option names.

pattern

Searches for the specified *pattern*.

DESCRIPTION

The **apropos** command searches the command and option database for all commands that contain the specified *pattern*. The *pattern* argument can include the wildcard characters asterisk (*) and question mark (?). The search is case-sensitive. For each command that matches the search criteria, the command help is printed as though **help -verbose** was used with the command.

Whereas **help** looks only at command names, **apropos** looks at command names, the command one-line description, option names, and option value-help strings. The search can be restricted to only command and option names with the **-symbols_only** option.

When searching for dash options, do not include the leading dash. Search only for the name.

EXAMPLES

In the following example, assume that the **get_cells** and **get_designs** commands have the **-exact** option. Note that without the **-symbols_only** option, the first search picks up commands which have the string "exact" in the one-line description.

```
prompt> apropos exact
 get_cells          # Create a collection of cells
  [-exact]           (Wildcards are considered as plain characters)
  patterns           (Match cell names against patterns)

 get_designs        # Create a collection of designs
  [-exact]          (Wildcards are considered as plain characters)
  patterns           (Match design names against patterns)

 real_time          # Return the exact time of day

prompt> apropos exact -symbols_only
 get_cells          # Create a collection of cells
  [-exact]           (Wildcards are considered as plain characters)
  patterns           (Match cell names against patterns)

 get_designs        # Create a collection of designs
  [-exact]          (Wildcards are considered as plain characters)
  patterns           (Match design names against patterns)
```

SEE ALSO

help(2)

as_collection

Find a collection by name

SYNTAX

string **as_collection** [-check]
collection1

string *collection1*

ARGUMENTS

-check

Return 1 if collection1 is a collection

collection1

The collection to convert

DESCRIPTION

This command looks up a string value and returns it as a collection it the collection is still live. All other values are passed through this command unmodified.

This command is also provides a simple way to check if the input is a collection.

EXAMPLES

Check if a value is a collection:

```
shell> as_collection -check [get_cells]
1
shell> as_collection -check hello
0
```

SEE ALSO

collections(2)
foreach_in_collection(2)

assign_3d_interchip_nets

Derives logical connections between bumps and drivers that have the shortest wirelength between them.

SYNTAX

status **assign_3d_interchip_nets**
[-bumps *cell_list*]
[-nets *net_list*]
[-matching_types *matching_types*]
[-set_port_terminals incremental | all]

Data Types

cell_list collection
net_list collection
matching_types list

ARGUMENTS

-bumps *cell_list*

Specifies the bumps for logical connection propagation. By default, all bumps in the design are considered. If only one bump is selected, its center-aligned bump is selected as a pair.

-nets *net_list*

Specifies the nets for logical connection propagation. By default, all top-level nets in design are available.

-matching_types *matching_types*

Specifies the matching types used to categorize different assignment groups. By default, all matching types are considered. If there is no matching type defined in the design, all bumps and drivers are considered in wirelength calculation.

-set_port_terminals incremental | all

Specifies the strategy to update the terminals(preferred_pin) for ports. Default value is **incremental**.

- **incremental**: only set terminals(preferred_pin) to the ports that have not been set and can be set with preferred_pin.
- **all**: set terminals(preferred_pin) to all ports no matter if they have terminals(preferred_pin) or not.

DESCRIPTION

This command builds logical connections between bumps and drivers with the shortest wirelength. The net for assignment should have the driver-pin pair connected. Meanwhile, the bump pin should be free for assignment. If there are one or more bump pins on the net, the net will be skipped. You can use the **disconnect_3d_bumps** command before performing net assignment or specifying the correct net for assignment.

EXAMPLES

The following example derives the logical connection between drivers on the net sip_data_a[19] with the bump pair {mini_cpu_chip_inst/BUMP_RING9 addmult_sip_inst/BUMP_RING9}.

```
prompt> assign_3d_interchip_nets -nets sip_data_a[19] \
  -bumps {mini_cpu_chip_inst/BUMP_RING9 addmult_sip_inst/BUMP_RING9}
```

assign_feedthrough_supply

Used to assign related supplies for feedthough ports of a given net or net connected to a given pin.

SYNTAX

status **assign_feedthourgh_supplies**
[-net nets]
[-pin pins]

Data Types

nets collection
pins collection

ARGUMENTS

-net

generate the related supplies for the feedthrough pins connected to these given nets

-pin

generate the related supplies for the given feedthrough pins and feedthrough pins on the net connected to these pins.

DESCRIPTION

The **assign_feedthough_supplies** command determines the best supplies to use for as the related supplies for the feedthough ports on a given net or a net connected to the given pin. The supplies are determined with the goal of minimizing the use of dual rail cell buffer/inverters in the feedthough domain. Only one of the -net or -pin must be specified and at least one of them should be specified.

SEE ALSO

place_pins(2)

assign_tsv

Assigns the specified TSV (Through Silicon Via) in the TSV list to the specified logical net and pins in the pin list.

SYNTAX

int **assign_tsv**
tsv_list
[-net *net*]
[-pins *pin_list*]
[-prefix *prefix*]
[-force]

Data Types

net net
pin_list list
prefix string

ARGUMENTS

tsv_list

Specifies the TSV to assign. If a TSV list is specified, the first TSV in the list is the source point for routing. At least one TSV must be specified. This is a required option.

-net *net*

Specifies the net to assign the TSV to. All specified objects are logically connected to the net. If all objects are initially unconnected to any net, a new net will be created with the given prefix that specified with option **-prefix**. If an existing net is already connected to some of the objects, the net will be reused. To avoid user error, the command does not allow two existing nets to be assigned together. This option and the **-pin** option are mutually exclusive.

-pins *pin_list*

Specifies a list of pins to assign to the TSV. This option and the **-net** option are mutually exclusive.

-prefix *prefix*

Specifies a prefix for the name of a new net, if created.

-force

Force the TSV to connect to the specified net.

DESCRIPTION

This command assigns the specified TSV in the tsv_list to the specified logical net and pins in the pin_list.

EXAMPLES

The following example assigns the specified TSV.

```
prompt> assign_tsv tsv1
```

associate_checkpoint_action

Associates an action with checkpoint names.

SYNTAX

integer **associate_checkpoint_action**
[-before *{list_of_checkpoint_patterns}*]
[-after *{list_of_checkpoint_patterns}*]
[-replace *{list_of_checkpoint_patterns}*]
[-enable *name_of_action*]
[-disable *name_of_action*]

Data Types

list_of_checkpoint_names list
name_of_action string

ARGUMENTS

-before *list_of_checkpoint_patterns*

Specifies that the action should run before all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -after and -replace options.

-after *list_of_checkpoint_patterns*

Specifies that the action should run after all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before and -replace options.

-replace *list_of_checkpoint_patterns*

Specifies that the action should run as a replacement for the Tcl commands wrapped by the eval_checkpoint command. This happens for all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before and -after options.

-enable *name_of_action*

Specifies the name of the action to enable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -disable option. name_of_action must be an action previously defined with the create_checkpoint_action command.

-disable *name_of_action*

Specifies the name of the action to disable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -enable option. name_of_action must be an action previously defined with the create_checkpoint_action command. If an action is both disabled and enabled at a checkpoint, the disable setting takes precedence and the action will not run.

DESCRIPTION

This command configures an action to run at one more more checkpoints triggered by the eval_checkpoint command in the flow scripts. Actions are defined in the checkpoint system with the create_checkpoint_action command.

This command has two required options. The first is one of -enable or -disable, which takes the name of the action as its parameter. This option specifies the name of the action being associated, and whether that action should be enabled or disabled for the patterns that will be given with the -before/-after/-replace option. -enable and -disable are mutually exclusive on a single call to associate_checkpoint_action. But multiple calls can be done to this command in sequence to give both enable and disable constraints. The -enable and -disable settings from multiple invocations of associate_checkpoint_action are time-sequenced. For example, enabling an action to run at * (all checkpoints), and then disabling it to run at the 'create_placement' checkpoint will result in that action running at all checkpoints except for 'create_placement'. This is a typical application of the disable option, where an action is enabled to run at multiple checkpoints using a wildcard pattern, but then disabled for one or more specific checkpoints that were matched by that pattern.

The second required option is one of -before, -after, or -replace. This option specifies the timing of the execution of the action, relative to the checkpointed command. Only one of -before, -after, or -replace can be given.

- -before indicates that the action should run before the checkpointed command. A typical before action is setting an app option before running a command.
- -after indicates that the action should run after the checkpointed command. A typical after action does some post-command cleanup, like changing constraints.
- -replace indicates that the action should run in place of the checkpointed command. In this case, the action is run but the original Tcl command/s wrapped by eval_checkpoint do not execute. A typical usage of a replace action is to skip execution of a command (by replacing it with nothing), or to modify the options of a command. The 'get_current_checkpoint -command' command can be run inside such a replacement action to get the original command including it's options, so that they can be modified by the action.

  Any of the -before, -after, -replace options take a required parameter which is a Tcl list of checkpoint name patterns at which to execute the action. For example, -before "*placement* place_opt_initial_place" specifies that an action should execute before any checkpoint with the name place_opt_initial_place, or with a name that includes the sub-string 'placement'.

  Action definitions and associations should not be part of the golden flow scripts for the design or project. They are intended to execute non-default actions that deviate from the standard flow. They are typically included in the ./checkpoint.config.tcl file in your run directory, which is automatically sourced by the checkpoint system.

EXAMPLES

Configures the gropto action to run before any *initial_drc checkpoints, to enable GR-based high-fanout synthesis in and place_opt

```
## In ./checkpoint.config.tcl
create_checkpoint_action gropto {
  set_app_options \
-name place_opt.initial_drc.global_route_based \
```

```
-value true
}

associate_checkpoint_action -enable gropto -before *initial_drc

## Action will execute before this line in the flow script place_opt.tcl
eval_checkpoint place_opt_to_initial_drc {
place_opt -from initial_place -to initial_drc
}
```

Configures the high_eff_cong action to force high-effort congestion on all create_placement* and refine_placement* checkpoints. get_current_checkpoint -command is used to access and modify the original command options, and the -replace option is used to replace the original command contents. ## In ./checkpoint.config.tcl

```
create_checkpoint_action high_eff_cong {
 eval [get_current_checkpoint -command] -congestion_effort high
}

associate_checkpoint_action -enable high_eff_cong \
  -replace "create_placement* refine_placement*"

## Action will execute as a replacement for checkpoints like these in the flow scripts
eval_checkpoint create_placement_incr {create_placement -incremental}
eval_checkpoint refine_placement {refine_placement -effort high}
```

associate_checkpoint_report

Associates a report with checkpoint names.

SYNTAX

integer **associate_checkpoint_report**
[-before *{list_of_checkpoint_patterns}*]
[-after *{list_of_checkpoint_patterns}*]
[-enable *name_of_report*]
[-disable *name_of_report*]

Data Types

list_of_checkpoint_names list
name_of_report string

ARGUMENTS

-before *list_of_checkpoint_patterns*

Specifies that the report should run before all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -after option.

-after *list_of_checkpoint_patterns*

Specifies that the report should run after all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before option.

-enable *name_of_report*

Specifies the name of the report to enable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -disable option. name_of_report must be a report previously defined with the create_checkpoint_report command.

-disable *name_of_report*

Specifies the name of the report to disable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -enable option. name_of_report must be a report previously defined with the create_checkpoint_report command. If a report is both disabled and enabled at a checkpoint, the disable setting takes precedence and the report will not run.

DESCRIPTION

This command configures a report to run at one more more checkpoints triggered by the eval_checkpoint command in the flow scripts. Reports are defined in the checkpoint system with the create_checkpoint_report command.

This command has two required options. The first is one of -enable or -disable, which takes the name of the report as its parameter. This option specifies the name of the report being associated, and whether that report should be enabled or disabled for the patterns that will be given with the -before/-after option. -enable and -disable are mutually exclusive on a single call to associate_checkpoint_action. But multiple calls can be done to this command in sequence to give both enable and disable constraints. The -enable and -disable settings from multiple invocations of associate_checkpoint_action are time-sequenced. For example, enabling a report to run at * (all checkpoints), and then disabling it to run at the 'load_constraints' checkpoint will result in that action running at all checkpoints except for 'load_constraints'. This is a typical application of the disable option, where an action is enabled to run at multiple checkpoints using a wildcard pattern, but then disabled for one or more specific checkpoints that were matched by that pattern.

The second required option is one of -before or -after. This option specifies the timing of the execution of the report, relative to the checkpointed command. Only one of -before or -after can be given.

- -before indicates that the report should run before the checkpointed command. A before report is used to measure QoR right before a command executes.
- -after indicates that the action should run after the checkpointed command. An after report is used to measure QoR right after a command executes.

  Both the -before and -after options take a required parameter which is a Tcl list of checkpoint name patterns at which to execute the report. For example, -after "*final route_opt*" specifies that an report should execute after any checkpoint with a name ending in 'final', as well as all route_opt checkpoints.

  Typically, report are written to files in the ./checkpoint directory, but this is not enforced and you can write reports to any disk location.

  Report definitions and associations should not be part of the golden flow scripts for the design or project. They are intended to separate reporting from the flow, such that individual users can customize their reporting needs without touching the golden flow. They are typically included in the ./checkpoint.config.tcl file in your run directory, which is automatically sourced by the checkpoint system.

EXAMPLES

Save a block before route_opt for interactive debugging. get_current_checkpoint -name is used to give the block a unique name.

```
## In ./checkpoint.config.tcl
create_checkpoint_report save_block {
 save_block -as checkpoint_[get_current_checkpoint -name]
}

associate_checkpoint_report -enable save_block -before route_opt

## Block will be saved before this line from the route_opt.tcl flow script
eval_checkpoint route_opt { route_opt }
```

Generate useful timing reports throughout the flow. Disables timing report generation at the read_constraints checkpoints. Uses the get_current_checkpoint -name and -position commands to give unique names to the reports before or after any checkpoint.

```
## In ./checkpoint.config.tcl
create_checkpint_report timing {
 set name [get_current_checkpoint -name]
 set pos [get_current_checkpoint -position]
 redirect -file ./checkpoint/$name.$pos.qor.rpt { report_qor }
 redirect -append ./checkpoint/$name.$pos.qor.rpt { report_qor -summary }
 redirect -file ./checkpoint/$name.$pos.path.rpt { report_timing -max_paths 10 }
}

associate_checkpoint_action -enable timing -before route_opt*
associate_checkpoint_action -enable timing -after *
associate_checkpoint_action -disable timing -after read_constraints
```

associate_mv_cells

Associates the UPF strategies to the power management cells in the current design, and reports the correlation between power management cells in the netlist and the UPF strategies.

SYNTAX

status **associate_mv_cells**
[-isolation_cells]
[-level_shifters]
[-retention_registers]
[-power_switches]
[-all]
[-all_blocks | -blocks *block_designs*]
[-host_options *host_option_name*]

ARGUMENTS

-all_blocks

Associate MV cells for all the child blocks in the current design and the current design itself. This option is mutually exclusive with *-blocks*. Only one of them can be specified at a time.

-blocks *block_designs*

Specifies the list of child block designs to associate MV cells. This option is mutually exclusive with *-all_blocks*. Only one of them can be specified at a time.

-host_options *host_option_name*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

-isolation_cells

Reports the correlation and discrepancies between isolation cells and isolation strategies.

-level_shifters

Reports the correlation and discrepancies between level-shifter cells and level-shifting strategies.

-retention_registers

Reports the correlation and discrepancies between retention cells and retention strategies.

-power_switches

Reports the correlation and discrepancies between power switches and UPF power-switch strategies.

-all

Reports the correlation and discrepancies between all type of power management cells and the strategies.

DESCRIPTION

The **associate_mv_cells** command analyzes the current design and associates existing power-management cells according to the UPF strategies. It also checks and reports the correlation between the power-management cells in the netlist and the corresponding UPF strategies. The checking is based only on the UPF strategies. This command does not check for electrical violations.

If none of the power-management cell types are specified, this command associates all types of the power-management cells in the design.

EXAMPLES

The following example shows the report from the **associate_mv_cells** command when you do not specify any argument. All types of power-management cells are reported.

```
prompt> associate_mv_cells
prompt>Information: Total 223 power switch cells have been associated. (MV-021)
prompt>Information: Total 100 retention cells have been associated. (MV-021)
prompt>Information: Total 40 isolation cells have been associated. (MV-021)
prompt>Information: Total 50 level shifter cells have been associated. (MV-021)
1
```

check_mv_design(2)

associate_performance_via_ladder

Associate via rules on lib_pins.

SYNTAX

status **associate_performance_via_ladder**
-lib_pins lib_pin_names
-output association_file_name
-reset
-dont_use

Data Types

lib_pin_names string or collection of lib_pins
association_file_name string

ARGUMENTS

-lip_pins *lib_pin_names*

Specifies lib_pin_names which need performance via ladder candidates.

-output *association_file_name*

Specifies output via ladder association file name. [Default: auto_perf_via_ladder_association.tcl]

-reset

Reset existing via ladder candidates from lib_pins

-dont_use

Allow via_ladder candidates on lib_cells with dont_use attr

DESCRIPTION

This command generates association file for via rules on each lib_pin through set_via_ladder_candidate. This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following is the usage examples.

```
prompt> associate_performance_via_ladder
1

prompt> associate_performance_via_ladder -lib_pins [get_lib_pins */*D12*/Z]
1
```

SEE ALSO

set_via_ladder_candidate(2)

report_via_ladder_candidates(2)

associate_supply_set

Associates a supply set or supply set ref to a supply set handle. The supply set handle should be a pre-defined supply set for the power domain. User defined supply sets cannot be used as supply set handle.

SYNTAX

string **associate_supply_set**
[-handle {supply_set_handle}*]
supply_set_ref

Data Types

supply_set_ref string
supply_set_handle string

ARGUMENTS

-handle {*supply_net_handle*}*

Specifies the name of the predefined supply set of the given domain. This should be the name constructed from the power domain name or strategy name. Predefined *supply_set_handles* for the power domain include: *domain_name.primary*, *domain_name.default_isolation* and *domain_name.default_retention*. This argument is required.

supply_set_ref

Specifies the supply set to be associated with the specified handle.

DESCRIPTION

The **associate_supply_set** command associates a supply set with a power domain or strategy handles. Handles are names rooted in the active scope. Handles should be predefined supply sets for the power domain. If shall be an error if :

1) A supply set handles are already associated with a supply set.

2) The associations of handles to supply sets form a loop of associations.

EXAMPLES

The following example associates a supply set named SS1 to PD.primary

```
prompt> associate_supply_set SS1 -handle PD.primary
```

SEE ALSO

create_supply_net(2)

attach_drc_error_data

Attaches a DRC error data object to the current block.

SYNTAX

status **attach_drc_error_data**
-name *name*
drc_error_data
[-keep]

Data Types

name string
drc_error_data collection

ARGUMENTS

-name *name*

Specifies the name for the new DRC error data file to attach to the current block. The name must be unique; the command fails if the specified name is already used by an error data file attached to the block.

drc_error_data

Specifies the collection that contains DRC error data object to attach. The collection must be derived from an external error data file, such as a previously exported error data file, a manually created error data file, or an error data file from a third-party tool.

-keep

Keeps the specified error data collection open and in memory.

By default, the command closes the specified error data collection.

DESCRIPTION

The **attach_drc_error_data** command attaches the specified error data file to the current block.

The command returns 1 if successful; 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example attaches the current physical DRC error data to a file that is named "dppinassgn.err".

```
prompt> attach_drc_error_data -name dppinassgn.err [get_drc_error_data]
1
```

collections(2)

audit_scripts

audit_scripts

Reads in a script, examines the application options and variables used in the script, and reports any changes to those application options or variables against a specified version of the tool.

The command also reports references to .tbc files.

SYNTAX

status **audit_scripts**
-input *script_name_or_path*
[-skip_hidden]
[-from *version*]

Data Types

script_name_or_path string
version string

ARGUMENTS

-input *script_name_or_path*

Specifies the location of the user scripts you want to audit. You can specify a single Tcl file or a directory name. If you specify a directory, the command audits all files in the directory with the .tcl suffix.

The tool issues an error message if *script_name_or_path* is not a valid file or directory.

-from *version*

A string specifying the tool version to compare your scripts against.

Note that only some tool versions are available for comparison, and that these versions can change across releases. To get a current list of the tool versions available for comparison, run the following command:

```
prompt> audit_script -input . -from x
Error: Value 'x' for option '-from' is not valid. Specify one of:
   18.06-sp5, 18.06-sp4, 18.06-sp2, 17.09-sp5 (CMD-031)
```

By default, if the -from option is not specified, the command compares your script against the most current tool version available.

-skip_hidden

By default, the **audit_scripts** command reports hidden application options, variables, and Tcl commands. If you specify the -skip_hidden option, these items will not be reported.

DESCRIPTION

The **audit_scripts** command reads in one or more scripts, checks the scripts for any deprecated, removed, or otherwise changed application options and variables, and reports the results in an annotated version of each script. The annotated scripts are written to a subdirectory named ./audit, each with the same name as the original file.

An annotated script contains AUDIT_INFO and AUDIT_ERROR comments that provide information about each application option, application variable, and Tcl command change. These comments are also written to the command line output as information messages.

An annotated script might look like this:

```
# AUDIT_INFO at line 105: application option 'cts.verbose.buf' is unhidden.

# AUDIT_ERROR at line 147: application variable 'abor_enhance_inv_pair' is removed.

# AUDIT_ERROR at line 156: system-default of application option
'cts.use_global_route_atree_topology' is changed from true to atree.
```

AUDIT_INFO comments identify the following:

- Application options/variables that have become hidden or unhidden
- Application options that have been deprecated
- Application options whose scope has changed (global v. block-scoped)
- Application variables that can be replaced by application options
- References to .tbc files

AUDIT_ERROR comments identify the following:

- Application options/variables that have been removed
- Application options/variables whose data type has changed
- Application options/variables whose value, user-default value, or system-default value has changed (via an internal or user script)

Note that the **audit_scripts** command evaluates application options and variables that have been specified with the following commands only:

set_app_options
reset_app_options
get_app_option_value

get_app_options
report_app_options
help_app_options

set
set_app_var
get_app_var
report_app_var
write_app_var
printvar

The **audit_scripts** command also evaluates commands that access application variables as Tcl variables:

set *variable_name value*
echo $*variable_name*

To repair any changed application options or variables in your scripts, you may either

Manually repair the application options/variables in your original scripts

Manually repair the application options/variables in the annotated scripts, and then copy the annotated scripts to the location of your original scripts

EXAMPLES

The following example audits the input script test.tcl and writes out an annotated test.tcl script to the ./audit directory:

prompt> **audit_scripts -input test.tcl**

This second example audits all the Tcl scripts in the scripts directory and writes out the annotated scripts to the ./audit directory:

prompt> **audit_scripts -input scripts**

balance_clock_groups

Execute clock balance action among the clock balance groups.

SYNTAX

string **balance_clock_groups**

DESCRIPTION

This command will balance clocks insertion delay for all clock balance groups created by **create_clock_balance_group**.

SEE ALSO

create_clock_balance_group(2)
report_clock_balance_groups(2)
remove_clock_balance_groups(2)
get_clock_balance_groups(2)

change_abstract

Changes the view of the cells.

SYNTAX

status **change_abstract**
[-view design | abstract]
[-label *label_name*]
[-lib *library*]
[-reload]
[-force]
[-update_ref_libs]
-references *reference_list*
-cells *cell_list*

Data Types

label_name string
library string
reference_list list
cell_list collection

ARGUMENTS

-view design | **abstract**

Change the listed references or cells to the given view type. If the **-view** option is not given, then the new referenced block will have the same view type as the original block.

Valid arguments for **-view** are **design** and **abstract**.

-label *label_name*

Change the listed references to the block with the given label. To change to the default label, specify an empty *label_name* as **change_abstract -label ""**.

If the **-label** option is not given, the new referenced block will have the same label as the original block.

-lib *library*

Change the listed references to the block in the given library. The given library must be already opened. If the **-lib** option is not given, the new referenced block will be opened from the same library as the original block.

To change to a new block from a given library, that library must first be listed in the "ref-lib list" of the designs that contain it unless the **-update_ref_libs** option is specified. Use the **set_ref_libs** command to add the library to the ref-lib list.

-reload

Reload the blocks of the listed references from disk. The in-memory copy of the block will be discarded. This option cannot be used in combination with **-view**, **-label**, or **-lib**. The reference will point to the original block after the command is executed.

The **-reload** option is useful if you want to load a block that has recently been updated by some other processing. For example, the block may have been optimized on a distributed server.

Specifying the **-reload** option automatically turns on the **-force** option.

-force

Change the block reference, even if the ports of the new referenced block do not match the original block. By default, the **change_abstract** command issues an error message and exits.

When the new block has different ports, there is a chance that your design will be compromised. For example, if the new block is missing ports, it may be necessary to drop connections and/or constraints.

-update_ref_libs

Add the block library to the ref-lib list of the designs that contain it if it is not already in the ref-lib list. If an existing library in the ref-lib list has the same name as the block library, it is replaced with the block library.

-references *reference_list*

Specifies a list of names of referenced blocks. All cells that point to the referenced block will be changed as specified by the **-view**, **-label**, **-lib**, and **-reload** options. The list must not contain patterns or collections, only simple block names.

-cells *cell_list*

Specifies one or more physical hierarchy cells to change. You must specify the **-view** option together with the **-cells** option. The **-cells** option must not be used with **-label** or **-lib**.

DESCRIPTION

This command changes the current bound block of the given cells. The operation of the **change_abstract** command is similar to the **change_view** and **set_reference** commands, except that hierarchical design constraints that cross block boundaries are preserved. The **change_view** and **set_reference** commands discard all constraints that are inside or cross the boundary of the changed references.

The **change_abstract** command works only with "design" and "abstract" views. These two views are guaranteed to have equivalent function and equivalent port interfaces. This makes it possible to preserve constraints. If you are trying to change to or from other views, or if your port interface is different, you should use the **set_reference** command instead.

Alternative to change_abstract

The **change_view** and **set_reference** commands discard all constraints that are inside or cross the boundary of the changed references. If you use commands other than **change_abstract** you will need to reapply constraints to your design when you are done. You can do this by rereading constraints from your original SDC file.

EXAMPLES

The following example replaces the references to blocks blockA and blockB to the place_opt label of the blocks.

```
prompt> change_abstract -label place_opt -references {blockA blockB}
```

The following example replaces the design view of the given subblocks with an abstract view. Constraint that were originally applied to the subblock from the top level are preserved. The constraints that were saved with the abstract subblock are not promoted to the top level.

```
prompt> change_abstract -view abstract -cells {i_mmu i_fpu1}
```

The following example replaces all cell instances of "FPU" with an abstract view.

```
prompt> change_abstract -view abstract -references FPU
```

The following example uses the **-update_ref_libs** option to replace the reference to block "blockC" located in reference library "oldPath/refLibC" to the one located in the library "newPath/refLibC" and update the reference library list to contain "newPath/refLibC" instead of "oldPath/refLibC".

```
prompt> open_lib newPath/refLibC
prompt> change_abstract -lib newPath/refLibC -references blockC
      -update_ref_libs
```

create_abstract(2)
remove_scenarios(2)
remove_modes(2)
remove_corners(2)

change_link

Changes the design to which a cell is linked.

SYNTAX

status **change_link**
[-design *design*]
cells
design_name

Data Types

cells list
design_name string

ARGUMENTS

-design *design*

Specifies the design from which to change the link for the given cell(s). If no design is specified, the current design is used.

cells

Specifies the cells in the current design for which the link is to be changed.

design_name

Specifies the name of the design to which the cells in *cells* are to be linked.

DESCRIPTION

The **change_link** command specifies a design for which the link for a cell is to be changed. Hence a cell is changed to be one occurrence of the specified design.

The cell can only be changed to a compatible design. For example, the design must have the same number of ports with the same name and direction as the cell.

Although the *design_name* argument accepts names in the format *library/library_cell*, it does not imply that the actual library cell used for the new cell will be from the specified library. The actual library cell used is determined by the current link library settings.

During **change_link** activity, all Synopsys database format link information is copied from the old design to the new design. If the old design is a synthetic module, all attributes of the old synthetic module are moved to the new link. After running the **change_link**

command, link the design with the **link_block** command.

EXAMPLES

The following example shows the use of **change_link** to change the reference of the U1 cell to BUFX3 from INVX3:

```
prompt> get_attribute [get_cells U1] ref_name
INVX3
1

prompt> change_link [get_cells U1] BUFX3
1

prompt> get_attribute [get_cells U1] ref_name
BUFX3
1
```

SEE ALSO

link_block(2)
set_reference(2)

change_names

Changes the names of ports, cells, and nets in a design by applying a set of rules previously defined by the **define_name_rules** command, or renames a specified instance.

SYNTAX

status **change_names**
[-rules *rule_name*]
[-hierarchy]
[-names_file *names_file*]
[-restore]
[-force]
[-include_sub_blocks]
[-log_changes *log_file*]
[-dont_touch *object_list*]
[-instance *instance*]
[-new_name *new_name*]
[-verbose]
[-skip_physical_only_cells]

Data Types

rule_name string
names_file string
log_file string
object_list collection
instance collection
new_name string

ARGUMENTS

-rules *rule_name*

Specifies the name of a rule set previously defined by the **define_name_rules** command, or the predefined **verilog** rule set. The command changes the names of objects in the design according to the specified rule set.

-hierarchy

Changes objects in the full hierarchy of the design and will not cross over into other physical hierarchies or sub-blocks. By default, only the objects of top logical hierarchy are changed.

-names_file *names_file*

Specifies a file of manual name changes. These name changes are not subject to any name rules, but a warning is reported if any name changes are not unique. By default, the command automatically makes name changes based on the names

mentioned in the names file. If you specify this option, the tool ignores the **-rules** option.

-restore

Reverses the changes recorded in the *names_file* during the current session and restores the contents of the file to the state it was in when opened.

-force

Force option along with *names_file* option, changes the names of regular bus members, even the names file entries makes it irregular. Once it becomes irregular, it is bitblasted. Without force option if the result of change_names with names_file makes a bus from regular to irregular, those changes are not applied.

-include_sub_blocks

By default, objects of top logical hierarchy are considered. When *-hierarchy* option is used then all objects within current physical hierarchy is considered and it doesn't cross over into other physical hierarchies or sub-blocks. With this option specified, it will cross over into other physical hierarchies also and in doing so it will consider only the bound views. If an instance in top level is bound to non-design view of a sub-block like for example, abstract, then the command will error out. This is because design view can't be derived from a non-design view and changing non-design view will cause it to go out of sync with its design view. In order to consistently rename all the design data and associated timing constraints, only design views should be used for linking. This option can't be used independently and has to be used along with *-hierarchy*. If any of the sub-blocks is not yet linked then using this option will first link those sub-blocks and then change the names. Include_sub_blocks option is not supported along with *-names_file* option.

-log_changes *log_file*

Specifies a log file in which to record the name changes. By default, no log file is written.

-dont_touch *object_list*

Specifies a list of modules that are not to be changed. You can specify any modules in the hierarchy of the current design to exclude from name changing.

-instance *instance*

Changes the name of an instance in the design. This option can be used only with the **-new_name** option, and not with other options. The command changes the instance name to the specified new name.

-new_name *new_name*

Specifies the new instance name when the **-instance** option is used. The new name may contain only alphanumeric characters and the underscore character (_) and must start with a letter. New name specified must not be the full hierarchical name, instead it should only be the leaf level name. The new name cannot be a reserved word used by Verilog, SystemVerilog, or VHDL, and must not conflict with an existing instance, port, and net name within the same design. Any leading backslash character is removed.

-verbose

Reports every name change. By default, the tool reports only a summary showing the number of name changes for each object type.

-skip_physical_only_cells

Specifies that physical only type of cells should not be considered for name changes. This is applicable for nets and ports of these type of cells as well.

DESCRIPTION

The **change_names** command changes the names of ports, cells, and nets in the current design as needed to conform to specified naming rules. By applying an appropriate set of naming rules, you can write out design data files that are compatible with the requirements of the target external tool when you use the **write_verilog**, **write_def**, or **write_gds** command.

To define a set of naming rules to be used with the **change_names** command, use the **define_name_rules** command. Alternatively, you can use the predefined **verilog** rule set.

To report the available sets of rules, including the predefined **verilog** rule set, use the **report_name_rules** command.

To preview the changes to the design that would be made by applying the **change_names** command, but without actually preforming those changes, use the **report_names** command.

To change the name of a specific instance in the design, use the **change_names** command with the **-instance** and **-new_name** options. These options cannot be used together with the other command options.

The **change_names** command can change the names of objects in design libraries only, not the names of leaf-level cells in reference libraries. To modify reference libraries, use the Library Manager tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Names File Format

To specify a name change, you must specify the following four fields:

design_name object_type object_name new_name

The **design_name** field is a design currently read into the tool.

The **object_type** field is **port**, **cell**, or **net**.

The **object_name** field is the name of an object within the specified design.

The **new_name** field is the name that replaces the existing name.

If the file contains a report bar formed by min 10 dashed line (--------), the tool ignores all information above the report bar.

The tool parses all lines after the report bar (or all lines, if the file does not contain a report bar).

By default, the tool parses each line into four fields, which are separated by whitespace characters, such as blanks, tabs, or new lines.

This format matches the format of the **report_names** command output, which allows you to redirect the output of the **report_names** command to a file, edit it, and then use it as input to the **change_names** command.

The following example shows a names file format.

Design Type Object New Name

TOP cell U$1 U_1

TOP net NET_NAME_IS_WAY_TOO_LONG NET_NAME_IS_WAY_TOO

TOP net 12345 N12345

prompt> **change_names -names_file name.change -verbose**

EXAMPLES

The following commands change the names of ports, nets, and cells in the top logical hierarchy of the current design by converting all lowercase "a" characters to uppercase "A".

```
prompt> define_name_rules my_map_rule -map {{"a","A"}}
1
prompt> change_names -rules my_map_rule
 Information: Using name rules 'my_map_rule'.
 Information: 908 objects (124 ports, 144 cells, ... ) changed in design 'core1'.
1
```

The following command changes the name of instance u0_0 to u0_AB. (This command does not use any naming rules.)

```
prompt> change_names -instance u0_0 -new_name u0_AB
1
```

The following command changes the name of instance old_inst_name in hierarchy A/D to new_inst_name. (This command does not use any naming rules.)

```
prompt> change_names -instance A/D/old_inst_name -new_name new_inst_name
1
```

The following command changes the names in the design to meet Verilog naming conventions using the predefined **verilog** rule set. Using the **define_name_rules** command is not needed.

```
prompt> change_names -rules verilog
 Information: Using name rules 'verilog'.
 information: 601 objects (123 ports, ... ) changed in design 'topAC'.
1
```

Note: The predefined **verilog** rule set used in this example is somewhat different from using the **-special verilog** option in the **define_name_rules** command. The **-special verilog** option in the **define_name_rules** command implicitly invokes the following rules:

-collapse_name_space
-equal_ports_nets
-inout_ports_equal_nets
-remove_irregular_port_bus
-remove_irregular_net_bus

Using **change_names -rules verilog** invokes these same rules, but also invokes the following additional rules:

-check_internal_net_name
-check_bus_indexing
-flatten_multi_dimension_busses
Do not use reserved words (long list)
Use only alphanumeric characters
Start names with a letter

Using the **-special verilog** option in the **define_name_rules** command is more flexible because you can add more rules to your custom rule set. The **change_names -rules verilog** command cannot be customized.

For details of the exact rules invoked by the **verilog** keyword, use the **report_name_rules** command.

SEE ALSO

define_name_rules(2)
report_names(2)
report_name_rules(2)

change_reference

Rebinds hierarchical cells to a new reference cell

This command is deprecated, please use set_reference command.

SYNTAX

collection **change_reference**
[-design *reference_design*]
[-module *module_name*]
[-verbose]
cell_list

Data Types

reference_design design name or collection
module_name string
cell_list list

ARGUMENTS

cell_list

Specifies the list of hierarchical cells to be rebound to new reference. Each cell must be in scope (at or below the current instance).

-design *reference_design*

Specifies the new design to which the specified cells are to be bound. The specified cells must be currently bound to another design. The argument can be a design name or a collection of one design. The cells must be bound to a design with the same port interface as the new design. This argument is mutually exclusive with *-module*.

-module *module_name*

Specifies the name of an existing module in the current design to which the specified cells are to be bound. The specified cells must be currently bound to another module. The new module must have the same port interface as the module the cells are currently bound to. This argument is mutually exclusive with *-design*

-verbose

Prints additional information.

DESCRIPTION

The **change_reference** command changes the reference of the given list of hierarchical cells. All the specified cells must have the same current reference. The new reference and the current reference of the cells must have the same exact port interface. This means that the number of ports, port directions and port names must be the same. Further, the current and new references must be of the same *type*. This means that if the current reference of the cell is a design, the new one must also be a design and if the current reference is a logical module in the current design, the new one also must be a logical module in the current design. The new reference must already exist. Further, when the reference is a design, the reference design with the view bound currently, must exist. The view bound to the cell is not changed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following examples, change_reference is used for changing the reference of cells bound to designs and logical modules

```
prompt> change_reference -design [get_designs alu_1] u1
1

prompt> change_reference -module logical_alu {u2 u3}
2
```

set_reference(2)
uncommit_block(2)
uniquify(2)

change_selection

Changes the selection in the GUI, taking a collection of objects and changing the selection according to the type of change specified.

SYNTAX

int **change_selection**
[-name *slct_bus*]
[-replace]
[-add]
[-remove]
[-toggle]
[-type *object_type*]
collection

Data Types

slct_bus	string
object_type	list
collection	list

ARGUMENTS

-name *slct_bus*

Specifies to change the selection bus by using the value of *slct_bus*. By default, the command changes the selection bus by using the name *global*.

-replace

Replaces the current selection with the objects in the collection. This is the default behavior of the command if you do not specify any optional parameter.

-add

Adds the objects in the collection to the current selection. By default, this option is off.

-remove

Removes the objects that are specified in the collection from the current selection. By default, this option is off.

-toggle

Adds each item that is specified in the collection to the selection bus if it is not currently contained there. If it is currently contained in the selection bus, remove it. By default, this option is off.

-type *object_type*

Specifies the type to change. Only those items from the collection that are of the type specified by *object_type* are used to change the selection. The valid values are **design**, **port**, **net**, **cell**, **pin**, and **path** (timing path). By default, the command uses the entire collection.

collection

Specifies the collection of objects to use to change the selection. The type of change that is applied to the current selection with the *collection* is specified by the optional parameters listed above. By default, this option is off.

DESCRIPTION

The **change_selection** command changes the selection in the GUI. When selections are changed, the GUI updates all relevant windows to reflect it.

A collection of objects and the type of change are given as input to the command. The collection of objects might be returned as the result of another command such as the **get_designs** command. If the collection is empty and you use the **-replace** option (or let the command default by specifying no option), the current selection is cleared.

If you use the **-type** option, only the type of objects specified are used to change the current selection. For example, if you use **-type design**, the command uses only the design objects in the collection to change the current selection. If you do not use **-type** option, all objects in the collection are used to change the current selection. For example, if you use the **-add** option without using the **-type** option, all objects, regardless of their type, are added to the current selection.

For information about collections, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example replaces the current selection with the collection of design objects, regardless of type.

```
prompt> change_selection [get_designs]
```

The following example adds a cell named U5 to the selection made in the example above.

```
prompt> change_selection -add [get_cells U5]
```

The following example removes all pin objects from the current selection.

```
prompt> change_selection -remove -type pin [get_selection]
```

The following example clears the selection.

```
prompt> change_selection ""
```

The following example creates a new selection bus and adds a net named n1 to the selection.

```
prompt> set slct [create_selection_bus]
prompt> change_selection  -name $slct [get_nets 1]
```

SEE ALSO

collections(2)
create_selection_bus(2)
filter(2)
filter_collection(2)
get_selection(2)
query_objects(2)

change_selection_no_core

Indicates that objects had no core representation

SYNTAX

change_selection_no_core -name *Slct*
[-add]
[-remove]
-type *Type*
-names *NameList*

Slct *String*
Type *String*
NameList *list of strings*

ARGUMENTS

-name *Slct*

Slct specifies the name of a selection container for which changes were logged.

-add

This option is specified if the objects were added to the selection container. This is mutually exclusive with option -remove.

-remove

This options is specified if the objects were removed from the selection container. This is mutually exclusive with option -add.

-type *Type*

Type is the type of the objects the names of which are specified with *NameList*.

-names *NameList*

NameList is the list of names of the involved objects. All the objects are of type *Type*.

DESCRIPTION

When the change of contents of a selection container gets logged it can happen that not all the objects involved in the change can be represented by the core. If this happens then this command is logged for the objects that did not have a core representation. For each type with objects without core representation a separate command is logged. Also a separate command is logged for objects

that were added and objects that were removed. The arguments of the logged command specify which selection container changed, if the objects were added or removed, the type of the objects and their string representations.

Having this command logged documents that the contents of the log file is incomplete and a replay might not work correctly.

Depending on variable *selection_logging_no_core_action* the command behaves differently.

If the value of the variable is the string "clear" the command clears the selection container *Slct*.

If the value of the variable is the string "error" the command raises a Tcl error.

In all other cases the command does nothing.

SEE ALSO

change_selection_too_many_objects(2)

change_selection_too_many_objects

Indicates that too many objects were involved in selection change

SYNTAX

change_selection_too_many_objects -name *Slct*
[-add]
[-remove]

Slct *String*

ARGUMENTS

-name *Slct*

Slct specifies the name of a selection container for which changes were logged.

-add

This option is specified if the objects were added to the selection container. This is mutually exclusive with option -remove.

-remove

This options is specified if the objects were removed from the selection container. This is mutually exclusive with option -add.

DESCRIPTION

When the change of contents of a selection container gets logged it can happen that the number of objects involved in the change exceeds the number specified by the preference of category *Globals* and key *selection_loggin_max_names*. In this case not all objects involved in the change are logged but instead this command is logged. A separate command is logged if the number of added objects or the number of removed objects exceed the given limit. The arguments of the logged command specify which selection container changed and if the objects were added or removed.

Having this command logged documents that the contents of the log file is incomplete and a replay might not work correctly.

Depending on variable *selection_logging_too_many_objects_action* the command behaves differently.

If the value of the variable is the string "clear" the command clears the selection container *Slct*.

If the value of the variable is the string "error" the command raises a Tcl error.

In all other cases the command does nothing.

SEE ALSO

change_selection_no_core(2)

change_view

Changes the view of the cells.

Changes the view of the cells.

SYNTAX

status **change_view**
[-view *view_type*]
[-label *label_name*]
[-lib *library*]
[-reload]
[-force]
[-update_ref_libs]
-references *reference_list*
-cells *cell_list*

Data Types

view_type string
label_name string
library string
reference_list list
cell_list collection

ARGUMENTS

-view *view_type*

Specifies the name of view type to use.

If you do not specify the **-view** option, the command resets the reference view of the specified cells to the original view set by the linker and the view switch list.

Valid values for the *view_type* argument are **abstract**, **conn**, **design**, **error**, **frame**, **layout**, **outline**, and **timing**.

-label *label_name*

Change the listed references to the block with the given label. To change to the default label, specify an empty *label_name* as **change_abstract -label ""**.

If the **-label** option is not given, the new referenced block will have the same label as the original block.

-lib *library*

Change the listed references to the block in the given library. The given library must be already opened. If the **-lib** option is not

given, the new referenced block will be opened from the same library as the original block.

To change to a new block from a given library, that library must first be listed in the "ref_lib list" of the designs that contains it. unless the **-update_ref_libs** option is specified. Use the **set_ref_libs** command to add the library to the ref_lib list.

-reload

Reload the blocks of the listed references from disk and discard the in-memory copy of the block. This option cannot be used in combination with **-view**, **-label**, or **-lib**. The reference will point to the original block after the command is executed.

The **-reload** option is useful if you want to load a block that has recently been updated by some other processing. For example, the block may have been optimized on a distributed server.

Specifying the **-reload** option automatically enables the **-force** option.

-force

Change the block reference, even if the ports of the new referenced block do not match the original block. By default, the **change_abstract** command issues an error message and exits.

When the new block has different ports, there is a chance that your design will be compromised. For example, if the new block is missing ports, it may be necessary to drop connections and/or constraints.

-update_ref_libs

Add the block library to the ref-lib list of the designs that contain it if it is not already in the ref-lib list. If an existing library in the ref-lib list has the same name as the block library, it is replaced with the block library.

-references ***reference_list***

Specifies a list of names of referenced blocks. All cells that point to the referenced block will be changed as specified by the **-view**, **-label**, **-lib**, and **-reload** options. The list must not contain patterns or collections, only simple block names.

-cells ***cell_list***

Specifies one or more physical hierarchy cells to change. You must specify the **-view** option together with the **-cells** option. The **-cells** option must not be used with **-label** or **-lib**.

DESCRIPTION

This command changes the current bound view for one or more cell instances.

If the specified view type does not exist for one or more of the cell instances, the command returns an error status and does not change the bound view for those cells. However, the command does change the bound view for the other cells.

The bound view for cells in the top block is persistent. The bound view for cells in child blocks is not persistent. After a block hierarchy is saved and restored, the bound views in the top block are preserved and the bound views for cells within child blocks revert to the binding saved for that cell within that child block.

CAUTION

The **change_view** command is not intended for use on designs that have top-down constraints applied. If you use the **change_view** command, constraints that apply to the block or span the block boundary are lost and you must reapply your constraints from an SDC file. If your design has top-down constraints, you should use the **change_abstract** command.

Once all the invocations of **change_view** are done, a follow up call to the command **link_block -force** is to be done in some cases. This should be done when the block to which the cell is to be changed is either of **module** or **blackbox** design type.

EXAMPLES

The following example replaces the existing design view with the outline view for the cell instance named u1/mem1:

```
prompt> change_view -view outline u1/mem1
```

The following example specifies that the design view is to be used for the cell instance named u1/mem1:

```
prompt> change_view -view design u1/mem1
```

The following example specifies that the view switch list should be used to determine the bound view for the cell instance named u1/mem1:

```
prompt> change_view u1/mem1
```

The following example specifies that the abstract view is to be used for all cells that reference the block named MIDDLE:

```
prompt> change_view -view abstract -references MIDDLE
```

The following example uses the **-update_ref_libs** option to replace the reference to block "blockA" located in reference library "oldPath/refLibA" to the one located in the library "newPath/refLibA" and update the reference library list to contain "newPath/refLibA" instead of "oldPath/refLibA".

```
prompt> open_lib newPath/refLibA
prompt> change_view -lib newPath/refLibA -references blockA
      -update_ref_libs
```

characterize_block_pg

Writes out power and ground creation constraints, including via master rule, pattern, strategy, and strategy via rules, for each block in preparation for distributed PG creation. The constraints are based on the top-level power ground creation constraints in the hierarchical design. The command creates a power ground constraint script for each block with the same reference design. The script can be used to regenerate power and ground at the block level. The scripts are created under the pgroute_output directory in the current path. The command writes out a mapping file when you use the **-compile_pg_script** option. The map file specifies the PG constraints and script to use with the **compile_pg** command during distributed PG creation.

SYNTAX

status **characterize_block_pg**
[-output_directory *directory_name*]
[-compile_pg_script *file_name*]

Data Types

directory_name string
file_name string

ARGUMENTS

-output_directory *directory_name*

Specifies the output directory name for the generated block-level PG script files. The directory is created under the current path. If not specified, "pgroute_output" is used as the output directory.

-compile_pg_script *file_name*

Specifies the **compile_pg** script file name. The script can contain PG route application options and **compile_pg** commands, but should not include PG via master rule, pattern, strategies and strategy via rule commands.

When this option is specified, the command writes out a PG mapping file called "pg_mapfile" into the output directory specified by the **-output_directory** option. This mapping file specifies the PG constraint and PG **compile_pg** script for each block, and is needed for distributed PG creation. The PG constraint for the current top-level design is not included inside the mapping file since the top-level PG constraint has already been defined and is persistent.

By default, the mapping file is not generated. A sample map file is as follows:

```
leon3s    PG_CONSTRAINT  ./leon3s_pg.tcl
leon3s_2  PG_CONSTRAINT  ./leon3s_2_pg.tcl
leon3s_3  PG_CONSTRAINT  ./leon3s_3_pg.tcl

leon3s    COMPILE_PG     ./compile_pg_script.tcl
leon3s_2  COMPILE_PG     ./compile_pg_script.tcl
leon3s_3  COMPILE_PG     ./compile_pg_script.tcl
```

```
leon3mp   COMPILE_PG    ./compile_pg_script.tcl
```

DESCRIPTION

This command characterizes PG creation constraints, including via master rule, pattern, strategy, and strategy via rule for each block based on the top-level constraints in the hierarchical design.

This command writes out a map file that contains a list of PG constraint files and block names for each block. Before proceeding with distributed PG creation with the **run_block_compile_pg** command, the mapping file name must be assigned with the **set_constraint_mapping_file** command.

EXAMPLES

The following example characterizes PG creation constraints for all-level of physical hierarchy in the hierarchical design.

```
prompt> characterize_block_pg -compile_pg_script pg_script.tcl
```

The following example characterizes PG creation constraints for up-to second level of physical hierarchy in the hierarchical design.

```
prompt> set_editability -value false -from_level 3
prompt> characterize_block_pg -compile_pg_script pg_script.tcl
```

characterize_topology_plans

Pushes down topology plans, nodes, edges, and repeaters into blocks within the hierarchy as needed.

SYNTAX

string **characterize_topology_plans**
[*topology_plan_list*]

Data Types

topology_plan_list collection

ARGUMENTS

topology_plan_list

Specifies a list of topology plans to characterize. The list can contain topology plan names, patterns, or collections. A collection can be specified by using the **get_topology_plans** command.

DESCRIPTION

The **characterize_topology_plans** command pushes down topology plans, nodes, edges, and repeaters into blocks within the hierarchy. If *topology_plan_list* is specified, those topology plans are characterized. If it is not specified, then all topology plans in the current block are characterized.

EXAMPLES

The following example pushes down topology plans, nodes, edges, and repeaters into blocks for the current topology plan.

prompt> **characterize_topology_plans [current_topology_plan]**

SEE ALSO

optimize_topology_plans(2)

propagate_topology_plans(2)

check_3d_design

Checks a 3D-IC design for physical and electrical connectivity. The command checks connectivity and chip design information inside the 3D IC and between two neighboring stacked chips.

SYNTAX

status **check_3d_design**
[-chip_placement]
[-physical_contact]
[-logical_physical_consistency]
[-matching_type]
[-bump_cluster]
[-physical_design_rule]
[-verbose]
[-error_view]

ARGUMENTS

-chip_placement

Checks the vertical level and overlap of the top-level chip. If two chips are specified with the same z (vertical level) value, they should not overlap. If two chips are neighboring, the chip with the larger virtual top-level area should contain the other one.

-physical_contact

Checks the correctness of physical contacted bumps. Inter-chip physical contact information includes the following:

- Non-aligned bump pairs
- Bumps that do not physically connect to a bump on the adjacent side of a vertical neighboring chip
- Bumps that contact more than one bump of a neighboring chip
- Overlap of a bump and another bump in a single chip

-logical_physical_consistency

Checks the logical and physical consistency of the design. If the top-level port instance pair does not have a corresponding physical bump pair, the command issues an error message.

-matching_type

Checks the matching type mismatch on logical connection and physical contact among all dies in the 3D design.

-bump_cluster

Checks the bump cluster in design for the following conditions:

- Bump cluster in a chip should has no more than 1 nets;
- If one bump in the physical contact pair belongs to a cluster, the other bump in the physical contact pair should also belong to another cluster.

-physical_design_rule

Checks the following constraints:

- TSV to TSV spacing constraint, which use the "minCutSpacing" defined in the tech file
- TSV to cell boundary spacing constraint, which use the "tsvKeepoutSpacing" defined in the tech file

-verbose

Prints detailed information. If you omit this option, the command prints only part of messages and a summary of the information.

-error_view

Specify the file name that would be used for GUI error browser. The default file name is "check3dDesign.err".

DESCRIPTION

In a 3D-IC, multiple chips are stacked vertically or placed side by side on a silicon interposer. At the top-level of a 3D-IC, the entire chip stack is modeled as a virtual top-level design and the individual chips are modeled as cells. If you specify **-physical_contact**, the command checks the physical connections between every neighboring chip and ensures that the contacting bumps are in the correct alignment. The command checks the elevation of each chip based on the Z-value specified by the **set_cell_location** command. Chips with the same Z-value are considered to be at the same elevation and are checked for chip overlaps. Chips with adjacent Z-values are considered to be neighboring chips and are checked for physical contact.

Note: The **check_3d_design** command should be used at the last step of 3D-IC design flow and run at the top level.

The **check_3d_design** command writes warning and error messages that indicate potential problems in the 3D-IC design. These problems might need to be corrected before manufacturing the 3D design. The command checks the following conditions:

- Cannot get the chip placement information
- Vertical level (Z-value) of each chip
- Chip coordinates at the top level
- Z-values of chips that do not start from 0
- Z-values of chips that are not continuous
- Chips on same level (with same Z-value) that are overlapped
- Two vertical neighboring chips are partially overlapped rather than the large chip completely covering the small chip
- Bumps are overlapped in the chip
- Non-aligned bump pairs
- Bumps do not physically connect to bump on adjacent side of vertical neighboring chip
- Bumps contact to more than one bumps of neighboring chip
- There is no bump pair on the adjacent sides between two vertical neighboring and overlap chips

- The physical bump connections between two contacting chips do not match the logical netlist specification
- Logically connected pins of two chips on top-level design that do not have physical connected bump pairs
- Matching type mismatch between bump pairs
- Logical connected bumps or drivers on same net have different matching types
- Bump clusters have more than 1 nets
- Physical contacts are cluster inconsistent
- Chips with net to package does not have zValue = 0
- Nets on top level does not link 2 terminals
- Spacing between TSV and chip boundary violate tsvKeepoutSpacing constrain defined in tech file
- Spacing between TSV and TSV violate minCutSpacing constrain defined in tech file

To ensure that the 3D-IC flow is successful, you should resolve any reported errors. See the man pages for the reported error message to get more information and guidance.

Prerequisites

create_3d_mirror_bumps
propagate_3d_connections
propagate_3d_matching_types
set_cell_location

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs all 3D-IC checks on the design.

prompt> **check_3d_design**

The following example command performs a physical contact bumps check of the stacked chips.

prompt> **check_3d_design -physical_contact**

SEE ALSO

propagate_3d_matching_types(2)
report_3d_chip_placement(2)
set_cell_location(2)

check_boundary_cells

Checks boundary cell placement violations in a design.

SYNTAX

status **check_boundary_cells**
[-error_view *view_name*]
[-voltage_area {*objects*}]

Data Types

view_name string
objects list

ARGUMENTS

-error_view *view_name*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name.

-voltage_area {*objects*}

Specifies the voltage areas to check boundary cells.

DESCRIPTION

This command checks the boundary cell placement violations according to the boundary cell rules set by *set_boundary_cell_rules*. The violations can be classified as:

1. Continuity Violation: For this rule, all the boundary cells should be a complete circuit. If no, there will be a violation. If user only insert boundary cells along all the left and right edges, the boundary cells should cover all the left and right edges. If no, there will be a violation.

2. Corner And Boundary Cell Violation: This rule requires that all the corner and boundary cells are at the correct location.

3. Orientation Violation: This rule requires that all the corner and boundary cells are at the correct orientation.

4. Short Edge And Segment Violation: This rule requires that the length of each horizontal edge of every macro (including hard keepout margin), hard placement blockage, voltage area (including guard band) must be greater than the threshold specified by the

option *-min_horizontal_jog*. If not, there will be a violation. This rule also requires that the length of each segment must be greater than the threshold specified by the option *-min_row_width*. If not, there will be a violation.

This command does not check if there is no_1x violation and does not honor the following 4 options of the **set_boundary_cell_rules** command:

- -tap_distance
- -prefix
- -separator
- -do_not_swap_top_and_bottom_inside_corner_cell

EXAMPLES

The following example checks if there is any continuity violation, correct corner and boundary cell violation or correct orientation violation in current boundary cell placement.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \
        -right_boundary_cell myLib/CellRight \
        -top_boundary_cells myLib/CellTop \
        -bottom_boundary_cells myLib/CellBottom
prompt> check_boundary_cells
```

SEE ALSO

compile_targeted_boundary_cells(2)
check_targeted_boundary_cells(2)

check_bufferability

Checks for a buffering supply, available lib_cells, and bufferability problems on a net segment

SYNTAX

status **check_bufferability**
[-nets *net_list*]
[-driver *pin_or_port*]
[-loads *pins_or_ports*]
[-hierarchy *logical_hierarchy_name*]
[-voltage_area *voltage_area_name*]
[-voltage_area_shape *voltage_area_shape_name*]
[-coord *location*]
[-verbose]
[-nosplit]

Data Types

net_list collection
pin_or_port collection
pins_or_ports collection
logical_hierarchy_name collection
voltage_area_name collection
voltage_area_shape_name collection
location point

ARGUMENTS

-nets *net_list*

Specify net segments to check their bufferability. It can be a net name or collection. The nets must exist in the design. If this option is used, the **-driver, -loads,** and **-hierarchy** options are not needed and are ignored if specified. This command checks bufferability for only these net segments. Other segments of the same net might have different bufferability results.

-driver *pin_or_port*

Specify a single physical net driver; the command checks the bufferability between the driver and a set of loads in a specified hierarchy. The driver should be a leaf cell output pin, an input port of the current design, or a bidirectional leaf pin or port. It can be specified as a name or collection. The driver must exist in the design. If this option is specified, **-hierarchy** must also be specified. The driver does not have to be logically connected to the specified **-loads**, nor related to the specified **-hierarchy**. This option is ignored if used together with the **-nets** option. Without **-loads** option, it will check bufferability in target hierarchy with no loads.

-loads *pins_or_ports*

Specify one or more physical net loads; the command checks the bufferability between the loads and a driver in a specified hierarchy. The loads should be leaf cell input pins, output ports of the current design, or bidirectional leaf pins or ports. The loads can be specified as a list of names or as a collection. The loads must exist in the design. If this option is specified, **-driver** and **-hierarchy** must also be specified. The loads do not have to logically connected by the same net to each other or to the specified **-driver**, nor do they have to be related to the specified **-hierarchy**. This option is ignored if used together with the **-nets** option.

-hierarchy ***logical_hierarchy_name***

Specify a logical hierarchy in which to check bufferability between a specified driver and loads. Only logical hierarchies are accepted, any leaf cell objects used with the **-hierarchy** option results in an error. The logical hierarchy can be specified as a name or a collection. The hierarchy must exist in the design. This option should be used together with the **-driver** option. The hierarchy does not have to be logically related to the specified **-driver** and **-loads**. This option is ignored if used together with the **-nets** option.

-voltage_area ***voltage_area_name***

Specify a voltage area in which to check bufferability. This option is optional. The voltage area can be specified as a name or collection. The voltage area must exist in the design. The voltage area does not have to be related to the hierarchy of any of the specified **-nets, -driver, -loads,** or **-hierarchy**. If this option is not specified, it will find the native voltage area for the given nets or the given hierarchy. The option **-voltage_area**, **-voltage_area_shape** and **-coord** are mutually exclusive to each other.

-voltage_area_shape ***voltage_area_shape_name***

Specify a voltage area shape in which to check bufferability. This option is optional. The voltage area shape can be specified as a name or collection. The voltage area shape must exist in the design. If secondary PG constraints are defined and a dual-rail cell is needed, the check will determine if the given VA shape has a strap available as per the secondary PG constraints. The option **-voltage_area**, **-voltage_area_shape** and **-coord** are mutually exclusive to each other.

-coord ***location***

This option is optional. It takes a point consisting of a tcl list of x coordinate and y coordinate. If secondary PG constraints are defined and a dual-rail cell is needed, the check will determine if the given point has a strap available as per the secondary PG constraints. The option **-voltage_area**, **-voltage_area_shape** and **-coord** are mutually exclusive to each other.

-verbose

Specify that verbose output be generated. By default, **check_bufferability** gives basic information about bufferability, including the available buffering supply, number of type of available lib_cells, and whether any bufferability problems exist. In verbose mode, detailed information is reported regarding how the buffering supply is determined. Also, it prints a full list of available and unavailable lib_cells, including reasons that those lib_cells are unavailable.

-nosplit

Specify nosplit style reporting behavior. By default, line wrapping of long rows of data is done automatically. In nosplit mode, line wrapping is not done. Readable column alignment is still maintained in nosplit mode.

DESCRIPTION

=== Summary ===

The **check_bufferability** command checks net bufferability. Use this command to understand the following information about a net:

- What supply net is used for buffering
- Whether single rail, dual rail, or insulated dual rail buffers are used for buffering
- How many and which buffer and inverter lib_cells are available for buffering the net

- Whether there are design constraints or other factors that would prevent buffering, despite an available buffering supply and available lib_cells

=== Use Models ===

There are two use models for calling **check_bufferability**:

check_bufferability -nets [-voltage_area|-voltage_area_shape|-coord]

check_bufferability -driver [-loads] -hierarchy [-voltage_area|-voltage_area_shape|-coord]

In the first use model, the **-nets** option specifies net segments on which to check bufferability. A net might consist of many logical segments, which can be accessed using **get_nets -segments**. Bufferability can be different for each net segment, so it is important to specify the correct net segment to get back correct bufferability results. To get a full understanding of the bufferability of the entire net, it might be necessary to call **check_bufferability** multiple times on different net segments. Reasons that bufferability can change for different segments of the same net include:

- The net crosses into different power domains and voltage areas. Each power domain can have different primary and available supplies. So, the net segments of one power domain might be bufferable using single rail buffers with the domain primary supply, but dual rail buffers are needed for the segments of a different power domain.
- The fanouts of the net segments change. For example, in a switched domain, one net segment might fanout to a switched load and an always-on load, requiring dual rail buffering to reach the always-on load. But, querying a different net segment that only fans out to the switched load shows that single-rail buffers can be used.
- Design constraints are present that affect net segments or hierarchies differently. For example, **set_dont_touch** constraints can be applied to some net segments but not others. Another example is **set_target_library_subset** constraints that restrict available lib_cells in different logical hierarchies. Either of these constraints can cause one segment of a net to be unbufferable while other segments remain bufferable.

In the second use model, the **-driver** and **-loads** options are used to specify a net driver and one or more net loads which must be buffered. This approach can be used to do a more restricted bufferability query on a net than using the **-nets** option. For example, if using **-nets** shows the net has no available buffering supply, you can use **-driver** and **-loads** to remove some of the loads from consideration, and see if the net is bufferable for the remaining loads.

The **-driver** and **-loads** options can also be used to perform a hypothetical bufferability query between a certain set of related supplies. The specified driver and loads do not have to belong to the same net, or hierarchy, or voltage area. You can specify any arbitrary drivers and loads in the design. When making such a hypothetical query, you are asking "what is the bufferability of a net with the same related supply as the specified driver, going to loads with the same related supplies as the specified loads?"

When using the **-driver** and **-loads** options you must also use the **-hierarchy** option. This specifies which logical design hierarchy in which to check bufferability. This information is required to do an accurate bufferability query, because things like target library subset constraints or bias optimization have hierarchy dependent impact on bufferability.

When using **-driver, -loads,** and **-hierarchy**, the command tries to identify a real net segment in the design that corresponds to those specified options. If it finds one, then it prints an information, and can perform the full range of bufferability checks. If the command cannot identify a real net segment, then certain bufferability checks like dont_touch and is_ideal cannot be performed, since they are associated with net segments.

When using **-driver** and **-hierarchy** without **-loads** option, it specifies a special situation for a hypothetical or real dangling net without any loads.

In both use models, the voltage area is very important, as it defines the primary supply and available supplies that could be used for buffering. Without **-voltage_area** option, the command will choose native voltage area of the given net or hierarchy.

You can check bufferability either in the native voltage area of the net or in any arbitrary voltage area. Normally, buffers can only be physically placed in the voltage area that is native to the net segment being buffered. By enabling the physical feedthrough buffering feature, you can disconnect the logical from the physical and allow buffers to be placed in voltage areas non-native to the net segment hierarchy. This is enabled by:

set_app_options -name opt.common.allow_physical_feedthrough -value true

create_voltage_area_rule -allow_physical_feedthrough true

By enabling the logical feedthrough buffering feature, you expect buffers are placed in the new hierarchy. The new hierarchy is non-native for the given net segment, but native for the given voltage area. Furthermore, additional new hierarchical ports need to be punched from net segment hierarchy to new hierarchy to connect the buffers. This is enabled by:

create_voltage_area_rule -allow_logical_feedthrough true

If you use **check_bufferability** to query a net segment that exists in a logical hierarchy that is not native to the specified voltage area, this implies that you are doing a logical or physical feedthrough buffering query. **check_bufferability** issues a warning if such a query is done when both logical and physical feedthrough buffering are set to false.

=== Buffering Supply Availability ===

The first thing checked by **check_bufferability** is the supply net availability for buffering. Supply availability is determined first by finding the related supply of the driver pin and all load pins. You can manually check this using the **get_related_supply_nets** command. The set of candidate supplies for buffering is all the related supplies of the driver and loads of the net, plus their PST-equivalent supplies. This set of candidates is then filtered based on the supply availability in the specified voltage area. Finally, a buffering supply is selected from among the candidate supplies that meets these criteria:

- Does not introduce an isolation violation between the driver and any of the loads. To satisfy this condition, the chosen supply must be less-than-or-equal on compared to the driver supply, and more-than-or-equal-on compared to all load supplies
- Does not introduce a voltage shifting violation
- Single rail buffering is preferred to dual rail buffering, so the domain primary supply is chosen if possible

This process is used for determining the buffering supply of most nets. Some nets have special loads that require a different approach. These special loads include isolation cells, enable level-shifters, and overdriven level shifters. The related supply of these special cell inputs is invalid -- it is just the same as the output related supply. To guarantee that no MV violation is introduced, the buffering supply is restricted to only the driver supply for such nets. Using any other supply risks introducing an MV violation that cannot be detected until simulation is run on the output netlist from IC Compiler II.

check_bufferability reports the results of the supply availability check as a set of supplies that can be used: power, ground, as well as nwell and pwell supplies for bias designs. It also reports the type of buffer needed to use those supplies:

- Single rail: If the buffering power supply is the domain primary power supply
- Dual rail: If the buffering power supply is not the domain primary power supply
- Insulated dual rail: For bias design only, when a dual rail buffer is needed and the required backup supply for the buffer is more on than the domain primary nwell supply

As previously mentioned, which net segment is queried by **check_bufferability** is critical to the results of the buffering supply availability check. To get a complete picture of net bufferability, it is important to query a net segment from each power domain that the net logically enters. The first net segment encountered in each power domain is typically the most useful to query. It will give the most pessimistic result, since it will have the most load fanouts that could have different or even conflicting related supplies. Also, in most cases, it is most representative of what the data or CTS buffering engines will see for the available buffering supply.

By default, **check_bufferability** prints a one line summary message that gives the buffering supply information. To get more detailed information about the related supplies and special MV characteristics of any of the driver or load pins, use the **-verbose** option.

=== lib_cell Availability ===

If a valid buffering supply is determined, then **check_bufferability** next evaluates available lib_cells that can be used to buffer the net. If no valid buffering supply is determined, then lib_cell checking cannot be performed, and **check_bufferability** issues a warning.

check_bufferability evaluates every buffer and inverter lib_cell in the libraries as candidates for buffering the net. There are 7

reasons that a buffer or inverter cannot be used:

1. lib_cell purpose exclusion: The lib_cell has been excluded based on the **set_lib_cell_purpose** settings. **check_bufferability** uses an appropriate lib_cell purpose for querying buffering, depending on which engine can do high-fanout buffering for the net. It uses *optimization* purpose for data nets, *cts* purpose for clock nets, *cts* purpose for mixed clock and data nets that have been correctly isolated by the tool using clock/data isolation buffers, and both *optimization* and *cts* purpose for any mixed clock and data nets that have not been isolated from each other.
2. dont_touch constraint: If **set_dont_touch** is applied on the lib_cell, it cannot be used for buffering.
3. Target library subset exclusion: **set_target_library_subset** constraints exclude this lib_cell from being used in the hierarchy of the **-nets** or **-hierarchy** option.
4. site_def mismatch: The site_def of the lib_cell doesn't match the site_def of any site_rows in the specified voltage area. This can also occur if the site_def names match, but the characteristics are mismatched, like if the height of the lib_cell site_def and site_row site_defs is mismatched. To manually check site_def information, use the site_def attribute on lib_cell, site_row, or site_array objects.
5. Bias mismatch: This occurs for lib_cells that don't match the bias context. For example, any lib_cells without nwell and pwell pg_pins would be rejected for use in a bias block. Similarly, insulated dual-rail lib_cells would be excluded if regular dual-rail lib_cells are required.
6. Voltage mismatch: The lib_cell pg_pin voltage doesn't match that required by the buffering supply. For example, the net needs to be buffered with a 1.0V supply, but the lib_cell supply is 2.0V.
7. Incompatible supply rails: This usually occurs if the number of pg_pins on the lib_cell doesn't match what is expected. For example, if a single-rail buffer is needed, then dual-rail buffers are rejected due to the extra backup power pin.

check_bufferability reports the lib_cell availability as a count of available buffers and inverters on the same summary line that shows the buffering supply information. For example:

```
Information: Can insert single rail buffers (25 lib_cells) and inverters (33
lib_cells) with supply nets (power: VDD, ground: VSS). (MV-453)
```

To get more detailed information that lists every available buffer and inverter, as well as every unavailable buffer and inverter including the reason that it is unavailable, use the **-verbose** option.

=== Bufferability Problems ===

After performing buffering supply checking and lib_cell availability checking, **check_bufferability** also checks for buffering problems related to design constraints and other factors. Any of these that occur are listed as part of the standard output of **check_bufferability** under the 'Bufferability Problems' section. These reasons are:

- The net has no driver
- The net has multiple drivers
- The net is dont_touch
- The net is ideal
- The net is driven by constant 1 or 0
- The net is tri-state
- The net belongs to a read-only block
- The net is not in the block of the given voltage area
- The net's hierarchy is not in the domain scope of the given voltage area
- Freeze ports are found and not able to find LFT hierarchy

- No LFT buffer insertion is allowed for the given voltage area, please check its voltage area routing rule.
- Logical or physical feedthrough buffering must be enabled to buffer the net in the given voltage area
- No legal supply nets are available for buffering
- No legal supply nets are available for buffering: nwell/pwell supply nets are less on than primary power/ground for the given voltage area
- No legal lib cells are available for buffering

In some cases, all of these checks cannot be performed. **check_bufferability** always prints a warning if any checks are skipped.

The 'No legal supply nets area available for buffering' message occurs if the buffering supply checking fails. In this case, lib_cell availability checking is skipped.

The 'No legal lib cells are available for buffering' message occurs if 0 buffers and 0 inverters are available based on the lib_cell availability checking.

Checking of net dont_touch and is_ideal properties can only be done if a real net segment is identified by the command. They are skipped if the **-driver** and **-hierarchy** options are used to perform a hypothetical bufferability query.

If the net has no driver, then supply net availability and lib_cell availability checking is skipped.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

Check bufferability for all net segments with prefix SNPS in native voltage area.

```
prompt> check_bufferability -nets [get_nets -hierarchical {SNPS*}]
```

Check bufferability for net n1 in voltage area VA1. It is bufferable with single rail buffers.

```
prompt> check_bufferability -nets n1 -voltage_area VA1

Information: Can insert single rail buffers (8 lib_cells) and inverters (6
lib_cells) with supply nets (power: VDD1, ground: VSS). (MV-453)
```

Check bufferability for net n2 in voltage area VA2. It is bufferable with dual rail buffers.

```
prompt> check_bufferability -nets n2 -voltage_area VA2

Information: Can insert dual rail buffers (14 lib_cells) and inverters (14
lib_cells) with supply nets (power: VDD2, ground: VSS). (MV-454)
```

Check bufferability for net n3 in voltage area VA3. It is not bufferable because there are no lib_cells available for buffering. But, a valid supply for dual rail buffering is found.

```
prompt> check_bufferability -nets n3 -voltage_area VA3

Information: Cannot insert dual rail buffers or inverters because of no
```

```
    available lib_cells. But required supply nets (power: VDD3, ground: VSS) are
    available. (MV-457)
```

Check bufferability for net n4 in voltage area VA4. It has a valid buffering supply and available lib_cells, but is not bufferable for other reasons.

```
prompt> check_bufferability -nets n4 -voltage_area VA4

    Information: Cannot insert buffers or inverters because of non-MV reasons. But
    single rail buffers (12 lib_cells) and inverters (14 lib_cells) with supply
    nets (power: VDD4, ground: VSS) are available. (MV-463)
```

check_bump_spacing

Check spacing among bumps.

SYNTAX

status **check_bump_spacing**
[-reference_cells *ref_cell_list*]
[-report]
[-min_spacing *distance*]
[-max_count *number*]
[-distance_style *flyline_distance* | *manhattan_total* | *manhattan_max*]

Data Types

ref_cell_list list
distance float
number integer

ARGUMENTS

-reference_cells *ref_cell_list*

Specifies the referene of bump cells to be considered during current run. If this option is not specified, all bump cells are considered.

-report

If selected, the command will report bump location statistics. No checking will be performed.

-min_spacing *distance*

Specifies the minimum allowable distance. This option must be used for bump spacing checking. This option cannot be used with *-report* option.

-max_count *number*

Specifies the maximal numebr of violations to be reported. This option cannot be used with *-report* option. The default value is 10.

-distance_style *flyline_distance* | *manhattan_total* | *manhattan_max*

Specifies how the distance is computed. If *flyline_distance* is chosen, the distance is the distance bwtween the centers of the two bumps. If *manhattan_total* is chosen, the distance is the Manhattan distance bwtween the centers of the two bumps. If *manhattan_max* is chosen, the distance is either the horizontal or vertical distance, whichever is larger, bwtween the centers of the two bumps. The default choice is *flyline_distance*.

DESCRIPTION

This command reports the spacing among bumps or violations of bump spacing. The distance between a pair of bumps is computed using the corresponding centers of the bumps.

EXAMPLES

The following command reports the bump spacing.

```
prompt> check_bump_spacing -report
```

The following command reports whether there exists pairs of bumps whose distance is less than 10 micron. At most 100 violations will be reported.

```
prompt> check_bump_spacing -min_spacing 10 -max_count 100
```

create_bump_array(2)

check_busplan_constraints

Checks the validity of the current busplan constraints defined by the **set_busplan_constraints** command.

SYNTAX

status **check_busplan_constraints**
[-ref_buses]
[-check_ref]
[buses]

Data Types

buses string

ARGUMENTS

-ref_buses

Returns a list of "referencing" busplans, based on the list of passed-in buses. If bus1 is referenced by bus2 specified with the *set_busplan_constraints -from bus2 -to bus1 -type equal* command, then **check_busplan_constraints -ref_buses bus1** will return the list containing bus2.

-check_ref

Checks the constraints of the referencing buses instead of checking the constraints of the passed-in buses.

The following command:

set result [check_busplan_constraints -check_ref $busList]

is equivalent to these commands:

set refList [check_busplan_constraints -ref_buses $busList]
set result [check_busplan_constraints $refList]

By default, the command checks the constraints of the passed-in buses.

buses

Specifies the names of busplans to check for constraint validity. The buses must be created with the **create_busplans** command.

DESCRIPTION

Checks the validity of current busplan constraints as previously defined by the **set_busplan_constraints** command. The result will be a Tcl list containing 2 Tcl sub-lists. The first sub-list contains a list of busplans that are currently failing to match their constraint. The second sub-list contains a list of busplans that will potentially fail to match their constraints, given the current suggestions from pipeline register planning.

For example, suppose bus1 has the constraint <= 3, and is included in the "buses" parameter.

If bus1 has had 4 virtual registers inserted for planning purposes, then bus1 will be included in the first sub-list, since the current situation fails the constraint (n <= 3) and the second sub-list, since it is also potentially failing in the current state.

On the other hand, if bus1 has had no virtual register inserted, but planning computations suggests bus1 needs 4 or more registers total to meet timing, bus1 will be placed into the second sub-list only. The bus currently meets its constraint, however, following the planning suggestions will cause it to fail its constraint. If bus1 can meet timing with 1, 2 or 3 virtual registers (whether inserted or computed), the constraint will be considered met and bus1 will not be included in either sub-list.

EXAMPLES

Create a constraint for a busplan named bus1, and check the constraint. Assume busplan bus1 needs 2 registers to meet timing. In this example, the 2 registers are inserted with the **modify_busplan** command.

```
prompt> set_busplan_constraints -from bus1 -to_value 2 -type equal
1
prompt> check_busplan_constraints bus1
{} {}

# Add 2 virtual registers
prompt> modify_busplan -add_register -after group1 \
  -location {100 100} bus1
{register1}
prompt> modify_busplan -add_register -after group1 \
  -location {100 100} bus1
{register2}

# If timing is met
prompt> check_busplan_constraints bus1
{} {}

# If timing is not met
prompt> check_busplan_constraints bus1
{} {bus1}

# Insert another register
prompt> modify_busplan -add_register -after group1 \
  -location {100 100} bus1
{register3}

prompt> check_busplan_constraints bus1
{bus1} {bus1}
```

check_clock_gate_library_cell_availability

Checks whether there are ICG library cells available for clock gate insertion in the design.

SYNTAX

status **check_clock_gate_library_cell_availability**
[-objects *object_list*]
[-verbose]

Data Types

object_list list

ARGUMENTS

-objects *object_list*

Specifies the objects on which the check will apply. Valid objects are hierarchical instances, power domains and designs. The check will be performed on all the hierarchical instances assciated with the objects in *object_list*. If the option is not used, the check will be performed on all the hierarchical instances in the current design.

-verbose

Shows more information for every hierarchical instance on which the check failed.

DESCRIPTION

This command will check whether there are ICG library cells available, according with the current library constraints and clock gate style settings, for every hierarhical instance indicated in parameter *-objects*, or in the entire design.

The command will succeed (and return 1) if all the checked hierarchical cells have ICG library cells available for clock gate insertion.

The command will fail (and return 0) if at least one hierarchical cell exists with no ICG library cells available for insertion.

ICG library cells in the library can be rejected because of the following reasons:

\(bu General Reasons, which apply to the entire design. +0.25i

- [LIBRARY]

  \n+[step]. "it is a dont_touch libcell or it does not match the expected libcell purpose".

\(bu Instance-specific Reasons, which depends on the hierarchical cell. +0.25i

- [STYLE]

  \n+[step]. "it has no te port when required"
  \n+[step]. "it has no obs port when required"
  \n+[step]. "its en port does not match active high/low requirements => it is active high, when active low was expected" or vice versa.
  \n+[step]. "its te port does not match active high/low requirements => it is active high, when active low was expected" or vice versa.
  \n+[step]. "its clk output port does not match inversion requirements => it is inverted, when non-inverted was expected" or vice versa.
  \n+[step]. "its obs port does not match inversion requirements => it is inverted, when non-inverted was expected" or vice versa.
  \n+[step]. "it does not match sequential/latch requirements => it is latch-based, when latch-free was expected" or vice versa.
  \n+[step]. "it does not match edge requirements => it is rising edge, when falling edge was expected" or vice versa.
  \n+[step]. "it does not match pre/post control requirements => it is pre-control, when post-control was expected" or vice versa.

- [OPCONDS]

  \n+[step]. "it does not match hierarchy operating conditions".

EXAMPLES

The following example shows the output in case of success on all the hierarchies in the design.

```
prompt> check_clock_gate_library_cell_availability
There are ICG library cells available on all hierarchies. (CGT-4303)
1
```

The following example shows the output in case of success on objects mid1 and mid2.

```
prompt> check_clock_gate_library_cell_availability \
  -objects [get_cells {mid1 mid2}]
There are ICG library cells available on all objects. (CGT-4303)
1
```

This example shows the output in case of failure when there are no ICG library cells in the libraries.

```
prompt> check_clock_gate_library_cell_availability
Warning: There are no ICG library cells available in the library. (CGT-3301)
0
```

This example shows the output in case of failure when there are no ICG library cells for instance mid1 and mid2.

```
prompt> check_clock_gate_library_cell_availability \
  -objects [get_cells {mid1 mid2 mid3}]
Warning: There are no ICG library cells available for hierarchical cell
  mid1. (CGT-3302)
Warning: There are no ICG library cells available for hierarchical cell
  mid2. (CGT-3302)
0
```

This example shows the verbose output in case of failure when there are no ICG library cells for instance mid1 and mid2, after setting a clock gate style that requires observation output, when some of the library cells are restricted and the remaining do not have observation output port.

```
prompt> set_clock_gate_style -observation_output \
  -target {neg_edge_flip_flop pos_edge_flip_flop} \
  -objects [get_cells {mid1 mid2 mid3}]
1
prompt> check_clock_gate_library_cell_availability \
  -objects [get_cells {mid1 mid2 mid3}] \
  -verbose
Some hierarchies have no ICG libcells available. (CGT-4304).
ICG library cell tcbn90ghvtbc/CKLHQHVTD1 cannot be used for all-designs
  because it is a dont_touch libcell or it does not match the expected
  libcell purpose. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD2 cannot be used for all-designs
  because it is a dont_touch libcell or it does not match the expected
  libcell purpose. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD3 cannot be used for all-designs
  because it is a dont_touch libcell or it does not match the expected
  libcell purpose. (CGT-4305)
Warning: There are no ICG library cells available for hierarchical cell
  mid1. (CGT-3302)
ICG library cell tcbn90ghvtbc/CKLHQHVTD4 cannot be used for mid1 because
  it has no obs port when required. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD6 cannot be used for mid1 because
  it has no obs port when required. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD8 cannot be used for mid1 because
  it has no obs port when required. (CGT-4305)
Warning: There are no ICG library cells available for hierarchical cell
  mid2. (CGT-3302)
ICG library cell tcbn90ghvtbc/CKLHQHVTD4 cannot be used for mid2 because
  it has no obs port when required. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD6 cannot be used for mid2 because
  it has no obs port when required. (CGT-4305)

set_clock_gate_style(2)

check_clock_trees

Checks the clock trees of current design for possible problems with netlist, timing constraints, clock constraints, routing constraints, or other tool configurations that can adversely impact clock tree synthesis.

SYNTAX

status **check_clock_trees**
[-clocks clock_list]
[-message_limit *number*]

Data Types

object_list list or collection
number integer

ARGUMENTS

-clocks clock_list

Checks only those clock trees that appear in the clock_list. By default, the command checks all clocks in the design.

-message_limit *number*

Specifies the number of messages to be printed in each checks detail report. Default all of the messages will be printed. Number should be greater than 0

DESCRIPTION

Use the check_clock_trees command before clock tree synthesis to check for common problems that might impact clock tree synthesis.

EXAMPLES

SEE ALSO

check_consistency_settings

Compares the settings between this tool and the PrimeTime, StarRC, or IC Compiler tool for good timing correlation between the two tools.

SYNTAX

status **check_consistency_settings**
[-tool *type*]
[-work_dir *path_name*]
[-output *filename*]
[-script *filename*]

Data Types

type string
path_name string
filename string

ARGUMENTS

-tool

Indicates the target tool to check against. Valid values are pt, icc, icc2, and starrc.

-work_dir

Specifies the directory that contains the scripts to check. If the script file specified by the **set_consistency_settings_options** command includes some nested scripts, you must use this option to ensure those nested scripts can be sourced correctly.

-output

Specifies the output file to use to save the correlation checking result.

-script

Specifies the output file to use to save the tcl file which make ICC2 RC extraction setting the same as StarRC.

DESCRIPTION

The **check_consistency_settings** command compares the settings between this tool and the PrimeTime, StarRC, or IC Compiler tool for good timing correlation between the two tools. The command reports an error for each setting that is different from the recommended setting and reports the proper setting in the applicable tool.

Before using this command, run the **set_consistency_settings_options** command to set up the executable location and setup script.

Multicorner-Multimode Support

This command applies only to current scenario for timing correlation checking, or applies to the **-corner** and **-early** options of **set_consistency_settings_options** command for extraction correlation checking.

EXAMPLES

The following example uses the **check_consistency_settings** command to check consistency between this tool and the PrimeTime tool. The **set_consistency_settings_options** command sets up the executable location and related setup script such as pt.tcl.

```
prompt> set_consistency_settings_options \
  -exec_path /software/syn/bin -tool pt -script pt.tcl
prompt> check_consistency_settings -tool pt
Error: The timing_remove_clock_reconvergence_pessimism setting is
 inconsistent between Fusion Compiler and PrimeTime. The Fusion Compiler
 value is TRUE; the PrimeTime value is "false". (CORR-803)
Error: The timing_remove_clock_reconvergence_pessimism PrimeTime variable
should be set to TRUE. (CORR-800)
```

The following example uses the **check_consistency_settings** command to check consistency between the tool and the StarRC tool. The **set_consistency_settings_options** command sets up the executable location and related setup script such as starrc.tcl.

```
prompt> set_consistency_settings_options \
  -exec_path /software/syn/bin -tool starrc -script starrc.tcl \
  -corner maxCorner
prompt> check_consistency_settings -tool starrc
Error: The temperature(OPERATING_TEMPERATURE) setting is inconsistent
  between Fusion Compiler and StarRC. The Fusion Compiler value is 25;
  the StarRC value is 0.00. (CORR-803)
Error: The virtual_shield_extraction Fusion Compiler setting should be set
  to FALSE. (CORR-812)
Error: The TEMPERATURE_SENSITIVITY StarRC setting should be set to NO.
  (CORR-800)
```

SEE ALSO

set_consistency_settings_options(2)

check_design

Runs pre-defined or user-defined checks on current design. Messages generated by the checks run, are captured into an EMS database file and also into a text log file. Summary of the messages generated is also reported.

SYNTAX

status **check_design**
-checks *names_of_checks*
[-ems_database *ems_database_name*]
[-open_message_browser]

Data Types

names_of_checks list
ems_database_name string

ARGUMENTS

-checks *names_of_checks*

List of the names, of one or more user-defined or pre-defined checks, which will run on the current design.

A check pre-defined by the tool is called a pre-defined check. Examples of pre-defined checks are **pre_route_stage**, **mv_design**, **clock_trees**, **hier_timing**, **hier_pre_placement** etc. An user can create her own check with **create_check_design_strategy** command, which are called user-defined checks. User can get the list of all pre-defined and user-defined checks by invoking **get_design_checks** command.

Check **mv_design** is called an atomic-check since it is defined using a single UI command **check_mv_design**. Check **pre_route_stage** is called a mega-check since it is defined as a collection of atomic-checks.

Checks **pre_placement_stage**, **pre_clock_tree_stage** and **pre_route_stage** are the three available pre-defined mega-checks. Check **pre_placement_stage** can be run on a design in pre-placement stage. Similarly, checks **pre_clock_tree_stage** and **pre_route_stage** can be run on a design in pre-clock-tree stage and pre-route stage respectively.

There are several pre-defined atomic-checks like **mv_design**, **routability**, **clock_trees**, **hier_timing**, **hier_pre_placement** etc., which can be run by the user based on her requirements at different stages of design.

Below is a list of pre-defined atomic checks and mega-checks. You can run get_design_checks command to get this list as well.

Atomic-checks: cts_qor, design_extraction, legality, rp_constraints, feedthroughs, mib_alignment, finfet_grid, pg_drc, pg_missing_vias, pin_placement, routes, physical_constraints, dp_pre_floorplan, dp_pre_create_placement_abstract, dp_pre_block_shaping, dp_pre_macro_placement, dp_pre_power_insertion, dp_pre_pin_placement, dp_pre_push_down, dp_pre_create_timing_abstract, dp_pre_timing_estimation, dp_pre_budgeting, dp_pre_clock_trunk_planning, dp_floorplan_rules, mv_design, routability, clock_trees, scan_chain, design_mismatch, analyze_design_violations, timing, hier_timing, hier_pre_placement, hier_pre_clock_tree, hier_pre_route, hier_pre_compile, block_ready_for_top, netlist,

3d_netlist, unbound, design_states.

Mega-checks: pre_placement_stage, pre_clock_tree_stage, pre_route_stage.

-ems_database *ems_database_name*

Name of EMS database which will store the Error, Warning and Info messages generated by the checks.

If this option is not specified, then by default, "check_design.ems" is used as the name of EMS database and if an EMS database by name "check_design.ems" already exists, then its contents will be overwritten.

The EMS database name can contain only alpha-numeric characters and underscore character("_"). User is expected to provide the EMS database name with suffix ".ems". If user does not provide the suffix ".ems", then suffix ".ems" will be appended to the given name, automatically by the command, and used as EMS database name.

-open_message_browser

Opens the message browser window in GUI, which displays the messages captured in the EMS database.

DESCRIPTION

This command is an unified framework to perform design checks. The command writes the Error, Warning and Info messages generated by running checks on design, to Enhanced Messaging System(EMS) database file and into a text log file. All the messages generated by the checks are captured into text log file. Only a sub-set of messages generated are captured into EMS database. The messages NOT captured into EMS database are referred to as Non-EMS messages. Summary information is displayed by the command to indicate the number of EMS and Non-EMS messages along with their message-ids and message templates.

To look into the Error, Warning and Info messages generated by the checks and debug the issue, one can open the EMS database in GUI, by opening message browser window. If user does not prefer GUI then the messages can be viewed in text log file. The name of the log file is time-stamp based and a new log file is generated for every run of **check_design** command. The log file name is of the form "check_design<T>.log", where "<T>" indicates the time-stamp. The log file is saved in the current directory.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information. But checks run by the command may depend on scenario-specific information.

EXAMPLES

The following example runs the predefined mv_design atomic check.

```
prompt> check_design -checks mv_design

****************************************
 Report : check_design
 Options: { mv_design }
 Design :
 Version:
 Date   : Tue May 19 03:28:59 2015
****************************************
```

```
Running atomic-check "mv_design"

prompt>
```

The following example runs the predefined pre_clock_tree_stage mega check.

```
prompt> check_design -checks pre_clock_tree_stage
```

The following example runs the predefined pre_route_stage mega check.

```
prompt> check_design -checks pre_route_stage
```

The following example runs the pre_route_stage, mv_design, and routability checks.

```
prompt> check_design -checks {pre_route_stage mv_design routability}
```

The following example creates a user-defined atomic-check named my_atomic_check and runs it.

```
prompt> create_check_design_strategy -define_check my_atomic_check \
  {check_mv_design -power_connectivity -max_message_count 0}
prompt> check_design -checks my_atomic_check
```

The following example creates a user-defined mega-check named my_mega_check and runs it.

```
prompt> create_check_design_strategy -define_group my_mega_check \
  {my_atomic_check mv_design routability}
prompt> check_design -checks my_mega_check
```

The following example runs the mv_design check and stores the output messages in an EMS database file named my_database.ems.

```
prompt> check_design -checks mv_design -ems_database my_database.ems
```

The following example runs the mv_design check and opens the EMS database in the GUI.

```
prompt> check_design -checks mv_design -open_message_browser
```

The following example checks for issues related to design planning before floorplanning.

```
prompt> check_design -checks { dp_pre_floorplan }
```

The following example checks for issues related to design planning before creating placement abstracts and shaping blocks.

```
prompt> check_design \
  -checks { dp_pre_create_placement_abstract dp_pre_block_shaping }
```

SEE ALSO

create_check_design_strategy(2)

get_design_checks(2)

check_design_for_clock_trunk_planning

Check the design for CTP feasibility.

SYNTAX

status **check_design_for_clock_trunk_planning**
[-clocks *clock_list*]
[-summary]

Data Types

clock_list collection

ARGUMENTS

-clocks *clock_list*

Specifies the clocks for which clock trunk planning checker is to be run. By default, all clocks are checked.

-summary

This boolean argument specifies if the summary report is to be printed.

DESCRIPTION

This command runs the CTP related checks from top.

EXAMPLES

The following example runs CTP checker for clock 'clk1' and also prints the summary.

prompt> **check_design_for_clock_trunk_planning -clocks clk1 -summary**

SEE ALSO

check_hier_design(2)

check_design_states

Checks design states of current block like linked, mapped.

SYNTAX

status **check_design_states**
[-verbose]

ARGUMENTS

-verbose

Prints the unmapped cells information.

DESCRIPTION

This command checks the linked and mapped design states of the current design. This command will print whether the design is linked or not and the mapped percentage of the cells of the current design.

When command option **-verbose** is specified the command will report the unmapped cells information.

This command has no dependency on scenario-specific information.

EXAMPLES

The check_design_states command displays the following information when no option is specified.

```
prompt> check_design_states
****************************************
Report : check_design_states
Design : top
Version:
Date   : Thu Nov 28 02:17:49 2019
****************************************

Design is linked
Design is 66.67% mapped
1
```

The check_design_states command displays the following information when option '-verbose' is specified.

```
prompt> check_design_states -verbose
****************************************
Report : check_design_states
Design : top
Version:
Date   : Thu Nov 28 02:23:40 2019
****************************************

Design is linked
Design is 66.67% mapped

Information: cell reg_p_i1/I_0 is unmapped. (NDMUI-915)
Information: cell I_0 is unmapped. (NDMUI-915)
1
```

check_duplicates

Checks, reports and optionally removes any duplicate shapes and vias detected in the block.

SYNTAX

status **check_duplicates**
[-blocks {*block*}]
[-verbose]
[-remove]
[-object_types {*type_list*}]
[-return_as_collection]

Data Types

block collection
type_list list

ARGUMENTS

-blocks {*block*}

Specifies the block for finding duplicates. If this is not specified, duplicate objects will be found in the current block. A summary of the total count of duplicate objects found will be printed.

-verbose

When you specify this option, the command writes all the duplicate objects in a text file duplicates.txt.gz in the current folder. This file will contain the list of all duplicate objects found in the design. If there are no duplicates found, an empty file will be generated.

-remove

When you specify this option, the command reports and also removes all the duplicate objects found. It will generate a text file duplicates.txt.gz in the current folder which will contain detailed information about each of the duplicate objects deleted. A summary of the removed objects will be printed in the log file. If there are no duplicates found, an empty file will be generated.

-object_types *type_list*

Specifies the list of object types to be reported as duplicates. Valid values for this option are *shapes* and *vias*.

-return_as_collection

When you specify this option, this command will return duplicates in a collection. This option cannot be specified with **-remove** option.

DESCRIPTION

Checks, reports and optionally removes all the duplicates found in the specified block. If no block is specified through **-blocks** option, current block will be used. If **-verbose** option is not used, only a limited entries of duplicates will be printed in the log file. A total of 20 rows and 5 duplicate objects in each row will be printed by default. To get complete list of objects, use **-verbose** option. When this option will be used, the complete list of objects will be printed in the text file duplicates.txt.gz file in current folder.

If you specify the **-remove** option, reported duplicate objects will be removed. In the log file, a summary of total objects removed will be printed. A complete list of removed objects will be printed in the text file duplicates.txt.gz file created in current folder.

EXAMPLES

The following example reports duplicate objects found in the current block.

```
prompt> check_duplicates
****************************************

SEE ALSO

check_equivalent_power_domains

Check whether the power domains are equivalent and satisfy the criteria to share a single voltage area.

SYNTAX

status **check_equivalent_power_domains**
power_domains
[-functional_equivalence]
[-verbose]

Data Types

power_domains list

ARGUMENTS

power_domains

Specifies the power domains to be checked. The command fails if the number of power domains are less than two.

-functional_equivalence

Specifies that domain supplies are considered as equivalent based on functional equivalence. If this options is not specified, by default, domain supplies are considered as equivalent based on electrical equivalence.

-verbose

Shows the groups of equivalent power domains to share a primary voltage area.

DESCRIPTION

The **check_equivalent_power_domains** command checks whether the specified power domains are equivalent or not to share a voltage area. The command will return 1 if the specified power domains are equivalent and satisfy the criteria to share a primary voltage area, 0 otherwise.

This command supports the shared voltage area flow only with mv.upf.multi_pd_shared_voltage_area_flow set to new.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example compares two power domains that are not equivalent to share a voltage area.

```
prompt> check_equivalent_power_domains {pd1 pd2}
 0
```

The following example compares two power domains that are equivalent to share a voltage area.

```
prompt> check_equivalent_power_domains {pd3 pd4} -functional
 1
```

The following example compares power domains that are not equivalent to share a voltage area and shows the groups of distinct power domain subsets.

```
prompt> check_equivalent_power_domains {pd1 pd2 pd3 pd4} -verbose
Information: List of equivalent power domains - {pd1} {pd2} {pd3 pd4}. (UPF-483)
 0
```

SEE ALSO

report_power_domains(2)
create_voltage_area(2)
set_voltage_area(2)
get_equivalent_power_domains(2)

check_error

Returns true if message IDs specified in shell.common.check_error_list were encountered in previous commands.

SYNTAX

status **check_error**
[-verbose]
[-reset]

ARGUMENTS

-verbose

Displays the list of message IDs found during previous commands.

By default, the command only returns the error status.

-reset

Resets the list of previously found message IDs. After resetting the error list, the **check_error -verbose** command returns an empty list.

By default, the command does not modify the message list.

DESCRIPTION

The **check_error** command is used to compare error, warning, or informational messages issued by previous commands to the list of message IDs specified by **shell.common.check_error_list** application option. While it is most commonly used for error messages, the application option can contain error, warning, or informational message IDs.

If the **check_error** command finds message IDs that are specified in the **shell.common.check_error_list** application option, the command returns 1. If the **check_error** command does not find any messages that are specified by the **shell.common.check_error_list** application option, the command returns 0.

Messages that are suppressed by the **suppress_message** command are reported by **check_error**. If you want suppressed messages to be ignored by **check_error** then you must remove their message IDs from the **shell.common.check_error_list** application option.

EXAMPLES

The following example shows how to use the **check_error** command to check if execution errors are specified by the **shell.common.check_error_list** application option:

```
prompt> set_app_option -name shell.common.check_error_list -value {DES-001}

prompt> check_error
0

prompt> get_cells
Error: Current block is not defined. (DES-001)

prompt> check_error
1

prompt> check_error -verbose
{DES-001}
1
```

The following command resets the error list:

```
prompt> check_error -reset -verbose
{DES-001}
1

prompt> check_error -verbose
0
```

To use the **check_error** command in a script to see if specified errors occurred in the previous commands, use the following command:

```
prompt> if { [check_error] } {
   echo failure_message
   exit
} else {
   echo success_message
}
```

SEE ALSO

shell.common.check_error_list(3)
suppress_message(2)

check_feedthroughs

Checks the feedthroughs on physical blocks.

SYNTAX

string **check_feedthroughs**
[-unused_feedthroughs]
[-reused_feedthroughs]
[-redundant]
[-net_constraints]
[-topo_constraints]
[-include_original_feedthroughs]
[-include_buffered]
[-shape L | M | N]
[-pure]
[-self]
[-mixed]
[-close_to_edge]
[-tolerance_distance *feedthrough_tolerance_distance*]
[-filter_by_length]
[-feedthrough_length *feedthrough_length*]
[-cells *list_of_blocks*]

Data Types

feedthrough_tolerance_distance	float
feedthrough_length	float
list_of_blocks	list

ARGUMENTS

-unused_feedthroughs

Checks and reports feedthroughs pins that are not connected to a top-level net. Feedthroughs are not allowed in some designs. An example is a design with multiple instantiated blocks (MIB), where a feedthrough needs to be created on one MIB instance while it cannot be used by other MIB instances.

-reused_feedthroughs

Checks and reports feedthrough pins that are reused across multiple instantiated block (MIB) instances. This check only applies to MIB blocks.

-redundant

This option directs the command to look for redundant connections created on feedthrough nets. The pins it returns and reports

are unnecessarily created either in the original netlist (if the **-include_original_feedthroughs** option is used) or by pin-placement during feedthrough creation. The option cannot be used with any other option except for the **-include_original_feedthroughs** option.

-net_constraints

Checks and reports feedthrough per-net, per-block feedthrough constraint violations. The command reports nets that violate feedthrough constraints and returns the associated feedthrough pins.

-topo_constraints

Checks and reports nets that violate their associated topological constraints. The command reports nets that violate feedthrough constraints and returns the associated feedthrough pins where applicable.

-include_original_feedthroughs

Includes original feedthrough pins (not inserted by the tool) for checking. An original feedthrough is a feedthrough that exists in the original netlist. By default, original feedthrough pins are not checked.

-include_buffered

Skips over repeaters and buffers, when timing libraries are loaded, (effectively including buffered feedthroughs) when identifying, reporting, and checking feedthroughs.

-shape L | M | N

Reports feedthroughs of the specified shape. "L shaped" feedthroughs are two pin feedthroughs that have pins on adjacent edges. The **-tolerance_distance** option is used to specify how far these two feedthrough pins can be from the shared corner. "M shaped" feedthroughs have multiple-fanout pins. "N shaped" feedthroughs have feedthrough ports on the same edge. This option can only be used with the **-cells**, **-self**, or the **-tolerance_distance** options. The command also includes all feedthroughs for shape checking, including original feedthrough ports. However, "L" and "N" shape feedthrough reporting is limited to pure feedthroughs.

-pure

Reports and returns only the pure feedthroughs in the design. Pure feedthroughs are defined as feedthroughs that have no physical pins or connections (except for inverters/buffers) inside the block that they pass through. This option can only be used with the **-cells** or **-self** option.

-self

Reports and returns those ports and terminals of the top-level block that are feedthroughs. That is they are connected (potentially through multiple nets/hierarchies) to other top-level ports. This option can only be used with the **-include_original_feedthroughs**, **-include_buffered**, **-pure**, **-mixed**, **-shape**, **-close_to_edge**, and **-filter_by_length** options.

-mixed

Reports and returns only the mixed feedthroughs in the design. There are two types of mixed feedthroughs: 1. the feedthrough net has physical connections to combinational cell (besides inverters/buffers) inside the block that it passes through; 2. the feedthrough net owns both original and non-original feedthrough ports. This option can only be used with the **-cells** and **-self** options.

-close_to_edge

Checks for feedthrough ports that are within the specified distance from the same edge of the physical block. For a feedthrough port to be considered close to a given edge it should lie on a different edge and also on an edge that is of a different orientation than the edge it is close to. The check is limited to pure feedthroughs. The **-tolerance_distance** option can be used to specify the distance (in microns) from the edge. The default tolerance distance is 100 microns.

-tolerance_distance *feedthrough_tolerance_distance*

Specifies the tolerance distance that is used with the **-shape** and **-close_to_edge** options. When used with **-close_to_edge**, the feedthrough ports that are less than specified distance (in microns) from the same edge will be reported. When used with **-shape**, the distance applies to L-shaped feedthroughs only. The L-shaped feedthroughs that have both ports within specified distance from the same corner are reported. By default, the tolerance distance is 100 microns.

-filter_by_length

Checks for feedthroughs with nets whose length is less than the value specified by the **-feedthrough_length** option. Use this option to identify shorted feedthroughs. Note that the unplaced pins will be excluded in net length measurement.

-feedthrough_length ***feedthrough_length***

Reports feedthroughs for nets with a length that is less than the specified *feedthrough_length* (in microns). The option can only be used with the **-filter_by_length** option and **-self** options. If routing is present for the net, the length of the route is used. Otherwise, half perimeter wire-length (from the bounding box of the net) is used to calculate the length. By default, the feedthrough length is 1000 microns.

-cells ***list_of_blocks***

Specifies a list of blocks or cells for feedthrough checking.

DESCRIPTION

This command is used to check and report feedthroughs issues, and returns a collection of feedthrough pins that correspond to the specified arguments/filters. If no option is specified, the command simply returns a collection of all the feedthrough pins. To include original feedthrough ports (not inserted by the tool) the **-include_original_feedthroughs** option can be used. To include buffered feedthrough nets for checking/reporting the **-include_buffered** option can be used.

By default the command looks for and checks feedthroughs at multiple levels of physical hierarchy (MPH support). The **set_editability** command can be used to enable or disable checking on individual reference-blocks or levels of physical hierarchy. For net constraint and topological checking a particular net is checked only if the instance in which it originates (its parent instance/hierarchy) is enabled for design planning.

EXAMPLES

The following example checks for unused feedthrough pins on all blocks.

```
prompt> check_feedthroughs -unused_feedthroughs
```

The following example checks for L-shaped feedthroughs on all blocks.

```
prompt> check_feedthroughs -shape L
```

The following command returns all tool inserted feedthrough ports

```
prompt> check_feedthroughs
```

The following command returns all feedthrough ports including the original feedthrough ports in the design.

```
prompt> check_feedthroughs -include_original_feedthroughs
```

check_finfet_grid

Checks for violations of object placement or boundary to the FinFET grid.

SYNTAX

status **check_finfet_grid**
[-objects *object_name_or_collection*]
[-hierarchical]

Data Types

object_name_or_collection collection

ARGUMENTS

-objects *object_name_or_collection*

Specifies the objects to be checked. Currently supported object types are core_area, site_row, site_array, macro cell, I/O pad cell, flip chip river cell, and block cell. Other object types are not supported by this checker command. Specify the objects either by using an object access command, such as **get_site_rows**, or by specifying object name patterns in a Tcl list. By default, all supported objects in the current design are checked.

-hierarchical

Controls whether the objects within sub-blocks are checked. The **-hierarchical** option and **-objects** options are mutually exclusive. By default, the command only check objects in the current block.

DESCRIPTION

FinFET technology uses a grid which is about 40nm in pitch. The grid might have different pitch values in the x- and y-directions. Since FinFET is transistor in polysilicon layer, the boundary or placement of physical objects based on transistor should conform to FinFET grid. This command checks the physical design for violations against the FinFET grid. Standard cells must conform to FinFET grid. Since standard cells are placed in site rows, this command checks site rows rather than standard cells. If site rows are on FinFET grid, standard cells should be on FinFET grid automatically.

If you receive error messages when you run this command, see the man pages for the error message IDs for information on how to fix the FinFET grid violations. After you fix the violations, run this command again to verify your fixes.

EXAMPLES

The following example shows the default command run.

prompt> **check_finfet_grid**

The following example shows command run on hierarchical design.

prompt> **check_finfet_grid -hierarchical**

The following example only checks hard macro cells.

prompt> **check_finfet_grid -objects [get_cells -hierarchical -filter "design_type==macro"]**

The following example only checks I/O pad cells.

prompt> **check_finfet_grid -objects [get_cells -filter "design_type==pad" -hierarchical]**

SEE ALSO

get_cells(2)
get_site_rows(2)

check_floorplan_rules

Reports violations of related floorplan spacing, enclosure, halo, length, area, width rules and track constraints.

SYNTAX

collection **check_floorplan_rules**
[*list_of_rule_names*]
[-object_types *list_of_object_types*]
[-lib_cells *collection_of_lib_cells*]
[-exclude_rules *list_of_rule_names*]
[-exclude_lib_cells *collection_of_lib_cells*]
[-objects *macro_list*]
[-bbox { {*llx lly*} {*urx ury*} }]
[-error_view *view_name*]
[-enable_rule_override true | false]

Data Types

list_of_rule_names list
list_of_object_types list
collection_of_lib_cells list
macro_list list
llx float
lly float
urx float
ury float
view_name string

ARGUMENTS

list_of_rule_names

Specifies the list of floorplan rule names to report related violations. By default is checking all floorplan rules set by user.

-object_types ***list_of_object_types***

Report floorplan rule violations on the listed object types. The object types include hard_macro, std_cell_area, soft_macro, block_boundary, core_area. This option cannot be specified with the **-bbox** and **-objects** options.

-lib_cells ***collection_of_lib_cells***

Report floorplan rule violations on the listed lib cells. This option cannot be specified with the **-bbox**, **-objects** and **-exclude_lib_cells** options.

-exclude_rules ***list_of_rule_names***

Specifies the list of floorplan rules that will not report violations.

-exclude_lib_cells ***collection_of_lib_cells***

Specified the lib cells that the violations will not be reported on them. If this option is specified with "-exclude_rules", only the violations match the "-exclude_lib_cells" and "-exclude_rules" will not be reported. This option cannot be specified with the **-bbox**, **-objects** and **-lib_cells** options.

-objects ***macro_list***

Report floorplan rule violations on the listed macros. This option cannot be specified with the **-bbox**, **-object_types**, **-exclude_lib_cells** and **-lib_cells** options.

-bbox { {*llx lly*} {*urx ury*} }

Report floorplan rule violations of macros that fully inside this region. This option cannot be specified with the **-objects**, **-object_types**, **-exclude_lib_cells** and **-lib_cells** options.

-error_view ***view_name***

Specifies the name of the generated error view. If this options is specified, the command saves the error view data to a file in XML format with the specified name. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name. If this options is not specified, an attachment is created/modified and saved in to the design database with the file name as "#block_name#_floorplanRules.err" .

-enable_rule_override true | false

When set true, if a lib_cell has its own rule, the corresponding rules for hard_macro would not apply to instances of this lib_cell; In other words, one or more lib_cell rules to an object_type/lib_cell of a certain constraint type overrides any general rule to the same object_type/lib_cell of the same constraint type. Besides this, when it set true, cmd allow lib_cell-routing_blockage enclosure rule to override both hard_macro-routing_blockage enclosure rules and halo rules; Similarly, allow lib_cell-routing_blockage halo rule to override both hard_macro-routing_blockage enclosure rules and halo rules. The default value is false.

DESCRIPTION

This command check floorplan rule violations set by the commands: **set_floorplan_spacing_rules set_floorplan_enclosure_rules set_floorplan_halo_rules set_floorplan_width_rules set_floorplan_area_rules set_track_constraint**

EXAMPLES

The following command checks floorplan rule_1 on hard and soft macros.

```
prompt> check_floorplan_rules rule_1 -object_types {hard_macro soft_macro}
```

Assuming DTCD_lib is the ref lib of a DTCD cell and DTCD cell has the design type of hard macro, the following command reports all macro cell violations except for DTCD cells.

```
prompt> set_floorplan_spacing_rules -name R1 \
  -from_lib_cells DTCD_lib -to_object_types std_cell_area
```

```
prompt> set_floorplan_spacing_rules -name R2 \
  -from_object_types hard_macro -to_object_types std_cell_area

prompt> check_floorplan_rules R2 -enable_rule_override
```

check_freeze_silicon

Performs feasibility analysis on ECO-cell-to-spare-cell mapping for the current design. This command is typically used in a freeze silicon ECO flow.

SYNTAX

status **check_freeze_silicon**

Data Types

This command has no data types.

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **check_freeze_silicon** command performs feasibility analysis on ECO-cell- to-spare-cell mapping for the current design. The report includes feasibility analysis on ECO cell to spare cell mapping and ECO cell to programmable spare cell (PSC) mapping.

For ECO cells without a PSC type, the report includes:

- The total number of ECO cells and spare cells in the design
- ECO cell mapping feasibility analysis
- Detailed information about the number of ECO cells and spare cells for each library cell

For ECO cells with a PSC type, the report includes:

- The total number of ECO cells and PSC on the design
- ECO cell mapping feasibility analysis for each voltage area and PSC type group
- ECO cells vs. PSC detail report
- Abutted PSC width detail report

When a PSC mapping rule is defined, the "Derived PSC Type", "Derived PSC Width" and "Total PSC Width" columns are shown in the mapping analysis report. The report only includes valid programmable spare cells, while the invalid programmable spare cells due to the PG overlap rule violation are skipped a and the ECO-079 and ECO-090 warning messages are issued.

The command reports feasibility analysis results on ECO cells without a PSC type, then reports ECO cells with a PSC type. The two sections are separated by a section header.

It is recommended that the command is used before the **place_freeze_silicon** command to help you analyze ECO cells and spare cells in your design and to be aware of potential spare cell mapping failures.

The command behavior is the same regardless of the **design.eco_freeze_silicon_mode** application option setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a feasibility check report.

```
prompt> check_freeze_silicon

check_hier_design

Checks a hierarchical design for possible issues related to top-level closure. Messages generated by this command are captured in an EMS database file and in the log file.

SYNTAX

status **check_hier_design**
[-stage timing | pre_placement | pre_clock_tree | pre_route | pre_compile]
[-references *reference_design_names*]

Data Types

reference_design_names list

ARGUMENTS

-stage timing | pre_placement | pre_clock_tree | pre_route | pre_compile

Performs atomic checks for the specified design stage.

-stage timing performs timing-related checks.

-stage pre_placement performs both timing and pre-placement related checks.

-stage pre_clock_tree performs timing, pre-placement, and pre-clock-tree checks.

-stage pre_route performs pre-route checks.

-stage pre_compile performs checks to ensure that blocks linked to top are ready for compile.

By default, only timing checks are run if this option is not specified.

-references *reference_design_names*

Specifies the names of design references, for physical hierarchies in the top-level design, on which to run checks. By default, all physical hierarchies are checked if this option isn't specified.

DESCRIPTION

This command performs design checks for use in the top-level closure flow. The command writes the Error, Warning and Info messages to Enhanced Messaging System(EMS) database file and into a text log file.

EXAMPLES

The following example performs timing-related checks.

```
prompt> check_hier_design -stage timing
```

The following example performs pre-placement checks on the RISC_CORE block.

```
prompt> check_hier_design -stage pre_placement -references RISC_CORE
```

The following example performs timing-related checks and writes the results to the EMS database named check_hier.ems

```
prompt> create_ems_database check_hier.ems
prompt> check_hier_design -stage timing
prompt> save_ems_database -all
```

check_design(2)
create_ems_database(2)
save_ems_database(2)

check_host_options

Checks that the specified host option is working properly in your environment.

SYNTAX

status **check_host_options**
-host_options *host_option_name*
[-work_dir *directory*]

Data Types

host_option_name string
directory string

ARGUMENTS

-host_options *host_option_name*

Specifies the name of the host option to be checked. Host options are created using the **set_host_options** command. This is a required option.

-work_dir *directory*

Specifies a working directory where various data and log files will be written. By default, the directory is ./work_dir. This directory must be a network disk accessible by all workers.

DESCRIPTION

This command tests the specified distributed processing host option to ensure that the host option is correctly specified for your environment. The command launches a worker process using the host options. This worker process only informs the master process that it is alive and exits.

You should use this command to test your host option settings before beginning a distributed processing run. If this command does not complete successfully, do not use the given host option with any other command because it will not work. Instead, determine the reason for the failure and fix the given host option, or run without distributed processing.

If you have problems getting this command to complete successfully, try first using a simpler host option. You can also try using rsh rather than LSF or GRD.

EXAMPLES

This simple example sets the host option named myLSFtest for LSF distributed processing, then checks the setting.

```
prompt> set_host_options -name myLSFtest -submit_command "bsub"
1
prompt> check_host_options -host_options myLSFtest
Checking host option: myLSFtest
check_host_options successful.
```

SEE ALSO

set_host_options(2)

check_io_placement

Performs I/O placement checking.

SYNTAX

list **check_io_placement**
[-cells *cell_collection*]
[-matching_types *matching_type_collection*]
[-io_guides *io_guide_collection*]
[-pad_assignment_file *file*]
[-filename *filename*]
[-output_directory *directory*]
[-error_view *view_name*]
[-overlap all | pad2pad | pad2filler | filler2filler | bump | corner2pad]
[-bump_assignment]
[-pad_to_guide_assignment]
[-signal_constraints]
[-power_constraints]
[-unplaced]
[-flipping]
[-gap]
[-min_pitch]

Data Types

cell_collection list
matching_type_collection list
io_guide_collection list
file string
filename string
directory string
view_name string

ARGUMENTS

-cells *cell_collection*

Specifies cell instances, such as bumps, pads, fillers, for I/O placement checking. If this option is used, only the specified cells are checked. If this option is used but the specified cells are not valid objects for some specified checks, the specified cells are ignored for those checks. Option **-cells** cannot be used together with option **-signal_constraints**, **-power_constraints**, **-min_pitch**, and **-gap**.

-matching_types *matching_type_collection*

Specifies user-defined matching types for I/O placement checking. If this option is used, only the specified matching types are checked. If this option is used and the specified matching types are not valid objects for the specified checks, this specified matching types are ignored for those checks. Option **-matching_types** cannot be used together with option **-pad_to_guide_assignment**, **-signal_constraints**, **-power_constraints**, **unplaced**, **-min_pitch**, **-gap** and **-flipping**.

-io_guides ***io_guide_collection***

Specifies the I/O guides for I/O placement checking. If this option is used, only the specified I/O guides are checked. If this option is used and the specified guides are not valid objects for the specified checks, this specified matching types are ignored for those checks. Option **-io_guides** cannot be used together with option **-bump_assignment**, **unplaced** and **-flipping**.

-pad_assignment_file ***file***

Specifies the file which contains a list of I/O pad cells and corresponding I/O guides that are allowed for the I/O pad. Entries in this file specify a constraint that limits the pad placement to only the listed I/O guide candidates. If the file is not specified or file cannot be opened, the limitations in file will not be checked. This option can only be used with option **-pad_to_guide_assignment**.

The pad assignment file lists the constraints for the specified I/O pads. Each line contains one or more pad names followed by a list of allowed I/O guide names. I/O guides not in the list cannot be used to place the pads. If more than one pad is listed on one line, the pads must be placed within a pair of curly braces. No curly braces are needed for I/O guides. Each line must end with a semicolon.

```
{pad1 pad2} guide1 guide2;
pad3 guide1 guide3 guide0;
```

-filename ***filename***

Specifies the name of the file where the reports of I/O placement checking are written. Only 10 lines are printed to prompt for each report. In the file, the complete reports are shown. The option cannot be used together with **-output_directory** option.

-output_directory ***directory***

Writes individual report files for each check (overlap, bump assignment, and so on) to the specified directory. The report file names are the name of the check. If the directory does not already exist, the command tries to create the directory. If creation is successful and write permissions are appropriate, the output is written to individual files created in this directory instead of the console. The option cannot be used together with the **-filename** option.

-error_view ***view_name***

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file.

If this option is omitted, the error view data is stored as an attachment to the design database. When the design is closed and saved, the error view data is saved to the design database as well. The saved error view data does not change until the next *check_io_placement* command.

-overlap all | pad2pad | pad2filler | filler2filler | bump | corner2pad

Checks different kinds of overlaps, including pad-pad overlap, pad-filler overlap, filler-filler overlap, bump overlap and corner-pad overlap. One or multiple valid strings must be provided to enable corresponding checks. The valid strings are all, pad2pad, pad2filler, filler2filler, bump. If "all" is specified, the other string is ignored and all kinds of overlap are checked.

If a certain type of overlap checking is specified and invalid objects are specified, only the valid objects are checked and the invalid objects are ignored. For example, if bump overlap checking is specified and some bumps cells and filler cells are specified, the filler cells are ignored.

-bump_assignment

Checks if bump assignment after place_io is consistent with defined matching types (if any) and logical nets. This option works alone or together with **-cells** and **-matching_types**. If the option is specified by itself, all bumps are checked for correct bump

assignment. If the other type of objects are specified, they are ignored for this checking.

-pad_to_guide_assignment

Checks if current pad-to-guide assignment is consistent with the definition. If the option is specified by itself, all pads are checked for placement on the correct guides. Use the **-cells** option to specify the pads to check. If **-io_guides** is specified, all pads that should be placed on specify I/O guides are checked. To use together with **-pad_assignment_file** option, a pad assignment file must be provided. All the pads mentioned in the file are checked. The other type of objects are ignored for this checking.

-signal_constraints

Checks if there are signal I/O pads violating constraints set by **set_signal_io_constraints**. Signal I/O constraints include order, pitch, spacing, offset of pads and boundary-spacing. If the option is specified by itself, all I/O guides with signal I/O constraints are checked.

Note that option **-cells** cannot be used with **-signal_constraints**, as signal I/O constraints can only be set with guides. And in some cases, such as specifying one cell to check for signal pads order, it does not make sense.

-power_constraints

Checks if there are power pads violating constraints set by **set_power_io_constraints**. Power I/O constraints include share, ratio, spacing and offset.

Note that option **-cells** cannot be used with **-power_constraints**, as power I/O constraints can only be set with guides. And in some cases, such as specifying one cell to check for power pads ratio, it does not make sense.

-unplaced

Checks if there are any unplaced pads. If this option is specified by itself, all pads are checked if it is unplaced. If other types of cells are specified, such as fillers, those cells are still checked but with a warning indicating those cells are not pads. If no cells are specified, by default only all pads are checked.

-flipping

Checks if the I/O pads are consistent with the is_flipped attribute as set in the design. If a pad is not placed on any guide, the pad is also considered to violate placement.

-gap

Checks if there is a gap between any two adjacent cells on I/O guides. The unfilled space that is outside the length of the I/O guides are not considered as gap. The valid cell types include pads, corners, fillers and break cells.

-min_pitch

Checks if the min_pitch set with I/O guides are honored by place_io.

DESCRIPTION

This command performs one or multiple kinds of I/O placement checks and return a collection of cells with violations. All options are optional. If no option is used, the command runs all checks. As each checking has different valid objects and options to work with, each check finds the valid objects for the check within the specified objects. Each check ignores the options that specify invalid objects. If the objects specified by an option is not valid for any checking, a warning is issued to indicate the option is not used.

By default, the reports of checks are printed to the console. Each check is written out in a section in report and each section can shows 10 lines of violations at most. You can choose to write out the complete report to files or a directory with options.

EXAMPLES

The following example checks bump assignment for all bumps and signal I/O constraints for specified guides.

```
prompt> check_io_placement -bump_assignment -signal_constraints -io_guides [get_io_guides *]
```

check_legality

Checks the legality of the current placement.

SYNTAX

status **check_legality**
[-verbose]
[-cells *list_of_cells*]
[-check_distance *distance*]
[-output_tcl]

Data Types

list_of_cells collection
distance float

ARGUMENTS

-verbose

Prints a detailed report of all possible violations. By default, the command reports only a summary of all violations.

-cells *list_of_cells*

Specifies the cells to check.

When you use this option, the **check_legality** command performs legality check only on the specified cells and cells within the checking distance, which reduces runtime.

By default, the checking distance is three row heights. To adjust the checking distance, use the **-check_distance** option.

-check_distance *distance*

Specifies the checking distance in number row heights. The specified distance must be a float value greater than or equal to zero.

The checking distance determines the neighboring cells to include in legality checking when you use the **-cells** option.

By default, the distance is three row heights.

This option can be used only with the **-cells** option.

-output_tcl

Writes a Tcl file that contains all illegal cells with different violation types. The current process ID (pid) is appended to the file name so the tool can determine if the Tcl file was created in this session.

This option applies only to the classic legalizer. When the advanced legalizer is enabled (the

place.legalize.enable_advanced_legalizer application option is **true**), the command does not write a Tcl file. Instead, the command writes an error file that you can view in the GUI error browser.

By default, no Tcl file is generated.

If you are using the classic legalizer and you use this option, by default, the generated Tcl file contains all moveable cells with violations. You can change this by modifying two variables in the Tcl file, GLOBAL_VIOLATION_TYPE and GLOBAL_VIOLATION_MODE. For information about the valid values for these variables, see the header section at the beginning of the Tcl file.

You can use the generated Tcl file for different purposes, such as

- Fixing violations based on a specific violation type rather than all violation types. For example, use this file to select only overlapped cells and leave other violations as-is.
- Highlighting all violated cells or specific types of violations and avoid parsing the output of the **check_legality -verbose** command.
- Selecting violated cells based on moveable, application fixed, or fixed type. For example, you can select only CTS spacing violations marked as application fixed.
- Using the script information with your own scripts after the collection is created. The generated collection can be used with your own scripts.

DESCRIPTION

The **check_legality** command checks the legality of the current placement and output a report of violation statistics.

By default, the command runs the classic legalizer. To run the advanced legalizer, set the **place.legalize.enable_advanced_legalizer** application option to **true**.

The reported violations can be classified as

- Cells that are not on rows
- Cells overlapping each other
- Cells overlapping blockages
- Cells with orientation that is not allowed for the row on which the cell is placed
- Cells with a core site type not equal to that of the row on which the cell is placed
- Cells with power strap violations
- Cells with advanced technology (20 nm and below) violations
- Cells with placement spacing rule violations

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example checks the legality of all cells and prints a summary of all violations.

prompt> **check_legality**

The following example checks all BUF* cells in the design.

prompt> **check_legality -cells [get_cells BUF*]**

The following example checks cells in the my_cell_list collection.

prompt> **check_legality -cells $my_cell_list**

The following example checks cells added in the my_cell_list collection and cells within 5.5 row heights.

prompt> **check_legality -cells $my_cell_list -check_distance 5.5**

The following example checks all BUF* cells in the design using the default three row height checking distance and writes out a Tcl file including all violated cells.

prompt> **check_legality -cells [get_cells BUF*] -output_tcl**

SEE ALSO

create_placement(2)
legalize_placement(2)
place.legalize.enable_advanced_legalizer(3)

check_legalizer_sanity

Does a series of sanity checks on the design to handle dirty data input.

SYNTAX

status **check_legalizer_sanity**

DESCRIPTION

The **check_legalizer_sanity** command performs a series of sanity checks on the current design (eg. - testing the library, user input design constraints) to avoid legalizer issues.

Running this command before running legalize_placement helps user identify dirty (bad design) inputs that might cause issues like long runtime or hang later, beforehand. The output generated is in the form of Error/Warning messages.

This command helps the user to save time by debugging the cause before legalization runs into problems at later stages; and decide how to proceed.

EXAMPLES

The following example runs the **check_legalizer_sanity** command:

```
prompt> check_legalizer_sanity
```

SEE ALSO

check_legality(2)

check_license

Checks the availability of the specified license feature.

SYNTAX

status **check_license**
feature_name
[-quiet]

Data Types

feature_name string

ARGUMENTS

feature_name

Feature name to be checked for existence in the license server.

-quiet

Do not print any error message if the check failed.

DESCRIPTION

The **check_license** command checks for the existence of the feature in the license server. It does not check out the license feature. If the feature exists on the server, the command returns 1. Otherwise, the command prints an error message and returns 0. The printing of this message can be suppressed via **-quiet** option.

The **list_licenses** command provides a list of the features that are currently checked out.

EXAMPLES

This example checks the availability of the Fusion-Compiler-AG license feature:

```
prompt> check_license Fusion-Compiler-AG
1
```

SEE ALSO

get_licenses(2)
list_licenses(2)
remove_licenses(2)

check_lvs

Checks for inconsistencies in the physical layout of the current design.

SYNTAX

status **check_lvs**
[-nets *collection_of_nets*]
[-checks {short open floating_routes all}]
[-max_errors *maximum_number_of_errors*]
[-check_child_cells true | false]
[-exclude_child_cell_types *exclude_types*
[-check_zero_spacing_blockages true | false]
[-check_top_level_blockages true | false]
[-open_reporting { bounding_box | detailed }]
[-report_floating_pins true | false]
[-treat_terminal_as_voltage_source true | false]

Data Types

collection_of_nets collection
maximum_number_of_errors integer
exclude_types list

ARGUMENTS

-nets *collection_of_nets*

Specifies the nets to check. By default, all nets are checked.

-checks {short open floating_routes all}

Specifies the types of errors to check as follows:

- **short:** check for shorts between nets.
- **open:** check for open nets.
- **floating_routes:** check if any floating routes exist.
- **all:** check all error types above

By default, all error types are checked.

-max_errors *maximum_number_of_errors*

Specifies the maximum number of errors for each type of violations specified with the **-checks** option. Set the value to 0 to specify

an unlimited error count. The default is 20.

-check_child_cells true | false

Specifies whether to check shorts between child cells and top-level shapes. If true, all shapes in child cells are checked. The default is false.

-exclude_child_cell_types {*exclude_types*}

Specifies cell types to ignore when checking shorts between child cell and top-level shapes. Specify one or more of the following cell types: **abstract**, **analog**, **black_box**, **corner**, **cover**, **diode**, **end_cap**, **fill**, **filler**, **flip_chip_driver**, **flip_chip_pad**, **lib_cell**, **macro**, **module**, **pad**, **pad_spacer**, **physical_only**, and **well_tap**.

You must specify the **-check_child_cells** option with this option.

-check_zero_spacing_blockages true | false

Specifies whether to check shorts on zero spacing blockages. The default is false.

-check_top_level_blockages true | false

Specifies whether to check shorts on top-level blockages. The default is true.

-open_reporting { bounding_box | detailed }

Specifies how open violations are shown in the error browser.

- **bounding_box:** Report bounding box of open net
- **detailed:** Report the detailed open locations in the error browser; it might require longer runtime to find detailed open locations

When the number of connected components of an open net is more than 100 and the **-open_reporting** option is set to **detailed**, 100 approximated open locations will be reported. The default is bounding_box.

-report_floating_pins true | false

Specifies whether to report floating pins when checking open or floating_routes violations. The default is false.

-treat_terminal_as_voltage_source true | false

When set to true, the check_lvs command assumes that all terminals of pg nets are voltage sources. The default is false.

DESCRIPTION

The **check_lvs** command detects physical layout versus schematic errors. Violations discovered by the checker are available as an error set for browsing with the GUI error browser.

The command can use multiple CPU cores to generate the report based on the **set_host_options -max_cores** command setting. If this value is not set, the command runs on a single core.

The command generates an error file named "block_name"_lvs.err. To view the errors on GUI, load the error file by using the Error Browser.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports shorts, opens, and floating route violations for all nets in the design.

prompt> **check_lvs**

The following example reports only short violations for all nets in the design.

prompt> **check_lvs -checks short**

The following example reports short, and open violations for net N1, N2, and N3.

prompt> **check_lvs -nets {N1 N2 N3} -checks {short open}**

The following example reports short violations without checking shapes in child cell.

prompt> **check_lvs -checks short -check_child_cells false**

The following example reports open violations in detail on error browser.

prompt> **check_lvs -checks open -open_reporting detailed**

SEE ALSO

check_routes(2)
set_host_options(2)

check_mib_alignment

Checks the alignment of each multiply instantiated block (MIB) instance against power straps, ground straps, standard cell rows, and wire tracks in the current design.

SYNTAX

int **check_mib_alignment**
[-pg]
[-cell_row]
[-wire_tracks]
[-layers *layers*]
[-blocks *blocks*]
[-verbose]

Data Types

layers collection
blocks collection

ARGUMENTS

-pg

Checks the alignment of each MIB instance against the power and ground straps that intersect MIB instances in the current design. If any MIB instances are not aligned correctly with power and ground straps, the command issues a warning message with the location of the misalignment.

-cell_row

Checks the alignment of each MIB instance against standard cell rows and cell row site which intersect the MIB in the current design. If any MIB instances are not aligned correctly with cell rows or cell row site, the command issues a warning message.

-wire_tracks

Checks the alignment of each MIB instance against wire tracks in the current design. If any MIB instances are not aligned correctly with wire tracks, the command issues a warning message.

-layers *layers*

Specifies the layers on which to check the alignment of MIB instances against power straps, ground straps, and wire tracks. This option is used with the **-pg** or **-wire_tracks** options.

-blocks *blocks*

Specifies the reference block name to which the MIB instances belong, for checking the alignment of MIB instances against power straps, ground straps, and wire tracks.

-verbose

Prints complete misalignment report for the checked MIB instances. Without this option, the command prints a compact report (default).

DESCRIPTION

This command checks alignment of each MIB instance against power straps, ground straps, cell rows, and wire tracks respectively or checks all of them without corresponding options. The misaligned MIB instances cannot be pushed down successfully. Misalignment messages are reported in GUI->Window->Message Browser Window when EMS database is created using command create_ems_database.

EXAMPLES

The following example checks for power and ground strap alignment across all the MIB instances in the design.

```
prompt> check_mib_alignment -pg -verbose
```

The following example checks for MIB alignment against wire tracks.

```
prompt> check_mib_alignment -wire_tracks -verbose
```

SEE ALSO

push_down_objects(2)
report_mibs(2)

check_mib_for_pin_placement

Checks multiply instantiated block (MIB) instances for potential pin placement issues.

SYNTAX

string **check_mib_for_pin_placement**
[-swapped_connections]
[-top_level_terminal_locations]
[-asymmetric_connections]
[-cells *list_of_blocks*]
[-nets *net_collection*]

Data Types

list_of_blocks list
net_collection collection

ARGUMENTS

-swapped_connections

Checks and reports pins on MIB instances that do not connect to the corresponding pins across the instances of the reference block. The check can be run before and after pin placement. The check is limited to comparing two-pin nets that connect MIB instances.

-top_level_terminal_locations

Checks and reports top-level terminals that connect to the same MIB pin, but at difference locations. The check can be run before and after pin-placement.

-asymmetric_connections

Checks for pins across MIB instances where the MIB block pin does not connect to the same number or type of pins (asymmetric pins). The check can be run before and after pin placement. Unlike the **-swapped_connections** check, the **-asymmetric_connections** check is not limited to two-pin nets that connect two unique MIB instances. Instead, this check examines all MIB pins in the design for asymmetry. By definition, swapped connections are a subset of asymmetric connections. The command skips pins that are connected to tie-high or tie-low nets. When this option is used the command returns asymmetric connections/pins as well as pins connected to these asymmetric connections to help with further analysis.

-cells *list_of_blocks*

Specifies a list of blocks or cells for checking. The check considers all the MIB blocks in the design for checking, but limits reporting and the collection of pins to the set of blocks specified in the *list_of_blocks*.

-nets *net_collection*

Specifies a collection of nets for mib checking. The check considers all the MIB blocks in the design for checking, but limits reporting and the returned collection of pins to those pins that connect to the specified set of nets. If this option is not specified the command looks at all MIB pins.

DESCRIPTION

This command checks and reports potential multiply instantiated block (MIB) pin placement issues. If an issue is detected, the command returns a collection of pins with potential problems. The command can be used before or after pin placement to detect potential issues with MIB pins. You must specify at least one of **-top_level_terminal_locations** or **-swapped_connections** options.

The **set_editability** can enable/disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled by **set_editability**.

MIB pins that are dangling or tied-off are ignored by this command. That is the comparisons of MIB pin connectivity are limited to those pins that are neither dangling nor tied off.

EXAMPLES

The following example checks for swapped MIB pin connections pins on all blocks.

```
prompt> check_mib_for_pin_placement -swapped_connections
```

set_editability(2)

check_multibit_library

Reports the compatible multibit and single bit cells in the library for banking and debanking.

SYNTAX

status **check_multibit_library**
[-banking]
[-debanking]
[-generate_map_file *file_name*]

ARGUMENTS

-banking

Reports all compatible multibit lib cells for each single bit lib cell for banking.

-debanking

Reports all compatible single bit lib cells for each multibit lib cells for debanking.

If neither \fb-banking nor **-debanking** option is specified, the \fb-banking will be specified by default.

-generate_map_file *file_name*

Specifies the name of output file that contains the mapping information. The file contains a series of function equivalent lib cell groups for single bit cells. The file also contains the mapping of multibit bit-width to the combination of lower multibit lib cells in each function equivalent group.

DESCRIPTION

This command lists all the compatible lib cells for banking and debanking. The report also includes the reasons of incompatibility. The report lists the compatible and incompatible multibit lib cells for each single bit lib cell. On the other hand, the report lists the compatible and incompatible single bit lib cells for each multibit lib cell if -debanking option is specified.

If the -generate_map_file is specified, the output file will be generated. The output file contains a collection of the function equivalent lib cells. The output file also shows how to use the lower multibit lib cells to compose a multibit cell whose bit-width is under 32 for each function equivalent group.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example generate a compatible lib cells report for banking and a output mapping file.

```
prompt> check_multibit_library -generate map_file.txt

****************************************
Report : check_multibit_library
Flow   : BANKING
****************************************

--------------------------------------------------------------------------------
Single bit Lib cell          Compatibility      Multi bit Lib cell
--------------------------------------------------------------------------------
SB_Reg_Lib1                  COMPATIBLE         MB_Reg_Lib1
                                                MB_Reg_Lib2
                                                MB_Reg_Lib3

SB_Reg_Lib2                  VOLT INCOMPATIBLE  MB_Reg_Lib4
                                                MB_Reg_Lib5
                                                MB_Reg_Lib6

Singlebit with NO Multibit Equivalents
--------------------------------------------------------------------------------
SB_Reg_Lib3
SB_Reg_Lib4
SB_Reg_Lib5

The map_file.txt contains the information as below:
FUNC_GROUP_1 { SB_Reg_Lib6 SB_Reg_Lib7 SB_Reg_Lib8 }
 8 { 1 MB_Reg_Lib7 }
 4 { 1 MB_Reg_Lib8 }
 2 { 1 MB_Reg_Lib9 }
```

The FUNC_GROUP_1 { SB_Reg_Lib6 SB_Reg_Lib7 SB_Reg_Lib8 } shows the function equivalent group for single bit lib cells.

2 { 1 MB_Reg_Lib9 } shows the target multibit bit-width 2 would be composed by 1
of MB_Reg_Lib9 multibit lib cells.

check_mv_design

Checks for violations in a multi-voltage design.

SYNTAX

status **check_mv_design**
[-max_message_count *message_count*]
[-erc_mode]
[-power_connectivity]
[-voltage_threshold *threshold*]
[-interface_only]

Data Types

message_count integer
threshold float

ARGUMENTS

-max_message_count *message_count*

Set the maximum number of occurrences for each error type. If you set it to zero or 'all', that means the number of occurrences of the message is unlimited. If this option is not specified, the limit is 20 by default.

-erc_mode

If specified, the command will run in electrical-rule-checking mode and ignore any UPF strategies specified in the power intent. If this option is not specified, the command will consider UPF strategies.

-power_connectivity

If specified, the command will check pg nets and power and ground connections of the design.

-voltage_threshold *threshold*

Set the voltage threshold for level shifting violations. If this option is not specified, the threshold is zero by default.

-interface_only

If specified, the command will check violations related to block boundary interface of current block and sub-block(s) only and other internal violations will be excluded.

DESCRIPTION

The **check_mv_design** command checks multi-voltage related electrical rules for the design, and issues error and warning messages as appropriate.

EXAMPLES

The following command prints all multi-voltage related violations in the design.

```
prompt> check_mv_design -power_connectivity -max_message_count all

--------- Power domain rule ----------
No errors or warnings.

--------- Supply net rule ----------
Warning: Unable to derive power and ground type for supply net vddx. (UPF-049)
Information: Total 1 UPF-049 violations. (MV-080)
Error: Supply net 'vddx' has no valid driver(s). (MV-011)
Information: Total 1 MV-011 violations. (MV-080)

--------- Supply port rule ----------
Warning: HighConn of supply port 'U11/vdd089' is unconnected. (MV-022)
Warning: LowConn of supply port 'U11/vdd089' is unconnected. (MV-022)
Information: Total 2 MV-022 violations. (MV-080)

--------- Isolation cell rule ----------
No errors or warnings.

--------- Level shifter cell rule ----------
No errors or warnings.

--------- Retention cell rule ----------
No errors or warnings.

--------- Switch cell rule ----------
No errors or warnings.

--------- Isolation rule ----------
Error: The related supply net 'vdd' of driver pin 'in1' is less always-on than
the related supply net 'vdd2' of load pin 'ff2/D'. (MV-013)
Error: The related supply net 'vdd' of driver pin 'clk' is less always-on than
the related supply net 'vdd2' of load pin 'ff2/CK'. (MV-013)
Information: Total 2 MV-013 violations. (MV-080)

--------- Voltage shifting rule ----------
Error: Driver pin 'in1' (related supply net: vdd [0.6V]) cannot drive load pin
'ff2/D' (related supply net: vdd2 [0.5V]) due to voltage difference. (MV-012)
Error: Driver pin 'clk' (related supply net: vdd [0.6V]) cannot drive load pin
'ff2/CK' (related supply net: vdd2 [0.5V]) due to voltage difference. (MV-012)
```

```
Information: Total 2 MV-012 violations. (MV-080)

--------- PG net rule ----------
No errors or warnings.

--------- Tie-off connection rule ----------
Warning: The tie-off connection 'm1' has not been implemented. (MV-027)
Information: Total 1 MV-027 violations. (MV-080)

--------- PG pin rule ----------
No errors or warnings.

--------- Power connectivity rule ----------
No errors or warnings.

--------- Signal pin rule ----------
No errors or warnings.

SEE ALSO

load_upf(2)

check_netlist

Checks the netlist for any connectivity errors or violations and issues warning messages accordingly.

SYNTAX

int **check_netlist**
[-cells]
[-nets]
[-ports]
[-hierarchical]
[-multiple_designs]
[-summary]

ARGUMENTS

-cells

Specifies that netlist checks to be performed on cell instances. This option involves checking the input and output pin connections of the cell instances as well as the inside connections for hierarchical cell instances.

-nets

Specifies that netlist checks to be performed on nets. This option involves checking for drivers, loads and multiple drivers of a net. It also checks if a net is constant driven or it is three state net.

-ports

Specifies that netlist checks to be performed on ports. This option involves checking of the port connections such as whether an output port is being driven, an input port has a load.

-hierarchical

Performs the checks on the objects across all levels of physical hierarchy. This option is FALSE by default.

-multiple_designs

Reports warning messages related to multiply-instantiated designs.

-summary

Displays a summary of the warning messages instead of one message per warning. This does not affect the way error messages are issued.

DESCRIPTION

The command checks the design for netlist connectivity errors and any design violations. This command gives a preliminary information about the state of the netlist and if there are any potential problems with the netlist. This informs about the potential errors that might occur during the later stages.

The command performs checks cells/nets/ports based on the options provided. The command by default performs checks on cells, net and ports. When no option is given, the **check_netlist** command performs checks for cells, nets and ports of the top level hierarchy. If **-hierarchy** is given, the command would perform the checks across all levels of physical hierarchy. The option **-multiple_designs** flags multiple instances of a module. If a module is instantiated in two different designs, a warning message is issued.

If an open EMS database exists before this command is executed, the messages are saved to the EMS databse. The Message Browser window in GUI provides a summary of the number of messages for each check type as well as each individual message.

This command has no dependency on scenario-specific information.

EXAMPLES

The check_netlist command displays the following information when no option is specified.

```
prompt> check_netlist

check_objects_for_push_down

Checks a collection of nets or charging stations for potential problems before running the **push_down_objects** command.

SYNTAX

collection **check_objects_for_push_down**
object_collection
[-cells *cells*]

Data Types

object_collection collection
cells collection

ARGUMENTS

object_collection

Specifies the collection of signal nets or charging stations to be checked. The collection can only include signal nets or charging stations, but not both. This option is required.

Only **signal_routing** objects and charging stations are checked by this command. The **signal_routing** objects include wires, paths, vias, via arrays and terminals that connect to signal nets. The charging stations are non-primary voltage areas that contain repeater buffers.

-cells *cells*

Specifies the block instances to check for pushing down objects. By default, all blocks are checked for push-down readiness.

DESCRIPTION

This command checks signal nets or charging stations for potential issues before pushing them into blocks with the **push_down_objects** command. The check returns a collection of nets or charging stations that might have problems. You can check only one object type, net or charging station, at a time.

If the command finds no problems with any of the objects passed (nets or charging stations), the command returns an empty collection. If the command encounters some problem unrelated to specific checks for objects, the command returns a "0" status rather than a collection.

When nets or shapes of nets are included in the object collection, this command traverses the routing and looks for 1) collinear routes and vias, 2) problems with physical routing that are incompatible with the logical definition of the net, 3) incomplete routing at the top level.

If charging stations are included, the command checks that the voltage area is non-primary and finds the deepest block that the voltage area overlaps. The depth of hierarchy that is examined is controlled by the **set_editability** command. Use this command to define the range of hierarchy depth or the blocks to check. The command checks if that block has the necessary UPF objects (PG supply nets) for receiving that voltage area.

This command uses the option settings specified by the **set_push_down_object_options** command. Set all options for the net or charging station objects that are planned for push-down before running the **check_objects_for_push_down** command.

For net routing, the command checks the routing and determines whether feedthrough ports are required. By default, feedthrough requirements (such as top-level continuity, and logical-vs-physical consistency of the routing) are not checked unless the command detects pin constraints for the net that indicate that the **push_down_objects** command would be free to allow feedthroughs on the net. If so, and the routing requires a feedthrough port on the block, feedthrough requirements are checked for the net.

Feedthroughs for nets can be enabled or disabled by the **set_individual_pin_constraints -nets netname -allow_feedthroughs true**|**false** command.

EXAMPLES

The following example checks the routing objects for nets NETA and NETB for potential push down problems.

```
prompt> check_objects_for_push_down [get_nets {NETA NETB}]
```

The following example checks the charging station named "gas_station" for potential push down problems.

```
prompt> check_objects_for_push_down [get_voltage_areas gas_station]
```

SEE ALSO

report_push_down_object_options(2)
set_push_down_object_options(2)
set_individual_pin_constraints(2)

check_pg_connectivity

Verifies physical connectivity of the power ground network.

SYNTAX

status **check_pg_connectivity**
[-nets *pg_nets*]
[-write_connectivity_file *file_name*]
[-check_macro_pins one | all | none]
[-check_block_pins one | all | none]
[-check_pad_pins one | all | none]
[-check_std_cell_pins one | all | none]
[-max_floating_cluster_size *size*]
[-error_view_name *file_name*]

Data Types

pg_nets collection
file_name string
size integer

ARGUMENTS

-nets *pg_nets*

Specifies the power ground nets to be checked. By default, the command checks all power ground nets.

-write_connectivity_file *file_name*

Specifies the output file name. If specified, the tool writes detailed net connectivity information to the file.

-check_macro_pins one | all | none

Specifies how macro pins are checked for the specified nets. "one" means that a macro is connected if at least one pin shape of the net is connected. "all" means that a macro is connected only if all pin shapes of the net are connected. "none" means that macro pins are not checked. By default, the value is "one".

-check_block_pins one | all | none

Specifies how block pins are checked for the specified nets. "one" means that a block is connected if at least one pin shape of the net is connected. "all" means that a block is connected only if all pin shapes of the net are connected. "none" means that block pins are not checked. By default, the value is "all".

-check_pad_pins one | all | none

Specifies how pad pins are checked for the specified nets. "one" means that a pad is connected if at least one pin shape of the

net is connected. "all" means that a pad is connected only if all pin shapes of the net are connected. "none" means that pad pins are not checked. By default, the value is "one".

-check_std_cell_pins one | **all** | **none**

Specifies how std cell pins are checked for the specified nets. "one" means that a std cell is connected if at least one pin shape of the net is connected. "all" means that a std cell is connected only if all pin shapes of the net are connected. "none" means that std cell pins are not checked. By default, the value is "one".

-max_floating_cluster_size ***size***

Specify the maximum size of floating cluster to be returned by the command and reported by the error browser.

-error_view_name ***file_name***

Specifies the error view name. If not specified, the default error view name will be "[block_name]_floatingPG.err".

DESCRIPTION

This command checks the physical connectivity of the power ground network. The command generates information for floating wires, vias, pads, macro pins, and standard cell pins. The information can be viewed by using the error browser. More detailed info can also be written to a file. The command also returns a collection of floating vias and wires. You can easily remove these floating objects using **remove_objects** command.

EXAMPLES

The following example checks the connectivity of the VSS net, and checks whether all macro power ground pins are connected to the network.

prompt> **check_pg_connectivity -nets VSS -check_macro_pins all**

SEE ALSO

check_pg_missing_vias(2)
compile_pg(2)
connect_pg_net(2)

check_pg_drc

Verifies and reports technology routing design rules violations and illegal overlaps of PG net objects.

SYNTAX

status **check_pg_drc**
[-nets {*collection_of_nets*}]
[-ignore_std_cells]
[-do_not_check_shapes_in_lib_cells]
[-do_not_check_shapes_in_hier_blocks]
[-ignore_clock_nets true | false]
[-check_metal_on_track true | false]
[-ignore_keepout_margins]
[-check_min_metal_area_on_pins true | false]
[-load_routing_of_all_nets]
[-check_detail_route_shapes]
[-coordinates {{*llx lly*} {*urx ury*}}]
[-bottom_layer *min_layer_name*]
[-top_layer *max_layer_name*]
[-no_gui]
[-output *text_file*]

Data Types

collection_of_nets collection or list
llx float
lly float
urx float
ury float
min_layer_name string
max_layer_name string
text_file string

ARGUMENTS

-nets {*collection_of_nets*}

Specifies the nets to verify. By default, all PG nets are checked.

-ignore_std_cells

Prevents the command from loading content of standard library cells. This may be useful, for example, if placement of the cells is not "legalized". By default, the command loads and checks all internal objects of such cells.

-do_not_check_shapes_in_lib_cells

When this option is specified, the command does not report drc errors, which involve internal shapes of same library cell only. Cells under this option include cells of the following design_type: lib_cell, filler, end_cap, well_tap, diode. By default, such errors are reported. For example, small unconnected pin, included into PG net may cause "minimal metal area" error in a report.

-do_not_check_shapes_in_hier_blocks

When this option is specified, the command does not report drc errors, which involve internal shapes of any cell other than library cells described in option "-do_not_check_shapes_in_lib_cells". For example, design_type macro, pad, etc. By default, such errors are reported.

-ignore_clock_nets true | false

Specifies whether routing objects of clock nets should be ignored. By default, the tool ignores clock net objects.

-check_metal_on_track true | false

Specifies whether to check metal-shape alignment with a track on a metal layer (if corresponding rules are set in the technology file). By default, the tool does not do such checking.

-ignore_keepout_margins

When this option is specified, the command does not check any overlaps of routing objects with keepout-margin areas. By default, all such cases are reported as illegal-overlap errors.

-check_min_metal_area_on_pins true | false

Specifies whether the command should check metal area of unconnected pins. By default, insufficient area of such pins is reported as an error.

-load_routing_of_all_nets

This is request to consider existing routing shapes and vias of all nets. By default, routing shapes and vias of non-PG nets are completely ignored.

-check_detail_route_shapes

When this option is specified, the command takes into account routing shapes and vias of PG nets which have usage attribute "detail_route". By default, such shapes are ignored.

-coordinates {{*llx lly*} {*urx ury*} ...}

Specifies a rectangular area where to perform design rule checking. *llx* and *lly* are coordinates that define the lower-left corner of the area. *urx* and *ury* are coordinates that define the upper-right corner. By default, PG DRC checking is performed on the entire design.

When this option is specified, the tool considers objects within the specified rectangle, and nearby objects associated with the PG nets.

-bottom_layer *min_layer_name*

Specifies the bottom routing layer on which to perform DRC checking. If this option is specified, the tool ignores objects on layers lower than *min_layer_name*. By default, the tool checks down to the lowest routing layer of design.

-top_layer *max_layer_name*

Specifies the top routing layer on which to perform DRC checking. If this option is specified, the tool ignores objects on layers higher than *max_layer_name*. By default, the tool checks up to the highest routing layer of design.

-no_gui

Prevents the tool from writing to the GUI error set. If this option is specified, a text report is written to the file specified by the **-output** option. If **-output** is not specified, the tool writes the report to a file named "./pg_routing_errors.txt".

-output ***text_file***

Specifies the name of the output report file. By default, the tool does not write a text report, unless the **-no_gui** or this option is specified. If **-no_gui** is specified and **-output** is omitted, the tool writes the report to a file named "./pg_routing_errors.txt".

DESCRIPTION

This command checks and reports violations of technology design rules and illegal overlaps of objects (shapes, vias and pins) of power and ground nets.

Checking is performed either on entire design area, or in the area specified by the **-coordinates** option.

The checking result from this command is available as an error set for browsing with the GUI error browser, or as text report that is written to a file, or both.

For the text report, the command writes the error type, violated rule, layer, and other details regarding the error as follows.

```
=================
Error type:     insufficient space between two diff-net via-cuts
Violated rule:  Cut-Min_Spacing-Rule
Layer:          CO
Minimal spacing: 0.05
Actual  spacing: 0.0238(southwest - northeast)
Spacing box:    {900.621 412.336} {900.633 412.357}
Via #1:         box = {900.579 412.294} {900.621 412.336}
                net = VDD
Via #2:         box = {900.633 412.357} {900.675 412.399}
            net = VSS
```

The command can use multiple CPU cores to generate the report, based on the *set_host_options -max_cores* command setting. If this value is not set, the command runs on a single core.

EXAMPLES

The following example checks technology design rules for all PG nets in the entire design. The report is generated as an error set for the GUI error browser. The command can use up to 6 CPU cores:

```
prompt> set_host_options -max_cores 6
prompt> check_pg_drc
```

The following example checks only objects of the VDD net on layer MET4. The text format report is written to a file named "./net_vdd_on_M4.drc":

```
prompt> check_pg_drc -no_gui -output ./net_vdd_on_M4.drc -nets VDD \
  -bottom_layer MET4 -top_layer MET4
```

The following example checks rules within the specified rectangular area and generates both kinds of report:

```
prompt> check_pg_drc -coordinates {{287.0 362.0} {412.0 530.0}} \
```

-output ./PG-errors_in_window.txt

set_host_options(2)
gui_open_error_data(2)

check_pg_missing_vias

Checks missing vias within the power and ground network.

SYNTAX

status **check_pg_missing_vias**
[-nets *pg_nets*]
[-via_rule_file *rule_file_name*]
[-output_file *output_file_name*]
[-write_default_via_rule_file]
[-shape_use *shape_use_list*]
[-ignore_shield_route]
[-ignore_small_intersections]
[-honor_routing_blockage]

Data Types

pg_nets collection
rule_file_name string
output_file_name string
shape_use_list list

ARGUMENTS

-nets *pg_nets*

Specifies the PG nets to be checked. By default, the command checks all PG nets.

-via_rule_file *rule_file_name*

Specifies the via rule file which includes all the via rules to be checked. By default, the command checks vias between adjacent orthogonal layers.

The via rule file can include multiple via rules.

The supported rules are

- **stack_via**: Checks for stacked vias.

  By default (**false**), this rule is not checked.

- **parallel**: Checks for vias between parallel layers.

  When you specify this rule, you must also specify the pitch with the **pitch** attribute.

  By default (**false**), this rule is not checked.

- **pitch** Specifies the via pitch for parallel wires.
- **macro_pin**: Checks for vias connecting to macro or power-switch PG pins.

  By default (**false**), this rule is not checked.
- **terminal**: Checks for vias from terminal in upper layer to wires in lower layer

  By default (**false**), this rule is not checked.

The via rule format is as follows:

```
viaRuleName {
  bottom_layer: bottom_metal_layer_name (required)
  top_layer: top_metal_layer_name      (required)
  stack_via: true | false
  parallel: true|false
  pitch: number
  macro_pin: true | false
  terminal: true | false
}
```

The following example checks vias between M2 and M7, including stacked vias and macro pins.

```
viaRule1 {
  bottom_layer: M2
  top_layer:    M7
  stack_via:    true
  macro_pin:    true
!}
```

-output_file *output_file_name*

Specifies the output file name. If specified, the tool writes detailed information about missing vias to the file.

-write_default_via_rule_file

Writes the default via rule to defaultViaRule.txt.

-shape_use

If specified, the command will only check vias against shapes with specified shape_use in the option. If not specified, the command will check vias against shapes with all shape_use.

-ignore_shield_route

If specified, the command will not check vias against shapes with shape use shield_route.

-ignore_small_intersections

If specified, the command will not report error if the via site is smaller than the minimum contact code on the layer.

-honor_routing_blockage

If specified, the command will not report error if the via site is covered by routing blockages.

DESCRIPTION

This command checks for missing vias between overlapping regions of different metal layers. The error info can be viewed from error browser or written to a file. You can define via rules to be checked by writing the rules to a file and importing the file with the **-via_rule_file** option.

EXAMPLES

The following example checks the vias for the VSS net based on rules defined in viaRule.txt.

```
prompt> check_pg_missing_vias -nets VSS -via_rule_file viaRule.txt
Check net VSS vias...
Number of missing vias: 0
Checking net VSS vias took 0 seconds.
```

compile_pg(2)

check_physical_constraints

Checks the design for any issues in the floorplan objects and constraints such as macro or fixed cell instances, site rows, blockages, core/die area, layers, tracks, bounds, and so on.

SYNTAX

int **check_physical_constraints**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The command checks the design for any issues with the physical constraints. Use this command to discover potential issues which could lead to problems later in the flow. Depending on the severity, the command issues an information, warning, or error message.

The command checks whether floorplan data is available or not, and checks for the presence of core and die areas. It also performs various checks on site rows, move bounds, group bounds, layers, tracks, fixed and macro cell instances, and placement blockages.

Basic Floorplan:
The command checks that basic floorplan information, like boundary and core, is defined for the block or that the information is valid.
Checks if the unit tile is missing in reference library.

Site Rows:
Checks if the site height is multiple of the normal site height.
Checks if the site row overlaps another site row.
Checks if the site row needs to be aligned.
Checks if there are both horizontal and vertical site rows.
Checks if it is a non-zero extra spacing in rows which is not supported.

Cell Instance:
Checks if the keepout margin is outside the core area.
Checks if the I/O pad cell instance is in the core area or overlaps with other cell instance.
Checks if the orientation of cell instance is legal.
Checks if the macro is placed and fixed.
Checks if the macro is out of the core area.
Checks if the macro is overlapping with other macro or blockage.

Placement Blockages/Bounds:
Checks if the movebound is completely covered by blockage.

Checks if the placement blockage is partially or completely outside the core area.
Checks if the move bound is partially or completely overlap with other.
Checks if the utilization of group bound/move bound is above 90%.

Layers/Tracks:
Checks if the tracks are defined.
Checks if the track crosses core area.
Checks if the preferred routing direction is defined.
Checks if the consecutive metal layers have the same preferred routing direction.
Checks if the layer spacing is greater than the pitch minus width.
Checks if a layer has non-PG shapes/shape patterns on it.
Checks if a layer is defined in the technology file.

If an open EMS database exists before this command is executed, the messages are saved to the EMS database. The Message Browser window in the GUI provides a summary of the number of messages for each check type as well as each individual message.

This command has no dependency on scenario-specific information.

EXAMPLES

The **check_physical_constraints** command displays the following information.

```
prompt> check_physical_constraints
****************************************
Report : check_physical_constraints
Design : mult36
Version: L-2016.03-SP3-BETA
Date   : Fri Jun  3 03:10:22 2016
****************************************
Warning: The spacing of layer 'VTL_N' is greater than the difference
  of the pitch and width of the layer. (DCHK-105)
Warning: The spacing of layer 'VTL_P' is greater than the difference
  of the pitch and width of the layer. (DCHK-105)
Warning: The spacing of layer 'PO' is greater than the difference of
  the pitch and width of the layer. (DCHK-105)
Information: The layer 'M8' does not contain any PG shapes. (DCHK-104)
Information: The layer 'M9' does not contain any PG shapes. (DCHK-104)
Warning: The orientation of cell instance 'tapfiller_TAPCELLBWP16P90_0'
  does not match any legal orientations. (DCHK-103)
Warning: The orientation of cell instance 'tapfiller_TAPCELLBWP16P90_1'
  does not match any legal orientations. (DCHK-103)
1
```

check_pin_placement

Performs pin placement checking.

list_of_objects list

ARGUMENTS

-alignment true | false

Checks block pin alignment QoR. The alignment check is limited to two-pin nets with at least one connection to a block (or Hard-Macro/ETM if the appropriate **-cell_type** option is used) and no connection to a standard cell pin. Nets not connected to a block or connected to standard cell pins, or those with more than two connections, are not checked. Nets are not checked if they are connected to blocks that are disabled for planning. When used with the **-self** option the check is limited to two-pin nets with one connection to a top-level terminal (and no connection to standard-cell pins).

If this option is not specified, the command skips alignment checking. Note that two pins are considered unaligned if their pin bounding boxes are mis-aligned by greater than the **-alignment_tolerance_distance**. But if the tolerance option is not used and the bounding boxes of two pins overlap and the extent of the overlap is greater than two-thirds of smaller bounding box then pins are not considered to be unaligned.

On the other hand if the **-alignment_tolerance_distance** is specified/used then that distance is used to compute alignment.

Note that by using the option along with the **-cell_type** option, alignment can be checked between hard macro to hard macro instances or ETM to ETM cells.

-alignment_tolerance_distance *tolerance_distance*

Checks that pins are aligned within the specified *tolerance_distance*. The command only reports misaligned pins when the distance between two pins is greater than specified *tolerance_distance*. The distance is the vertical distance if two pins are on horizontal layers, or the horizontal distance if two pins are on vertical layers. The distance is to be specified in microns. You must use the **-alignment true** option with the **-alignment_tolerance_distance** option. When this option is not specified the default value of zero microns is used.

-layer_mismatch_only true | false

Limits the alignment check to two-pin nets that are aligned but have pins on different layers. This option can be used only with the **-alignment** option. When set to true the summary report, detailed net report and list of violating pins returned will all correspond to only such nets.

The default value of this option is false.

-blocked_only true | false

Limits the alignment check to two-pin nets that are aligned but are blocked by a physical block (or hard macro) between the two pins. This option can be used only with the **-alignment** option. When set to true the summary report, detailed net report and list of violating pins returned will all correspond to only such nets. Note that if the physical block is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

-alignment_report_file *file*

Specifies the name of the file where the detailed net alignment reports are written. This option can only be used with the **-alignment** and **-report_net_details** options.

-alignment_histogram true | false

This option is used to generate a histogram of the mis-aligned nets that are alignable. The histogram is based on mis-aligned distance. The nets are grouped in buckets of 50 microns according to their misaligned distance. The option can be used only with the **-alignment** option. The default value is false.

-connection_type ALL | BLOCK_TO_BLOCK | BLOCK_TO_MACRO | BLOCK_TO_IO

Limits the alignment check to two-pin nets of the specified type. This option can be used only with the **-alignment** and **-single_pin** options.

For the single pin check, specifying this switch limits single pin checking to that subset of interfaces. For example between only blocks and hard-macros. Note that this option cannot be used with the **-cell_type** option.

If this option is not specified, the default is ALL, which runs the check on all the two-pin nets in the design.

-cell_type ALL | BLOCK | HARD_MACRO | EXTRACTED_TIMING_MODEL

Directs the command to check the pins of only the specified type of cells. The default value is BLOCK, which limits the checking only to pins on physical blocks. The option cannot be used in conjunction with the **-self** option.

Pin checking on Hard-Macro and Timing-Model instances is limited only to short, preroute, missing, single-pin , alignment, wire-track and wide-track checks. This option is silently ignored for all other checks and the remaining checks will only run on pins of physical blocks.

When the value specified is ALL, then block ETM and hard-macro pins are checked for appropriate violations.

-pin_type ALL | SIGNAL_PINS | PG_PINS

Directs the command to check the pins of only the specified type, that is either power/ground or signal pins or both.

The default is signal_pins, which limits the checking only to pins on physical blocks connected to signal nets.

A pin is considered a power/ground pin by the checker if it connected to a power/ground net and is itself also of the power/ground type. The **place_pins** command also treats PG nets/pins similarly (refer to its man-page for relevant details).

PG (power/ground) pin checking is limited only to the short, single-pin, missing wire-track, wide-track and pin-size checks. This option is silently ignored for all other checks and the remaining checks will only run on signal pins.

When the value specified is ALL, both signal and PG pins are checked for appropriate violations.

Using this option along with the **-nets** , **-pins** or **-ports** options results in filtering of the specified set (of nets, pins or ports) according to the passed pin type value. That is if pin-type SIGNAL is used along with **-pins** then only those pins from the set of pins that are of type SIGNAL will be used for pin checking.

Note that short and spacing violations of signal pins with power/ground pins is checked by default, that is even when the value for this option is signal_pins. When the value is set to ALL then short violations between two PG pins are also checked. Note that checking for spacing violations between two PG pins is not supported.

-corner_keep_out true | false

Checks for corner keepout violations on the edges of physical blocks. If this option is not specified, the command skips the check.

The default value of this option is false.

-detour_tolerance *tolerance_ratio*

Checks that the net detours are within the specified *tolerance_ratio*. You must use the **-pin_detour true** option with the **-detour_tolerance** option. The command reports only nets with the ratio of the total-bounding box to the standard-cell bounding box that is greater than the specified value. The default *tolerance_ratio* is one.

-error_view *view_name*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it will be ignored. If no extension is specified, the filename will be appended with the ".err" extension.

If this option is omitted, the error view data is stored as an attachment to the design database. When the design is closed and saved, the error view data is saved to the design database as well. The saved error view data does not change until the next *check_pin_placement* command.

-exclude_unplaced_objects true | false

This option can be used with the **-alignment** or **-pin_detour** options. When used with the alignment option, it excludes nets that have unplaced connections from the alignment check, when set to true. In this context (when used with alignment check), "Un-Placed" refers to a pin on an unplaced cell.

When used with the detour check it skips unplaced cells and dangling block pins from the detour computation. For details on how such dangling pins are handled by default refer to the **-pin_detour** option description.

By default, this option is false.

-filename *file*

Specifies the name of the file where the reports of pin placement checking are written. Cannot be used in conjunction with *-output_directory* option

-layers true | false

Determines if pins are placed on legal metal layers as specified by the *-allowed_layers* option of the *set_block_pin_constraints* or the *set_individual_pin_constraints* command. The command also checks for violations of any per-edge layer constraints that are specified in the pin-constraint file. For information about the default minimum and maximum metal layers used for pin placement, see the *set_block_pin_constraints* command man page.

For pins that are connected to and covered by a top-level terminal, the check ensures that such pins are on the same layer as that top-level terminal. Individual or block-level layer constraints are not checked for such pins.

If this option is not specified, the command skips the layer check.

The default value of this option is false.

-location true | false

Determines if pins with location constraints are placed on their constrained location. Both on-edge and off-edge pins are checked against their location constraints.

For information about setting location constraints on pins review *set_individual_pin_constraints* command. If this option is not specified, the command skips the location check. The default value of this option is false.

-missing true | false

Reports block pins without a pin shape. By default, this option is true.

-nets ***net_collection***

Limits the pin placement check to the specified collection of nets.

-net_length ***net_length***

Limits the detour check to only those nets whose length is greater than the specified value. The default is zero microns, which means that all nets will be checked for detour. Currently this option can only be used with the **-pin_detour true** option. The units for *net_length* are microns. If routing is present for the net, the total length of the route is used. Otherwise, half the perimeter wire-length (from the bounding box of the net) is used to calculate the length.

-off_edge true | **false**

Determines if part of a pin outline coincides with an edge. A block cell pin is flagged if none of the pin edges coincide with its block edges. If this option is not specified, the tool skips the off edge check.

The default value of this option is false.

-offset true | **false**

Checks if pin-placement violates (in decreasing order of priority) individual, topological or bundle pin offset constraints. If multiple constraints exist on the same pin (say individual and bundle for example) then the constraint with higher priority is given precedence and checked against.

If this option is not specified, the command skips the check. Note that even if the offset option is used without the **-side** option explicitly set to true, the command automatically runs the sides check as well. If certain pin/port placement already violates side constraints, it will automatically skip for offset checking.

If a range is specified (when specifying the offset constraint) then the pin's placement is checked against that range. If a specific offset is specified then the pin should be placed either at that offset or at the closest valid wire-track to that offset.

The default value of this option is false.

-order true | **false**

Checks pin placement for order constraint violations. The order constraints specified in pin-constraint file with the **read_pin_constraints** command are used for this check.

The default value of this option is false.

-output_directory ***directory***

Writes individual report files for each check (layer, offset, side, and so on) to the specified directory. If the directory does not already exist, the command tries to create the directory. If creation is successful and write permissions are appropriate, the command checking output is written to individual files created in this directory instead of the prompt. The files created also have a list of pins associated with the particular violation. The option cannot be used together with the *-filename* option. If you omit the **-output_directory** option and specify the **-filename** option, the command writes a single file that combines the checks.

-pins ***pins***

Limits the pin placement check to the specified collection of pins.

-pin_blockage true | **false**

Checks if a pin overlaps with an associated pin blockage or if the terminal of the pin abuts to or overlaps with a routing blockage, and if the layer of the pin is the same as the layers associated with the blockage. If this option is not specified, the command skips the pin blockage check.

The default value of this option is false.

-pin_detour true | false

Checks for pin-detour violations. The option is used to report pins that might not be optimally placed. The check reports nets that have a bounding-box greater than the bounding box of the standard-cell pins and top-level terminals/ports that it connects.

The check runs on nets that have at least two pins with a minimum of one block pin. This includes nets that connect top-level ports/terminals to block pins. Pins that are unplaced are not included in the bounding box comparison. Also unconnected or dangling block pins are accounted for by projecting the center point of the standard-cell bounding box (corresponding to the nets connections) onto the edge of the dangling block pins. This projected point(s) are added to the standard-cell bounding box to compute a more meaningful detour ratio in the presence of dangling connections.

When this option is used along with the **-self** option, it limits the detour checking to only those nets that have a connection to a top level port in addition to having at least one block pin.

The option **-exclude_unplaced_objects** can also be used along with this option to filter out or skip dangling block pins from the detour computations. When set to true, block pins that have no external connections or those whose external connections are only other dangling block pins are excluded from the detour computations.

When the app option **plan.pins.path_based_pin_placement** is used the detour check reverts to use the register based bounding box instead of standard-cell based one (for qualifying nets). For details on how that bounding box is computed refer to the man-page for that option.

When the app option **plan.pins.detour_supernet_mode** is used the detour check skips over repeaters and considers the flat net during detour computation. Note that the path based option has precedence over the supernet based option. Please refer to the man-page of these options for more details.

Note that a net is skipped for detour checking if all the physical blocks it connects to are disabled.

The default value of this option is false.

-pin_density_map true | false

Checks and reports on the prompt and the GUI the block pin density on the edges of each physical block in the design. The report is per layer and each edge is sub-divided into buckets or windows for density computation. The density on each layer in each bucket is defined as the ratio of the number of pins by the number of available slots/wire-tracks (on that layer) within the bucket/window. The text version of this report is automatically redirected into a new file called block_pin_density.rpt created in the current working directory. If the directory is not editable or the file cannot be created, a warning is issued and the report is instead redirected to the prompt.

The option **-window_length** can be used to control the size of the window. If not specified a default window size as a multiple of site row height is used.

The default value of this option is false.

-pin_direction true | false

Checks for pin direction mismatch violations. It is divided into two categories.

- abutted or stacked pin direction mismatch
- multi-driven or floating nets that connect to hierarchical physical blocks

By abutted or stacked pins, it refers to two pins abutted or stacked by abutting hierarchical physical block edges, and these two pins are connected by the same net. Two abutted pins must be on two hierarchical physical blocks of the same physical hierarchy. Two stacked pins must be on two hierarchical blocks that one is the parent of the other.

Please note, the power, ground, or tie-off nets are not checked for pin direction mismatch.

For a pair of abutted pins, only the following are considered as legal:

- one is input and the other is output, or

- one is inout and the other does not matter

For a pair of stacked pins, only the following are considered as legal:

- both pins are input or both pins are output, or
- one is inout and the other does not matter

For a net that is not multi-driven nor floating, it must satisfy

- it must have a driver from a pin or port of input, output or inout pin direction, and
- if the driver is of input or output direction, there can be only one such driver

The default value of this option is false.

-pin_guide true | **false**

Checks if the center of a pin is outside the associated pin guide and if the layer of a pin is NOT on a layer specified by the pin guide. If this option is not specified, the command skips the pin guide check.

The default value of this option is false.

-pin_mask_constraint true | **false**

Checks if there are any mask_constraint violations on the block pins, such as abutted block pins with conflicting mask_constraint settings, block pin and wire track with conflicting mask_constraint settings, and so on. When checking if the block pin and the wire track have conflicting mask_constraint settings, the tool only checks the wire track owned by the block. If the block does not have a wire track within it, then the tool will check the block pin against top-level wire track instead.

By default, this option is false.

-pin_size true | **false**

Checks if pins honor their width and length constraints. If the pins do not have width or length constraints, but are on the double patterning layers, this option checks if the pins honor the default double patterning pin length requirement. If pins have width and length constraints and are also on double patterning layers, this option checks only if the width and length constraints are honored. If there are non-default routing rules associated with the pin that have size/width constraints, those are checked as well. If a pin is placed on a wire track with non-zero track width, then the command checks to ensure that the pins width is the same as the track width.

If there is a min-area rule specified on the technology file for the layer, then the pins-area is checked against this rule.

It also checks to ensure that the pin-length is a perfect multiple of the grid size (if a grid is present/defined). For detailed explanation of the handling of pin length, width and area constraints, see the man page for the **place_pins**

The default value of this option is false.

-pin_spacing true | **false**

Determines if any of the following object-pairs along the edge (the two objects overlap in the direction perpendicular to the edge), are closer than the number of wire tracks (or distance) specified by the *-pin_spacing* option of the *set_block_pin_constraints* or the *set_individual_pin_constraints* command.

- two signal pins
- a signal pin and a power/ground pin (Note that spacing between two power/ground pins is not checked.)
- a signal pin and a pre-route shape/via

If there are NDR rule constraints associated with the pin (or associated net) then the spacing is checked against those constraints as well. The command also checks for violations of any per-edge layer constraints that are specified in the pin-constraint file.

The report has sub-sections for these different type of constraints. Note that the spacing check between pins is limited to pins on

the same block edge.

If this option is not specified, the pin spacing check is not performed.

The default value of this option is false.

-technology_spacing_rules true | false

Determines if any two signal pins (or a signal pin and power/ground pin) or a signal pin and a pre-route are closer than any of the technology related spacing constraints. The supported spacing rules that are checked are the corresponding layers minimum spacing rule (as defined in technology file), fat-metal spacing rules and basic, color-based span spacing rules that might be defined in technology file.

Note that spacing is only checked for pins/shapes along a block edge. That is off-edge pins are not checked for spacing violations. Also pre-route shapes from inside a hard-macro are not considered when checking spacing.

For two objects to be checked for spacing (except for end to end spacing), they must overlap in the direction perpendicular to the edge. End to end spacing checks the spacing between the ends of two objects (signal pins and signal/PG routing shapes), for objects to qualify for end to end spacing they must overlap in the direction of the edge (without being shorted together). Note that the spacing check between pins is limited to pins on the same block edge.

The report has sub-sections for these different type of rules. Note that spacing between two power/ground pins is not checked and that the **-pin_spacing** option only checks user specified constraints (like block or individual pin spacing constraints) and this option checks only technology related rules/constraints.

The default value of this option is true.

-ports *ports*

Limits the pin placement check to the specified collection of ports.

-pre_route true | false

Determines if any pin is shorted with any preroute (signal or power/ground) or via. The check is used to ensure that no pins overlap with and are on the same layer as a section of preroute. Note that the *-shorts* option does not check for shorts against preroute.

Note that even when used with the **-cell_type HARD_MACRO** option the checker does not load and check against any preroutes that might exist inside the hard-macro. It does however check the hard-macro pins for shorts against any preroutes that are created outside the hard-macro itself.

The default value of this option is false.

-report_net_details true | false

Reports detailed net information on pins with alignment violations. You must use the **-alignment true** option with the **-report_net_details** option. If this option is not specified, the command does not include net details in the report output. When the **alignment_report_file** option is used the report is written to that specified file.

The following definitions are relevant to this report :

Aligned: The distance between the two pins is less than specified *tolerance_distance*. The distance is the vertical distance if two pins are on horizontal layers, or the horizontal distance if two pins are on vertical layers. The default value of *tolerance_distance* is zero microns.

Unaligned: The distance between the two pins is more than the specified *tolerance_distance*.

Blocked: There is a physical block (including hard macros) along the line between the two pins of the net. Note that if the physical block (that lies along the line between the two pins of the net) is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

Unblocked: There isn't a physical block or hard macro along the line between the two pins of the net. Note that if the physical block (that lies along the line between the two pins of the net) is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

Unalignable: The pins of the net are unalignable due to some combination of pin side, pin-blockages, pin-guides corner-keepout constraints and the relative placement of the blocks. Pins of two child blocks that are not on facing edges are considered unalignable. A net that connects a parent block port/pin to a pin on the parents child block is considered alignable if it possible to align the two pins of the net by placing the parent block port/pin on another allowed side.

Alignable: These nets are alignable given the constraints listed above. Most typically two pin nets are considered alignable when the pins are placed on facing edges.

The report is divided into 5 parts: (1) aligned nets on different layers, (2) aligned blocked nets, (3) unaligned alignable nets, unblocked, (4) unaligned alignable nets, blocked, (5) unalignable nets. Each section begins with one of the following commented header lines to indicate the type of unaligned or aligned nets.

- aligned nets on different layers:
- aligned blocked nets:
- unaligned alignable unblocked nets:
- unaligned alignable blocked nets:
- unaligned unalignable nets:

Following the header line, the report lists the details of each aligned or misaligned net. The details include the name of the net and its two pins, the type of the net/connection and whether the net is aligned or misaligned. The report also reports if the net is blocked/unblocked and if either pin is fixed.

The connection is between two pins that are from a block cell or top design (BLOCK), top-level I/O pins (IO), pad cell(PAD) or hard macro(HM). One of the pins must connect to a block cell. The following shows an example connection:

Two-Pin net {NetName} with pins {PinA} and {PinB} of type BLOCK->IO
is aligned. The net is blocked. {PinA} is Fixed.

For nets that are unalignable, the reason that they cannot be aligned is provided.

The default value of this option is false.

-routing_corridor true | false

Checks if the center of a pin is outside the associated routing corridor and if the layer of a pin is NOT on a layer specified by the corridor. If this option is not specified, the command skips this check.

For nets with feedthrough pins, the checking depends on the properties of the routing corridor. If the routing corridor is connected and covers all its associated pins/ports, then each pin (including feedthrough pins) created by pin-placement should be within the routing corridor. If the routing corridor is

not fully connected or does not cover all its associated pins/ports, then at least one of the original or feedthrough pins (per block) should be within the corridor.

In addition, if there is no overlap between a corridor and the block boundary, the pins of that block will not be checked against the corridor. When used with the **-self** option, the command checks all top-level ports against their associated routing corridors.

The default value of this option is false.

-shorts true | false

Checks for shorts that are caused by two pins on the same layer that touch or overlap each other. Pins that are connected to the same net are not considered to be shorted. If this option is not specified, the command performs the shorts check. For ports with

multiple-pins/EEQ-pins, each of the pins are checked for violations. And each individual violation is reported in the error-browser GUI. On the command prompt though any combination of two ports that are shorted are reported a single time (independent of the number of violations their individual pins create).

The default value of this option is true.

-self

Limits the pin placement check to the top level ports.

-sides true | false

Checks for pin side violations that are caused by a pin's placement violating side constraints. The violating side constraint can be any of the following (in order of decreasing priority): individual pin constraints, topological, bundle or block constraints. In the presence of multiple constraints (individual and block constraints for example) the one with the higher priority is given precedence and checked against.

Note that command reports violations and sides with respect to the reference block. The default value of this option is false.

-single_pin connected | unconnected | all

Checks for unroutable pins on abutted edges. Valid values for this option are:

- **connected**
  A block pin is flagged as a single (unroutable) pin if any one of the following are true:
  - The block pin is placed on a block edge that abuts another block

    edge and the block cell pin does not abut the other block pin on the same metal layer, or these two pins mismatch in width.
  - The block pin is placed on a block edge that coincides with the

    top-level cell boundary and connects to anything other than a terminal (top-level pin), unless the pin connects only to other pins on the same block and those pins are stacked on top of the pin.
  - The block pin is placed on a block edge that coincides with the

    top-level cell boundary and the block cell pin is connected only to a terminal, but the terminal is not stacked on top of the block cell pin on the same metal layer, or the terminal and the cell pin mismatch in shapes.
- **unconnected**
  A block cell pin is flagged as a single (unroutable) pin if either one of the following is true:
  - The block cell pin is logically unconnected to any pin or terminal

    and is placed on a part of the block edge that abuts another block edge.
  - The block cell pin is logically unconnected to any pin or terminal

    and is placed on a part of the block edge that coincides with the top-level cell boundary.

  When you specify **-single_pin unconnected**, the command also checks terminals. A terminal is flagged if it is logically unconnected and is located on a top-level cell boundary that abuts a macro edge.
- **all**
  A block cell pin is flagged as a single (unroutable) pin if any of the scenarios described for **connected** or **unconnected** occur.

The above checking applies only to pins that are placed on (abutted) edges. For **off-edge pins** that overlap with other physical blocks above/beneath them, the command checks to see if there is a corresponding matching pin above/below it. It also checks to ensure the matching pin is of the same size/shape and layer as the off-edge pin. Off-edge pins that have routing to other

terminals are skipped for this type of checking.

When checking for single pins the pin being checked is expected to be of the same type (signal or PG) as its matching/corresponding pin (whether abutted or stacked). Also the the abutted pins are expected to be of compatible directions.

For block edges that abut (or overlap in case of parent and child block) hard-macro edges, a pin placed on such an edge is considered legal if it either has a matching hard-macro pin or there is no blockage/routing-shape on the same layer within the abutted hard-macro abutted/adjacent to the port.

Note that **physical-only cells** (such as fillter of cap cells) are ignored by the single pin check. For pins abutted to their parent block pins, the single pin check also reports any cases where the child block pin is shorter than the abutted parent block pin. The opposite scenario (that is child block pin is longer) is not considered a violation.

Additionally the **-connection_type** option can be used to filter/restrict reporting/checking of single pin violations to a subset of edge interfaces.

If this option is not specified, the command skips the single pin check.

-stacking true | false

Checks if there exist any stacking violations. Whether or not a pin to pin stacking or a pin to power or ground preroute stacking is regarded as a violation is determined by the setting of *-stacking_allowed* option of command *set_block_pin_constraints*.

-synthesized_pins true | false

This check reports and returns all the pins inserted by the tool to avoid single pins, during pin-placement on abutted designs. If this option is not specified, the command skips this check.

The default value of this option is false.

-wire_track true | false

Determines if pins are centered on wire tracks. A vertical wire track on the same layer as the pin must coincide with the vertical central axis of the pin for pins on a horizontal edge. A horizontal wire track must coincide with the horizontal central axis of a pin on a vertical edge.

Off-edge pins are checked against the wire-track only if the **-off_edge** option is also set to true along with the **-wire_track** option. For an off-edge pin, the command verifies that off-edge pins are centered on wire tracks in the preferred direction of the metal layer of the pins. The pins are not checked against the wire tracks in the nonpreferred direction. If this option is not specified, the command skips the wire track check.

The default value of this option is false.

-wide_track true | false

Checks that pins satisfy track width constraints. When set to true, the check flags two types of violations: 1) pins that are placed on reserved-for-width tracks, 2) pins whose width is different than the width specified for the track.

The default value of this option is false.

-window_length *window_length*

Specifies the window length to be used during pin-density computation. The value is to be specified in microns, if not specified then the command uses a default value (that is reported on the prompt) for computing the pin density. The default value is a function of site row height.

If the specified window length is less than the default, the tool issues a warning message and uses the default. The default is a multiple of site-row height and is computed based on the design and library technology.

This option can only be used with the **-pin_density_map** option set to true.

list_of_objects

Specifies the collection of block cells for pin placement checking. The command checks pin placement only on the blocks you specify. If no blocks are specified, the command checks the pins on all block cells.

DESCRIPTION

This command performs the pin placement check on specified pins or ports of specified cell type (specified by options **-pins**, **-nets**, **-ports**, **-self**, **-cell_type**). If multiple options are specified, the pin placement check will be performed on the objects of the common sets, i.e. objects met all specified conditions. If none of these options are specified, the pin placement check will be performed on all of the block pins whose parent blocks are enabled.

When performing the pin placement checks, this command uses the constraint values set by the commands **set_individual_pin_constraints**, **set_topological_pin_constraints**, **set_bundle_pin_constraints**, or **set_block_pin_constraints** (these constraints can also be set by **read_pin_constraints** using pin constraints file). The command uses default pin constraints if there are no pin constraints applied.

If there are no options specified for the types of checks, the command checks only for missing pins, short pins and min spacing (specified by the technology file) violations. By default the command examines multiple levels of physical hierarchy (MPH support) for pin-constraint checking. The **set_editability** can be used to enable/disable checking on individual reference-blocks or levels of physical hierarchy. Some options have specific behavior relating to how they support disabled blocks. Please refer to the description under each option to understand the behavior.

EXAMPLES

The following example checks all blocks in the design for shorted and missing pins. It also determines if any two signal pins are closer than the number of wire tracks previously specified by the **-pin_spacing** option of the **set_block_pin_constraints** command.

```
prompt> check_pin_placement -shorts true -missing true -pin_spacing true
```

check_placement_constraints

Checks placement constraints before running **create_placement** or **place_opt**.

SYNTAX

status **check_placement_constraints**

DESCRIPTION

This command is used to check coarse placement constraints before running **create_placement** or **place_opt**. If any infeasible constraints are found, information about the constraints will be written out for the user to fix.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example checks placement constraints:

```
prompt> check_placement_constraints
```

SEE ALSO

create_placement(2)
place_opt(2)

check_pre_pin_placement

Checks for unfriendly user constraints and design issues that might cause pin placement errors. Run this command before performing pin placement.

SYNTAX

string **check_pre_pin_placement**
[-filename *file_name*]
[-self]

Data Types

file_name string

ARGUMENTS

-filename *file_name*

Writes out the placement check results to the specified file name. By default, the command only writes the pin placement check results to the console.

-self

When specified, check will be performed on top ports, instead of block pins. to the console.

DESCRIPTION

This command issues a warning message for one the following scenarios:

- The allowed-side constraint conflicts with the allowed-layer constraint.
- A edge of a block does not have tracks overlapping with it.
- An off-edge fixed pin has topological constraints.
- A fixed pin is outside of block boundary.
- Any side of the bbox for a block cannot be touched by the boundary for that block.
- Inconsistent boundary for a same block between design/abstract view and frame view.
- A fixed pin has topological constraints and its parent cell is facing the target cell, however the pin is not facing the target cell.

- A fixed pin has blockage, pin guide, route corridor or pin short violations.
- A fixed pin is abutted with another block, and the abutted-edge is close to a pin/routing/metal-blockage. In this situation the abutted pin that is created will overlap with the blockage.
- A topological constraint specifies a path that starts from and ends at the same block, but does not specify which pin the path should start from and end at.
- A topological constraint specifies direct connection between two cells which is impossible in the given floorplan.
- A topological constraint specifies direct connection between a port/pin and its target which is impossible in the given floorplan.
- A topological constraint specifies direct connection between sides for two cells which is impossible in the given floorplan.
- A topological constraint specifies very unfavorable side connection: the sides specified are opposite to the facing edges.
- Two cells can only be connected through other cells, while these other cells are neither allowed for feedthroughs, nor enabled for planning.
- A port/pin can only connect to its target through other cells, while these other cells are neither allowed for feedthroughs, nor enabled for planning.
- Inconsistent blockages across MIBs.
- Range/offset overlap between net/bundle constraints.
- Range/offset overlap between net/bundle constraint and pre-existing fixed pin.
- A net is included in multiple bundles.

EXAMPLES

The following command checks the design for possible issues before performing pin placement with the **place_pins** command.

```
prompt> check_pre_pin_placement
```

The following command checks the design for possible pin placement issues and writes out the list of checks performed and results to the file named

```
prompt> check_pre_pin_placement -filename pinplacement.rpt
```

SEE ALSO

place_pins(2)

check_pre_place_io

Check design data before IO placement and bump assignment.

SYNTAX

status **check_pre_place_io**
[-io_guides]
[-pad_assignment_file *filename*]
[-matching_types]

Data Types

filename string

ARGUMENTS

-io_guides

Check whether there exists any IO guide that cross any block boundary.

-pad_assignment_file *filename*

Check whether user pad assignment is correct.

-matching_types

Check whether the matching types do not have bumps in blocks, MIB violations, netlist violations, has enough bumps and has unique components. The checking for netlist violations is a step by step procedure. For all violating matching type net violations a specific warning will be issued and the user will also be informed if the matching type has to be removed from the design if it has conflicts with a specific net in the design.

DESCRIPTION

This command check for design data errors before user runs place_io command. It will not change the design data.

EXAMPLES

The following example performs design data checking.

```
prompt> check_pre_place_io -io_guides -pad_assignment_file file_name
```

digits integer

ARGUMENTS

-reset

Specifies to terminate current PrimeTime session.

-report_script *file_name*

Specifies a TCL script file to customize the reporting. when -report_script is specified, the -type and related options are all ignored.

-type global_timing | scenario_timing | summary | max_delay | min_delay | max_transition | max_capacitance | power

Specifies the type of QoR to check. The global_timing type is similar to reporting global timing in PrimeTime. The scenario_timing will report merged QoR and QoR for every scenario. The summary type is similar to reporting QoR summary. The max_delay and min_delay types are similar to the **report_timing** command reporting. The max_transition and max_capacitance types are similar to the **report_constraint** command reporting. The power type is similar to reporting power.

-pba_mode none | path | exhaustive

Specifies one of the following path-based timing analysis modes:

- **none** (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- **path** - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths. To control the ordering of the paths (either by original graph-based slack or recalculated path-based slack), set the **pba_path_mode_sort_by_gba_slack** variable.

- **exhaustive** - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode.

-group ***group_name***

Specifies a group of timing paths for timing and nets or cells for power.

Options only available for the max_delay and min_delay types

-from ***from_list***

Reports only paths that start from the specified list of pins, ports, nets, or cell instances; or from startpoints clocked by the named clocks. Valid startpoints are clock pins of sequential devices and input pins of the design.

-rise_from ***rise_from_list***

Same as the **-from** option, except that the path must start with a rising transition.

-fall_from ***fall_from_list***

Same as the **-rise_from** option, except that the path must start with a falling transition.

-to ***to_list***

Reports only paths that end at the specified list of pins, ports, nets, or cell instances; or at endpoints clocked by the named clocks. Valid endpoints are data input pins of sequential devices and output pins of the design.

-rise_to ***rise_to_list***

Same as the **-to** option, except that the path data must end with a rising transition.

-fall_to ***fall_to_list***

Same as the **-rise_to** option, except that the path data must end with a falling transition.

-through ***through_list***

Reports only paths in which the data goes through the named pins, ports, cell instances, or nets. You can use this option multiple times in a command.

-rise_through ***rise_through_list***

Same as the **-through** option, except that it applies only to paths with a rising transition at the specified objects.

-fall_through ***fall_through_list***

Same as the **-through** option, except that it applies only to paths with a falling transition at the specified objects.

-exclude ***exclude_list***

Excludes all paths in which the data goes from, through, or to the specified list of pins, ports, nets, or cell instances.

-rise_exclude ***rise_exclude_list***

Same as the **-exclude** option, but applies only to rising transitions at the named pins, ports, nets, or cell instances.

-fall_exclude ***fall_exclude_list***

Same as the **-exclude** option, but applies only to rising transitions at the named objects.

-nworst ***paths_per_endpoint***

Reports up to the specified number of worst paths per endpoint. The default is 1. A larger value results in a larger report and more

runtime.

-max_paths ***max_path_count***

Reports up to the specified maximum total number of paths among all path groups. The default is equal to the **-nworst** setting, or 1 if the **-nworst** option is not used.

-unique_pins

Reports only the single worst timing path through any given sequence of pins. No other paths are reported for the same sequence of pins from startpoint to endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin sequence, then paths starting with a falling edge are not reported for that sequence of pins.

-slack_greater_than ***minimum_slack***

Reports only paths with slack greater than the specified *minimum_slack* value; these paths have a negative slack better than the specified *minimum_slack* value (or a positive slack that is farther from causing a violation). This option is intended to be used with the **-slack_lesser_than** option to report paths within a specific range of slack.

-slack_lesser_than ***maximum_slack***

Reports only paths with slack less than the specified *maximum_slack* value; these paths have a negative slack worse than the specified *maximum_slack* value (or a positive slack that is closer to causing a violation).

-include_hierarchical_pins

Causes the timing path report to show points for the hierarchical pins crossed, as well as all leaf pins in the path. The hierarchical pins are shown only for documentation purposes; they are reported as having zero incremental delay and do not affect the timing results.

-start_end_pair

Reports the worst path for each startpoint-endpoint pair in the design, including all violating startpoint-endpoint pairs by default, or all startpoint-endpoint pairs with slack worse than the value specified by the **-slack_lesser_than** option if that option is used.

-path_type ***format***

Specifies the types of path information displayed in the timing report, using one of the following format keywords:

- **summary** -- Displays the path startpoint, path endpoint, and slack.
- **end** -- Displays the path endpoint, path delay, required time, and slack.
- **short** -- Displays a report like the default **full** report but omits the intermediate points between the startpoint and endpoint.
- **full** (the default) -- Displays the full data path, including all intermediate points and their incremental and cumulative delay, together with the launch and capture clock arrival times, data required time, and slack.
- **full_clock** -- Displays a **full** report with the addition of the clock path points from the clock source to the launch and capture points.
- **full_clock_expanded** -- Displays a **full_clock** report with the addition of the clock path points between the primary clock source and its related generated clock source point. This report is different from a **full_clock** report only when the clock is a generated clock.

-input_pins

Shows cell input pins as well as cell output pins in the timing path. As a result, the report shows the incremental net and cell delays separately at each point, instead of combined. By default, the report shows only the cell output pins.

-nets

Shows nets in the timing path. By default, the report does not show nets.

-nosplit

Prevents line splitting. This can useful for scripts that extract information from the report. By default, the report generates a new line when the text cannot fit in the alloted space in a column.

-transition_time

Shows the transition time (slew) in the path report for each driver pin and load pin, appearing as an additional column labeled "Trans".

-capacitance

Shows the total capacitance in the path report for each net, appearing as an additional column labeled "Cap".

-significant_digits *digits*

Specifies the number of digits after the decimal point displayed for time values in the generated report.

-crosstalk_delta

Reports crosstalk delta delay values at cell input pins in a column labeled "Delta". The **-input_pins** option is automatically selected. The delta values are computed during crosstalk signal integrity analysis.

-derate

Shows derating factors in a column labeled "Derate".

-variation

Includes parametric on-chip variation (POCV) information in the report in columns labeled "Mean" and "Sensit" if POCV analysis is enabled in PrimeTime.

-exceptions dominant | **overridden** | **all**

Reports user-specified timing exceptions that are satisfied per timing path being reported.

Specifying dominant reports the dominant timing exception in the path. It can be one of the following: false path, minimum and maximum delays, and multicycle paths.

Specifying overridden reports all the timing exceptions that were overridden by the dominant timing exception.

-voltage

Reports the operating voltage for each path element in a column labeled "Voltage", allowing you to debug voltage levels in multivoltage designs.

Options only available for the noise type

-verbose

Reports noise details such as aggressor bump height, width and slack. This option works only with the noise type.

-save_session

Specifies the directory to save PrimeTime session.

DESCRIPTION

When your design is optimized with PrimeTime ECO using the **fix_pt_eco** command, you may want to check QoR in PrimeTime timing values. Use the **check_pt_qor** command to view PrimeTime timing values. The **check_pt_qor** command checks PrimeTime's timing, DRC, and power, and shows their values. By default, the command reports top level timing summary with setup and hold WNS, TNS, and violation count. It is as same as specifying the *-type global_timing*. When the summary type is specified, the command reports QoR summary including setup, hold, max transition, and max capacitance violations. When the max_transition or max_capacitance type is specified, the command reports pins with negative slacks. When the max_delay or min_delay type is specified, the command reports the timing path with its slack values.

When you specify the power type, the command shows leakage, dynamic and total powers in all scenarios.

If you want to customize the reporing, specifify -report_script, which is mutually exclusive with -type.

If you need to terminate PrimeTime, specify the *-reset* option. If the *-reset* option is specified, other options are ignored.

EXAMPLES

Without any options, it shows global setup and hold timing summary, which is similar to PrimeTime's *report_global_timing* command.

```
prompt> check_pt_qor
```

You can view max or min delay timing path in PrimeTime timing by using the -type max_delay or -type min_delay option, which is similar to PrimeTime's report_timing command.

```
prompt> check_pt_qor -type max_delay
```

You can use standard reporting options like -from, -to, -through, etc to specify the timing path that you are interested in.

```
prompt> check_pt_qor -type max_delay -from U1/CK -to U2/D
```

The example below shows max_transition violations.

```
prompt> check_pt_qor -type max_transition
```

For QoR summary, use the -type summary option, which is similar to PrimeTime's report_qor command.

```
prompt> check_pt_qor -type summary
```

For PrimeTime PX power reporting, the -type power option is used as shown below.

```
prompt> check_pt_qor -type power
```

[-error_data *errdata_name*]
[-honor_layer_constraints true | false]
[-obey_access_edges true | false]
[-obey_direction_preference true | false]
[-report_no_access_edge true | false]
[-standard_cell_search_range *integer*]
[-via_ladder true | false]

Data Types

integer integer
errdata_name string

ARGUMENTS

-access_edge_whole_side true | false

Controls the access points when access edges are obeyed (**-obey_access_edges true**).

An access edge is marked by a narrow rectangle, a short line, or a single point. The access edge mark either fully or partially overlaps one of the port edges. When the overlap is not full, such as when the access edge mark is a single point, there are two possible interpretations of the connection rule.

By default (**true**), the connection can be made to any point on the marked port edge. If set to **false**, the connection must be made to the exact access edge mark.

-allow_via_rotation true | false

Controls whether the tool can use rotated vias at pin connections.

By default (**true**), rotated vias are allowed.

-blocked_range *integer*

Specifies the number of pitches for the same-layer accessibility check for macro and top-level ports.

The default is 10.

-blocked_range_via_side *integer*

Specifies the number of pitches for the accessibility check on the other side of an access via.

The default is 10.

This check applies only to macro and top-level ports.

-check_congestion_map_overflow *integer*

Checks global route congestion map overflow larger than or equal to the given value. Please be noted, this check runs a fast global route to get a coarse result. When the user needs an accurate congestion map, please run report_congestion command.

The range of value is 0 to 100. The default value is 30. When the given value is 0, this check is disabled.

-check_frozen_net_blocked_ports true | false

Controls whether the command checks for blocked frozen net ports.

By default (**false**), the command does not check frozen net ports.

-check_lib_via_cut_blockage true | false

Controls whether the command checks for incorrect real metal via cut blockages in the reference libraries.

A via cut blockage is treated as a piece of real metal if all of the following attributes are **false**:

- **icc_route_guide**
- **icc_system_layer_blockage**
- **is_design_rule_blockage**
- **is_boundary_blockage**
- **is_external_boundary_blockage**
- **is_zero_spacing**

When the size of a via cut blockage does not fit a legal cut size (cutWidthTbl, cutHeightTbl, minWidth) specified for the layer in the technology file, it is an incorrect real metal via cut.

In general, the attributes except **is_zero_spacing** are special attributes that are generated from the tool flow. You can set the **is_zero_spacing** attribute to **true** to represent a routing blockage or to **false** to represent a real metal blockage.

An incorrect real metal via cut blockage degrades the routing performance and DRC convergence.

By default (**false**), the command does not check for incorrect real metal via cut blockages in the reference libraries.

-check_min_grid true | false

Controls whether the command checks and reports design objects that are not on the user (manufacturing) minimum grid.

By default (**true**), the command performs the minimum-grid checks.

-check_no_net_pins true | false

Controls whether the command checks the accessibility for pins without an assigned net.

By default (**false**), the command does not check pins without nets.

-check_non_standard_cell_blocked_ports true | false

Controls whether the command checks for blocked macro, top-level, and non-standard-cell ports.

By default (**true**), the macro, top-level, and non-standard-cell ports are checked.

-check_out_of_boundary true | false

Controls whether the command checks and reports the pins that are outside of the design boundary. The design boundary is the same as the die size.

By default (**true**), the command performs the out-of-boundary checks.

-check_pg_blocked_ports true | false

Controls whether the command checks for blocked power and ground ports.

By default (**false**), the command does not check the power and ground ports.

-check_real_metal_blockage_overlap_pin true | false

Controls whether the command checks for real metal routing blockages that touch or overlap a pin inside the reference libraries.

A routing blockage is treated as a piece of real metal when all of the following attributes are **false**:

- **icc_route_guide**
- **icc_system_layer_blockage**
- **is_design_rule_blockage**
- **is_boundary_blockage**
- **is_external_boundary_blockage**
- **is_zero_spacing**

In general, the attributes except **is_zero_spacing** are special attributes that are generated from the tool flow. You can set the **is_zero_spacing** attribute to **true** to represent a routing blockage or to **false** to represent a real metal blockage.

By default (**false**), the command does not check for real metal routing blockages that touch or overlap a pin inside the reference libraries.

When **true**, the command issues a warning message to inform you to review the blockage's attributes.

-check_redundant_pg_shapes true | false

Controls whether the command checks for redundant power and ground shapes that overlap at the same location.

By default (**true**), the command checks for duplicated redundant power and ground shapes.

-check_routing_track_space true | false

Controls whether the command checks for power and ground (PG) via obstacles in the space around each routing track by using the default or nondefault spacing requirement.

By default (**false**), the command does not check for PG via obstacles in the space around each routing track.

When **true**, the command issues a warning message to inform you that these PG vias might degrade the routing quality. The command checks only the PG vias.

-check_shield true | false

Controls whether the command performs checks on the routing shapes related to the shielding flow.

By default (**true**), the command checks the attributes of the routing and shield shapes for known problems in the shielding flow. It does not check the correctness of the shield shapes.

There are three shielding-related checks:

- Non-PG net shape with a **shape_use** attribute of **shield_route**.

  Only PG net shapes can have a **shape_use** attribute of **shield_route**.

- Long PG net wire with a **shape_use** attribute of **detail_route**.

  In general, a PG wire with a **shape_use** attribute of **detail_route** is a tie-off wire. A very long PG wire could be a part of a PG mesh or rail.

- Net with a shield nondefault rule that has a shape whose **shape_use** attribute is not **detail_route**.

For all Zroute commands except **check_routability**, you can disable the shield data checker by setting the **route.common.check_shield** application option to **true**.

-check_standard_cell_blocked_ports true | false

Controls whether the command checks for blocked standard cell ports.

By default (**true**), the standard cell ports are checked.

-check_via_cut_blockage true | false

Controls whether the command checks for incorrect real metal via cut blockages in the design.

A via cut blockage is treated as a piece of real metal if all of the following attributes are **false**:

- **icc_route_guide**
- **icc_system_layer_blockage**
- **is_design_rule_blockage**
- **is_boundary_blockage**
- **is_external_boundary_blockage**
- **is_zero_spacing**

When the size of a via cut blockage does not fit a legal cut size (cutWidthTbl, cutHeightTbl, minWidth) specified for the layer in the technology file, it is an incorrect real metal via cut.

In general, the attributes except **is_zero_spacing** are special attributes that are generated from the tool flow. You can set the **is_zero_spacing** attribute to **true** to represent a routing blockage or to **false** to represent a real metal blockage.

An incorrect real metal via cut blockage degrades the routing performance and DRC convergence.

By default (**true**), the command checks for incorrect real metal via cut blockages in the design.

-connect_standard_cells_within_pins true | false

Controls whether via connections to standard cell pins must be fully inside the pins.

By default (**false**), the via connections do not need to be fully inside the pins.

-error_data *errdata_name*

Specifies the name of the generated error data file.

The default is *check_routability*.err.

If the specified error data file already exists, the command overwrites it.

-honor_layer_constraints true | false

Controls whether the command considers the layer constraints when checking the accessibility of ports and the connectivity of nets.

The layer constraints include the global minimum and maximum routing layer constraints set by the **-min_routing_layer** and **-max_routing_layer** options of the **set_ignored_layers** command; the net-specific minimum and maximum routing layer constraints set by the **-min_routing_layer** and **-max_routing_layer** options of the **set_routing_rule** command; and the freeze layer constraints set by the **route.common.freeze_layer_by_layer_name** and **route.common.freeze_via_to_frozen_layer_by_layer_name** options of the **set_app_options** command.

By default (**true**), the command considers the layer constraints when checking for blocked ports and nets.

-obey_access_edges true | false

Controls whether pins can be connected only at their access edges.

By default (**false**), pins can be connected at any point.

-obey_direction_preference true | false

Controls whether only preferred direction access is allowed.

By default (**false**), access is allowed in both the horizontal and vertical directions. When set to **true**, access is allowed only in the preferred direction.

This option applies only to non-standard-cell ports. Standard-cell ports are usually accessed only by vias. When a wire on the port layer is needed, it can be in any direction.

-report_no_access_edge true | false

Controls whether the command reports the unconnected pins without predefined access edges.

By default (**false**), pins without access edges are not reported.

-standard_cell_search_range *integer*

Specifies the number of pitches for the same-layer accessibility search of standard cell pins.

The default is 2.

-via_ladder true | **false**

Controls whether the command performs the via ladder flow sanity checks.

By default (**false**), the command does not perform the via ladder flow sanity checks. When **true**, the command performs only the via ladder flow sanity checks and does not perform the default checks.

DESCRIPTION

The **check_routability** command checks many issues known to degrade the routing performance or quality, including identification of blocked ports, out-of-boundary ports, minimum manufacturing grid violations, off-routing-track ports, and many miscellaneous sanity checks for routing objects. The command reports the results as part of the standard output and in an error data file. You can display the error data file in the GUI error browser. Some reports are available only in the standard text output and not in the GUI.

The **check_routability** command does not check the routing design rules. To check the routing design rules, use the **check_routes** command.

Most of the issues reported by the **check_routability** command are warnings. Review the generated report to verify that these suspicious issues are intended.

Issues reported as errors should be corrected before running any routing commands.

For legacy reasons, note that some "off-grid" messages mean "off-routing-track".

A logical port can have several physical pins. A port is considered blocked if none of its pins is accessible.

A top-level or macro pin is considered accessible if a legal path can be extended from the pin to a certain distance around it. This path can be on the pin layer or can extend to a neighboring layer by a single via. The required distance on the pin layer and on the layer at the other side of the via are set by the **-blocked_range** and **-blocked_range_via_side** options.

A standard cell pin is considered accessible if there is a legal path that extends to the next layer or a path on the pin layer that extends to the distance set by the **-standard_cell_search_range** option or a shorter path on the pin layer ended by a via to a neighboring layer.

- You can fix blocked ports by removing or modifying the blockages, by moving or modifying the ports, or by modifying the netlist.
- You can fix out-of-boundary ports by moving them or, if appropriate, by fully removing them.
- You can either fix minimum-grid violations or intentionally accept them.

You can run the **check_routability** command at any stage of the routing flow. However, it is most useful when run before global routing. It can be useful to run the command after routing to identify the root cause of certain routing failures.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command performs accessibility checks, out-of-boundary checks, and minimum-grid checks. You should run it before

global routing and, if needed, modify the design according to the generated report.

```
prompt> check_routability
```

The command writes a report to the standard output. The report includes either "no violation" messages or a detailed list of the violations. The following example shows a report for a design with violations:

```
==========================================
==    Check for min-grid violations     ==
==========================================

 ===== Technology min-grid violations =====

 >>> Y minimum grid violation in contact cut via2 20.5544 on layer V2.

 >>>> Found 1 Technology min-grid violations

 ====== Library  min-grid violations ======

 >>> Y minimum grid violation for boundary of library cell AND2X4 at
   (0.0000 -0.0230)_(0.3440 -0.0230).
 >>>> Found 1 Library min-grid violations

 ======= Design min-grid violations =======

 >>> Minimum grid violation in path half width (0.0160) at
   (13.9600 8.7510)_(13.9600 8.7760) on layer M2
   (shape use=DetailRoute, net=vdd).

 >>>> Found 1 Design min-grid violations

>>>>>> Total of 3 min-grid violations

======================================
==  Check for out-of-boundary ports  ==
======================================
>>> Port chip4 clkin at (-0.40 50.500)_(0.20 50.700) on layers M3,M4
  is out of boundary
>>>>>> Found 1 out-of-bound ports

======================================
==     Check for blocked ports      ==
======================================
>>>>>> Port blocked by layer constraints- min/max and freeze layer settings
>>> Port AO222X2_inst_4 pinA at (328.0950 34.4850)_(328.2700 35.9150)
  on layer M1 is blocked by layer constraints(reference=AND2X4, net=A).

>>>>>> Port blocked by check port access

>>> Port AO222X2_inst_4 pinB at (20.4000 40.7500)_(20.4500 40.8500)
  on layer M1 is blocked (reference=AND2X4 , net=A).
>>>>>> The design cannot be cleanly routed because it has 2 completely
  blocked ports

>>>>>> Net blocked by layer constraints- min/max and freeze layer settings
>>> Net netA at (328.0950 34.2050)_(339.300,35.915) is blocked with its
  ports isolated by layer constraints.
```

```
>>> Net netB at (328.0950 34.2050)_(339.300,35.915) is blocked with its
  ports isolated by layer constraints and the shapes on freeze layer
  can't be accessed.

>>>>>> The design cannot be cleanly routed because it has 2 blocked Nets
```

The following command performs only out-of-boundary and minimum-grid checks:

```
prompt> check_routability \
  -check_standard_cell_blocked_ports false \
  -check_non_standard_cell_blocked_ports false
```

The following command does not report minimum-grid violations:

```
prompt> check_routability -check_min_grid false
```

check_routes

Verifies and reports routing design rule checking (DRC) violations, net opens, antenna rule violations, voltage-area rule violations, and via conversion rates.

SYNTAX

status **check_routes**
[-nets *nets*]
[-open_net true | false]
[-report_all_open_nets true | false]
[-drc true | false]
[-antenna true | false]
[-voltage_area true | false]
[-check_from_user_shapes true | false]
[-check_from_frozen_shapes true | false]
[-coordinates *list_of_regions*]

Data Types

nets collection
list_of_regions list

ARGUMENTS

-nets {*collection_of_nets*}

Specifies the nets to check.

If you use this option, the command checks only for open nets (**-open_net** option), antenna violations (**-antenna** option), and voltage-area violations (**-voltage_area** option) of the specified nets. All other options are ignored.

By default, all nets are verified.

-open_net true | false

Controls whether the command checks for open nets in the block.

By default (**true**), the command checks for open nets.

-report_all_open_nets true | false

Controls whether the command reports all violations when checking open nets.

By default (**false**), the command reports a maximum of 200 open net violations.

-drc true | false

Controls whether the command checks for design rule violations on the specified nets.

By default (**true**), the command checks for design rule violations.

-antenna true | false

Controls whether the command checks for charge-collecting antenna rule violations on the specified nets.

By default (**true**), the command checks for charge-collecting antenna rule violations. Antenna checking requires antenna rules to be defined in the cell library. If no antenna rules are defined, the command skips this check regardless of this option setting.

When a port has multiple physical pins and routing shapes connect to one of the pins to cause antenna violations, antenna violations will not be reported on all of those pins of the port by default. To report violations on all if those pins, use options "-check_from_user_shapes" or "check_from_frozen_shapes".

-voltage_area true | false

Controls whether the command checks for voltage-area rule violations on the specified nets.

By default (**true**), the command checks for voltage-area rule violations.

-check_from_user_shapes true | false

Controls whether the command includes user-created shapes in the checks.

By default (**false**), user-created shapes are not included in the checks.

-check_from_frozen_shapes true | false

Controls whether the command includes frozen shapes in the checks.

Frozen shapes include shapes on frozen layers and shapes of frozen nets.

- A layer is frozen when the **route.common.freeze_layer_by_layer_name** application is set to **true** for the layer.
- A net is frozen when its **physical_status** attribute is set to **locked**. However, the command treats shapes on frozen PG nets that do not have a type of stripe or ring as not-fixed. Shapes on signal nets and of user route type are treated as fixed if option 'check_from_user_shapes' is set to false.

By default (**false**), frozen shapes are not included in the checks.

-coordinates *list_of_regions*

Specifies the rectangular or rectilinear regions in which to perform design rule checking.

Each rectangular region is specified by its lower-left and upper-right coordinates:

{*llx lly*} {*urx ury*}).

Each rectilinear region is specified by its boundary points:

{*x y*} {*x y*} {*x y*} {*x y*} ...)

The coordinate unit is microns. Each region defines a target area for design rule checking. The specified regions can overlap or be disjoint. If you specify more than one area, the command checks the union of all specified areas.

In addition, the command might flag some DRC violations in the neighborhood of the specified regions.

When you specify this option, the following net-based design rules are not checked:

- Open net
- Antenna

- Voltage area
- Tied to rail and tied to rail directly
- Direct connection of secondary power and ground pins and maximum connections for secondary power and ground pins
- Direct connection of comb routing, maximum connections for comb routing, and daisy-chain distance for comb routing

In addition, when you use this option, the command does not report wire length, via count, and redundant via insertion rate.

You cannot use the following net-related options with the **-coordinates** option: **-nets**, **-open_net**, **-voltage_area**, **-report_all_open_nets**, and **-antenna**.

If you do not specify this option, the command checks the entire block.

DESCRIPTION

Verifies, checks, and reports routing statistics for a block. The statistics are based only on the signal routes; PG routes are not included. To report routing statistics that include PG routes, use the **report_design** command.

The **check_routes** command reports the following information for a routed design:

- Open nets
- DRC violations
- Charge-collecting antenna violations

  Antenna analysis is performed only if antenna rules are defined in the cell library.
- Voltage-area violations
- Wire length

  The command reports the total wire length, the total routed wire length, and the wire length per layer.
- Contacts

  The command reports the total number of contacts, the total number of routed contacts, and the number of instances of each via master.
- Wires

  The command reports both the total number of wires and the total number of routed wires.
- Point connections (PtConns)

  A point connection is a wire that has only one connection one each end.
- Redundant via conversion rate

  The command reports the following types of redundant via rates:

  - Total optimized via conversion rate

    The total optimized via conversion rate is computed as

    optimized_via_count / total_number_of_vias

The optimized via count includes both double vias and DFM-friendly bar vias.

The total number of vias (Total Number of Contacts in the generated report) includes both fixed and routed vias. Fixed vias are vias that the router cannot optimize, such as vias at the preroute stage or vias that have a **route_type** attribute of **user_enter**. Routed vias are vias that were routed by the router and can be optimized.

- Total double via conversion rate

  The total double via conversion rate is computed as

  double_via_count / total_number_of_vias

  The double via count includes only the double vias.

- Optimized via conversion rate based on total routed via count

  The optimized via conversion rate based on total routed via count is computed as

  optimized_via_count / number_of_routed_vias

  The number of routed vias (Total Number of Routed Contacts in the generated report) includes only the routed vias.

Note that the via conversion rates reported by the **check_routes** command do not include PG vias. To report the double via conversion rates that include PG vias, use the **report_design -routing** command.

If you specify the **-nets** option, the **check_routes** command checks only for open nets, antenna violations, and voltage-area violations of the specified nets. It does not check for DRC violations, regardless of the setting of the **-drc** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports DRC violations, open nets, antenna violations, and voltage-area violations for all nets in the block.

```
prompt> check_routes
```

The following example checks for open nets, antenna violations, and voltage-area violations, but not for DRC violations.

```
prompt> check_routes -drc false
```

The following example checks for open nets, antenna violations, and voltage-area violations for the N1, N2, and N3 nets. Note that these rules are checked by default, and DRC violations are not checked.

```
prompt> check_routes -nets {N1 N2 N3}
```

The following example reports only antenna and voltage-area violations for the N1 and N2 nets.

```
prompt> check_routes -nets {N1 N2} -open_net false
```

SEE ALSO

route_detail(2)

check_routing_corridors

Checks that all shapes are connected for each routing corridor, and that each corridor contains the pins that connect to the nets associated with the corridor.

SYNTAX

status **check_routing_corridors**
routing_corridor

Data Types

routing_corridor string

ARGUMENTS

routing_corridor

Specifies the name of the routing corridor to be checked. This is a required option. You can specify only one corridor.

DESCRIPTION

This command checks the specified routing corridor for the following properties:

- The shapes that make up the routing corridor are connected
- All pins of the nets associated with the corridor are covered by the routing corridor shapes

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example checks the routing corridor associated with the n7 net.

```
prompt> check_routing_corridors [get_routing_corridors -of_objects [get_nets {n7}]]
Error: Regions in routing corridor 'RC_0' are not connected. (NDMUI-102)
Error: Routing corridor 'RC_0' does not cover pin 'alu/U332/A2'. (NDMUI-103)
```

check_rp_constraints

Checks relative placement constraints of the specified relative placement groups and reports possible issues, which could lead to critical or non-critical failure.

SYNTAX

collection **check_rp_constraints**
[*rp_group_list*]
[-verbose]
[-*analyze_placement*]
[-region { {llx lly} {urx ury} }]
[-trials number_of_trials]
[-no_pdc]
[-no_adv]
[-threshold threshold]
[-no_rp_constraints]

Data Types

rp_group_list collection
llx float
lly float
urx float
ury float
number_of_trials integer
threshold float

ARGUMENTS

rp_group_list

Specifies the relative placement groups that will be checked. If no any input is provided then all relative placement groups will be checked.

-verbose

Specifies to report exact location of the failures in relative placement group.

-analyze_placement

Specifies that placement analysis will be performed on the relative placement groups. When this option is specified, the other relative placement constraints will not be checked.

-region { {llx lly} {urx ury} }

Specifies the boundary of the region where placement analysis is to be performed. A relative placement group will be considered legal for the sites in this region only if it is placed completely within the region. For an anchored relative placement group, this option will be ignored. This option can be used only along with *-analyze_placement* option.

-trials number_of_trials

Specifies the number of random sites where the placement of relative placement group will be checked. The default value is 100. A value of 0 will force the placement analysis to be performed on all compatible sites. This option can be used only along with *-analyze_placement* option.

-no_pdc

Specifies that no PDC checks are to be performed while doing placement analysis. This option can be used only along with *-analyze_placement* option.

-no_adv

Specifies that no advance rule checks are to be performed while doing placement analysis. This option can be used only along with *-analyze_placement* option.

-threshold threshold

Specifies the threshold pass rate. Relative placement groups with pass rate below the specified threshold value will be reported. This option can be used only along with *-analyze_placement* option.

-no_rp_constraints

When this option is specified, tool will only check if the relative placement group has been successfully placed. The relative placement constraints such as row alignment, column alignment, utilization will not be checked. This option can be used only along with *-analyze_placement* option.

DESCRIPTION

The **check_rp_constraints** command checks relative placement constraints of the specified relative placement groups for possible issues, which could lead to critical or non-critical failures.

The command returns a collection containing the relative placement groups having possible constraint failures. If no constraint failures are seen then an empty string is returned.

When *-analyze_placement* option is provided, the placement analysis of the specified relative placement groups will be performed. For each relative placement group, placement analysis will be done at the random free sites chosen from specified region. For an anchored relative placement group, the placement analysis would be done only at the specified anchor location. The pass rate for a relative placement group is defined as the number of sites at which it could be placed successfully divided by number of free sites at which placement analysis was tried. By default pass rate for all groups is reported, but user could specify threshold to report groups for which pass rate is below threshold. The command returns the collection of reported relative placement groups.

EXAMPLES

The following examples use **check_rp_constraints** to report constraint failures:

prompt> **check_rp_constraints rp_volt1**

```
****************************************************************************
Report : Relative Placement Summary
Total number of specified top level relative placement groups: 1
Total number of relative placement groups which may not honor its constraints: 1
****************************************************************************
RP Group: rp_volt1
----------------------------------------------------------------------------
Warning: The height of relative placement group 'rp_volt1' is more than
the height of voltage area or exclusive move bound. (RPGP-018)

{rp_volt1}
```

prompt> **check_rp_constraints rp_volt2 -verbose**

```
****************************************************************************
Report : Relative Placement Summary
Total number of specified top level relative placement groups: 1
Total number of relative placement groups which may not honor its constraints: 1
****************************************************************************
RP Group: rp_volt2
----------------------------------------------------------------------------
Warning: The bounding box of the anchored relative placement
group 'rp_volt2' is going outside the voltage area or exclusive move bound.
(RPGP-020)
----------------------------------------------------------------------------
Object Type                    Name
----------------------------------------------------------------------------
Exclusive Move Bound                ex_mv_bound1
Voltage Area                   volt1
----------------------------------------------------------------------------

{rp_volt2}
```

The following examples use **check_rp_constraints** to perform placement analysis:

prompt> **check_rp_constraints rp_top_all -analyze_placement**

```
****************************************************************

check_sadp_tracks

Checks the tracks in the design based on self-aligned double patterning (SADP) track rules.

SYNTAX

status **check_sadp_tracks**

ARGUMENTS

The **check_sadp_tracks** command takes no arguments.

DESCRIPTION

This command checks the self-aligned double patterning (SADP) tracks in the current block. The command checks for conflicts within each SADP track set and between different SADP tracks:

- Two tracks should not overlap exactly.
- Spacing between adjacent tracks must be sufficient to ensure SADP rule compliance.

EXAMPLES

The following example checks the SADP tracks in the current block.

```
prompt> check_sadp_tracks
Total Errors = 0
```

SEE ALSO

create_sadp_track_rule(2)
generate_sadp_tracks(2)
remove_sadp_track_rule(2)
report_sadp_track_rule(2)

check_safety_intent

Command for detecting whether the design contains certain types of functional safety intent.

SYNTAX

string **check_safety_intent**
[-verbose]

ARGUMENTS

-verbose

If -verbose is specified, the detected type(s) of functional safety intent is reported.

DESCRIPTION

The command **check_safety_intent** tells whether any functional safety intent (i.e. safety_register_rules, safety_register_groups, repelling_group_bounds) is defined in the current block. When the current block contains such functional safety intent, the returned value is "1". If no such intent is found, the returned value is "0".

This command might be useful when you wish to provide a unified flow-script for both designs with functional safety intent as well as designs without it.

EXAMPLES

The following is an example of the textual report generated by **check_safety_intent -verbose**:

```
prompt> check_safety_intent

Information: Block ChipTop contains FuSa intent (repelling group bounds). (SR-009)
1
prompt>
```

SEE ALSO

report_safety_status
report_safety_register_rules
report_safety_register_groups

check_scan_chain

Allows scan chain structural consistency checking based on the scan chain information stored in the current design.

SYNTAX

status **check_scan_chain**
  [-chain_name *chain_name*]

Data Types

chain_name string

ARGUMENTS

-chain_name *chain_name*

Displays detailed information about the structural checking of the specified scan chain, including location of inconsistency.

DESCRIPTION

This command performs a scan chain structural checking based on the scan chain information stored in the current CEL. If the scan chain passes all the structural checks, then the scan chain status is "VALIDATED"/V and the chain can be physically design-for-test (DFT) optimized. If the scan chain fails the structural checks then the scan chain status is "FAILED"/F and the chain cannot be physically optimized.

By default, the command generates a summary report. To generate a detailed report for a specific scan chain, use the **-chain_name** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example checks for scan chain structural consistency.

```
prompt> check_scan_chain
****************************************
```

```
Report : SCANDEF check
...

****************************************
 Checking between SCANDEF file and design:

check_script

Statically check a script using the a static Tcl syntax checker based on TclPro Procheck and the Synopsys checking extensions for this tool.

SYNTAX

string **snpsTclPro::check_script** [-no_tclchecker_warning]
[-quiet]
[-onepass]
[-verbose]
[-suppress *messageID*]
[-application *appName*]
[-W1]
[-W2]
[-W3]
[-Wall]
filePattern

string *messageID*
string *appName*
string *filePattern*

ARGUMENTS

-no_tclchecker_warning

Don't warn that TclDevKit cannot be found

-quiet

prints minimal error information

-onepass

perform a single pass without checking proc args

-verbose

prints summary information

-suppress *messageIDs*

prevent given messageIDs from being printed

-application *appName*

Check script against application other than this one

-W1

print only error messages

-W2

print only error and usage warnings

-W3

print all errors and warnings

-Wall

print all types of messages (same as W3)

filePattern

file(s) to be checked

USING THE PACKAGE

The **check_script** command is in the snpsTclPro Tcl package, and all of the commands in this package are defined in the namespace snpsTclPro. The way to use this command is to load the package, which will import the commands it exports into the global namespace. This is shown below.

```
shell> package require snpsTclPro
1.0
```

These commands can be added to the .synopsys setup file for the system, user, or current directory, or the commands can be typed when the package is needed.

DESCRIPTION

The **check_script** command simplifies running the TclDevKit tclchecker program. This application is available for purchase from ActiveState (http://www.activestate.com). If the TclDevKit is not available then there is a limited Synopsys Tcl syntax checker that is used by this command. The Synopsys version of this code does not understand Tcl8.4 constructs, and some other checking is limited.

These checkers will check builtin Tcl commands, as well as the Synopsys extension commands which are found in the script. **check_script** will locate the Synopsys checking extensions for the application and will then invoke the checker. The limited checker does not require any external license. It is part of the Synopsys installation.

The **check_script** command will raise a Tcl error if the checker detects errors in the scripts being checked.

The **check_script** command is provided as a convenience to streamline the use of the syntax checker within Synopsys applications. The checker can also be called directly on scripts, without requiring a license for the Synopsys application whose script is being checked. This checker script is available in the auxx/tcllib/bin/check_script in the installation directory of your application. When run standalone the -application option must be specified.

Synopsys Checker Extensions

The Synopsys extensions to the TclPro checker define a number of new warnings and errors. These messages are listed below, along with a short explanation of them.

Error **MisVal**
An option to a command which requires a value is missing its value.

Error **MisReq**
A required option or argument was not specified.

Error **Excl**
Two options which are mutually exclusive were both specified.

Error **ExtraPos**
An extra positional argument was specified to a command.

Error **BadRange**
The value specified for a given argument was outside of the legal range.

Error **UnkCmd**
The command specified is not known by the application.

Error **UnkOpt**
The specified option is not legal for the command.

Error **AmbOpt**
The option specified is not complete and matches 2 or more options for the command.

Warning **NotLit**
This warning indicates that the argument specified to an option was not a literal and therefore could not be checked. This message is suppressed by default. It can be enabled by setting the environment variable SNPS_TCL_NOLITERALWAN to true.

Warning **DupIgn**
An option was specified multiple times to the command, and the first value specified will be the one used. The other values will be ignored.

Warning **DupOver**
An option was specified multiple times to the command, and the last value specified will be the one used. The other values will be ignored.

EXAMPLES

```
shell> check_script myscript.tcl

Loading snps_tcl.pcx...
Loading coreConsultant.pcx...
scanning: /u/user1/myscript.tcl
checking: /u/user1/myscript.tcl
test.tcl:3 (warnVarRef) variable reference used where variable name expected
set $a $b
    ^
test.tcl:5 (SnpsE-MisReq) Missing required positional options for foreach_in_collection: body
foreach_in_collection x {
}
^
test.tcl:9 (SnpsE-BadRange) Value -1 for 'index_collection index' must be >= 0
```

```
index_collection $a -1
child process exited abnormally
Error: Errors found in script.
      Use error_info for more info. (CMD-013)

shell> check_script -Wall anotherScript.tcl

Loading snps_tcl.pcx...
scanning: /u/user1/anotherScript.tcl
checking: /u/user1/anotherScript.tcl
```

CAVEATS

The Synopsys extension messages cannot be suppressed.

Aliases and abbreviated commands will be flagged as undefined procedures.

namespace(2)

check_shapes

Checks and reports all the shapes which meet specified condition in the current block.

SYNTAX

status **check_shapes**
[-uncolored]

ARGUMENTS

-uncolored

Checks and reports uncolored shapes in the current block. A summary of the total count of uncolored shapes found will be printed.

DESCRIPTION

Checks and reports all the shapes which meet specified condition in the current block, the shapes are not only layer shapes but also via shapes.

EXAMPLES

The following example checks and reports uncolored shapes in the current block.

```
prompt> check_shapes -uncolored
****************************************

SEE ALSO

check_starrc_in_design

validates a configuration file for running In-Design signoff extraction with the StarRC tool.

SYNTAX

status **check_starrc_in_design**
-effort *low* | *medium* | *high*

Data Types

effort string

ARGUMENTS

-effort *low* | *medium* | *high*

- **low**(the default) - to check the settings specified in the config file in set_starrc_in_design for config file path, starrc image path, layer mapping file path, corner mapping, version checks.
- **medium** - to create StarRC command file in Check_StarRC_DesignName sub-directory for users to review or run standalone StarRC, in addition to low effort check.
- **high** - to run StarRC with the generated command file and put the StarRC data in the Check_StarRC_DesignName sub-directory for users to check, in addition to medium effort check.

DESCRIPTION

This command validate the configuration file or run StarRC by using the derived command file with three levels of the validation efforts.

SEE ALSO

set_starrc_in_design(2)
report_starrc_in_design(2)

check_supply_equivalence

Check the supply nets are equivalent.

SYNTAX

status **check_supply_equivalence**
supply_nets
[-functional]
[-pst]
[-verbose]

Data Types

supply_nets list

ARGUMENTS

supply_nets

Specifies the supply nets to be checked. The command fails if the number of supply nets are less than two.

-functional

Specifies that the check is based on functional equivalence. If this options is not specified, the check is based on electrical equivalence by default. This option is mutually exclusive with **-pst** option.

-pst

Specifies that the check is based on PST-equivalence. If this options is not specified, the check is based on electrical equivalence by default. This option is mutually exclusive with **-functional** option.

-verbose

Shows the groups of equivalent supply nets.

DESCRIPTION

The **check_supply_equivalence** command checks whether the specified supply nets are equivalent or not. This command returns 1 if the supply nets are equivalent, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example compares two supply nets that are not electrically equivalent.

```
prompt> check_supply_equivalence {vdda vddb}
 0
```

The following example compares two supply nets that are functional equivalent.

```
prompt> check_supply_equivalence {vdda vddb} -functional
 1
```

The following example compares two supply nets that are pst-equivalent.

```
prompt> check_supply_equivalence {vdda vddb} -pst
 1
```

The following example compares supply nets that are not equivalent and shows the groups of equivalent supply nets.

```
prompt> check_supply_equivalence {vdd1 vdd2 U0/vdd1} -verbose
Information: List of supplies grouped by equivalence - {vdd1 U0/vdd1} {vdd2}. (UPF-183)
 0
```

check_targeted_boundary_cells

Checks placement violations of the boundary cells around target objects in the current design.

SYNTAX

status **check_targeted_boundary_cells**
-target_objects {*target_objects*}
[-include_touching_placement_blockages]
[-error_view *view_name*]

Data Types

target_objects	list
view_name	string

ARGUMENTS

-target_objects {*target_objects*}

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified. This option is a required option.

-include_touching_placement_blockages

Specifies that placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

-error_view *view_name*

Specifies the name of the generated error view. Error view data is saved to a file in XML format with the specified name. No attachment is created nor saved into the design database. If the view_name file already exists under current directory, the file will be overwritten. The file extension must be specified as ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name.

DESCRIPTION

This command checks placement violations of boundary cells around target objects according to the boundary cell rules set by *set_boundary_cell_rules*. The violations can be classified as:

1. Continuity Violation:

For this rule, all the boundary cells should be a complete circuit. If no, there will be a violation. If user only insert boundary cells

along all the left and right edges, the boundary cells should cover all the left and right edges. If no, there will be a violation.

2. Corner And Boundary Cell Violation:

This rule requires that all the corner and boundary cells are at the correct location.

3. Orientation Violation:

This rule requires that all the corner and boundary cells are at the correct orientation.

4. Short Edge And Segment Violation:

This rule requires that the length of each horizontal edge of every macro (including hard keepout margin), hard placement blockage, voltage area (including guard band) must be greater than the threshold specified by the option *-min_horizontal_jog*. If not, there will be a violation. This rule also requires that the length of each segment must be greater than the threshold specified by the option *-min_row_width*. If not, there will be a violation.

This command does not check if there is no_1x violation and does not honor the following 4 options of the **set_boundary_cell_rules** command:

-tap_distance

-prefix

-separator

-do_not_swap_top_and_bottom_inside_corner_cell

EXAMPLES

The following example checks for continuity violations, correct corner and boundary cell violations or correct orientation violation in current targeted boundary cells placement.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \
        -right_boundary_cell myLib/CellRight \
        -top_boundary_cells myLib/CellTop \
        -bottom_boundary_cells myLib/CellBottom
prompt> check_targeted_boundary_cells -target_objects {PB_7 PB_8}
```

SEE ALSO

check_boundary_cells(2)

compile_targeted_boundary_cells(2)
remove_boundary_cell_rules(2)
report_boundary_cell_rules(2)
set_boundary_cell_rules(2)

check_tcd_cells

Checks TCD cell placement in the current design and writes out results to the Error Browser.

SYNTAX

status **check_tcd_cells**
-lib_cells *lib_cells*
-window_size *{width height}*
-window_step *{x y}*
[-include_small_windows]

Data Types

lib_cells list of lib cells
width float
height float
x float
y float

ARGUMENTS

-lib_cells *lib_cells*

Specifies the TCD library cells.

-window_size *{width height}*

Specifies the window size width and height.

-window_step *{x y}*

Specifies the x- and y-increment for the next window.

-include_small_windows

Includes small windows at the last row and column for TCD checking. By default, the command excludes small windows.

DESCRIPTION

This command checks if TCD cells exists in each window. You can use the Error Browser to check the results. Each window is the size specified by the **-window_size** option. The first window starts at the lower-left corner of the core. The next window moves both horizontally and vertically by the step specified by the **-window_step** option. If the window step is smaller than the window size,

there will be overlaps between adjacent windows. Overlaps ensure that there is a TCD cell within the window size area.

For example, if the core bounding box has corners at (0,0) and (100,100), the window size is (50,50), the window step is (25,25), and the **-include_small_windows** option is specified, there will be a total of 16 windows as follows:

(0,0) - (50,50)
(25,0) - (75,50)
(50,0) - (100,50)
(75,0) - (100,50)
(0,25) - (50,75)
(25,25) - (75,75)
(50,25) - (100,75)
(75,25) - (100,75)
(0,50) - (50,100)
(25,50) - (75,100)
(50,50) - (100,100)
(75,50) - (100,100)
(0,75) - (50,100)
(25,75) - (75,100)
(50,75) - (100,100)
(75,75) - (100,100)

EXAMPLES

The following example checks if one TCD cell named DM1 exists in each window of size (50,50) and window step of (25,25), including small windows.

```
prompt> check_tcd_cells -lib_cells { DM1} -window_size {50 50} \
  -window_step {25 25} -include_small_windows
```

create_backend_tcd_cells(2)
create_frontend_tcd_cells(2)

check_timing

Checks for possible timing problems in the current design.

SYNTAX

status **check_timing**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-all]
[-include *check_list*]
[-exclude *check_list*]
[-override_defaults *check_list*]

Data Types

check_list list
mode_list list
corner_list list
scenario_list list

ARGUMENTS

-modes *mode_list*

Specifies the modes for which to do the timing checks. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is checked separately. If this option is not given, the command does checks for every scenario that is active with the specified corner(s). It is an error to give this option with the **-scenarios** option.

-corners *corner_list*

Specifies the corners for which to do the timing checks. Each active scenario of the modes specified by the **-modes** option and the corners specified by the **-corners** option is checked separately. If this option is not given, the command does checks for every scenario that is active with the specified mode(s). It is an error to give this option with the **-scenarios** option.

-scenarios *scenario_list*

Specifies the scenarios for which to do the timing checks. Each of the specified scenarios is checked separately. It is an error to give this option with the **-modes** or the **-corners** options. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command does checks for all active scenarios and all modes of the design.

-include *check_list*

Adds the checks listed in *check_list* to the default checks. It is an error to give this option with the **-all** option.

-exclude *check_list*

Subtracts the checks listed in *check_list* from the default checks.

-override_defaults *check_list*

Overrides the default checks by using the argument specified in *check_list*. It is an error to give this option with the **-all** option. The options **-include**, **-exclude** and **-override_defaults** can be used together, the precedence is **-exclude > -include > -override_defaults**.

-all

Performs all the checks listed in the following *check_list*. It is an error to give this option with the **-include** or the **-override_defaults** option.

check_list

Specifies the list of checks to be performed. Each element in this list is one of the following strings:

- clock_crossing
- data_check
- gated_clock
- generated_clock
- loops
- multiple_clock
- no_clock
- no_input_delay
- unconstrained_endpoints

DESCRIPTION

This command checks the timing attributes placed on the current design and issues warning messages as needed. The messages provide information that identifies and corrects potential errors. The warnings do not necessarily indicate design problems.

This command performs the default checks when no options are specified:

- gated_clock
- generated_clock
- loops
- no_clock
- no_input_delay
- unconstrained_endpoints

The alphabetically ordered list below shows the meaning of each check:

clock_crossing

Checks clock interactions when there are multiple clock domains. If a clock launches one or more paths that are captured by

other clocks, it will have an entry in the clock crossing report.

- If the two clocks are exclusive or asynchronous clocks, the path is marked with an asterisk (*).
- If the two clocks are set false path (**set_false_path** from clk1 to clk2), the path is marked with a pound sign (#).
- If all the paths between the two clocks are set as false paths, the path is not reported.

data_check

Warns if no clocked signal or multiple clocked signals reach a data check register reference pin. The analysis is done separately for each of the clocked domains.

gated_clock

Warns if the gated clock doesn't reach any register CP pin. The check only performs for ICG cells.

generated_clock

Checks the generated clock network. Five types of issues are reported:

- The definition point of the generated clock has no path to the source point.
- The generated clocks form a loop.
- The specified edge mismatch
- The generated clock is unexpanded
- The generated clock without clock period.

loops

Warns of combinational feedback loops. If the feedback loop is not broken by the **set_disable_timing** command, it is automatically broken by disabling one or more timing arcs.

multiple_clock

Issues a info when multiple clocks reach a register clock pin.

no_clock

Warns if no clock reaches a register clock pin. In this case, no setup or hold checks are performed on data pins related to that clock pin, and the path starting at the clock pin is not relative to a clock.

no_input_delay

Warns if no clock-related delay is specified on an input port, where it propagates to a clocked latch or output port.

unconstrained_endpoints

Warns about unconstrained timing endpoints. This warning identifies the reason of the unconstrained endpoints:

USAGE

There are two ways to run the **check_timing** command:

1. Use the **check_timing** command directly.

   ```
   prompt> check_timing
   Warning: The endpoint 'out1' is unconstrained by the reason of 'false path'.(TCK-001)
   ```

2. Use in the **check_design** flow.

The **check_timing** command is integrated into the **check_design** command as "timing" checks. In the **check_design** flow, all the messages are organized by EMS.

```
prompt> check_design -checks timing
```

This command triggers the **check_timing** command in the **check_design** flow and stores all the messages to the EMS database.

You can redefine the **check_design** checks by using the **create_check_design_strategy** command. For example, to redefine the **timing** check so that it runs the **check_timing** command with the **-include** option, use the following commands:

```
prompt> create_check_design_strategy \
  -define_check timing {check_timing -include {xx}}
prompt> check_design -checks timing
```

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following example does default checks without any options:

```
prompt> check_timing
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
Warning: A loop 'u4/A u4/Z u3/A u3/Z' is detected, the arc 'u3/A to u3/Z'
  is disabled to break the loop. (TCK-011)
```

The following example adds the clock_crossing check:

```
prompt> check_timing -include {clock_crossing}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
Warning: The register launch clock 'clk1' and capture clock 'clk3'
  are from different domains. (TCK-010)
Warning: A loop 'u4/A u4/Z u3/A u3/Z' is detected, the arc 'u3/A to u3/Z'
  is disabled to break the loop. (TCK-011)
```

The following example removes the loops check:

```
prompt> check_timing -exclude {loops}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
```

The following example adds the clock_crossing check and removes the loops check:

```
prompt> check_timing -include {clock_crossing} -exclude {loops}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
```

```
Warning: The register launch clock 'clk1' and capture clock 'clk3' are
  from different domains. (TCK-010)
```

The following example only does the **unconstrained_endpoints** check:

```
prompt> check_timing -override_defaults {unconstrained_endpoints}
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
```

check_topology_plans

Checks one or more topology plans during different stages of implementation. This command performs a sanity check on base topology plans or checks the quality of results after the topology plan is optimized.

SYNTAX

string **check_topology_plans**
[-filename *file_name*]
[-error_view *view_name*]
[-mode *check_mode*]
plan_list

Data Types

file_name string
view_name string
check_mode string
plan_list list

ARGUMENTS

plan_list

Specifies the topology plans to check. By default, checking is performed on all topology plans in the design.

-filename *file_name*

Writes out the check results to the specified file name. By default, the command writes the check results to the console.

-error_view *view_name*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it will be ignored. If no extension is specified, the command appends ".err" to the specified filename.

-mode *check_mode*

Specifies the mode of the check. The following modes are supported:

pre_optimization : Performs a sanity check of the topology plans before optimization

post_optimization : Checks the quality of the topology plan optimization results

pre_implementation : Performs a sanity check of the topology plans before implementation

post_implementation : Checks the quality of the topology plan implementation results

EXAMPLES

The following example checks the current topology plan after performing optimization with the **optimize_topology_plans** command.

```
prompt> check_topology_plans -mode post_optimization [current_topology_plan]
No violation has been found.
```

SEE ALSO

characterize_topology_plans(2)

check_vclp_design

Used to invoke and perform verification using VC LP.

SYNTAX

status **check_vclp_design**
[-golden_upf_files]
[-write_verilog_options]
[-save_upf_options]

Data Types

-golden_upf_files string
-write_verilog_options string
-save_upf_options string

ARGUMENTS

-golden_upf_files

If FC/ICC2 has Golden UPF Mode enabled, VC LP can be invoked only in Golden UPF Mode and this command option is mandatory. This option can take a list of one or more Golden upf file paths. The file paths must be enclosed in "". The supplemental UPF along with the name map file will be automatically written out by check_vclp_design and VCLP will be run in golden UPF mode.

-write_verilog_options

This option is used to specify additional command options to the write_verilog command that will be invoked under the hood in check_vclp_design.

-save_upf_options

This option is used to specify additional command options to the save_upf command that will be invoked under the hood in check_vclp_design.

DESCRIPTION

The **check_vclp_design** command is used to invoke VCLP from within ICC2/Fusion Compiler and perform verification using VCLP. The VC_STATIC_HOME environment variable must be set, prior to the invocation of this command. To read the design and perform the checks, VCLP sources a template file whose parameters are set up by **check_vclp_design**. Unless users specifically set up the template file by setting the environment variable ICC2_VCLP_TEMPLATE, the template file used by VCLP will be sourced based on

the VC_STATIC_HOME setting. The default template is sufficient for most users.

Following is a list of actions the **check_vclp_design** command performs:

- Opens up VCLP (vc_static_shell) from inside ICC2/Fusion Compiler.
- Performs all the initializations needed for VCLP including setting up the required parameters for VCLP Template file.
- Detects the reference libraries used in the ICC2/Fusion Compiler Run (.nlib files) and extracts the path for the corresponding .db files from the .nlib files and feeds the .db files to VCLP
- Invocation of this command triggers a full run of VCLP. (Verilog netlist and UPF are written out internally and passed as input to VCLP)
- Keeps a communication channel open with VCLP so that users can interact with VCLP with other commands such as **vclp_exec_cmd** or **vclp_zoom_highlight**.

The default write_verilog/save_upf written out internally by check_vclp_design is as below: save_upf -exclude {corner_cells cover_cells end_cap_cells filler_cells pad_spacer_cells physical_only_cells} write_verilog -exclude {leaf_module_declarations corner_cells cover_cells end_cap_cells filler_cells pad_spacer_cells physical_only_cells} -hierarchy all

For designs with block abstracts, ETM, Budget shell, Blackboxes; users will need to edit the template file and point to the new template file with the ICC2_VCLP_TEMPLATE environment variable.

The -golden_upf_files option is mandatory when Golden UPF Mode is enabled. The -write_verilog_options and -save_upf_options command options can only be used in combination and not separately.

SEE ALSO

check_mv_design(2)
vclp_exec_cmd(2)

clock_opt

Synthesize and route the clocks in the current design and then further optimize the design based on the propagated clock latencies.

SYNTAX

status **clock_opt**
[-list_only]
[-from build_clock | route_clock | final_opto | global_route_opt]
[-to build_clock | route_clock | final_opto | global_route_opt]

ARGUMENTS

-list_only

This switch prints out the major stages that constitute the default flow for clock_opt. These stages are: (i) build_clock, (ii) route_clock, (iii) final_opto. Note that the "-list_only" switch cannot be combined with either of the "-from" or "-to" switches.

-from build_clock | **route_clock** | **final_opto**

Specifies either build_clock, route_clock or final_opto as the first stage of the **clock_opt** command.

By default, the flow begins with the build_clock stage if the **-from** option is not specified.

-to build_clock | **route_clock** | **final_opto**

Specifies either build_clock, route_clock or final_opto as the last stage of the **clock_opt** command.

By default, the flow ends with the final_opto stage if the **-to** switch is not specified.

DESCRIPTION

The default behavior of this command is as follows:

(1) Synthesizes and optimizes the clock trees.

(2) Completes the detailed routing of the clock trees.

(3) Further optimizes the design for timing,electrical DRC violations, area, power, and routability, based on actual propagated clock latencies, and legalizes the design placement at the end.

If GR based optimization has been enabled, the clock_opt command will additionally do global_routing, followed by GR-based optimization, and the output will be a design with fully updated global routes and timing based on global routes. Whenever GR based optimization has been run within clock_opt, the subsequent signal routing flow will automatically skip global routing.

If final_opto step is executed after global_route_opt step, it will remove routes before continuing with final_opto step.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example synthesizes, optimizes and routes the clock trees in the current design, followed by further circuit optimization on the design and ends up with an optimized design with a legalized placement:

```
prompt> clock_opt
```

The following example takes in a placed design with synthesized clock trees as its input and first routes the clock trees, then optimizes the circuits in the design for timing, electrical DRC violations, power, area, and routability, and ends up with an optimized design with a legalized placement:

```
prompt> clock_opt -from route_clock -to final_opto
```

The following example takes in a design which has already been run through the clock_opt flow up through the final_opto stage and runs just the global route (GR) based optimization stage (subject to being enabled via the clock_opt.flow.enable_global_route_opt app_option) . The output is a design with global routes and timing based on the global routes.

```
prompt> clock_opt -from global_route_opt
```

clone_macro_group_packing

Clone macro group packing.

SYNTAX

status **clone_macro_group_packing**
-source source_macro_group
-destinations list_of_macro_groups

Data Types

list_of_macro_groups collection of macro groups

ARGUMENTS

-source source_macro_group

Specifies source macro group.

-destinations list_of_macro_groups

Specifies destinaiton macro groups.

DESCRIPTION

This command copis macro grouping packing from source macro group to destination macro groups. The command will go over each macro group specified in the destination macro groups and use following steps to copy it to a destination macro group.

\n+[step]. If the number of macros of source macro group and destination macro group are not the same, it will not copy the packing from source to desitination and skip it.
\n+[step]. Sorting macros of source macro group and destinaiton macro group based on macro names. Each macro in the source macro list corresponds to the macro of destinaiton macro list at the same location in the list.
\n+[step]. Comparing corresponding macros from these two macro list one by one. If any two macros have different size, the packing cannot be copied and the the destination group is skipped.
\n+[step]. Copy the contour of source macro group to detination macro group in an approriate location.
\n+[step]. Copy location of macro in source macro group to its corresponding macro in the destination macro group. These two macros will have same

relative locations to their contours.

EXAMPLES

The following command copy packing of macro group G1 to destination G2 and G3.

prompt> **clone_macro_group_packings** -source G1 -destination {G2 G3}

clone_macro_group_packing(2)
get_macro_group_packing_clone_candidates(2)

close_blocks

Closes one or more opened block, releasing them from memory when it is no longer used.

SYNTAX

status **close_blocks**
[-save]
[-force]
[-purge]
[*blocks*]

Data Types

blocks collection

ARGUMENTS

-save

This option is used to save the block before closing it (if necessary). This will prevent a failure in the event a close would cause a purge and the block has been modified but not saved.

-force

This option is used to force the block to be closed regardless of whether or not it has been saved. It can be used instead of the **-save** option to force the close but without affecting a save for an open and modified block.

-purge

This option is used to force block from memory, regardless of how many times it has been opened. This seems unsafe but is not since all applications note when blocks are removed from memory. It can be somewhat drastic, so it should be used with care.

blocks

A block name with optional library, label, and view specifications, or a collection of blocks. If the library specification is not present, the **current_lib** is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then *design view* is used. If the option is not given, the **current_block** is used.

DESCRIPTION

This command decrements and open block's open count and removes one or more block from memory when the reference count drops to 0 (or if the **-purge** option is used). It will fail if the block has been modified but not yet saved, and reference count would

drop to 0 causing the block to be removed from memory, and the **-save** or **-force** option are not used. In the case where the **-save** option is used, the block is saved (only if necessary) before the reference count is decremented. If the **-force** option is used, the command proceeds regardless of the modify status. Please use this option carefully as it is possible to lose data. The **-purge** option is used to force a removal of the block from memory, regardless of its reference count. It will fail if the block has been modified but not yet saved, unless the **-save** or **-force** option is used also.

This command returns the number of blocks removed and 0 if not. If an illegal name(with a slash) is given for the block, a TCL error is raised.

EXAMPLES

This example closes the current block.

```
prompt> close_blocks
1
```

This example forces closed the block Mid, which is being used in Top. This has two effects. First, the instances in Top of Mid become unbound. Second, the block Bot will also be purged since its reference count is decremented when Mid is closed.

```
prompt> close_blocks Mid
1
```

This example closes the block Top, saving it in the process.

```
prompt> close_blocks -save Top
1
```

This example closes a modified and unsaved block that has been opened twice. The first close_blocks only decrements the reference to 1 but doesn't remove the block from memory yet. The second close_blocks would cause an error because the block hasn't been saved:

```
prompt> create_block Top
{top_lib:Top.design}

prompt> open_block Top
Information: Incrementing open_count of block 'top_lib:Top.design' to 2.
{top_lib:Top.design}

prompt> close_blocks Top
Information: Decrementing open_count of block 'top_lib:Top.design' to 1.
1

prompt> close_blocks Top
Error: close_blocks failed. Design 'Top.design' in library 'top_lib' is modified.
```

close_drc_error_data

Closes a physical DRC error data collection.

SYNTAX

status **close_drc_error_data**
drc_error_data
[-save]
[-force]

Data Types

drc_error_data collection

ARGUMENTS

drc_error_data

Specifies the collection of physical DRC error data objects to close.

-save

Saves the pending changes in the exported physical DRC error data before closing the error data file.

This option applies only to external error data files. If the error data file is attached to the current block, use the **save_block** command to save the error data file.

The **-save** and **-force** options, are mutually exclusive; you can specify only one.

-force

Closes the specified collection of physical DRC error data, discarding any unsaved pending changes.

The **-save** and **-force** options, are mutually exclusive; you can specify only one.

DESCRIPTION

The **close_drc_error_data** command decrements the open count of the specified error data collection.

The tool increments the open count for an error data file each time you run the **open_drc_error_data** or **create_drc_error_data** command for the error data file. The tool decrements the open count for an error data file each time you run the **close_drc_error_data** command. The error data collection is removed from memory when the open count reaches zero.

If the error data has unsaved pending changes, the command fails unless you use the **-save** or **-force** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example opens the external physical DRC error data file named my_design_dppinassgn.err, and then closes it.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> close_drc_error_data $data
1
```

close_ems_databases

Closes the EMS databases in memory.

SYNTAX

status **close_ems_databases**
[-save]
[*ems_databases*]

Data Types

ems_databases list

ARGUMENTS

-save

Writes the currently opened EMS databases to disk before closing them. By default, the EMS databases are not written to disk by this command.

ems_databases

List or collection of EMS databases to be closed.

DESCRIPTION

This command closes the current EMS database in memory, if no argument is specified. If a list or collection of EMS databases is provided as an argument, this command closes only the specified EMS databases, if they are open. The **-save** option writes the EMS databases to disk before closing them.

EXAMPLES

The following example closes the current EMS database, if present.

prompt> **close_ems_databases**

The following example writes out the current EMS database to disk, then closes it.

```
prompt> close_ems_databases -save
```

The following example closes all currently opened EMS databases.

```
prompt> close_ems_databases [get_ems_databases]
```

The following example saves and closes all currently opened EMS databases.

```
prompt> close_ems_databases -save [get_ems_databases]
```

SEE ALSO

get_current_ems_database(2)
get_ems_databases(2)
open_ems_database(2)
save_ems_database(2)
set_current_ems_database(2)

close_lib

Decrements the open count of a library. A library is removed from memory when its open count is zero.

SYNTAX

status **close_lib**
[-save_designs]
[-force]
[-purge]
[-all]
[-compress]
[-auto_saved_data keep | clear]
[*library*]

Data Types

library collection

ARGUMENTS

-save_designs

Saves any designs in the design library that are open and modified but not yet saved. If the design library contains a technology section that has been modified, it is also saved.

When you use this option, the modified designs and technology section are saved regardless of whether the design library is removed from memory.

This option is not supported in the library manager.

-compress

To be used with "-save_designs" to save libraries in compressed format. This option is applicable to design library only. It is error to use this option without -save_designs.

-force

Removes the library from memory, even if its technology section or some of its designs have been modified but not saved (and you did not use the **-save_designs** option).

-purge

Removes the library from memory, regardless of its open count.

-all

Removes all libraries from memory, regardless of their open counts.

-auto_saved_data keep | clear

Specifies whether to clear or keep auto_saved data of the library. By default, auto-saved data will be kept.

library

Specifies the library to close. This can either be a name or a collection of a single library.

By default, the command closes the current library.

DESCRIPTION

This command decrements the open count of the specified library. The command closes the library and removes it from memory when at least one of the following conditions is satisfied:

- The open count is zero.
- The **-purge** option is used.
- The **-force** option is used.

If you try to remove a library from memory that is on the reference library list of another open design library, the tool issues an error message and does not remove the library from memory.

In the library manager, you can use this command to remove a library from an aggregate library workspace.

EXAMPLES

The following example removes the current design library from memory after saving saving any open and modified-but-not-saved designs.

```
prompt> close_lib -purge -save_designs
1
```

The following example saves the open and modified-but-not-saved designs in all open design libraries and then removes the design libraries from memory.

```
prompt> close_lib -all -save_designs
1
```

close_rail_result

Closes the current rail result.

SYNTAX

status **close_rail_result**

DESCRIPTION

This command closes the current rail result.

After the rail result is closed, you cannot access any rail analysis result information such as taps, voltage drop attributes, and power attributes.

EXAMPLE

The following example closes the current rail result.

```
prompt> open_rail_result static
prompt> get_attribute [ get_cell U35 ] static_power
1.0876e-06
prompt> close_rail_result
1
```

SEE ALSO

analyze_rail(2)
open_rail_result(2)
report_rail_result(2)

collection_to_list

Format collection contents as a Tcl list or Scheme string

SYNTAX

list **collection_to_list**
[-name_only]
[-no_braces]
[-brace_with_quotes]
[-newline]
[-truncate *elem_count*]
[-no_sort]
-objects *object_list*
obj_spec_list

Data Types

elem_count int
object_list collection
obj_spec_list collection

ARGUMENTS

-name_only

Prints the object names without specifying the object types.

-no_braces

Prints the output list without beginning and closing curly braces.

-brace_with_quotes

Replaces beginning and closing curly braces with quotes.

-newline

Print each object on a new line.

-truncate *elem_count*

Specifies the number of objects to print. The rest of the elements are truncated.

-no_sort

Does not sort the output data.

-objects *object_list*

Specifies the objects to format as a Tcl list.

This option is mutually exclusive with the *obj_spec_list* argument; you must specify either this option or the *obj_spec_list* argument.

obj_spec_list

Specifies the objects to format as a Tcl list.

This option is mutually exclusive with the **-objects** option; you must specify either this argument or the **-objects** option.

DESCRIPTION

The **collection_to_list** command prints a formatted Tcl list that corresponds to the collection provided as input. The Tcl list is sorted based on the object type and name (or only on the object name if you use the **-name_only** option). To output the list without sorting, use the **-no_sort** option.

EXAMPLES

The following example prints the Tcl list that corresponds to the collection passed as input.

```
prompt> collection_to_list [get_pins]
{{pin FF0/CLK} {pin FF0/D} {pin FF0/Q} {pin FF1/CLK} {pin FF1/D}
{pin FF1/Q} {pin SUB/A[0]} {pin SUB/A[1]} {pin U1/A} {pin U1/Y}}
```

The following example prints the object name only (without the object type) as a Tcl list.

```
prompt> collection_to_list [get_pins] -name_only
{FF0/CLK FF0/D FF0/Q FF1/CLK FF1/D FF1/Q {SUB/A[0]} {SUB/A[1]} U1/A U1/Y}
```

The follow example prints the Tcl list without beginning and ending curly braces.

```
prompt> collection_to_list [get_pins] -name_only -no_braces
FF0/CLK FF0/D FF0/Q FF1/CLK FF1/D FF1/Q {SUB/A[0]} {SUB/A[1]} U1/A U1/Y
```

The follow example prints each object on a new line.

```
prompt> collection_to_list [get_pins] -newline
{{pin FF0/CLK}
{pin FF0/D}
{pin FF0/Q}
{pin FF1/CLK}
{pin FF1/D}
{pin FF1/Q}
{pin SUB/A[0]}
{pin SUB/A[1]}
{pin U1/A}
{pin U1/Y}}
```

The follow example prints the first five objects with each object on a new line.

```
prompt> collection_to_list [get_pins] -newline -truncate 5
{{pin FF0/CLK}
{pin FF0/D}
{pin FF0/Q}
{pin FF1/CLK}
{pin FF1/D}}
```

collections

Describes the methodology for creating collections of objects and querying objects in the database.

DESCRIPTION

Synopsys applications build an internal database of objects and attributes applied to them. These databases consist of several classes of objects, including designs, libraries, ports, cells, nets, pins, clocks, and so on. Most commands operate on these objects.

By definition:

A collection is a group of objects exported to the Tcl user interface.

Collections have an internal representation (the objects) and, sometimes, a string representation. The string representation is generally used only for error messages.

Collections represent an ordered sequence of database objects. These collections provide constant time random access to the objects contained in the sequence.

A set of commands to create and manipulate collections is provided as an integral part of the user interface. The collection commands encompass two categories: those that create collections of objects for use by another command, and one that queries objects for viewing. The result of a command that creates a collection is a Tcl object that can be passed along to another command. For a query command, although the visible output looks like a list of objects (a list of object names is displayed), the result is an empty string.

An empty string "" is equivalent to the empty collection, that is, a collection with zero elements.

To illustrate the usage of the common collection commands, the man pages have examples. Most of the examples use PrimeTime as the application. In all cases, the application from which the example is derived is indicated.

Homogeneous and Heterogeneous Collections

A homogeneous collection contains only one type of object. A heterogeneous collection can contain more than one type of object. Commands that accept collections as arguments can accept either type of collection.

Lifetime of a Collection

Collections are active only as long as they are referenced. Typically, a collection is referenced when a variable is set to the result of a command that creates it or when it is passed as an argument to a command or a procedure. For example, in PrimeTime, you can save a collection of design ports by setting a variable to the result of the **get_ports** command:

```
pt_shell> set ports [get_ports *]
```

Next, either of the following two commands deletes the collection referenced by the *ports* variable:

```
pt_shell> unset ports
pt_shell> set ports "value"
```

Collections can be implicitly deleted when they go out of scope. Collections go out of scope for various reasons. An example would be when the parent (or other antecedent) of the objects within the collection is deleted. For example, if our collection of ports is owned by a design, it is implicitly deleted when the design that owns the ports is deleted. When a collection is implicitly

deleted, the variable that referenced the collection still holds a string representation of the collection. However, this value is useless because the collection is gone, as illustrated in the following PrimeTime example:

```
pt_shell> current_design
{"TOP"}

pt_shell> set ports [get_ports in*]
{"in0", "in1"}

pt_shell> remove_design TOP
Removing design 'TOP'...

pt_shell> query_objects $ports
Error: No such collection '_sel26' (SEL-001)
```

Iteration

To iterate over the objects in a collection, use the **foreach_in_collection** command. You cannot use the Tcl-supplied **foreach** iterator to iterate over the objects in a collection, because the **foreach** command requires a list, and a collection is not a list. In fact, if you use the **foreach** command on a collection, it destroys the collection.

The arguments of the **foreach_in_collection** command are similar to those of foreach: an iterator variable, the collection over which to iterate, and the script to apply at each iteration. Note that unlike the **foreach** command, the **foreach_in_collection** command does not accept a list of iterator variables.

The following example is an iterative way to perform a query in PrimeTime. For more information, see the **foreach_in_collection** man page.

```
pt_shell> \
foreach_in_collection s1 $collection {
  echo [get_object_name $s1]
  }
```

Manipulating Collections

A variety of commands are provided to manipulate collections. In some cases, a particular command might not operate on a collection of a specific type. This is application-specific. Consult the man pages from your application.

- **add_to_collection** - This command creates a new collection by adding a list of element names or collections to a base collection. The base collection can be the empty collection. The result is a new collection. In addition, the **add_to_collection** command allows you to remove duplicate objects from the collection by using the *-unique* option.
- **append_to_collection** - This command appends a set of objects (specified by name or collection) to an existing collection. The base collection is passed in through a variable name, and the base collection is modified directly. It is similar in function to the **add_to_collection** command, except that it modifies the collection in place; therefore, it is much faster than the **add_to_collection** command when appending.
- **remove_from_collection** - This command removes a list of element names or collections from an existing collection. The second argument is the specification of the objects to remove and the first argument is the collection to have them removed from. The result of the command is a new collection. For example, in PrimeTime:

  ```
  pt_shell> set dports \
  [remove_from_collection [all_inputs] CLK]
  {"in1", "in2", "in3"}
  ```

- **compare_collections** - This command verifies that two collections contain the same objects (optionally, in the same order). The result is "0" on success.
- **copy_collection** - This command creates a new collection containing the same objects in the same order as a given

collection. Not all collections can be copied.

- **index_collection** - This command extracts a single object from a collection and creates a new collection containing that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index. Not all collections can be indexed.
- **sizeof_collection** - This command returns the number of objects in a collection.

Filtering

In some applications, you can filter any collection by using the **filter_collection** command. This command takes a base collection and creates a new collection that includes only those objects that match an expression.

Some applications provide a *-filter* option for their commands that create collections. This allows objects to be filtered out before they are ever included in the collection. Frequently this is more efficient than filtering after the they are included in the collection. The following examples from PrimeTime filters out all leaf cells:

```
pt_shell> filter_collection \
[get_cells *] "is_hierarchical == true"]
{"i1", "i2"}
pt_shell> get_cells * -filter "is_hierarchical == true"
{"i1", "i2"}
```

The basic form of a filter expression is a series of relations joined together with AND and OR operators. Parentheses are also supported. The basic relation contrasts an attribute name with a value through a relational operator. In the previous example, *is_hierarchical* is the attribute, *==* is the relational operator, and *true* is the value.

The relational operators are

```
==   Equal
!=   Not equal
>    Greater than
<    Less than
>=   Greater than or equal to
<=   Less than or equal to
=~   Matches pattern
!~   Does not match pattern
```

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only true or false.

Additionally, existence relations determine if an attribute is defined or not defined, for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
```

These operators apply to any attribute as long as it is valid for the object class. See the appropriate man pages for complete details.

Sorting Collections

In some applications, you can sort a collection by using the **sort_collection** command. It takes a base collection and a list of attributes as sort keys. The result is a copy of the base collection sorted by the given keys. Sorting is ascending, by default, or descending when you specify the *-descending* option. In the following example from PrimeTime, the command sorts the ports by direction and then by full name.

```
pt_shell> sort_collection [get_ports *] \
{direction full_name}
{"in1", "in2", "out1", "out2"}
```

Implicit Query of Collections

In many applications, commands that create collections implicitly query the collection when the command is used at the command line. Consider the following examples from PrimeTime:

```
pt_shell> set_input_delay 3.0 [get_ports in*]
1
pt_shell> get_ports in*
{"in0", "in1", "in2"}
pt_shell> query_objects -verbose [get_ports in*]
{"port:in0", "port:in1", "port:in2"}
pt_shell> set iports [get_ports in*]
{"in0", "in1", "in2"}
```

In the first example, the **get_ports** command creates a collection of ports that is passed to the **set_input_delay** command. This collection is not the result of the primary command (**set_input_delay**), and as soon as the primary command completes, the collection is destroyed. The second example shows how a command that creates a collection automatically queries the collection when that command is used as a primary command. The third example shows the verbose feature of the **query_objects** command, which is not available with an implicit query. Finally, the fourth example sets the variable iports to the result of the **get_ports** command. Only in the final example does the collection persist to future commands until iports is overwritten, unset, or goes out of scope.

color_macro_pins

Colors the pins of the macro block using ICV with colored runset.

SYNTAX

status **color_macro_pins**

DESCRIPTION

The **color_macro_pins** command assigns the colors to pins of instantiated macro blocks in hierarchical design having double pattern process layers. The color to a pin is assigned on the basis of track colors, though there may not be 100% alignment possible.

This command invokes the IC Validator tool with a colored runset either on the NDM lib or GDS to assign the colors to pins based on track colors.

This command supports the following inputs - GDS and NDM Lib. There are different app options required to be set based on the given input. In case of GDS input flow, parameters such as technology file, layer map file, track offset, preferred routing direction, rule type, track color preference and others can be specified through app options.

All the app options for this command are specifed under the category of signoff.color_macro.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **color_macro_pins** command on the current block using the TSMC 16nm node colored runset:

```
prompt> set_app_options -name signoff.color_macro.rule_type \
  -value "tsmc16"
prompt> color_macro_pins
```

The following example shows the color attribute, **mask_constraint**, set on the pin shapes:

```
prompt> get_attribute [get_shapes -of_objects [get_port <port-name>]] \
  mask_constraint
```

commit_blackbox_timing

Commits black box timing information specified by **create_blackbox_constraint**, **create_blackbox_delay**, and other black box timing commands.

SYNTAX

status **commit_blackbox_timing**
[-convert_placement_abstract true | false]

ARGUMENTS

-convert_placement_abstract true | false

Converts the placement abstract to a timing abstract with black box timing (BBT) data. Specify **-convert_placement_abstract false** to prevent the command from overwriting an existing placement abstract view. By default, this option is true and the command overwrites the existing abstract view of the design and replaces it with a compact timing abstract view with black box timing.

DESCRIPTION

This command saves the black box timing information you created with the **create_blackbox_constraint**, **create_blackbox_delay**, and other black box timing commands. The command creates or updates the abstract view of the current block to include the black box timing data.

EXAMPLES

The following example creates an abstract view, with black box timing information, for the current design.

```
prompt> create_clock -period 10 -name main_clock [get_ports Clk]
prompt> set_blackbox_clock_port [get_ports Clk]
prompt> create_blackbox_clock_network_delay -value 0.5 [get_ports Clk]
prompt> create_blackbox_load_type -lib_cell buf0 loadType1
prompt> create_blackbox_drive_type -lib_cell buf8 driveType1
prompt> set_blackbox_port_load -type loadType1 [all_inputs]
prompt> set_blackbox_port_drive -type driveType1 [all_outputs]
prompt> create_blackbox_delay -rise_from Clk -to [all_outputs] -clock main_clock -value 0.3
prompt> create_blackbox_constraint -from Clk -edge rise -to [all_inputs] \
```

```
        -clock main_clock -value 0.3
prompt> commit_blackbox_timing
```

commit_block

Creates a separate physical hierarchy design from a logical hierarchical cell.

SYNTAX

collection **commit_block**
[-library *library*]
[-verbose]
modules

Data Types

library string
modules collection

ARGUMENTS

-library *library*

Specifies the library in which to create the new design. By default, the current design library is used.

-verbose

Reports additional debugging information.

modules

Specifies the name of a logic cell to commit into a physical block. You can specify a module name or a collection containing one module object. This option is required.

DESCRIPTION

This command commits a logical hierarchy cell to a physical hierarchy block and returns a collection containing the committed cell.

The shape of the committed block is dependent upon whether cell hierarchy type is "module" or "module boundary". If it is "module", there is no physical boundary by which to determine a physical boundary of a resulting block. In this case, the command will create a default square boundary based upon criteria such as the number of leaf-cells/blocks in the module. Also in this case, the **commit_block** command will not attempt to place member cells within the committed reference block since it has no certain origin by which to place child cells inside the reference block. So in this scenario, the cells in the reference block will be unplaced. Also in this scenario, the instance of the block will be placed outside the top block core boundary.

If the module cell hierarchy type is "module boundary" and you have placed the module boundary in the core area, then the

command has what it needs to create a block boundary, and an origin that it can use to place the cells in the reference block, and will do so. In this scenario, the resulting block instance will be placed based upon the determined origin of the module boundary associated with the module instance. In any case, regardless of where the module boundary is placed, the resulting placement of cells in the committed block will show the exact same geometric relationship to the block origin in the reference block as the member cell instances of the module instance has to the lower left corner of the module boundary before **commit_block**. This is because **commit_blocks** merely transforms the relative locations from the top to the block based upon the cell instance's location relative to the module boundary lower-left corner location.

The **commit_block** command propagates routing, move bounds, relative placement groups and other logical-based elements to the block level during the commit process. All routing associated with module-owned nets is propagated automatically to the block. All move bounds that are enclosed by the module boundary, and whose cells are only those that belong to the module being committed, are propagated to the block. All group bounds whose cell members exclusively belong to the module instance are also propagated automatically to the block. All relative placement groups that are enclosed by the module boundary, and whose cells exclusively belonging to the module being committed, are propagated to the block.

Also as part of the commit process, certain overlap-based propagations occur. This includes placement blockages and route guides that are completely within the module boundary of the module being committed. If there is no module boundary, then placement blockages and route guides are not propagated.

If the module type is "module" (or normal), and the module instance has multiple fixed placed instances, the command auto-derives a bounding box defined by these instances, and creates a block boundary. The boundary is based on the bounding box and the block origin is placed at the lower-left corner of the bounding box, with R0 orientation. If there are multiple instances of this module with fixed placed instances, the command chooses a reference among the fixed-placed child instance of the module instance and creates and places the first block instance as mentioned above.

For each subsequent instance, the fixed-placed reference instance is used to determine the location and orientation the remaining MIB block instances. You must carefully confirm that ALL fixed-placed child instances are exactly consistent with each of the other MIB module instances' child instances. If the instances are not consistent, the results of committing the MIB instances are very unpredictable. The command DOES NOT pre-check that all MIB module instances are consistently placed. You must check the placement consistency before using the **commit_block** command to auto-infer shapes and orientations of MIB committed block instances.

If an instance of the committed block results in placement over any site arrays, copies of these site arrays are created within the block based upon that overlap with top-level site arrays. If there is no overlap (type is "module") with any site array after commit, then a default site array is still created in the block, based upon the top default site array, but this site array is not guaranteed to be aligned with the top site array because the committed block instance does not overlap the top default site array. This is generally not an issue because in this situation, it is normally the case that subsequent flow steps will involve block shaping, which will propagate the default site array after the block has been placed and shaped, and at that point the block-level site array should then be in alignment.

By default, a hard inner keepout margin is created in the committed block. The committed block's default inner keepout is equal to one row height, and its default outer keepout is equal to twice of the minimal wire track width.

Use the following application options to specify how the inner keepout is created:

plan.commit.inner_keepout_margin hard | soft | none

user_unit_distance must include unit # appended to the distance value plan.commit.inner_keepout_margin_size *user_unit_distance*

plan.commit.outer_keepout_margin hard | soft | none

user_unit_distance must include unit # appended to the distance value plan.commit.outer_keepout_margin_size *user_unit_distance*

examples:

set_app_options -list {plan.commit.inner_keepout_margin hard}

set_app_options -list {plan.commit.inner_keepout_margin_size 0.3um}

set_app_options -list {plan.commit.outer_keepout_margin hard}

set_app_options -list {plan.commit.outer_keepout_margin_size 0.1um}

set_app_options -list {plan.commit.inner_keepout_margin none}

set_app_options -list {plan.commit.outer_keepout_margin none}

Note that application option values are persistent in the database.

Note that the **commit_block** command fails under the following conditions:

- The specified library is not the design library or one of the current reference libraries.
- The module does not exist or is not a hierarchical logic cell.
- The library already contains a design with the name of the new design to be created.

EXAMPLES

The following example commits the cells that are instantiated from module A to blocks.

```
prompt> commit_block A
```

commit_secondary_pg_placement_constraints

commit all secondary pg constraints

SYNTAX

status **commit_secondary_pg_placement_constraints**

ARGUMENTS

There is no argument for this command

DESCRIPTION

After all secondary pg constraints are created, users need to issue this command so that the tool can process all the constraints and internally generate the physical regions which will allow dual rail cells to be inserted in.

If the floorplan, UPF, secondary supply straps or secondary pg constraints are changed or removed, users also need to issue this command so that the tool can process all the remain constraints and internally regenerate or remove any special physical regions created due to the prior existed secondary pg constraints.

EXAMPLES

The following example commit all secondary pg constraint

prompt> **commit_secondary_pg_placement_constraints**

SEE ALSO

create_secondary_pg_placement_constraints(2)
remove_secondary_pg_placement_constraints(2)
report_secondary_pg_placement_constraints(2)

commit_upf

Commit the UPF constraints of the design.

SYNTAX

status **commit_upf**
[-skip_resolve_pg_net]

ARGUMENTS

-skip_resolve_pg_net

If specified, the command will not resolve potential conflicts between power intent and pg net connections.

DESCRIPTION

This command commits the UPF intent of the design. It indicates that the UPF constraints of the design are finalized and complete.

By default, the command tries to resolve potential conflicts between the power intent and PG net connections. To disable this behavior, set the **mv.upf.auto_resolve_pg_net** application option to **false**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example commits the UPF intent of the design.

prompt> **commit_upf**

SEE ALSO

load_upf(2)

compare_app_options

Reads and compares application option settings between two tool sessions. Settings data is written to a binary data file by the **write_app_options** command.

SYNTAX

integer **compare_app_options**
-previous_data *data_file*
-current_data *data_file*
[-value_diffs]
[-csv *file_name*]
[-metadata]

Data Types

data_file string
file_name String. Report contents to this file in CSV format.

ARGUMENTS

-previous_data *data_file*

Specifies the file that contains the binary application option settings data. The *data_file* argument can be a local file name or a full path name to the file. The data specified by this option is the previous or original data and is displayed on the left side of the comparison output report.

-current_data *data_file*

Specifies the file that contains the binary application option settings data. The *data_file* argument can be a local file name or a full path name to the file. The data specified by this option is the current or data to be compared against the original and is displayed on the right side of the comparison output report.

-value_diffs

Generate an alternate report which combines all app option value differences into one table.

-csv *file_name*

Specifies the output CSV file name. The report contents will be output to this file in CSV format. The *file_name* argument can be a local file name or a full path name to the file.

-metadata

Add the metadata which includes comment information of compared data to the CSV file.

DESCRIPTION

This command creates a single report with multiple tables reporting these differences for each application option that differs between the two input files:

- Status
- Changes in Default Value
- Changes in Global Value
- Changes in Block Value
- Changes in Global status
- Changes in ReadOnly status
- Changes in Deprecated status
- Changes in Persistent status
- Changes in Disabled status
- Changes in Application Variables

The report will also show Added and Removed application options.

- Added application options are in the current data file, but not in the previous_data file
- Removed application options are in the previous data file, but not in the current_data file

The command writes the report to the console. To save the output to a .csv file, you could run the command as follows:

```
compare_app_options \
   -previous_data file1.data \
   -current_data file2.data \
   -csv compare.csv
```

Use the **compare_app_options** command to generate reports such as:

- Application option differences when block A is loaded vs. block B
- Application option differences between different startup Tcl scripts
- Application option differences between different tool releases

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example generates the binary application option data files for two tool sessions and compares the files.

```
# In the first tool session
prompt> write_app_options -output app_option_SP1.data
```

```
# In the second tool session
prompt> write_app_options -output app_option_SP2.data
prompt> compare_app_options -previous_data app_option_SP1.data \
  -current_data app_option_SP2.data
```

This example writes the binary application option data and shows the differences in application options between design A and design B.

```
# Design A is now the current design
prompt> current_design designA
prompt> write_app_options -output designA.data

# Design B is now the current design
prompt> current_design designB
prompt> write_app_options -output designB.data

# Compare application options
prompt> compare_app_options -previous_data designA.data \
  -current_data designB.data
```

The following example shows a sample report generated by the **compare_app_options** command.

```
prompt> compare_app_options -previous_data old.data \
  -current_data new.data

Opened Previous File: old.data
    Total: 1176

compare_checksum

This utility is for comparing checksums generated by write_checksum.

SYNTAX

status **compare_checksum**
-icc2 *icc2_checksum_path*
-pt *pt_checksum_path*

Data Types

icc2_checksum_path string
pt_checksum_path string

ARGUMENTS

-icc2 ***icc2_checksum_path***

Specifies the directory that contains the IC Compiler II checksums to compare. This option is required.

-pt ***pt_checksum_path***

Specifies the directory that contains the PrimeTime checksums to compare. This option is required.

DESCRIPTION

The **compare_checksum** compares checksums generated by write_checksum of input consistency checker.

The command would run in the background. The output of the command is redirected to

- correlation.out

  The compare checksum reports files will be

  - DesignChecksumSummary.rpt

  - DesignChecksumDetail.rpt
  - LibraryChecksumSummary.rpt
  - LibraryChecksumDetail.rpt
  - ParasiticsChecksumSummary.rpt
  - ParasiticsChecksumDetail.rpt
  - ConstraintsCheckerSummary.rpt

- ConstraintsCheckerDetail.rpt

By default, the **write_checksum** command generates all the checksums in the current directory.

EXAMPLES

The following example generates compare checksum reports in the current directory. The IC Compiler II checksums are in ./icc2/scenario and the PrimeTime checksums are in ./pt.

```
prompt> compare_checksum -icc2 ./icc2/scenario1 -pt ./pt
```

SEE ALSO

write_checksum(2)

compare_collections

Compares the contents of two collections. If the same objects are in both collections, the result is "0" (like string compare). If they are different, the result is nonzero. The order of the objects can optionally be considered.

SYNTAX

int **compare_collections**
[-order_dependent]
collection1
collection2

Data Types

collection1	collection
collection2	collection

ARGUMENTS

-order_dependent

Indicates that the order of the objects is to be considered; that is, the collections are considered to be different if the objects are ordered differently.

collection1

Specifies the base collection for the comparison. The empty string (the empty collection) is a legal value for the *collection1* argument.

collection2

Specifies the collection with which to compare to *collection1*. The empty string (the empty collection) is a legal value for the *collection2* argument.

DESCRIPTION

The **compare_collections** command is used to compare the contents of two collections. By default, the order of the objects does not matter, so that a collection of cells u1 and u2 is the same as a collection of the cells u2 and u1. By using the **-order_dependent** option, the order of the objects is considered.

Either or both of the collections can be the empty string (the empty collection). If two empty collections are compared, the comparison succeeds (that is, **compare_collections** considers them identical), and the result is "0".

EXAMPLES

The following example from PrimeTime shows a variety of comparisons. Note that a result of "0" from **compare_collections** indicates success. Any other result indicates failure.

```
pt_shell> compare_collections [get_cells *] [get_cells *]
0
pt_shell> set c1 [get_cells {u1 u2}]
{"u1", "u2"}
pt_shell> set c2 [get_cells {u2 u1}]
{"u2", "u1"}
pt_shell> set c3 [get_cells {u2 u4 u6}]
{"u2", "u4", "u6"}
pt_shell> compare_collections $c1 $c2
0
pt_shell> compare_collections $c1 $c2 -order_dependent
-1
pt_shell> compare_collections $c1 $c3
-1
```

The following example builds on the previous example by showing how empty collections are compared.

```
pt_shell> set c4 ""
pt_shell> compare_collections $c1 $c4
-1
pt_shell> compare_collections $c4 $c4
0
```

SEE ALSO

collections(2)

compare_floorplans

Writes a report that lists any differences in objects and their locations between the current design and floorplan information for another design written by the **write_floorplan** command.

SYNTAX

int **compare_floorplans**
[-input *dir_name*]
[-verbosity minimum | low | high]
[-top_level_only]

Data Types

dir_name string

ARGUMENTS

-input *dir_name*

Specifies the name of the directory under which the file *floorplan_compare_data.txt* is located. The default is *./floorplan*. The command writes an error message and exits if the directory does not exist, or if the file is missing.

-verbosity minimum | low | high

Determines the level of comparison detail to report. The **minimum** argument prints the number of differences for each object type. The **low** argument prints up to five examples for each object type. The **high** argument prints up to 1000 differences of each type. By default, the level is minimum.

-top_level_only

Compares only top-level objects and skip comparison for lower-level objects.

DESCRIPTION

The **compare_floorplans** command creates a report containing a list of objects that are either in *floorplan_compare_data.txt* file but not in the design database, or in the design database but not in *floorplan_compare_data.txt*. The object types that are considered are macros and pins. Feedthrough pins are not considered. The command creates a file named *compare_output*, in the current directory, that creates lists of new objects that are in the existing in database but not in the file. For example:

```
set _new_macros [get_cells { macro1_name macro2_name ...}]
set _new_ports {...}
```

For objects in the *floorplan_compare_data.txt* file but not in the database, the command outputs names and locations or boundaries in the same file. The command outputs two levels, for example, pins and macros at the top level and inside blocks. The command skips the output for the third level and beyond.

Note that the *floorplan_compare_data.txt* file is generated by the **write_floorplan** command. The **compare_floorplans** command is typical used to compare different versions of the same design. For example, begin by running the **write_floorplan** command on one version of the design. Then, load the new version and use the **compare_floorplans** command to determine if any differences exist between the two versions.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example writes a report based on comparing the current design with the *floorplan_compare_data.txt* file in the script directory.

```
prompt> compare_floorplans -input script
```

The following example prints more detailed information, but outputs data related to the top-level only.

```
prompt> compare_floorplans -verbosity high -top_level_only
```

SEE ALSO

write_floorplan(2)

compare_supplies

compares voltage levels or relative ON-ness between two given supplies.

SYNTAX

status **compare_supplies**
supply_list
[-on_status]
[-voltage_level]

Data Types

supply_list list
on_status boolean
voltage_level boolean

ARGUMENTS

supply_list

Specifies a list of 2 supplies. The first supply specified is treated as the 'reference' supply to which the second supply ('specified' supply) will be compared to. Supplies can either be supply net names or supply set handles.

-on_status

If specified, this option will return one of 4 values: "equal" if the reference supply is equal to the specified supply. "more_on" if the specified supply is more ON as compared to the reference supply. "less_on" if the specified supply is less ON as compared to the reference supply. "independent" if the specified supply may be more or less ON as compared to the reference supply depending on the PST State.

-voltage_level

If specified, this option will return one of 4 values: "equal", if both reference and specified supplies are at the same voltage and no level-shifting is needed. "higher", if reference supply is lower voltage as compared to the specified supply. "lower", if the reference supply is higher voltage as compared to the specified supply. "independent, if the reference supply is higher/lower voltage as compared to the specified supply depending on the PST State. If the two supplies specified belong to the same correlated supply group, they will be compared based on the rules for supplies in the same correlated supply group.

DESCRIPTION

This command is used to compare voltage levels or relative always-ON levels of two given supplies. Options -on_status and -

voltage_level can be used separately or in combination. Supplies list must consist of exactly 2 supplies. If the specified supply has no states defined, we will treat it as equal to the reference supply and return equal for both on_status and voltage_level.

SEE ALSO

report_pst(2)

compile

Runs synthesis flow

SYNTAX

status **compile**
[-no_boundary_optimization]
[-no_autoungroup]
[-checkpoint]

Data Types

ARGUMENTS

-no_boundary_optimization

Disables optimization across hierarchical boundaries.

-no_autoungroup

Disables automatic ungrouping, preserving hierarchy.

-checkpoint

Writes 2 intermediate checkpoint databases.

DESCRIPTION

This command runs the synthesis flow. Note: This command is deprecated. It is replaced with **compile_fusion** command.

EXAMPLES

prompt> **compile**

SEE ALSO

compile_fusion(2)

compile_boundary_cells

Creates and places boundary cells into a design. This command is used to replace the command *create_boundary_cells*.

SYNTAX

status **compile_boundary_cells**
  [-add_placement_blockage]
  [-voltage_area {*objects*}]

Data Types

objects list

ARGUMENTS

-add_placement_blockage

Add placement blockage to meet boundary cells rules.

-voltage_area {*objects*}

Specifies the voltage areas to insert boundary cells.

DESCRIPTION

This command adds boundary cells around the boundaries of objects, such as voltage areas, macros, blockages, and the core area, according to the boundary cell rules set by *set_boundary_cell_rules*.

EXAMPLES

The following example creates boundary cells on both the left and the right edges of boundaries.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \
        -right_boundary_cell myLib/CellRight
prompt> compile_boundary_cells
```

SEE ALSO

check_boundary_cells(2)
check_targeted_boundary_cells(2)
compile_targeted_boundary_cells(2)
remove_boundary_cell_rules(2)
report_boundary_cell_rules(2)
set_boundary_cell_rules(2)

compile_fusion

Runs the flow of synthesis, placement, and optimization.

SYNTAX

compile_fusion
[-list_only]
[-from *startStage*]
[-to *endStage*]
[-check_only]

Data Types

startStage string
endStage string

ARGUMENTS

-list_only

Shows the stages that constitute the **compile_fusion** command.

This option cannot be used with the **-from** or **-to** option.

-from *startStage*

Specifies the starting stage for the **compile_fusion** command. Valid values are any of the seven stages reported by *-list_option* option.

The default value is *initial_map* stage similar to classic **compile** command

-to *endStage*

Specifies the final stage for the **compile_fusion** command. Valid values are any of the seven stages.

The default value is **final_opto** with legalized placement similar to **place_opt** command.

If both the **-to** and **-from** options are specified, the *startStage* stage cannot be preceded by the *endStage* stage in the order specified by the **-list_only** option.

-check_only

Checks any discrepancy found in the library and design.

If any of the **-to** or **-from** option is specified, the library and design will be checked to be sufficient only for the stages that will actually run.

DESCRIPTION

By default, the command performs the following tasks in sequence:

- Maps the generic cells to library cells and performs logic optimization.
- Optimizes timing based on logic only, not considering physical data.
- Places the current design.
- Optimizes the placed design for timing, electrical DRC violations, area, power, and routability.
- Performs incremental placement to optimize timing and routability.
- Further optimizes the placed design.
- legalizes the design placement at the end.

EXAMPLES

The following example run all seven stages of the flow. It starts from logic synthesis and ends up with an optimized design with legalized placement:

```
prompt> compile_fusion
```

The following example runs only the **initial_opto** stage. It performs incremental placement to optimize timing and routability:

```
prompt> compile_fusion -from initial_opto -to initial_opto
```

The following example runs the last stages of the flow. It takes in a placed and optimized design as its input, further optimizes the placed design, and ends up with an optimized design with legalized placement:

```
prompt> compile_fusion -from final_place
```

The following example runs the post-compile DFT insertion flow It takes in a placed and optimized design as its input, performs DFT insertion and ends up with an optimized design with legalized placement:

```
prompt> compile_fusion -to initial_opto
prompt> insert_dft
prompt> compile_fusion -from final_place
```

The following example migrates some pre-place_opt settings to the middle of compile_fusion for a unified UPS flow.

```
prompt> compile_fusion -to initial_opto
prompt> source physical_opto_settings.tcl
prompt> compile_fusion -from final_place
```

SEE ALSO

place_opt(2)

compile_pg

Creates a power and ground network including straps, rings, macro connections, standard cell connections and via connections based on the specified power ground strategies.

SYNTAX

status **compile_pg**
[-strategies *strategy_list*]
[-via_rule *rule_list*]
[-ignore_drc]
[-ignore_via_drc]
[-show_phantom]
[-undo]
[-tag *tag_name*]
[-create_ml_data]
[-use_ml_model]

Data Types

strategy_list list
rule_list list
tag_name string

ARGUMENTS

-strategies *strategy_list*

Creates a power network based only on the specified list of strategies. By default, the tool creates a power ground network using all strategies which have been defined.

-via_rule *rule_list*

Specifies the via rule list between strategies and existing shapes. The via rule list *rule_list* contains strategy-level via rules defined by the **set_pg_strategy_via_rule** command. If no strategy via rule is specified, the default via defined in the technology file is created at all intersections between any two orthogonal shapes on different layers.

-ignore_drc

Creates the power network while ignoring DRCs for both wires and vias. By default, all DRCs are considered when creating the power network. This option is mutually exclusive with the **-ignore_via_drc** option.

-ignore_via_drc

Creates the power network while ignoring via DRCs. By default, all DRCs are considered when creating the power network. When this option is set, DRCs for wires are checked and fixed, DRCs within each stacked via are checked and fixed. Only DRCs

between stacked vias and neighboring objects are ignored. This option is mutually exclusive with **-ignore_drc** option.

-show_phantom

Generates report for wires/vias that should be created but failed due to fixing DRC violation. Detailed information will be displayed in error browser. The report includes two parts, phantom wire and phantom via. Wire information and DRC violation are included in one phantom wire. Only DRC violations that cut part of wire shape while fixing will be included in phantom wire. Abutted phantom wires will be merged and reported together. Via information and DRC violation are included in one phantom via. Via information includes top/bottom wire information, via def, net name. DRC violation shows initial violation before fixing. If **-ignore_drc** or **-ignore_via_drc** is specified, phantom via will not be generated.

-undo

Removes the power and ground network created by the most recent **compile_pg** command.

-tag *tag_name*

Specifies a tag name to assign to all new vias and shapes created by this command. This tag name is used as contents of an user attribute tag for filtering collections at later stages (see the example in the EXAMPLES section). By default, no tags are assigned.

-create_ml_data

This option enables this command to create training data for training ML model for fixability prediction. When this option is set, the command only creates ML training data, not creating PG wires/vias.

-use_ml_model

This option enables this command to load pre-trained ML model for fixability prediction.

DESCRIPTION

This command creates the power network based on the specified power ground strategies.

Signal routes by default are ignored for DRC checking and correction during PG creation. Use the following app option to honor signal route DRC during PG creation.

```
prompt> set_app_options -list {plan.pgroute.honor_signal_route_drc true}
```

EXAMPLES

The following example creates a power ground network using only the example1 and example2 strategies. The rule1 via rule is defined by the **set_pg_strategy_via_rule** command.

```
prompt> compile_pg -strategies {example1 example2}\
            -via_rule rule1
```

The following example compiles strategy example1 using 4 threads defined in the global host_options mt for via creation.

```
prompt> set_host_options -max_cores 4
prompt> compile_pg -strategies {example1}
```

The following example creates collections of vias and wires that are tagged with the name pg1.

```
prompt> compile_pg -tag pg1
prompt> set vias [get_vias -filter tag==pg1]
prompt> set wires [get_shapes -filter tag==pg1]
```

The following example creates ML training data in memory, output training data to files in the directory ./pg_model, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> compile_pg -create_ml_data
prompt> train_pg_ml_model
```

The following example creates ML training data in memory, output training data to files in directory pg_data_1, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> compile_pg -create_ml_data
prompt> create_pg_ml_data -output_directory pg_data_1
prompt> train_pg_ml_model -input_directory {pg_data_1}
```

The following example loads pre-trained ML model in the directory ./pg_model for fixability prediction to reduce runtime of PG via creation.

```
prompt> compile_pg -use_ml_model
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: **gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"**.

compile_targeted_boundary_cells

Creates and places boundary cells around target objects in current design.

SYNTAX

status **compile_targeted_boundary_cells**
-target_objects {*target_objects*}
[-include_touching_placement_blockages]
[-ignore_row_orientation]

Data Types

target_objects list

ARGUMENTS

-target_objects {*target_objects*}

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified. This option is a required option.

-include_touching_placement_blockages

Specifies that when boundary cells are created and placed, placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

-ignore_row_orientation

Specifies that when flipping between top and bottom.

DESCRIPTION

This command adds boundary cells around the boundaries of target objects, such as voltage areas, macros, blockages, and the core area, according to the boundary cell rules set by *set_boundary_cell_rules*.

EXAMPLES

The following example creates boundary cells around target placement blockages on both the left and the right edges of

boundaries.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \
        -right_boundary_cell myLib/CellRight
prompt> compile_targeted_boundary_cells -target_objects {PB_7 PB_8}
```

compute_area

Calculates the area of a geometric region.

SYNTAX

float **compute_area**
[-objects *object_list*]
[*pos_object_list*]

Data Types

object_list collection
pos_object_list collection

ARGUMENTS

-objects *object_list*

Specifies the objects to be used to define the geometric region to calculate the area of. Objects may be a heterogenous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

This is a required option if the *pos_object_list* option is not specified.

pos_object_list

Specifies the objects to be used to define the geometric region to calculate the area of. This positional option is provided for compatibility with other tools.

DESCRIPTION

This command calculates the area of the region specified by *objects*.

SEE ALSO

compute_budget_constraints

Creates budget pin constraints based on virtual in-place optimization (VIPO) timing.

SYNTAX

status **compute_budget_constraints**
[-setup_delay]
[-boundary]
[-latency_targets actual | estimated]
[-busplans *buses*]
[-modes *mode_list*]
[-estimate_timing]
[-no_estimate_timing]
[-pins *pin_list*]
[-input]
[-output]
[-unspecified]
[-feedthrough]
[-slack *slack_value*]
[-fanin_cone]
[-fanout_cone]
[-balance true | false]
[-ocv_percent *percent*]
[-ocv_delay *delay*]

Data Types

buses list
mode_list list
pin_list list
slack_value float
percent float
delay float

ARGUMENTS

-setup_delay

Calculates budget values for setup delay. See the description section for more details. This can be specified in combination with the **-boundary**, and/or **-latency_targets** options. If none are specified, setup and boundaries are computed.

-boundary

Calculates budget values for drives and loads at the block boundary. See the description section for more details. This can be

specified in combination with the **-setup_delay**, and/or **-latency_targets** options. If none are specified, setup and boundaries are computed.

-latency_targets actual | estimated

Calculates new clock latency targets to be used during budgeting. This can be specified in combination with the **-setup_delay**, and/or **-boundary** options. If none are specified, setup and boundaries are computed. No other budget values are changed. During budget generation, you can use the clock latency targets to account for clock tree variation early in the design flow before clock tree synthesis (CTS). This option automatically sets the budget parameters for clock latency targets in your design. This is equivalent to manually using the **-early_latency**, **-late_latency** and **-crp** options with the **set_latency_budget_constraints** command. The **-latency_targets** option must be specified together with the **-balance** option.

The argument to **-latency_targets** determines how the budget values are selected.

- **actual**: Budget values are selected to closely match the current clock latencies in your top-level design. The latencies can be either ideal or propagated, depending on whether your SDC file contains **set_propagated_clock** commands.
- **estimated**: Budget values are selected to closely match the predicted latency of your top-level clock tree. The prediction is based on the current placement of your clock tree elements (the clock trunk, ICGs, clock pins). The current timing of the clock tree is not used. Estimated clock latencies are queried from the "clock trunk planning" tool, so you need to make sure that you have run that first.

-busplans *buses*

Automatically determines a fixed budget for segments along a budget path. This option is equivalent to manually setting the **-delay** option of the **set_segment_budget_constraints** command. The "buses" argument passed to this option must first have been declared using the **create_budget_busplan** command. See the **create_budget_busplan** man page for more details.

-modes *mode_list*

Specifies the list of modes to use to create the budget constraints. If this option is not specified, the command processes all modes with an active corner.

-estimate_timing

The automatic budgeter can run in one of two modes. In regular mode, automatic budgeting creates constraints based on the worst delays across all active timing corners. In estimate_timing mode, the automatic budgeter calculates the budget by using the delays in the estimated_corner. This is desirable when some or all of your design is unoptimized. Normally the mode is decided by the **plan.budget.estimate_timing_mode** application option. The **-estimate_timing** option uses the estimate_timing mode for calculating constraints.

-no_estimate_timing

The automatic budgeter can run in one of two modes. In regular mode, automatic budgeting creates constraints based on the worst delays across all active timing corners. In estimate_timing mode, the automatic budgeter will base the budget only on delays in the estimated_corner. This is desirable when some or all of your design is unoptimized. Normally the mode is decided by the **plan.budget.estimate_timing_mode** application option. The **-no_estimate_timing** option uses the regular mode for calculating constraints.

-pins *pin_list*

Updates budget values for only the specified pins. You can further restrict the list of pins with the **-input** and **-output** options. By default, the command processes all pins of all budgeted blocks.

-input

Updates budget values for only input pins to blocks. You can further restrict the list of pins with the **-pins** option. By default, the command processes all pins of all budgeted blocks.

-output

Updates budget values for only output pins to blocks. You can further restrict the list of pins with the **-pins** option. By default, the command processes all pins of all budgeted blocks.

-unspecified

Updates budget values for only pins with no existing delay budget. By default, the command processes all pins of all budgeted blocks.

-feedthrough

Updates budget values only for paths with feedthroughs. A feedthrough path has a combinational connection that goes from the input of a block to the output of a block. By default, the command updates all paths, including those that start or end in the local block.

-slack *slack_value*

Updates budget values only for paths through pins where the budget slack is less than **slack_value**. Budget slack is defined as the amount by which the actual path delay is less than the budgeted path delay. If you specify **-slack 0.0**, only paths where the budget is tighter than the actual delay are rebudgeted.

-fanin_cone

Updates budget values only for pins that are in the timing fanin cone of the selected pins. This is useful when you want to rebudget many pins along the same path. By default, only selected pins are processed.

-fanout_cone

Updates budget values only for pins that are in the timing fanout cone of the selected pins. This is useful when you want to rebudget many pins along the same path. By default, only selected pins are processed.

-balance true | false

Sets latency targets as if there is zero skew between two blocks, even if the current timing analysis shows otherwise. You should set **-balance** to true whenever some of your clock timing is propagated (not ideal) or estimated, but you have not finished balancing your clocks across the whole chip.

During budgeting, it is possible that the clocks of your designs are not yet balanced. For example, you might have run clock tree synthesis in one of your blocks and not another. Or, you have run clock tree synthesis in each of your blocks, but have not yet balanced the blocks with each other. When you specify **-balance true** to true, the budgeter assumes that clocks are balanced.

If you want some clocks in your design to have a latency that is offset from other clocks, use the **-latency_offset** option of the **set_latency_budget_constraints** command to adjust the interclock balance.

You must specify the **-balance** option together with the **-latency_targets** option.

-ocv_percent *percent*

Adjusts the calculated early and late budget latencies so that they both vary by at least the specified *percent* value from the average.

When you use the **-latency_targets** option, it is possible that on-chip variation (OCV) is not considered. This happens if you are using ideal clocks and you did not supply separate early and late latencies. For example, if both the early and late latency in the design are 10, and you specify **-ocv_percent 5**, the early and late budget latency targets are set to 9.5 and 10.5, respectively.

The **-ocv_percent** option can only be specified together with the **-latency_targets** option.

-ocv_delay *delay*

Adjusts the calculated early and late budget latencies so that they both vary by at least the specified *delay* value from the average.

When you use the **-latency_targets** option, it is possible that OCV is not considered. This happens if you are using ideal clocks

and you did not supply separate early and late latencies. For example, if both the early and late latency in the design are 0, and you specify **-ocv_delay 0.2**, the budget latency targets will be set to -0.2 and 0.2, respectively.

The **-ocv_percent** option can only be specified along with the **-latency_targets** option.

DESCRIPTION

This command automatically assigns new budget constraints for setup delay, boundary parasitics and drive, and/or clock latency. These are controlled by using the **-setup_delay**, **-boundary**, and **-latency_targets** options. If you specify none of these options, setup and boundary will be assumed. See the argument descriptions above for more information.

Note that constraints for hold delay do not depend on whether or not you run the **compute_budget_constraints** command. If you set the **plan.budget.write_hold_budgets** application option to true, hold constraints will automatically be calculated and output by the **write_budgets** command.

The **compute_budget_constraints** can be used to create setup delay constraints on your budget blocks. Running this command is equivalent to calling **set_pin_budget_constraints** directly, except that the constraints are automatically generated. Constraints are generated to distribute slack of top-level paths to the various budget blocks. You can use the **report_budget** command to analyze the results.

Path delays are automatically processed and constraints are set which are the same as those that can be manually set by the following options of the **set_pin_budget_constraints** command:

- -from_percent
- -from_delay
- -to_percent
- -to_delay
- -internal_percent
- -internal_delay

This will affect **set_input_delay** and **set_output_delay** constraints in your final budget.

Block boundaries are automatically processed and constraints are set which are the same as those that can be manually set with the **-early_boundary** and **-late_boundary** options of the **set_pin_budget_constraints** command. This will affect the **set_driving_cell**, **set_load** and **set_max_transition** constraints in your final budget.

By default, **compute_budget_constraints** processes all pins of all budget blocks. Blocks are assigned for budgeting by the **set_budget_options -add_blocks block_name** command. By default, all modes with an active corner are processed, unless you specify **-modes**.

When processing setup delays and boundary constraints, you can limit where **compute_budget_constraints** operates by using one or more of the **-pins**, **-input**, **-output**, **-feedthrough**, or **-slack** options. The **-fanin_cone** and **-fanout_cone** options allow **compute_budget_constraints** to also adjust budgets in the transitive fanin or output of specified pins.

Use the **set_budget_options** command to specify general options to be used when creating timing budgets. To manually set other specific budget parameters, use the **set_pin_budget_constraints**, **set_latency_budget_constraints**, and **set_boundary_budget_constraints** commands.

Use the **write_budgets** command to generate SDC that can be applied to lower level blocks. The **report_budget** command generates useful information about the current budget calculation, allocation, and whether that budget is currently being met. Use the **write_script -include budget** command to save a Tcl script that includes your current settings from this command.

This command returns 1 on success, 0 otherwise.

Multiply Instantiated Blocks

The **compute_budget_constraints** command automatically creates equal budgets for similar pins of multiply instantiated blocks (as directed by the **-same_as_mib** option of the **set_pin_budget_constraints** command). The budget represents the best compromise across the contexts of the multiple instances. However, if it appears that one or more instance pins has a constraint that is impossible to meet, those constraints might be different. You can report the pins with seemingly impossible constraints by using the **report_budget -warning_pins** command.

EXAMPLES

Automatically fill in the budget specification for any pin in any mode where no budget has yet been specified. Be careful not to overwrite previously set boundary budgets.

```
prompt> compute_budget_constraints -unspecified -setup_delay
```

Automatically fill in the budget specification for any pin in any mode where no budget has yet been specified. Also make sure that boundary budgets are automatically created for all pins, regardless of whether or not they have delay budgets.

```
prompt> compute_budget_constraints -unspecified
prompt> compute_budget_constraints -boundary
```

Manually set internal delay budgets for all blocks, then use the **compute_budget_constraints** command to automatically fill in the unspecified feedthrough budgets. Also make sure that boundary budgets are created for all pins.

```
prompt> set_budget_options -add_blocks { core/CPU core/MMU exif }
prompt> set_pin_budget_constraints -all -internal_percent 20
prompt> compute_budget_constraints -unspecified -feedthrough
prompt> compute_budget_constraints -boundary
```

Automatically recalculate all existing budget constraints at the input of core/CPU in the current mode.

```
prompt> compute_budget_constraints -input -pins core/CPU/*
```

Find any pin in "mode2" where the budget is being met by less than 0.05 nanosecond. Assign a new budget to those pins and to pins in the fanin and fanout of those pins.

```
prompt> compute_budget_constraints -modes mode2 -slack 0.05 \
  -fanin_cone -fanout_cone
```

Set up block clock latency targets for early in the flow. Use the current ideal clock specifications, but enforce OCV variability.

```
prompt> compute_budget_constraints -latency_targets actual \
  -balance true -ocv_percent 5
```

Set up block clock latency parameters for early in the flow. Use estimated latency and OCV. Use the **-balance true** option in the assumption that balancing will be done later in the flow.

```
prompt> compute_budget_constraints -latency_targets estimated \
  -balance true
```

Set up block clock latency parameters to exactly match the circuit. The **-balance false** option assumes that the top-level clocks are already balanced.

```
prompt> compute_budget_constraints -latency_targets actual \
  -balance false
```

See the **write_budgets** man page for more examples of the **-latency_targets** option.

compute_clock_latency

Updates the network latencies of real and virtual clocks after clock tree synthesis.

SYNTAX

status **compute_clock_latency**
[-verbose]

Data Types

No data types

ARGUMENTS

-verbose

Displays additional columns in the update report to show reference clock, latency calculation method and the number of register clock pins used to calculate the latency.

DESCRIPTION

This command is used primarily to correct your block's timing constraints after clock tree synthesis. Clock tree synthesis inserts clock networks, which changes the latency on your clocks, and the apparent length of the datapaths at your block boundary. The **compute_clock_latency** command can adjust the clock latency on your I/O clocks so that the datapath length is maintained and your boundary constraints are still good. See the example below for more information.

The command calculates and updates the I/O latencies of real and virtual clock objects for all active mode and corner combinations. To calculate and update clock latencies, this command follows the directives set by **set_latency_adjustment_options** command for each mode. If no directives are given, then only the I/O latencies of real clock objects are updated. The latencies are calculated as the median of the clock network latencies at the clock sinks of the clock tree. For ideal clocks, a **set_clock_latency** command is run by the tool on the clock objects. For propagated clocks, I/O path latency is set internally on the clock objects. The I/O path latency is used in timing the input/output ports. The command updates latencies for all the active mode and corner combinations.

Note that **compute_clock_latency** is run automatically by the tool as part of integrated CTS and optimization flows. So it is important to use the **set_latency_adjustment_options** command, even if you don't intend to call **compute_clock_latency** explicitly.

Multicorner-Multimode Support

This command works on all active scenarios.

EXAMPLES

This example adjusts the latency on the specified I/O clocks. First, you must associate your I/O clocks with your internal clocks by using the **set_latency_adjustment_options** command. Then, when you run **compute_clock_latency**, the latency of the I/O clock will be set to match your internal clock. Notice that the **write_io_constraints** command can set latency adjustment options with **set_latency_adjustment_options** in the budget script.

```
prompt> set_latency_adjustment_options \
  -reference_clock my_internal_clock \
  -clocks_to_update my_io_clock
prompt> synthesize_clock_trees
prompt> compute_clock_latency

Mode:mode2          Latency(early)   Latency(late)
Clock      Updated  rise   fall   rise   fall   Corner
-------------------------------------------------------------
clock      Yes    0.9336    --  0.9336    --    c2
clock_dup  No       --     --     --     --    --
clock_dup_2 Yes    1.6785    --  1.7258    --    c2
vclk1      Yes    0.9572    --  0.9572    --    c2
vclk2      Yes    0.9336    --  0.9336    --    c2

Mode:mode1          Latency(early)   Latency(late)
Clock      Updated  rise   fall   rise   fall   Corner
-------------------------------------------------------------
clock      Yes    0.9336    --  0.9336    --    c1
clock_dup  No       --     --     --     --    --
clock_dup_2 Yes    1.6785    --  1.7258    --    c1
vclk1      Yes    0.9572    --  0.9572    --    c1
vclk2      Yes    0.9336    --  0.9336    --    c1
```

The following example generates a report with additional information by using the **-verbose** option.

```
prompt> compute_clock_latency -verbose

vclk2      No       --     --     --     --    --     No
  --        --             0
```

SEE ALSO

set_latency_adjustment_options(2)

write_io_constraints(2)

compute_dff_connections

Traces connections in the current netlist. The results are used by the Data Flow Flylines tool in the GUI.

SYNTAX

status **compute_dff_connections**
[-max_reg *register_count*]
[-max_gate *gate_count*]
[-max_fanout *fanout_count*]
[-include_blocks *list_of_designs*]
[-retrace_blocks *list_of_designs*]
[-host_options *host_option_name*]
[-work_dir *working_directory*]
[-dont_include_abstracts]

Data Types

register_count int
gate_count int
fanout_count int
list_of_designs collection
host_option_name string
working_directory string

ARGUMENTS

-max_reg *register_count*

Specifies the maximum number of registers a path can contain and still be stored. Paths containing more than this number of registers are not stored for display. By default, this value is 3.

-max_gate *gate_count*

Specifies the maximum number of total gates a path can contain and still be stored. Gates are considered combinational cells that are not buffers or inverters. Paths containing more than this number of gates are not stored for display. By default, this value is 20.

-max_fanout *fanout_count*

Specifies the maximum fanout permitted for any net found while tracing the path. If a net with fanout greater than this limit is encountered, the path is not stored for display. By default, this value is 64.

-include_blocks *list_of_designs*

Specifies the abstract views for which to load previously saved trace data. The abstract view must be currently loaded or available in the library, and the **-max_reg**, **-max_gate**, and **-max_fanout** option values must be consistent with the previously saved data. If no compatible trace data file exists for the abstract view, you must also specify the *-retrace_blocks* option. By default, the commands loads all design views and abstract views for blocks returned by the *get_designs* command.

-retrace_blocks *list_of_designs*

Specifies a collection of abstract designs and physical blocks for which to retrace the netlist. *list_of_designs* is a set or subset of designs returned from the *get_designs* command. The specified designs are opened in design view and traced using the current tracer settings. The trace data is saved into a tracer data file that can be loaded by the Data Flow Flylines component in the GUI. Any design specified for this option must also be specified for the *-include_blocks* option. Note: after tracing any designs in this manner, the main design is reloaded and relinked, and all existing object collections become invalid and must be re-created.

-host_options *host_option_name*

Specifies the name of the host option to use for distributed processing. By default, this is empty and distributed processing is not used. See also *set_host_options*.

-work_dir *working_directory*

Specifies the directory in which to write the tracer files. By default, the command writes to a directory named "work_dir".

-dont_include_abstracts

Ignores abstracts and traces only in design views.

DESCRIPTION

This command invokes the Data Flow Flylines tracer. The tracer traces through the current netlist and stores paths that meet the specified constraints. These paths can then be displayed using the Data Flow Flylines GUI component. Several options are available to restrict the types of paths stored and limit the runtime required by the tracer (which might take several minutes for a larger design).

This command uses the settings specified by the *create_dff_trace_filters* command to stop tracing when any of the specified filter pins or filter nets are encountered during tracing.

If the current design contains abstract blocks, they can still be included in the tracer results. By specifying the *-include_blocks* and *-retrace_blocks* (if required) options, the specified abstract view designs can be opened in design view, either in the current session or a distributed session, depending on the current distributed processing settings. For more information, see the man pages for **set_host_options** and **run_block_script**.

After saving tracer data files for the abstract designs, these sessions are closed and the saved tracer data files can be merged into the main tracer results. This only applies to abstract designs, and designs in design view are always automatically included in the main tracer results.

EXAMPLES

The following example traces the current design using these constraints: paths with a register depth of 2 or less, a maximum gate count of 25 or less, and a maximum fanout of 64, which is default. The Data Flow Flylines tool can be used to view the results in the GUI.

```
prompt> compute_dff_connections -max_reg 2 -max_gate 25
```

The following example traces the current design, but also forces a retrace of the ABS1 abstract block and includes the ABS1 and ABS2 abstract blocks in the main trace results.

```

compute_infeasible_path_overrides

checks infeasible path margins.

SYNTAX

status **compute_infeasible_path_overrides**
[-modes *mode_list*]
[-corners *corner_list*]
[-scenarios *scenario_list*]
[-group *group_list*]
[-apply_override_constraints]
[-output *file_name*]
[-nworst *paths_per_endpoint_per_path_group*]
[-max_paths *max_path_count_per_path_group*]
[-verbose]

Data Types

mode_list	list
corner_list	list
scenario_list	list
group_list	list
file_name	string

ARGUMENTS

-modes *mode_list*

Specifies the scenarios to check infeasibility. If this option is given, all scenarios of the given modes are used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-corners *corner_list*

Specifies the scenarios to check infeasibility. If this option is given, all scenarios of the given corners and the current mode is used. The **-scenarios** option must not be specified with this option. If both **-modes** and **-corners** are specified, all scenarios whose mode is specified by **-modes** and whose corner is specified by **-corners** are used.

-scenarios *scenario_list*

Specifies the scenarios to check infeasibility. The **-modes** or **-corners** option must not be given with this option.

-group *group_list*

Specify the list of path group names for checking infeasibility. Default is all path groups.

-apply_override_constraints

This option generates and applies path margins. Added path margins are all commented with SYNOPSYS_INFEASIBLE_PATH_OVERRIDE.

-output *file_name*

Specifies the name of the generated file containing timing exceptions to resolve infeasibility.

-nworst *paths_per_endpoint*

Specifies the number of paths to search per endpoint. Value is applied to each path group. The default value is 1000.

-max_paths *max_path_count*

Specifies the number of paths to report. The default value is 10000. The max_paths value is applied to each path group.

-verbose

This option generate arrival time at startpoint and required time at endpoint along with infeasibility (arrival time at startpoint - required time at endpoint)

DESCRIPTION

This command checks timing paths infeasibility.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

this example checks infeasibility in scneario s1

prompt> **compute_infeasible_path_overrides -scenario s1**

This example checks infeasibility in current scenario and applies set_path_margin exceptions to resolve infeasibility.

prompt> **compute_infeasible_path_overrides -apply_override_constraints**

SEE ALSO

remove_path_margin(2)

compute_polygons

Performs a boolean geometric operation and returns the result as a geo_mask.

SYNTAX

collection **compute_polygons**
-operation AND | OR | XOR | NOT
-objects1 *object_list*
-objects2 *object_list*

Data Types

object_list collection

ARGUMENTS

-operation AND | OR | XOR | NOT

Specifies the Boolean operation to perform:

AND Get the region covered by both *objects1* and *objects2*
OR Get the region covered by either *objects1* or *objects2*
XOR Get the region covered by *objects1* or by *objects2* but not both
NOT Get the region covered by *objects1* but not by *objects2*
TOUCHING Get the region covered by the poly_rects in *objects1* that abuts or overlaps with one or more poly_rects in *objects2*
INTERSECT Get the region covered by the poly_rects in *objects1* that overlaps with one or more poly_rects in *objects2*

This is a required option.

-objects1 *object_list*

Specifies the objects to be used to define the geometric region of the first argument of the operation. Objects can be a heterogeneous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

This is a required option.

-objects2 *object_list*

Specifies the objects to be used to define the geometric region of the second argument of the operation, and has the same form and functionality as the *-objects1* argument.

This is a required option.

DESCRIPTION

This command performs the specified Boolean operation on *objects1* and *objects2*, and returns a collection that contains the result as a geo_mask object.

EXAMPLES

The following example returns a geo_mask with a region that is the union of two shapes.

```
prompt> compute_polygons -objects1 [get_shapes RECT_0] -operation AND \
    -objects2 [get_shapes RECT_1]
```

The following example returns a geo_mask with the region composed of the shapes on a layer, except for the areas of shapes that lie within a rectangle.

```
prompt> compute_polygons -objects1 [get_layers M1] -operation NOT \
    -objects2 [create_poly_rect -boundary {{0 0} {200 100}}]
```

SEE ALSO

connect_freeze_silicon_tie_cells

Connect target pins to tie cells in freeze silicon mode.

SYNTAX

status **connect_freeze_silicon_tie_cells**
[-cells *cells*]
[-max_fanout *number*]
[-max_wire_length *distance*]
[-tie_high_lib_cell *lib_cell*]
[-tie_low_lib_cell *lib_cell*]

Data Types

cells collection
lib_cell collection
number integer
distance distance

ARGUMENTS

-cells *cells*

Specifies the target cells to be connected to tie cells. These cells must have pins already connected to tie-low nets or tie-high nets. This option is optional, and if this option is not specified, target cells include all cells which have pins already connected to tie nets in the design.

-max_fanout *number*

Specifies the maximum number of pins that can be driven by a single tie-high or tie-low cell. If you do not specify this option, the maximum fanout is 8.

-max_wire_length *distance*

Specifies the maximum Manhattan wire length in microns from a tie-high or tie-low cell to each driven cell pin. If you do not specify this option, the maximum wire length is 100.

-tie_high_lib_cell *lib_cell*

Specifies the reference cell type of tie cells to be used for tie high connections. If not specified, all types of tie high cell can be used for tie high connections If you use this option, you must also use the **-tie_low_lib_cell** option.

-tie_low_lib_cell *lib_cell*

Specifies the reference cell type of tie cells to be used for tie low connections. If not specified, all types of tie low cell can be used for tie low connections If you use this option, you must also use the **-tie_high_lib_cell** option.

DESCRIPTION

This command connect pins that are already connected to tie nets to tie cells in freeze silicon mode. If users specify the option **-cells** , only pins of these cells that are connected to tie nets will be connected to tie cells. And these pins are connected to surrounding tie cells as close as possible.

This command can work in freeze silicon mode, and spare tie cells can be used to create new tie cells in freeze silicon mode if needed.

The pins that already connected to tie nets are only connected to tie cells in the same voltage area of these pins by this command.

This command support spare tie cells and non-spare tie cells. Non-spare tie cells can only be connected to pins in the same hierarchy. But for a spare tie cell, it could be moved to another hierarchy (swap out and a new tie cell is created) and connected to pins in that hierarchy.

Cells must be placed before the command, include tie cells and cells that need to be connected to tie cells. And cells inside sub block are also not supported.

Users can specify maximum fanout (the maximum number of pins that can be driven by a single tie cell) and maximum wire length (the maximum Manhattan wire length between a pin and its tie cell driver) constraints.

Users can specify tie high and tie low lib cells, and then only tie cells of the specified lib cells can be used for tie connections. If not specified, all tie-high and tie-low cells can be used for tie connections.

When this command succeeds, the toll will report a summary like this:

```
****************************************
Report : ECO connect_freeze_silicon_tie_cells Summary
 ...

****************************************
Total 168 pins are connected to tie cells.

Voltage Area DEFAULT_VA:
   Connect    6 pins to tie-low cells.
   Connect    4 pins to tie-high cells.

Voltage Area pd2:
   Connect  102 pins to tie-low cells.
   Connect   34 pins to tie-high cells.

Voltage Area pd3:
   Connect    6 pins to tie-low cells.
   Connect    2 pins to tie-high cells.

Voltage Area pd4:
   Connect    8 pins to tie-low cells.
   Connect    6 pins to tie-high cells.
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

In the following example, there is no option specified, and all pins that already connected to tie nets will be connected to tie cells.

```
prompt> connect_freeze_silicon_tie_cells

****************************************
Report : ECO connect_freeze_silicon_tie_cells Summary
 ...

****************************************
Total 22 pins are connected to tie cells.

Voltage Area pd3:
   Connect    6 pins to tie-low cells.
   Connect    2 pins to tie-high cells.

Voltage Area pd4:
   Connect    8 pins to tie-low cells.
   Connect    6 pins to tie-high cells.
1
```

In the following example, only pins of the specified cells are connected to tie cells if they are already connected to tie nets.

```
prompt> connect_freeze_silicon_tie_cells -cells {alu/EcoCell*}
```

In the following example, the options *-max_fanout* and *-max_wire_length* are specified, and the command will follow these constrains when connect pins to tie cells.

```
prompt> connect_freeze_silicon_tie_cells -max_fanout 5 -max_wire_length 20
```

In the following example, the options *-tie_high_lib_cell* and *-tie_low_lib_cell* are specified, and the command will only use tie cells of the specified lib cells for tie connections.

```
prompt> connect_freeze_silicon_tie_cells -tie_high_lib_cell tcbn90ghvt/TIEHHVT \
   -tie_low_lib_cell tcbn90ghvt/TIELHVT
```

connect_logic_net

Connects a logic net to logic ports.

SYNTAX

status **connect_logic_net**
net_name
[-ports *port_list*]
[-reconnect]

Data Types

net_name string
port_list list

ARGUMENTS

net_name

Specifies the net name.

-ports *port_list*

Specifies the logic ports connected to the net. The ports must be on the interface of the active scope or on the design elements that are located in the active scope and its descendants.

-reconnect

Allows a port that is already connected to a net to be disconnected from the existing net and connected to the newly specified net.

DESCRIPTION

The connect_logic_net command connects a logic (non-PG) net to the specified logic ports. The net is propagated through implicitly created ports and nets throughout the logic hierarchy in the descendant subtree of the active UPF scope as required to support connections created by connect_logic_net. A unique global driver needs to be present among the logic net and logic ports if there exists a logic port not in the same hierarchy as any segment of the given net in the active UPF scope. This command will not support multiple driver nets. That is, it will not implement connection if there are multiple drivers specified, or the net has multiple drivers.

On the path from a specified logic port to the logic net:

-

no internal port can be created on a power domain boundary when establishing a new connection;

-

there cannot be a different net already connected to the logic port.

The **-reconnect** option disconnects any existing net from the specified port and connects the newly specified net to all the ports present in the port_list.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

connect_net(2)
create_logic_port(2)
create_logic_net(2)

connect_net

Connects a net or scalar nets of net_bus to port, pins and scalar ports of port_bus.

SYNTAX

int **connect_net**
[-design *design*]
-net *net*
-port_name *port_name*
net
terms

Data Types

design string
net list
port_name string
terms list

ARGUMENTS

-design *design*

Specifies the design in which to connect the nets. If no design is specified, the nets are connected in the current design.

-net *net*

Specifies the net or net_bus to connect. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified, then terms must contain the same width port_bus or length of the scalar port array list should be same as bus width of the net_bus.

net

Specifies the net or net_bus to connect. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified, then terms must contain the same width port_bus or length of the scalar port array list should be same as bus width of the net_bus. This positional argument is provided for compatibility with other tools.

-port_name *port_name*

Specifies the base name to use as the name of new ports that are created on subdesigns to make the connection.

terms

Specifies a list of ports, port_bus and pins to which the net is to be connected. The ports and pins must exist in the current design. If a specified port, scalar port of port_bus or pin is already connected, the command issues an error message.

DESCRIPTION

This command connects a net or scalar net of the net_bus to the specified ports, port_bus and pins, possibly across several levels of hierarchy. port_bus connections across hierarchies is not supported. A net can be connected to many ports and pins, however you cannot connect a port or pin to more than one net. Ports and nets are created as needed to cross hierarchy.

If a port or pin cannot be connected, the port or pin is skipped. The remaining ports and pins in the *terms* are connected.

The number of connected ports and pins are returned.

To disconnect objects on a net, use the **disconnect_net** command. To display ports and pins on a net, use the **all_connected** command.

EXAMPLES

The following example connects a net named *NET0*. The **all_connected** command returns the objects connected to *NET0*.

```
prompt> connect_net -net NET0 [get_ports { A1 A2 } ]

prompt> connect_net -net NET0 [get_pins U1/A]

prompt> all_connected NET0

{"A1", "A2", "U1/A"}
```

The following example connects a net_bus named *N[7:0]* to port_bus named *P[7:0]* so that N[7] is connected to P[7], N[6] is connected to P[6] ..,N[0] to P[0].

```
prompt> connect_net -net N P
8

# The nets can be explicitly mentioned as follows
prompt> connect_net -net [get_net_buses N] [get_port_buses P]
8

prompt> all_connected N[1]
{"P[1]"}
```

SEE ALSO

all_connected(2)
disconnect_net(2)

connect_pg_net

Connects power, ground, and tie-off pins to the specified power and ground nets. The command supports both an automatic mode and a manual mode. The default is automatic mode. In automatic mode, the tool derives the power and ground nets from the power domain connections. Automatic mode requires committed UPF descriptions and logic libraries with power and ground pins. In manual mode, you specify the power and ground nets. In automatic mode, the tool reports PG net and PG pin connections status at the end.

SYNTAX

status **connect_pg_net**
[-automatic]
[-all_blocks]
[-block *block_list*]
[-design *design*]
[-net *net*]
[*port_pin_list*]
[-create_nets_only]
[-verbose]

Data Types

block_list list
design collection
net list
port_pin_list list

ARGUMENTS

-automatic

Specifies automatic mode. This option cannot be used with **-net** or port_pin_list options.

-all_blocks

Traverses all physical blocks during auto PG connection. This option cannot be used with **-block**, **-net** or port_pin_list options.

-block *block_list*

Traverses the current design, as well as the physical blocks specified in *block_list* during auto PG connection. Blocks in *block_list* that are not in current design are ignored. This option cannot be used with **-all_blocks**, **-net** or port_pin_list options.

-design *design*

Specifies the design in which to connect power and ground nets. If no design is specified, the power and ground nets are connected in the current design.

-net *net*

Specifies the PG net to connect. The *net* argument can be a name or collection. The net must be a scalar (single-bit) PG net and must exist in the current design.

port_pin_list

Specifies a list of ports and pins to which the net is to be connected. The ports and pins must exist in the current design. If a specified port or pin is already connected, the command disconnects the existing connection and makes a new connection.

-create_nets_only

Will only automatically create topmost PG nets based on power constraints, even the design contains unmapped cells.

-verbose

Prints the details of the changes to the power, ground, and tie-off connections.

DESCRIPTION

This command creates the power and ground network for your design by connecting the power, ground, and tie-off pins to the power and ground nets in your design.

The command supports two modes: automatic mode and manual mode.

In automatic mode, the tool derives the power and ground nets from the power domain connections. UPF must be committed before running **connect_pg_net** in automatic mode. In addition, automatic mode requires logic libraries with power and ground pins. In automatic mode, the tool creates the power and ground nets if they do not already exist.

In manual mode, use **-net** option to specify the power and ground nets. Using **-net** option invokes the tool in manual mode. You can use manual mode for single-voltage or multivoltage designs.

EXAMPLES

The following example uses the **connect_pg_net** command in automatic mode to connect all unconnected power and ground pins based on the power domain connections.

```
prompt> connect_pg_net -automatic

****************************************
Report : Power/Ground Connection Summary
Design : TOP
Version: N-2017.09-SP6-VAL
Date   : Tue Jun 19 02:45:44 2018
****************************************
P/G net name                          P/G pin count(previous/current)
--------------------------------------------------------------------------------
Power net VDD1SD                          0/8
Power net VDD3                           0/6
Power net VDD2                           0/6
Power net VDD1                           0/0
Unconnected nwell pins                    20
```

```
Ground net VSS                          0/20
Unconnected pwell pins                    20
--------------------------------------------------------------------------------
Information: connections of 40 power/ground pin(s) are created or changed.
```

The following example uses the **connect_pg_net** command in manual mode to connect power pin vdd_io on cell I_PAD1 to power net VDD_IO. The command also connects power pin vdd_core on the same cell to power net VDD_CORE.

```
prompt> connect_pg_net -net VDD_IO   [get_pins I_PAD1/vdd_io]
prompt> connect_pg_net -net VDD_CORE [get_pins I_PAD1/vdd_core]
```

SEE ALSO

commit_upf(2)

connect_pg_via_ladders

Connect via ladders to closest PG straps.

SYNTAX

status **connect_pg_via_ladders**
[-nets *pg_nets*]
[-cells *instances*]
[-pins *pins*]
[-target_layer string]
[-target_shapes *shapes*]
[-ignore_drc]
[-tag string]
[-via_masters *via_masters*]
[-shape_use *shape_use*]
[-number_of_targets integer]
[-max_extension *distance*]

Data Types

pg_nets string or list of string
instances collection
shape_use string
pins collection
shapes collection
via_masters string or list of string
distance float

ARGUMENTS

-nets *pg_nets*

Specifies the power ground nets to be connected. -nets must be used together with -cells. -nets is exclusive with -pins.

-cells *instances*

Specifies the instances to be connected. Tool only makes connection of instances having via ladders created for corresponding pins. -cells must be used together with -nets. -cells is exclusive with -pins.

-pins *pins*

Specified the pins to be connected. Tool only makes connection of pins with which via ladders associated. -pins is exclusive with -cells and -pins.

-target_layer string

Specifies the target layer on which power straps should be connected.

-target_shapes *shapes*

Specifies a collection of shapes which the via ladders should be connected to.

-ignore_drc

Specifies if drc should be checked for the connection.

-tag string

Specifies the tag info for created PG shapes/vias.

-shape_use *shape_use*

Specified the shape use of created PG shapes/vias. By default it is stripe

-via_masters *via_masters*

Specifies the via masters to be used for via ladder connection. If not specified, default contact code will be used.

-number_of_targets integer

Specifies the number of straps to which the via ladder should connect. If not specified, only one connection will be made for each via ladder.

-max_extension distance

Specifies the maximum extension of the via ladder to make connection. If not specified, the range is not limited. If max extension is specified, the command will try all the targets within the range, in the order of distance, until the number of connections specified by -number_of_targets is met. If max extension is not specified, the command only tries the number of targets specified by -number_of_targets, no matter if a connection can be made successfully or not.

DESCRIPTION

This command tries to connect top level shape of via ladders to existing PG mesh. It will only use straight connections. As a result, there might be via ladders left open.

EXAMPLES

The following example make via ladders of secondary pg pins vdd_ron to PG straps on M5.

prompt> **connect_pg_via_ladders -nets vdd_ron -cells $cell_collection -target_layer M5**

SEE ALSO

compile_pg(2)
route_group(2)

connect_pins

Connects a set of pins together across hierarchy.

SYNTAX

int **connect_pins**
-incremental
-non_incremental
-driver *pin*
-port_name *port_name*
loads

Data Types

pin collection
port_name string
loads list

ARGUMENTS

-incremental

Make the operation incremental. The driver pin must be connected to a net otherwise the option does not have any effect. Any existing loads on the net connected to the driver pin are preserved. Please note that connect_pins behavior defaults to -incremental usage, therefore explicit use of -incremental is not required.

-driver *pin*

Specifies the driving pin of the network. It can be a name or collection. The pin must exist in the current design.

-port_name *port_name*

Specifies the base name to use as the name of new ports that are created on subdesigns to make the connection.

loads

Specifies a list of ports and pins to which the driving pin is to be connected. The ports and pins must exist in the current design.

-non_incremental

Make the operation non-incremental. If a specified load port or pin is already connected to something else, it will be disconnected and then connected to the driving pin.

DESCRIPTION

This command connects a set of pins together, possibly across several levels of hierarchy. Ports and nets are created as needed to cross hierarchy. Existing nets and ports may be reused to complete a connection.

The number of connected load ports and pins are returned.

To disconnect objects on a net, use the **disconnect_net** command. To display ports and pins on a net, use the **all_connected** command.

EXAMPLES

The following example connects a the driving pin u20/ZN to a number of input pins across several levels of hierarchy. The **getPins** command then returns the list of pins connected across the hierarchy.

```
prompt> connect_pins -driver u20/ZN {u21/I u1/u22/I u2/u23/I u4/u2/u24/I u2/u2/u2/u25/I}}

5

prompt> get_pins -leaf -of_objects [get_nets -of [get_pins u20/ZN]]

u1/u22/I u2/u2/u2/u25/I u2/u23/I u20/ZN u21/I u4/u2/u24/I
```

get_pins(2)

connect_power_switch

Connects the pins of the power switch cells in the design.

SYNTAX

int **connect_power_switch**
-source *object*
-port_name *port_name*
-mode hfn | daisy | fishbone | clustering | shortest
[-ack_out *object*]
[-ack_port_name *port_name*]
[-direction <horizontal | vertical>*]
[-start_point <lower_left | upper_left | lower_right | upper_right>*]
[-ring_direction clockwise | counter_clockwise]
[-lib_pin *library_pin_names*]
[-voltage_area *voltage_areas*]
[-object_list *objects*]
[-keep_order]
[-fine_grained_lib_pins *library_pin_pairs*]
[-connect_sleep_and_ack_in_shared_domains]

Data Types

object string
port_name string
library_pin_names list
voltage_areas list
objects collection
library_pin_pairs list

ARGUMENTS

-source *object*

Specifies the pin or port from which to connect. The direction of the pin or port cannot be inout. In clustering mode, this option supports a collection of pins and ports.

-port_name *port_name*

Specifies the base name to use as names of switch ports when a new port is created on the subdesigns to make the connection. It is a required option.

-mode hfn | **daisy** | **fishbone** | **clustering** | **shortest**

Specifies whether the switch connections are to be made in high fanout, daisy , fishbone, clustering, or shortest style. It is a

required option.

-ack_out *object*

Specifies the pin or port that is to be used as acknowledge-out connection. It is optional and is only allowed with **-mode daisy** or **-mode fishbone**.

-ack_port_name *port_name*

Specifies the base name to use as names of acknowledge ports when a new port is created. This is required with the **-ack_out** option in **-mode daisy** or **-mode fishbone**.

-direction <horizontal | vertical>*

Specifies the direction for the daisy and fishbone connections. Requires **-mode daisy** or **-mode fishbone**. It is used only when the tool tries to infer the daisy chain direction based on the instantiated switch cell locations. This option can also be used to specify the direction of connections for branches connected to the main trunk in **-mode fishbone**.

If **-mode daisy** and multiple **-object_list** are specified, **-direction** can take a list of values, one for each object list, to specify the connection direction for power switch cells in each object list. If there are more **-object_list** than the number of values listed in **-direction**, the last value in **-direction** will be used as the connection direction for the rest of the object lists.

-start_point lower_left | upper_left | lower_right | upper_right

Specifies the starting point for the daisy mode connections. Requires **-mode daisy** or **-mode fishbone**. It is used to infer the startpoint for daisy or fishbone connections. This is helpful in connecting the source pin to the nearest starting switch cell. For fishbone connections, this option determines the starting point for the trunk of fishbone connections. This option can only be used with **-direction**. This is not a required option.

If **-mode daisy** and multiple **-object_list** are specified, **-start_point** can take a list of values, one for each object list, to specify the starting position for power switch cells in each object list. If there are more **-object_list** than the number of values listed in **-start_point**, the last value in **-start_point** will be used as the startng point for the rest of the object lists.

-ring_direction clockwise | counter_clockwise

Specifies the direction for Ring style switch placement. Now this option can support switches inserted using **create_power_switch_ring** or by other non-SNPS tool. When this option is specified with **-direction**, the **-direction** will be ignored. And this option supports **daisy** mode only.

-lib_pin *library_pin_names*

Specifies the list of library input and output pins that should be used in all the connections modes. This is a required option for switch cells that have multiple switch and acknowledge pins. The command issues an error message if a switch cell with multiple input or output is used but does not have its library pins specified in this option.

-voltage_area *voltage_areas*

Specifies the voltage areas. The command tries to collect the switches in the specified voltage area and connect them. This command supports both single shape and disjoint voltage areas.

-object_list *objects*

Specifies the list of cells on which to perform the connections. If **-mode daisy** or **-mode fishbone** is specified, the tool will automatically sort the object list to do the connections.

If **-mode daisy** is specified, multiple **-object_list** are allowed. In this setting, the relative order of power switch cells in different **-object_list** will be maintained while power switch cells in the same **-object_list** will be sorted. For example, if sw1 is in the first **-object_list** and sw2 is in the second **-object_list**, sw1 will always appear before sw2 in the final power switch chain.

-keep_order

Specifies whether to keep the order of power switch cells you specify with -object_list option. It only works for **-mode daisy**. You cannot specify -keep_order for **-mode hfn** or **-mode fishbone**. Without -keep_order option, tool will sort power switch cells automatically.

-fine_grained_lib_pins ***library_pin_pairs***

Specifies the list of sleep and ack library pin pairs of fine-grained macro cells. This option can only be used with **-connect_sleep_and_ack_in_shared_domains**.

-connect_sleep_and_ack_in_shared_domains

When this command option is specified, the tool will connect the sleep input and ack output of other shared power domains if they are unconnected. The ack output specified in the '-ack_port' command option will be connected to and drive the control inputs and ack outputs of other shared power domains in daisy-chain fashion.

DESCRIPTION

The **connect_power_switch** command connects control and ack_out pins of power switch cells that are instantiated and placed in the design. Connection modes and ordering for the switches are specified by options. The command can identify the switch cells in the design based on Liberty syntax and can connect them in either high-fanout, daisy-chain or fishbone style.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples showcase the command usage:

```
prompt> connect_power_switch \
   -source enable \
   -port_name enable_va_0 \
   -mode daisy \
   -direction horizontal \
   -voltage_area voltage_area_2
1
prompt> connect_power_switch \
   -source enable \
   -port_name enable_va_0 \
   -mode daisy \
   -direction horizontal \
   -object_list $switch_list1 \
   -start_point lower_right
1
prompt> connect_power_switch \
   -source enable \
   -port_name enable_va_0 \
   -mode fishbone \
   -direction horizontal \
   -object_list $switch_list1
```

```
1
prompt> connect_power_switch \
   -source enable \
   -port_name enable_va_0 \
   -mode daisy \
   -direction horizontal \
   -lib_pin {lib1/header32/SLEEP1 lib1/header32/SLEEPOUT1}
   -object_list {Header_switch1 Header_switch100}
1
prompt> connect_power_switch \
   -source [get_pins {BUF1/Y BUF2/Y}] \
   -port_name enable_va_0 \
   -mode clustering \
   -object_list [get_cells {Header_switch*}]
1
prompt> connect_power_switch \
   -source mult_on \
   -port_name mult_on_test \
   -mode daisy \
   -ring_direction clockwise \
   -voltage_area [get_voltage_areas InstDecode/PD]
1
prompt> connect_power_switch \
   -source enable \
   -port_name enable_va_0 \
   -ack_out enable_out \
   -ack_port_name enable_out_va_0 \
   -mode daisy \
   -direction {horizontal vertical horizontal} \
   -start_point {lower_right lower_left lower_right} \
   -object_list $switch_list1 \
   -object_list $switch_list2 \
   -object_list $switch_list3
1
```

connect_supply_net

Connects the supply net to the specified supply ports and pins.

SYNTAX

status **connect_supply_net**
supply_net_name
-ports *list*
-vct *vct_name*

Data Types

supply_net_name string
list list
vct_name string

ARGUMENTS

supply_net_name

Specifies the name of the supply net to connect. If a supply net with the specified name does not exist in the current scope, the supply net cannot be connected. This is a required option and must be specified.

-ports *list*

Specifies which supply ports and pins to connect to the supply net. The name is a hierarchical name.

-vct *vct_name*

Specifies the value conversion table (VCT) to be used in this connection. A value conversion table (VCT) defining how values are mapped from UPF to an HDL model or from the HDL model to UPF.

The tool supports the following 14 predefined VCT names: UPF2VHDL_SL, UPF_GNDZERO2VHDL_SL, UPF2SV_LOGIC, UPF_GNDZERO2SV_LOGIC, VHDL_TIED_HI, SV_TIED_HI, VHDL_TIED_LO, SV_TIED_LO, VHDL_SL2UPF, VHDL_SL2UPF_GNDZERO, SV_LOGIC2UPF, SV_LOGIC2UPF_GNDZERO, SV_LOGIC2UPF_MD, and SV_LOGIC2UPF_GNDZERO_MD.

The tool also support user defined vcts created by **create_hdl2upf_vct** and *create_upf2hdl_vct*.

DESCRIPTION

The **connect_supply_net** command connects a supply net to any supply port or pin. The command overrides (has higher

precedence than) any auto-connection semantics that might otherwise apply. If a design element is not connected explicitly to any supply net using the **connect_supply_net** command, it will share the primary power or ground supply net with the power domain that it belongs to.

The supply net must be created in the same power domain as the supply port, before they can be connected. The instance that contains the pin must also be in the extent of the same power_domain. If the specified supply net or port or pin is not in the extent of same power domain, this command fails.

This command returns 1 on success, returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example connects a supply net VSS with supply port VSS:

```
prompt> create_power_domain PD1 -elements INST_1
PD1
prompt> create_supply_net VSS -domain PD1
VSS
prompt> create_supply_port VSS -domain PD1
VSS
prompt> connect_supply_net VSS -ports VSS
1
```

convert_aocv_pocv

Converts AOCV derating factor tables to POCV coefficient tables.

SYNTAX

status **convert_aocv_pocv**
[-depth *depth_row*]
[-corners *corner_list*]

Data Types

depth_row integer
corner_list list

ARGUMENTS

-depth *depth_row*

Specifies to use the *depth_row* entry in the AOCV table to do the conversion. By default, the first entry of the depth row in the AOCV table is used.

-corners *corner_list*

Indicates the list of corners for which the AOCV derate factors are to be converted and the converted POCV coefficients are to be applied. If this option is not provided, the corner associated with the current scenario is used.

DESCRIPTION

This command converts AOCV tables annotated on design objects (previously loaded by **read_ocvm** command) to POCV tables and applies the converted POCV tables onto the same design object.

The AOCV to POCV conversion is based on the following equation.

POCV_coefficient_late = (AOCV_derate - 1) / 3
POCV_coefficient_early = (1 - AOCV_derate) / 3

In the above equation, AOCV_derate refers to the *depth_row* entry in the AOCV table. If the AOCV table has distance information, the worst-case distance is used.

One advantage of using this command is reducing the pessimism in AOCV GBA analysis.

To report the converted POCV tables, use **report_ocvm** command. To remove the converted POCV tables, use **remove_ocvm**

command.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the **-corners** option.

EXAMPLES

The following example converts the AOCV tables for corner1.

```
prompt> convert_aocv_pocv -corners corner1
```

SEE ALSO

read_ocvm(2)
report_ocvm(2)
remove_ocvm(2)

convert_shape_patterns_to_shapes

Converts shape_patterns to shapes in the current design.

SYNTAX

collection **convert_shape_patterns_to_shapes**
[-verbose]
[-force]
shape_pattern_list

Data Types

shape_pattern_list collection

ARGUMENTS

-verbose

Display additional debugging information.

-force

Ignore the locked status of objects. If this option is not provided and any of the affected objects has locked status, the command will generate a Tcl error and exit.

shape_pattern_list

Specifies a list of shape_patterns to convert and replace with shapes. The list can contain shape_pattern collections specified with the **get_shape_patterns** command.

DESCRIPTION

This command creates new shapes to replace the specified shape_patterns and returns a collection containing the new shapes.

Upon success the specified shape_patterns would be removed and their replacement shapes created by this command are returned.

EXAMPLES

The following example converts a shape_pattern to shapes.

```
prompt> convert_shape_patterns_to_shapes [get_shape_patterns RECT_PATTERN_31_0]
{RECT_31_1829 RECT_31_1830 RECT_31_1831 RECT_31_1832}
```

SEE ALSO

create_shape(2)
get_shape_patterns(2)
get_shapes(2)
remove_shape_patterns(2)
remove_shapes(2)

convert_shapes_to_shape_pattern

Converts shapes to shape patterns in the current design.

SYNTAX

collection **convert_shapes_to_shape_pattern**
[-base_shape *shape*]
[-m_displacement *delta*]
[-n_displacement *delta*]
[-verbose]
[-force]
[-shapes *shapes*]
[-region *geometry*]
[-layers *layers*]
[shape_list]

Data Types

base_shape collection
delta distance:direction | {x-distance:x-direction
y-distance:y-direction}
distance float
direction string
shapes collection
geometry collection
layers collection
shape_list collection

ARGUMENTS

-base_shape

Specifies the shape in the input list that should be used as the base_shape at the first (0,0) position.

-m_displacement

Specifies the uniform offset in first dimension.

-n_displacement

Specifies the uniform offset in second dimension.

-verbose

Display additional debugging information.

-force

Ignores the locked status of objects. If this option is not provided and any of the affected objects has locked status, command will generate a Tcl error and exit.

-shapes *shapes*

Specifies a list of shapes to convert and replace with shape patterns. The list can contain shape collections specified with the **get_shapes** command. The option "**shapes**" is mutually exclusive with "**region**", "**layers**" and "**shape_list**".

-region *geometry*

Specifies a list of regions to get shapes and convert and replace them with shape patterns. The option "**region**" is mutually exclusive with "**shapes**", "**layers**" and "**shape_list**".

-layers *layers*

Specifies a list of layers to get shapes and convert and replace them with shape patterns. The option "**layers**" is mutually exclusive with "**shapes**", "**region**" and "**shape_list**".

shape_list

Specifies a list of shapes to convert and replace with shape patterns. The list can contain shape collections specified with the **get_shapes** command. The option "**shape_list**" is mutually exclusive with "**shapes**", "**region**" and "**layers**".

DESCRIPTION

This command creates new shape patterns to replace the specified shapes and returns a collection containing the new shape patterns.

If the optional option *shape_list* is specified, all input shapes must have the same shape_type, owner net and uniform spacing. In case the order of shapes in input collection is different from the expected positional order of the shapes in the converted shape_pattern, the base_shape must be specified to guide the conversion. In case of non-uniform spacing between the input shapes caused by the absence of shape at any position, the user must provide the expected uniform spacing in both dimensions to guide the conversion. The tool would error violation of these requirements and abort the conversion.

The option "**shapes**" and "**layers**" and "**region**" are mutually exclusive with "**shape_list**" and useful for auto detection of via matrixes.

EXAMPLES

The following example converts all shapes to shape patterns.

```
prompt> convert_shapes_to_shape_pattern -shapes [get_shapes]
{RECT_PATTERN_31_0 RECT_PATTERN_31_1}
```

The following example converts specified shapes to a shape pattern.

```
prompt> convert_shapes_to_shape_pattern [get_shapes \
            -filter {shape_type==rect && layer_name==M1}]
{RECT_PATTERN_31_0}
```

The following example converts shapes to a shape_pattern where the last shape in the input collection is used as the base_shape and the uniform displacements are specified to guide the conversion to shape_pattern with unoccupied (hole) positions.

```
prompt> convert_shapes_to_shape_pattern \
            -base_shape [index_collection [get_shapes] end] \
            -m_displacement {50:north} \
            -n_displacement {20:east} \
            [get_shapes -filter {shape_type==rect && layer_name==M1}]
{RECT_PATTERN_31_0}
```

SEE ALSO

convert_via_matrixes_to_vias

Converts via matrixes to vias in the current design.

SYNTAX

collection **convert_via_matrixes_to_vias**
[-verbose]
[-force]
via_matrix_list

Data Types

via_matrix_list collection

ARGUMENTS

-verbose

Display additional debugging information.

-force

Ignore the locked status of objects. If this option is not provided and any of the affected objects has locked status, the command will generate a Tcl error and exit.

via_matrix_list

Specifies a list of via matrixes to convert and replace with vias. The list can contain via matrix collections specified with the **get_via_matrixes** command.

DESCRIPTION

This command creates new vias to replace the specified via matrixes and returns a collection containing the new vias.

Upon success the specified via matrixes would be removed and their replacement vias created by this command are returned.

EXAMPLES

The following example converts a via matrix to vias.

```
prompt> convert_via_matrixes_to_vias [get_via_matrixes VIA_MATRIX_0]
{VIA_S_0 VIA_S_1 VIA_S_2 VIA_S_3 VIA_S_4 VIA_S_5}
```

SEE ALSO

create_via(2)
get_via_matrixes(2)
get_vias(2)
remove_via_matrixes(2)
remove_vias(2)

convert_vias_to_via_matrix

Converts vias to via matrixes in the current design.

SYNTAX

collection **convert_vias_to_via_matrix**
[-verbose]
[-force]
[-vias *vias*]
[-region *geometry*]
[-via_defs *via_defs*]
via_list

Data Types

via_list collection
vias collection
geometry collection
via_defs collection

ARGUMENTS

-verbose

Display additional debugging information.

-force

Ignores the locked status of objects. If this option is not provided and any of the affected objects has locked status, command will generate a Tcl error and exit.

via_list

Specifies a list of vias to convert and replace with a via matrix. The list can contain via collections specified with the **get_vias** command. The option "**via_list**" is mutually exclusive with "**vias**", "**region**" and "**via_defs**".

-vias *vias*

Specifies a list of vias to convert and replace with via matrixes. The list can contain via collections specified with the **get_vias** command. The option "**vias**" is mutually exclusive with "**via_list**", "**region**" and "**via_defs**".

-region *geometry*

Specifies a list of regions to get vias and convert and replace them with via matrixes. The option "**region**" is mutually exclusive with "**via_list**", "**vias**" and "**via_defs**".

-via_defs ***via_defs***

Specifies a list of via_defs to get vias and convert and replace them with via matrixes. The option "**via_defs**" is mutually exclusive with "**via_list**", "**vias**" and "**region**"

DESCRIPTION

This command creates new via matrixes to replace the specified vias and returns a collection containing the new via matrixes. If the optional option *via_list* is specified, the specified vias must be of the same via_def and via_type because the base via of the via matrix can be one of a simple, simple array, or custom via. If the specified vias don't have matching attributes for conversion to base via representation of a via matrix, the command would fail retaining the specified vias.

Upon success the specified vias would be removed and their replacement via matrix created by this command is returned. The option "**vias**" and "**via_defs**" and "**region**" are mutually exclusive with "**via_list**" and useful for auto detection of via matrixes.

EXAMPLES

The following example converts vias to a via matrix with a base simple via.

```
prompt> convert_vias_to_via_matrix [get_vias -filter {via_def_name==VIA23 && via_type==simple_via}]
{VIA_MATRIX_0}
```

The following example converts all vias to via matrixes.

```
prompt> convert_vias_to_via_matrix -vias [get_vias]
{VIA_MATRIX_0 VIA_MATRIX_1}
```

copy_block

Copies a block to a new block in the same or a different library and view

SYNTAX

collection **copy_block**
[-force]
[-from_block *source_block*]
-to_block *destination_block*

Data Types

source_block string
destination_block string

ARGUMENTS

-force

Forces overwrite of the block specified by -to_block *block_name*. This option is used when the destination is open and modified but not yet saved.

-from_block *source_block*

Specifies the source block name with optional library, label, and view specifications. The *source_block* specification is as follows:

[libName:]blockName[/labelName][.viewName]

or a collection of one block. If the library specification is not present, the current library is used. If label specification is not present, then the default label is used. If the view specification is not present, the design view is used. By default, the **current_block** is used as the source.

-to_block *destination_block*

Specifies the destination block name with optional library and view specifications. The *destination_block* specification is as follows:

[libName:]blockName[/labelName][.viewName]

If the library, block, or view specifications are not present, the values from the source block are used. This option is required.

DESCRIPTION

This command copies a source block to a destination with the same or different library and block. The destination block will have a mode attribute with a value of "a" and the destination block can be further modified without any change in open mode. If you try to copy a block over itself, the command issues an error message. The command fails if the destination library is not present or is opened in read-only mode. The command also fails if the destination block is open and has been modified but not saved and the **-force** option is omitted. The command also fails if you specify an illegal name for the source or destination library, block, or view. If successful, the destination block is returned.

This command returns the block if successful, or O if not. If an illegal name is given for the source or destination block names, a Tcl error is raised.

When no view is explicitly specified for both source and destination then all available views of source block are copied into destination block and the design view of destination block is returned.

A given source block view can't be copied into a different destination block view, like a design view can't be copied to an abstract view. An error is issued while trying to do such operation.

The copied destination block is by default available in memory only. This behavior can be controlled using app option **design.on_disk_operation** where setting the app option to true means copied destination block will be saved to disk.

The copied destination block doesn't become the current block. It needs to be explicitly set.

EXAMPLES

This example copies block *Top* in library *lib* to block *Top2* in same library for subsequent block exploration. The destination library and view are taken from the original block.

```
prompt> copy_block -from_block lib:Top -to_block Top2
{"lib:Top2.design"}
prompt> current_block lib:Top2
```

If library *lib* is already open and is current library then using *-from_block Top* and *current_block Top2* in above example is sufficient.

This example copies a block *Top* in current library into a different existing library MyOtherDesigns for subsequent block exploration.

```
prompt> copy_block -from_block Top -to_block MyOtherDesigns:Top
{"MyOtherDesigns:Top.design"}
prompt> current_block MyOtherDesigns:Top
```

This example copies a block *Top* in current library into a different existing library MyOtherDesigns with a different name *Top2* and saves it to disk.

```
prompt> set_app_options -name design.on_disk_operation -value true
prompt> copy_block -from_block Top -to_block MyOtherDesigns:Top2
Information: Saving block 'MyOtherDesigns:Top2.design'
{"MyOtherDesigns:Top2.design"}
```

copy_busplan

Copy specified parts of busplan.

SYNTAX

int **copy_busplan**

[-from_start *element*]
[-from_end *elements*]
[-to_start *element*]
[-to_end *elements*]
[-from *bus*]

Data Types

element bus elements
elements collection of bus elements
bus bus

ARGUMENTS

-from_start *element*

Specify the starting bus element to copy from. This is mutually exclusive with -from.

-from_end *elements*

Specify the ending bus elements to copy from. This is mutually exclusive with -from.

-to_start *element*

Specify the starting bus element to copy to. This is mutually exclusive with -from.

-to_end *elements*

Specify the ending bus elements to copy to. This is mutually exclusive with -from.

-from *bus*

Specify the busplan to copy from. This will automatically determine the parts of the bus going through MIBs. It will determine the other MIB instances and the buses going through the other MIB instances. It will then copy the MIB section from the given bus to the other buses.

Note that all the buses must all be MIB port compliant. This means that all the buses must use the same ports in the MIB. For example suppose there are 2 MIBS, B1 and B2, and if there is feedthrough bus element corresponding to the ports B1/data[0..10] and there is a feedthrough bus element corresponding to the ports B2/data[0..10]. Then in this case these 2 MIB bus port sets are

MIB port compliant. On the other hand if the feedthrough bus element is different, eg, corresponding to the ports B2/data[0..9] then that is not MIB port compliant.

DESCRIPTION

Copy busplan virtual pins, virtual registers, and location information. There are 2 mechanisms. First, it can be used to copy sub-sections of buses. Using the 4 options, "-from_start *element*", "-from_end *elements*", "-to_start *element*", "-to_end *elements*" a from sub-section and to sub-section can be defined. Then copy will copy from the from sub-section to the to sub-section.

A second mechanism is using option "-from *bus*" and this is used to ensure busplans inside MIBs are the same.

EXAMPLES

This example shows copying a section of bus bus1 to another bus, bus2. The section of bus1 to copy is starting from bus element bus1:group2 and going to bus1:group3. This section will be copied to the section of bus2 starting from bus element bus2:group3 and going to bus2:group4.

```
prompt> copy_busplan -from_start [filter_collection \
  [get_attribute [get_busplan bus1] elements] name==group2] \
  -from_end [filter_collection \
    [get_attribute [get_busplan bus1] elements] name==group3] \
  -to_start [filter_collection \
    [get_attribute [get_busplan bus2] elements] name==group3] \
  -to_end [filter_collection \
    [get_attribute [get_busplan bus2] elements] name==group4]
1
```

SEE ALSO

create_busplans(2)
set_net_estimation_rule(2)

copy_collection

Duplicates the contents of a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

collection **copy_collection**
collection1

Data Types

collection1 collection

ARGUMENTS

collection1

Specifies the collection to be copied. If an empty string is used for the *collection1* argument, the command returns the empty string (a copy of the empty collection is an empty collection).

DESCRIPTION

This command is no longer needed and is provided only to make old scripts work without modification.

EXAMPLES

The following example from PrimeTime shows the result of copying a collection. Functionally, it is not much different that having multiple references to the same collection, except it is slower.

```
pt_shell> set c1 [get_cells "U1*"]
{"U1", "U10", "U11", "U12"}
pt_shell> set c2 [copy_collection $c1]
{"U1", "U10", "U11", "U12"}
pt_shell> unset c1
pt_shell> query_objects $c2
{"U1", "U10", "U11", "U12"}
```

SEE ALSO

collections(2)

copy_floorplan

Copies the floorplan data from the design view of source design label to the design view of the target design label in the same or a different library.

SYNTAX

collection **copy_floorplan**
[-to_block *top_block*]
-from_block *from_top_block*
[-objects *objects*]
[-include *include_list*]
[-exclude *exclude_list*]
[-hierarchical]
[-force]
[-verbose]

Data Types

top_block	string
from_top_block	string
objects	collection
include_list	list
exclude_list	list

ARGUMENTS

-force

Forces copying of those floorplan objects of source block to the destination block even if they already exist. To check existing floorplan objects, names are matched. In the default mode, matching objects are not copied.

-from_block *from_top_block*

Specifies the source design label name with optional library, block and label specifications. The *from_top_block* specification is as follows:

[libName:]blockName[/labelName]

If the library specification is not present, the current library is used. If label specification is not present, then the default label is used. This is a required option.

-to_block *top_block*

Specifies the destination design label name with optional library and label specifications. The *top_block* specification is as follows:

[libName:]blockName[/labelName]

If the library, block, or label specifications are not present, the values from the source block are used. By default, the **current_block** is used as the destination.

-include ***include_list***

Specifies the types of floorplan data to copied to the output design view. This option cannot be specified together with the **-exclude** or **-objects** options. If this option is not specified, all types are included by default.

The supported types are:

- blockages
- bounds
- cells
- corridors
- die_area
- edit_groups
- io_guides
- macros
- module_boundaries
- pin_guides
- pins
- route_guides
- rows
- tracks
- vias
- scan_chains
- routing_directions
- voltage_areas
- fills
- pg_metal_fills
- routing_rules
- pg_regions
- port
- supernet
- bundle
- topology_plan

Specify **-include macros** to output only macro cells and skip standard cells. Specify **-include cells** to output all cells.

-exclude *exclude_list*

Specifies the types of data to exclude from the output. This option cannot be specified with the **-include** option or **-objects** options. If this option is specified, the command writes all types, except the types specified in *exclude_list*. The allowed data types are the same as for the **-include** option.

-objects *objects*

Specifies the floorplan objects to be copied to the destination design view. Supported object types are:

- "block"
- "design"
- "routing_blockage"
- "shaping_blockage"
- "placement_blockage"
- "bound"
- "cell"
- "routing_corridor"
- "core_area"
- "edit_group"
- "fill_cell"
- "io_guide"
- "io_guide"
- "via"
- "shape"
- "net"
- "pin_guide"
- "pg_region"
- "routing_guide"
- "site_row"
- "site_array"
- "track"
- "voltage_area"
- "routing_rule"
- "port"
- "supernet"

- "bundle"
- "topology_plan"

-verbose

This option enables display of verbose messages.

-hierarchical

This option enables copying of the floorplan objects hierarchically. This option is mutually exclusive with "*-objects*".

DESCRIPTION

This command copies the floorplan data from the design view of source design label to the design view of the target design label with the same or different library and block. The command fails if the destination library is not open or is opened in read-only mode. The command also fails if you specify an illegal name for the source or destination design label or if the design view is not available for a particular design label. If successful, the destination block is returned.

This command returns the block if successful, or O if not. If an illegal name is given for the source or destination block names, a Tcl error is raised.

The operation happens only between design views. If the destination design is not specified, the current block is used as the destination design if the view is design view.

The command only copies the floorplan objects which exist in the source but not in the destination. To find whether a particular floorplan object exists, the name is matched. If the name of a particular floorplan object already exists, the object is skipped and is not copied. This can be overriden by specifying the **-force** option.

EXAMPLES

This example copies floorplan data of design view of design label *Top* to design view of block *Top2*. Only the floorplan objects not present in Top2 are copied.

```
prompt> copy_floorplan -from_block lib:Top/place_opt -to_block lib:Top2/place_opt
{"lib:Top2.design"}
```

This example copies a block Top into a new library MyOtherDesigns. Only the floorplan objects not present in Top2 are copied MyOtherDesigns:TOP\place_opt.

```
prompt> copy_floorplan -from_block lib:Top/place_opt -to_block MyOtherDesigns:TOP\place_opt

{"MyOtherDesigns:Top.design"}
```

SEE ALSO

get_blocks(2)

open_lib(2)
remove_blocks(2)
reopen_block(2)
copy_block(2)
save_block(2)

copy_lib

Copies one or more design libraries from one location to another.

SYNTAX

collection **copy_lib**
[-force]
[-merge | -no_designs]
[-from_lib *source_name*]
-to_lib *destination_name*

Data Types

source_name collection
destination_name string

ARGUMENTS

-force

Overwrites the destination library when the library is modified but not yet saved. If this option is not specified, the command stops and issues an error message if the library is modified but not yet saved.

-merge

Merges the source library into the destination library. This option is used for incremental update. Normally, the destination library is (re)initialized before the copy begins. This option can be used only if both the source and destination libraries are design libraries. Note that lib-cell libraries cannot be merged, and library attributes, technology, and parasitic_tech data are not merged. If the destination library does not already contain technology or parasitic_tech data, the command copies the technology or tech_parasitic data from the source library to the destination library. Only libraries with compatible technology can be merged, and the command performs a technology compatibility test if both the source and destination libraries contain technology sections. The **-merge** option fails if the source and destination technologies are incompatible.

-no_designs

Copies the source library to the destination library, without copying the designs in the source library. This option is mutually exclusive with the **-merge** option. The command copies the library attributes, ref_lib list, view_switch list, technology, and parasitic_tech from the source library without copying any of the designs. This option is useful when splitting a source library that contains subblocks into a separate destination libraries that each contain a subblock.

-from_lib *source_name*

Specifies the source library. You can specify either a list of library names or a collection of libraries. If you specify a list or collection of multiple libraries, the designs in each library are copied to the destination library. If there are duplicate designs in the source libraries, the design from the first library in the list that contains the duplicate is copied to the destination library. If the **-**

no_designs option is used, the **-from_lib** option must contain a single library. If this option is not specified, the command uses the current library. Use the **current_lib** command to determine the current library.

-to_lib ***destination_name***

Specifies the destination library name.. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after he last '/' becomes the name of the library. It will be an error if the a library, file, or directory of the same name already exists on disk.

DESCRIPTION

This command copies one or more source libraries into a destination library. If technology data and a ref_lib list exists, they are copied as well. Note that the command fails if there are conflicts in technology data among the source libraries or between the source and destination libraries when the **-merge** option is used. When there are conflicts in design data, the data from the first library in the source list is used (or from the destination library if the **-merge** option is used and a conflict exists). Note that conflicts are resolved on the design level, not down to the view level. For example, if a source library has topLib1:Mid.timing and another source library has topLib2:Mid.design, only the first design is copied. The destination target is reinitialized (deleted) before the copy unless the **-merge** option is used. When the source and destination libraries contain a reference library list, the source reference list is appended to the target library and the duplicate entries are removed.

The command returns the library if successful, or 0 otherwise. If an illegal name is given, a Tcl error is raised.

Note that when overriding an existing library (without the **-merge** option), there is no automatic rebinding to the new design or technology data in the library. All original designs in the library are removed, and designs from other libraries that used to bind to those removed designs become unbound. Any other libraries or designs that used to bind to the technology data of the overridden library are also be unbound and are saved without a technology section.

It is also an error to copy (or merge) from (or into) lib-cell library. It is also an error to copy over a library that is opened for read-only, or to copy over a library that has unsaved and modified data without using the **-force** option.

EXAMPLES

The following example copies library lib1 into the library design_lib.

```
prompt> copy_lib -from_lib "lib1" -to_lib design_lib
{"design_lib"}
```

The following example copies the designs from lib1 and lib2 into the library top_lib.

```
prompt> copy_lib -from_lib "lib1 lib2" -to_lib top_lib
{"top_lib"}
```

The following example merges the designs from lib1 and lib2 into the library mid_lib, without reinitializing mid_lib

```
prompt> copy_lib -merge -from_lib "lib1 lib2" -to_lib mid_lib
{"mid_lib"}
```

The following example copies the technology and ref_lib list from lib1 to lib2 without copying the designs.

```
prompt> copy_lib -no_designs -from_lib "lib1" -to_lib lib2
{"lib2"}
```

copy_module

Copies a module in a design

SYNTAX

collection **copy_module**
[-design *design*]
-from *module*
-to *to_module*]
[-force]

Data Types

design string or collection
module string or collection
to_module string

ARGUMENTS

-design *design*

Specifies the design in which to copy the module. If not specified, then module is copied in the current design.

-from *module*

Specifies source module to be copied, as a string or collection. If specified as a string then it is searched in current design.

-to *to_module*

Specifies destination module name.

-force

Forces overwrite of the module specified by **-to** only if it is not the top module of its design and is not instantiated anywhere.

DESCRIPTION

This command copies a specified module to a destination design provided it doesn't already exist. If it already exists in destination then **-force** can be used to overwrite the module provided it is not instantiated anywhere and is not the top module.

A module is hierarchically copied over to the destination. Thus this command can result in copying over many modules into destination. If the module is copied over to a different library then it is checked that reference library of destination library is a subset

of reference library of source library. Otherwise the command will fail.

SEE ALSO

get_modules(2)
get_designs(2)
move_block(2)
remove_modules(2)

copy_objects

Copies specified objects and creates multiple copies if specified.

SYNTAX

status **copy_objects**
[*object_list*]
[-delta {*x y*}]
[-from {*x y*}]
[-to {*x y*}]
[-rotate_by *angle*]
[-group]
[-x_times *x_times*]
[-y_times *y_times*]
[-x_pitch *x_pitch*]
[-y_pitch *y_pitch*]
[-x_pitch_type gap | delta]
[-y_pitch_type gap | delta]
[-net *net*]

Data Types

object_list collection or selection
x float
y float
angle string
x_times integer
y_times integer
x_pitch float
y_pitch float
net collection

ARGUMENTS

object_list

Specifies a collection or selection set that contains objects to copy. If this option is not specified, the global selection set is used.

-delta {*x y*}

Specifies the distance in the x- and y-directions which to copy the objects from their current location. This option is mutually exclusive with the **-to** option.

-from {*x y*}

Specifies the reference point on the object, or the collection of objects to be copied, for the **-to** option. By default, the command uses the lower-left corner of the bounding box of the given object, or collection of objects, as the reference point. This option must be used together with the **-to** option.

-to {*x y*}

Specifies the new x- and y-location of the reference point for the object or objects. This option is mutually exclusive with the **-delta**.

-rotate_by *angle*

Specifies the rotation angle of the objects.

The valid values are:

0, **90**, **180**, **270**, **CW90**,
CW180, **CW270**, **CCW90**, **CCW180**, **CCW270**,
FLIPX, **FLIPY** **R0**, **R90**, **R180**,
R270, **MX**, **MXR90**, **MY**, **MYR90**

The rotation value definitions are:

CW90 : 90 degrees clockwise
CW180 : 180 degrees
CCW180 : 180 degrees
CW270 : 270 degrees clockwise
CCW90 : 90 degrees counterclockwise
CCW270 : 270 degrees counterclockwise
FLIPX : reflect about the x-axis
FLIPY : reflect about the y-axis

The following values are synonymous:

0, **R0**
90, **CCW90**, **R90**
180, **CCW180**, **R180**
270, **CCW270**, **R270**
FLIPX, **MY**
FLIPY, **MX**

-group

Specifies that the objects should rotate around a common pivot point. If omitted, the rotation is performed around the object centers.

-x_times *x_times*

Specifies the number of copies in x-direction.

-y_times *y_times*

Specifies the number of copies in y-direction.

-x_pitch *x_pitch*

Specifies the delta or gap in x-direction.

-y_pitch *y_pitch*

Specifies the delta or gap in y-direction.

-x_pitch_type gap | **delta**

Specifies the x pitch as delta or gap. Legal values are gap or delta.

-y_pitch_type gap | **delta**

Specifies the y pitch as delta or gap Legal values are gap or delta.

-net ***net***

Specifies the net for the copied object.

DESCRIPTION

This command copies one or more objects and returns a collection of the copies if input *object_list* is a collection of objects. Otherwise, the command adds copies in specified selection set and returns the status.

You can place the copies at a specific location or specify a delta from the location of the original object.

You can create multiple copies of each specified object, and you can specify the pitch between adjacent copies of the same object.

All the attributes of an original object are applied to its copies if possible.

EXAMPLES

The following example copies the selected object and places the copy 100 database units to the right and 200 database units above the original object:

prompt> **copy_objects -from {0 0} -to {100 200}**

The following example creates 8 copies of the selected object placed in a 2 by 4 grid with delta (100,100) and no space between the objects.

prompt> **copy_objects -from {0 0} -to {100 100} -x_times 2 -y_times 4**

The following example uses an alternative syntax to specify the objects.

prompt> **copy_objects [get_selection] -from {0 0} -to {100 100} -x_times 2 -y_times 4**

snap_objects(2)

copy_relative_placement

Copies the relative placement of macros.

SYNTAX

collection **copy_relative_placement**
-from *edit_group*
[-to *edit_group_list*]
[-to_cells *cell_list*]

Data Types

edit_group string
edit_group_list list
cell_list list

ARGUMENTS

-from *edit_group*

Specifies the edit group from which to copy the relative placement.

-to *edit_group_list*

Specifies a list of edit groups; relative placement will be copied to each edit group in the list.

-to_cells *cell_list*

Specifies a list of cells to which to copy the relative placement. The tool creates an edit group for these cells.

DESCRIPTION

This command copies macro relative locations from one edit group to another edit groups or a collection of macros. At least one of **-to** and **-to_cells** must be provided. Use this command to arrange the corresponding macros from similar modules in the same way. The command returns the collection of edit groups passed as **-to** argument and/or the edit group created for **-to_cells** argument.

EXAMPLES

The following example copies relative placement from edit group E1 to edit groups E2 and E3.

prompt> **copy_relative_placement -from [get_edit_groups E1] -to [get_edit_groups {E2 E3}]**

The following example copies relative placement from edit group E to the selected macros.

prompt> **copy_relative_placement -from [get_edit_groups E] -to_cells [get_selection]**

SEE ALSO

create_edit_group(2)

copy_to_layer

Create shapes on a layer corresponding to a geometric region.

SYNTAX

collection **copy_to_layer**
-layer *layer*
-geo_masks *geo_masks*
[-shape_use *use*]
[-net *net*]

Data Types

layer collection
geo_masks collection
use string
net collection

ARGUMENTS

-layer *layer*

Specifies the layer on which shapes should be created. There must be exactly one layer in this input collection.

This is a required option.

-geo_masks *geo_masks*

Specifies the objects that define the geometric region to be mapped to shapes on the specified layer. If the *shape_use* option is detail_route, one shape will be created on the layer for each contiguous poly-rectangular region contained in the collection of geo_masks. If the *shape_use* option is stripe, then one shape will be created on the layer for each rectangle in the rectangular decomposition (fracture) of the collection of geo_masks.

This is a required option.

-shape_use *use*

Specifies the usage of the shapes created by the command.

Valid values are

- **detail_route** (the default)
  Shapes are used for detail routed signal nets. They will be of type rect or polygon.

- **stripe**
  Shapes that belong to a power strap. They will be of type path.
- **pg_augmentation**
  Shapes for PG augmentation. They will be of type path.

-net ***net***

Specifies the net that will own the resulting shapes.

DESCRIPTION

This command creates shapes on the specified layer corresponding to a specified geometric region.

When the **shape_use** option is set to detail_route or is unspecified, then a shape will be created for each contiguous poly-rectangular region described by *geo_masks*. For each such region, if it is rectangular and manhattan-angled then a rectangle will be created, otherwise a polygon will be created.

When the **shape_use** option is set to stripe or pg_augmentation, then a path shape will be created for each rectangle in the rectangular decomposition (fracture) of the poly-rectangular region described by *geo_masks*. The orientation of the paths will match the routing_direction of the specified layer, or will be horizontal if the routing_direction is unknown.

The new shapes created are returned as a collection.

EXAMPLES

The following example creates a rectangle on a layer:

```
prompt> set pr [create_poly_rect -boundary {{0 0} {200 100}}]
{{{0.0000 0.0000} {200.0000 100.0000}}}
prompt> set new_shapes [copy_to_layer -layer [get_layers M1] \
  -geo_masks [create_geo_mask -objects $pr]]
{RECT_10_0}
```

cputime

Retrieves the overall user time associated with the current process.

SYNTAX

float **get_cputime**
  [-all]
  [-format]

string *format*

ARGUMENTS

all

If specified then it gives cpu time for this process and it's children.

format

This argument takes a *printf* style formatting string for a floating point number.

DESCRIPTION

The *get_cputime* command returns the accumulated user time, in seconds, for the current process. If the *format* string is omitted, an integer number of seconds is returned. If the format string is specified, a floating point number is returned. The number includes fractions of a second elapsed and is formatted in accordance with given specifier. Refer to the Unix man page for *printf* for a detailed description of how to format a floating point argument.

```
prompt> get_cputime "%g"
3.74
```

SEE ALSO

get_mem(2)

create_3d_mirror_bumps

Copies and places bumps and bump clusters or bond pads from the source die to the target die.

SYNTAX

status **create_3d_mirror_bumps**
-from *source_chip_name*
-to *target_chip_name*
[-ref_cell *lib_cell*]
[-prefix *prefix_name*]
[-bumps *bump_list*]
[-cluster_bump_mapping *pattern_cell_pair_list*]
[-bond_pad]
[-pins *pin_lis*]
[-force]

Data Types

source_chip_name string
target_chip_name string
lib_cell string
prefix_name string
bump_list list
pattern_cell_pair_list list
pin_lis list

ARGUMENTS

-from *source_chip_name*

Specifies the source chip as a master die. This option is required.

-to *target_chip_name*

Specifies the target chip as a slave die. This option is required.

-ref_cell *lib_cell*

Specifies the library cell. This option is required for bump and cannot be specified with the **-bond_pad** option.

-prefix *prefix_name*

Specifies the prefix of the target mirrored objects.

-bumps *bump_list*

Specifies the bump list in source chip to be mirrored. By default, all bumps are mirrored. This option cannot be specified with the **-bond_pad** option.

-cluster_bump_mapping ***pattern_cell_pair_list***

Specifies the bump cluster pattern cells in source chip and target chip. The pattern cell pair list is specified as {{source_pattern_cell target_pattern_cell} {} ...}. This option cannot be specified with the **-bond_pad** option.

-bond_pad

Mirrors bond pads from source chip to target chip.

-pins ***pin_list***

If source chip is a hard macro, this option can be used to specify the pin list in the source chip to be mirrored. By default, all pins will be mirrored if the source chip is a hard macro.

-force

Specifies whether to mirror the objects if there are overlaps.

DESCRIPTION

This command copies and places bumps and bump clusters or bond pads from the source die to the target die when the dies are stacked vertically.

EXAMPLES

The following example copies bump cells from chip "Logic" to chip "Interposer" with the library cell "UBUMP", using the prefix "synopsys".

```
prompt> create_3d_mirror_bumps -from Logic -to Interposer \
  -ref_cell UBUMP -prefix synopsys
```

The following example copies bump cluster which has pattern cell "BUMP8" from chip "Logic" to chip "Interposer" with pattern cell "BUMP4".

```
prompt> create_3d_mirror_bumps -from Logic -to Interposer \
  -cluster_bump_mapping {{BUMP8 BUMP4}}
```

SEE ALSO

set_cell_location(2)

create_3d_top_design

Creates a 3dic virtual top design.

SYNTAX

collection **create_3d_top_design**
[-force]
-max_dimensions *max_dimensions_list*
[-package_type *package_type*]
top_design_name

Data Types

max_dimensions_list list
package_type string
top_design_name string

ARGUMENTS

-force

Overwrites the block if one with the same name already exists in the current library.

-max_dimensions *max_dimensions_list*

Specifies the maximum allowed width and height of the package. This can be used to check if all 3DIC dies and the silicon interposer (if any) can fit into the package. The Z dimension is unlimited.

-package_type *package_type*

Specifies the type of the package substrate. The value can be one of: **fan_out**, **hybrid**, **interposer**,**stacked**, **unspecified**. The default is **unspecified**.

top_design_name

Specifies the top design name.

DESCRIPTION

The **create_3d_top_design** command creates a new block in the current library to be used as the top-level design. There is no manufacturing tape-out associated with this design. The design type of the new block is 3DIC.

EXAMPLES

The following example creates a new block named top in the current library created by **create_lib**.

```
prompt> create_lib top.exp
{top.exp}
prompt> create_3d_top_design -force -max_dimensions {15000 10000} -package_type interposer top
Information: Creating block 'top.design' in library 'top.exp'. (DES-013)
{top.exp:top.design}
prompt> get_attribute [current_block] design_type
3dic
```

SEE ALSO

create_die_block(2)
create_bump_block(2)
create_die(2)
create_lib(2)

create_3d_virtual_blocks

Creates virtual interface blocks.

SYNTAX

collection **create_3d_virtual_blocks**
[-design *design*]
[-blocks { { *die1*[:*num_layers*] *die2*[:*num_layers*] }... }]
[-layers *num_layers*]
[-in_netlist]
[-die_separation *separation_value*]

Data Types

design collection
die1 string
num_layers integer
die2 string
separation_value float

ARGUMENTS

-design *design*

Specifies the design in which to create the virtual interface blocks. If no design is specified, the virtual interface blocks are created in the current design.

-blocks { { *die1*:*num_layers die2*:*num_layers* }... }

Specifies the die cells between which to create the virtual interface block. One or more pairs of die cell names can be specified. The number of routing layers to copy from each die can be specified after each name, which overrides the value specified by the *-layers* option.

-layers *num_layers*

Specifies the number of routing layers to copy from each die. If not specified, three layers are copied from each die. This can be overridden on a per-die basis in the *-blocks* specification.

-in_netlist

Connects the virtual interface blocks to the top netlist between the dies. If not specified, the virtual interface blocks are not connected to the top netlist.

-die_separation *separation_value*

Specifies the die separation distance used for micro bumps in the virtual interface blocks.

DESCRIPTION

This command creates virtual interface blocks between the specified dies or interposer cells. If no dies or interposer cells are specified, this command creates virtual interface blocks between all die and interposers in design which have their z-offset values set.

EXAMPLES

The following example creates virtual interface blocks between all dies and interpose in the design based on their z-offset values. The virtual interface blocks are connected to the top netlist.

```
prompt> create_3d_virtual_blocks -in_netlist
```

The following example creates a virtual interface block between two dies containing four routing layers from each die.

```
prompt> create_3d_virtual_blocks -blocks {die1 die2} -layers 4
```

The following example creates a virtual interface block between two dies containing two routing layers from the first die and three routing layers from the second die.

```
prompt> create_3d_virtual_blocks -blocks {die1:2 die2:3}
```

create_abstract

Creates abstract view of designs.

SYNTAX

status **create_abstract**
[-placement]
[-estimate_timing]
[-timing_level none | boundary | compact | full_interface]
[-host_options host_option_name]
[-work_dir path]
[-blocks *block_designs*]
[-all_blocks]
[-force_recreate]
[-read_only]
[-include_objects {*include_objects_collection*}]
[-target_use implementation | planning]
[-preserve_block_instances true | false]

Data Types

block_designs list
include_objects_collection collection of ports, pins and nets

ARGUMENTS

-placement

Creates the abstract view with no timing information. When this option is specified, the tool will not trace timing paths to the ports of the design. Instead, the tool examines the logical hierarchy of the design, and creates an abstract view with the necessary netlist data for top-level global placement. If the design has timing constraints loaded, constrained objects will be included in the placement abstract. A placement abstract is always editable. So this option overrides *-read_only*. By default, the generated abstract view contains timing information.

-estimate_timing

Run the **estimate_timing** command on interface logic and incorporate the estimated timing result in the abstract view.

-timing_level none | **boundary** | **compact** | **full_interface**

Specifies the amount of timing detail to include in the abstract. Abstracts with less detail require less memory and CPU.

You can select one of three timing levels:

- **none** : The abstract excludes timing information at the top level. This is the default abstract type when **-placement** is

specified.

Use this abstract for pure physical operations (all design planning steps prior to **estimate_timing**, doing some purely physical operations at top-level).

The value 'none' is deprecated and will be removed in a future release.

- **boundary** : The abstract includes minimal netlist ensuring connectivity of block ports to the first level of logic. Pure feedthrough, clock combinational feedthrough and internal clock path driving output port are retained

  Use this abstract for better transition fixing of the top level segment of boundary nets when abstract is linked to top.

- **compact** : The abstract includes timing information for all critical setup and hold paths at the boundary of the original design. When the abstract is instantiated at the top level, you can use the abstract to show the best and worst timing through any input port or output port of the abstracted design. These abstracts have a very high level of compression when compared to the full design, and have significant runtime and memory benefits. This is the default when **-placement** is not specified.

  When you build a "compact" timing abstract, it is necessary to evaluate timing paths in the design that is being abstracted. Because of this, you should have the following SDC constraints defined in your block, prior to creating the "compact" abstract:

  - All clocks and all generated clocks
  - All set_case_analysis and set_disable_timing
  - All exception constraints (**set_false_path**, **set_multicycle_path**) that affect timing paths that enter or leave the block.

  Use this abstract for all top-level implementation flows.

- **full_interface** : The abstract includes timing information for almost all paths at the boundary of the original design. Because all boundary paths are represented, it is not necessary to prepare a full SDC file for the original design before creating the abstract. However, you should have the following SDC constraints defined in your block before creating the "full_interface" abstract:

  - All clocks and all generated clocks

  "Full_interface" abstracts contain nearly all of the boundary logic in the original design; some boundary logic is filtered out to reduce the abstract size. In particular, logic connected only to high-fanout networks is filtered. Usually, the filtered logic includes clock networks, scan enable, and reset. For these signals, only the essential part of the logic is kept. You can control the filtering of high-fanout networks by setting the "abstract.high_fanout_limit" app option.

  Use this abstract when your block SDC is not ready.

-host_options host_option_name

Specifies that the given host option should be used for distributed processing. If not specified, the tool will look for the global host option and use the global host option if it has distributed processing settings.

When **-blocks** or **-all_blocks** is specified, the tool might need to create abstract view for more than one block. Some of the blocks can run at the same time, depending on the hierarchy nesting.

-work_dir *path*

Specifies the directory to put all generated scripts and log files. This option is only used when **-blocks** or **-all_blocks** is specified. When **-blocks** or **-all_blocks** is specified, the tool need to create abstract view for one or more child blocks of the current block. Scripts and log files are generated for abstract view creation at the child blocks' level. The tool puts all the scripts and log files under a directory on disk.

If this option is not specified, the *work_dir* setting for the specified host option would be used. If no **-host_options** is specified, the *work_dir* of the global host option would be used. If there is no global host option and no **-host_options** is specified, the default is *./work_dir*.

-blocks *block_designs*

Specifies the list of child block designs to create abstract view. The parent design will switch to use the abstract view as reference for the instantiations of the corresponding designs, if they are not referencing to abstract view already. This option is mutually exclusive with **-all_blocks**. If no **-blocks** or **-all_blocks** is specified, the abstract view for the current design is created.

In a multi-level physical hierarchy design, only one level of physical hierarchy can be abstract view.

-all_blocks

Specifies that abstract view is to be created for all the child blocks in the current design, given that the block is the lowest in the physical hierarchy tree that is allowed to have abstract view. The parent design will switch to use the abstract view as reference for instantiations of the corresponding designs, if they are not referencing to abstract view already. This option is mutually exclusive with **-blocks**. If the **-blocks** or **-all_blocks** option is not specified, the command creates an abstract view for the current design.

In a multi-level physical hierarchy design, the tool will create abstract for the lowest level of block.

-force_recreate

This option only works with **-blocks** or **-all_blocks**. Without **-blocks** and **-all_blocks**, the command will always re-create the abstract view of the current block.

When **-blocks** or **-all_blocks** is specified, the tool would first search the physical hierarchy tree looking for the blocks to create abstract view. After the tool finds a certain block that should create abstract view for, it checks whether the block already has an abstract view and whether this abstract view is of the same type the user wants to create now. By default, the tool would not attempt to re-create the abstract view if the existing one is of the same type.

If the **-force_recreate** option is specified, the tool would do the proper view merge, delete the existing abstract view, and create a new abstract view, even if the existing one is of the correct type. This can be useful when the user wants to make sure that the blocks use the up-to-date abstract views.

-read_only

Specifies that the abstract view being created is read-only. By default, when an abstract view is created, the design view of the block is locked and becomes read-only. By specifying this option, you are asking the tool to make the abstract view read-only and keep the editability of the design view.

This option has no effect when **-placement** is specified. The two options are mutually exclusive.

-include_objects {*include_objects_collection*}

Specifies that some objects need to be retained in the abstract. These objects can be ports, leaf pins, hierarchical pins or nets. Specifying a pin (leaf or hierarchical) will cause the cell of the pin to be included in the abstract. Specifying a net *n* will cause the pins on the same flat net as *n* that are also specified in the *include_objects_collection* to be connected in the abstract. At least one leaf-level driver and one leaf-level load on the flat net containing *n* need to be specified for the connection to occur.

This option can be used for both timing and placement abstracts. This option cannot be used together with options **-blocks**, **-all_blocks** and **-estimate_timing**.

-target_use implementation | planning

Specifies the stage in which the created abstract is targeted to be used. Based on the target stage, tool will apply appropriate internal settings.

You can select one of the two stages:

- **implementation** : The abstract is targeted to be used in top-level implementation.

  Abstract creation is allowed in any level of physical hierarchy.

- **planning** : The abstract is targeted to be used in design planning.

  Abstract creation by default is allowed only on blocks which does not have any descendant block that can be abstract view. This can be overridden by setting the **abstract.allow_all_level_abstract** application option to true.

-preserve_block_instances true | **false**

This option is relevant to designs with nested physical hierarchies. This option determines whether lower levels of physical hierarchies are preserved or whether the hierarchy is made part of the current hierarchy. If this option is set to false, tool will create a flattened abstract. The default value of the option is true.

DESCRIPTION

This command creates an abstract view of the current block. If the block already has an abstract view, this command removes the existing abstract and generates a new abstract view. All leaf cells of the block needs to be mapped prior to abstract creation.

This command also saves the current block to disk.

Abstract view contains all the information that is needed for design planning. For top-level implementation, in addition to abstract, create a frame view using the **create_frame** command.

By default, the abstract view is editable and the design view is locked and becomes read-only. You can open and modify the design view, but *save_block* or *save_lib* would not be able to save the modified design view to disk. If you want to save the modified design view, you have a choice. You can either call *remove_abstract* to remove the abstract view and release the write lock on the design view, or call *create_abstract* to remove the old abstract view, save the modified design view to disk and create a new abstract view.

Design Flow for Abstracts

By default, an editable abstract view is created. At the same time, the design view of the block is locked and becomes read-only.

After the abstract view of the block is created, you can change the instantiation of the block in a parent block to reference to the abstract view using the *change_abstract* command.

If the abstract view is editable and instantiated in a parent block, you can make changes to it in the parent block context. Changes in the abstract view are brought back into the full netlist design view through merge. Merge happens automatically when the design view is loaded. You can also call merge explicitly using the command *merge_abstract*.

The merge operation requires that the full netlist design view remain unchanged between the time that the abstract is created with the **create_abstract** command and the abstract is merged back to the design view.

Resuming Editing of the Full Netlist

When an editable abstract view is created. At the same time, the design view of the block is locked and becomes read-only. The read-only design view can still be opened and modified in memory. But if you want to commit the in-memory modifications to disk, you won't be able to do it with *save_block* or *save_lib* command. There are three ways to save the in-memory modification of an abstract-locked design view to disk:

1. You can save it to another design using *save_block -as xxx*.

2. If you no longer need to use the abstract view, you can call *remove_abstract* to delete the abstract view and release the lock on the design view. Then, you will be able to use *save_block* or *save_lib* to save the design view.

3. If you want to get an updated abstract view according to the latest design view in-memory, you can call *create_abstract* command. The *create_abstract* command will delete the existing abstract view, release the lock on the design view, save the design view to disk, create the new abstract view, and lock the design view again if no *-read_only* is specified.

Summary for timing abstract creation

When a timing abstract is created, the tool by default retains

- Data and clock paths needed for analysis and optimization at top-level

  In addition, some cells are retained because they are used in timing constraints or exceptions. The log will contain a summary reporting how many cells were kept because of exceptions. The summary also reports how many pins in the design were affected by each type of exception or constraint. Specifically, the report includes:

  - **User size only** : Number of pins on cells that are size only (set by the command set_size_only)
  - **Exception** : Number of pins referred to by timing exceptions like set_false_path, set_multicycle_path, set_max_delay etc.
  - **Clock** : Number of pins that are a clock source, a generated clock source or a master pin for a generated clock.
  - **Clock Gating** : Number of pins that belong to clock gating cells.
  - **Constraint** : Number of pins referred to in constraints like set_input_delay, set_output_delay, set_max_time_borrow etc.
  - **Case analysis** : Number of pins with case analysis values (defined with set_case_analysis command).
  - **Cell mode** : Number of pins that have cell mode constraints (defined with set_cell_mode command).
  - **Disable timing** : Number of pins that have disable timing exception (defined using the set_disable_timing command).
  - **CTS exception** : Number of pins that have CTS exceptions on them, for example set_clock_balance_points.
  - **PVT** : Number of pins that have PVT exceptions, like set_operating_conditions, set_voltage, set_temperature etc.
  - **Latency** : Number of pins that have a clock latency set (this affects only pins that are not on sequential cells).
  - **Clock sense** : Number of pins that have a set_clock_sense set.

Multi-mode and multi-corner support

During create_abstract, the tool

- identifies and retains interface logic across all active modes
- Retains pins with constraints across all modes (active and inactive)
- Retains parasitics for all corners (active and inactive)

  Ensure that all the scenarios used at top-level are defined and active while creating abstract.

Multivoltage support

During create_abstract, the tool

- stores the UPF relevant to the retained interface logic. This is promoted to the top-level during linking.

Multi-level physical hierarchy design

- Creating abstract for using in Design Planning Flow

  In a multi-level physical hierarchy design, only one level of physical hierarchy can be an abstract view. By default, it's the

lowest level of blocks.

- Creating abstract for Top-level Place and Route

  Nested abstracts are supported for top-level place and route. Set the abstract.allow_all_level_abstract application option.

Creating abstracts with power annotation

- Set the abstract.annotate_power application option to create abstracts with power information. This enables you to perform power analysis of the complete design while at top-level

Creating abstracts for Signal EM Analysis

- Set the abstract.enable_signal_em_analysis application option to true before running **create_abstract**. This enables you to signal EM analysis inside abstracts while at top-level

EXAMPLES

The following example creates an abstract view, with timing information, for the current design.

```
prompt> create_abstract
```

The following example creates an abstract view that is suitable for top-level global placement.

```
prompt> create_abstract -placement
```

The following example creates an abstract view that is suitable for top-level optimization.

```
prompt> create_abstract
```

The following example runs **estimate_timing** on the interface logic of the current design, then creates an abstract view that includes the result of the estimated (virtually optimized) timing.

```
prompt> create_abstract -estimate_timing
```

The following example calls *create_abstract* from the top level, finds all the child blocks that are abstract view or can be an abstract view, and create the up-to-date abstract view including merging any changes from existing abstract view to the design view, also change the instantiations in parent blocks to reference to the block's abstract view.

```
prompt> create_abstract -all_blocks -force_recreate
```

In the following example we assume that the design contains a net n1 that connects a driver D1 to loads L1, L2, L3, L4. Using the sequence of commands shown, will ensure that the abstract contains the cells of the pins D1 and L3 and that D1 and L3 are connected by a net in the abstract.

```
prompt> set c_pins [get_pins {D1 L3}]
prompt> set c_nets [get_nets {n1}]
prompt> set cAll [add_to_collection $c_pins $c_nets]
prompt> create_abstract -include_objects $cAl
```

The following example creates a flattened abstract if a block has nested blocks in it. If the block does not have any nested blocks, it simply creates abstract for the block.

```
prompt> create_abstract -preserve_block_instances false
```

create_abut_rules

Creates spacing rules or keepout margins for cells in a design.

SYNTAX

status **create_abut_rules**
[-soft_keepout]
[-hard_keepout]
[-keepout_width *width*]
[-number_of_references *number*]
[-use_lib]
[-output] *filename*

Data Types

width float
number int
filename string

ARGUMENTS

-soft_keepout

Uses soft keepout margins instead of spacing rules.

-hard_keepout

Uses hard keepout margins instead of spacing rules.

-keepout_width *width*

Specifies the soft keepout margin width to use, in microns. This option should only be used if the *-soft_keepout* or *-hard_keepout* option is used. The default value is the site width.

-number_of_references *number*

Specifies the number of top pin_density values, from which to obtain references to apply spacing rules or keepout margins. The default is 6.

-use_lib

Specifies that library reference cells are used as a source for top pin_density lib cells, instead of reference cells found in the design.

-output *filename*

Specifies the output command filename.

DESCRIPTION

The **create_abut_rules** command helps to improve routability of a design by spacing cells further apart with the use of keepout_margins or by flipping cells. Before running this command, run the **check_routes** command to ensure that the DRC error information is up-to-date.

The command **create_abut_rules** creates either spacing rules (default) or soft/hard keepout margins on reference cells with the top six (default) largest pin_density values. These reference cells are found in the design. If the *-use_lib* option is specified, then the libraries are used to derive the reference cells. An output file is written out.

EXAMPLES

The following example runs the **create_abut_rules** command using the top 4 pin density values to derive reference cells found in the design to apply spacing rules to.

```
prompt> create_abut_rules -number_of_references 4 -output abut_4.tcl
```

The following example creates a soft keepout margin of width 2 microns using the libraries as reference cells to apply soft keepout margins to.

```
prompt> create_abut_rules -number_of_references 5 -output soft_abut_5.tcl \
  -soft_keepout -keepout_width 2
```

create_backend_tcd_cells

Inserts back-end testkey critical dimension cells (TCDs) into the design.

SYNTAX

status **create_backend_tcd_cells**
-lib_cells *layer_lib_cells*
-window_size *{width height}*
[-tcd_spacing *{dist_layer1_layer2}*]
[-other_cell_spacing *{dist_layer}*]
[-icovl_spacing *{dist_layer}*]
[-stack_with_macro *layer_list*]
[-stack_with_frontend *layer_list*]
[-stack_with_backend *{layer_list}*]
[-avoid_route_guide *{layer_list}*]
[-density *{density_layer}*]
[-orientation *{orient_layer}*]
[-check_only]
[-include_small_windows]
[-bbox *{{x1 y1} {x2 y2}}*]
[-snap_to_fin_grid]
[-place_at_window_center]
[-combined_tcd_cells]

Data Types

layer_lib_cells string
width float
height float
layer_libcells string
dist_layer1_layer2 string
dist_layer string
layer_list list
density_layer string
orient_layer string

ARGUMENTS

-lib_cells *layer_lib_cells*

Specifies the metal layer and corresponding back-end TCD library cells. For example, { {M1 cell1 cell2} {M2 cell3 cell4} } specifies back-end TCD library cells cell1 and cell2 are for layer M1; library cells cell3 and cell4 are for layer M2.

-window_size ***{width height}***

Specifies width and height of insertion window size.

-tcd_spacing ***{ dist_layer1_layer2}***

Specifies the minimum distance between two layers of back-end TCD cells. For example, {{10 M1 M4} {20 M2 M3} } specifies that the spacing between M1 and M4 TCD cells is 10um, and the spacing between M2 and M3 TCD cells is 20um. If no spacing value is specified, the default spacing is 0um and TCD cells can abut but cannot overlap. The command issues an error message if two back-end TCD layers have a spacing rule specified with **-tcd_spacing** and also have an overlap specified with **-stack_with_backend**.

-other_cell_spacing ***{dist_layer}***

Specifies the minimum distance between back-end TCD cells with non back-end TCDs and ICOVL cells. This rule does not apply to cells specified with the **-stack_with_macro** and **-stack_with_frontend** options. For example, { { 10 M1} {10 M3 } { 20 M2 } } specifies that the minimum spacing between a M1 back-end TCD and a non back-end TCD cell is 10um, and the minimum spacing between a M3 back-end TCD and a non back-end TCD cell is also 10um, and the minimum spacing between a M2 back-end TCD and a non back-end TCD cell is 20um. By default, the default spacing is 0um and cells can abut but cannot overlap.

-icovl_spacing ***{ dist_layer}***

Specifies the spacing between back-end TCDs and ICOVL cells. For example, { { 10 M1} {10 M4} { 20 M2} {20 M3} } specifies that the spacing between ICOVL cell and M1, M4 layer back-end TCDs is 10um, and the spacing between ICOVL cells and M2 and M3 layer back-end TCDs is 20um. By default, the default spacing is 0um and cells can abut but cannot overlap.

-stack_with_macro ***layer_list***

Specifies a list of back-end TCD metal layers that are allowed to stack with macros. For example, {M1 M5} specifies that M1 layer back-end TCDs can stack with macros without M1 layer metal objects, and M5 back-end TCDs can stack with macros without M5 layer metal objects. Other metal layer back-end TCDs are not allowed to stack with any macros. Note that the command will only check if a macro containing any top-level objects on the specified metal layers. It will not open and check cells inside a macro.

-stack_with_frontend ***layers***

Specifies a list of back-end TCD metal layers that can overlap with frontend TCDs. For example, { M1 M3 } specifies that M1 and M3 layer backend TCDs can overlap with frontend TCDs.

-stack_with_backend ***{layer_list}***

Specifies which layers of back-end TCDs can overlap. For example, { { M1 M2} { M3 M4 } } specifies that back-end TCDs of M1 and M2 layers can overlap, and back-end TCDs of M3 and M4 layers can overlap.

-avoid_route_guide ***{layer_list}***

Specifies which layer of back-end TCDs must avoid route guides and routing blockages on another layer. For example, { { M1 M3 } { M2 M4 } } specifies that M1 layer back-end TCDs should avoid route guides and routing blockages of layer M3; and M2 layer back-end TCDs should avoid route guides and routing blockages for layer M4.

-density ***{density_layer}***

Specifies the target percentage of windows that contain a back-end TCD cell. For example, { {80 M1} {80 M3} { 50 M2} } specifies that the target density for M1 layer and M3 layer back-end TCDs is 80%, and the target density for M2 layer back-end TCDs is 50%. The command tries to evenly distribute the TCDs. For example, if the target density is 50%, it tries to insert one back-end TCD for every other window. By default, the density is 100% and each window should have one back-end TCD.

-orientation ***{orient_layer}***

Specifies the back-end TCD orientation. Valid orientation values are R0, R90, R180, R270, MX, MXR90, MY, MYR90. For example, { {R0 M1} {R0 M2} { MX M3} {MX M4} } specifies that M1 and M2 layer back-end TCDs have an orientation of R0, and M3 and M4 layer back-end TCDs have an orientation of MX. If the specified orientation is not one of TCD cell's allowable

orientation (attribute allowable_orientation), the command issues a warning message. By default, the orientation is N.

-check_only

Checks the current design for back-end TCD violations based on rules specified in other options. An error message is issued for each violation.

-include_small_windows

Includes small windows at the last row/column for TCD insertion. By default, these small windows are excluded.

-bbox ***{{x1 y1} {x2 y2}}***

Specifies an insertion area. This area is divided into the specified window size for TCD insertion. By default, the core area is the insertion area.

-snap_to_fin_grid

Places the lower-left corner of the TCD cell to align with the FinFET grid. By default, alignment is not required.

-place_at_window_center

Changes the placement preference of TCD to be close to window center when specified to:

1. Place TCD in center of window

2. Stack with cells specified in -stack_with_* options

3. Place TCD in the channel between blocks or IPs (if blocks are not abut)

4. Place TCD at blocks or IP corner

By default, TCD cells are not placed at the center of window.

-combined_tcd_cells

Treat the cell is a combined front-end and back-end TCD cell. Placement blockages will be generated when combined TCD cells are placed.

DESCRIPTION

This command inserts back-end testkey critical dimension cells (back-end TCDs), which are used to increase design for manufacturability (DFM) and yield.

Back-end TCDs are inserted after power planning and contain only one metal layer. You can stack back-end TCDs over front-end TCDs to save placement area.

TCD width and height are not even multiples of unit tile width and height. They are placed as are regular macros.

Back-end TCDs may stack with front-end TCDs. back-end TCDs with metal layer M cannot place over layer M routing. If a front-end TCD is on layer M routing, then a back-end TCD with metal layer M cannot stack with this front-end TCD.

Back-end TCD insertion should prevent core cell area penalty by honoring the following insertion priority:

- Place the cell at the center of the window if **-place_at_window_center** option is specified
- Stack the cell with cells specified in stack_with_* option
- Place the cell in the channel between blocks or IPs (if blocks are not abut)

- Place the cell in blocks or IP corner
- Place the cell in the core area

EXAMPLES

The following example inserts the back-end TCD cells DM1 and DM2 into windows of width 1000 microns and height of 1200 microns. DM1 has its metal layer on M1. DM2 has its metal layer on M2. Spacing between DM1 is 10 microns. Spacing between DM2 is 20 microns. Spacing between DM1 and other cells is 2 microns. Spacing between DM2 and other cells is 5 microns. DM1 can stack with front-end TCD cells.

```
prompt> create_backend_tcd_cells \
  -lib_cells {{ M1 DM1} {M2 DM2}} -window_size {1000 1200} \
  -tcd_spacing { { 10 M1} { 20 M2 } } \
  -other_cell_spacing { { 2 M1 } { 5 M2 } \
  -stack_with_frontend {M1}
```

SEE ALSO

create_frontend_tcd_cells(2)
check_tcd_cells(2)

create_blackbox

Creates a black box design and updates the reference for the specified cell.

SYNTAX

status **create_blackbox**
[-new_name *bb_name*]
[-type physical | macro]
[-library *lib_name*]
[-target_boundary_area *area*]
[-boundary *boundary*]
cell

Data Types

bb_name string
lib_name string
area float
boundary list
cell list

ARGUMENTS

-new_name *bb_name*

Specifies the name of the new design. This is an optional argument. This option is only used when creating blackbox on a cell that has unresolved reference. It is ignored if the command is issued on a successfully bound logical hierarchy cell. By default, the command creates a design with the same name as the current reference of the specified cell.

-type physical | macro

Specifies the type of black box to create. Physical black boxes are physical blocks and follow the Physical Partition Design Planning Flow. The logical or macro type black boxes are created for unbound instances and empty hierarchies. After creating the black box, it is treated as any other macro in the design and is placed by the macro placer. The default type is physical.

-library *lib_name*

Specifies the library in which to create the new design. This is an optional argument. By default, the new design is created in the current library. If specified, the library must be one of the reference libraries for the library which contains the current design.

-target_boundary_area *area*

Specifies the target area of the black box design.

This option is mutually exclusive with **-boundary**.

-boundary *boundary*

Specifies the boundary for the black box design.

This option is mutually exclusive with **-target_boundary_area**.

cell

Specifies a cell whose reference is to be converted to a black box. The list can contain names, patterns, or collections. The cell must be a logical hierarchy cell or a cell with unresolved reference. All other cells in the design with the same reference, would have their reference changed to the black box as well.

DESCRIPTION

When the specified cell has unresolved reference, this command creates a new empty design with the same port interface as the unresolved reference of the cell. The reference of the cell and all other cells with the same unresolved reference is changed to the new design. Any other cells in designs linked to this design as child designs, or designs where this design is linked with the same unresolved reference, are updated as well.

When the specified cell is a logical hierarchy cell, the **create_blackbox** command converts the cell into a physical block and creates a new design with the content of the original cells logical hierarchy. The reference of the cell and all other cells with the same reference is changed to the new design.

The new design created by this command is a black box typed design.

To query the instances that are unbound, use the is_unbound attribute. For empty hierarchies, use the is_empty attribute.

After creating the black box, use the design_type==black_box filter expression to search for physical black boxes. Use the is_logical_black_box attribute for macro style black boxes.

EXAMPLES

The following example creates a new design in the test library by using the port interface and name of the reference of the cell p0. The reference of this cell is unresolved at this point.

```
prompt> create_blackbox -library test p0
1
```

The following example commits the logical hierarchy cell p0 to a physical block and marks the reference block design as black box. The black box design's target_boundary_area is set to 10000.

```
prompt> create_blackbox -target_boundary_area 10000 p0
1
```

SEE ALSO

get_cells(2)

create_blackbox_clock_network_delay

Specifies the clock network delay for clock input ports or blackbox clocks.

SYNTAX

status **create_blackbox_clock_network_delay**
[-max | -min]
[-modes *mode_list*]
[-corners *corner_list*]
-value *delay_value*
from_objects

Data Types

mode_list list
corner_list list
delay_value float
from_objects ports or blackbox clocks

ARGUMENTS

-max

Specifies that the network delay is for maximum delay (setup analysis) only. This option is mutually exclusive with **-min**. By default, when neither **-max** nor **-min** is specified, the network delay is applied to both min (hold) and max (setup).

-min

Specifies that the network delay is for minimum delay (hold analysis) only. This option is mutually exclusive with **-max**. By default, when neither **-max** nor **-min** is specified, the network delay is applied to both min (hold) and max (setup).

-modes *mode_list*

Specifies the list of modes for which to apply the network delay. By default, the clock network delay is applied to all modes.

-corners *corner_list*

Specifies the list of corners for which to apply the network delay. By default, the clock network delay is applied to all corners.

-value *delay_value*

Specifies the network delay value.

from_objects

Specifies the input clock ports or blackbox clocks for which to apply the network delay. The specified ports must already be

identified as clock ports with the **set_blackbox_clock_port** command. The specified blackbox clocks must already be create by the **create_blackbox_generated_clock** command.

DESCRIPTION

This command specifies clock network delay inside of the current block from the specified clock input ports or blackbox clocks. Clock ports are specified with the **set_blackbox_clock_port** command and blackbox clocks are create by the **create_blackbox_generated_clock** command before running the **create_blackbox_clock_network_delay** command.

EXAMPLES

The following example specifies that the maximum clock network delay from port *clk* is 1.2 for max and the minimum clock network delay is 1.0.

```
prompt> create_blackbox_clock_network_delay -max -value 1.2 clk
prompt> create_blackbox_clock_network_delay -min -value 1.0 clk
```

SEE ALSO

create_blackbox_generated_clock(2)
get_blackbox_generated_clocks(2)

create_blackbox_constraint

Creates setup and hold constraints for specified ports or blackbox clocks.

SYNTAX

status **create_blackbox_constraint**
-from *from_objects*
-edge rise | false
-to *ports* | -rise_to *ports* | -fall_to *ports*
[-setup | -hold]
[-modes *mode_list*]
[-corners *corner_list*]
[-clock *clock*]
-value *delay_value*

Data Types

from_objects port objects or blackbox clocks
mode_list list of modes
corner_list list of corners
clock clock object
delay_value float

ARGUMENTS

-from *from_objects*

Specifies the clock ports or blackbox clocks which the constraint is from.

-edge rise | fall

Specifies whether the constraint is from the rising edge or falling edge of the clock signal at the specified clock ports.

-to *ports*

Specifies the signal ports that the constraint is for. This creates a constraint for both rise and fall signal at the ports.

-rise_to *ports*

Specifies the signal ports that the constraint is for. This creates a constraint for the rising signal at the ports.

-fall_to *ports*

Specifies the signal ports that the constraint is for. This creates a constraint for the falling edge signal at the ports.

-setup

Specifies that this is a setup constraint. This option is mutually exclusive with the **-hold** option. By default, when neither **-setup** nor **-hold** is specified, the constraint applies to both setup and hold.

-hold

Specifies that this is a hold constraint. This option is mutually exclusive with the **-setup** option. By default, when neither **-setup** nor **-hold** is specified, the constraint applies to both setup and hold.

-modes *mode_list*

Specifies the list of modes what the constraint is for. By default, the constraint is applied to all modes.

-corners *corner_list*

Specifies the list of corners that the constraint is for. By default, the constraint is applied to all corners.

-clock *clock*

Specifies that the constraint time value is the percentage of the given clock's period. The final value of the constraint is the clock period multiplied by the value specified with **-value** option. By default, the value specified with **-value** option is the absolute value for the constraint.

-value *delay_value*

Specifies the delay value for the constraint. When **-clock** is specified, this value means the constraint's value is a certain percentage of the clock period. Without **-clock**, the specified value is the final value for the constraint.

DESCRIPTION

This command defines setup and hold constraints from the specified edge of clock signal at the specified clock ports or blackbox clocks to the specified signal ports. The "from_objects" are clock ports defined by the **set_blackbox_clock_port** command or blackbox clocks defined by the **create_blackbox_generated_clock** command. The "to" ports can be either input or inout signal ports.

The value of the constraint can be described as an absolute value or as a percentage of a specified clock's period.

Multicorner-Multimode Support

EXAMPLES

The following example defines constraints for signal rise at port *$data* from the clock's rising edge at clock port *clk*. The setup constraint value is 0.6. And the hold constraint value is 30 percent of main_clock's period.

```
prompt> create_clock -name main_clock -period 10 [get_ports clk]
prompt> set_blackbox_clock_port clk
prompt> create_blackbox_constraint -from clk -edge rise -to $data -setup -value 0.6
prompt> create_blackbox_constraint -from clk -edge rise -to $data \
  -clock main_clock -value 0.3 -hold
```

SEE ALSO

create_blackbox_delay(2)
set_blackbox_clock_port(2)
create_blackbox_generated_clock(2)
get_blackbox_generated_clocks(2)

create_blackbox_delay

Specifies delay paths between the specified ports or blackbox clocks.

SYNTAX

status **create_blackbox_delay**
-from *from_objects* | -rise_from *from_objects* | -fall_from *from_objects*
-to *ports* | -rise_to *ports* | -fall_to *ports*
[-max | -min]
[-modes *mode_list*]
[-corners *corner_list*]
[-clock *clock*]
-value *delay_value*

Data Types

from_objects port objects or blackbox clocks
mode_list list of modes
corner_list list of corners
clock clock object
delay_value float

ARGUMENTS

-from *from_objects*

Specifies the originating ports or blackbox clocks for the timing paths. This option is mutually exclusive with the **-rise_from** and **-fall_from** options. This option creates timing paths for both the rising and falling edges from the specified ports or blackbox clocks.

-rise_from *from_objects*

Specifies the originating ports or blackbox clocks for the rising edge for the timing paths. This option is mutually exclusive with the **-from** and **-fall_from** options. This option creates timing paths for the rising edge to the specified ports or blackbox clocks.

-fall_from *ports*

Specifies the originating ports or blackbox clocks for the falling edge for the timing paths. This option is mutually exclusive with the **-from** and **-rise_from** options. This option creates falling timing paths for the specified ports or blackbox clocks.

-to *ports*

Specifies the destination ports for the timing paths. This option is mutually exclusive with the **-rise_to** and **-fall_to** options. This option creates timing paths for both the rising and falling edges to the specified ports.

-rise_to *ports*

Specifies the destination ports for the rising edge for the timing paths. This option is mutually exclusive with the **-to** and **-fall_to** options. This option creates timing paths for the rising edge to the specified ports.

-fall_to ***ports***

Specifies the destination ports for the falling edge for the timing paths. This option is mutually exclusive with the **-to** and **-rise_to** options. This option creates timing paths for the falling edge to the specified ports.

-max

Specifies that the value is for the maximum delay (setup analysis) only. This option is mutually exclusive with the **-min** option. By default, when neither **-max** nor **-min** is specified, the value applies to both minimum (hold) and maximum (setup).

-min

Specifies that the value is for the minimum delay (hold analysis) only. This option is mutually exclusive with the **-max** option. By default, when neither **-max** nor **-min** is specified, the value is for both minimum (hold) and maximum (setup).

-modes ***mode_list***

Specifies the list of modes that the value applies to. By default, the delay path value is applied to all modes.

-corners ***corner_list***

Specifies the list of corners that the value applies to. By default, the delay path value is applied to all corners.

-clock ***clock***

Specifies that the value is the percentage of the given clock's period. The final delay value for the path is the clock period multiplied by the value specified with **-value** option. By default, the value specified with **-value** option is the absolute delay value for the paths.

-value ***delay_value***

Specifies the path delay value. When **-clock** is specified, this value means that the path delay is the specified percentage of the clock period. If the **-clock** option is not specified, the *delay_value* is the delay value for the paths.

DESCRIPTION

This command defines a set of paths between a set of ports or blackbox clocks and a set of ports as part of the black box timing information. The "from_objects" can be ports or blackbox clocks. The ports can be either input ports or inout ports and can be signal ports or clock ports. The blackbox clocks are created by the **create_blackbox_generated_clock** command. The "to" ports can be either output inout signal ports. Clock ports are specified with the **set_blackbox_clock_port** command before running this command.

The delay value for a path can be described as an absolute value or as a percentage of a specified clock's period.

For a partial netlist, the "to" ports must be ports with no block internal net connection in the original design netlist.

Multicorner-Multimode Support

EXAMPLES

The following example defines a path that rises from port *DataIn* and rises to port *DataOut* with a delay of 0.6 for setup analysis and 0.5 for hold analysis.

```
prompt> create_blackbox_delay -rise_from DataIn -rise_to DataOut -value 0.6 -max
prompt> create_blackbox_delay -rise_from DataIn -rise_to DataOut -value 0.5 -min
```

The following example defines a path from the rising edge of main_clock to the rising or falling edge of port *DataOut*. The delay value is 30 percent of the clock period for main_clock.

```
prompt> create_clock -name main_clock -period 10 [get_ports ClkIn]
prompt> set_blackbox_clock_port ClkIn
prompt> create_blackbox_delay -rise_from ClkIn -to DataOut -clock main_clock -value 0.3
```

SEE ALSO

create_blackbox_drive_type

Creates an output drive type for black box timing.

SYNTAX

status **create_blackbox_drive_type**
-lib_cell *lib_cell_object*
[-input_transition_rise *transition_time*]
[-input_transition_fall *transition_time*]
name

Data Types

lib_cell_object string
transition_time float
name string

ARGUMENTS

-lib_cell *lib_cell_object*

Specifies the buffer or inverter library cell as the driver cell for this drive type.

-input_transition_rise *transition_time*

Specifies the rise transition time at the input pin of the driver cell. The default is zero.

-input_transition_fall *transition_time*

Specifies the fall transition time at the input pin of the driver cell. The default is zero.

name

Specifies the name for this drive type. Commands such as **set_blackbox_port_drive** can use this name to identify the drive type.

DESCRIPTION

This command creates an output port drive type as part of the black box timing information for the current block.

The drive type created by this command can be used by the **set_blackbox_port_drive** command to describe the driver of a particular port.

Multicorner-Multimode Support

EXAMPLES

The following example defines the driver at output port *DataOut* as a cell whose reference library cell is *BUF8* in reference library *stdreflib1* with 0.01ns rise and fall transition time at the input pin.

```
prompt> create_blackbox_drive_type -lib_cell [get_lib_cells stdreflib1/BUF8] \
      -input_transition_rise 0.01 -input_transition_fall 0.01 driveType1
prompt> set_blackbox_port_drive -type driveType1 [get_ports DataOut]
```

SEE ALSO

create_blackbox_load_type(2)
commit_blackbox_timing(2)
set_blackbox_port_drive(2)
set_blackbox_port_load(2)

create_blackbox_generated_clock

Creates a blackbox generated clock object.

SYNTAX

collection **create_blackbox_generated_clock**
-name *clock_name*
[-source *master_pin*]
[-divide_by *divide_factor* | -multiply_by *multiply_factor* |
[-invert]
-master_clock *clock*

Data Types

clock_name string
master_pin list
divide_factor int
multiply_factor int
clock string

ARGUMENTS

-name *clock_name*

Specifies the name of the blackbox generated clock. The name must have not been used by other clocks. This option is required.

-source *master_pin*

Specifies the master clock source (a clock source pin in the design) from which to derive the clock waveform.

-divide_by *divide_factor*

Specifies the frequency division factor. If the *divide_factor* value is *2*, the blackbox generated clock period is twice as long as the master clock period. This option cannot be used together with option **-multiply_by**.

-multiply_by *multiply_factor*

Specifies the frequency multiplication factor. For example, if the *multiply_factor* value is *3*, the blackbox generated clock period is one-third as long as the master clock period. This option cannot be used together with option **-divide_by**.

-invert

Inverts the blackbox generated clock signal in the case of frequency multiplication and division.

-master_clock *clock*

Specifies the master clock to be used for this blackbox generated clock. This option is required.

DESCRIPTION

Creates a blackbox generated clock object in the blackbox timing model. The blackbox generated clock object is available for use with the **create_blackbox_delay**, **create_blackbox_constraint**, and **create_blackbox_clock_network_delay** commands. Use the **get_blackbox_generated_clocks** command to get the blackbox generated clock objects.

The command can specify the clock source from which it is generated. You must specify the master clock for this generated clock. If the source pin/port is not specified, the specified master clock must have a source pin/port.

The blackbox generated clock can be created as a frequency divided clock (by using the **-divide_by** option), frequency multiplied clock (by using the **-multiply_by** option), or special divide by one (by setting *divide_factor* or *multiply_factor* as 1). The frequency divided or frequency multiplied clock can be inverted by using the **-invert** option.

EXAMPLES

The following example creates a frequency divide_by 2 blackbox generated clock.

```
prompt> create_clock -period 1 -name CLK CLK
prompt> create_blackbox_generated_clock -name GCK -divide_by 2 \
  -source CLK -master_clock CLK
prompt> get_blackbox_generated_clocks GCK
{GCK}
```

create_blackbox_load_type

Creates an input load type for black box timing.

SYNTAX

status **create_blackbox_load_type**
-lib_cell *lib_cell_object*
name

Data Types

lib_cell_object string
name string

ARGUMENTS

-lib_cell *lib_cell_object*

Specifies the buffer or inverter library cell as the load cell for this load type.

name

Specifies the name for this load type. Commands such as **set_blackbox_port_load** can use the name to identify the load type.

DESCRIPTION

This command creates an input port load type as part of the black box timing information for the current block.

The load type created by this command can be used by the **set_blackbox_port_load** command to describe the load of a particular port.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example defines the load at input port *DataIn* as being five *BUF8* cells from the reference library *stdreflib1*.

```
prompt> create_blackbox_load_type -lib_cell [get_lib_cells stdreflib1/BUF8] loadType1
prompt> set_blackbox_port_load -type loadType1 -factor 5 [get_ports DataIn]
```

SEE ALSO

create_block

Creates a new block or overwrite an existing block in a module library.

SYNTAX

collection **create_block**
[-force]
block_name

Data Types

block_name string

ARGUMENTS

-force

This option is used to overwrite the block if it already exists in the target library.

block_name

The name of the block to create, with optional library, label, and view specifications. This is specified as follows:

[libName:]blockName[/labelName][.viewName]

If the library specification is not present, the **current_lib** is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then design is used.

DESCRIPTION

This command creates a new block with an empty top module. It can also be used to re-initialize an existing block into an empty one. The top module name will match the new or re-initialized block. The top module of the block is made the current block. The open-mode will be set to "new". The open_count is (re-)set to 1.

This command returns a collection of the newly created block if successful, or "" if not. If an illegal name ('/', or empty space) is given, then a TCL error is raised.

EXAMPLES

The following example creates a block "top" in library "r4000":

```
prompt> create_block r4000:top
{"r4000:top.design"}
```

create_bond_pad_array

Creates a bond pad (hybrid bond link) array in the current design.

SYNTAX

int **create_bond_pad_array**
-layer *layer_name*
[-name *array_name*]
-width *width*
-height *height*
[-bbox { {*llx lly*} {*urx ury*} }]
[-boundary *polyrect*]
-delta {*dx dy*}
[-pattern inline | staggered_1 | staggered_2]
[-repeat {*columns rows*}]
[-origin {*x y*}]

Data Types

layer_name string
array_name string
width float
height float
llx float
lly float
urx float
ury float
polyrect list
dx float
dy float
columns integer
rows integer
x float
y float

ARGUMENTS

-layer *layer_name*

Specifies the bond pad array layer. This is a required option.

-name *array_name*

Specifies the bond pad array name.

-width *width*

Specifies the bond pad shape width. This is a required option.

-height *height*

Specifies the bond pad shape height. This is a required option.

-bbox { {*llx lly*} {*urx ury*} }

Specifies the region in which to place the bond pad. This option and the **-boundary** option are mutually exclusive. If neither this option nor **-boundary** option is used, the entire design area is used.

-boundary *polyrect*

Specifies a *polyrect* region in which to place the bond pad. This option and the **-bbox** option are mutually exclusive. If neither this option nor **-bbox** option is used, the entire design area is used. The *polyrect* is described as a list of location coordinates.

-delta {*dx dy*}

Specifies the horizontal pitch (*dx*) between adjacent columns and the vertical pitch (*dy*) between adjacent rows. This is a required option.

-pattern inline | staggered_1 | staggered_2

Specifies the placement pattern of the bond pad. Valid values for this option are: inline, staggered_1, and staggered_2. The inline argument places bond pad at every grid point. The staggered_1 argument places bond pad only at grid points where the sum of column index and row index is even. The staggered_2 argument places bond pad only at grid points where the sum of column index and row index is odd. If this option is not specified, the command creates an inline bond pad array.

-repeat {*columns rows*}

Specifies the total number of columns and rows in the bond pad array. The command does not create bond pad outside of the bond pad array bounding box, even if you specify a column or row count beyond the bounding box. If this option is not specified, the command fills the bounding box or design area with bond pads.

-origin {*x y*}

Specifies the spacing between the lower-left corner of bond pad array bounding box and the lower-left corner of the bounding box of the bond pad located at column 0 and row 0. If this option is not specified, the command derives the origin so that the bond pad array is centered in the bounding box.

DESCRIPTION

This command creates an array of bond pads.

EXAMPLES

The following example creates an array of bond pads.

```
prompt> create_bond_pad_array -layer AP -width 20 -height 20 \
  -delta {200 200} -bbox {{350 400} {1350 1400}}
```

cell_and_port_and_group_list list

ARGUMENTS

-name *bound_name*

Specifies the name of the bound.

-boundary *regions*

Creates move bounds with the specified boundaries. You can specify one or more rectangles, polygons, and geometric objects. If you specify more than one placeable area, the coarse placer can place cells in any of the move bound's bound shapes. These placeable areas can overlap or be disjoint.

To specify a rectangle, use the following format to specify the lower-left and upper-right corners of the rectangle:

{{*llx lly*} {*urx ury*}}

To specify a polygon, use the following format to specify the coordinates of the polygon:

{{*x1 y1*} {*x2 y2*} {*x3 y3*} ... {*xn yn*}}

Each rectangle and polygon defines a target placement area for the objects. The areas can overlap or be disjoint. The coordinates are relative to the chip origin.

You can also specify polygons as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. For poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. For layers, the resulting area includes the area of every shape in the layer.

This option is mutually exclusive with the **-dimensions** option; you can specify only one.

-dimensions *bound_dimension*

Creates a group bound with the specified dimensions.

For a group bound, specify the dimension as {*width height*}.

For a diamond bound, specify the dimension as {*length*}. When you use this format, you must also specify the **-diamond** option.

This option is mutually exclusive with the **-boundary** option; you can specify only one.

-diamond *central_object*

Creates a diamond bound centered on the specified object, which can be a port, cell, or pin. You can specify only one object.

The objects in the bound are constrained to lie within the distance specified by the **-dimensions** option (measured as a Manhattan distance) of the specified object. A diamond bound is always a soft bound.

If you specify this option, you must also specify the **-dimensions** option.

-effort low | **medium** | **high** | **ultra**

Specifies the effort used by the tool to keep the cells within in a soft bound.

If you set the effort to **ultra**, the cells are kept in the bound very strictly, with almost no part of any cell . Lower effort levels allow cells to be pushed or pulled beyond the edge of the bound, effort is useful when you want most cells to be contained, but you want to allow placement flexibility to fix timing, wire length, or congestion. Most large bounds work well with **medium** effort.

If you specify the **-boundary** or **-dimensions** option, the default effort is **ultra**. Otherwise, the default effort is **medium**.

You cannot specify the **-effort** option with the **-diamond**, **-repelling**, **-exclusive**, or **-type hard** options.

-type soft | **hard**

Sets the bound type to be either hard or soft.

The default is **soft**.

When you specify **-type hard**,

- You must also specify the **-boundary** or **-dimensions** option
- You cannot specify the **-effort** option

-exclusive

Sets the bound to be exclusive. This option is allowed only for move bounds. A move bound that is exclusive requires all of its cells to be placed inside it and prohibits the placement of other cells in the same area. Exclusive move bounds are respected by both coarse placement and legalization.

-macro_group

Sets the bound to be macro_group bound. This option is allowed only for move bounds.

This option specifies that the bound can contain only cells whose reference is of **macro** design type.

This option is mutually exclusive with **-exclusive**, **-hierarchical_only** and **-design_type** options.

-hierarchical_only

Specifies that the bound can contain only cells that represent module boundary objects, which are created by the **explore_logic_hierarchy** command. This option is allowed only for move bounds. No other cells or ports can be added to move bounds of this type.

This option creates move bounds that are used during floorplanning; the have no effect on other placement or legalization.

-design_type *design_type*

Specifies that the bound can contain only cells whose reference is of the specified design type. This option is allowed only for move bounds. The valid values for this option are **abstract**, **analog**, **black_box**, **corner**, **cover**, **diode**, **end_cap**, **feedthrough**, **fill**, **filler**, **flip_chip_driver**, **flip_chip_pad**, **lib_cell**, **macro**, **module**, **pad**, **pad_spacer**, and **well_tap**. No other cells or ports can be added to move bounds of this type.

This option creates move bounds that are used during floorplanning; they have no effect on other placement or legalization. The expected usage is to create move bounds that contain only hard macros.

-repelling diamond | rect

Specifies that the bound is repelling rather than attractive. Repelling bounds keep the bound contents spread apart by the specified shape region.

-cell *cell*

Specifies the physical cell in which to add the bound. The bound is created in the cell's reference block using the coordinate system of the cell's top block. The cell must reference a block, not a library cell, unless this command is run in the library manager. In the library manager, bounds can be created in library cells.

If you do not specify this option, the bound is created in the current block.

cell_and_port_and_group_list

Specifies the cells, ports, and groups to assign to the bound. The list can contain names, patterns, or collections. Group objects are only valid when creating a repelling bound. Furthermore, repelling bounds may contain either cells and ports or groups, but not a mix.

It is an error to specify a port that has already been assigned to another bound.

If this bound is a move bound, it is an error to specify a cell that has already been explicitly assigned to another move bound.

If this bound is a group bound, it is an error to specify a cell that has already been explicitly assigned to another group bound.

If a cell is hierarchical, its child cells are also implicitly in the bound, as well as any cells added to its hierarchy in the future, unless the child cell is assigned to another bound.

Cells that belong to a relative placement group cannot be individually assigned to a bound. All cells of a relative placement group must be assigned to a bound together.

If you do not specify this argument, the tool creates an empty bound. You can later assign cells and ports to the bound by using the **add_to_bound** command.

DESCRIPTION

This command defines region-based placement constraints for coarse placement. There are two different types of bounds:

- Move bound

  A move bound restricts the placement of cells within fixed regions (bound shapes) of the core area. To create a move bound, specify the absolute coordinates with the **-boundary** option.

- Group bound

  A group bound restricts the placement of cells within a floating region. Cells are placed within a bound but its absolute coordinates are not fixed, instead they are optimized by the placer.

  To specify the floating region size for a group bound, use the **-dimensions** option. If you do not specify the **-dimensions** (or **-boundary**) option, the tool creates an automatic group bound, whose floating region is automatically determined by the placer.

Repelling bounds function like group bounds, but instead of defining an area within which the objects should be placed, they indicate an area of separation that should exist between each pair of objects in the bound.

Generally, there is no guarantee that cells will be placed completely within a bound. For example, coarse placement will violate bounds if the quality of its primary placement objectives would otherwise be degraded. In these situations, you should revisit your and floorplan to ensure that the block is not overconstrained. Alternatively, you can use the **-type hard** option to create a hard bound (the default is soft). The coarse placer tries to honor hard bounds as hard constraints while sacrificing other objectives, such as timing and routability. You should not use many hard bounds because this might result in inferior placement solutions.

To assign cells and ports to an existing bound, use the **add_to_bound** command. To unassign cells and ports from a bound, use the **remove_from_bound** command.

EXAMPLES

The following example creates a hard exclusive move bound named "movebound1" with one rectangular and one polygon bound shape. The bound contains the invA1 cell and reset port.

```
prompt> create_bound -name "movebound1" -boundary {{{100 100} {200 200}} \
  {{1000 1000} {2000 1000} {2000 4000} {1500 4000} {1500 2000} {1000 2000}}} \
  -type hard -exclusive {invA1 reset}
```

The following example creates a move bound named "movebound2" that contains the hierarchical cell named mid. It also implicitly contains all cells within the mid hierarchical cell.

```
prompt> create_bound -name "movebound2" -boundary {{0 0} {200 200}} \
  [get_cells mid]
```

The following example creates a move bound named "movebound3" with rectilinear bound shapes that have the same boundaries as the merged areas of voltage_area_shapes whose names start with VA_SHP_.

```
prompt> create_bound -name "movebound3" \
  -boundary [get_voltage_area_shapes VA_SHP_*]
```

The following example creates an automatic group bound named "groupbound1" with ultra effort that contains all physical cells whose names start with adder.

```
prompt> create_bound -name "groupbound1" -effort ultra { adder* }
```

The following example creates a diamond bound named "temp3"centered on the MOD/U1/A pin. The MOD/INST1 and MOD/INST2 cells are constrained to be at most 64 microns of Manhattan distance away from MOD/U1/A.

```
prompt> create_bound -name "temp3" -dimensions 64 \
  -diamond MOD/U1/A {MOD/INST1 MOD/INST2}
```

The following example creates a macro_group move bound named "macroGroupMovebound".

```
prompt> create_bound -name "macroGroupMovebound" -macro_group -boundary {{0 0} {200 200}}
```

create_bound_shape

Creates a bound shape on a move bound.

SYNTAX

collection **create_bound_shape**
-bound *bound_object*
-boundary { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } |
geometric_objects

Data Types

bound_object	collection
llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection

ARGUMENTS

-bound *bound_object*

The bound on which to create the bound shape.

-boundary { {*llx lly*} {*urx ury*} } | {{*x y*} {*x y*} {*x y*} {*x y*}...} | geometric_objects

Specifies the boundary of the bound shape. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

A polygon may also be specified as the combined area of a heterogenous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

DESCRIPTION

The create_bound_shape command creates a bounding region on a move bound. A move bound may have multiple bound shapes.

This command will not allow bounding region creation on a macro_group move bound. User can create bound shapes on macro_group move bound while creating the bound itself using create_bound.

EXAMPLES

prompt> **create_bound_shape -bound "movebound1" -boundary {{100 100} {200 200}}**

prompt> create_bound_shape -bound "movebound2" -boundary [get_shapes RECT_0]

objects list

ARGUMENTS

-left_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the beginning of each cell row.

-right_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the end of each cell row.

-bottom_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the bottom object boundaries. In a double-back design, adjacent rows are flipped; the bottom boundary cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the top of object boundaries. In a double-back design, adjacent rows are flipped; the top boundary cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-left outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-bottom_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-right outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-left outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-top_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-right outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-bottom_right_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-top_left_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the top-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-top_right_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the top-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-mirror_left_outside_corner_cell

Places left outside corner cells in a mirrored orientation.

-mirror_right_outside_corner_cell

Places right outside corner cells in a mirrored orientation.

-mirror_left_inside_corner_cell

Places left inside corner cells in a mirrored orientation.

-mirror_right_inside_corner_cell

Places right inside corner cells in a mirrored orientation.

-mirror_left_boundary_cell

Places left boundary cells in a mirrored orientation.

-mirror_right_boundary_cell

Places right boundary cells in a mirrored orientation.

-mirror_left_inside_horizontal_abutment_cell

Places left inside horizontal abutment cells in a mirrored orientation.

-mirror_right_inside_horizontal_abutment_cell

Places right inside horizontal abutment cells in a mirrored orientation.

-tap_distance *distance*

Specifies the distance in microns between tap cells.

-top_tap_cell *lib_cell_name*

Specifies the tap cell to be placed at the top boundary. The tool inserts this tap cell at the specified interval on top boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the top tap cell is used on unflipped top boundary rows and on flipped bottom boundary rows. This option must be used with the **-tap_distance** option.

-bottom_tap_cell *lib_cell_name*

Specifies the tap cell to be placed at the bottom boundary. The tool inserts this tap cell at the specified interval on bottom boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the bottom tap cell is used on unflipped bottom boundary rows and on flipped top boundary rows. This option must be used with the **-tap_distance** option.

-prefix *boundary_cell_prefix*

Specifies the prefix for the created boundary cells. By default, no prefix is added. When you use this option, the command uses the following naming convention for created boundary cells:

boundarycell!*prefix*!*library_cell_name*!*number*

By default, no prefix is added and the command uses the following naming convention:

boundarycell!*library_cell_name*!*number*

-separator *boundary_cell_separator*

Specifies the separator character that is used when composing the instance name of the boundary cell. The boundary cell instance name consists of a prefix, the library reference cell name and an incrementing number. For example, the instance name "boundarycell!MY_CELL!25" has the boundary cell prefix, the MY_CELL library reference cell name, the incrementing number 25, and the boundary cell separator !. This naming convention allows you to do pattern matching selection of the boundary cells.

By default, the separator character is an exclamation mark (!) and the command uses the following naming convention for created boundary cells:

boundarycell![*prefix*!]*library_cell_name*!*number*

-insert_into_blocks

Performs boundary cell insertion in the subblocks. By default, the tool performs boundary cell insertion only in the top-level block.

-at_va_boundary

Places horizontal boundary cells on both sides of the voltage area boundaries. When you use this option, rows are treated as cut by voltage area boundaries. Therefore, boundary cells are placed on both sides of a voltage area boundary. By default, voltage area boundaries are ignored during boundary cell insertion.

-no_1x

Prevents the tool from placing boundary cells on a row when the row length equals two times the corner cell width plus one unit tile width. Note that if the row length equals two times the corner cell width, the tool inserts boundary cells on that row.

This option can be used only when the **-top_right_outside_corner_cell**, **-bottom_right_outside_corner_cell**, **-top_left_outside_corner_cell** and **-bottom_left_outside_corner_cell** options are all specified.

-min_row_width *width*

Skips rows with a row width that is smaller than the specified width value.

-add_metal_cut_allowed

Adds metal cut allowed underneath the standard cell placeable area. Metal cut allowed and forbidden preferred grid extension routing guides are created. Metal cut allowed routing guides cover the area taken up by all the placable site rows reduced by the vertical and horizontal shrink factor. The vertical shrink factor is expressed as a percentage of the smallest site row height and the default is 50%. It can be set using the chipfinishing.metal_cut_allowed_vertical_shrink_factor app option. The horizontal shrink factor is expressed as a percentage of the smallest site row width. It can be set using the chipfinishing.metal_cut_allowed_horizontal_shrink_factor app option. Finally, forbidden preferred grid extension routing guides are created to cover the remaining area up to the boundary.

-do_not_swap_top_and_bottom_inside_corner_cell

Prevents swapping of the top and bottom inside-corner cells for flipped rows.

By default, if a top inside-corner cell is on a flipped row, the tool uses a bottom inside-corner cell instead. If a bottom inside-corner cell is on a flipped row, the tool uses a top inside-corner cell instead.

DESCRIPTION

This command adds boundary cells around the boundaries of objects, such as voltage areas, macros, blockages, and the core area.

EXAMPLES

The following example creates boundary cells on both the left and the right edges of boundaries.

```
prompt> create_boundary_cells -left_boundary_cell myLib/CellLeft \
        -right_boundary_cell myLib/CellRight
```

create_budget_busplan

Create a busplan to define the timing of budget segments

SYNTAX

int **create_budget_busplan**
[-name *name*]
[-rule *net_estimation_rule*]
-from *pins_or_ports*
-nets *nets*
[-force]

Data Types

name string
net_estimation_rule string
pins_or_ports collection
nets collection

ARGUMENTS

-name *name*

Specify the name of the busplan object. If you do not specify a name, a unique name will be generated automatically.

-rule *net_estimation_rule*

Specify a net estimation rule. The rule must have be declared previously with the **set_net_estimation_rule** command. If you do not define a rule, the "default" rule is used. The rule is used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

-from *pins_or_ports*

Specify the pins or ports where the busplan begins. If you specify ports, they must be input ports. If you specify pins, they must be output pins of budgeted blocks. Budgeted blocks should be declared by using the **-add_blocks** option of the **set_budget_options** command.

You must specify one of **-from** and **-nets**.

-nets *nets*

Specify a set of nets through which the busplan should pass. The net must be in the direct fanout of a legal bus start point, separated by buffers or inverters. See **-from** option description for a definition of legal bus start points.

You must specify one of **-from** and **-nets**.

-force

Create the busplan, even if it crosses another busplan. If you use this option, then some or all of the existing busplans are removed and replaced by the new busplan definition. By default, a busplan is not created in a place where another busplan already crosses.

DESCRIPTION

This command creates a database object called a "busplan", that can be used to define the timing of budget segments. A busplan is a collection of paths through the design that start at top-level ports or block outputs and end at top-level ports or block inputs. The paths can cross multiple levels of hierarchy and can traverse the following circuit elements:

- buffers and inverters
- level shifters
- isolation cells
- flip-flops and latches

Busplans are declared by specifying either **-from** or **-nets** to indicate where the bus starts. If a path containing only the given elements leads to a legal end point, the busplan is created. You can specify many start pins, ports or nets at the same time to form a multibit busplan.

The busplan also has a net_estimation_rule object associated with it, which you set by using the **-rule** option. The net estimation rule object must be previously declared by using the **set_net_estimation_rule** command. The rule will be used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

After creating a busplan, the budgeter can extract budgeted "segments" which lie along the path of the busplan. You can use the **-busplans** option of the **report_budget** command to see these budget segments. Each budget segment will represent a connection between budgeted blocks, or a feedthrough path through a budgeted bloc.

Use the **-busplans** option of the **compute_budget_constraints** to apply the timing of your busplans to your budget. See the example below for details.

This command returns 1 on success, 0 otherwise.

EXAMPLES

Create a net estimation rule with 0.5 ns_per_mm propagation time. Define 4 bit busplan starting at block1 and ending at block3. Report on the segments along the busplan. (Note that the bus fed through block2.) Apply the calculated delays from the busplan to the budget.

```
prompt> set outpins B1/OUT1[*]
prompt> set_net_estimation_rule fast_rule -parameter ns_per_mm -value 0.5
prompt> create_budget_busplan -name bus1 -rule fast_rule -from $outpins
prompt> report_budget -busplans bus1
****************************************
Report : report_budget -busplans
 ...
```

```

create_buffer_trees

Builds buffer trees from the specified driver pins or nets

SYNTAX

status **create_buffer_trees**
[-from *pin_net_list*]
[-incremental]
[-global_route_based]

Data Types

pin_net_list list

ARGUMENTS

-from *pin_net_list*

Specifies the list or collection of driver pins or nets for which the tool will create buffer trees. When the **-from** option is not specified, the **create_buffer_trees** command works on all drivers.

-incremental

Enables incremental buffer tree building from the specified drivers. In the default non-incremental mode, any existing buffer tree downstream from the driver is first removed, and the buffer tree is completely rebuilt. In incremental mode, the existing buffer tree is kept, and buffering is only done on the nets directly driven by the specified drivers.

-global_route_based

Enables global route based buffer tree building (GRopto). By default, buffer trees are built using virtual route topologies and extraction. With the **-global_route_based** option, first a congestion map update is performed, then the global router is used to derive buffer tree topologies and to calculate net RCs when building the tree.

DESCRIPTION

create_buffer_trees is used to build buffer trees from a specified list of drivers. Those drivers are specified by the **-from** option, and can be given as a list or collection of driver pins or nets. If nets are given, then the driver pins of those nets are used as the buffer tree drivers. **create_buffer_trees** can be run on the full design by omitting the **-from** option, but this is not the recommended use model. If you are doing initial buffer tree building after initial coarse placement of the design, or you want to fully rebuild all buffer trees after an incremental coarse placement, the recommended use model is to call **place_opt -from initial_drc -to initial_drc**.

create_buffer_trees is a preroute optimization command, and typically would be used after initial buffer trees are built in the

place_opt initial_drc step, and sometime before routing is performed on the design with **route_auto**. **create_buffer_trees** does not route the buffer trees, and it does not legalize the placement. If you are working with a routed design, more targeted post-route buffering can be done using the **add_buffer_on_route** command.

Typical use models for **create_buffer_trees** include:

- Custom building specific buffer trees that have unique requirements, like different lib_cells or routing layers.
- Repairing buffers trees that were damaged by manual modifications to the design placement, such as a user Tcl script that tweaks the placement of registers or other categories of standard cells.

By default, **create_buffer_trees** does full buffer tree building downstream of the specified drivers. This includes removal of any existing buffers and inverters, then rebuilding of the full tree. With the **-incremental** option, **create_buffer_trees** will do no removal of existing buffers. It will only buffer the nets directly driven by the specified drivers, and won't trace through any pre-existing downstream buffers during tree building.

By default, **create_buffer_trees** uses the virtual router to derive the routing topologies that guide the buffer insertion, and it also uses the current preroute extraction model to estimate RCs on the nets driven by the inserted buffers (the default preroute extraction model is called RDE, or route-driven estimation). If the **-global_route_based** option is used, then **create_buffer_trees** will instead use the global router for the buffering topologies as well as the RCs on the nets. "GRopto" is a term sometimes used to refer to buffer tree building with global routing information. Those global routes are not kept in the design after buffering, they are discarded. Using the **-global_route_based** option also triggers a global route congestion map update, so that the buffering topologies are fully congestion aware. Note that using this option will increase the runtime of the command. **create_buffer_trees** does not honor the **place_opt.initial_drc.global_route_based** app option which triggers GRopto mode in the **place_opt initial_drc** command -- you muse use the **-global_route_based** option to get equivalent behavior in **create_buffer_trees.** In either virtual route or global route mode, the calculated RCs on the nets are influenced by any min or max layer settings or non-default routing rules applied to the nets driven by the buffer trees.

If you are building multiple buffers trees, runtime is improved by calling **create_buffer_trees** one time with a collection or list of those drivers specified by the **-from** option, rather than calling **create_buffer_trees** multiple times in a roe.

create_buffer_trees honors the **set_lib_cell_purpose** constraints, and will only use buffers and inverters that were made available with the *optimization* purpose. If you change the **set_lib_cell_purpose** constraints later in the flow, it is possible for some buffers on those trees to then be resized to lib_cells from the new **set_lib_cell_purpose** constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

place_opt(2)

create_bump_array

Creates an array of bump cell instances.

SYNTAX

int **create_bump_array**
[-name *bump_array_name*]
[-lib_cell *bump_cell_name*]
[-lib_cell_collection *lib_cell_list*]
[-bbox { {*llx lly*} {*urx ury*} }]
[-boundary *polyrect*]
-delta {*dx dy*}
[-pattern inline | staggered_1 | staggered_2]
[-repeat {*columns rows*}]
[-origin {*x y*}]
[-orientation N | W | S | E | FN | FS | FE | FW]

Data Types

bump_array_name string
bump_cell_name string
lib_cell_list collection of library cells
llx float
lly float
urx float
ury float
polyrect list
dx float
dy float
columns integer
rows integer
x float
y float

ARGUMENTS

-name *bump_array_name*

Specifies the bump array name. This name is used to name the bumps within the array. If this option is not used, the array is named default_bump_array_*index*, where *index* is a positive integer. The bump cell instances in the array are named as *bump_array_name*_colIndex_rowIndex, where colIndex and rowIndex are integers that represent the column and row of the bump instance, respectively.

-lib_cell *bump_cell_name*

Specifies the name of bump library cell. All bump instances in a bump array must have the same library cell. User can specify a simple cell name. The tool will search all libraries for the right lib_cell. User can specify the library name and lib_cell name. The library name must be described first followed by lib_cell name. The two names are separated by *:* or */*. User can also specify the view name. The full name of the lib_cell is described as library_name:cell_name.view_name. User can also use hierarchy delimiters, namely library_name/cell_name/view_name. User must describe library name and cell name if they want to describe view name.

-lib_cell_collection *lib_cell_list*

Specifies the collection of a library cell using *get_lib_cells* command. User can also use the full name of a bump lib_cell. This option and *-lib_cell* option are mutually exclusive. If user specify multiple library cells, only the first one is used. User must either use this option or *-lib_cell* option.

-bbox { {*llx lly*} {*urx ury*} }

Specifies the region in which to place the bump cell instances. No bump cell instances or parts of a bump cell instance can extend beyond the specified region. This option and the **-boundary** option are mutually exclusive. If neither this option nor **-boundary** option is used, the entire design area is used.

-boundary *polyrect*

Specifies a *polyrect* region in which to place the bump cell instances. No bump cell instances or parts of a bump cell instance can extend beyond the specified region. This option and the **-bbox** option are mutually exclusive. If neither this option nor **-bbox** option is used, the entire design area is used. The *polyrect* is described as a list of location coordinates.

-delta {*dx dy*}

Specifies the horizontal spacing (*dx*) between adjacent columns and the vertical spacing (*dy*) between adjacent rows. This is a required option.

-pattern inline | staggered_1 | staggered_2

Specifies the placement pattern of the bump array. Valid values for this option are: inline, staggered_1, and staggered_2. The inline argument places bump instances at every grid point. The staggered_1 argument places bump instances only at grid points where the sum of column index and row index is even. The staggered_2 argument places bump instances only at grid points where the sum of column index and row index is odd. If this option is not specified, the command creates an inline bump array.

-repeat {*columns rows*}

Specifies the total number of columns and rows in the bump array. The command does not create bump instances outside of the bump array bounding box, even if you specify a column or row count beyond the bounding box. If this option is not specified, the command fills the bounding box or design area with bump cells.

-origin {*x y*}

Specifies the spacing between the lower-left corner of bump array bounding box and the lower-left corner of the bounding box of the bump cell instance located at column 0 and row 0. The bump array bounding box is either specified by **-bbox** option or the bounding box of the shape specified by **-boundary** option. If neither **-bbox** nor **-boundary** is used, the bump array bounding box is the entire die area.

If you do not use **-origin** but you specify the **-repeat** option, the command derives the origin so that the bump array is centered in the bounding box. It is important that user chooses the column or row count of the **-repeat** option small enough so that the bump array can be entirely inside the bump array bounding box. If the column or row count is too large, the calculated origin can be outside of the bump array bounding box when the bump array is centered in the bounding box. The bumps outside of the bump array bounding box will not be created in the design.

If this option is not specified and **-repeat** option is not selected either, the command uses (0,0) as the origin.

-orientation N | W | S | E | FN | FS | FE | FW

Specifies the orientation of all bumps in the array. If this option is not specified, the default orientation is N.

DESCRIPTION

This command creates an array of bump cell instances.

EXAMPLES

The following command creates an array of bump cells named BUMP_PAD, with horizontal and vertical spacing of 200. The bump cells are created within a bounding box of {{350 400} {2350 2400}}.

```
prompt> create_bump_array -lib_cell BUMP_PAD -delta {200 200} -bbox {{350 400} {2350 2400}}
```

SEE ALSO

create_bump_pattern(2)
place_io(2)

create_bump_block

Creates a reference cell of a bump.

SYNTAX

collection **create_bump_block**
[-force]
-dimensions *dimensions_list*
[-origin *coordinate*]
-layer *layer_name*
-port_name *port_name*
[-library *lib_name*]
bump_name

Data Types

dimensions_list list
coordinate list
layer_name string
port_name string
lib_name string
bump_name string

ARGUMENTS

-force

Overwrites the bump if one with the same name already exists in the target library.

-dimensions *dimensions_list*

Specifies the width and height of the die block in micron.

-origin *coordinate*

Specifies the coordinate of origin.

-layer *layer_name*

Specifies the layer on which the bump rectangle should be created.

-port_name *port_name*

Specifies the port name of the bump.

-library *lib_name*

Specifies the target library that contains the process technology of the bump to be created. If not specified, the bump cell is created in the current library.

bump_name

Specifies the bump name to be created.

DESCRIPTION

The **create_bump_block** command creates a reference cell of a bump that consists of a rectangle at the specified layer with the given port name. This is for quick exploration flow when no actual bump cell is available in the library. For manufacturing, a bump should be properly designed to meet the manufacturing rules.

EXAMPLES

The following example creates a bump named ubump.design in the library top.exp.

```
prompt> create_bump_block ubump -force -dimensions {30 30} -origin {0 0} -layer M9 -port_name BUMP -library top.exp
Information: Creating block 'ubump.design' in library 'top.exp'. (DES-013)
{top.exp:ubump.design}
```

create_bump_cluster

Creates a bump cluster in current design based on given pattern cell design, at given coordinate location, and with specified orientation.

SYNTAX

int **create_bump_cluster**
-pattern_cell *pattern_cell_name_or_collection*
-coordinates {*llx lly*}
[-net *net_name*]
[-cluster_name *cluster_name*]
[-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90]
[-coord_spec bl | c]
[-force]

Data Types

pattern_cell_name_or_collection string or collection
llx float
lly float
net_name string
cluster_name string

ARGUMENTS

-pattern_cell *pattern_cell_name_or_collection*

Specifies the pattern cell to be used for creating bump cluster. If a collection is specified, it must contain exactly one pattern cell. This is a required option.

-coordinates {*llx lly*}

Specifies the coordinate location for lower left corner of pattern cell to be placed. Note, if orientation is specified, this is the lower left corner after orientation has been applied. This is a required option.

-net *net_name*

Specifies the net name to be used for connecting all cells inside bump cluster. If specified net does not exist, a new net is created. Default net name is based on bump cluster name, and is of form: *cluster_name*_net.

-cluster_name *cluster_name*

Specifies the name to be used for edit_group containing all cells of bump cluster created by this command. If *cluster_name* is not provided, command generates a unique cluster name of form: bump_cluster_xxx, where xxx is a unique integer suffix.

-orientation R0 | **R90** | **R180** | **R270** | **MY** | **MXR90** | **MX** | **MYR90**

Specifies the orientation of bump cluster as placed at given {*llx lly*} coordinate location. If this option is not specified, the default orientation is R0.

-coord_spec bl | c

Specify the user specified coordinates is for bottom left (bl) or center (c) of the new bump cluster. If this option is not specified, the default coord_spec is bottum left.

-force

Specifies that bump cluster should be created even if it overlaps with an existing bump cluster. By default, a bump cluster is not created if it detects an overlap with an existing bump cluster.

DESCRIPTION

This command creates a bump cluster in current design based on given pattern cell design, at given coordinate location, and with specified orientation.

EXAMPLES

The following example creates a bump cluster.

prompt> **create_bump_cluster -pattern_cell *:TSV4BUMP81 -coordinates {1000 1000}**

SEE ALSO

create_bump_pattern

Creates bumps and matching types for a cluster of pads.

SYNTAX

int **create_bump_pattern**
-file_name *pattern_file*
-bump_prefix *prefix*

Data Types

pattern_file string
prefix string

ARGUMENTS

-file_name *pattern_file*

Specifies the name of a text file which describes the bump patterns to be created.

-bump_prefix *prefix*

Specifies the prefix of bump names. The bump names are created by adding an underscore and integer index at the end of the bump prefix. The default prefix is **default_bump_array**.

DESCRIPTION

This command creates one or multiple bumps for some placed IO pads. It also generates one or multiple matching types for impending bump assignment using command **place_io**.

You must create a text file, called a pattern file, to describe the bumps and matching types to be created by this command. The format of this file is described as follows. Specifically, the following line should be used at the beginning of a pattern file to select the bump reference cell. The string **bump_lib_cell** is a keyword and must be placed at the beginning of the line. The **LIB_CELL_NAME** is the full name of the reference cell, including the library name. If a simple string is used as **LIB_CELL_NAME**, current library is assumed.

bump_lib_cell LIB_CELL_NAME

The following line should also be used at the beginning of a pattern file to specify the pitch value of bump rows or columns. In particular, **bump_pitch** is a keyword and must be placed at the beginning of the line. The **DISTANCE** is in microns.

bump_pitch DISTANCE

If the pattern file contains multiple lines which define a bump reference cell or bump pitch, the values later in the file will override the previous values and affect the bumps created afterwards.

Bumps and matching types are created for individual clusters of pads, one cluster at a time. For each pad cluster, which is called an IO group, a single unit of description is used in the pattern file. This unit starts with the keyword **io_group**. There must be a left curly bracket after the keyword **io_group**. The detailed description follows the left curly bracket. The unit ends with a right curly bracket.

io_group { ..._detailed_description... }

In the detailed description part, you must first describe all pads in the cluster. Each pad name must be placed in a pair of curly brackets by itself. Within the same pair of curly brackets, you can add a string type attribute for the pad. The attribute string is separated from the pad name by one or more white space characters. If no attribute string is given, the attribute of the pad is a single letter **s**. All pad names and their own curly brackets are placed in a linear order. The entire order is placed within a pair of curly brackets as follows.

{
{pad1 _string_of_pad1}
{pad2}
}

All pads must be placed before running the **create_bump_pattern** command. The minimum-size rectangle that covers all pads is called the pad boundary box. If the width of the box is larger than the height, the pads are considered to be placed in rows. If the height of the box is larger than the width, the pads are considered to be placed in columns. If the width is the same as the height, the pads are with no orientation.

Bumps to be created and placed are described in groups. Each group of bumps are aligned along a single line. The orientation of the bump group is defined after the pads are described. Specifically, the line starts with a left curly bracket followed by a keyword **orientation**. The value of orientation follows and can be **row**, **column**, or **perpendicular**. The default value is **perpendicular**, which means that the bump line is perpendicular to the pad placement orientation. Clearly, this value cannot be used if pads have no orientation. The line that defines bump group orientation must end with a right curly bracket. The following line shows an example.

{ orientation row }

After the orientation of the bump groups is specified, the bump groups are defined. Each bump group is a single line of bumps whose orientation is defined using aforementioned orientation line. To describe a line of bumps, five elements are used, each of which is placed in a pair of curly brackets. The first element is the distance between the center line of bumps and the center of pad boundary box. Negative values are used when the pad boundary box center is above or at the right side of the bump center line. Positive values are used when the pad boundary box center is below or at the left side of the bump center line. A single bump line is divided into two parts by the pad boundary box. The second and third elements are used to describe the part either on the left or below pad boundary box when bumps are placed in a row or column, respectively. The second element is the distance between the center of the rightmost or top bump and the left or bottom boundary edge of the pad boundary box, respectively. If the value is positive, the bump center is on the left side or below the corresponding edge. The value is negative otherwise. The third element is a sequence of strings, each of which represents a unique bump. The first string represents the rightmost or top bump. The order is from right to left or from top to bottom. The fourth and fifth elements are used to describe the part of bumps either on the right side or above pad boundary box when bumps are placed in a row or column, respectively. The fourth element is the distance between the center of the leftmost or bottom bump and the right or top boundary edge of the pad boundary box, respectively. If the value is positive, the bump center is on the right side or above the corresponding edge. The value is negative otherwise. The fifth element is a sequence of strings, each of which represents a unique bump. The first string represents the leftmost or bottom bump. The order is from left to right or from bottom to top.

The two parts of a line of bumps have the same pitch, which is defined by **bump_pitch** line outside of current **io_group** unit. However, you can add a sixth element to define a different pitch value for and only for the current bump line.

Multiple lines can be used to describe multiple rows or columns of bumps within an **io_group** unit. The full path name of the first pad in the pad description is used as the name of the IO group. The bump names are created by adding an underscore and integer index at the end of the bump prefix.

Bumps to be created have string attributes. Pads also have string attributes. The bumps and pads with the same attribute string form a single matching type, which is created by the **create_bump_pattern** command. The name of the matching type is created by

combining the IO group name, an underscore character, and the string of attribute. However, the hierarchy delimiter / is replaced by an underscore _. The uniquify number is created based on the ratio of bumps and pads in the matching type.

A pattern file can contain comment lines. A comment line starts with a **#** symbol. In addition, a two-character string // indicates all characters afterwards are comments.

EXAMPLES

A sample pattern file is shown below. The second and third elements are empty pairs of curly brackets, indicating that all four bumps are on the right side of the pad boundary box. There is no bump on the left side. **pad1** and **pad2** have an attribute equal to **s**. Three matching types will be created, for **vdd**, **gnd**, and **s**, respectively.

```
bump_lib_cell BUMP
bump_pitch  200
io_group {
{ {pad1} {pad2} {pad3 vdd} {pad4 gnd} }
{ orientation row }
{ {0} {} {} {60} {vdd gnd s s} }
}
```

SEE ALSO

create_bump_array(2)
create_matching_type(2)

create_bundle

Creates a new bundle of nets in the design.

SYNTAX

collection **create_bundle**
[-name *bundle_name*]
[*objects*]

Data Types

bundle_name string
objects objects

ARGUMENTS

-name *bundle_name*

Specifies a unique name for the bundle. If this option is not specified, the command generates a bundle named BUNDLE_n, where n is the current number of existing bundles plus one.

objects

Specifies the objects to add to the bundle. If this option is not specified, the tool creates an empty bundle. Objects specified can be supernets.

DESCRIPTION

This command creates a new homogeneous bundle of nets or supernets in the current design. If you specify a name for the bundle with the **-name** option, the name must be unique. Use the **remove_bundles** command to delete a bundle.

EXAMPLES

The following examples create new bundles in the design.

```
prompt> create_bundle
{BUNDLE_5}
prompt> create_bundle -name my_bundle
```

```
{my_bundle}
prompt> create_bundle -name my_bundle_3 [get_nets abc]
{my_bundle_3}
```

SEE ALSO

add_to_bundle(2)
get_bundles(2)

remove_from_bundle(2)
report_bundles(2)

create_bundles_from_patterns

Groups nets into bundles based on net name and the number of nets in the net group.

SYNTAX

status **create_bundles_from_patterns**
[-net_name_prefix *prefix*]
[-net_order ascending | descending]
[-minimum_nets *min*]
[-maximum_nets *max*]
[-no_braces]
[-no_brackets]
[-no_angle_brackets]
[-no_underlines]
[-no_colons]
[-no_parentheses]
[-bundle_grouping]

Data Types

prefix string
min integer
max integer

ARGUMENTS

-net_name_prefix *prefix*

Specifies the net name prefix to match when creating bundles. By default, the command creates bundles by matching any unique net group names that contain eight or more bits.

-net_order *ascending* | *descending*

Specifies the net sorting order. By default, the order is ascending.

-minimum_nets *min*

Specifies the minimum number of nets in a bundle. By default, the tool creates bundles for net groups with eight or more nets.

-maximum_nets *max*

Specifies the maximum number of nets in a bundle. By default, there is no limit to the number of nets in a bundle.

-no_braces

Ignore net group names that contain braces ({}).

-no_brackets

Ignore net group names that contain brackets ([]).

-no_angle_brackets

Ignore net group names that contain angle brackets (<>).

-no_underlines

Ignore net group names that contain underscore characters (_).

-no_colons

Ignore net group names that contain colon characters (:).

-no_parentheses

Ignore net group names that contain parentheses (()).

-bundle_grouping

Enable bundle grouping to enable the command to create bundles of other bundles.

DESCRIPTION

This command groups nets into bundles based on net name and number of bits. You can use this command to quickly create bundles from net groups without specifying individual **create_bundle** commands. Net group names are extracted from the design by the tool, or by specifying the **-net_name_prefix** option. You can also specify the bit ordering in the bundle with the **-net_order** option. The tool extracts the net groups and determines the number of bits in the group. Only net groups with eight or more bits, or groups that meet the group size criteria set with the **-minimum_nets** and **-maximum_nets** options, are made into net bundles.

This command supports net group indexes that contain the following characters:

bus[i]
bus{i}
bus<i>
bus(i)
bus_i
bus:i

EXAMPLES

The following example creates a bundle of signals that begin with "ahbmi" and reports the contents of the bundle.

```
prompt> create_bundles_from_patterns -net_name_prefix ahbmi
Information: There are 1 new bundles defined. (LED-102)
{B_ahbmi}

prompt> report_bundles [get_bundles {B_ahbmi}]
Begin bundle report ..
  Bundle NAME: `B_ahbmi'
  Number of objects in bundle 24
```

```
  Bundle Type 'net'
  Objects in bundle
    Position = 0, net ahbmi[0]
    Position = 1, net ahbmi[1]
    Position = 2, net ahbmi[2]
    ...
End bundle report
1
```

create_bus_routing_style

Creates an analog constraint group with bus_style intent in the current design.

SYNTAX

collection **create_bus_routing_style**
[*constraint_group_name*]
-for *objects*
[-gap *distance*]
[-shield_placement default | double_interleave | half_interleave | interleave | outside]
[-corner_type cross | default | river]
[-valid_layers *layer_list*]
[-layer_spacings {*layer1 spacing1* ...}]
[-layer_widths {*layer1 width1* ...}]
[-force]

Data Types

constraint_group_name string
objects string or collection
distance float
layer_list list
layer1 string
spacing1 float
width1 float

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group. By default, the command generates a unique constraint group named "bus_style_n", where n is a unique, monotonically increasing integer value.

-for *objects*

Specifies the objects - can be nets, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

-gap *distance*

Specifies the spacing between the outermost bus bits and other shapes in the block. The default is zero.

-shield_placement default | double_interleave | half_interleave | interleave | outside

Specifies the shielding type for the main bus trunk, if needed. Allowed values are *default*, *double_interleave*, *half_interleave*,

interleave and *outside*. The default is *default*.

-corner_type cross | **default** | **river**

Specifies the bus corner type. Allowed values are *cross*, *default* and *river*. The default is *default*.

-valid_layers *layers*

Specifies the list of layer names to be used for bus trunk. If specified, layers type is set to range, otherwise it is set to default. When specified the min and max layers are derived from the list.

-layer_spacings {*layer1 spacing1* ...}

Specifies the spacing of a layer used in trunk routing. This is a list of alternating layers and spacings, for example, {M1 5.0 M2 6.0}.

-layer_widths *list*

Specifies the width of a layer used in trunk routing. This is a list of alternating layers and widths, for example, {M1 5.0 M2 6.0}.

-force

Forces the deletion of an existing constraint group if the name matches the specified *constraint_group_name*. The default is false, and the command exits with an error if the name already exists.

DESCRIPTION

The **create_bus_routing_style** command creates a constraint group for a collection of nets, bundles, and topology_edges with bus_style intent. The constraint is used by Custom Router.

You can specify the valid set of layers for trunk routing, layer-specific spacings and widths. The shielding placement of bus trunk can also be specified.

EXAMPLES

The following example creates a constraint group with system generated name "bus_style_1" for nets matching pattern "pr*" which will be of bus_style intent. The shield placement is interleave. Also a spacing of 3 will be used for layer M2 and spacing of 5 will be used for layer M3. The 'pr*' nets are routed with Custom Router.

```
prompt> create_bus_routing_style -for pr* -shield_placement interleave \
-layer_spacings {M2 3 M3 5}
{bus_style_1}
```

SEE ALSO

get_constraint_groups(2)
remove_constraint_groups(2)

create_busplans

Creates one or more busplan objects. Busplan objects are used during bus planning.

SYNTAX

int **create_busplans**
[-name *name*]
[-rule *net_estimation_rule*]
[-auto]
[-from *pins_or_ports*]
[-to *pins_or_ports*]
[-nets *nets*]
[-force]
[-add_start_end_cells *cells*]
[-verbose]
[-reset]

Data Types

name string
net_estimation_rule string
pins_or_ports collection
nets collection
cells collection

ARGUMENTS

-name *name*

Specify the name of the busplan object. If you do not specify a name, a unique name of the form bus* will be generated automatically.

-rule *net_estimation_rule*

Specify a net_estimation_rule, which must be previously declared by using the **set_net_estimation_rule** command. If you do not define a rule, the "default" rule is used. The rule is used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

-auto

Specify that the tool should automatically find buses in the design. You must specify one of *-auto*, *-from* or *-nets*.

-from *pins_or_ports*

Specify where the busplan should begin. If you specify ports, they must be input ports. If you specify pins, they must be output

pins of blocks.

You must specify one of *-auto*, *-from* or *-nets*.

-to *pins_or_ports*

Specify where the busplan should end. If you specify ports, they must be output ports. If you specify pins, they must be input pins of blocks.

-nets *nets*

Specify a set of nets through which the busplan should pass. The net must be in the direct fanout of a legal bus startpoint, separated only by buffers or inverters. See the documentation of the *-from* option for a definition of legal bus start points.

You must specify one of *-auto*, *-from* or *-nets*.

-force

Create the busplan, even if it crosses another busplan. If you use this option, then some or all of the existing busplans are removed and replaced by the new busplan definition. By default, a busplan will not be defined in a place where another busplan already exists.

-add_start_end_cells *cells*

Specifies to add to the list of cell instances where buses can start or end. By default it will contain all top level hard macros and blocks. This information is stored by the command, you do not need to use **-add_start_end_cells** on the next command invocation.

-verbose

Output more information when running.

-reset

Remove all busplan information from design.

DESCRIPTION

This command creates a database object called a "busplan", that can be used to do register planning. A busplan is a collection of paths through the design that start at top-level ports or block outputs and end at top-level ports, or block inputs. The paths may cross through multiple levels of hierarchy and may also traverse through the following circuit elements:

- buffers and inverters
- level shifters
- isolation cells
- flip-flops and latches

Busplans are declared by specifying either *-from* or *-nets* to indicate where the bus starts or the tool can automatically find and create busplans using *-auto*. You can specify many start pins, ports or nets at the same time, to form a multibit busplan.

The busplan also has a net_estimation_rule object associated with it, which you set by using the *-rule* option. The net_estimation_rule object must have been previously declared by using the **set_net_estimation_rule** command. The rule will be used when calculating the delay of segments in the busplan. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

This command returns 1 on success, 0 otherwise.

EXAMPLES

Create a net estimation rule with 0.5 ns_per_mm propagation time. Define 8 bit busplan starting at block B1 and ending at block B2. Report on the segments along the busplan.

```
prompt> set_net_estimation_rule fast_rule -parameter ns_per_mm -value 0.5
prompt> create_busplans -name bus1 -rule fast_rule -from B1/OUT1[*] -to B2/IN1[*]
prompt> report_busplans -start_end_cells bus1

create_cell

Creates one or more cells referencing a library cell, module, or via_def

SYNTAX

collection **create_cell**
[-design *design*]
cell_names
reference

Data Types

design collection
cell_names list
reference collection

ARGUMENTS

-design *design*

Specifies the design in which to create the cells. If no design is specified, the cells are created in the current design.

cell_names

Specifies the names of the cells to be created in the design. Each cell name must be unique.

reference

Specifies the name of the library cell or module the created cells should instantiate, the reference must already exist.

The reference may also be a via_def when creating through-silicon via ("TSV") cells, in which case the via_def must be of type "through_silicon_via_def". TSV cells, which are identified by their *is_tsv* attribute being true, are created by this command if the reference is either a TSV via_def or a design with design_type "tsv". If a TSV design, it must meet certain criteria, which as of this writing are:

- Its *design_type* attribute must be "tsv",
- It must have exactly one port with two terminals,
- Its *boundary* attribute must be set.

DESCRIPTION

This command creates new cells in the current design (unless otherwise specified by -design). One cell is created for each of the

names listed.

EXAMPLES

The following example creates three instances of the library cell *mylib/ND2*.

```
prompt> create_cell {U23 U1/U24 U2/U7/U25} myLib/ND2

{U23 U1/U24 U2/U7/U25}
```

The following example creates three instances of the library cell *ND2*. It will work similer to **/ND2*

```
prompt> create_cell {U23 U1/U24 U2/U7/U25} ND2

{U23 U1/U24 U2/U7/U25}
```

The following example creates two instances of the module MID.

```
prompt> create_cell {U110 U111} [get_modules MID]

{U110 U111}
```

The following example creates an instance of the lib cell myLib/ND4 using **get_blocks** to find the reference. **get_blocks -all** is needed if the lib_cell is not open already.

```
prompt> create_cell U210 [get_blocks -all myLib:ND4.design]

{U110 U111}
```

create_cell_array

Inserts cells in the block in an array style.

SYNTAX

status **create_cell_array**
-lib_cell *lib_cell*
[-voltage_area *voltage_area*]
[-boundary *polygon*]
[-x_pitch *distance*]
[-y_pitch *distance*]
[-x_offset *distance*]
[-y_offset *distance*]
[-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90]
[-checkerboard even | odd]
[-snap_to_site_row true | false]
[-preserve_boundary_row_lib_cells *lib_cell_list*]
[-prefix *prefix*]

Data Types

lib_cell string
voltage_area collection
polygon list
distance float
lib_cell_list collection
prefix string

ARGUMENTS

-lib_cell *lib_cell*

Specifies the library cell to insert. You must specify a single library cell. This is a required option.

-voltage_area *voltage_area*

Specifies the voltage area in which to insert the cells.

If you do not specify this option or the **-boundary** option, the insertion region is the core area.

If you specify both the **-voltage_area** and **-boundary** options, the insertion region is the overlapping region between the specified voltage area and polygon.

-boundary *polygon*

Specifies the region in which to insert the cells.

If you do not specify this option or the **-voltage_area** option, the insertion region is the core area.

If you specify both the **-voltage_area** and **-boundary** options, the insertion region is the overlapping region between the specified voltage area and polygon.

-x_pitch ***distance***

Specifies the horizontal distance between the centers of two cells.

If you do not specify this option, the command inserts a single column of cells whose spacing is specified by the **-y_pitch** option.

If you do not specify this option or the **-y_pitch** option, the command inserts a single cell at the specified offset location.

-y_pitch ***distance***

Specifies the vertical distance between the centers of two cells.

If you do not specify this option, the command inserts a single row of cells whose spacing is specified by the **-x_pitch** option.

If you do not specify this option or the **-x_pitch** option, the command inserts a single cell at the specified offset location.

-x_offset ***distance***

Specifies the horizontal offset from the insertion region boundary.

The default is 0.

-y_offset ***distance***

Specifies the vertical offset from the insertion region boundary.

The default is 0.

-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of the inserted cells. Valid values are **R0**, **R90**, **R180**, **R270**, **MX**, **MY**, **MXR90**, and **MYR90**.

If you do not specify this option, the default orientation depends on the setting of the **-snap_to_site_row** option.

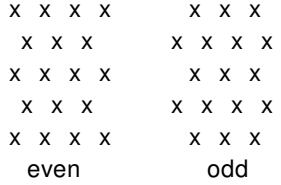
- If **true**, the default orientation is the same as the site row orientation.
- If **false**, the default orientation is **R0**.

-checkerboard even | **odd**

Inserts cells in a checkerboard fashion. There are two types of checkerboard: **even** or **odd**.

- The even checkerboard type specifies that the first cell is placed at the lower-left corner of the insertion region.
- The odd checkerboard type specifies that a blank space is placed at the lower-left corner of the insertion region.

The following figure shows the checkerboard insertion patterns:



If you do not specify this option, the command inserts the cells as a normal array.

-snap_to_site_row true | **false**

Specifies if the new cells are snapped to site rows.

The default is **true**.

-preserve_boundary_row_lib_cells ***lib_cell_list***

Specifies the library cells, such as critical area breaker cells or boundary cells, that require an abutting tap cell. If an empty space in the checkerboard pattern occurs above or below an instance of one of the specified library cells, the command inserts a tap cell in that empty space.

This option is valid only when used with the **-checkerboard** option.

-prefix ***prefix***

Specifies the prefix added to the inserted cell names.

When you use this option, the command uses the following naming convention for the inserted cells:

<*prefix*>__<*lib_cell*>_R#_C#_*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted cells:

headerfooter__<*lib_cell*>_R#_C#_*number*

DESCRIPTION

The **create_cell_array** command inserts an array of cells into the block.

To insert power-switch cells, use the **create_power_switch_array** command instead of this command.

EXAMPLES

The following example inserts an array of HEAD_16DM cells in the current block.

```
prompt> create_cell_array -lib_cell HEAD_16DM \
  -x_pitch 10 -y_pitch 10
Insert 684 cell HEAD16DM successfully.
```

SEE ALSO

create_power_switch_array(2)
create_tap_cells(2)

create_cell_array_pattern

Creates a cell array pattern in the current or specified block.

SYNTAX

collection **create_cell_array_pattern**
[-name *name*]
[-cell *cell*]
[-type solid | checkerboard]
[-lib_cell_name *name*]
[-row_column_ratio *ratio*]
[-horizontal_spacing *spacing*]
[-vertical_spacing *spacing*]
[-halo *factor*]

Data Types

name string
cell collection
ratio int_pair
spacing integer
factor float

ARGUMENTS

-name *name*

Specifies the name of the cell_array_pattern. The name may not contain the special characters '~' or '/'. If unspecified, the command will generate a name automatically using the prefix "CELL_ARRAY_PATTERN" with a system-generated number appended.

-cell *cell*

Specifies that this cell_array_pattern should be created in the block referenced by *cell*.

-type solid | checkerboard

Specifies the type of the cell_array_pattern. "solid" means that an instance of the lib_cell should be in every eligible site within the pattern. "checkerboard" means that an instance of the lib_cell should be in every other eligible site along each row, with the rows staggered such that an instance of the lib_cell is in every other eligible site along the columns as well.

-lib_cell_name *name*

Specifies the name of the lib_cell to be instantiated within the pattern.

-row_column_ratio *ratio*

Specifies the ratio of rows to columns in the cell_array_pattern. The ratio is an integer pair, with each integer >= 1. Note that the actual number of rows and columns can be any positive integer multiple of these values.

-horizontal_spacing *spacing*

Specifies the number of sites along each row of the cell_array_pattern between each eligible site for lib_cell placement within the pattern.

-vertical_spacing *spacing*

Specifies the number of sites along each column of the cell_array_pattern between each eligible site for lib_cell placement within the pattern.

-halo *factor*

Specifies the halo of the cell_array_pattern. The *factor* is the multiplier of the cell_array_patterns width and height, which indicates the width of the halo in the respective horizontal and vertical directions.

DESCRIPTION

The **create_cell_array_pattern** command creates a new cell_array_pattern in the current block, or the block specified by the *-cell* argument. A cell_array_pattern stores a description of how to place lib_cells associated with topological objects during the interconnect planning phase.

The name of a cell_array_pattern must be unique within its block.

Here is an illustration of two types of cell_array_patterns, each with row_column_ratio of {2 3} and horizontal and vertical spacing of 1:

type = solid, number of rows = 2

[*][ ][*][ ][*] [ ][ ][ ][ ][ ] [*][ ][*][ ][*]

type = checkerboard, number of rows = 4

[*][ ][ ][ ][*][ ][ ][ ][*][ ][ ] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [ ][ ][*][ ][ ][ ][*][ ][ ][ ][*] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [*][ ][ ][ ][*][ ][ ][ ][*][ ][ ] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [ ][ ][*][ ][ ][ ][*][ ][ ][ ][*]

EXAMPLES

The following example creates a cell_array_pattern in the current block:

```
prompt> create_cell_array_pattern
{CELL_ARRAY_PATTERN0}
```

The following example creates a cell_array_pattern with name "mycap", type "checkerboard", row/column ratio of 2/3, and a halo that is 10% of the dimensions of the pattern:

```
prompt> create_cell_array_pattern -name mycap -type checkerboard -row_column_ratio {2 3} -halo 0.1
{mycap}
```

SEE ALSO

get_cell_array_patterns(2)

create_cell_bus

Creates one cell bus and it cell members referencing a library cell or module.

SYNTAX

collection **create_cell_bus**
[-design *design*]
[-create_cells]
[-block *block*]
[-cell *cell*]
-reference *module*
cell_names

Data Types

design collection
block collection
cell collection
cell_bus_name string

ARGUMENTS

-design *design*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

-create_cells

Creates cell bus members if they do not exist.

-block *block*

Specifies the block where the cell bus is to be added. If specified, **create_cell_bus** has the same effect as **edit_module** in which the module is changed and changes are applied to all module occurrences.

-cell *cell*

Specifies the cell where the cell bus is to be added. The cell bus is created on the cell's reference module. **create_cell_bus** first uniquifies the reference if needed, then creates the cell bus. When not specified, the cell bus is created on the current module.

-reference *module*

Specifies the name of the library cell or module the created cell_bus's member should instantiate, the reference must already exist.

cell_bus_name

Specifies the cell bus name and its range using the **name [start: end]** format. Specify a cell bus named busA with cell from 1 *to* 5 as **busA[1:5]**. Specify a cell bus named busB with cell from 5 *downto* as **busB [5:1]**.

DESCRIPTION

This command creates a cell bus, collects or creates cell bus members, and puts them into the cell bus created.

The command returns the created cell_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates cell bus named *bus1* from cell 1 to 5 as bus[1], bus[2], bus[3], bus[4], bus[5] whose reference is RISC_CORE.

```
prompt> create_cell_bus -reference RISC_CORE bus1[1:5]
{"bus1"}
```

The following example first creates cells with reference as RISC_CORE, then creates a cell bus named *bus2* from the created cell with indexes 5 downto 1 as bus2[5], bus2[4], bus2[3], bus2[2], bus2[1]

```
prompt> create_cell_bus -reference RISC_CORE bus2[5:1] -create_cells
{"bus2"}
```

SEE ALSO

get_cell_buses(2)
remove_cell_buses(2)

create_channel_congestion_map

Creates a congestion map for the channel areas of the design.

SYNTAX

int **create_channel_congestion_map**
[-channel_width_threshold *threshold*]
[-boundary *coordinates*]
[-congestion_map_only true | false]

Data Types

threshold	float
coordinates	list

ARGUMENTS

-channel_width_threshold *threshold*

Specifies the threshold for the channel width in microns. Only areas with a width less than or equal to the threshold are considered a channel. By default, if you omit both the **-channel_width_threshold** and **-boundary** options, the tool defines the channel width as 10% of the longest chip dimension and generates a congestion map for the entire design.

-congestion_map_only true | false

Creates the congestion map without creating global route segments (glinks). By default, this option is false and the command generates glinks. If design has existing glinks, the command will not remove them if this option is true and the new congestion map could potentially be out of sync comparing with the existing glinks.

-boundary *coordinates*

Specifies the area in which to generate the considered map. The areas are boundaries specified by a list of rectangles or polygons, with units in microns. Specify the coordinates by using one of the following formats:

-boundary {{*llx lly*} {*urx ury*}}
-boundary {{*x1 y1*} {*x2 y2*} {*x3 y3*} ...}

In the first format, *llx* and *lly* specify the lower-left x- and y-coordinates, and *urx* and *ury* specify the upper-right x- and y-coordinates. In the second format, you specify each corner on the polygon to define the boundary.

When used together with **-channel_width_threshold** option, the command routes channel areas defined by either the **-channel_width_threshold** or **-boundary** options. By default, if you omit both **-channel_width_threshold** and **-boundary** options, the tool defines the channel width as 10% of the longest chip dimension and generates a congestion map for those channels in the entire design.

DESCRIPTION

This command creates a global route-based congestion map for the specified channel or boundary areas. An area is considered a channel if it is enclosed by macro cell boundaries, die boundaries, or block boundaries.

Since this command uses global routing to generate a congestion map, it is possible that congestion might appear in areas outside of the channel areas.

Since this command uses fast, very low effort global routing and other simplifying assumptions to generate a congestion map quickly, it will produce results that are more pessimistic than a congestion map generated by the **route_global -floorplan true** command. Similarly, the results from the **route_global -floorplan true** command will be slightly more pessimistic than results from **route_global**, because **route_global -floorplan true** performs fast, lower effort global routing along with simplifying assumptions to complete global routing quickly.

This command returns 1 on success, 0 otherwise.

EXAMPLES

The following example creates a channel congestion map for channel areas with a width less than 10 microns.

```
prompt> create_channel_congestion_map -channel_width_threshold 10
```

SEE ALSO

route_global(2)

create_check_design_strategy

Defines checks which can be run through **check_design** command.

SYNTAX

status **create_check_design_strategy**
[-define_check *atomic_check_name*]
[-define_group *mega_check_name*]
definition

Data Types

atomic_check_name	string
mega_check_name	string
definition	list

ARGUMENTS

-define_check *atomic_check_name*

Specifies the name of the atomic check to create. See **check_design** for definition of atomic-check.

If the specified name is the name of a predefined check (built-in check), the command issues an error message.

If the specified name is the name of an existing user-defined check, the new definition overwrites the previous definition.

The **-define_check** and **-define_group** options are mutually exclusive.

-define_group *mega_check_name*

Specifies the name of the mega check to create. See **check_design** for definition of mega-check.

In place of **mega_check_definition**, user should provide a list of atomic-check names. These atomic-check names can be names of any user-defined or pre-defined atomic-checks.

If the specified name is the name of a predefined check (built-in check), the command issues an error message.

If the specified name is the name of an existing user-defined check, the new definition overwrites the previous definition.

The **-define_check** and **-define_group** options are mutually exclusive.

definition

Defines the check.

When you use the **-define_check** option, this argument defines the atomic check. You must specify a single command with or without its options.

When you use the **-define_group** option, this argument defines the mega check. You must specify a list of atomic-check names. These atomic-check names can be the names of any user-defined or predefined atomic checks.

DESCRIPTION

User can use this command to,

(1) Define a new atomic-check or mega-check, whose name does not match any of the existing pre-defined or user-defined checks. For example, user can define a new check by name say, **my_check** and none of the pre-defined checks or existing user-defined checks have the name **my_check**.

(2) Re-define existing user-defined checks. For example, lets say a user-defined check by name **my_pre_placement_stage** already exists. User can give a new definition to the check **my_pre_placement_stage**, which overrides the previous definition.

To report the checks defined or modified by the **create_check_design_strategy** command, use the **report_check_design_strategy** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

(1) The following example defines a new user-defined check **my_mv_design**,

```
prompt> create_check_design_strategy -define_check my_mv_design \
   {check_mv_design -power_connectivity -max_message_count 0}
```

(2) The following example defines a mega-check named **mv_cts** using the existing atomic-checks named mv_design, cts_qor, and legality:

```
prompt> create_check_design_strategy -define_group mv_cts \
   {mv_design cts_qor legality}
```

SEE ALSO

check_design(2)
report_check_design_strategy(2)
get_design_checks(2)

create_checkpoint_action

Defines an action in the checkpoint system that can then be associated to run at a checkpoint.

SYNTAX

string **create_checkpoint_action**
action_name
tcl_commands

Data Types

action_name string
tcl_commands list

ARGUMENTS

action_name

Specifies the name of the action or flow change for the checkpoint system. A mandatory option specifying the name of the flow change. The name of the flow change must be unique, otherwise it will overwrite the previous definition.

tcl_commands

Specifies the block of TCL commands to be associated with the given action or flow change for the checkpoint system.

DESCRIPTION

Defines an action with the given name in the checkpoint system. An action can be any block of one or more Tcl commands. This command defines an action, but it does not execute the action. For an action to run, it must be associated to one or more checkpoints using the associate_checkpoint_action command. An action can be associated to run before, after, or as a replacement for the checkpoint contents.

Actions are used to modify behavior of the default flow. They allow experimental flow changes to be defined independently of the golden flow scripts. They may be defined in the ./checkpoint.config.tcl file in the run directory, which will automatically be sourced by the checkpoint system.

The simplest and most common example is an action which applies an app option setting before a checkpoint. But more complex actions are possible, such as applying multiple tool constraints, or modifying the options on a checkpointed command.

Actions execute at the same script scope as the checkpoint to which they are associated. So, any local variables or other variables made available through the global or upvar commands can be used inside that action. For this reason, ensure that any variables

you define inside an action do not conflict with variables defined at the scope in which it will run.

EXAMPLES

Defines an action called postroute_ccd that activates the CCD route_opt app option. Then action is then associated to run before the first_route_opt checkpoint. When the first_route_opt checkpoint is executed in the block's flow script, this action will execute beforehand.

```
## checkpoint.config.tcl
create_checkpoint_action postroute_ccd {
        set_app_options -name route_opt.flow.enable_ccd -value true
}

associate_checkpoint_action -enable postroute_ccd -before first_route_opt

## Flow route_opt.tcl script
eval_checkpoint first_route_opt { route_opt }
```

Defines and associates an action to replace the existing create_placement call at the incremental_place checkpoint with an option to force high congestion effort. The get_current_checkpoint -command option is used to access the current checkpointed command contents and modify them with the new option.

```
## checkpoint.config.tcl
create_checkpoint_action high_effort_congestion {
        eval [get_current_checkpoint -command] -congestion -congestion_effort high

}

associate_checkpoint_action -enable high_effort_congestion \
        -replace incremental_place

## Flow place_opt.tcl script
eval_checkpoint incremental_place {
        create_placement -incremental -timing_driven
}
```

get_checkpoint_data(2)

create_checkpoint_report

Defines a report in the checkpoint system that can then be associated to run at a checkpoint.

SYNTAX

string **create_checkpoint_report**
report_name
tcl_commands

Data Types

report_name string
tcl_commands list

ARGUMENTS

report_name

Specifies the name of the report for the checkpoint system. A mandatory option specifying the name of the report. The name of the report must be unique, otherwise it will overwrite the previous definition.

tcl_commands

Specifies the block of TCL commands to be associated with the given report for the checkpoint system.

DESCRIPTION

Defines a report with the given name in the checkpoint system. A report can be any block of one or more Tcl commands. This command defines a report, but it does not execute the report. For a report to run, it must be associated to one or more checkpoints using the associate_checkpoint_report command. A report can be associated to run before or after a checkpoint. Unlike actions, reports cannot replace a checkpoint's contents.

Reports are used to generate output from the tool at a checkpoint. They allow report definitions to be defined independently from the golden flow scripts. Each user may apply their preferred reporting setup to write out the required data needed for debugging run results. Typically, reports are defined in the ./checkpoint.config.tcl file in the run directory, which will automatically be sourced by the checkpoint system.

Checkpoint reports are typically used to write out common reports like report_qor, report_timing, check_mv_design, check_routes, other default tool reports, or custom user reports.

Reports execute at their own scope. They do not have access to the variables at the scope of the associated checkpoint, unless they

are made available in the create_checkpoint_report body with the Tcl global or upvar command. Any variables you define in the body of create_checkpoint_report will not conflict with variables at the checkpoint scope.

EXAMPLES

This example defines a report named timing that generates common timing related reports into the ./checkpoint directory. The get_current_checkpoint -name command is used to get the name of the current checkpoint, which is used to give each written report a unique and meaningful name.

This report is then associated to run after all *-final checkpoint names. When the flow script runs, any eval_checkpoint commands with checkpoint names matching *-final will run this report.

```
## checkpoint.config.tcl
create_checkpoint_report timing {

set name [get_current_checkpoint -name]
redirect -file ./checkpoint/${name}.qor.rpt { report_qor }
redirect -append ./checkpoint/${name}.qor.rpt { report_qor -summary }
redirect -file ./checkpoint/${name}.timing.rpt { report_timing }

}
associate_checkpoint_report -enable timing -after *-final
```

This example defines a report that saves a block to the NDM design database. Since it can be useful to save a before or after an important flow step, the report uses the get_current_checkpoint -position option to uniquely name the saved block, indicating whether it was saved 'before' or 'after' the checkpoint. This report can then be associated to run before or after any checkpoint names where the user wants to save the database.

```
## checkpoint.config.tcl
create_checkpoint_report save_block {

set name [get_current_checkpoint -name]
set position [get_current_checkpoint -position]
save_block -as checkpoint_${position}_${name}

}
```

create_clock

Creates a clock object.

SYNTAX

collection **create_clock**
-period *period_value*
[-name *clock_name*]
[-waveform *edge_list*]
[-add]
[*source_objects*]
[-comment *comment*]

Data Types

period_value float
clock_name string
edge_list list
source_objects list
comment string

ARGUMENTS

-period *period_value*

Specifies the clock period in library time units. This is the minimum time over which the clock waveform repeats. The *period_value* must be greater than or equal to zero.

-name *clock_name*

Specifies the name of the clock being created, enclosed in quotation marks. If you do not use this option, the clock gets the same name as the first clock source specified in the *sources* option. If you did not specify *sources*, you must use the **-name** option, which creates a virtual clock not associated with a port or pin. You can use both the **-name** option and the *sources* option to give the clock a more descriptive name than the first source pin or port. If you specify the *-add* option, you must use the **-name** option and the clocks with the same source must have different names.

-waveform *edge_list*

Specifies the rise and fall edge times of the clock waveforms of the clock, in library time units, over an entire clock period. The first time in the *edge_list* is a rising transition, typically the first rising transition after time zero. There must be an even number of edges, and they are assumed to be alternating rise and fall. The edges must be monotonically increasing, except for a special case with two edges, where fall can be less than rise. The numbers should represent one full clock period. If you do not specify this option, a default waveform is assumed, which has a rise edge of 0.0 and a fall edge of *period_value*/2.

-add

Specifies whether to add this clock to the existing clock or to overwrite. Use this option to capture the case where multiple clocks must be specified on the same source for simultaneous analysis with different clock waveforms. When you specify this option, you must also use the *-name* option.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the tool must explore all possible combinations of launch and capture clocks. Use the **set_false_path** command to disable unwanted clock combinations.

source_objects

Specifies the objects used as sources of the clock. The sources can be ports, pins or nets in the design. If you do not use this option, you must use the **-name** option, which creates a virtual clock not associated with a port, pin or net. If you specify a clock on a pin that already has a clock, the new clock replaces the old one unless you use the **-add** option. When a net is used as the source, the first driver pin of the net is the actual source used in creating the clock.

-comment ***comment***

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

Creates a clock object. It is created in the current design and is applied to the specified *sources*.

If successful, the command returns a collection containing the new or modified clock.

If you do not specify a *sources* value, but give a *clock_name* value, a virtual clock is created. You can create a virtual clock to represent an off-chip clock for input or output delay specification. For more information about input and output delay, see the **set_input_delay** and **set_output_delay** man pages.

If one of the *sources* is already the source of a clock, the source is removed from that clock. This clock is eliminated if it has just one source.

The **create_clock** command also defines the waveform for the clock. The clock can have multiple pulses per period.

The **create_clock** command is used together with the **set_clock_latency**, **set_clock_uncertainty**, **set_propagated_clock**, and **set_clock_transition** commands to specify properties of clock networks. By default, a new path group is created for the clock. This new path group brings together the endpoints related to this clock for cost function calculation. To remove the clock from its assigned group, use the **group_path** command to reassign the clock to another group or to the default path group. For more information, see the **group_path** man page.

The new clock has ideal clock latency and transition time; no propagated delay through the clock network is assumed and a transition time of zero is used at the clock source pin. To enable propagated latency for a clock network, use the **set_propagated_clock** command. To set an estimated latency, use the **set_clock_latency** command.

To show information about clocks in the design, use the **report_clock** command. To create a collection of clocks matching a pattern and optionally matching filter criteria, use the **get_clocks** command.

To undo **create_clock**, use the **remove_clock** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example creates a clock on a port named *PHI1* with a period of *10.0*, a rise at *5.0*, and a fall at *9.5*.

```
prompt> create_clock PHI1 -period 10 -waveform { 5.0 9.5 }
```

The following example shows a clock named *PHI2* with a falling edge at *5* and a rising edge at *10* with a period of *10*. Because the edges for the **-waveform** option should be ordered as first rise, then fall, and should increase in value, the fall edge can be given as *15*. This places the next falling edge after the first rise edge at *10*.

```
prompt> create_clock PHI2 -period 10 -waveform { 10 15 }
```

The following example creates a virtual clock *PHI2* with a period of *10.0*, a rise at *0.0*, and a fall at *5.0*.

```
prompt> create_clock -name PHI2 -period 10 -waveform {0.0 5.0}
```

The following example creates a clock named *clk2* with multiple sources.

```
prompt> create_clock -name clk2 -period 10 \
  -waveform {2.0 4.0} {clkgen1/Z clkgen2/Z clkgen3/Z}
```

The following example creates a clock named *CLK* on pin *u13/Z* with a period of *25*, a fall at *0.0*, a rise at *5.0*, a fall at *10.0*, a rise at *15.0*, and so on.

```
prompt> create_clock u13/Z -name CLK -period 25 -waveform { 5 10 15 25}
```

create_clock_balance_group

Creates a clock balance group containing clocks or skew groups that need to be balanced together.

SYNTAX

string **create_clock_balance_group**
-objects *object_list*
-name *group_name*
[-offset_latencies *offset_value_list*]
[-corner *corner_name*]

Data Types

object_list	collection
group_name	string
offset_value_list	list
corner_name	string

ARGUMENTS

-objects *object_list*

Specifies the list of clocks or skew groups to be balanced together. This list cannot contain a combination of clocks and skew groups. Note that objects list should contain at least two objects.

-name *group_name*

Specifies the name of the clock balance group.

-offset_latencies *offset_value_list*

Specifies the ordered list of offset latency values for the clocks in '-objects' argument. The default value is 0.0 for all objects in the objects list.

-corner *corner_name*

Specifies the corner to which the offset latencies are applied.

DESCRIPTION

This command creates a new clock balance group in which all clocks have the similar insertion delay or differences by offset values if '-offset_latencies' is specified. Clocks will be balanced by using the **balance_clock_groups** command.

(a) If no offset latencies are specified, balance_clock_groups takes the longest insertion delay among the objects as the target latency and balances with 0 offset. (b) If offset latency values are set, it balances the clocks and skew groups to achieve the desired insertion delay among them with corresponding offset latencies applied.

Multicorner-Multimode Support

EXAMPLES

The following example creates a new clock balance group named 'balance_group1'.

```
prompt> create_clock_balance_group -objects {clk1 clk2 clk3} \
    -name balance_group1 \
    -offset_latencies { 0.0 0.1 -0.5 }
```

create_clock_buffer

Inserts a buffer in the clock tree.

SYNTAX

string **create_clock_buffer**
[-clock *clock_name*]
[-sinks *pins_or_ports*]
[-source *pin_or_port*]
[-replace *cell*]
[-new_net_name *net_name*]
[-new_cell_name *cell_name*]
[-location {*x y*}]
[-snap true | false]

Data Types

clock_name string
pins_or_ports collection
pin_or_port string
cell string
net_name string
cell_name string
x float
y float

ARGUMENTS

-clock *clocks*

Selects the buffer based on clock-specific buffer selection rules for this clock. By default, no clock-specific buffer selection rules are considered.

-sinks *pins_or_ports*

Specifies the pins or ports to buffer. The newly inserted buffer becomes the driver of these sinks. The specified pins or ports must be driven from the same physical net, and must all be within the same physical hierarchy block. The logical nets might be different.

Exactly one of the options **-sinks**, **-source** or **-replace** must be specified.

-source *pins_or_port*

The pin or port behind which the buffer will be inserted. The newly inserted buffer becomes a sink of this source.

Exactly one of the options **-sinks**, **-source** or **-replace** must be specified.

-replace *cell*

Replaces an existing buffer with the specified new buffer. The new buffer will be connected in the same way as the old buffer. This option is used to ensure that the buffer honors the CTS buffer selection rules.

Exactly one of the options **-sinks**, **-source** or **-replace** must be specified.

-new_net_name *net_name*

Specifies a prefix to use for the new net that connects the driver of the sinks to any sinks of that driver which are not driven by the new buffer. Use this option only with the **-sinks** option, since otherwise there will be no such remaining sinks.

-new_cell_name *cell_name*

Specifies the prefix to use for the new buffer. A number will be added at the end to make the name unique. By default, the prefix is "cts_guide".

-location {*x y*}

Specifies the location to use for the new buffer. The actual location is determined by finding the nearest point not blocked by hard placement blockages or blocks. If there is no top-level free space (as in a fully-abutted design), overlap with a block is allowed.

-snap true | **false**

Specifies whether the buffer should snap to the nearest point that is not covered by a block. By default, snapping is performed, and the tool attempts to find a location at the top-level near to the indicated location to place the buffer. However, if the intention is to push the buffer down into some block, snapping can be disabled with the **-snap false** option. Note that if no top-level area is available (as in a fully-abutted design), then snapping is disabled regardless. Also note that the tool always snaps away from hard placement blockages.

DESCRIPTION

The **create_clock_buffer** command inserts a buffer in front of the specified sets of sinks, using the same rules for buffer selection as the **synthesize_clock_trees** command.

Use this command to insert guide buffers in the clock tree before clock tree synthesis to guide the clock tree synthesis.

The command returns the name of the newly inserted buffer.

EXAMPLES

Insert a buffer in front of a single sink.

```
prompt> create_clock_buffer -clock CLK -sinks [get_pins cell1/A]
cell1/cts_guide1
```

SEE ALSO

synthesize_clock_trees(2)

create_clock_drivers

Creates a set of clock driver cells in the netlist. The clock driver cells are legalized near user-specified locations. The created cells are either buffer cells, or clones of an existing template cell in the netlist. The cells can also be created inside physical hierarchy blocks.

SYNTAX

status **create_clock_drivers**
-loads *net_pin_port_list*
[-prefix *string*]
[-keepouts *poly_rect_list*]
[-max_displacement *distance*]
[-locations *coordinate_list*]
[-boxes *integer_pair*]
[-boundary *poly_rect*]
[-lib_cells *lib_cell_list*]
[-template]
[-input_pin *hier_in_pin_list*]
[-hierarchy *hier_list_per_block*]
[-short_outputs]
[-output_net_name *string*]
[-transfer_wires_from *net*]
[-configuration *config_list*]

Data Types

net_pin_port_list list or collection of a net or pins and ports
coordinate {x_coordinate y_coordinate}, in user units
coordinate_list list of coordinates
net a logical net in the block
distance distance in user units
poly_rect a polygon definition (see create_poly_rect for format)
poly_rect_list list of poly_rect
lib_cell_list list of lib_cells
integer_pair list of two positive integers {columns rows}
hier_in_pin_list list of hierarchy and input_pin pairs
hier_list_per_block list of physical hierarchy and corresponding logical hierarchy pairs
string a string value

ARGUMENTS

-loads *net_pin_port_list*

The outputs of the inserted cells will drive the loads as specified with the **-loads** option. The **-loads** option takes a single net or a

set of load pins and/or ports. If a net is specified, all load pins/ports of that (physical) net form the load pins of the inserted cells. If load pins or ports are specified explicitly, then all the specified pins and ports should initially be connected to the same (physical) net. However, not all sink pins of a net may be specified as load pins. The unspecified sink pins of the net will not be driven by the inserted cells, but will remain connected to the original net. If **-template** option is specified in the Multi-Level Physical Hierarchy flow, a list comprising the output net of the template cell in each physical hierarchy must be specified using this option.

-prefix ***string***

All newly created cells will get this prefix in front of their name. The default value is **clk_drv**. This same prefix is also applied to the names of new nets or ports that are created for a clock driver.

-keepouts ***poly_rect_list***

Specifies a list of poly_rects where no driver cells should be placed. If a preferred location is in one of the poly_rects, then no driver will be placed at that location.

-max_displacement ***distance***

The inserted clock drivers are legalized taking fixed cells, macros, blockages, and other clock cells into account. When after legalization the distance of the cell center to the preferred location is larger than the distance specified with the **-max_displacement** option, no driver will be inserted near that preferred location. By default, no maximum displacement is in effect, and cells will be legalized as close as possible to the preferred location.

-locations ***coordinate_list***

Specifies a list of preferred locations where cells should be placed. The cells are legalized such that the center of the inserted cells is as close as possible to these coordinates.

-boxes ***integer_pair***

The **-boxes** option accepts a list of two positive integers defining the number of columns and rows of a location grid. The bounding box of the boundary is subdivided in equally sized boxes according to the specified number of columns and rows. Then the preferred locations are formed by the centers of these boxes. The boundary can be specified explicitly using the **-boundary** option. If not specified, the boundary of the core area is used.

-boundary ***poly_rect***

Specifies the area in which the inserted cells should be placed. If the preferred location of any of the cells to be inserted is not covered by the area enclosed by the boundary, then the cell will not be inserted. The default boundary is the boundary of the core area.

-lib_cells ***lib_cell_list***

Specifies a list of buffer lib_cells that can be used as clock driver cells. All specified lib_cells should have lib_cell purpose **cts** included. For each preferred location, the corresponding voltage area is queried, and the **first** lib_cell in the list that qualifies for that voltage area will be used for the location. If none of the provided driver types qualifies, then no buffer is inserted at that location. This options is mutually exclusive with the **-template** option if the lib cell of the template is neither a buffer nor an inverter.

-template

Specifies that the existing driver cell of the load net (the template cell) should be cloned to create clock driver cells. Using a template cell, it is possible to have inverters or clock gates as clock drivers. All newly created cells will be inserted in same hierarchy level as the original template cell, and are only inserted if the preferred location is in the same voltage area as the original driver. This option is mutually exclusive with the **-lib_cells** option if the lib cell of the template is neither a buffer nor an inverter.

-input_pin

Only valid in combination with **-template**. It specifies a list of pairs of hierarchy and the clock input pin of the template cell. This option is required if the template cell has multiple inputs (Example: clock gating cell, multiplexer etc.) and the template is for a

level higher than 1 (see **-configuration**). Otherwise it is optional. In the Multi-Level Physical Hierarchy flow, the input pin must be specified for each physical hierarchy where a multi-input template cell exists. A list of pairs of hierarchy name and respective clock pin name needs to be specified. For top level the keyword "TOP" should be used as the hierarchy name.

-hierarchy *hier_list_per_block*

Specifies a list of pairs of physical hierarchy and corresponding logical hierarchy in which the clock drivers should be inserted. This option is invalid in conjunction with the **-template** option. For top level the keyword "TOP" should be used as hierarchy name. The logical hierarchy may be specified for few physical blocks and will be auto determined for physical blocks for which the information is not specified.

-short_outputs

Specifies that the output pins of the drivers should all be connected to the same physical net. In this way, multi-driven clock meshes or clock straps can be supported.

-output_net_name *string*

Specifies the name of the shorted output net. This option is only valid when option **-short_outputs** is given.

-transfer_wires_from *net*

Specifies an existing net with shapes and/or vias. These shapes and vias will be moved from the existing net to the shorted output net of the drivers. This option is only valid when option **-short_outputs** is given.

-configuration *config_list*

Specifies multiple levels of clock drivers to be inserted. Each entry in the *config_list* corresponds to a clock driver level. An entry is itself a list of options. The following options can be used in a configuration entry:

-level *integer*
[-prefix *string*]
[-keepouts *poly_rect_list*]
[-max_displacement *distance*]
[-locations *coordinate_list*]
[-boxes *integer_pair*]
[-boundary *poly_rect*]
[-lib_cells *lib_cell_list*]
[-template]
[-input_pin *hier_in_pin_list*]
[-hierarchy *hier_list_per_block*]
[-short_outputs]
[-output_net_name *string*]
[-transfer_wires_from *net*]

The required **-level** option accepts a positive integer indicating the level for the configuration entry. Level 1 is the level near the root, and the level number counts up going towards the leaves of the multi-level clock driver structure. The semantics of the other options is the same as for the corresponding option at the command level. For **-prefix**, **-keepouts**, **-max_displacement**, **-boundary**, and **-lib_cells**, the default value is the value of the command-level corresponding option.

DESCRIPTION

The **create_clock_drivers** command inserts a number of clock buffers into the netlist using the reference library cell specified with the **-lib_cells** option. If you specify more than one buffer library cells, for each inserted buffer, the tool inserts the first usable buffer in the list. The library cell selection process takes power domain and driver/load characteristics into account. The **-loads** option takes a single net or a set of load pins. If a net is specified, then all load pins of that (physical) net form the load pins of the buffers. If load

pins are specified explicitly, then all the specified pins should initially be connected to the same (physical) net. However, not all sink pins of a net may be specified as load pins. The unspecified load pins of the net will not be driven by the inserted buffers, but will remain connected to the original net. All specified load pins will be connected to a single inserted clock driver cell. A subsequent tap assignment step is required to distribute the loads over the inserted buffers. The inputs of the inserted repeaters will connect to the original (physical) net of the load pins. If option **-hierarchy** is given, then all buffers will be inserted in the specified hierarchical cell. Otherwise, the tool will choose an appropriate hierarchy level to insert the cells. The number of inserted repeaters is implicitly defined by specifying a number of ideal (preferred) locations. Repeaters will be inserted at legal locations near the specified ideal locations. During legalization, only fixed cells, marked clock cells, and blockages are considered when determining the legal locations. So, inserted repeaters may overlap with existing data path cells or flipflops. In order to end with a legalized design, run the **legalize_placement** command after the **create_clock_drivers** command. Locations can be specified explicitly by using the **-locations** option and/or implicitly through a regular pattern using **-boxes** and **-boundary**. The default boundary is the core area of the block. The **-boxes** option accepts two positive integers defining the number of columns and rows of a location grid. The bounding box of the boundary is subdivided in equally sized boxes according to the specified number of columns and rows. Then the ideal locations are formed by the centers of these boxes. The ideal locations are pre-filtered using the keepout regions and the boundary. If an ideal location is covered by a keepout region or not covered by the boundary area, then that location is not used. The ideal locations define preferred location of the centers of the cells. So, legalization will try to get the center of the buffers as close as possible to the specified locations. If **-max_displacement** is defined and a legalized cell would land more than the specified distance from the ideal location, then the buffer cell will not be inserted. The inserted buffers will have the **physical_status** attribute set to **fixed** and the **user_dont_touch** attribute set to **true**.

Using the **-lib_cells** option, only simple repeaters (buffers or inverters) can be specified. If non-repeater cells (e.g. clock gates) are to be placed in a regular pattern, then a template version of the cells should be included in the incoming netlist. By specifying the **-template** option instead of **-lib_cells** (these options are mutually exclusive if the library cell of the template is neither a buffer nor an inverter), the command is instructed to make clones of the unique driver cell of the load pins. The clone insertion follows the same rules as the buffer insertion with respect to keepouts, legalization, and load assignment. A clone will only be inserted when the ideal location is in the same voltage area as the voltage area of the template cell if the template cell is neither a buffer nor an inverter. The clones will be in the same hierarchical level as the template cell. If the template cell is a buffer or inverter and the location is in a different voltage area and hence power domain this implies that the **opt.common.allow_physical_feedthrough** application option must be set to **true**. The **-hierarchy** option is not supported when **-template** is given. When inverters are used as lib_cells, the polarity of the clock should not change. This implies that in the single-level insertion, no inverters can be specified through **-lib_cells** because that would invert the clock. Instead, an inverter should be added to the incoming netlist and **-template** can be used to clone this existing inverter.

The command can also insert multiple levels of clock drivers using the **-configuration** option. For the lowest level, all loads in a voltage area will be connected to a single clock driver in that voltage area. The other clock drivers in the voltage area will have dangling outputs. A subsequent tap assignment step is required to distribute the loads over the clock drivers. For the higher levels, an assignment of the clock drivers at level N to the clock drivers of level N-1 is performed based on proximity. At these non-leaf levels, drivers that have no loads assigned will not be inserted. So at non-leaf levels, there will be no drivers with dangling outputs. This results in a multi-level structure where only one of the leaf drivers (per voltage area) drives the original loads, and the other leaf drivers have dangling outputs.

In all situations, the polarity of the clock should be preserved at all template levels and at the leaves. This implies that an even number of inverter levels should be inserted in between template levels, as well as an overall even number of inverter levels. It is an error if a polarity change would occur, and the command will not insert any cell in that case.

In a multi-level structure, the building of a level should be aware of what input pins of the downstream level are to be driven. For single-input downstream cells (e.g. buffers or inverters) this is clear. For multi-input cells such as clock gates or multiplexers, the input pin of the template cell should be specified explicitly using the **-input_pin** option. This option accepts a string pair consisting of hierarchy of the template cell and the pin name of the lib_cell to be driven by the upsteam level. Since root level 1 does not have a driving level, it is not required to specify the input_pin name for level 1, even if this is a multi-input template level.

This command also supports Multi-Level Physical Hierarchy (MLPH) flow. Using this flow, the cells can be inserted inside physical blocks present at any level of physical hierarchy. To enable this feature, the application option **cts.multisource.enable_mlph_flow** must be set to true. The locations of the cells can be specified using the **-locations** option or the **-boxes** option. The **-locations** option would take the coordinates with respect to top level of design. Based on the top-level location, the cell would be inserted inside the physical block present at that location. The **-hierarchy** option can be used to specify the logical hierarchy in each physical block which should be used for buffer insertion. For top level, the keyword "TOP" must be used for physical hierarchy block. The **-**

hierarchy option can be specified in global scope as well as per level. The value for a particular level of buffer insertion will take precedence over global scope.

The MLPH flow supports single level cell insertion as well as multi-level cell insertion using the **-configuration** option. Loads of the original clock net are connected to appropriate cells in the single level cell insertion, while they are connected to appropriate cells in the leaf level in the multi-level cell insertion. The load connectivity is done based on the physical hierarchy of the inserted cells as well as the loads. Loads of the original clock net may reside in different physical hierarchies. In this flow, the loads present in a particular physical hierarchy are connected to any one of the cells inserted in that physical hierarchy. If there are no loads in a physical hierarchy, the output pin of all the cells inserted in that block are left dangling. It is recommended, that the cells should be inserted in all physical blocks in which any loads are present. However, in case there are loads present in a physical block but no cell could be inserted in it, then the loads would be connected to a suitable cell present in a different physical hierarchy.

In the multi-level cell insertion, the load assignment of the non-leaf level cells is done based on the proximity of the loads. This may result in a cell present in a physical block driving loads present in other physical blocks. New logical ports may be created in this process if necessary.

The MLPH flow also supports the **-template** option. If the template cells are to be cloned in different physical hierarchies, then the template cell should pre-exist in all those hierarchies. The output net of the template cells in all physical hierarchies should be provided using the **-loads** option. The template cells present in different physical hierarchies may have different masters. The template cell master in a particular physical block is used for cloning cells in that particular physical block. In case a template cell is present in a physical hierarchy but no location falls on top of that physical hierarchy, then the pre-existing template cell would be deleted. The logical hierarchy of the pre-existing template cells is used for cloned cells in the corresponding physical block. For a multi-input template cell, the input pin which should be used for connection in the clock network should be specified for each hierachy using the -input_pin option.

In the MLPH flow, the physical blocks where cells are to be inserted should be editable and port-punching should also be enabled. The optimization of physical blocks must be enabled using the application option **top_level.optimize_subblocks**. In addition, the MSCTS full MV flow should also be turned ON using the application option **cts.multisource.enable_full_mv_support**. An error message would be generated in case the physical block is read-only.

In a typical flow **create_clock_drivers** is used to insert Htree cells/loads. The command **synthesize_multisource_global_clock_trees** is then used to build and route the global clock tree (Htree). This command uses the highest two metal layers allowed for the nets connecting the created cells to route the long distances. These layers can be controlled by using the **set_clock_routing_rules** and **set_routing_rule** commands in conjecture with an explicit nondefault routing rule created with the **create_routing_rule** command. The layers should be within global minimum and maximum layers specified with the **set_ignored_layers** command.

The **create_clock_drivers** command uses the **cts.multisource.enable_pin_accessibility_for_global_clock_trees** application option to control the placement of inserted cells such that they are accessible from the selected Htree routing layers. This ensures good global clock tree (Htree) routing topology and hence the QoR. In cases where command is not used to insert Htree cells/loads, large displacements are observed or cells are dropped it might be useful to set this application option to **false**.

If a clock mesh has been created prior to inserting clock drivers using this command, the tap drives as well as mesh drivers can be snapped close to the clock mesh route shapes. This feature can be enabled using the **cts.multisource.enable_clock_driver_snapping** application option.

To undo the changes made by the **create_clock_drivers** command, use the **remove_clock_drivers** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example creates a grid of 8 by 8 clock driver cells that drive a multi-driven mesh net named clk1_mesh. The drivers

are placed in a regular pattern that covers the full core area (no -boundary option). No drivers will be placed in the bottom-left keepout area. Any existing shapes and vias on net clk1 will be transferred to the newly created mesh net clk1_mesh.

```
prompt> create_clock_drivers -loads [get_net clk1] \
    -lib_cells [get_lib_cells */CKBUF*] \
    -boxes {8 8} \
    -short_outputs \
    -transfer_wires_from [get_net clk1] \
    -output_net_name clk1_mesh \
    -keepouts [list {{0 0} {850 630}} ]
```

The following example creates a grid of 4 by 4 clones of the original driver cell of the load net. On top of that there is an additional clone at the bottom left. If the cells need to move more than 4 um from their preferred location, they will not be inserted.

```
prompt> create_clock_drivers -loads [get_net clk] \
    -template \
    -boxes {4 4} \
    -locations [list {0 0}]\
    -max_displacement 4
```

The following example inserts 4 levels of clock drivers. The first level is a single inverter in the center of the boundary driving 4 inverters at the second level. These drive the CK pin of 16 clones of the original driver of the net. The cloned drivers drive the 64 leaf buffers for which the name starts with HTREE_LEAF. The name of the other inserted driver cells starts with HTREE (the command-level default). For all cells, except the template clones, the maximum allowed displacement is 4 user units. For the template clones, the maximum displacement is 20 user units.

```
prompt> set invs [get_lib_cells */CKINV*]
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_net clk] \
    -prefix HTREE \
    -max_displacement 4 \
    -boundary $boundary \
    -lib_cells $invs \
    -configuration [list \
      [list -level 1 -boxes {1 1}] \
      [list -level 2 -boxes {2 2}] \
      [list -level 3 -boxes {4 4} -template -input_pin {{TOP CK}} \
              -max_displacement 20] \
      [list -level 4 -boxes {8 8} -lib_cells $bufs \
              -prefix HTREE_LEAF] \
    ]
```

The following example inserts a single level of clock drivers in 2x2 configuration in the Multi-Level Physical Hierarchy (MLPH) flow.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] -lib_cells $bufs -prefix TAP -boxes {2 2}
```

The following example inserts a 4 level buffer tree in the MLPH flow.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
```

```
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] \
                -lib_cells $bufs \
                -configuration [list [list -level 1 -prefix TAP1 -boxes {1 1}] \
                        [list -level 2 -prefix TAP2 -boxes {2 1}] \
                        [list -level 3 -prefix TAP3  -boxes {2 2}] \
                        [list -level 4 -prefix TAP4 -boxes {4 4}] \
                ]
```

The following example inserts a 4 level buffer tree in the MLPH flow in the specified logical hierachies. Assume there are 2 physical hierachies A and C. The buffers are inserted in logical hierachies A1 and C1 inside blocks A and C respectively. Additionally the logical hierarchy I1/I2 inside top block is used for buffer insertion at top level.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] \
                -lib_cells $bufs \
                -hierarchy {{TOP I1/I2} {A A1} {C C1}} \
                -configuration [list [list -level 1 -prefix TAP1 -boxes {1 1}] \
                        [list -level 2 -prefix TAP2 -boxes {2 1}] \
                        [list -level 3 -prefix TAP3  -boxes {2 2}] \
                        [list -level 4 -prefix TAP4 -boxes {4 4}] \
                ]
```

The following example inserts a 4 level buffer tree in the MLPH flow. The first 3 levels are inserted using the specified lib cells. The 4th level clones the template cell present in different physical hierarchies. Each of the physical hierarchies where cloning is required must already have a template cell instantiated in the netlist.

In this example there is a top block with 2 sub-blocks namely “A” and “C”. The output net name of the template cell in top block is “clk1”, while in blocks “A” and “C” it is “A/clk1” and “C/clk1” respectively. All these 3 nets should be specified in the -loads option.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets {clk1 A/clk1 C/clk1}] \
                -lib_cells $bufs \
                -configuration [list [list -level 1 -prefix TAP1 -boxes {1 1}] \
                        [list -level 2 -prefix TAP2 -boxes {2 1}] \
                        [list -level 3 -prefix TAP3  -boxes {2 2}] \
                        [list -level 4 -prefix TAP4 -boxes {4 4} -template] \
                ]
```

The following example inserts a 4 level buffer tree in the MLPH flow. The first 3 levels are inserted using the specified lib cells. The 4th level clones the multi-input template cell present in different physical hierarchies.

In this example there is a top block with 2 sub-blocks namely “A” and “C”. The output net name of the template cell in top block is “clk1”, while in blocks “A” and “C” it is “A/clk1” and “C/clk1” respectively. The template cell present in each of the physical hierarchies is a multi-input cell. In top level hierarchy the input pin of template cell to be used for connection is "a0" while in hierarchies "A" and "C", the input pin to be used for connection is "a1". These are specified using the **-input_pin** option. For specifying the top-hierachy the keyword "TOP" is used.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets {clk1 A/clk1 C/clk1}] \
                        -lib_cells $bufs -configuration [list \
                          [list -level 1 -prefix TAP1 -boxes {1 1}] \
                          [list -level 2 -prefix TAP2 -boxes {2 1}] \
                          [list -level 3 -prefix TAP3  -boxes {2 2}] \
                          [list -level 4 -prefix TAP4 -boxes {4 4} -template -input_pin {{TOP a0} {A a1} {C a1}}] \
                         ]
```

create_clock_rp_groups

Creates relative placement groups for leaf level clock tree cells and immediate drivers.

SYNTAX

int **create_clock_rp_groups**
[-min_sinks *sinks*]
[-max_sinks *sinks*]
[-distance *distance*]
[-timing_driven]
[-max_rp_rows *rows* | -auto_shape]
[-cells *cell_list*]

Data Types

sinks	integer
distance	float
rows	integer
cell_list	collection

ARGUMENTS

-min_sinks *sinks*

Specifies the minimum number of sinks that should be driven by a driver cell, to be considered for grouping. If any driver cell is driving less than the given number of sinks then relative placement group will not be created for driver and sinks. The default value is 2.

-max_sinks *sinks*

Specifies the maximum number of sinks that should be driven by a driver cell, to be considered for grouping. If any driver cell is driving more than the given number of sinks then relative placement group will not be created for driver and sinks. The default value is 128.

-distance *distance*

Specifies the maximum allowed distance between the sinks in one relative placement group. It is manhattan distance in microns. If distance between sinks is more than the given distance then more than one relative placement groups will be created. The default value is 100 microns.

-timing_driven

Specifies that the timing critical sinks should not be considered for grouping. By default all the flops having negative slack are not considered.

-max_rp_rows *rows*

This option controls the shape of the relative placement group and specifies the maximum number of rows. If total number of cells in relative placement group (sinks and driver) are more than the given rows then multiple columns will be created. The default value for the rows is 32. If number of sinks are 128 or more then shape of relative placement group will be decided automatically.

-auto_shape

Specifies that the shape of the relative placement group should be decided automatically. The shape is decided based on the spread of the cells of the relative placement group.

-cells *cell_list*

Specifies the list of names or collection of cells to be clustered. If cells are not given then command will consider all cells of the design for grouping.

DESCRIPTION

The **create_clock_rp_groups** command creates relative placement groups for clock tree sinks. Normally one relative placement group is created for one group of sinks being driven by same clock driver and the drive also becomes part of the relative placement group. It can create more than one relative placement group for sinks of same clock driver depending on the options given to the command.

EXAMPLES

The following example uses the **create_clock_rp_groups** command to create relative placement groups with default values.

```
prompt> create_clock_rp_groups
1
```

The following example uses the **create_clock_rp_groups** command to create relative placement groups, where sinks of one group are not far than 50 microns from each other, and all considered clock drivers drive equal or more than 3 sinks.

```
prompt> create_clock_rp_groups -distance 50 -min_sinks 3
1
```

The following example uses the **create_clock_rp_groups** command to create relative placement groups for clock sinks with maximum 16 rows.

```
prompt> create_clock_rp_groups -max_rp_rows 16
1
```

create_clock_skew_group

Creates a new user-defined skew group.

SYNTAX

collection **create_clock_skew_group**
[-name skew_group_name]
[-mode *mode*]
[-clock *clock*]
-objects object_list

Data Types

skew_group_name	string
mode	collection
object_list	collection

ARGUMENTS

-name *skew_group_name*

Specifies the name of the skew group. If not specified the tool generates a unique one on its own.

-mode *mode*

Specifies the mode for which the skew group needs to be created. If not specified the current mode is assumed.

-objects *object_list*

List of pins and/or ports which need need to be grouped.

-clock *clock*

Specifies the clock for which the skew group needs to be created. If not specified the skew group is applied to all the clocks going through the pins.

DESCRIPTION

This command creates a user-defined skew group. Sink pins specified in a skew group will be balanced against each other to meet the specified desired skew and target early delay.

Incremental addition of sink pins in a skew group definition is not supported.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the **-mode** option.

EXAMPLES

The following example creates a skew group for the current mode named grp1 with reg_g2/D1/CK and reg_g2/D2/CK as sink pins:

```
prompt> create_clock_skew_group -name grp1 \
  -objects {reg_g2/D1/CK reg_g2/D2/CK}
```

SEE ALSO

create_clock_straps

Creates straight clock shapes (straps) and vias to implement clock meshes or clock spines. The straps and vias are attached to existing clock nets. A clock mesh is a two-dimensional grid in a horizontal and a vertical layer, where the straps are connected by vias at the intersection points. Clock spine structures can be either one-dimensional or two-dimensional. One dimensional spines, are straps in a single direction. In a two-dimensional spine structure, each *spine* in the spine direction connects to multiple *stripes* in the orthogonal direction. Shapes connected to one spine however, do not connect to shapes of a different spine. This command can generate meshes, one-dimensional spines and two-dimensional spines. It can also create stripes that connect to automatically detected pre-existing spines.

SYNTAX

status **create_clock_straps**
[-nets *net_list*]
[-boundary *poly_rect*]
[-keepouts *poly_rect_list*]
[-layers *layer_list*]
[-widths *distance_list*]
[-grids *iterator_list*]
[-margins *distance_list*]
[-create_ends]
[-types *type_list*]
[-length *distance*]
[-backoff *distance*]
[-detect_length *distance*]
[-spine_direction *direction*]
[-bias]
[-bias_to_nets *net_list*]
[-bias_margins *distance_list*]
[-allow_floating *true*|*false*]
[-allow_splitting *true*|*false*]
[-clear]

Data Types

net_list	list or collection of nets
layer_list	list or collection of one or two layers
distance	distance in user units
distance_list	list of one or two distances
type_list	list of one or two types in {*user_route stripe detect*}
iterator_list	list of one or two grid iterators
poly_rect	a polygon definition (see create_poly_rect for format)
poly_rect_list	list of poly_rect
direction	*horizontal* or *vertical*

ARGUMENTS

-nets *net_list*

For each of the nets, shapes and vias will be created/deleted according to the specification in the other arguments. Typically, a single net will be specified. Multiple nets are only allowed when the *-clear* option is specified or when one of the specified types is *detect*. The specified logical net(s) should exist.

-boundary *poly_rect*

Specifies the boundary for strap creation. All created shapes are confined to this boundary. The default boundary is the core area of the design.

-keepouts *poly_rect_list*

Depending on the value of the *-allow_splitting* option, straps will be chopped or skipped such that they do not overlap any of the specified poly_rect's in the keepout list.

-layers *layer_list*

This command can create net shapes in horizontal, vertical, or both directions. If straps in both directions are required, then specify the horizontal and the vertical layer. If only straps in one direction are required, then specify the layer in that direction.

-widths *distance_list*

Specifies the width of the straps in horizontal and/or vertical direction.

-grids *iterator_list*

Specifies the locations (grid-lines) of the straps. For each required direction one iterator should be provided. If both directions are required, the first iterator corresponds to horizontal straps and the second iterator to vertical straps. Each iterator has the form *start* or *{start end step}*. In its first form, only one location (grid-line) is specified. In its second form, a set of locations (grid-lines) is specified : start + i * step, for each integer i with (i >= 0) and (start + i*step <= end).

-margins *distance_list*

Specifies the maximum distance of a created strap to its specified grid-line. If it is impossible to create the shape within this distance the shape will not be created. The default value is 0, indicating that the straps should be created exactly on the specified grid-lines. If that is not possible, they will be dropped.

-create_ends

Specifies that straps should be created on the edges of the bounding box of the boundary as well. These straps are additional to the straps as specified by the grid iterator(s). The boundary can be specified with the -boundary option. Note that only the edges in the specified direction(s) will be considered.

-types *type_list*

Specifies the type of straps to be created in the corresponding directions. Each type has the value *user_route*, *stripe*, or *detect*. The value *detect* is only valid when also another value is specified. If one of the values is *detect* then we are implicitly in spine creation mode and not in mesh creation mode. Moreover, *detect* indicates that there are already spine shapes in the *detect* direction and that only straps in the other direction should be created. These created straps will connect to the existing spine shapes by means of vias. The created shapes will have their *shape_use* attribute set to their corresponding type-value. Shapes in the *detect* direction are only considered to be part of a spine if their length is at least -detect_length. Also, considered shapes in the *detect* direction are mapped onto the same spine if their distance is smaller than the specified margin in the *detect* direction.

-length *distance*

Specifies implicitly that we are in spine creation mode. The length specifies the maximum length of the stripes that connect to the detected or created spines.

-backoff *distance*

Specifies implicitly that we are in spine creation mode. The backoff specifies the minimum distance between stripes of different spines.

-detect_length *distance*

This option is only valid if one of the specified types is *detect*. Specifies the minimum length of an existing shape in the *detect* layer in order to consider it a spine shape.

-spine_direction *direction*

Specifies the direction of the spines. This option is not allowed when one of the specified types is *detect*. In that case, the *detect* direction is always the spine direction. This option is required in spine mode if none of the types is *detect*.

-bias

Specifies that shielding with existing power or ground nets is preferred.

-bias_to_nets *net_list*

Specifies that shielding with nets from the net_list is preferred. These nets add to the power and ground nets if the -bias option is used.

-bias_margins *distance_list*

Specifies how far the shielding shape can be from the specified grid-line of the clock shape. If a shielding shape is found within the specified distance, and the shielding length is at least half of the clock shape, then the clock shape will be created next to the shielding shape. The default bias margin is

0. For the case of spines, which is when -types detect, -length, -backoff or -spine_direction is specified, the bias_margin can be a single value or a tuple. if the value is a single value, it applies to the first layer mentioned -in the -layers list. If there is a second layer, its bias_margin will be default i.e. 0.

-allow_floating *true*|*false*

If set to *true*, allow straps in clock meshes or two-dimensional spines that are not connected to a shape in the orthogonal direction. If set to *false*, then straps that do not connect to a shape in the orthogonal direction will be skipped. The default value is *false*.

-allow_splitting *true*|*false*

If set to *true*, allow partial or multiple straps at a specified grid line when blockages or keepouts prevent full-length straps. If set to *false*, only allow full-length straps at the grid lines. If a full-length strap cannot be generated due to blockages or keepouts, the strap will be skipped. The default value is *true*.

-clear

Remove the straps of the specified nets that were created in previous calls of create_clock_straps.

DESCRIPTION

This command creates a set of horizontal and/or vertical straight net shapes (straps) suitable to build a clock mesh or a clock spine structure. A clock mesh is a two-dimensional grid of metal straps in two orthogonal layers. The straps in one layer are connected to

the straps in the orthogonal layer by means of vias or via stacks at the intersection points. A clock spine structure can be one-dimensional or two-dimensional. A one-dimensional spine structure is a set of straps (the spines) in a single layer. A two-dimensional spine structure is a set of *spines* where each spine intersects with a set of *stripes* in the orthogonal direction. Each spine is connected to its stripes at the intersection points by means of vias or via stacks. The straps belonging to one spine do not connect to straps of a different spine. So each strap in the stripe direction is connected to exactly one strap in the spine direction.

The options *-layers*, *-widths*, *-margins*, *-grids*, *-types*, and *-bias_margins* accept a list of one or two values. All these options (if specified) should have the same number of values. If the number of values is one, then one-dimensional spines will be created. If the number of values is two, then a mesh or two-dimensional spines will be created. In the latter case, the first value in each list refers to the horizontal direction, and the second value to the vertical direction. If only one value is given in the lists, then the direction of the specified layer defines the direction of the one-dimensional spines. There is one exception to this rule, however. If one of the two *-types* values is *detect*, then only one grid iterator can be specified. This grid then applies to the non-detect direction.

The mesh or stripe structure covers a recti-linear area which can be specified explicitly with the **-boundary** option. The default area is the core area. The area as specified by the *-keepouts* option will not be covered by clock straps. Note that routing blockages and/or existing shapes will also block area and will prevent clock straps from being created at these locations.

The layers of the straps are specified as a list with the **-layers** option. The specified layers should be routing layers. If two layers are specified, these do not have to be adjacent. Connection between orthogonal non-adjacent layers will be made using via stacks. Typically, however, adjacent layers will be used to create clock meshes or two dimensional spines.

The **-widths** option specifies the width of the created straps in the corresponding direction. This is a required option. Typically, clock straps in meshes or spines are wider than the minimum width for the layer. These wider straps have less resistance and result in faster signal propagation in the mesh or spines.

The locations of the clock straps are specified using the *-grids* option. Each item in the list specifies an iterator that defines equidistant positions in the corresponding direction. The format of an iterator is *{start end step}*. E.g. if the corresponding layer is vertical and the iterator is {350 1350 100}, then the iterator defines vertical grid lines at x-coordinates 350, 450, 550, ..., 1350. The iterator values are in user units. These locations are the preferred locations for the clock straps in the corresponding direction.

The command will try to create clock straps at the grid-lines. However, if these grid-lines are off-track, or if part of the grid-lines is blocked, the command can search in the proximity for a better on-track strap location. The search area is defined by the *-margins* option. This option indicates how far the center line of the created strap can be from the specified grid-line.

When the *-create_ends* option is specified, also straps will be created at the edges of the bounding box of the boundary. These straps are additional on top of the straps defined by the *-grids* option. For a rectangular mesh structure, these end straps will create a ring at the edges of the bounding box. For one-dimensional spines, the *-create_ends* option causes two additional spines to be created at the boundary edges in the direction of the spines. For two-dimensional spine structures, the *-create_ends* option only applies to the stripes that are created orthogonal to the spines. So two additional stripes are created at the boundary edges that correspond to the stripe direction.

The *-types* option specifies the *shape_use* attribute of the created straps and vias. Valid shape_use values are *user_route* and *stripe*. If the value is *user_route*, the comb router is not allowed to connect to the shapes. If the value is *stripe*, then the comb router can connect to these shapes. The special type value *detect* can be used to indicate that no shapes should be created in the corresponding direction, but that existing shapes should be identified as spines, and that only stripes should be created. Shapes of both ports and nets can be detected as spine shapes. For existing net shapes to be detected as spines, their *shape_use* attribute should be set to *user_route* or *stripe*. Port (terminal) shapes with *shape_use* attribute *user_route* or *stripe* will also be detected as spine shapes. When no shapes with shape_use value *user_route* or *stripe* exist on neither the net nor the port then all shapes of the port, irrespective of the shape_use value, will be considered as spines. A value of *detect* implies that a two-dimensional spine structure will be created. Note the terminology here. Stripes are the straps that are orthogonal to the spines. Both spines and stripes can have shape_use *stripe*, although it is typical that the spines have type/shape_use *user_route* and the stripes have type/shape_use *stripe*. When spines are automatically detected, these may belong to different nets. All spines of the specified nets in the *-nets* option will be detected. The stripes of a spine will be attached to the spine's net.

Both the *-length* and the *-backoff* options implies creation of a two-dimensional spine structure. The *-length* option specifies the maximum length of the stripes connected to the spines. The *-backoff* options specifies the minimum distance between stripes of different spines. If the maximum length would violate the backoff value, then the length of the stripe is reduced to honor the backoff value. The default length value is infinite. The default backoff value is twice the minimum spacing rule in the stripe layer.

When the *-types* value is *detect*, the command will identify existing spines. Spine shapes should be in the corresponding layer. The shapes should be owned by either the net or port connected to the net where the straps are created for. If a net or port has shapes with shape_use *user_route* or *stripe* then those shapes will be considered as spines. If no such shapes exist, then any port shape is taken into account, irrespective of the shape_use value. In order for a shape to be considered a spine shape, the width should at least be the corresponding *-widths* value. Multiple spine shapes that are within a distance of the corresponding *-margins* value, are considered to be part of a single pre-existing spine. Only resulting spines with a length longer than the *-detect_length* value are considered as spines for stripe creation.

When a two-dimensional spine structure needs to be created, the spine direction should be specified using the *-spine_direction* option. The spine direction is either *horizontal* or *vertical*.

The location of the created clock straps can be biased such that they are shielded by existing power and ground shapes. Using the *-bias* option, the command will identify power and ground shapes that can be used for shielding. If these shapes are with the corresponding *-bias_margins* value, and the shielded length is at least 50% of the strap length, then the clock strap will be created adjacent to the identified power or ground shape. It is also possible to specify other nets than power and ground nets using the *-bias_to_nets* option. If you use both *-bias* and *-bias_to_nets*, then both power and ground shapes and shapes from the specified bias nets can be used for shielding.

If the value of option *-allow_splitting* is set to *false*, then the command will only create full-length single straps per grid-line. E.g. if a grid-line is partially covered by blockages, keepouts and/or other shapes, then no strap will be created for that gridline. If the value of *-allow_splitting* is set to *true*, then partial and/or multiple straps per grid-line are allowed, and shorter straps may be created in between the blockages. If a stripe strap cannot be connected to a spine shape in the orthogonal direction, then it will not be created unless the *-allow_floating* option is set to *true*. The default value for *-allow_splitting* is *true*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example creates a grid with horizontal straps on M7 and vertical straps on M8. The length of straps is limited by the specified boundary. It includes the top, bottom, left and right straps that form a ring around the mesh. The strap shapes are owned by the net called clk1_mesh. This net should exist. The command inserts horizontal straps near vertical positions 20, 120, 220, ..., 1120. The maximum deviation to these positions is

10. It inserts vertical straps near horizontal positions 60, 210, 360, ...,

960. The width of the straps is 2.4 in both directions. The shape_use attribute of the created shapes will be set to *stripe* (default). A keepout region is created in the botton-left area. Straps that are overlapping with this keepout region will be chopped due to the '-allow_splitting true' option. With '-allow_splitting false', straps that would overlap with the keepout region will be skipped.

```
prompt> create_clock_straps -nets [get_net clk1_mesh] \
   -boundary {{0 0} {1200 980}} \
   -layers {M7 M8} \
   -widths {2.4 2.4} \
   -grids {{20 1200 100} {60 980 150}} \
   -margins {10 10} \
   -create_ends \
   -keepouts [list {{0 0} {120 240}} ]\
   -allow_splitting true
```

The following example creates a one-dimensional spine structure. Spines are in horizontal layer M7 and have a width of 3.6. The spines are near locations 50, 170, 290, ..., 770. If a power or ground net can be found within 20 distance of the specified location, then the strap is shifted such that is shielded by the power or ground shape. The shape_use attribute of the created shapes will be

set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \
   -layers M7 \
   -widths 3.6 \
   -grids {{50 800 120}} \
   -margins 10 \
   -types user_route \
   -bias -bias_margins 20
```

The following example creates a two-dimensional spine structure. Spines are in vertical layer M8 and have a width of 3.6. The stripes are in horizontal layer M7 and have a width of 2.4. Stripes that cannot connect to their spine will still be created and left floating. The shape_use attribute of the spines will be set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \
   -layers {M7 M8} \
   -widths {2.4 3.6} \
   -grids {{20 1200 100} {60 980 150}} \
   -margins {10 10} \
   -types {stripe user_route} \
   -allow_floating true
```

The following example creates a two-dimensional spine structure based on existing spine shapes in the design (type detect). In effect it will only create the stripes. The created stripes are in horizontal layer M7 and have a width of 2.4. Existing spine shapes should be in layer M8. The minimum width for shapes to be considered as a spine shape is 3.6. When spine shapes are closer than 10 to each other, they will be considered part of a single spine. Only spines with a resulting length of at least 200 will be considered. Since the vertical spines are detected, there is only one grid iterator for the horizontal stripes. The maximum length of a stripe is 110, but if that would violate the backoff value of 5, the stripe length will be reduced. The shape_use attribute of the stripes will be set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \
   -types {user_route detect} \
   -layers {M7 M8} \
   -widths {2.4 3.6} \
   -grids {{20 1200 100}} \
   -margins {10 10} \
   -length 110 \
   -backoff 5 \
   -detect_length 200 \
   -types {user_route detect}
```

create_command_group

Creates a new command group.

SYNTAX

string **create_command_group** [-info *info_text*]
group_name

ARGUMENTS

-info *info_text*

Help string for the group

group_name

Specifies the name of the new group.

DESCRIPTION

The **create_command_group** command is used to create a new command group, which you can use to separate related user-defined procedures into functional units for the online help facility. When a procedure is created, it is placed in the "Procedures" command group. With the **define_proc_attributes** command, you can move the procedure into the group you created.

The *group_name* can contain any characters, including spaces, as long as it is appropriately quoted. If *group_name* already exists, **create_command_group** quietly ignores the command. The result of **create_command_group** is always an empty string.

EXAMPLES

The following example demonstrates the use of the **create_command_group** command:

prompt> **create_command_group {My Procedures} -info "Useful utilities"**

prompt> **proc plus {a b} { return [expr $a + $b] }**

prompt> **define_proc_attributes plus -command_group "My Procedures"**

```
prompt> help
My Procedures:
  plus

  ...
```

SEE ALSO

define_proc_attributes(2)

proc(2)

create_context_for_sub_block

Creates context for block instances.

SYNTAX

status **create_context_for_sub_block**
-block_instance *block_instance_name*
-nets *net_name_list*
physical_model_file_name
[-electric_model_file *file_name*]

Data Types

block_instance_name string
net_name_list list
physical_model_file_name string
file_name string

ARGUMENTS

-block_istance

Specifies the name of the block instance to generate block context.

-nets

Specifies a list of the nets to generate block context.

physical_model_file_name

Specifies the name of the output physical block context model file.

-electric_model_file

Specifies the name of the output electric block context model file. This option is optional.

DESCRIPTION

This command creates context for the specified block instance. The command models the full-chip environment for the block instance, including physical and electrical models:

o Physical model, which describes the location of the connections between block and full-chip designs. These tap locations are

derived by tracing the RedHawk parasitics data. The physical model is generated when the **create_context_for_sub_block** command process is complete, and is written to an output PLOC file.

o Electrical model, which is an effective resistance- and capacitance-based model. The tool uses the native resistance engine to calculate effective resistance which is used to calculate equivalent current during peak dynamic voltage drop analysis. By default, the tool models the full-chip context for the specified blocks. The capacitance data are derived by the RedHawk extraction engine.

o Limitation: this feature only support to create context from Redhawk result

EXAMPLE

The following example shows how to create and use the block context during the block-level voltage drop analysis.

```
prompt> open_block top
prompt> ... # IR analysis setup
prompt> analyze_rail ...
prompt> create_context_for_sub_block -block_instance U1 -nets {VDD VSS} U1.ploc
prompt> create_context_for_sub_block -block_instance U1 -nets {VDD VSS} U1.ploc -electric_model_file U1.context
1

prompt > open_block block
prompt > set_app_options -name rail.pad_files -value U1.ploc
prompt > set_app_options -name rail.block_context_model_file -value U1.context
prompt > analyze_rail ...
```

SEE ALSO

analyze_rail(2)
rail.pad_files(3)
rail.block_context_model_file(3)

create_corner

Creates a corner in the current design.

SYNTAX

string **create_corner**
[-copy *corner_name*]
corner_name

Data Types

corner_name string

ARGUMENTS

corner_name

Specifies the name of the new corner.

-copy *corner_name*

Specifies the name of the corner to copy from.

DESCRIPTION

This command creates a corner in the current design. Corners are used to contain a set of constraints for the design. Unique corners are used to specify different combinations of operating conditions and parasitic parameters. Corners are used together with modes, which are used for different operating modes and power schemes. Timing analysis done for various mode and corner combinations as configured by the **set_scenario_status** command.

Operating condition and parasitics parameters are contained in the current corner. When the design is linked, a single corner named "default" is automatically created and assigned as the current corner. If the **create_corner** command is used, the current_corner is set to the newly-created corner. You can set the current corner to a different corner with the **current_corner** command.

To create a collection of corners matching a pattern and optionally matching filter criteria, use the **get_corners** command. To get a collection of all corners in the design, use the **all_corners** command.

To undo the **create_corner** command, or remove a corner, use the **remove_corners** command.

EXAMPLES

The following example creates a corner named "LowVoltage5" and assigns it as the current corner.

```
prompt> create_corner LowVoltage5
```

set_scenario_status(2)

create_custom_shields

Creates custom shielding for the specified nets with Custom Router, if the nets have shield constraints in effect.

SYNTAX

status **create_custom_shields**
[-nets *nets*]
[-keep_session true | false]

Data Types

nets collection

ARGUMENTS

-nets *nets*

Specifies the collection of nets to be shielded. If not specified, the entire design will be shielded. Nets without shielding constraints will be skipped.

-keep_session *true* | *false*

Specifies whether or not the custom router view of the data will be retained after the command completes. Use true only if you expect to perform additional custom route commands immediately after the current command. The default is false.

DESCRIPTION

The **create_custom_shields** command creates custom shielding shapes for a set of specified nets.

create_cut_metals

This command creates cut metals at metal cut ends.

SYNTAX

status **create_cut_metals**

Data Types

DESCRIPTION

This command creates cut metals at metal cut ends before gdsout. Tool creates cut metals based on the dimensions and the rules defined in the technology file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

prompt> **create_cut_metals**

SEE ALSO

remove_cut_metals(2)

create_default_topology_plans

Create a default topology plan for a bundle.

SYNTAX

collection **create_default_topology_plans**
[-net_estimation_rule *rule_name*]
[-allow_feedthrough none | select_on | select_off | all]
[-allow_feedthrough_type pure | mixed | any]
[-allow_feedthrough_select *object_list*]
[-allow_flyover none | select_on | select_off | all]
[-allow_flyover_select *object_list*]
[-launch_budget *float*]
[-capture_budget *float*]
[-comment *comment*]
[*bundle_list*]

Data Types

bundle_list collection
object_list collection
rule_name string
comment string

ARGUMENTS

bundle_list

Specifies the list of bundles to create default topology plans. If not specified then it means all the bundles within the current design.

-net_estimation_rule *rule_name*

Specifies the name of the net_estimation_rule of the topology_plan.

-allow_feedthrough none | select_on | select_off | all

Specifies the allow_feedthrough setting of the topology_plan.

"none" indicates that no feedthrough is allowed for the plan.

"select_on" indicates that feedthrough is only allowed through the objects specified in the *-allow_feedthrough_select* option.

"select_off" indicates that feedthrough is allowed through all objects except those specified in the *-allow_feedthrough_select* option.

"all" indicates that feedthrough is allowed through all objects.

-allow_feedthrough_type pure | mixed | any

Specifies the allow_feedthrough_type setting of the topology_plan.

-allow_feedthrough_select *object_list*

Specifies the collection of objects for which the *-allow_feedthrough_select* option is applied.

-allow_flyover none | select_on | select_off | all

Specifies the allow_flyover setting of the topology_plan.

"none" indicates that no flyover is allowed for the plan.

"select_on" indicates that flyover is only allowed over the objects specified in the *-allow_flyover_select* option.

"select_off" indicates that flyover is allowed over all objects except those specified in the *-allow_flyover_select* option.

"all" indicates that flyover is allowed over all objects.

-allow_flyover_select *object_list*

Specifies the collection of objects for which the *-allow_flyover_select* option is applied.

-launch_budget *float*

Specifies the launch budget of the topology_plan.

-capture_budget *float*

Specifies the capture budget of the topology_plan.

-comment *comment*

Specifies the comment of the topology_plan. This is a general-purpose string that can be used for documentation.

DESCRIPTION

The **create_default_topology_plans** command creates a default topology plan for each of the bundle specified by *bundle_list*, or all bundles if not specified, if the corresponding bundle does not have an associated topology plan.

For each bundle that the command is to create a topology plan, there will be one topology node created for the driver block, and one topology node created for each of the load block, and one topology edge per each pair of the node of the driver block and the node of the load block.

If the command line options *-net_estimation_rule*, *-allow_feedthrough*, *-allow_feedthrough_type*, *-allow_feedthrough_select*, *-allow_flyover*, *-allow_flyover_select*, *-lauch_budget*, *-capture_budget*, or *-comment* are provided, they will be applied to the created topology plans as well.

Upon success, the command returns the list of topology plans created.

EXAMPLES

The following example creates default topology plans for all bundles of the current design that do not have associated topology plans yet.

```
prompt> create_default_topology_plans
```

SEE ALSO

create_topology_plans(2)

create_dense_tap_cells

Inserts tap cells with a dense pattern within the specified region. For regions with intensified substrate noise, the command also inserts tap walls along the region boundary.

SYNTAX

status **create_dense_tap_cells**
-lib_cell *cell_name*
-distance *tap_distance*
[-bbox *coordinates*]
[-offset *distance*]
[-pattern every_row | every_other_row | stagger]
[-skip_fixed_cells]
[-prefix *cell_prefix*]
[-separator *cell_separator*]
[-at_distance_only]
[-isn_layer *layer_list*]
[-isn_layer_distance { *{{layer1 distance1 layer_offset1} {layer2 distance2 layer_offset2} ...}*]
[-boundary_lib_cell *cell_name*]
[-horizontal_boundary_spacing *spacing*]
[-left_boundary_flipped]
[-right_boundary_flipped]

Data Types

cell_name string
tap_distance float
coordinates rectangle
distance float
cell_prefix string
cell_separator string
layer_list list
spacing float

ARGUMENTS

-lib_cell *cell_name*

Specifies the library cell that is used as the tap cell. You must specify a single library cell. This is a required option.

-distance *tap_distance*

Specifies the distance in microns between two tap cells in a row. This distance is referred to as the tap distance. This is a required option.

The tap distance specified for this command is typically shorter than the tap distance used by the **create_tap_cells** command, which creates a denser tap cell pattern.

-bbox ***coordinates***

Specifies the rectangular region in which to insert the tap cells. A rectangle is specified as a list of four coordinates, {*{llx lly} {urx ury}*}, which represent the lower-left and upper-right corners of the rectangle in microns.

If you do not use this option or the **-isn_layer** and **-isn_layer_distance** options, the command will error out. This option cannot be specified with the **-isn_layer** and **-isn_layer_distance** options.

-offset ***distance***

Specifies the distance in microns that the tap pattern should be shifted to the right. This option does not set the absolute location of the tap cells, only shifts the existing pattern.

If the offset distance is a multiple of the tap distance, the effective offset is 0. For example, if the tap distance is 10 microns and the offset is 32 microns, the effective offset is 2 (32 - 3x10).

The default is 0.

-pattern every_row | every_other_row | stagger

Specifies the tap cell insertion pattern. The supported patterns are

- **every_row** (the default)
  The command adds tap cells to every row using the specified tap distance. The tap distance specified for this pattern should be approximately twice the design rule distance limit.
- **every_other_row**
  The command adds tap cells to every other row for odd rows only. This reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately twice the design rule distance limit.
- **stagger**
  The command adds tap cells to every row. The tap cells on even rows are offset with half the tap distance relative to the odd rows, producing a checkerboard-like pattern. This pattern also reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately four times the design rule distance limit.

-skip_fixed_cells

Prevents the command from inserting tap cells in locations that are occupied by fixed cells.

When you use this option, the tool treats a fixed cell like a blockage, which breaks the row and might cause a tap cell to be inserted on each side of the fixed cell. To prevent the insertion of tap cells that overlap fixed cells without breaking the row, use the **-preserve_distance_continuity** option with the **-skip_fixed_cells** option.

By default, the command inserts a tap cell in each calculated tap location, even if it is occupied by a fixed cell.

-prefix ***cell_prefix***

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

tapfiller!*cell_prefix*!*lib_cell*!*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

tapfiller!*lib_cell*!*number*

-separator *cell_separator*

Specifies the separator character that is used when composing the instance name of the tap cell.

The default is "!".

-at_distance_only

Creates tap cells only at the specified distance, distance/2, or distance/4 (stagger mode). Note that using this option can cause DRC violations.

-isn_layer *layer_list*

Specifies the special non-manufacturing layers defined in the technology file that is used to identify regions where the silicon substrate is subject to intensified substrate noise (ISN).

When a design, hard macro, or soft macro has a substrate noise source, an ISN layer rectangle is specified within a certain radius of the noise source.

If you do not use this option or the **-bbox** and **-isn_layer_distance** options, the command will error out. This option cannot be specified with the **-bbox** and **-isn_layer_distance** options.

-isn_layer_distance { *{{layer1 distance1 layer_offset1} {layer2 distance2 layer_offset2} ...}*

Specifies multiple ISN layers, their corresponding tap distances and layers' corresponding shifting value to right for intensified substrate noise regions. The dense tap cells will be inserted in the order of the least dense to the most dense regions. If the layers overlap, the most dense tap distance will prevail. The layer names must not duplicate. When this options is used, the -isn_layer and the -distance options are not allowed. For the input value, "layer" and "distance" value are required, "offset" value is optional and the default value is 0.

If you do not use this option or the **-bbox** and **-isn_layer** options, the command will error out. This option cannot be specified with the **-bbox** and **-isn_layer** options.

-boundary_lib_cell *cell_name*

Specifies the library cell used to create the tap walls. You can specify only a single library cell.

When you use this option, the command performs the following tasks:

1. Inserts vertical tap walls along the left and right edges of the placeable area boundary.
2. Inserts horizontal tap walls along the top and bottom edges of the placeable area boundary.
3. Marks the inserted tap cells as FIXED.

-horizontal_boundary_spacing *spacing*

Specifies the spacing between two tap cells in microns for horizontal tap walls. If the spacing value is not multiple of the site width, it will be rounded to the smaller value that is a multiple of the site width. If the value is less than the width of the tap cell or not specified, there will be no spacing between two tap cells.

The default is 0.

-left_boundary_flipped

Flips the cells of tap walls on the left boundary.

-right_boundary_flipped

Flips the cells of tap walls on the right boundary.

DESCRIPTION

The **create_dense_tap_cells** command inserts a dense pattern of tap cells in the specified regions. Before using this command, you must use the **create_tap_cells** command to perform standard tap cell insertion.

The tap walls and dense tap cells are necessary to ensure proper operation of the digital circuit. The tap walls and cell placement observe the prohibited vertical abutment rules.

Within the specified region, the command performs the following tasks:

1. Deletes the existing tap cells.
2. Reinserts the tap cells using the pitch specified with the **-distance** or **-isn_layer_distance** option.
3. Marks the inserted tap cells as FIXED.

You can also perform dense tap cell insertion in intensified substrate noise (ISN) regions by using the **-isn_layer** or **-isn_layer_distance** option. For details about the insertion process for ISN regions, see the description for the **-isn_layer**, **-isn_layer_distance** and **-boundary_lib_cell** options.

If you specify the **-boundary_lib_cell** option, the command also inserts tap walls along each region boundary of specified region. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cell in the library contain no substrate or well taps.

EXAMPLES

The following example inserts dense tap cells in the ISN region.

```
prompt> create_dense_tap_cells -lib_cell myLib/Cell1 \
  -isn_layer LUP_075 -distance 30
```

SEE ALSO

create_interior_tap_walls(2)
create_exterior_tap_walls(2)
create_tap_cells(2)
create_tap_meshes(2)

create_density_rule

Creates a density rule in a block or technology file.

SYNTAX

collection **create_density_rule**
[-library *library*]
[-tech *tech*]
[-max_density *intValue*]
[-min_density *intValue*]
[-window_size *floatValue*]
-layer *layer_name*
[-max_gradient_density *intValue*]

Data Types

library collection
tech collection
floatValue float
layer_name string
intValue integer

ARGUMENTS

-library *library*

Specifies the library in which to create the density rule. The density rule is added to the technology data contained by or referenced by the specified library.

If you do not specify this option or the **-tech** option, the density rule is created in the technology data of the current library.

-tech *tech*

Specifies the technology data in which to create the density rule.

If you do not specify this option or the **-library** option, the density rule is created in the technology data of the current library.

-max_density *intValue*

Defines the maximum percentage of metal allowed in the window.

-min_density {*intValue*}

Defines the minimum percentage of metal allowed in the window.

-window_size {*float value*}

Defines the size of the window for the density check.

By default, the window step size is half of the defined window size.

-layer ***layer_name***

Defines the metal layer for which the rule is specified.

This is a required option.

-max_gradient_density {*floatValue***}**

Specifies the maximum allowable change in fill density between adjacent windows.

DESCRIPTION

The **create_density_rule** command creates a new density rule in the specified technology data and returns a collection of the created object.

The **signoff_create_metal_fill** command uses the density rules during metal fill insertion.

Typically, density rules are defined in the **DensityRule** sections in a technology file. The technology file should contain a **DensityRule** section for each metal layer.

EXAMPLES

The following example creates a density rule in the technology data of the current library.

```
prompt> create_density_rule -max_density 61 -min_density 11 \
  -layer M1 -window_size 101.00 -max_gradient_density 21
```

SEE ALSO

get_density_rules(2)
remove_density_rules(2)
signoff_create_metal_fill(2)

create_design_rule

Creates a design rule (design_rule) in the specified technology object.

SYNTAX

collection **create_design_rule**
[-tech *tech_object*]
[-library *library*]
-layer1 *layer*
-layer2 *layer*
-min_spacing *distance*

Data Types

tech_object collection
library collection
layer collection
distance float

ARGUMENTS

-tech *tech_object*

Specifies the technology object in which design rule need to be created.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

-library *library*

Specifies the library in which to create the design rule. The command creates the rule in the technology object associated with the specified library. In an implementation tool, the library is a design library. In the library manager, the library is a cell library. You can specify the library using the library's name or a collection that contains the library.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

-layer1 *layer*

Specified the first layer of two layers between which design rule need to be created. This option takes collection as input. User must provide valid layer object or layer number as input.

-layer2 *layer*

Specified the second layer of two layers between which design rule need to be created. This option takes collection as input. User must provide valid layer object or layer number as input.

-min_spacing *distance*

Specified the minimum spacing between the layers on which design rule exists. This option takes distance as input i.e. floating point number that represents the spacing in microns.

DESCRIPTION

This command creates a new design rule in the specified technology object. The tool treats the rule same as a rule defined in the DesignRule section of the technology file. For more information about defining design rules, see the "DesignRule Section" in the *Synopsys Technology File and Routing Rules Reference Manual*.

If the command is successful, it returns a collection that contains the created rule; otherwise, it returns an empty string. If there is a command syntax error, it returns a TCL_ERROR.

EXAMPLES

The following example creates a design rule in the technology object of the current library.

```
prompt> create_design_rule -layer1 [get_layers M3] \
  -layer2 [get_layers M4] - min_spacing 1.1
```

set_design_rule_attribute(2)

create_dff_trace_filters

Adds filter patterns to the list of filters used by the **compute_dff_connections** command

SYNTAX

create_dff_trace_filters
-type pin | net
-patterns *list_of_patterns*
-filename *filename*
[-blocks *list_of_blocks*]

Data Types

list_of_patterns list
filename string
list_of_blocks list

ARGUMENTS

-type pin | net

Specifies the type of filter to add, either *pin* or *net*. This indicates which type of objects the patterns will be matched against: either pins (and ports) or nets.

-patterns *list_of_patterns*

Specifies a list of patterns to add to the indicated filter type list. A pattern can be a local name (path relative to the parent block cell), or a global name for the top block. Patterns support the simple wildcard characters "*" and "?". Regular expressions are not supported. Patterns are NOT verified at insertion time and it is possible to insert patterns that do not match anything in the current design.

-filename *filename*

Specifies that the set of filter patterns is read from a file. The file is generated by a previously saved trace filter file written by the **write_dff_trace_filters** command. This option is mutually exclusive with all other options.

-blocks *list_of_blocks*

Specifies a list of block names to use as the base name for this pattern when searching for pin/port/net objects. If **-blocks** is not specified, the default implies a special "all blocks" list, and the associated patterns will be tried against all blocks in the current design. Block names do not support wildcard characters. Block names are not verified at insertion time. It is possible to insert block names that do not match any blocks in the current design.

DESCRIPTION

This command creates trace filter patterns used by the Data Flow Flylines (DFF) tracer command **compute_dff_connections**. Any patterns inserted into this list are applied by the DFF tracer as "stop pins/ports" or "stop nets". Any pin/port or net matched by a pattern will stop the DFF tracer from proceeding any further down this path segment.

A GUI interface to manage filter patterns is available as part of the DFF Gui component's Reload option.

BLOCK NAMES, PATTERNS and ABSTRACTS/MIBs

Block names should represent the names of physical blocks used in the main design. For example, the output of **get_attribute [get_designs] name** provides valid block names. Patterns should then be relative to the block, rather than to the global instance name (unless they belong to the top-level design). For example, if an abstract design B1 is linked in the current design as TOP/MORE/INST_B1 and there exists a macro pin TOP/MORE/INST_B1/M1/p1, then to add this pin as a filter pin, the arguments would be: **-block B1 -patterns M1/p1**.

This separation of reference block name and instance name is necessary when tracing through abstracts. When abstracts are loaded in design view for tracing, they are loaded as the main design of that session, and so the instance prefix is discarded. That is, when abstract B1 is traced, the correct path to the macro pin is just M1/p1 with no other path prefix. Separating the patterns in this manner makes this transition seamless.

If abstract design B1 is also a multiply instantiated block (MIB), the situation is even more complicated. There could exist two instances of block B1 at TOP/MORE/INST_B1a and TOP/MORE/INST_B1b. If a filter pin pattern was now specified as TOP/MORE/INST_B1a/M1/p, you might expect that only the macro pin in INST_B1a would be filtered, but not the one in INST_B1b. However, block B1 is only traced one time, and it cannot be traced both with and without the filter pin. That is, filtering a pin in only SOME instances of a MIB is not supported to avoid confusion. It would be possible if the block was in design view, but then fail if the block was later switched to an abstract view. To avoid this problem, this type of unpredictable pattern is discouraged. When using the **-filename** option, a warning is issued if a pattern is read-in that matches only SOME instances of a MIB by using a global path.

The special "all blocks" list is available for global patterns like matching all scan pins in the design, if they have a specific character pattern that can match them like "SCAN". One pattern for each level of the netlist is still required. Since this could easily match unwanted pins or nets, its use should be reserved for special situations.

PATTERN MATCHING

When the DFF tracer runs, it will process each pattern in turn, and for each block that has an instance in the current session, it will apply the pattern to the instance path of that block. This means that the same pattern file can be used with a design with physical hierarchy, whether the blocks are in design view or abstract view. Switching back and forth should not affect the interpretation of filter patterns.

GENERAL USAGE

This command prepares a list of filter patterns to be used by the **compute_dff_connections** command when tracing through the netlist. The block names and patterns are not verified to exist at insertion time. Rather, at runtime, only those patterns matching a netlist object will be applied. This allows the use of only global filter patterns file for an entire project, whether working on the whole design, or just one block.

EXAMPLES

The following example adds a pattern "M1/*" to the trace filter list to filter out all pins of macro M1 in block p0.

```
prompt> create_dff_trace_filters -type pin -blocks p0 -patterns "M1/*"
```

SEE ALSO

compute_dff_connections(2)
remove_dff_trace_filters(2)
write_dff_trace_filters(2)

create_dft_netlist

Creates a DFT netlist from the current design.

SYNTAX

status **create_dft_netlist**
-type extest

ARGUMENTS

-type extest

Specifies the type of DFT netlist to create. There is only one valid type supported:

- **-type extest**

  This DFT netlist type removes all logic in the design except that needed to operate in the outward-facing EXTEST mode. Only the following logic types are kept: wrapper chains and wrapper control logic, interface logic between wrapper chains and I/O ports, test mode decode logic, and 1500 controller and any other logic required for EXTEST operation.

  This DFT netlist type is supported only for wrapped cores.

DESCRIPTION

The **create_dft_netlist** command creates a DFT netlist from the current design. Currently only one type, **extest**, is supported

This command modifies the current design in memory. After running it, write out the DFT netlist file using the **write_verilog** command. Because the **create_dft_netlist** command removes logic from the design in memory, these should be the last steps in your core creation script.

This command cannot be used in an ILM generation flow.

EXAMPLES

The following example creates and writes out an EXTEST-only netlist: after writing the full-netlist design files:

```
# insert DFT IP and compile
insert_dft
```

```
compile

# write block-level design
save_block -as post_compile

# write an EXTEST-only netlist
create_dft_netlist -type extest
write_verilog block_1_EXTEST.vg
```

SEE ALSO

save_block(2)
set_wrapper_configuration(2)

create_die

Instantiates a die or a stack of die instances in the current design

SYNTAX

collection **create_die**
-location *coordinate*
-z_offset *value*
-orientation *orientation*
[-stack *number*]
die_name
die_block_reference

Data Types

coordinate	list
value	int
orientation	string
number	int
die_name	string
die_block_reference	string

ARGUMENTS

-location

Specifies the location of the die in the current design. The values of x and y are in the unit of micron. The value of z is a non-negative integer with lower z value at the bottom. For a die stack, specifies the bottom-most z location. All dies in the stack have the same x and y location with one level z increment.

-z_offset *value*

Specifies the z location of the die.

-orientation *orientation*

Specifies the orientation of bond pads in the array. Value can be one of: **R0, R90, R180, R270, MX, MXR90, MY, MYR90, N, W, S, E, FN, FW, FS, FE**

-stack *number*

Specifies the number of dies in the die stack. If unspecified, only one die is created.

die_name

Specifies the die name.

die_block_reference

Specifies the referenced die block.

DESCRIPTION

The **create_die** command instantiates a die or a stack of die instances in the current design which is a 3DIC environment. A stack of dies has identical process technology, width, height, x and y locations. The *die_block_reference* might be a die block that has been previously created i with the *create_die_block* command.

EXAMPLES

The following example creates a new block named top in the current library created by **create_lib**.

```
prompt> create_die si_interposer_inst interposer:si_interposer -location {0 0} -z_offset 0 -orientation N
{si_interposer_inst}
```

SEE ALSO

create_die_block(2)
create_bump_block(2)
create_3d_top_design(2)

create_die_block

Creates a die block in the target library.

SYNTAX

collection **create_die_block**
[-force]
-dimensions *dimensions_list*
[-origin *coordinate*]
[-library *lib_name*]
[-design_type *design_type*]
die_block_name

Data Types

dimensions_list list
coordinate list
lib_name string
design_type string
die_block_name string

ARGUMENTS

-force

Overwrites the block if one with the same name already exists in the current library.

-dimensions *dimensions_list*

Specifies the width and height of the die block in micron.

-origin *coordinate*

Specifies the coordinate of origin.

-library *lib_name*

Specifies the target library that contains the process technology of the die block to be created. Creating the die in the current library is not recommended as the current design is a 3DIC environment that might contain multiple process technology.

-design_type *design_type*

Specifies the type of the die. The value can be one of: **bridge**, **die**, **interposer**, **substrate**. The default is **die** type. An interposer is a large die that encompass all other dies in a 2.5D package. A bridge is a small die that offers lateral interconnect within a small local region between two dies. A substrate is a multiple metal layer non-silicon substrate for fanout RDL routing.

die_block_name

Specifies the die block name.

DESCRIPTION

The **create_die_block** command creates a die block in the target library. The die block created is empty and should be populated later.

EXAMPLES

The following example creates a new block named si_interposer in the library top.exp.

```
prompt> create_lib top.exp
{top.exp}
prompt> create_die_block si_interposer -force -dimensions {15000 10000} -library top.exp -design_type interposer -origin {0
Information: Creating block 'si_interposer.design' in library 'top.exp'. (DES-013)
{top.exp:si_interposer.design}
```

create_bump_block(2)
create_die(2)
create_lib(2)

create_differential_group

Creates an analog constraint group with differential_pair or differential_group intent in the current design.

SYNTAX

collection **create_differential_group**
[*constraint_group_name*]
-for *objects*
[-twist_style default | diagonal | orthogonal | none]
[-twist_interval *distance*]
[-twist_offset *distance*]
[-gap *distance*]
[-shield_placement default | double_interleave | half_interleave | interleave | outside]
[-valid_layers *layers*]
[-layer_spacings *layer_spacing_pairs*]
[-layer_widths *layer_width_pairs*]
[-force]

Data Types

constraint_group_name string
objects collection
distance float
layers collection
layer_spacing_pairs list
layer_width_pairs list

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group. By default, the command generates a unique constraint group named "differential_pair_n", where n is a unique, monotonically increasing integer value.

-for *objects*

Specifies the net objects in the analog constraint group. The *objects* argument can be a collection of objects or a string that contains the name of the objects.

-twist_style default | diagonal | orthogonal | none

Specifies how the nets of the constraint group will be twisted. The allowed values are default, diagonal, none and orthogonal. Default is none.

-twist_interval *distance*

Specifies the twist interval between the nets in the constraint group. This is applicable only when twist style is not none. The default is zero.

-twist_offset ***distance***

Specifies the twist offset for the nets in the constraint group. This is applicable only when **-twist_style** is not none. The default is zero.

-gap ***distance***

Specifies the spacing between the outermost bit nets and other shapes in the block. The default is zero.

-shield_placement default | double_interleave | half_interleave | interleave | outside

Specifies how the main bus trunk will be shielded if one or more nets of the constraint group are shielded. Allowed values are default, double_interleave, half_interleave, interleave and outside. The default is "default".

-valid_layers ***layers***

Specifies the list of layer names to be used for the main trunk. If specified, layers type is set to range, otherwise it is set to default. When specified, the min and max layers are derived from the list.

-layer_spacings ***layer_spacing_pairs***

Specifies the layer and spacing pairs used in trunk routing. This is a list of alternating layer and spacing, for example, {M1 3.0 M2 4.0}.

-layer_widths ***layer_width_pairs***

Specifies the layer and width pairs used in trunk routing. This is a list of alternating layer and width, for example, {M1 3.0 M2 4.0}.

-force

Deletes an existing constraint group if the name matches the specified *constraint_group_name*. The default is false and the command exits with an error if the name already exists.

DESCRIPTION

The **create_differential_group** command creates a constraint group for a collection of nets with differential_pair or differential_group intent. You must specify two or three nets with the **-for** option. When two nets are specified, the nets form a differential_pair. When three nets are specified, the nets form a differential_group. The constraint is used by Custom Router.

You can specify which layers are valid for the trunk routing and can also specify layer-specific spacing and width values. If one or more nets are shielded, the shielding placement of main trunk can also be specified.

You can specify how the nets in the differential_pair or differential_group can be twisted with the interval and offset.

EXAMPLES

The following example creates a constraint group with a system-generated name of "differential_pair_0" for nets prn and prp which will be of differential_pair intent. The twist style will be none and shield placement will be default. The 'prn' and 'prp' nets are routed with the Custom Router.

```
prompt> create_differential_group -for {prn prp}
{differential_pair_0}
```

The following example creates a constraint group with a system-generated name of "differential_group_1" for nets pr*. Assuming that there are three nets, the nets form a differential_group. The twist style will be none and shield placement will be interleave. A spacing of 3 will be used for layer M2 and spacing of 5 will be used for layer M3. The 'pr*' nets are routed with Custom Router.

```
prompt> create_differential_group -for pr* -shield_placement interleave \
  -layer_spacings {M2 3 M3 5}
{differential_group_1}
```

get_constraint_groups(2)
remove_constraint_groups(2)
report_constraint_groups(2)

create_diodes

Creates diodes to fix user-specified antenna violations.

SYNTAX

status **create_diodes**
-options *list_of_violations*

Data Types

list_of_violations list

ARGUMENTS

-options *list_of_violations*

Specifies the antenna violations to be fixed by inserting diodes. You can specify one or more antenna violations. Each antenna violation is described by a list that contains the following elements:

- *port_name*
  Specifies the name of the port with the antenna violation.
- *block_instance_name*
  Specifies the name of the block instance with the antenna violation. For diode insertion on top level ports, specify name of top design for this entry.
- *diode_frame_view_name*
  Specifies the name of the frame view of the diode to insert.
- *number_of_diodes*
  Specifies the number of diodes to insert.
- *max_routing_layer_name*
  Specifies the name of the maximum routing layer within which the diode should be connected to the antenna violating pin.
- *max_routing_distance*
  Specifies the maximum distance in microns along the route from the diode pin to the antenna violating pin.

Note: To use this command to insert diodes for top-level ports (terminals) and connect to them you must specify top design name for the *block_instance_name* entry.

This is a required argument.

DESCRIPTION

This command inserts diodes to fix user-specified antenna violations. This command does not do any antenna analysis on the nets. It inserts the specified number of diodes and connects them. After this is done, it is assumed that the antenna violations are fixed.

This command supports the use of spare diodes in the design. If a spare diode of the same frame view exists near the specified antenna port within the specified distance, it can be used to make a connection. This feature can be controlled with the **diode_insertion_mode** router detail route option. This command supports reuse of filler cell locations to insert diodes. It can be controlled using the **reuse_filler_locations_for_diodes** router detail route option. This command can be used to create new diodes or reuse diodes that are close to the antenna violating port. If the only legal location or spare diode is far off, the command will not be able to insert or reuse that diode or location. The distance up to which search is made is bounded by local area and is determined by the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This command creates diodes to fix user-specified antenna violations on the A port of the CI cell instance by using two diodes with a FRAM view of Adiode within the metal5 layer and within two microns of the port.

```
prompt> create_diodes -options {{A CI Adiode 2 metal5 2}}
```

This command creates diodes to fix two user-specified antenna violations.

```
prompt> create_diodes -options {{A CI Adiode 2 metal5 2}
{B CI2 Bdiode 1 metal6 3}}
```

This command creates diodes for the ABC top-level port of a design with top cell name TCell.

```
prompt> create_diodes -options {{ABC TCell Adiode 2 metal5 2}}
```

SEE ALSO

set_app_options(2)

create_drc_error

Creates a physical DRC error object.

SYNTAX

collection **create_drc_error**
-error_data *drc_error_data*
-error_type *drc_error_type*
[-status error | fixed | ignored | waived]
[-polygons *shape_list*]
[-polylines *shape_list*]
[-endpoints *coord_list*]
[-points *shape_list*]
[-layers *layers*]
[-objects *objects*]
[-must_fix]
[-direction *direction*]
[-required_spacing *distance*]
[-actual_spacing *distance*]
[-width_required *distance*]
[-height_required *distance*]
[-shape_uses *shape_uses*]
[-pin_edge *pin_edge*]
[-information *information*]

Data Types

drc_error_data collection
drc_error_type collection
shape_list list
coord_list list
layers collection
objects collection
direction string
distance float
shape_uses list
pin_edge integer
information string

ARGUMENTS

-error_data *drc_error_data*

Specifies the error data in which to create the physical DRC error.

-error_type *drc_error_type*

Specifies the error type for which to create the physical DRC error. The error type value becomes available as the **error_type** attribute for the error.

-status error | fixed | ignored | waived

Sets the initial status of the new error. Available values are: *error, fixed, ignored,* and *waived*. If omitted, the status value **error** is used. The status value becomes available as the **status** attribute for the error.

-polygons *shape_list*

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

-polylines *shape_list*

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the **polylines** attribute for the error.

-endpoints *coord_list*

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This option is a required option when create open error. The coordinates become available as the **endpoints** attribute for the error.

-points *shape_list*

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the **points** attribute for the error.

-layers *layers*

Specifies layers associated with the given shapes or coordinates. The layers are associated with the given shapes or coordinates. If more than one shape is required to describe the error and an exact association of shapes to layers is needed, provide one shape to the **create_drc_error** command and use the **create_drc_error_shapes** command to add the additional shapes with the associated layers. The layers become available as the **layers** attribute for the error.

-objects *objects*

Specifies design objects associated with the new error. The objects become available as the **objects** attribute for the error.

-must_fix

Sets the **must fix** flag on the error. The default is false. The must fix value becomes available as the **must_fix** attribute for the error.

-direction *direction*

Sets the direction of a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The direction is used in rendering the spacing violation in the GUI layout view. The direction value becomes available as the **direction** attribute for the error.

-required_spacing *distance*

Sets the required spacing distance which was not met in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The required distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The required spacing value becomes available as the **required_spacing** attribute for the error.

-actual_spacing *distance*

Sets the actual spacing distance which did not meet requirements in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The actual distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The actual spacing value becomes available as the **actual_spacing** attribute for the error.

-width_required *distance*

Sets the required width of the drc_error object, which is the required width of the violating object. The required width has meaning in the context of a violation in the "size" error_class, where the width of the object does not meet the requirement.

-height_required *distance*

Sets the required height of the drc_error object, which is the required height of the violating object. The required height has meaning in the context of a violation in the "size" error_class, where the height of the object does not meet the requirement.

-shape_uses *shape_uses*

Sets the shape uses associated with the error. The *shape_uses* values can be used to filter errors in the GUI error browser where the attribute is called "route types". The *shape_uses* become available as the **shape_uses** attribute for the error.

-pin_edge *pin_edge*

Sets the pin edge associated with the error. Given any shape, rectangular or rectilinear shape, the edge numbers are a list of positive integers that start from 1. The lower left-most vertical edge is the starting edge with side number 1. Going clockwise, the side numbers of the next edges are 2, 3, and so on. The pin edge is reported as a part of the detailed textual report in the GUI error browser. The pin edge value becomes available as the **pin_edge** attribute for the error.

-information *information*

Sets the error instance specific information string attribute. Information for an error instance is generally set by setting the brief_info and verbose_info attributes of the owning error type and formatting error instance specific data into these strings. However, there are times that information specific to an error instance must be set. In this case, use this attribute to set the information string.

DESCRIPTION

The **create_drc_error** command creates a physical DRC error object in the given error data for the given error type. Additional shapes with associated layers can be added to a drc_error object after creation by using the **create_drc_error_shapes** command.

Most of the attributes associated with a drc_error object are read-only and can only be set at the time of creation. Exceptions to this is the error status, which can be modified using the **set_attribute** command. All attribute values set at creation can then be accessed with the **get_attribute** command. In addition, the attribute values are displayed in the GUI error browser and the GUI layout view.

Brief and verbose information strings are accessible for each drc_error object as the **brief_info** and the **verbose_info** attributes, respectively. These strings are also displayed in the GUI error browser. These information strings are not attached to the drc_error object in the database but rather with the drc_error_type associated with the drc_error object. A message construction service customizes the information strings for each drc_error object by substituting attribute values from the drc_error object into the strings. A detailed description of the message construction is provided in the man page for **create_drc_error_type**.

EXAMPLES

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the spacing class. A DRC error instance is then created for the new type.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \
   -name "route spacing" -error_class spacing \
   -required_objects {net net} \
   -brief_info "A spacing violation between net %net:0% and net %net:1% was detected." \
   -brief_format message \
   -severity error]
{"route short"}

prompt> create_drc_error -error_data $data \
   -error_type $type -objects [get_nets {"F_12_" "F_11_"}] \
   -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200} {78.8600 186.3200}} \
   -layers METAL -status error -direction vertical \
   -required_spacing 3.400 -actual_spacing 31.400
{"123"}
```

SEE ALSO

create_drc_error_shapes(2)
create_drc_error_type(2)
open_drc_error_data(2)
remove_drc_errors(2)

create_drc_error_data

Creates an error data file and returns a collection that contains the error data object.

SYNTAX

collection **create_drc_error_data**
[-name *name*]
[-file_name *file_name*]
-checker_name *checker_name*
[-checker_version *version_string*]
[-information *info_string*]

Data Types

name string
file_name string
checker_name string
version_string string
info_string string

ARGUMENTS

-name *name*

Specifies the name of the attached error data file to create. The error data file is attached to the current block.

The **-file** and **-file_name** options are mutually exclusive; you must specify one.

-file_name *file_name*

Specifies the name of the external error data file.

The naming convention for an error data file is to append an underscore, the checker name, and the ".err" suffix to the design name. For example, for a design named "my_design" and a checker named "test", the error data file name is named "my_design_test.err".

The **-file** and **-file_name** options are mutually exclusive; you must specify one.

-checker_name *checker_name*

Specifies the name of the rule checking engine creating the error data file.

For example, for the route check performed by the router, the engine name might be "zroute".

-checker_version *version_string*

Specifies the version string for the checker engine.

-information ***info_string***

Specifies an informative message to associate with the error data.

DESCRIPTION

The **create_drc_error_data** command creates the specified error data file. The command fails if the specified error data file already exists.

If created with the **-name** option, the error data file is attached to the current block and is included in the block operation when the block is saved, copied, moved, and so on. To save an error data file created in this manner, run the **save_block** for the associated block.

If created with the **-file_name** option, the error data file is written to disk and is not attached to the current block. The error data file is not included in the block operation when it is saved, copied, moved, and so on. The created error data file is opened in read/write mode. To save an error data file created in this manner, run the **save_drc_error_data** command.

The command returns a collection that contains the error data object associated with the error data file. If no error data object is created, the command returns an empty string.

The **create_drc_error_data** command increments the open count for the error data object. The **create_drc_error_data** (and **open_drc_error_data**) commands must be balanced by an equal number of **close_drc_error_data** commands to close the error data object.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an attached error data file named "dppinassgn.err", with a checker name of "dppinassgn", and a short information string.

```
prompt> set data [create_drc_error_data -name dppinassgn.err \
  -checker_name dppinassgn \
  -information "This error data contains pin assignment and \
    placement errors for the my_design design"]
{"dppinassgn.err"}
```

The following example creates an external error data file named "my_design_dppinassgn.err", with a checker name of "dppinassgn", and a short information string.

```
prompt> set data [create_drc_error_data \
  -file_name my_design_dppinassgn.err \
  -checker_name dppinassgn \
  -information "This error data contains pin assignment and \
    placement errors for the my_design design"]
{"my_design_dppinassgn.err"}
```

create_drc_error_shapes

Creates shapes and layers and adds to a physical DRC error object.

SYNTAX

status **create_drc_error_shapes**
-error_data *error_data*
drc_error
[-polygons *shape_list*]
[-polylines *shape_list*]
[-endpoints *coord_list*]
[-points *shape_list*]
[-layers *layers*]

Data Types

error_data collection
drc_error collection
shape_list list
coord_list list
layers collection

ARGUMENTS

-error_data *error_data*

Specifies the error data in which to find the physical DRC error to modify.

drc_error

Specifies the error to which to add the shapes and layers.

-polygons *shape_list*

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

-polylines *shape_list*

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the **polylines** attribute for the error.

-endpoints *coord_list*

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This

option is a required option when create open error. The coordinates become available as the **endpoints** attribute for the error.

-points ***shape_list***

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the **points** attribute for the error.

-layers ***layers***

Specifies the layers associated with the given shapes or coordinates. The layers become associated with the given shapes.

DESCRIPTION

The **create_drc_error_shapes** command adds additional shapes and layers to an existing physical DRC error object in the given error data. Shapes and layers are added to the DRC error object at the time of creation. If more than one shape is required to describe the error and exact association of shapes to layers is needed, use the **create_drc_error_shapes** command to add the additional shapes with the associated layers. The layers become available as the **layers** attribute for the error. The command requires at least one of shape options be specified.

EXAMPLES

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the basic class. A DRC error instance is then created for the new type. Additional shapes and layers are then added.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \
   -name "shapely error" -error_class basic \
   -required_objects {net} \
   -severity error]
{"route short"}

prompt> set error [create_drc_error -error_data $data \
   -error_type $type -objects [get_nets {F_12_}] \
   -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200} {78.8600 186.3200}} \
   -layers METAL]
{"45"}

prompt> create_drc_error_shapes -error_data $data $error\
   -polygons {{74.8600 189.4600} {75.8800 189.4600} {75.8800 186.3200} {74.8600 186.3200}} \
   -layers METAL5
```

SEE ALSO

create_drc_error(2)
create_drc_error_type(2)

open_drc_error_data(2)

create_drc_error_type

Creates a physical DRC error type object.

SYNTAX

collection **create_drc_error_type**
-error_data *drc_error_data*
-name *type_name*
-error_class base | spacing | short | open_locator
[-brief_info *info_string*]
[-brief_format ascii | message]
[-verbose_info *info_string*]
[-verbose_format ascii | message]
[-severity error | information | recommendation | warning]
[-required_objects {layer net pin port cell pinGuide}]
[-num_detected_errors *num_errors*]

Data Types

drc_error_data collection
type_name string
info_string string
num_errors integer

ARGUMENTS

-error_data *drc_error_data*

Specifies the error data in which to create the physical DRC error type.

-name *type_name*

The name for the error type being created. Names must be unique in the scope of the owning error data.

-error_class base | spacing | short | open_locator

Specifies the kind of errors represented by the new error type. The error class determines how the shapes of the associated DRC error instances are rendered in the GUI layout view. It also determines some expected attributes for its error instances. Available values are: base, spacing, short, and open_locator.

The **base** class allows its types to define required associated design objects. The **spacing** class allows its types to define required associated design objects and the error instances to describe a mismatch in actual and required spacing distance. Spacing errors can also be defined with a direction. The **short** class allows its types to define required associated design objects and is rendered with a diagonal cross inside of its shape. The **open_locator** class is for open nets and expects to be associated with a single net and to have two endpoints describing an open in a net as its shape description.

-brief_info *info_string*

Specifies a brief information string for display. Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The brief information string is expected to be a compact description that is suitable for display in a tabular format in the GUI error browser.

-brief_format ascii | message

Specifies the display format of the brief information string specified with **-brief_info**. If the format is *ascii*, the brief info string is displayed exactly as specified with the **-brief_info** option, without modification. If the format is *message*, the brief info string is parsed for special tokens. The tokens are replaced with error instance attribute values before display.

-verbose_info *info_string*

Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The verbose information string should be a detailed description that is suitable for display in a report format in the GUI error browser.

-verbose_format ascii | message

Specifies the display format of the verbose information string specified with **-verbose_info**. The format can be one of: **ascii** or **message**. If the format is **ascii**, the verbose info string is displayed exactly as specified with the **-verbose_info** option, without modification. If the format is **message**, then the verbose info string is parsed for special tokens. The tokens are replaced with error instance attribute value before display.

-severity error | information | recommendation | warning

Specifies the severity of the message associated with instances of this type.

-required_objects {layer net pin port cell pinGuide}

Specifies the required object classes associated with this error. A type might require that a specific number of design objects be associated with its error instances. For example, a route spacing type error might require that all of its instances have two associated nets. If the spacing violation is between shapes of the same net, the same net can be repeated twice. By specifying required objects, the type allows instances to be filtered for null object association.

The required objects are specified with a list of the design object class names. If multiple instances of a design object type are required, the class name can be repeated. For example, to specify that two nets are required, use the option argument **{net net}**.

While this option allows definition of the required design object types, additional objects can be associated with an error instance in addition to the required design object types.

-num_detected_errors *num_errors*

Specifies the maximum number of detected errors that are allowed. Some checkers allow you to specify a limit on the number of errors detected per type. The checker can add information about how many errors were detected, vs. how many errors were added into the error database, by using this option.

DESCRIPTION

The **create_drc_error_type** command creates physical DRC error objects in the specified error data. Error types must have unique names in the scope of the owning error data and error types must be defined with an error class.

The command supports brief and verbose information strings for error type objects. These strings are displayed for each error instance in the GUI error browser. The strings can be customized with attribute values of an error instance by using the **message** format along with replacement of special tokens with attribute values.

A message construction service parses the error message for delimited tokens. If found, the command substitutes them with attribute values to construct a message appropriate for a specific DRC error instance. The token delimiter is the percent (**%**) character. To pass a percent symbol directly to the output message without modification, escape the character with a backslash: **\%**. A token has the form **%<error instance attribute name[:<ordinal value>]>[.<attribute name>]%** Error instance attributes are named as described below.

For associated design objects, the attribute name is the object type name. If there are multiple objects of the same object type, the specific associated object is identified with the ":<ordinal value>" qualifier. The value starts at zero for the first identified object. For example "pin:0" identifies the first associated pin and "pin:2" identifies the third pin associated with the error instance. If the ordinal value qualifier is omitted, the first object of that type is default. The special character "*" can be used in place of the ordinal value to mean all objects of the given type. The supported object type names are: **layer, net, pin, port, cell,** and **pinGuide**.

In addition, the attribute name **type** can be used to denote the associated error type. Append a period character (**.**) delimiter to the optional attribute name to access a specific attribute for the identified object. If the attribute qualifier is omitted, the object's name is used. Attribute names supported with the associated object are: name and full_name. In addition, pin and port objects support the attribute name **cell** which will print the name of the cell associated with the pin or port. Attribute names supported with the associated error type are: name, severity, and class.

For other error instance attribute fields, access an attribute value by using the attribute name for the object. For example, use **actual** for the actual distance in a spacing violation and **direction** for the direction of a spacing violation. Some of these attributes can also be given with the **:<ordinal value>** qualifier. For example, there can be multiple route types associated with an error. As with design objects, if the ordinal value qualifier is omitted, the first one is selected by default. The * glob character can be used to specify all values. The currently supported error instance attributes are: **status, shapes, bbox, direction, actual, required, routeType,** and **endpoint**.

EXAMPLES

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the short class.

```
prompt> set data [open_drc_error_data -file_name my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> create_drc_error_type -error_data $data \
   -name "route short" -error_class short \
   -required_objects {net net} \
   -brief_info "A short between net %net:0% and net %net:1% was detected." \
   -brief_format message \
   -severity error
{"route short"}
```

create_drc_error(2)
open_drc_error_data(2)

remove_drc_error_types(2)

create_eco_bus_buffer_pattern

Creates an ECO bus buffer pattern.

SYNTAX

collection **create_eco_bus_buffer_pattern**
-name *name*
-first_buffer left | right | top | bottom
-measure_from left | right | top | bottom
[-distance *length*]
[-repeat_after *number*]
[-user_specified_distance *length_list*]

Data Types

name string
length float
number integer
length_list list

ARGUMENTS

-name *name*

Specifies the name of the ECO bus buffer pattern to create. The name must be unique in a design.

-first_buffer left | right | top | bottom

Specifies the order in which the buffers are created. The order is relative to the location of the first buffer in the pattern. Buffer patterns for horizontal routes are specified by using **-first_buffer top** or **-first_buffer bottom**, and buffers are inserted on the route of the topmost or bottommost bit in the layout. Buffer patterns for vertical routes are specified by using **-first_buffer left** or **-first_buffer right**, and buffers are inserted on the route of the leftmost or rightmost bit in the layout.

-measure_from left | right | top | bottom

Specifies the side of the buffer to measure from when placing the next buffer in the pattern. Buffer patterns for horizontal routes are specified by using **-measure_from left** or **-measure_from right**. Buffer patterns for horizontal routes are specified by using **-measure_from top** or **-measure_from bottom**. The first buffer is placed at the reference side of the pattern, succeeding buffers are placed at the specified distance from the previous buffer in the opposite direction. For example, if you specify **-measure_from left** for a horizontal bus, the second buffer is placed to the right of the first buffer, the third buffer is placed to the right of the second buffer, and so on.

-distance *length*

Specifies the distance between the reference sides of two adjacent buffers. This option is mutually exclusive with the **-**

user_specified_distance option and is used together with the *-repeat_after* option.

-repeat_after ***number***

Restarts the pattern from the reference side after the specified *number* of buffers. If this option is not specified, the pattern continues and does not repeat. This option is mutually exclusive with the **-user_specified_distance** option and is used together with the *-distance* option.

-user_specified_distance ***length_list***

Specifies the distances between successive buffers. The first distance in the list is the distance between the reference sides of the first buffer and the second buffer. The second distance in the list is the distance between the reference sides of the second buffer and the third buffer, and so on. The pattern repeats after the last distance in the list is used, and the next buffer is placed at the reference side of the pattern again.

This option is mutually exclusive with the **-distance** and **-repeat_after** option.

DESCRIPTION

This command creates a buffer pattern with the specified placement edge, buffer-to-buffer placement distances, and pattern size. The command returns an ECO bus buffer pattern, which can be used with the **add_buffer_on_route -user_specified_bus_buffers** command.

EXAMPLES

The following example creates an ECO bus buffer pattern named bpLB. The first buffer is placed at the top left corner. Successive buffers are placed at a 2 micron pitch as measured from the left edge of the buffer. The pattern repeats from the left edge every eight buffers.

```
prompt> create_eco_bus_buffer_pattern -name bpLB \
  -measure_from left -first_buffer top -distance 2 -repeat_after 8
```

The following example creates and ECO bus buffer pattern named bpMF. Distances between buffers are specified with the **-user_specified_distance** option. The pitch between the first buffer and second buffer is 2, the pitch between the second buffer and third buffer is 4, the pitch between the third buffer and fourth buffer is 1. The fifth buffer is placed at the left edge of the pattern.

```
prompt> create_eco_bus_buffer_pattern -name bpMF \
  -measure_from left -first_buffer bottom \
  -user_specified_distance {2 4 1}
```

remove_eco_bus_buffer_patterns(2)
report_eco_bus_buffer_patterns(2)

create_edit_group

Creates an edit group in the current design.

SYNTAX

collection **create_edit_group**
[-name *edit_group_name*]
[-ungroup_on_remove first | second-to-last | last | never]
[-group_use user | bump_array | macro_array | io_group]
[-cell *cell*]

Data Types

edit_group_name string
cell collection

ARGUMENTS

-name *edit_group_name*

Specifies the name of the edit group.

By default, the command generates a name automatically. The command uses the prefix "EDIT_GROUP_" and appends a number in consecutive order, such as EDIT_GROUP_0, EDIT_GROUP_1, and so on.

-ungroup_on_remove first | second-to-last | last | never

Specifies when the edit group should be automatically removed from the design, depending on when objects in the edit group are removed. The *first* argument specifies that the edit group be removed when any member object is removed. The *second-to-last* or *last* arguments specify that the edit group be removed when the second-to-last or last member objects are removed, respectively. The *never* argument specifies that the edit group remain in the design even after all member objects are removed. By default, the *never* argument is used.

-group_use user | bump_array | macro_array | io_group

Sets the use context of this edit group. The default is *user*.

-cell *cell*

Specifies the physical cell where the edit group is to be added. The edit group is created in the cell's reference block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, edit groups can be created in library cells. When not specified, the edit group is created in the current block.

DESCRIPTION

The **create_edit_group** command groups objects into a named collection. You can use the edit group to define a relative positioning constraint on a collection of objects, so that they are physically transformed in a consistent manner. Edit groups created using this command are containers which are initially empty. Objects can be added to edit groups with the **add_to_edit_group** command, and removed with the **remove_from_edit_group** command. An object can belong to only one edit group at a time. Removing an object from an edit group does not remove the object from the design, however removing an object from the design automatically removes it from its containing edit group. Edit group nesting is permitted, so edit groups can contain other edit groups as member objects.

This command returns the edit group as a single element collection, an empty string if it fails, or a Tcl error if there is a command syntax error.

EXAMPLES

The following example creates an edit group named "edit_group1", which is automatically removed when its last member object is removed.

```
prompt> create_edit_group -name "edit_group1" -ungroup_on_remove last
```

create_ems_database

Creates an EMS database and returns it in a collection.

SYNTAX

collection **create_ems_database**
ems_database_name

Data Types

ems_database_name string

ARGUMENTS

ems_database_name

Specifies the name for the EMS database to be created. The name should contain the ".ems" suffix.

DESCRIPTION

The **create_ems_database** command creates an EMS database and makes it the current EMS database. The *ems_database_name* argument must honor the naming convention and end with ".ems", such as "cts.ems", "check_design.ems", and so on. Use the **save_ems_database** command after **create_ems_database** to write out the database to disk. The created EMS database name is returned in a collection.

EXAMPLES

The following example creates an EMS database named a.ems and makes it the current EMS database.

```
prompt> create_ems_database a.ems
{a.ems}
prompt> get_current_ems_database
{a.ems}
```

The following example shows the error you receive if you omit the .ems extension.

```
prompt> create_ems_database abc
Error: Illegal EMS filename. Filename needs to have suffix of '.ems' (EMS-004)
```

The following example shows the error you receive if you try to create an EMS database that already exists.

```
prompt> create_ems_database a.ems
Error: file 'a.ems" already exists. It cannot be created. (EMS-032)
```

SEE ALSO

create_ems_message

Creates an EMS message for user-defined EMS rule

SYNTAX

string **create_ems_message**
-rule *rule_name*
[-parameters *parameter_values*]

Data Types

rule_name string
parameter_values string

ARGUMENTS

-rule *rule_name*

Specifies the name of the user-defined rule for which the EMS message needs to be created. This is a mandatory option. If the rule name is invalid or if it does not match any existing user-defined rule name then an error message is displayed.

-parameters *parameter_values*

Specifies the values for the EMS parameters defined in the EMS rule. This is an optional option. The argument is a string, which is a sequence of one or more pairs separated by white-space, where each pair is of the format <parameter_name>: <parameter_value>. All the parameters defined in EMS rule should be provided with a value, or else the creation of EMS message fails and command returns an error message.

DESCRIPTION

The **create_ems_message** command creates an EMS message using the user-defined EMS rule name. Before invoking this command, you should have a current EMS database in memory. If one does not exist then it can be created using the **create_ems_database** command. This command also takes the values for parameters present in user-defined EMS rule.

EXAMPLES

prompt> **create_ems_rule -name "TEMP-001" -severity "Info"** \

```
  -message "Pin:%pin has capacitance:%cap" \
  -parameters "name:pin type:string command:get_pins ; name:cap type:double"
prompt> create_ems_rule -name "TEMP-002" -severity "Error" \
  -message "Cell %cell is not placed" \
  -parameters "name:cell type:string command:get_cells"
prompt> create_ems_rule -name "DUMMY-001" -severity "Warning" \
  -message "This is a dummy warning message without parameters"
prompt> create_ems_database a.ems
{a.ems}
prompt> set cap 0.0004
prompt> create_ems_message -rule "TEMP-001" \
  -parameters "pin:U1/I cap:$cap"
prompt> set cell U23
prompt> create_ems_message -rule "TEMP-002" -parameters "cell:$cell"
prompt> create_ems_message -rule "DUMMY-001"
prompt> report_ems_database
 ...
Information: Pin:U1/I has capacitance 0.0004 (TEMP-001)
Error: Cell U23 is not placed (TEMP-002)
Warning: This is a dummy warning message without parameters (DUMMY-001)
```

SEE ALSO

create_ems_database(2)
create_ems_rule(2)

create_ems_rule

Creates a user-defined EMS rule. An EMS rule is a template used to create EMS messages.

SYNTAX

create_ems_rule
-name *rule_name*
-severity *rule_severity*
-message *message_template*
[-parameters *parameter_properties*]

Data Types

rule_name string
rule_severity string
message_template string
parameter_properties string

ARGUMENTS

-name *rule_name*

Specifies the name used to uniquely identify this rule. This is a mandatory option. If a rule by this name already exists in EMS memory, then an error message will be displayed. The rule name should obey the regular expression [A-Z]+[-][0-9]+ i.e one or more upper-case letters, followed by hyphen character and which should be followed by one or more numerals. If rule name does not obey this regular expression, then an error message is displayed. The sub-string in the rule name before hyphen character is called the **domain** name. If there are many rules which are closely associated with each other then it is advised to choose the same **domain** name.

-severity *rule_severity*

Specifies whether the rule corresponds to an error, warning, or information. This is a required option. The valid values are **error**, **information**, **info**, **warning**, and **warn**. These string values can be in upper or lower case or a mix of both. But it is advisable to stick to one convention for the sake of uniformity. But when the EMS message is displayed in the shell or in the EMS GUI message browser, the severity string displayed will be one of **Error**, **Warning**, or **Information**.

-message *message_template*

Specifies the message template for the rule. This is a mandatory option. The message template can contain placeholders referred to as **parameters**. Parameters begin with a **%** character. The parameter name should obey regular expression [A-Za-z0-9_]+ i.e it should contain one or more of upper or lower case alphabets or numerals or underscore character. There should not be any whitespace between **%** and parameter name. If user wants to use literal **%** the she should use **%%**.

-parameters *parameter_properties*

Specifies the parameter properties for the rule. This is an optional option. If there are no EMS parameters for the rule being defined, then this option is not required. But if there are EMS parameters specified in message template, this option can be used to define the parameter properties. This option takes a string as an argument which contains groups of name-value pairs fields separated by a semi-colon (;). Each group describes properties of an EMS parameter, which again is a sequence of pairs of format <name>:<value>.

Currently, an EMS parameter can have at-most three properties: name-property, type-property and command-property. Here type-property and command-property are optional and name-property is mandatory. name-property will take a valid parameter name as value and which helps EMS to know properties of which parameter are defined. type-property can take one of **string**, **int**, **float** and **double** values. type-property is used to define the type of the EMS parameter. The command-property of the EMS parameter can take value as any of the **get_*** commands such as **get_pins**, **get_cells**, and so on, which take an object name as argument and return the object handle. This property is used to get the object handle corresponding to the EMS parameter name.

DESCRIPTION

The **create_ems_rule** command creates a user-defined EMS rule. An EMS rule is a message template with some auxiliary information used to create the EMS message. The user-defined rules created are not persistent across sessions.

EXAMPLES

```
prompt> create_ems_rule -name "TEMP-001" -severity "Info" \
  -message "Pin:%pin has capacitance:%cap" \
  -parameters "name:pin type:string command:get_pins ; name:cap type:double"
prompt> create_ems_rule -name "TEMP-002" -severity "Error" \
  -message "Cell %cell is not placed" \
  -parameters "name:cell type:string command:get_cells"
prompt> create_ems_rule -name "DUMMY-001" -severity "Warning" \
  -message "This is a dummy warning message without parameters"
prompt> create_ems_database a.ems
{a.ems}
prompt> set cap 0.0004
prompt> create_ems_message -rule "TEMP-001" \
  -parameters "pin:U1/I cap:$cap"
prompt> set cell U23
prompt> create_ems_message -rule "TEMP-002" -parameters "cell:$cell"
prompt> create_ems_message -rule "DUMMY-001"
prompt> report_ems_database
 ...
Information: Pin:U1/I has capacitance 0.0004 (TEMP-001)
Error: Cell U23 is not placed (TEMP-002)
Warning: This is a dummy warning message without parameters (DUMMY-001)
```

SEE ALSO

create_ems_database(2)
create_ems_message(2)

create_exterior_tap_walls

Creates a tap wall at a specified distance outside a boundary edge of a core area, hard macro, soft macro, or hard placement blockage.

SYNTAX

status **create_exterior_tap_walls**
-lib_cell *cell_name*
-bbox *coordinates*
-side top | bottom | left | right
[-x_margin *distance*]
[-y_margin *distance*]
[-prefix *cell_prefix*]
[-orientation *cell_orientation*]

Data Types

cell_name string
coordinates list
distance float
cell_prefix string
cell_orientation string

ARGUMENTS

-lib_cell *cell_name*

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

-bbox *coordinates*

Specifies the rectangular tap insertion region in microns. Specify the rectangle as a list of four coordinates, {{llx lly} {urx ury}}, which represents the lower-left and upper-right corners of the rectangle.

A tap wall is created along the longest edge of the core boundary, macro, or hard placement blockage encompassed by the rectangular region. The command issues an error message if it cannot find an edge.

This is a required option.

-side top | **bottom** | **left** | **right**

Specifies the side on which to create a tap wall. You must specify a single side. This is a required option.

-x_margin *distance*

Specifies the margin in microns of a horizontal tap wall.

The default is 0.

-y_margin *distance*

Specifies the margin in microns of a vertical tap wall.

The default is 0.

-prefix *cell_prefix*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

*<cell_prefix>__<lib_cell>*_R#_C#_*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

extTapWall__<*lib_cell*>_R#_C#_*number*

-orientation *cell_orientation*

Specifies the orientation of the placement of the tap cells. The valid values are: R0, R90, R180, R270, MX, MXR90, MY, MYR90.

The default is R0.

DESCRIPTION

This command adds an exterior tap wall to the design. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cells in the library do not contain substrate or well taps.

Exterior tap wall placement does not honor standard cell rows or sites and does not cross the object's boundary. Only one edge of the specified side is be processed in each command execution. If the tap insertion region spans multiple edges, only the longest edge is processed. If the tap insesrtion region does not contain an edge, the command issues an error message.

The tap cells are inserted within the tap insertion region, including the specified margins. A horizontal tap wall starts at the x-margin from the left of the bounding box. A vertical tap wall starts at the y-margin from the bottom of the bounding box. If the tap insertion region, including the margins is too small, the command does not insert tap cells.

You must ensure that the tap insertion region is empty. Otherwise, the inserted tap wall might overlap macros or other cells.

The command marks the inserted tap cells as fixed.

EXAMPLES

The following example creates tap walls outside the longest edge on the bottom of the core area.

```
prompt> create_exterior_tap_walls -lib_cell myLib/Cell1 \
  -side bottom -bbox {{-20 -20} {20 200}}
```

create_fill_cell

Creates a new fill cell in the current block.

SYNTAX

status **create_fill_cell**
-reference reference

Data Types

reference string

ARGUMENTS

-reference reference

Name of the internal design in this or another design.

DESCRIPTION

Creates a new fill cell in the current block using the specified reference. The specified reference, must be an internal design. If the specified reference is an internal design from another design, it is copied as an internal design in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a fill cell, using internal design "m1_fill" from design "myDesign" as reference.

```
prompt> create_fill_cell -create_reference myDesign.m1_fill.design
2
```

SEE ALSO

get_fill_cells(2)
remove_fill_cells(2)

create_frame

Creates a frame view for the current block by extracting blockage, pin, and via information from the design view.

SYNTAX

status **create_frame**
[-block_all auto | true | false | used_layers | *topBlockedLayerName*]
[-block_core_margin *layer_margin_list*]
[-derive_pattern_must_join true | exclude_pg | false]

ARGUMENTS

-block_all auto | true | false | used_layers | *topBlockedLayerName*

Controls whether the tool creates zero-spacing routing blockages in the frame view for the entire block, except for the area around the pins.

The valid values for this option are

- **false**
  The tool does not create zero-spacing routing blockages.
- **true**
  The tool creates a zero-spacing routing blockage on all layers.
- **used_layers**
  The tool creates a zero-spacing routing blockage only on layers used by the cell.
- **topBlockedLayerName**
  The tool creates a zero-spacing routing blockage only on the specified layer and the layers below it. The layer name must be a metal or poly layer defined in the technology file.
- **auto** (the default)
  The tool determines whether to create zero-spacing routing blockages based on the design type of the cell. For analog, black-box, and module design types, the tool creates zero-spacing routing blockages on all layers (**true**). For macro cells, the tool creates zero-spacing routing blockages only on used layers (**used_layers**). For all other design types, the tool does not create zero-spacing routing blockages.

When the tool does not generate zero-spacing routing blockages in the frame view, it copies all of the physical geometries from the design view to the frame view.

When the tool generates zero-spacing routing blockages in the frame view, it preserves the detailed shapes within the DRC distance from the edges of the routing blockages. The tool generates the metal shapes to cover the area beyond the DRC distance. If a cut shape is covered by generated metal shapes on both the upper and lower metal layers, the tool does not include the cut shape in the frame view. Otherwise, the tool preserves the cut shape. For more information about the DRC distance, see the description of the **-drc_distances** option.

The setting specified by this option applies to all layers. However, if this option setting conflicts with the setting of the **-block_core_margin** option for a layer, the **-block_core_margin** option has priority for that layer.

-block_core_margin *layer_margin_list*

Creates zero-spacing routing blockages on the specified layers with the specified margin between the core blockage and the cell boundary.

Specify this argument using the following syntax:

{ { *layer_name margin* } ... }

The *layer_name* value can be the layer name defined in the technology file or the keyword "used_layers" or "all_layers".

- For "used_layers", the margin value is for the non-empty metal or poly layers.
- For "all_layers", the margin value is for all metal and poly layers.

When there are combined settings, the priority from high to low is:

1) *layer_name*

2) used_layers
3) all_layers

The *margin* value can be zero, a positive number, or a negative number. When the specified margin is 0, the tool blocks the entire cell area, except for the area around the pins, with a zero-spacing routing blockage for the specified layer. A positive margin value specifies the distance between the generated zero-spacing routing blockage and the cell boundary. A negative margin value specifies the distance that the zero-spacing routing blockage extends outside the cell boundary.

The *margin* value can also be a keyword "auto_bloat", which means the tool automatically uses layer negative value of min_spacing of specified layer as the margin value. Therefore, the generated routing blockage is extended outside the cell boundary by min_spacing of the specified layer.

When generating zero-spacing routing blockages in the frame view, the tool preserves the detailed shapes within the DRC distance from the edges of the routing blockages. The tool generates the metal shapes to cover the area beyond the DRC distance. If a cut shape is covered by generated metal shapes on both the upper and lower metal layers, the tool does not include the cut shape in the frame view. Otherwise, the tool preserves the cut shape. For more information about the DRC distance, see the description of the **-drc_distances** option.

If this option setting conflicts with the setting of the **-block_all** option for a layer, this option setting has priority.

-drc_distances ***layer_distance_list***

Specifies the distance for each layer within which to preserve detailed shapes from the edges of a zero-spacing routing blockage generated by the **-block_all** or **-block_core_margin** option.

Specify this argument using the following syntax:

{ { *layer_name distance* } ... }

By default, the tool uses the maximum spacing value from the Layer section of the technology file for each layer.

-color_based_dpt_flow false | **true** | **auto**

Controls whether the tool creates the metal shapes beyond the DRC distance with attribute mask_constraint or not. The metal shapes are added by option block_all or block_core_margin in frame creation.

The valid values for this option are :

- **false**
  The metal shapes beyond the DRC distance are colorless and trimmed by colored shapes.
- **true**
  For metal layers, the metal shapes beyond the DRC distance are colored and trimmed by both colored and colorless shapes.

  For poly and below layers, the metal shapes beyond the DRC distance are still colorless and only trimmed by colored shapes.
- **auto** (the default)
  If the following color rules are defined in the technology file, the option is treated as **true**; otherwise, it is treated as **false**.

  sameColorSpanTblXMinSpacing
  sameColorSpanTblYMinSpacing
  diffColorSpanTblXMinSpacing
  diffColorSpanTblYMinSpacing

-connect_within_pin true | **false**

Controls whether the via enclosure must be within the pin shape.

This option affects via region creation. If **true**, the tool must place the via enclosure inside the pin shape when inserting vias in the

via region. If **false**, the tool can place the via enclosure outside of the pin shape when inserting vias in the via region.

The default is **true**.

-convert_metal_blockage_to_zero_spacing *layer_distance_mode_list*

Converts regular routing blockages on the specified layers in the design view to zero-spacing routing blockages in the frame view, and specifies the distance by which to enlarge the blockage when doing the conversion. Different enlarge distance can be specified for blockages touching pins and not touching pins by setting the mode as 'touch_pin' and 'no_touch_pin' accordingly. Mode 'all' implies the enlarge distance will be applied to all regular routing blockages on the specified layer.

Specify this argument using the following syntax:

{ { *layer_name distance mode*} ... }

The layer name must be a metal or poly layer defined in the technology file. The distance value must be no less than zero. The mode string must be one of 'touch_pin', 'no_touch_pin', or 'all'.

-create_zero_spacing_blockages_around_pins *layer_width_list*

Specifies the width to create zero-spacing routing blockages around pins by layer.

For the pin on cell boundary, the routing blockage will not be generated on the boundary side.

For the shallow pin, the routing blockage will not be generated on the channel area, which is from *pin* to *cell boundary*.

For the deep pin, all sides of the pin will have routing blockages.

Specify this argument using the following syntax:

{ { *layer_name width* } ... }

The width should be no less than zero.

-design_rule_via_blockage_layers *cut_layer_name_list*

Converts zero-spacing routing blockages on the specified cut layers of the frame view to design rule via routing blockages. The option accepts a list of cut layers defined in the technology file and works only for zero-spacing routing blockages on the specified layers.

A design rule via routing blockage is a routing blockage whose **is_design_rule_blockage** attribute is **true**. The purpose of a design rule via routing blockage is to honor the spacing between a via blockage layer and a via layer in the DesignRule section of the technology file. For example,

```
DesignRule {
  layer1 = 'via1Blockage'
  layer2 = 'V1'
  minSpacing = 0.084
}
```

-derive_pattern_must_join true | exclude_pg | false

Sets **pattern_must_join** attribute as **true** to the port which has multiple terminals on one metal layer. Only terminals on metal layers are considered, terminals on cut layers are ignored. The option value controls which type of port should be checked by this option.

The valid values for this option are

- **true**
  The tool derives **pattern_must_join** attribute for the following ports:
- The **port_type** attribute is not power/ground related.

- The **port_type** attribute is power/ground related, and the **is_secondary_pg** attribute is **true**.
- The **port_type** attribute is power/ground related, and the port name is specified in the **-include_routing_pg_ports** option.
- **exclude_pg**
  The tool derives **pattern_must_join** attribute only for the ports which are not power/ground related.
- **false** (the default)
  The tool does not set **pattern_must_join** attribute as **true** to any port.

-enable_via_regions_for_all_design_types true | false

Controls whether to create via regions for all design types.

The default is **false**. Only create via regions for standard cell group design types.

When this option is set to **true**, the tool also checks whether the -block_all or -block_core_margin is set to **true**. And then the tool checks the direction of pin shape direction, and cut channel to the closest boundary on same layer or upper layer base on the direction of pin shape.

- For "vertical" pin:
  If the pin is near to "bottom or top" boundary, create channel on "same" metal layer.
  If the pin is near to "left or right" boundary, create channel on "upper" metal layer.
- For "horizontal" pin:
  If the pin is near to "left or right" boundary, create channel on "same" metal layer.
  If the pin is near to "bottom or top" boundary, create channel on "upper" metal layer.
- For "square" pin:
  Create channel to the nearest boundary on "same" metal layer.

-hierarchical true | false

Controls whether to extract geometries in subblocks.

If **true**, the tool performs hierarchical extraction. If **false**, the tool ignores the geometries in subblocks.

The default is **true**.

-include_nondefault_via *via_list*

Specifies the nondefault vias to consider when calculating the via regions. Specify the nondefault vias by using the contact code names defined in the technology file.

The *via_list* can accept keyword "auto", which means when there is no via region created by default vias, the tool automatically includes the nondefault vias to calculate the via regions.

By default, the extraction process considers only the default vias.

-include_routing_pg_ports *port_list*

Specifies the power and ground port names that require via regions and access edges in the frame view. Usually, these ports are the secondary or bias power and ground ports, which are routed by the signal router.

By default, power and ground ports are ignored when generating via regions and access edges.

-keepout_spacing_for_non_pin_shapes *layer_setting_list*

Creates zero-spacing routing blockages around non-pin shapes on the specified layers with the specified *extension_spacing* from the shape boundary and with the specified *corner_keepout_spacing* from the shape corners.

An *edge_threshold* value is also specified for the layer so that frame can identify "edges" of non-pin shapes. If the created zero-

spacing routing blockages are overlap with pins, the overlap region on the non-edge sides are trimmed by pins.

Specify this argument using the following syntax:

{ { *layer_name* {*edge_threshold extension_spacing corner_keepout_spacing*} } ... }

The *edge_threshold* is for determining edges of shapes. If a segment along the contour of the connected non-pin shape has length smaller than or equal to the threshold, the segment is an edge. But if the segment belongs to concave part of the contour, it is still not an edge. The value should be zero or a positive number. If the value is zero, routing blockages are trimmed by pins on each side of the shape.

The *extension_spacing* is for creating zero-spacing routing blockages around non-pin shapes in direction top, bottom, left and right. The value should be zero or a positive number. If the value is zero, no routing blockage is created.

The *corner_keepout_spacing* is for creating zero-spacing routing blockages around corners of non-pin shapes. The value should be zero or a positive number, and it should be smaller than or equal to the *extension_spacing*. If the value is zero, no corner routing blockage is created.

If **-block_all** is **true** or **-block_core_margin** is specified for the same layer, this option becomes invalid.

-merge_metal_blockage true | **false**

Controls whether to merge metal shapes and regular routing blockages to reduce the number of shapes.

If **true**, the extraction process fills in the space between the two shapes when two nearby geometries are within the spacing threshold, creating a single larger shape for the blockages in the frame view. The spacing threshold is equal to minimum spacing times two plus minimum width.

The default is **false**.

-pin_channel_distances *layer_distance_list*

Specifies the pin channel cutting distance from the block boundary to core area per layer. If the distance of the pin from the block boundary is smaller than the pin channel cutting distance, the tool will cut channel from the pin through shapes or blockages to boundary.

By default, the tool uses layer minWidth + minSpacing from the technology file as the pin channel cutting distance.

-pin_must_connect_area_layers *connection_spare_layer_list*

Specifies connection layer and associated spare layer pairs to designate the required via connection area within the pin geometry.

Specify this argument using the following syntax:

{ { *connection_layer_name spare_layer_name* } ... }

The spare layer can be any layer except a layer with a standard mask name.

By default, the router can connect to any part of a large pin. To restrict the connection to a subarea of a large pin, specify the subarea polygon on a spare layer and specify the spare layer associated with each connection layer using this option.

The following example associates connection layer M1 with spare layer S1 and connection layer M2 and spare layer S2:

{ {M1 S1} {M2 S2} ... }

-pin_must_connect_area_thresholds *layer_width_list*

Specifies connection layer and the width threshold pairs for automatic determination of the required via connection area within the pin geometry.

Specify this argument using the following syntax:

{ { *layer_name width* } ... }

Specify the width threshold using the unit size defined in the technology file.

By default, the router can connect to any part of a large pin. To automatically restrict the connection to a subarea of a pin with various geometry widths, use this option to specify the width threshold for each layer.

For example,

{ {M1 0.56} {M2 0.63} ... }

The tool does not allow via connections in areas within a pin that have a width smaller than the specified threshold width for the layer.

-port_contact_selections *port_contact_code_list*

Specifies the contact codes to use for specific ports during via region generation.

Specify this argument using the following syntax:

{ { *port_name* { *contact_code_list* } } ... }

Specify the contact codes by using the names defined in the technology file.

Via regions for the specified ports use only the specified contact codes. Via regions for all other ports use only the default contact codes. The via regions generated by this option are hard constraints for the signal router.

-preserve_metal_blockage true | **false** | **auto**

Controls whether to preserve all metal shapes and routing blockages around pins as they exist in the design view.

If **true**, all metal shapes and routing blockages around pins are retained exactly. If **false**, the metal shapes and routing blockages are trimmed by pins only when the metal shapes and routing blockages touch a pin. The trimming distance is the maximum spacing value from the technology file. The trimmed metal shapes and routing blockages are converted to zero-spacing routing blockages.

The default value is **auto**. The tool determines whether to preserve the metal shapes and blockages based on the design type of the cell. For library cells, diode cells, end cap cells, fill cells, filler cells, feedthrough cells, and well-tap cells, the tool preserves the metal shapes (**true**). For all other design types, the metal shapes and blockages are trimmed (**false**).

If this option setting conflicts with the setting of the **-trim_metal_blockage_around_pin** option for a layer, the **-trim_metal_blockage_around_pin** option has priority for that layer.

-trim_metal_blockage_around_pin *layer_mode_list*

Specifies how to trim metal shapes and routing blockages around pins by layer. To prevent unpredictable spacing violations during routing, make sure that you set the proper value for this option.

Specify this argument using the following syntax:

{ { *layer_name* touch|all|none } ... }

If set to **touch**, only the metal shapes and routing blockages that touch a pin are trimmed. If set to **all**, all metal shapes and routing blockages around pins are trimmed. If set to **none**, no metal shapes and routing blockages are trimmed. The trimming distance is the maximum spacing value from the technology file. The trimmed metal shapes and routing blockages are converted to zero-spacing routing blockages.

The default is null, and the behavior is controlled by the setting of the **-preserve_metal_blockage** option.

When this option is specified for a layer, its setting has priority over the **-preserve_metal_blockage** setting for that layer.

-read_fill_cells true | **false**

Controls whether to extract geometries in fill cells.

If **true**, the tool performs extraction for fill cells. If **false**, the tool ignores the geometries in fill cells.

The default is **false**.

-remove_non_pin_shapes *layer_mode_list*

Specifies the mode to remove the non-pin shapes by layer.

Specify this argument using the following syntax:

{ { *layer_name* none|all|core } ... }

- **none**
  The non-pin shapes of the given layer are not removed and which is the default behavior.
- **all**
  All non-pin shapes of the given layer are removed.
- **core**
  The non-pin shapes inside the core area of the given layer are removed. The core area is within the DRC distance from the edge of the block boundary.

This option is recommended to use with the **-block_all** or **-block_core_margin** option. The combination can create proper blocked area from the boundary and make sure that there is no missing DRC for the routing wire due to the non-pin shapes are removed.

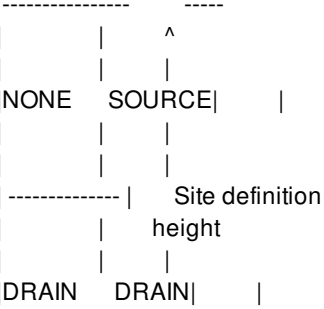
-source_drain_annotation *file_name*

Specifies the name of the input file that contains source-drain annotation information for the cell. The file identifies the type of transistor geometry (SOURCE, DRAIN, or NONE) that abuts each side (left or right) and subrow (upper or lower half of the tile height) of the cell. The tool reads this source-drain information from the file and annotates the information in the frame view. Each side of each subrow of the cell receives one annotation: SOURCE, DRAIN, or NONE; the default annotation is DRAIN. Extraction of this property requires the site definition information.

The following is an example source-drain annotation file:

```
CELL cell_name
  LEFT
    DRAIN ROW1_1
    NONE ROW1_2
  END LEFT
  RIGHT
    DRAIN ROW1_1
    SOURCE ROW1_2
  END RIGHT
END CELL
```

This example annotates a single-height standard cell as follows:



The ROW*x_y* notation means row number *x* and subrow number *y*, counting from bottom to top, starting with 1 and up to the number of rows:

ROW1_1 = row 1, lower half of row 1
ROW1_2 = row 1, upper half of row 1
ROW2_1 = row 2 (upper row of double-height cell), lower half of row 2
ROW2_2 = row 2 (upper row of double-height cell), upper half of row 2
...

DESCRIPTION

This command creates a frame view for the current block by extracting blockage, pin, and via information from the design view. The frame view of a block contains all the information needed for placement and routing. The exclusion of unnecessary data reduces the database size and routing time.

As part of the frame extraction process, the tool determines the region within each pin where the center of a via can connect. This region, called the via region for the pin, is part of the generated frame view. This information gives the router guidance about where it can make connections to a pin. As a result, the router can quickly find the via connection position. Calculating the via region during extraction saves significant runtime for router.

Obstructions in a frame view include three kinds of geometries: shape, regular routing blockage, and zero-spacing routing blockage. A shape is a non-pin geometry on the metal, cut, and device layers defined in the Layer sections of the technology file. A regular routing blockage is a routing blockage with an **is_zero_spacing** attribute of **false**. A zero-spacing routing blockage is a routing blockage with an **is_zero_spacing** attribute of **true**. The router checks all design rules defined in the technology file between the net shapes and the shapes in the frame view. The router treats a regular routing blockage as a shape to keep a safe distance from the surrounding objects. For a zero-spacing routing blockage, the router checks only that there is no overlap (zero spacing) between the blockage and the net shapes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example extracts the blockage, pin, and via information from the current block.

```
prompt> create_frame
```

The following example uses nondefault via definitions in addition to the default via definitions during via region extraction.

```
prompt> create_frame -include_nondefault_via {VIA23 VIA23A}
```

The following example generates a via region for contact codes VIA12HH and VIA12HV for port A and a via region for contact code VIA12 for port B.

```
prompt> create_frame \
  -port_contact_selections { {A {VIA12HH VIA12HV}} {B {VIA12}} }
```

SEE ALSO

create_abstract(2)

create_freeze_silicon_leq_change_list

Creates logic equivalence (LEQ) change list for engineering change order (ECO) cells. This command is typically used in the freeze silicon ECO flow.

SYNTAX

status **create_freeze_silicon_leq_change_list**
[-cells *cell_objects*]
-output *output_file_name*

Data Types

cell_objects collection
output_file_name string

ARGUMENTS

-cells cell_objects

Specifies the ECO cells for which to create LEQ change list. The given cells must meet three requirements:

- Be leaf cell.
- Have the is_fs_eco_add attribute as true.
- Have the eco_change_status attribute as one of create_cell, add_buffer, add_buffer_on_route, change_link and size_cell.

If this option isn't specified, this command will create LEQ change list for all mappable ECO cells in current design. These ECO cells meet the above mentioned requirements.

-output *output_file_name*

Specifies name of the file to write LEQ change list. If this file doesn't exist, the command will create one. If this file already exists, its contents are discarded and the file is treated as a new empty file.

DESCRIPTION

The **create_freeze_silicon_leq_change_list** command automatically searches for LEQ replacement for ECO cells. It skips same reference lib mapping. For each ECO cells, the command outputs a bunch of TCL commands to the specified file. These TCL commands either rebind ECO cell to a reference library that has instantiated spare cell, or replace ECO cell with its LEQ replacement.

The command first searches for a logic equivalence replacement for each ECO cell one by one. Spare cells in current design meets following requirements can be used to create LEQ change list:

- Its is_eco_fs_dont_use attribute hasn't been defined, or value of is_eco_fs_dont_use is false.
- Its fs_mapped_cell_name attribute hasn't been defined, or value of fs_mapped_cell_name hasn't been set.

Currently this command supports maximum of 2 gate level logic equivalence. This means if the LEQ replacement for a cell has its gate level greater than 2, the command won't create LEQ change list for the cell.

Logic equivalence has two types:

- Same function Id mapping

  If there is a spare cell having same function Id as the ECO cell, this command will reserve the spare cell for same function Id mapping.

- LEQ mapping

  If same function Id mapping fails, this command will try LEQ replacement rules on the cell, until find a LEQ replacement that can be composed of existing spare cells.

Then the command dumps LEQ change list to the output file:

- Same function Id mapping

  This command dumps **size_cell** command to the output file to rebind ECO cell to the reference library of the spare cell that has same function id as the ECO cell.

- LEQ mapping

  This command dumps **remove_cell** command to the output file first to remove ECO cell, then dump a series of **create_cell**, **create_net**, **connect_net** commands to create LEQ.

After running this command, User can check the commands in the output file and then source the file.

EXAMPLES

Suppose there is a ECO cell. Its reference library is AND2X1. Its function is AND. There is a spare cell in current design. Its reference library is AND2XL. AND2XL has same function id as AND2X1. The command will rebind the ECO cell to AND2XL.

```
prompt > create_freeze_silicon_leq_change_list -output leq.tcl
```

leq.tcl will have following content:

```
size_cell ECO_0 AND2XL -not_spare_cell_aware
```

If there is no same function Id spare cell, but there are two spare cells NAND and INV, then leq.tcl will look like:

```
remove_cell ECO_0
create_module AND2X1_leq_1
create_cell ECO_0 AND2X1_leq_1
current_instance ECO_0
create_port -direction in A
create_net A
connect_net A A
create_port -direction in B
```

```
create_net B
connect_net B B
create_port -direction out Y
create_net Y
connect_net Y Y
create_cell leq_cell_0 INVX2
create_net leq_net_1
connect_net leq_net_1 leq_cell_0/A
connect_net Y leq_cell_0/Y
create_cell leq_cell_1 NAND2X1
connect_net A leq_cell_1/A
connect_net B leq_cell_1/B
connect_net leq_net_1 leq_cell_1/Y
```

SEE ALSO

place_freeze_silicon(2)
check_freeze_silicon(2)

create_frontend_tcd_cells

Inserts front-end testkey critical dimension cells (TCDs) into the design.

SYNTAX

status **create_frontend_tcd_cells**
-lib_cells *libcells*
-window_size *{width height}*
[-tcd_spacing *distance*]
[-other_cell_spacing *distance*]
[-icovl_spacing *distance*]
[-respect_blockage none | hard_only | both]
[-density *fvalue*]
[-orientation *orient*]
[-check_only]
[-include_small_windows]
[-bbox *{{x1 y1} {x2 y2}}*]
[-snap_to_fin_grid]
[-place_at_window_center]
[-min_tcd_count *count*]
[-max_tcd_spacing *spacing*]

Data Types

libcells list of lib cells
width float
height float
distance float
fvalue float
orient orientation
x1 float
y1 float
x2 float
y2 float
count int
spacing float

ARGUMENTS

-lib_cells *libcells*

Specifies the front-end TCD library cells.

-window_size ***{width height}***

Specifies the width and height of insertion window size.

-tcd_spacing ***distance***

Specifies the minimum distance between two front-end TCD cells.

-other_cell_spacing ***distance***

Specifies the minimum distance between front-end TCD cells and cells other than front-end TCDs and ICOVL cells.

-icovl_spacing ***distance***

Specifies the spacing between front-end TCDs cells and ICOVL cells.

-respect_blockage none | **hard_only** | **both**

Specifies whether the front-end TCD cell should respect blockages. Possible values are **none**, **hard_only**, and **both** defined as follows:

- none: Ignore all blockages (Default).
- hard_only: Respect hard blockages only.
- both: Respect both hard and soft blockages.

-density ***fvalue***

Specifies the target percentage of windows that contains a front-end TCD cell.

-orientation ***orient***

Specifies the front-end TCD cell orientation. Valid values are R0, R90, R180, R270, MX, MXR90, MY, MYR90.

-check_only

Checks the current design for front-end TCD violations based on rules specified in other options. An error message is issued for each violation.

-include_small_windows

Includes small windows at the last row/column for TCD insertion. By default, these small windows are excluded.

-bbox ***{{x1 y1} {x2 y2}}***

Specifies an insertion area. This area will be divided into the specified window size for TCD insertion. By default, the die area is the insertion area.

-snap_to_fin_grid

Places the lower-left corner of the TCD cell to align with the FinFET grid. By default, alignment is not required.

-place_at_window_center

Changes the placement preference for TCD cells to be close to window center when specified to:

1. Place TCD in center of window

2. Place TCD in the channel between blocks or IPs (if blocks are not abut)

3. Place TCD at blocks or IP corner

By default, TCD cells are not placed at the center of window.

-min_tcd_count *count*

Specifies the minimum number of TCD that must be inserted by this command.

-max_tcd_spacing *spacing*

Specifies the maximum spacing between frontend TCD cells.

DESCRIPTION

This command inserts front-end testkey critical dimension cells (front-end TCDs), which are used to increase design for manufacturability (DFM) and yield.

Front-end TCDs are inserted during floorplanning stage, after macro placement and before tap cells, power switch cells, pre-inserted cells, and so on. Front-end TCDs have no metal layers and no power ports, therefore allowing routing over them.

TCD width and height are not even multiples of unit tile width and height. They are placed similar to regular macros.

A front-end TCD cell is a type of cover cell that allows overlap with other cells.

Front-end TCD cell insertion should prevent die cell area penalty by honoring the following insertion priority:

- Place at window center if -place_at_window_center option is specified
- Place TCD in the channel between blocks or IPs (if blocks are not abut)
- Place TCD in blocks or IP corner
- Place TCD in die area

EXAMPLES

The following example inserts the front-end TCD cell DM1 into windows of width 1000 microns and height 1200 microns. Spacing between DM1 cells is 10 microns. Spacing between DM1 cells and other cells is 2 microns.

```
prompt> create_frontend_tcd_cells -lib_cells {DM1} \
  -window_size {1000 1200} -tcd_spacing 10 -other_cell_spacing 2
```

create_generated_clock

Creates a generated clock object.

SYNTAX

collection **create_generated_clock**
[-name *clock_name*]
-source *master_pin*
[-divide_by *divide_factor* | -multiply_by *multiply_factor* |
-edges *edge_list*]
[-combinational]
[-duty_cycle *percent*]
[-invert]
[-preinvert]
[-edge_shift *edge_shift_list*]
[-add]
[-master_clock *clock*]
source_objects
[-comment *comment*]

Data Types

clock_name string
master_pin list
divide_factor int
multiply_factor int
edge_list list
percent float
edge_shift_list list
clock string
source_objects list
comment string

ARGUMENTS

-name *clock_name*

Specifies the name of the generated clock. If you omit this option, the clock receives the same name as the first clock source specified in the **-source** option. If you specify the **-add** option, you must use the **-name** option and the clocks with the same source must have different names.

-source *master_pin*

Specifies the master clock source (a clock source pin in the design) from which to derive the clock waveform. Note that the actual

delays (latency) for the generated clock are computed using its own source pins and not the *master_pin*.

-divide_by *divide_factor*

Specifies the frequency division factor. If the *divide_factor* value is *2*, the generated clock period is twice as long as the master clock period.

-multiply_by *multiply_factor*

Specifies the frequency multiplication factor. If the *multiply_factor* value is *3*, the generated clock period is one-third as long as the master clock period.

-edges *edge_list*

Specifies a list of integers that represents edges from the source clock that are to form the edges of the generated clock. The edges are interpreted as alternating rising and falling edges and each edge must be not less than its previous edge. The number of edges must be an odd number and not less than 3 to make one full clock cycle of the generated clock waveform. For example, *1* represents the first source edge, *2* represents the second source edge, and so on.

-combinational

The source latency paths for this type of generated clock only includes the logic where the master clock propagates. The source latency paths will not flow through sequential element clock pins, transparent latch data pins or the source pins of other generated clocks.

-duty_cycle *percent*

Specifies the duty cycle, as percentage, if frequency multiplication is used. Duty cycle is the high pulse width.

-invert

Inverts the generated clock signal in the case of frequency multiplication and division. This option first creates the gen- erated clock and then inverts the generated clock signal.

-preinvert

Creates a generated clock based on the inverted clock signal. This option first inverts the signal and then creates the gener- ated clock signal.

-edge_shift *edge_shift_list*

Specifies a list of floating point numbers that represents the amount of shift, in library time units, that the specified edges are to undergo to yield the final generated clock waveform. The number of edge shifts specified must be equal to the number of edges specified. The values can be positive or negative. positive indicates a shift later in time, negative a shift earlier. For example, *1* indicates that the corresponding edge is to be shifted by one library time unit.

-add

Specifies whether to add this clock to the existing clock or to overwrite. Use this option to capture the case where multiple generated clocks must be specified on the same source, because multiple clocks fan into the master pin. Ideally, one generated clock must be specified for each clock that fans into the master pin. If you specify this option, you must also use the **-name** and **-master_clock** options.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the tool must explore all possible combinations of launch and capture clocks. Use the **set_false_path** command to disable unwanted clock combinations.

-master_clock *clock*

Specifies the master clock to be used for this generated clock if multiple clocks fan into the master pin. If you specify this option, you must also use the **-add** option.

source_objects

Specifies a list of ports, pins or nets defined as generated clock source objects. When a net is used as the source, the first driver pin of the net is the actual source used in creating the generated clock.

-comment ***comment***

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

DESCRIPTION

Creates a generated clock object. Creates a generated clock in the current design. If successful, the command returns a collection containing the new or modified generated clock.

You can specify a pin or a port as a generated clock object. The command also specifies the clock source from which it is generated. The advantage of using this command is that whenever the master clock changes, the generated clock automatically changes.

The generated clock can be created as a frequency divided clock (by using the **-divide_by** option), frequency multiplied clock (by using the **-multiply_by** option), special divide by one (by using the **-combinational** option), or an edge-derived clock (by using the **-edges** option). The frequency-divided or frequency-multiplied clock can be inverted by using the **-invert** option. The shifting of edges of the edge-derived clock is specified by using the **-edge_shift** option. The **-edge_shift** option is used for intentional edge shifts and not for clock latency.

The number of edges specified by **-edges** to make one period of the generated clock waveform must be an odd number equal to or greater than 3. For example, in the following command:

create_generated_clock -source clk **-edges** { 1 3 5 } [get_pins flop/Q]

edge 1 indicates the first rising edge of the generated clock, edge 3 indicates the first falling edge of the generated clock, and edge 5 indicates the next rising of the generated clock. Note that the period of the generated clock is determined by the final entry in the edge list.

Non-increasing edges, such as **-edges { 1 1 3 }**, are allowed and usually used with **-edge_shift** to produce a generated clock pulse independent of the duty cycle of the master clock itself.

If a generated clock is specified with a *divide_factor* value that is a power of 2 (1, 2, 4, ...), the rising edges of the master clock are used to determine the edges of the generated clock. If the *divide_factor* value is not a power of two, the edges are scaled from the master clock edges.

Using the **create_generated_clock** command on an existing *generated_clock* object overwrites its attributes. The *generated_clock* objects are expanded to real clocks at the time of analysis.

The following commands can reference the generated_clock: **set_clock_latency**, **set_clock_uncertainty**, **set_propagated_clock**, and **set_clock_transition**.

For internally generated clocks, the tool automatically computes the clock source latency if the master clock of the generated clock has propagated latency and no user-specified value for generated clock source latency exists.

If the master clock is ideal and has source latency, and there is no user-specified value for the generated clock's source latency, then zero source latency is assumed.

To display information about generated clocks, use the **report_clocks** command.

Multicorner-Multimode Support

This command works only on the current mode.

EXAMPLES

The following example creates a frequency divide_by 2 generated clock.

```
prompt> create_generated_clock -divide_by 2 \
  -source [get_pins CLK] [get_pins u0]
```

The following example creates a frequency divide_by *3* generated_clock. If the master clock period is *30*, and master waveform is *{24 36}*, the generated clock period is *90* with waveform *{72 108}*.

```
prompt> create_generated_clock -divide_by 3 \
  -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a frequency multiply_by *2* generated_clock with a duty cycle of *60*%.

```
prompt> create_generated_clock -multiply_by 2 -duty_cycle 60 \
  -source [get_pins CLK] [get_pins u1]
```

The following example creates a frequency multiply_by *3* generated_clock with a duty cycle equal to the master clock duty cycle. If the master clock period is *30*, and master waveform is *{24 36}*, the generated clock period will be *10* with waveform *{8 12}*.

```
prompt> create_generated_clock -multiply_by 3 \
  -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a generated clock whose edges are edges *1*, *3*, and *5* of the master clock source.

```
prompt> create_generated_clock -edges {1 3 5} \
  -source [get_pins CLK] [get_pins u2]
```

The following example shows the generated clock in the previous example with each derived edge shifted by *1* time unit.

```
prompt> create_generated_clock -edges {1 3 5} -edge_shift {1 1 1} \
  -source [get_pins CLK] [get_pins u3]
```

The following example creates an inverted clock.

```
prompt> create_generated_clock -divide_by 1 -invert
```

The following example creates a rising edge pulse triggered by the rising edge of its master clock.

```
prompt> create_generated_clock -edges {1 1 3} -edge_shift {0 5 0} \
  -source [get_pins CLK] [get_pins u4]
```

The following example creates a falling edge pulse triggered by the rising edge of its master clock with a period 10.

```
prompt> create_generated_clock -edges {1 1 3} -edge_shift {0 5 0} \
  -invert -source [get_pins CLK] [get_pins u5]
```

The following example creates a frequency doubling pulse. A rising edge pulse triggered by both rising and falling edges of its master clock with a period of 10.

```
prompt> create_generated_clock -edges {1 1 2 2 3} -edge_shift {0 2.5 0 2.5 0} \
  -source [get_pins CLK] [get_pins u6]
```

create_geo_mask

Creates a geo_mask object.

SYNTAX

collection **create_geo_mask**
[-objects *object_list*]
[*pos_object_list*]
[-merge]

Data Types

object_list collection
pos_object_list collection

ARGUMENTS

-objects *object_list*

Specifies the objects to be used to define the geometric region to be covered by the geo_mask. Objects may be a heterogenous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

pos_object_list

Specifies the objects to be used to define the geometric region to be covered by the geo_mask. This positional option is provided for compatibility with other tools.

-merge

Indicates whether the resulting geo_mask should be merged. By default, the resulting geo_mask may contain distinct overlapping or adjacent regions. When this flag is set, the area in the geo_mask is simplified by removing overlapping area and merging adjacent regions.

DESCRIPTION

This command creates a new geo_mask object and returns a collection that contains the new object. geo_masks represent polygonal regions of arbitrary angularity, and can be used for geometrical computation. The region represented by a geo_mask may

not necessarily be contiguous, and may also be empty. Calling this command with no arguments will return a geo_mask representing an empty region with zero area.

EXAMPLES

The following example creates a geo_mask with a rectangular region.

```
prompt> create_geo_mask -objects [create_poly_rect -boundary {{0 0} {200 100}}]
```

The following example creates a geo_mask with a region defined by shapes on a layer, merged.

```
prompt> create_geo_mask [get_layers M1] -merge
```

create_grid

Creates a new user or block grid.

SYNTAX

collection **create_grid**
[-pg_strategy *PG_strategy*]
[-layers *layers*]
[-site_rows *rows*]
[-site_arrays *arrays*]
[-x_step *step*]
[-y_step *step*]
[-x_offset *offset*]
[-y_offset *offset*]
[-orientations *allowed_orientations*]
[-type block | user]
grid_name

Data Types

PG_strategy	string
layers	collection
rows	collection
arrays	collection
step	float
offset	float
allowed_orientations	list
grid_name	string

ARGUMENTS

-pg_strategy *PG_strategy*

Specifies the name of the PG strategy to use when creating the block grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid pitches and offsets from the PG strategy. It is mutually exclusive with any option for manual block grid.

-layers *layers*

Specifies the tech layers to consider within the PG strategy. This option is applicable only for auto-derived block grid creation. A PG strategy might involve many routing layers. By default, all the layers in the specified PG strategy are used to derive the grid. If *-layers* is specified, only the specified layers in the PG strategy are used. This option is mutually exclusive with any option for manual block grid.

-site_rows *rows*

Specifies the site rows to be considered in creating the grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid's pitches and offsets from the given site rows. The specified site rows must be uniform and of the same type of unit site def. This option is mutually exclusive with any option for manual block grid.

-site_arrays ***arrays***

Specifies the site arrays to be considered in creating the grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid's pitches and offsets from the given site arrays. This option is mutually exclusive with any option for manual block grid.

-x_step ***step***

Specifies the grid pitch in the x-direction. The default pitch is the litho grid pitch of the design. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

-y_step ***step***

Specifies the grid pitch in the y-direction. The default pitch is the litho grid pitch of the design. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

-x_offset ***offset***

Specifies the grid offset from the design origin in the x-direction. The default offset is 0. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

-y_offset ***offset***

Specifies the grid's offset from the design origin in the y-direction. The default offset is 0. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

-orientations ***allowed_orientations***

Specifies the allowed orientations for any associated block instance of the created block grid. This option is applicable only for block grid creation. Specifies one or more of: R0, MX, MY, R180. By default, all four orientations are allowed. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid. The allowed orientations of an auto-derived block grid are derived automatically from the PG strategy, layer, and site rows.

-type block | **user**

Specifies the type of grid to be created. By default a block grid is created. The **-type** option has two possible values: *block* for block grid, or *user* for user grid.

grid_name

Specifies the name of the grid to be created.

DESCRIPTION

This command creates a new grid. Two grid types are supported: block and user. The block grid can be used to tune block locations with commands such as *shape_blocks*, or by editing the layout in the GUI.

Use the **set_block_grid_references** command to associate the grid with a block reference design. Snapping the block instances to the block grid is done automatically inside the **shape_blocks** command and when editing the layout in the GUI with the snap

setting. You can also use the **snap_cells_to_block_grid** command to snap block instances to the block grid.

EXAMPLES

The following example creates an auto-derived block grid named gr1 from patterns on layers M4 and M5 of PG strategy s1.

```
prompt> create_grid -pg_strategy s1 -layers [get_layers {M4 M5}] gr1
```

The following example creates manual block grid named gr2 with pitch of 20 microns in the y-direction. All associated block instances must be placed in orientation R0, or flipped around the y-axis.

```
prompt> create_grid -y_step 20 -orientations {R0 MY} gr2
```

The following example creates a user grid named ug1 with a pitch of 10 microns in both x- and y-directions at an offset of 12 microns in the x-direction.

```
prompt> create_grid -type user -x_step 10 -y_step 10 -x_offset 12 ug1
```

SEE ALSO

create_group

Creates a group object in the current design.

SYNTAX

collection **create_group**
[-name *group_name*]
[-allow_duplicate_names]
[-type collection | set]
[-remove_when any_member_removed | empty | no_auto_removal | one_member]
[-shaping]
[*object_list*]

Data Types

group_name string
object_list list

ARGUMENTS

-name *group_name*

Specifies the name of the group. By default, the command generates a name automatically and uses the prefix GROUP_0, GROUP_1, and so on for new groups.

-allow_duplicate_names

Allows duplicate group names in the design. When a new group is created with the **-allow_duplicate_names** option, the tool allows other groups to be created with the same name.

By default, the tool ensures that group names are unique in the design. When a new group is created, the tool validates that no other group has the same name and ensures that no other group is ever assigned the same name.

-type collection | set

Sets the type of the group. By default, the type is *set*.

A member of the group can appear only one time in a *set* type. A member of the group can appear multiple times in a *collection* type group.

-remove_when any_member_removed | empty | no_auto_removal | one_member

Specifies when the group should be automatically removed from the design, based on the removal of member objects in the group.

- any_member_removed: Remove the group when any member object is removed from the group.

- empty: Remove the group when the last member from the group is removed.
- one_member: Remove the group when only one member is left in the group after removing a different member.
- no_auto_removal: Never remove the group automatically.

By default, the *no_auto_removal* argument is used.

-shaping

The -shaping argument creates the group as a shaping group. Shaping groups must be sets and may only contain shapeable objects (voltage areas, move bouds, cells, and shaping groups). This argument is mutually exclusive with -repelling.

-repelling

The -repelling argument creates the group as a repelling bound group. Repelling bound groups must be sets and remove when empty. Furthermore, they may only contain cells. This argument is mutually exclusive with -shaping.

object_list

Specifies the objects to be added to the group.

DESCRIPTION

The **create_group** command creates a group object. You can use a group object to implement a general purpose collection of design scoped supported objects. You can bundle these design scoped objects in a group and then can use as per the requirement.

Objects from the same design can be added to groups with the **add_to_group** command, and removed with the **remove_from_group** command. An object can belong to any number of groups at a time. Removing an object from a group does not remove the object from the design, however removing an object from the design automatically removes it from its containing group. Group nesting is permitted, so groups can contain other groups as member object, however cyclic relationship is not permitted between two groups so two groups cannot be member to each other.

This command returns the group as a single element collection, an empty string if it fails, or a Tcl error if there is a command syntax error.

EXAMPLES

The following example creates a group named "group1", which is automatically removed when its first member object is removed.

```
prompt> create_group -name "group1" -remove_when any_member_removed
{group1}
```

The following example creates a group named "group2" and adds the "CornUR" cell to the group.

```
prompt> create_group -name group2 [get_cells CornUR]
{group2}
```

SEE ALSO

remove_groups(2)
report_groups(2)

create_group_repeaters_guidance

Create net groups using smart net grouping algorithms.

SYNTAX

int **create_group_repeaters_guidance**
-nets *collection_of_nets*
[-group_space *site_height_multiplier*]
[-exclude_pin_ports]
[-ignore_layers]

Data Types

collection_of_nets	collection
site_height_multiplier	float

ARGUMENTS

-nets *collection_of_nets*

Sepcifies multiple nets for adding group repeaters. This option is required.

-group_space *site_height_multiplier*

Specified that repeater groups can be inserted on top of blocks. The default value is 2.0. This is optional.

-exclude_pin_ports

Driver and load pins are ignored when grouping nets. With this option, signal direction in a net group may not be the same.

-ignore_layers

Routing layers are ignored when grouping nets. With this option, nets in the same group may not route on the same layer.

DESCRIPTION

This command creates net groups based on their routing topology, signal direction, and routing layers. The net group IDs are set on net attribute *eco_net_group_id*.

EXAMPLES

The following examples show usages of command options.

prompt> **create_group_repeaters_guidance -nets nets**

prompt> **create_group_repeaters_guidance -nets -group_space 5 -exclude_pin_port**

SEE ALSO

add_group_repeaters(2)

create_hdl2upf_vct

Defines a value conversion table that can be used to convert HDL logic values into UPF net state type values. This command is supported only in UPF mode.

SYNTAX

status **create_hdl2upf_vct**
vct_name
-hdl_type {vhdl|sv [*typename*]}
-table {{*from_value to_value*}*}

Data Types

vct_name string
typename string
from_value HDL logic value
to_value UPF state type value

ARGUMENTS

vct_name

The value conversion table name.

-hdl_type {vhdl|sv *typename*}

The HDL type for which the value conversions are defined.

-table {{*from_value to_value*}*}

A list of the values of the HDL type to map to UPF state type values.

DESCRIPTION

The **create_hdl2upf_vct** command defines a value conversion table from an HDL logic type to the state type of the supply net value when that value is propagated from HDL port to a UPF supply net. It shall provide a conversion for each possible logic value that the HDL port can have. The **create_hdl2upf_vct** command does not check that the set of HDL values are complete or compatible with any HDL port type.

The *vct_name* argument provides a name for the value conversion table for later use with the **connect_supply_net** command (see 6.6).

The **-hdl_type** argument specifies the HDL type for which the value conversions are defined. This information allows a tool to provide completeness and compatibility checks. If the typename is not one of the language's predefined types or one of the types specified in the next paragraph, then it shall be of the form library.pkg.type.

The following HDL types shall be the minimum set of types supported. An implementation tool may support additional HDL types:

-) VHDL
  - Bit, std_[u]logic, Boolean
  - Subtypes of std_[u]logic
- SystemVerilog
  - reg/wire, Bit, Logic

The **-table** option defines the 1:1 conversion from HDL logic value to the UPF partially on and on/off states. The values are consistent with the HDL type values.

For example:

- When converting from SystemVerilog logic type, the legal values are 0, 1, X, and Z.
- When converting from SystemVerilog or VHDL bit, the legal values are 0 or 1.
- When converting from VHDL std_[u]logic, the legal values are U, X, 0, 1, Z, W, L, H, and -.

The conversion values have no semantic meaning in UPF. The meaning of the conversion value is relevant to the power-aware HDL model to which the supply net is connected.

SEE ALSO

create_upf2hdl_vct(2)
connect_supply_net(2)

create_icovl_cells

Inserts in-chip overlap (ICOVL) cells for layer-to-layer alignment control.

SYNTAX

status **create_icovl_cells**
-lib_cells *libcells*
[-partitions *inst_pair*]
[-xy_grid *int_pair*]
[-type backend | frontend]
[-tcd_spacing *distance*]
[-other_cell_spacing *distance*]
[-icovl_spacing *distance*]
[-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90
[-check_only]
[-bbox *{{x1 y1} {x2 y2}}*]
[-placement_blockage_extension *extension*]
[-routing_blockage_extension *extension*]
[-routing_blockage_layers *{start_layer end_layer}*]
[-over_icovl_routing_guide_extension *extension*]
[-over_icovl_routing_guide_layers *{start_layer end_layer }*]

Data Types

int_pair 2 integers
libcells list of library cells
inst_pair list of instance pairs
distance float
x1 float
y1 float
x2 float
y2 float
extension float
start_layer layer
end_layer layer

ARGUMENTS

-xy_grid *int_pair*

Divide the chip area into boxes based on specified grids. Insert one icovl cell to each grid box if possible. Either us -xy_grid or -partitions option to specify how icovl cells should be inserted

-lib_cells *libcells*

Specifies the collection of ICOVL library cells to insert as a set.

-partitions *inst_pair*

Specifies a list of integer pairs that describe how the insertion area should be divided and specify the number of ICOVL sets that should be inserted. The first number of each integer pair is the relative size of the insertion area. The second number of each pair is the number of ICOVL sets for this part. For example, the following option

-partitions {{1 1} {7 5} {2 2}}

specifies that insertion area should be vertically divided into 1+7+2=10 parts. The first partition is equal to 1 part and should contain one set of ICOVL cells. The second partition is equal to 7 parts and should contain 5 sets of ICOVL cells. The third partition is equal to 2 parts and should contain 2 sets of ICOVL cells.

-type backend | **frontend**

Specifies the type of ICOVL insertion. Valid values are *frontend* or *backend*. Use this option to indicate you are doing frontend or backend ICOVL insertion.

-tcd_spacing *distance*

Specifies the minimum distance between ICOVL and testkey critical dimension (TCD) cells.

-other_cell_spacing *distance*

Specifies the minimum distance between ICOVL cells and cells other than testkey critical dimension (TCD) and ICOVL cells.

-icovl_spacing *distance*

Specifies the spacing between ICOVL cells.

-orientation R0 | **R90** | **R180** | **R270** | **MX** | **MXR90** | **MY** | **MYR90**

Specifies the front-end ICOVL cell orientation. Valid values are R0, R90, R180, R270, MX, MXR90, MY, MYR90.

-check_only

Checks the current design for front-end ICOVL violations based on rules specified in other options. An error message is issued for each violation.

-bbox *{{x1 y1} {x2 y2}}*

Specifies an insertion area in which to insert the ICOVL cells. This area will be divided into the specified window size for ICOVL insertion. By default, the die area is the insertion area.

-placement_blockage_extension *extension*

Specifies the extension size of placement blockage for ICOVL cells in microns. The blockage will extend beyond ICOVL boundary by the size specified. When specified, the tool creates placement blockages around new ICOVL cells. Note that this placement blockage does not prevent existing cells from placement within the blockage. To keep other cells outside the placement blockage, apply a cell spacing rule that is greater or equal to placement blockage size. By default, no placement blockage extension is applied.

-routing_blockage_extension *extension*

Specifies the extension size of routing blockage for ICOVL cells in microns. The blockage will extend beyond ICOVL boundary by the specified size. Routing blockages will be created on layers specified in **-routing_blockage_layers**. You must specify the **-routing_blockage_layers** option together with the **-routing_blockage_extension** option. This option is not required.

-routing_blockage_layers *{start_layer end_layer}*

Specifies the metal routing blockage layers. Routing blockages will be created on each metal layer from *start_layer* to *end_layer*. To specify only one routing blockage layer, use the same layer name for both *start_layer* and *end_layer*, for example, **-routing_blockage_layers {M3 M3}**. This option is not required.

-over_icovl_routing_guide_extension *extension*

Specifies the size (in micron) for special over-ICOVL cell route guides to be created on ICOVL cells. Over-ICOVL routing guides are created over ICOVL cells and extend outward from an ICOVL cell edge by the specified size. This option must be used together with the **-over_icovl_routing_guide_layers** option. This option is not required.

-over_icovl_routing_guide_layers *{start_layer end_layer }*

Specifies the metal layers for special over-ICOVL cell routing guides to be created on ICOVL cells. To specify a single metal layer for the routing guide, use the same layer name for both start_layer and end_layer, for example, **-over_icovl_routing_guide_layers {M3 M3}**. This option is not required.

DESCRIPTION

This command inserts in-chip overlap (ICOVL) cells into the current design. ICOVL cells are used for layer-to-layer alignment control during fabrication to improve yield. ICOVL cells are included on one layer with different DP masks. ICOVL cells are inserted into the core area of the design. The core area is divided into partitions, where each partition can have a different size and require a different number of ICOVL cell sets. ICOVL cells are macros and are not allowed to overlap any other cells.

This command is used for both frontend and backend ICOVL cell insertion. Frontend ICOVL cells are inserted during the floorplanning stage, after macro and frontend TCD cell placement. Backend ICOVL cells are inserted after power planning.

EXAMPLES

The following command inserts frontend ICOVL cell sets. Each ICOVL sets has 3 ICOVL cells: icovl_m1, icovl_m2, and icovl_m3. The core area is divided into 4 partitions in the y-direction. From bottom to top, the first partition equals 10 percent of the core area and needs 1 ICOVL sets. The 2nd partition equals 30 percent and needs 2 ICOVL sets. The 3rd partition is 20 percent and needs 2 ICOVL sets, and 4th partition is 40 percent and needs 3 ICOVL sets. Routing blockages will be created on metal layers from metal1 through metal6. ICOVL cells will be placed in R0 orientation.

```
prompt> create_icovl_cells -lib_cells {icovl_m1 icovl_m2 icovl_m3} \
  -partitions { {1 1} {3 2} {2 2} {4 3}} \
  -placement_blockage_extension 20.0 \
  -routing_blockage_extension 3.0 \
  -routing_blockage_layers { metal1 metal6} \
  -icovl_spacing 10.0 \
  -tcd_spacing 5.0 \
  -other_cell_spacing 5.0 \
  -orientation R0 \
  -type frontend
```

Below example will divide chip area into 4 x 5 grids and insert one icovl cell into each grid if possible.

```
prompt> create_icovl_cells \
-lib_cells ICOVL_CELL  \
-tcd_spacing 90 \
-xy_grid { 4 5}
```

create_backend_tcd_cells(2)
create_frontend_tcd_cells(2)

create_interior_tap_walls

Creates a tap wall inside a boundary edge of a core area, hard macro, soft macro, hard placement blockage, or nondefault voltage area. The boundary typically already contains boundary cells.

SYNTAX

status **create_interior_tap_walls**
-lib_cell *cell_name*
-side top | bottom | left | right
[-x_spacing *spacing*]
[-bbox *coordinates*
[-prefix *cell_prefix*]
[-orientation R0 | R180 | MX | MY]

Data Types

cell_name string
spacing float
coordinates list
cell_prefix string

ARGUMENTS

-lib_cell *cell_name*

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

-side top | bottom | left | right

Specifies the side on which to create a tap wall. You must specify a single side. This is a required option.

-x_spacing *spacing*

Specifies the spacing between tap cells in microns for horizontal tap walls. This option is ignored for vertical tap walls.

If the specified value is not an integer multiple of the site width, the tool rounds it down to a multiple of the site width. If the value is less than the width of the tap cell, the tool uses zero spacing.

The default is 0, and there is no space between the tap cells.

-bbox *coordinates*

Specifies the rectangular tap insertion region in microns. Specify the rectangle as a list of four coordinates, {{llx lly} {urx ury}}, which represents the lower-left and upper-right corners of the rectangle.

A tap wall is created along the longest edge of the core boundary, macro, hard placement blockage, or nondefault voltage area

encompassed by the rectangular region. The command issues an error message if it cannot find an edge.

If you do not specify this option, the command creates an interior tap wall along each edge of the specified side.

-prefix ***cell_prefix***

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

*<cell_prefix>__<lib_cell>*_R#_C#_*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

tapfiller__*<lib_cell>*_R#_C#_*number*

-orientation R0 | **R180** | **MX** | **MY**

Specifies the orientation of the placement of the tap cells.

By default, the orientation follows the orientation of the row or site.

DESCRIPTION

This command adds an interior tap wall to the design. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cells in the library do not contain substrate or well taps.

Interior tap wall placement follows the usual rules of standard cell placement and snaps the tap cells to rows and sites. The command does not insert tap cells if the rows or sites are missing.

If you specify the **-bbox** option, the command creates a single tap wall along the longest edge segment. If the edge segment does not contain a corner, the tap wall aligns to the left or bottom of the tap insertion region. If the edge segment contains one corner, the tap wall aligns to the corner. If the edge segment contains two corners, the tap wall aligns to the left or bottom of the tap insertion region. When the edge segment contains two corners for a horizontal wall, the gap between the last cells the might be shortened.

Obstructions such as placement blockages, fixed cells, and macros might prevent successful placement of the tap cells, resulting in incomplete or missing tap walls.

The command marks the inserted tap cells as fixed.

EXAMPLES

The following example creates tap walls along the inside of all edges on the top side of the core area.

prompt> **create_interior_tap_walls -lib_cell myLib/Cell1 -side top**

create_interposer_routeplan

Places vias and routes for an interposer design.

SYNTAX

string **create_interposer_routeplan**
[-interposer_style default | fpga | single_hbm | vertical_routing]
[-pattern_file *filename*]

Data Types

filename string

ARGUMENTS

-interposer_style default | fpga | single_hbm | vertical_routing

Specifies the style of the design. Based on the selection, the tool will process different types of pattern files and perform different actions. If this option is not specified, the **default** style is used.

-pattern_file *filename*

Specifies a pattern file that contains information on how to place interposer vias and routes. The keywords supported in the pattern file depend on the **-interposer_style** option specified.

The pattern file contains one or more sections, where each section starts with a keyword followed by a pair of curly brackets. Inside the curly brackets, one or more constraints is specified. Each constraint is made of a pair of curly brackets which contains the information of the element. Comment lines begin with the pound sign (#) and inline comments begin with two forward slashes (//).

If the **default** style is chosen, the following sections and elements are supported:

The configuration section is specified by the *config* keyword and contains a **stack_level** specification and a **via_def** specification. The **stack_level** keyword is followed by a positive integer, where zero specifies that simple vias will be inserted and a positive integer specifies an additional number of stacked via levels. For example, {stack_level 1} specifies that the tool places the basic via and one additional level.

The **via_def** keyword is followed by a non-negative integer and a string. The integer represents the via level in the via stack and the string specifies the via reference, where the specified via reference is used to create new vias. If the integer following the via_def keyword conflicts with the level specified by stack_level, it will be ignored and the tool will issue a warning message. An example configuration section is given below which specifies a stacked via.

```
config {
  {stack_level 2}
  {via_def 0 via7}
  {via_def 1 via6}
```

```
  {via_def 2 via5}
}
```

In the config section, user can describe via arrays. Specifically, the orientation keyword specifies the orientation of the via w.r.t the via_def. It is followed by a string $ORIENTATION describing the orientation. The $bump_instance_name is optional. If it is used, the via configuration is only for the bump cell instance specified. Otherwise, it is the default and will be used for all bumps without individual via configuration information. The columns and rows keyword define the dimension of the via array. They are followed by positive integers. Similarly, they can have the optional $bump_instance_name.

```
config {
{orientation $ORIENTATION  [$bump_instance_name]}
{columns $positive_integer [$bump_instance_name]}
{rows $positive_integer [$bump_instance_name]}
}
```

It is important to note that, if a bump already has a via placed, which has a different configuration as that described by the pattern file, the existing via will not be changed. It is user's responsibility to remove the existing via before running the command with correct via configuration information in the pattern file.

The design rule section, specified with the *drc* keyword, contains spacing rules for via insertion and placement. This section contains the **bump**, **peer**, **layer**, **via_def_name**, and **via_def_index** specifications. The **bump** keyword is followed by a floating point number that specifies the minimum distance between the base via and any bump in microns. The **peer** keyword is followed by a floating point number and specifies the minimum distance between the base vias. The **layer** keyword is followed by a layer name string and a floating point number, and specifies the minimum distance between the base via and a preroute on the specified layer. Only the top and bottom layers of the base via are relevant, all other layers are ignored. The **via_def_name** keyword is followed by a string and a floating point number, and specifies the minimum distance between the base via and the specified type of via. If the specified via def is the base via, this element provides the same functionality as that of the second type element. Otherwise, since the via on any lower metal level is inside the base via, the distance is measured between the edges of the vias inside of the base via. The **via_def_index** keyword is followed by non-negative integer and a floating point number, provides similar functionality to **via_def_name**, but specifies the via by using a level index instead of a via_def name. The base via is on level 0, lower level vias beneath the base via will have indexes of positive values. An example of the design rule section is given below.

```
drc {
  {bump 0.1}
  {peer 0.1}
  {layer AP 0.1}
  {via_def_name VIA34 0.2}
  {via_def_index 1 0.2}
}
```

The via count section, specified with the *count* keyword, contains the rule for the number of vias or stacked vias to add to the interposer. The *bump* keyword specifies that a base via might be added for each front-side bump of a net. The *flat_net* keyword specifies that at most a single base via can be added for the entire flat net. If any part of the flat net has been routed on the layer of the bump, the via location will be selected on a preroute. Otherwise, a bump will be selected for via insertion. The third possible keyword is *bump_share*. If this mode is selected, tool will try to insert an interposer via for each bump of the net. If at least one bump is added for the net, no error message will be issued. Namely, bumps can share an interposer via. If no via can be inserted, an error message will be issued. Note that the vias do not include existing ones. If there are interposer vias already in the design for all bumps of the net, no error message will be issued. If this section is not given, the default value is *bump*. An example of the via count section is shown below.

```
count {
  flat_net
}
```

The exclusion section, specified with the *exclusion* keyword, specifies that specific bump cells, nets, or reference cells should be ignored. The *bump* keyword is followed by a bump instance string. The specified bump cell instance is ignored. The *net* keyword is followed by a flat net string. The specified net is ignored. The *reference_cell* keyword is followed by a reference cell string. All

bump instances of the specified reference cell are ignored for via insertion. By default, the tool processes the entire interposer design. An example of the exclusion section is given below.

```
exclusion {
 {bump BUMP_1}
 {net NET}
 {reference_cell REF_BUMP}
}
```

The inclusion section, specified with the *inclusion* keyword, specifies the part of netlist which the tool will process. Its format is identical to the exclusion section. All three keywords reference_cell, bump, net can be used. The inclusion and exclusion sections are mutually exclusive. An example of the inclusion section is given below.

```
inclusion {
 {bump BUMP_1}
 {net NET}
 {reference_cell REF_BUMP}
}
```

The location section, specified with the *location* keyword, contains location constraints for the new vias. This section contains the **x**, **y**, or **xy** keywords, specifying a horizontal coordinate, a vertical coordinate, both coordinates. The keyword is followed by the **relative** or **absolute** keyword. The **relative** keyword specifies values with respect to the center of the corresponding bump boundary box. The **absolute** keyword specifies values with respect to the interposer origin. The next field specifies one or two float values for the horizontal, vertical, or both coordinates. The optional last field specifies the bump instance name to use when applying the constraint. If there is no bump name, the constraint is applied to all bumps. An example of the location section is given below.

```
location {
 {x  relative 4      BUMP_1}
 {y  absolute 400    BUMP_2}
 {xy relative 2   2  BUMP_3}
}
```

It is important to note that if you specify both horizontal and vertical coordinates for a bump, the tool places a via at the specified location as long as there is not a via already at the exact same location. Therefore, if you run the tool multiple times with different horizontal and vertical coordinates, many vias will be placed for the same bump. It is your responsibility to remove any redundant vias.

The exception section specified with the *exception* keyword, contains many special constraints. If the *default* design style is chosen, user can use **45degree** make the tool place a via close to a corner of the corresponding bump boundary box. Note that this feature is only applied when the bump is at a corner of the correspond net bounding box. Vias placed on nets will not be affected. Using this option will reduce the overall wirelength of the interposer routing.

```
exception {
 {45degree}
}
```

If the *default* design style is chosen, the tool only places interposer vias within the bounding box of the corresponding net. No vias can be placed if there is no enough area for a single via inside the bounding box. User can use **box_enlarge_value** in the exception section specified with the *exception* keyword in the pattern file to increase the area where interposer vias can be placed. Specifically, both dimension of the net bounding box is increased by the amount specified by *box_enlarge_value*. User can use **box_dimension_threshold** in addition to **box_enlarge_value**. If **box_dimension_threshold** is used, only any net bounding box whose dimension is less than the value specified will be increased. The following example enlarges all net bounding box areas whose dimension is less than 10 micron by 0.5 micron.

```
exception {
 {box_dimension_threshold 10}
 {box_enlarge_value 0.5}
}
```

The tool is able to report net routing order by generating text files containing sets of net names. User needs to use the keyword **hbm_report_shielding_groups** followed by net patterns. Only two patterns are supported as shown below. Nets routed in different layers will be grouped in separate files. The filenames are upper_$index and lower_$index, corresponding to the two routing metal layers.

{hbm_report_shielding_groups interleave_4} {hbm_report_shielding_groups interleave_2}

If the **single_hbm** style is chosen, the following elements are supported. They are all inside the exception section. The keyword hbm_channel_direction describes the channel orientation.

{hbm_channel_direction vertical | horizontal}

The routing width and spacing in the bump array region of the HBM channel are specified by the keyword hbm_wire_width and hbm_wire_spacing, respectively. The routing width and spacing in the middle section of the channel are the same unless they are changed by constraints of other keywords. The values following the keywords must be positive. User is responsible for the correctness of the values.

{hbm_wire_width $micron} {hbm_wire_spacing $micron}

The keyword **hbm_via_bump_abutment** is a boolean constraint that determines the routing style produced by the tool. When it is set to true, all vias that connect the top RDL layer to any lower metal layer are placed with bump abutment. As a result, there is no need for RDL routing between vias and bumps. When **hbm_via_bump_abutment** is true, the Manhattan double-Z style is chosen for the routing in the middle section of the HBM channel. The following keywords are used to specifies the route widths and lengths for the middle section routing. Particularly, the middle segment length is described by keyword hbm_midtrack_lengths. The routing width and spacing for the two routing segments perpendicular to the channel orientation are described by keyword hbm_midtrack_turn_width and hbm_midtrack_turn_spacing, respectively. The routing width and spacing for the middle section routing are described by keyword hbm_midtrack_width and hbm_midtrack_spacing, respectively.

{hbm_midtrack_lengths $micron} {hbm_midtrack_turn_spacing $micron} {hbm_midtrack_turn_width $micron} {hbm_midtrack_spacing $micron} {hbm_midtrack_width $micron}

If keyword **hbm_via_bump_abutment** is false, the tool may not place vias with bump abutment. The vias are aligned to the corresponding routing. The gap between the via and bump bounding box is specified by the keyword hbm_rdl_via_offset. The vias are always placed above or on the right side of the corresponding bumps, for vertical and horizontal channels, respectively. When keyword **hbm_via_bump_abutment** is false, the 45-degree Z-style is chosen for the routing in the middle section of the HBM channel. The keyword hbm_middle_turn_offset specifies the length of top or right segment routing, for vertical and horizontal channels, respectively.

{hbm_rdl_via_offset $micron} {hbm_middle_turn_offset $micron}

The column or row of the HBM channel can be identified in two ways. First, user can specify two bounding boxes, at the two ends of the channel. Bumps inside of the two boxes are routed as part of the channel. The keyword for channel bounding boxes is hbm_bump_array_box, followed by the corner coordinates of the two boxes. If users want to exclude any bumps inside either box, keyword hbm_excluded_bump_in_box must be use for each of the excluded bumps.

{hbm_bump_array_box {llx_box1 lly_box1} {urx_box1 ury_box1} {llx_box2 lly_box2} {urx_box2 ury_box2}} {hbm_excluded_bump_in_box $bump_name}

The second way to describe a channel is to use the inclusion section to specify all the nets that connect two bumps. User also needs to describes any addition bumps in the channel that are not connected to any nets using the keyword hbm_float_bump. Furthermore, if any bump of the channel are connected to components other than front-side micro-bumps, the corresponding net needs to be described using the keyword hbm_2pin_through_net. Both hbm_float_bump and hbm_2pin_through_net are in the exception section.

{hbm_float_bump $bump_name} {hbm_2pin_through_net $net_name}

Two metal layers must be specified for HBM routing. The keywords are hbm_right_array_routing_layer, hbm_left_array_routing_layer, hbm_upper_array_routing_layer and hbm_lower_array_routing_layer. The keywords are followed by the corresponding layer names. The bump arrays at the two ends of the channel are divided into two regions. The bumps in the top or right region are routed using the layer specified with hbm_upper_array_routing_layer or

hbm_right_array_routing_layer. The other bumps in the bottom or left region are routed using the layer specified with hbm_lower_array_routing_layer or hbm_left_array_routing_layer.

{hbm_lower_array_routing_layer $layer_name} {hbm_upper_array_routing_layer $layer_name} {hbm_left_array_routing_layer $layer_name} {hbm_right_array_routing_layer $layer_name}

The routes created by the tool are called stubs. They are used in conjunction with a guidance file during the subsequent RDL routing step. There are two kinds of stubs. The boundary stubs are placed at the boundaries between the bump array regions and the middle routing region of the channel. The routing stubs are inside of the bump array region. The length of stubs can be specified by the keyword hbm_boundary_stublength and hbm_routing_stublength, respectively. The locations of the boundary stubs can be controlled by the keyword hbm_boundary_stub_corners. Specifically, if user choose the keyword auto_align after hbm_boundary_stub_corners, the boundary stub bounding box will be align to the corresponding bump array box. The offsets along the channel direction for the upper and lower end of the channel, high_offset and low_offset, can be given optionally. If not given, the offset values are derived by the tool based on bump dimension and wire routing pitch. Alternatively, user can specify the exact locations for the stubs. The location can be described using the absolute coordinates or the relative offset values with respect to the bump array box as follows.

{hbm_boundary_stub_corners auto_align [high_offset low_offset]} {hbm_boundary_stub_corners absolute | relative x_high y_high x_low y_low}

The boundary stubs are placed on two routing layers. The stubs on the two layers can overlap or be placed in an interleaved pattern. The keyword that controls the stub pattern is hbm_stub_alignment_type. User can choose three pattern as given below. The stub on the lower metal layer is used as the reference.

{hbm_stub_alignment_type inline | staggered_before | staggered_after}

When the keyword **hbm_via_bump_abutment** is false, the locations of boundary stubs can be set to any desired values although the same patterns must be used for both routing layers. Specifically, the gaps between pairs of adjacent boundary stubs are set using keyword hbm_boundary_stub_gaps followed by a list of values in microns. User must specify at least 23 values. Values more than 23 are ignored.

{hbm_boundary_stub_gaps gap_1 gap_2 ... gap_23}

If a repeating pattern exist, the following concise format can be used, in which the repeating pattern is specified in a pair of curly brackets, with the repeating number before.

{hbm_boundary_stub_gaps repeat_times {gap_1 gap_2 ... } }

Although the boundary stubs of high metal layer must be the same as that of the lower metal, the stub locations can be shifted by an offset w.r.t those of the lower metal layer. The offset of is given as below using keyword hbm_boundary_stub_staggered_offset. The value is perpendicular to the channel direction. It can be either positive or negative.

{hbm_boundary_stub_staggered_offset $value}

The keyword **hbm_bump_index_pair** is used in combination with keyword **hbm_boundary_stub_gaps**. User uses **hbm_bump_index_pair** to specify which two nets will be routed next to each other. The format is given below.

```
{hbm_bump_index_pair
{{rowIndex_0_0 column_index_0_0} {rowIndex_0_1 columnIndex_0_1}}
{{rowIndex_1_0 column_index_1_0} {rowIndex_1_1 columnIndex_1_1}}
...
{{rowIndex_N_0 column_index_N_0} {rowIndex_N_1 columnIndex_N_1}}
}
```

The orientation of bump rows is defined as the orientation perpendicular to the channel orientation. The first row and the first column are with the least coordinate value. If the bump is missing at the location specified by the row and column indexes, the bump pair is ignored. If the bump at the location specified by the row and column indexes is not connected to any net, the bump pair is also ignored.

When the keyword **hbm_via_bump_abutment** is true, the Manhattan double-Z style is chosen for the routing in the middle

section of the HBM channel. User can add shielding to the the middle section routing by adding the following in the pattern file.

{hbm_mid_shielding $NET_NAME}

The shielding will have the same width as the corresponding signal routes. The shielding wires are logically assigned to the net $NET_NAME. It is the user's responsibility to keep the routing width less than the routing spacing so that that routing result is valid. In an HBM routing procedure, two layers of metal are used for signal routing. The metal layer beneath either layer is potentially used for the shielding. If the shielding metal cannot be derived, the tool will error out. If both signal routing layers are used, both shielding layers are used. In case that only one signal routing layer is occupied, due to missing nets, only the shielding layer between the two signal routing layers is used for shielding. The shielding routes are not placed above nor below the signal routes. Instead the shielding routes are aligned to the gaps between the signal routes. In this routing style, the signal routings are evenly spaced. Therefore, a shielding route can potential be shared by the signal routes on both sides.

If a channel contains less than 48 nets, the channel is called incomplete channel. An incomplete channel has the same number of bumps but a smaller number of nets. In case that the number of nets is very small, user can force the routing to occur in portions of the bump array regions using the keyword as hbm_boundary_stub_range follows.

{hbm_boundary_stub_range $range_low_upper $range_high_upper $range_low_lower $range_high_lower}

The values are in microns. The pair ($range_low_upper $range_high_upper) and ($range_low_lower $range_high_lower) define corridors in the upper and lower bump array regions, respectively where routing shapes are placed. Since the range is reduced, user must ensure the range is wide enough for all existing nets. When **hbm_boundary_stub_range** and **hbm_via_bump_abutment** are used together, the tool performs a more agressive routing style to ensure routeability than the case without **hbm_boundary_stub_range**. Vias can be abutted to any edge of bumps.

A stub is placed along the routing track, connecting to corresponding bump access via if the following is specified in the pattern file. The stubs are only on the high metal layer.

{hbm_bump_access_dir true}

The length of the stubs can be controlled by the following keyword hbm_bump_access_length. The default value is half routing width plus routing spacing.

{hbm_bump_access_length $DISTANCE}

The tool created two routing guide files for the subsequent RDL routing step. User can provide a prefix for the file names using the keyword route_guidance_file. The actual file names are created by combining the prefix with the corresponding metal layer names. The default prefix is hbm_p2p.txt.

{route_guidance_file $prefix}

User can use the keyword **hbm_stacked_via_dimension** to specify the configuration of any low-level vias placed beneath the interposer vias connected to bump. This keyword is used in the **exception** as follows.

{hbm_stacked_via_dimension $x_size $y_size}

All low-level vias share the same configuration. The default values are 2x2 when **hbm_via_bump_abutment** is false. When the keyword **hbm_via_bump_abutment** is true, the default values are 2x6 and 6x2 for vertical channels and horizontal channels, respectively.

A new keyword **hbm_middle_layer_switch** is introduced in the **exception** section in the **single_hbm** style. When it is used, a special routing pattern is used for the HBM channel routing. Specifically, two metal layers are used to route each net between corresponding bump-access vias. This routing style is only applicable when **hbm_via_bump_abutment** is false. The location of switching is in the middle of two bumps but not overlaps with any routing direction switch in the middle of the HBM channel.

During HBM routing, a detour is used to route around a via. The default detour spacing is **pitch-via_dimension/2-wire_width/2**. A keyword **hbm_detour_spacing** is added so that users can use it in the **exception** section to specify the exact value of detour spacing, namely the distance between the via and detour route. All routing detours share the same value. Users are responsible for the correctness of the value.

{hbm_detour_spacing $micron}

For **single_hbm** routing style, the two bumps of the same net should be at the same relative position in their corresponding bump arrays. In practice, bump assignment mismatch could occur. By default, the tool will error out after detecting bump assignment mismatch and ask users to change bump-net assignment. However, if the assignment cannot be changed, user can use keyword **hbm_stub_order_fix** in the **exception** section to force the tool to proceed. The tool will try to route with a high tolerant to wirelength mismatch. The tool will error out if no solution can be derived.

If the **vertical_routing** style is chosen, the keyword **vertical_route** can be used in the **exception** section to describe how the route mesh will be created. An example is given below. The first string following the keyword describes the metal layer. It is followed by the width and spacing of the routes to be created on that layer. The default width and spacing is the dimension of a single-size via beneath the layer. The last integer is optional. It specifies how many tracks to be created. If the track count is not provided, tracks will be added to cover the entire C4. The dimension of vias between routes are derived based on the track widths.

{vertical_route $layer_name $micron $micron $integer}

DESCRIPTION

This command places vias and routes for an interposer based on the netlist. It has four modes of operation depending on the style of interposer: default, single_hbm, vertical_routing and fpga. In the default mode, the command will only insert vias. In the single_hbm or vertical_routing or fpga mode, both vias and routes can be added. You can provide a pattern file which contains constraints for via and route insertion. The vias inserted by this command can be a single via (base via) or via array which connects a front side bump on the redistribution layer to a metal layer below. Any other vias that are stacked below the base via can also be created based on the specification in the pattern file. Any blockages and preroutes on metal layers related to new vias are considered so that no design-rule violations will occur. If any bumps or nets already have vias placed, no redundant vias will be added. After vias are added, you can use any router to complete the routing of the interposer.

The single_hbm mode is for a single column or row of a high-bandwidth memory (HBM) channel. The tool creates vias and routes according to constraints in the pattern file. It also creates routing guidance files which are used by the subsequent RDL routing command to complete the routing. Many keywords for HBM channel route planning are used in the exception section of the pattern file. They are not applicable to other modes.

The vertical_routing mode is for the connection between a C4 bump and one or two micro-bumps. Given a high-speed net with a C4 bump and one or two micro-bumps, the tool will add vias and routing shapes to connect the C4 to the micro-bump or micro-bumps. Specifically, a RV via is added for each micro-bump. The via is abutted to its micro-bump. The top layer of the via is the layer of micro-bumps. If there is a single micro-bump, the default location of the via is along the top edge of the micro-bump. The via is entirely inside the C4 bump. If the default location of via is not inside the C4 bump, the via will be placed along the bottom edge. If the via cannot be placed inside the C4 bump, the tool will error out. If there are two micro-bumps, the default location is along the top or right edge, when the two micro-bumps are aligned horizontally or vertically, respectively. A single route on the bottom layer of the via is added. If there is a single micro-bump on the net, the route will be horizontal. Otherwise, the orientation of the route is the same as the alignment of the two micro-bumps. On the layers between the top routing layer and layer of C4 bump pins, routing tracks are created to form connection mesh. Specifically, the routings on the layer just below the top routing layer are perpendicular to the routing on the top routing layer. The routing orientation then switches between horizontal and vertical in a round-robin manner in the following layers below until reaching the layer of the C4 pins.

EXAMPLES

The following example places vias by using the default style.

prompt> **create_interposer_routeplan**

SEE ALSO

route_3d_rdl(2)
route_auto(2)
route_eco(2)

create_io_break_cells

Inserts I/O break cells into the floorplan.

SYNTAX

status **create_io_break_cells**
[-reference_cells *lib_cell_name_list*]
[-cells *cell_name_list*]
[-location start | end | both | *offset* | *cell*]
io_guide_list

Data Types

lib_cell_name_list string
cell_name_list string
offset float
cell string
io_guide_list list

ARGUMENTS

-reference_cells *lib_cell_name_list*

Specifies the library cell names of the break cells. For each name in the list, the command inserts a new cell instance with the name __added_break_cell_index, where index is an integer. All new cells are placed consecutively with no gap in between.

-cells *cell_name_list*

Specifies the instance names of the break cells. All cell instances must already exist in the design. Only cell instance names are supported, collections are not supported.

-location start | end | both | *offset* | *cell*

Specifies the location of the break cells to insert with respect to the corresponding I/O guide. You can specify only one guide when using this option.

When the keyword *start* or *end* is specified, the break cells are placed right before or after the I/O guide, respectively. You can also place the break cells at both ends of the I/O guide. If you specify **-location both**, only the **-reference_cells** option can be used.

The *offset* specifies the distance from the starting point of the I/O guide. When a *cell* is specified, the break cells are placed next to the specified cell, away from the guide starting point. If this cell is not placed in the guide, projection is used to determine the break cell location. That is, the cell is projected along its orientation direction toward the I/O guide. The crosspoint will be the location. Note that the cell must be in the correct orientation with respect to the I/O guide. Otherwise, no break cell are inserted.

io_guide_list

Specifies the list of I/O guides. This option is required.

DESCRIPTION

This command places one or more break cells at the intersection of two I/O guides or a specified location in one I/O guide. When one guide is given, the break cell location is determined by the **-location** option.

When two I/O guide names are given, the break cell location is derived from the two guides. If the two I/O guides are perpendicular, the location is the crossing point of the two I/O guides. If the two I/O guides are in parallel, they must have the same orientation. In addition, the extended lines of the two guides must overlap. There must be a gap between the two I/O guides. Otherwise, the command will error out. The break cell location always starts from the gap endpoint of the first I/O guide and extends toward the second I/O guide.

The orientations of the break cells are determined by the first I/O guide and the orientations of their reference cells. Specifically, if the first I/O guide has side set to bottom, the break cell orientations are the same as those of the reference cells. Namely, the break cell instances will be in R0 orientation. If the first guide is with different side values, the break cells will be rotated in the same way as that of IO guide with respect to a bottom guide. User can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, break cell orientations will be changed accordingly.

If the break cells are already in the netlist, use the **-cells** option. Otherwise, use the **-reference_cells** option. You can specify only one of the *-cells* and **-reference_cells** options.

EXAMPLES

The following example inserts a break cell with the instance name "break_left" between the io guides io_guide_left and io_guide_top.

```
prompt> create_io_break_cells -cells break_left {io_guide_left io_guide_top}
```

The following example inserts a break cell with the reference name "LEFT_BREAK".

```
prompt> create_io_break_cells -reference_cells LEFT_BREAK {io_guide_left io_guide_top}
```

The following example inserts a break cell with the reference name "LEFT_BREAK" after a pad cell instance named "PAD".

```
prompt> create_io_break_cells -reference_cells LEFT_BREAK -location PAD io_guide_left
```

SEE ALSO

create_io_filler_cells(2)
place_io(2)

create_io_corner_cell

Inserts an I/O corner cell into the floorplan.

SYNTAX

status **create_io_corner_cell**
[-reference_cell *lib_cell_name*]
[-cell *cell_name*]
[-force *block_pathname*]
io_guide_list

Data Types

lib_cell_name string
cell_name string
io_guide_list list
block_pathname string

ARGUMENTS

-reference_cell *lib_cell_name*

Specifies the library cell name of the corner cell. Only one name can be given. The command inserts a new cell instance with the name __added_corner_cell_*index*, where *index* is an integer. This option is mutually exclusive with the **-cell** option.

-cell *cell_name*

Specifies the instance name of the corner cell to be placed. Only one instance name can be given. This option is mutually exclusive with the **-reference_cell** option.

io_guide_list

Specifies the name of the two I/O guide names between which to place the corner cell. This option is required. The two guides must be perpendicular to each other.

-force *block_pathname*

Specifies the parent cell of the newly created corner cell. This option only takes effect if the newly created corner cell using -reference_cell overlaps with multiple hierarchical blocks. The bounding box of the new cell must overlap with the specified block path name.

DESCRIPTION

This command places a corner cell at the intersection of two I/O guides. The two I/O guides must be perpendicular. The location is the crossing point of the two I/O guides.

The orientation of the corner cell is determined by the first I/O guide and the orientation of its reference cell. Specifically, if the first guide is an IO guide with side set to bottom, the corner cell's orientation is the same as that of the reference cell. If first guide is with different side values, the corner cell be rotated in the same way as that of IO guide with respect to a bottom guide. User can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, corner cell orientation will be changed accordingly. For example, if users set the reference_orientation to R270, the corner cell will be in R0 orientation when the first guide has its side set to left.

If the corner cell is already in the netlist, use the **-cell** option. Otherwise, use the **-reference_cell** option. You can specify only one of the *-cell* and **-reference_cell** options.

EXAMPLES

The following example inserts a corner cell with the instance name "lt_corner" between the I/O guides io_guide_left and io_guide_top.

```
prompt> create_io_corner_cell -cell lt_corner {io_guide_left io_guide_top}
```

"SEE ALSO"

create_io_filler_cells(2)
place_io(2)

create_io_filler_cells

Inserts I/O filler cells into the specified I/O guides.

SYNTAX

status **create_io_filler_cells**
[-io_guides *io_guide_list*]
[-reference_cells *cell_list*]
[-overlap_cells *cell_list*]
[-extension_bbox *bounding_box*]
[-prefix *prefixString*]
[-top]
[-block *list_of_block_path_names*]
[-force *block_path_name*]
[-auto_tie_to_pg]

Data Types

io_guide_list collection
cell_list collection
bounding_box list
prefixString string
list_of_block_path_names string
block_path_name string

ARGUMENTS

-io_guides *io_guide_list*

Specifies the names or collection of the target I/O guides. If this option is not used and the **-top** and **-block** options are not used, all I/O guides which are logically on top are selected.

-reference_cells *cell_list*

Specifies the lib cell names of the filler cells. These filler cells cannot overlap regular signal or power pad drivers. The reference cells must have difference widths. If there are two filler cells with the same width, only one is used.

-overlap_cells *cell_list*

Specifies the lib cell names of the filler cells that can overlap with regular signal or power pad drivers. The reference cells must have difference widths. If there are two filler cells with the same width, only one is used.

-extension_bbox *bounding_box*

Specifies the bounding box in which filler cells are placed. The filler cells can only be placed in the specified guides and the

bounding box.

-prefix *prefixString*

Specifies the added filler cell name prefix with *prefixString*. If this option is not specified, the command will use the default prefix string __added_filler_instance.

-top

Specifies the tool to select all I/O guides which are logically on top.

-block *list_of_block_path_names*

Specifies the tool to select I/O guides from the mentioned block path names.

-force *block_path_name*

Specifies the parent cell of the newly created filler cell. This option only takes effect if the newly created filler cell overlaps with multiple hierarchical blocks. The bounding box of the new cell must overlap with the specified block path name.

-auto_tie_to_pg

Specifies the tool to connect newly inserted filler cells to logical nets based on physical abutment.

DESCRIPTION

This command inserts filler cells into I/O guides. New filler cells are named __added_filler_instance_*index*, where *index* is a positive integer.

The orientation of a filler cell is determined by the orientation of its reference cell and the I/O guide which the filler cell is placed in. Specifically, if the filler cell is placed in an I/O guide with side set to bottom, its orientation is the same as that of the reference cell. If the filler cell is placed in I/O guides with different side values, the filler cell will be rotated in the same way as that of I/O guide with respect to a bottom guide. You can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, the filler cell orientations will be changed accordingly. For example, if you set the reference_orientation to MY, a filler cell placed in a bottom guide will be flipped on the y-axis.

In case, the user specifies the -auto_tie_to_pg option all the terminals of all pins of the newly inserted filler cells for a gap are collected as well as the terminals of the prexisting cells in that gap. The net connection is made for the newly inserted filler cells based on physical contact between the pins. A transitive connection relationship is applied to establish the net connection. The nets are only connected to the filler pins if no errors are reported during filler placement.

The **-block** and **-top** options are mutually exclusive with the **-io_guides** option.

EXAMPLES

The following example inserts filler cell "FILLER" into all I/O guides.

prompt> **create_io_filler_cells -reference_cells FILLER**

SEE ALSO

create_io_break_cells(2)

create_io_guide(2)
get_io_guides(2)
place_io(2)
remove_io_guides(2)

create_io_guide

Creates an I/O guide in the current design.

SYNTAX

collection **create_io_guide**
[-name *io_guide_name*]
-line { {*x y*} *length* }
-side left | right | bottom | top
[-offset {*start_gap end_gap*}]
[-pad_cells *pad_cell_list*]
[-min_pitch *min_pitch*]

Data Types

io_guide_name string
x float
y float
length float
start_gap float
end_gap float
pad_cell_list list
min_pitch float

ARGUMENTS

-name *io_guide_name*

Specifies the name of the I/O guide. If this option is not used, the I/O guide is named default_guide_*index*, where *index* is a positive integer.

-line { {*x y*} *length* }

Creates an I/O guide along the horizontal or vertical line specified by a starting point {*x y*} and a length *length*. The orientation of the guide is defined by the **-side** option. Left and right lines must be vertical, and top and bottom lines must be horizontal. This is a required option. The line defines the outer edge of a target placement area for the pads associated with the I/O guide. The coordinates are relative to the chip origin.

-side left | **right** | **bottom** | **top**

Indicates the orientation of the I/O guide by specifying the outer edge. For instance, the I/O pads of a left guide are aligned on the right side of the guide line. All guides follow a clockwise orientation. For example, the starting point of a left guide is the bottom end of the line, and the starting point of a right guide is the top point of the line. This option is a required option.

-offset {*start_gap end_gap*}

Specifies the minimal distance (*start_gap*) between the first pad and the starting point of the guide and the minimal distance (*end_gap*) between the last pad and the ending point of the guide. By default, both offsets are zero.

-pad_cells *pad_cell_list*

Specifies a list of pad cells to be included in the I/O guide. The list can contain names, patterns, or collections. It is an error to include a pad cell whose reference module is not a pad type or a cell that has already been assigned to another I/O guide. This option is not required, you can create an empty I/O guide without specifying a pad cell list.

-min_pitch *min_pitch*

Specifies a minimum pitch between I/O drivers on the I/O guide. The distance between two consecutive I/O drivers can be zero, one or multiple times of the min pitch value. Min pitch will be honored during place_io.

There are some limitations. a. If there are conflicts between min pitch and signal I/O constraints or power I/O constraints, the tool will honor signal and power I/O constraints first. b. If there are multiple rings in design, only when there's no overlap between pads and I/O guides can the result be guaranteed.

DESCRIPTION

The **create_io_guide** command creates a line-based I/O pad constraints for I/O placement. The I/O placer uses the I/O guide to properly place the pads within the region. Unlike a move bound or group bound, I/O guides are ordered. Ordering is based on the constraints set by the **set_signal_io_constraints** command.

Note that it is possible to create an inconsistent I/O guide. There might be insufficient space within the specified line to fit the I/O pad cells with the required edge and spacing between pads. Secondly, there is nothing to enforce the position of the pad cells relative to the I/O guide. It is expected that the I/O placer will ensure that the I/O guide constraints are honored. If no *pad_cell_list* is provided as an argument, the command creates an empty I/O guide. You can add pad cells to the I/O guide with the **add_to_io_guide** command and remove pad cells from the I/O guide with the **remove_from_io_guide** command.

EXAMPLES

The following example creates an I/O guide named "io_guide1". The guide starts at location {100 100}, and extends north by 100 due to the **-side left** argument. The guide contains the pads "pad1" and "pad2", which align to the right of the I/O guide line.

```
prompt> create_io_guide -name "io_guide1" -line {{100 100} 100} \
 -side left -pad_cells { pad1 pad2 }
```

SEE ALSO

create_io_ring

Creates an IO ring in the current design.

SYNTAX

collection **create_io_ring**
[-name *ring_name*]
[-inside *outer_ring_name*]
[-offset *offset*]
[-guides *io_guide_list*]
[-bbox *bounding_box*]
[-corner_height *height*]
[-pad_cell_list *pad_list*]

Data Types

ring_name string
outer_ring_name string
offset float
io_guide_list list
bounding_box bBox
height float
pad_list list

ARGUMENTS

-name *ring_name*

Specifies the string used as the ring name. If the command creates new IO guides, the ring name is used as the prefix for the IO guides of the ring. Specifically, the left, right, top, and bottom IO guides are named by adding .left, .top, right, and .bottom to the ring name, respectively. By default, the ring name is named _default_io_ring*index*, where index is a positive integer.

-inside *outer_ring_name*

Specifies the name of the (outer) IO ring that is used as the outer boundary for the new ring. When this option is used, the target bounding box is the inner perimeter of the specified outer ring, if the outer ring has a valid corner height. Otherwise, the target bounding box is the bounding box of the outer ring.

-offset *offset*

Indicates the required offset from the target boundary. Namely, the bounding box of the ring is computed as a rectangle inside of the target bounding box. The value specified with the **-offset** option is the distance between the target bounding box and the outer bounding box of the newly created ring. The default offset is 0.

-guides *io_guide_list*

Specifies a list of IO guides to be included in the IO ring. The list may contain names, patterns, or collections. This command does not perform any checking, you are responsible for the correctness of the IO guides and the guides should define a valid ring structure. If you specify an IO guide that is already assigned to another IO ring, the command issues an error message. This option cannot be used with any other options except for the **-name** option. When you use this option to create an IO ring, the corner height of the ring remains at 0.

-bbox ***bounding_box***

Specifies the bounding box for the ring. If this option is not used and the target bounding box of the ring cannot be determined with other options such as **-inside**, the default bounding box is the inner bounding box of the smallest IO ring, or the die area if no IO ring exists.

-corner_height ***height***

Specifies the distance between the outer bounding box of the ring and inner bounding box of the ring. When you use the **-guides** option to create an IO ring, the corner height of the ring remains 0 until you set it to a different value. The default value is the height of the tallest pad cell instances assigned to the ring, or the height of the shortest pad cell instances in the design if no pad cell instance is assigned to the ring.

-pad_cell_list ***pad_list***

Lists the pad cell instances to assign to IO guides inside the ring. The pads will be evenly assigned to the IO guides if the total width of pads in each IO guide is not more than the guide length. This list is not required and you can create a IO ring without specifying a pad cell list.

DESCRIPTION

This command creates or groups a related set of IO guides that are used for IO placement. Note that it is possible to create an inconsistent IO ring, especially for the inner rings of a concentric set. If the **-guides** option is not used, the command creates a default IO ring. The size of the IO ring is assigned using the following priority:

- The *-bbox* argument
- The inner bounding box of the outer ring, if given
- The boundary for the design
- The inner boundary of the smallest existing ring

The command also creates four IO guides: _default_io_ring1.left, _default_io_ring1.bottom, _default_io_ring1.right, and _default_io_ring1.top. You can add additional IO guides to the IO ring with the **add_to_io_ring** command. You can also remove IO guides from the IO ring with the **remove_from_io_ring** command. You can also assign pad cell instances to the ring during the creation of the ring or add pad instances to each guide in the ring at a later time.

EXAMPLES

The following example creates two IO rings and populates them with pad cells:

```
prompt> create_io_ring -name io_ring1
prompt> add_to_io_guide io_ring1.bottom {ioPad_1 ioPad_2 ioPad_3 ioPad_4}
prompt> add_to_io_guide io_ring1.left {ioPad_5 ioPad_6 ioPad_7 ioPad_8}
prompt> add_to_io_guide io_ring1.top {ioPad_12 ioPad_11 ioPad_10 ioPad_9}
```

```
prompt> add_to_io_guide io_ring1.right {ioPad_16 ioPad_15 ioPad_14 ioPad_13}
prompt> create_io_ring -name io_ring2 -inside io_ring1
prompt> add_to_io_guide io_ring2.bottom {ioPad_17 ioPad_18 ioPad_19}
prompt> add_to_io_guide io_ring2.left {ioPad_20 ioPad_21 ioPad_22}
prompt> add_to_io_guide io_ring2.top {ioPad_25 ioPad_24 ioPad_23}
prompt> add_to_io_guide io_ring2.right {ioPad_28 ioPad_27 ioPad_26}
```

The following example creates four IO guides (io_guide1, io_guide2, io_guide3, and io_guide4), then places the guides into an IO ring named "io_ring1".

```
prompt> create_io_guide -name io_guide1 -side left -line {{0 0} 2000}
prompt> create_io_guide -name io_guide2 -side top -line {{0 2000} 2000}
prompt> create_io_guide -name io_guide3 -side right -line {{2000 2000} 2000}
prompt> create_io_guide -name io_guide4 -side bottom -line {{2000 0} 2000}
prompt> create_io_ring -name "io_ring1" -guides { io_guide1 io_guide2 io_guide3 io_guide4 }
```

create_keepout_margin

Creates design and cell keepout margins.

SYNTAX

collection **create_keepout_margin**
[-type hard | soft | hard_macro | routing_blockage]
[-outer *margin_spec*]
[-inner *margin_spec*]
[-layers *layers*]
[-tracks_per_macro_pin *number_of_tracks*]
[-min_padding_per_macro *padding_size*]
[-max_padding_per_macro *padding_size*]
[*design_and_cell_list*]

Data Types

margin_spec list
layers list
number_of_tracks float
padding_size float
design_and_cell_list list

ARGUMENTS

-type hard | soft | hard_macro | routing_blockage

Specifies the type of the keepout margin to create. Valid values are

- **hard** (the default)
  A hard keepout margin prevents objects from being placed in the keepout margin area throughout the entire flow. However, it would not prevent hard macros being placed in the keepout margin area.
- **soft**
  A soft keepout margin prevents the coarse placer from placing objects in the keepout margin area, but optimization and legalization can place objects within the keepout margin. Also, it would not prevent hard macros being placed in the keepout margin area.
- **hard_macro**
  A hard macro keepout margin prevents hard macros from being placed in the keepout margin area throughout the entire flow.
- **routing_blockage**
  A routing blockage keepout margin prevents PG routes from being placed in the keepout margin area.

-outer *margin_spec*

Specifies the padding margin to maintain outside of the design or cell boundary. This setting is used for physical designs and cells.

Use the following syntax to specify the margins:

{*left bottom right top*}

The margin parameters must be zero or positive and all four parameters are required. The directions are relative to the core area. The units are microns.

-inner *margin_spec*

Specifies the padding margin to maintain inside the design boundary. This option is not valid for leaf cells.

Use the following syntax to specify the margins:

{*left bottom right top*}

The margin parameters must be zero or positive and all four parameters are required. The directions are relative to the core area. The units are microns.

-layers *layers*

Specifies the layers for the routing_blockage type keepout. This option must by specified with, and can only be used with the **-type routing_blockage** keepout. Providing an empty layer list causes an error. Specify the layers by using the layer names from the technology file.

-tracks_per_macro_pin *number_of_tracks*

Specifies the number of tracks per macro pin. This option setting is used to calculate the keepout margin based on wire tracks. When you specify **-tracks_per_macro_pin**, the outer keepout margin is calculated by multiplying the number of tracks by the number of pins. For example, if you set *number_of_tracks* to 0.5, and the macro contains 100 pins on the side, the keepout margin for that side is 50 tracks.

100 pins * 0.5 tracks/pin = 50 tracks

The **-tracks_per_macro_pin** is mutually exclusive with the **-inner** and **-outer** options.

-min_padding_per_macro *padding_size*

Specifies the minimum padding distance per macro. This value is used to calculate the keepout margin based on pin count, and is valid only with the **-tracks_per_macro_pin** option. By default, the minimum padding is the minimum grid size, which is 0.

-max_padding_per_macro *padding_size*

Specifies the maximum padding size per macro. This value is used to calculate the keepout margin based on pin count, and is valid only with the **-tracks_per_macro_pin** option. By default, there is no maximum padding value.

design_and_cell_list

Specifies the list of physical designs and cells for which to create keepout margins.

DESCRIPTION

The **create_keepout_margin** command creates keepout margins for the specified physical designs and cells.

The outer and inner keepout margins can be set explicitly with the **-outer** and **-inner** options. Outer keepouts are allowed only on leaf cells and physical designs. Inner keepouts are allowed only on physical designs and are not supported on leaf cells.

Outer keepout margins can be created for macro cells based on the pin count by using the **-tracks_per_macro_pin** option. The minimum and maximum margins can be specified using the **-min_padding_per_macro** and **-max_padding_per_macro** options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates the soft outer keepout margin on a leaf cell.

```
prompt> create_keepout_margin -type soft \
  -outer {10 10 10 10}  [get_cells MY_LEAF_CELL]
```

The following example creates the hard outer and inner keepout margins on a design.

```
prompt> create_keepout_margin -type hard \
  -outer {10 10 10 10} -inner {5 5 5 5} [get_designs MY_DESIGN]
```

The following example creates the hard outer and inner keepout margins on a physical design.

```
prompt> create_keepout_margin -type hard \
  -outer {10 10 10 10} -inner {5 5 5 5} [get_cells MY_BLOCK]
```

The following example creates the hard outer keepout margin based on the pin count of the macro.

```
prompt> create_keepout_margin -tracks_per_macro_pin .6 \
  -min_padding_per_macro .1 -max_padding_per_macro 0.2 [get_cells MY_MACRO]
```

The following example creates the routing_blockage keepout margin for the PG router on a macro cell for the specified layers.

```
prompt> create_keepout_margin type routing_blockage \
  -outer {10 10 10 10} -layers {M1 M3 M5} [get_cells MY_MACRO]
```

create_layer

Creates a layer in the given tech object.

SYNTAX

collection **create_layer**
[-tech *tech_object*]
-name *layer_name*
-number *layer_number*
[-purpose *purpose_object*]
[-layer_type *layer_type*]
[-mask_name *mask_name*]
[-before *reference_layer*]
[-after *reference_layer*]

Data Types

layer_name	string
layer_number	int
layer_type	string
mask_name	string
reference_layer	string or collection

ARGUMENTS

-tech

Layer will be created in this tech object. If not specified then tech object of current library will be used.

-name *layer_name*

Specifies the name of the layer to be created.

-number *layer_number*

Specifies the number of the layer to be created.

-purpose

Layer will be created using this purpose object. If not specified then the default purpose used for layer creation is "drawing". This option is mutually exclusive with -before and -after.

-layer_type *layer_type*

Specifies the type of the layer to be created. Valid values are: **diffusion**, **implant**, **interconnect**, **local_interconnect**, **local_via_cut**, **mim_interconnect**, **mim_via_cut**, **n_implant**, **nwell**, **p_implant**, **place_and_route**, **pwell**, **sadp_trim**, **unknown**,

and **via_cut**. Default layer type is unknown.

-mask_name *mask_name*

Specifies the mask_name of the layer to be created.

-before *reference_layer*

Specifies the mask_order of the layer to be created relative to the given reference layer. The reference layer should be an ordered layer with valid mask_order before which the created layer will be inserted. Please note that this option would increment the mask_order of all higher order layers including the given reference layer to create space in the mask_order sequence for insertion of the created new layer. If unspecified, the mask_order of the created layer is -1 (unordered). This option is mutually exclusive with -after and -purpose.

-after *reference_layer*

Specifies the mask_order of the layer to be created relative to the given reference layer. The reference layer should be an ordered layer with valid mask_order after which the created layer will be inserted. Please note that this option would increment the mask_order of all higher order layers excluding the given reference layer to create space in the mask_order sequence for insertion of the created new layer. If unspecified, the mask_order of the created layer is -1 (unordered). This option is mutually exclusive with -before and -purpose.

DESCRIPTION

create_layer command creates a layer in the given technology. The layer creation requires a name and a number for the new layer. If a purpose is specified, then the new layer uses the given purpose, otherwise the new layer uses the default purpose "drawing".

If the command is successful, it returns the newly-created layer as a single-element collection. If the command fails, it returns TCL_ERROR with appropriate error message. If there is a syntax error, it returns a TCL_ERROR.

EXAMPLE

The following example creates a layer in the technology of the current design.

prompt> **create_layer -tech [get_techs [current_lib]] -name test_layer -number 100 -purpose signal**
{test_layer:signal}

The following example creates the same layer without -tech option.

prompt> **create_layer -name test_layer -number 100 -purpose signal**
{test_layer:signal}

The following example creates the same layer with mask_name and mask_order after layer M1.

prompt> **create_layer -name test_layer -mask_name test_layer -after M1 -number 100**
{test_layer}

SEE ALSO

remove_tech(2)
get_techs(2)

create_left_right_filler_cells

Inserts left or right filler cells for specific center cells.

SYNTAX

status **create_left_right_filler_cells**
-lib_cells *center_left_right_pair_list*
[-prefix *prefix*]
[-boundaries *polyrect_list*]
[-voltage_areas *va_list*]
[-rules *rule_list*]
[-follow_stdcell_orientation]

Data Types

center_left_right_pair_list	list
prefix	string
polyrect_list	list
va_list	list
rule_list	list

ARGUMENTS

-lib_cells *center_left_right_pair_list*

Specifies the list of center cell list, left filler cell list and right filler cell list pair. The format should be {{{center_cell_list1} {left_filler_list1} {right_filler_list1}} {{center_cell_list2} {left_filler_list2} {right_filler_list2}}...}. By default, the tool adds the left right filler cells in the order that you specify. We recommend to specify them from the largest to smallest. The center cell list, left filler list and right filler list allow wildcard "*" specification. If wildcard is used for left filler list and right filler list, the order will be the same with that you get from **get_lib_cells**. The center cell list can't be empty. Either the left or right filler list can be empty. For example, {{center_cell_list} {left_filler_list} {}} or {{center_cell_list} {} {right_filler_list}}. But left and right filler lists can't be empty simultaneously. Besides, a lib cell can't be repeated in two or more center cell lists. If so, only the last specification will be used.

-prefix *prefix*

Adds the specified prefix to the instance names of left right filler cells inserted by this command. You can later use the prefix to identify the filler cell instances.

-boundaries *polyrect_list*

Specifies the rectangular or rectilinear polygon regions (in microns) where left right filler cells are to be inserted. A rectangle is specified as a list of two points, {{*llx lly*} {*urx ury*}}, which represent the lower-left and upper-right corners of the rectangle.

By default, left right filler cells are inserted in the entire chip.

-voltage_areas *va_list*

Specifies the voltage areas in which to insert left right filler cells.

By default, the tool inserts left right filler cells in all voltage areas.

-rules *rule_list*

Specifies the special rules to follow during left right filler cell insertion.

You can specify one or more of the following keywords:

- **no_1x**
  Indicates this is no-1x design. Prevents tool from placing left right filler cells such that it would leave a 1x gap.

-follow_stdcell_orientation

Specifies the left and right filler cells to follow the center cell's orientation. If the center cell's orientation is R180 or MY, its left and right side will be swapped. Besides, its left right filler cells' orientation will be MY on R0 rows and R180 on MX rows. If the center cell's orientation is R0 or MX, its left right filler cells' orientation will be R0 on R0 rows and MX on MX rows.

By default, the tool will place the left right filler cells with the allowable orientation of the corresponding rows.

DESCRIPTION

This command inserts left or right filler cells for the specified center cells. The height of center cells must be multiple integer of the height of the left or right filler cells. There will be no gaps between the left or right filler cells and its corresponding center cells. Intercell spacing rules will be ignored.

After the left or right filler cells insertion, you may use check_legality to verify filler placement legality.

EXAMPLES

The following example inserts left and right filler cells for center cells whose reference library named mylib/Center_1 and it also inserts left filler cells for center cells whose reference library named mylib/Center_2. All the left and right filler cells will only be inserted within the specified region {{0 0} {500 500}}. If the sizes of the left filler cells are such that LeftFiller_4X > LeftFiller_2X > LeftFiller_1X, this ordering minimizes the number of left filler cells added by using the larger filler cells first. And it was the same case for the right filler cells.

```
prompt> create_left_right_filler_cells \
  -lib_cells { { {mylib/Center_1} \
               {mylib/LeftFiller_4X mylib/LeftFiller_2X} \
               {mylib/RightFiller_2X mylib/RightFiller_1X} } \
             { {mylib/Center_2} \
               {mylib/LeftFiller_2X mylib/LeftFiller_1X} \
               {} } \
           } \
  -boundaries {{0 0} {500 500}}
```

SEE ALSO

check_legality(2)

create_length_limit

Creates an analog constraint group with wire_length_limit intent in the current design.

SYNTAX

collection **create_length_limit**
[*constraint_group_name*]
-for *objects*
[-min_value *float*]
[-exclude *objects*]
[-driver *objects*]
[-force]

Data Types

constraint_group_name string
objects collection
float float

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group. If not specified then a system generated name is assigned.

-for *objects*

Specifies the objects - can be nets, pins, ports, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

-min_value *float*

Specifies the minimum value that needs to be achieved by each constituent object in the constraint group. The default is zero.

-exclude *objects*

Specifies the objects that need to be excluded from the analog constraint group. The objects can be pins or ports, and can be specified as strings (object names) or collections. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in **-for** option but want to exclude a few pins / ports connecting to that net.

-driver *objects*

Specifies the object to be treated as the driver for the analog constraint group. The object can be a pin or port, and can be specified as a string (object name) or collection. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in **-for** option but want to control the length of each driver to receiver connection.

-force

Specifies force deletion of existing constraint group by the same name as specified and re-creation of new constraint group. The default is false and the command exits with error if same name is encountered.

DESCRIPTION

The **create_length_limit** command creates a constraint group for a collection of nets, pins, ports, bundles, and topology_edges with wire_length_limit intent. Each constituent object must honor the minimum value specified for its wire length. Constraint applicable on pin/port check the net which is connecting pin/port to driver pin/port. The constraint is used by Custom Router.

EXAMPLES

The following example creates a constraint group named 'abc' for nets and bundles matching the pattern 'pr*' such that none of the constituent objects have wire length lesser than 10. The 'pr*' nets are routed with Custom Router.

```
prompt> create_length_limit abc -for pr* -min_value 10
{abc}
```

create_lib

Creates a design library.

SYNTAX

collection **create_lib**
[-technology *tech_path* | -use_technology_lib *tech_lib_name*]
[-scale_factor *scale_factor*]
[-ref_libs *ref_libs*]
[-convert_sites *site_name_pairs_list*]
[-base_lib *base_library_path*]
library_name

Data Types

tech_path string
tech_lib_name string
scale_factor int
ref_libs list
site_name_pairs_list list
base_library_path string
library_name string

ARGUMENTS

-technology *tech_path*

Specifies the technology file for this library.

-use_technology_lib *tech_lib_name*

Specifies the reference library to use as a dedicated technology library.

The library must contain a technology section and must be one of the libraries specified with the **-ref_libs** option.

This option is mutually exclusive with the **-technology** option, and it must be used with the **-ref_libs** option.

-scale_factor *scale_factor*

Specifies the length precision for this library. The length precision for the library and all of its reference libraries must be identical. The value is specified in terms of units per micron. By default, a length precision of 10000 is used, which implies one internal unit is equal to one Angstrom or 0.1 nm

Choose a *scale_factor* value that will result in a whole number of database units per minimum grid spacing. For example, if your minimum grid spacing is 1 nm, the default scale_factor of 10000 dbu per micron could be used. But if your minimum grid spacing is 0.25 nm, a scale factor of, for example, 4000, must not be used because rounding errors might result.

-ref_libs ***ref_libs***

Specifies the reference libraries for this library.

In addition to pre-built cell libraries, this option accepts physical source data such as physical libraries (which contain frame views of the cells), LEF files, and Milkyway libraries. The tool automatically builds cell libraries based on the physical source data.

You can specify the reference libraries and physical source data using absolute or relative paths. If you specify the libraries with a relative path or with no path, the tool uses the search path defined with the **search_path** variable to locate the libraries.

-convert_sites ***site_name_pairs_list***

Specifies the mapping for the site names in the technology file in the following format:

{*tech_file_site_name new_site_name*}

This option must be used with the **-technology** option.

-base_lib ***base_library_path***

Creates a sparse library based on the specified library. The base library must be a design lib and cannot be a lib-cell library. No other options can be specified when the **-base_lib** option is used. For example, the sparse library must use the same technology file and ref_libs as the base library.

library_name

Specifies the name of the new library. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after he last '/' becomes the name of the library. It is an error if a library, file, or directory with the same name already exists on disk.

The name can be a simple path, a path relative to the current working directory, or an absolute path. The name cannot contain spaces or the colon (":") character, which is used to delimit the library and design name.

The *library_name* is optional when *-base_lib* option is used. If unspecified, the name of the created local sparse library matches the name of the base library specified using the *-base_lib*.

DESCRIPTION

The **create_lib** command creates a new design library. The library can contain technology information specified with the **-technology** option. If there are sites defined in the technology file (and one is being used), you can use the **-convert_sites** option to map the sites from one name to another. This same option is used with the **read_def** command to ensure that the site names match among all the input data.

You can directly specify the library's reference library path list with the **-ref_libs** option. Alternatively, if you specify physical source data with the **-ref_libs** option, the tool creates the cell libraries and sets them as reference libraries. The supported physical source data includes physical libraries, which contain the frame views of the cells, LEF files, and Milkyway libraries. The logic libraries are determined from the **link_library** variable. The created cell libraries are put in the directory specified by the **lib.configuration.local_output_dir** application option. You can use the **lib.configuration.default_flow_setup** application option to point to a Tcl script with customized settings for the cell library creation. See the man pages of these application variables and options for detailed information about how to use them.

When the **-base_lib** option is used the **create_lib** command creates a new sparse library based upon an existing design library on disk. The sparse library uses the same technology file and ref_libs as the base library. Initially, a sparse library does not have any locally stored blocks. It copies the base library's catalog and ref_lib list into memory as its own and also remembers the full path of the base library for reference.

The library is then opened and made the current library.

If the command is successful, it returns the newly-created library as a single-element collection. If the command fails, it returns an empty string. If there is a syntax error, it returns a TCL_ERROR.

EXAMPLES

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{r4000}
prompt> current_lib
{r4000}
```

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file and has a scale factor of 4000.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000 -scale_factor 4000
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{r4000}
prompt> current_lib
{r4000}
prompt> get_attribute [current_lib] scale_factor
4000
```

The following example creates a library named top_lib in the ./lib_dir directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf lib_dir/top_lib
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{top_lib}
```

The following example creates a library named design_lib in the /home/user directory that uses the my_tech.tf technology file.

```
prompt> create_lib -technology my_tech.tf /home/user/design_lib
Information: Loading technology file 'my_tech.tf' (FILE-007)
{design_lib}
```

The following example creates a sparse library named top_sparse_lib based on the design library top_lib in the /home/user directory.

```
prompt> create_lib -base_lib /home/user/top_lib top_sparse_lib
Information: Creating Sparse View library 'top_sparse_lib' with base
library '/home/user/top_lib'. (NDM-103)
{top_sparse_lib}
```

The following example creates a library named design_lib and automatically creates cell libraries for it. The cell libraries are created based on the logic library files specified in the **link_library** variable and the physical library specified with the **-ref_libs** option.

```
prompt> set_app_var link_library \
  "* 1_pvt1.db 1_pvt2.db 2_pvt1.db 2_pvt2.db"
prompt> create_lib -technology my_tech.tf /home/user/design_lib \
  -ref_libs frame_only.ndm
 ... run lm_shell to build reference libraries.
 ..........................................................................
Information: Successfully built 3 reference libraries: 1.ndm 2.ndm
EXPLORE_physical_only.ndm
```

create_liner_cells

Create liner cells along die edge or core edge in the block.

SYNTAX

create_liner_cells
-lib_cell *cell_name*
[-horizontal_padding_cells *cells_name*]
[-vertical_padding_cells *cells_name*]
[-die_offset *{x_offset y_offset}*]
[-macro_offset *{x_offset y_offset}*]
[-core_offset *{x_offset y_offset}*]
[-step *{x_step y_step}*]
[-along_core_edge]

Data Types

cell_name string
cells_name list
x_offset float
y_offset float
x_step float
y_step float

ARGUMENTS

-lib_cell

Specifies the library liner cell to be inserted.

-horizontal_padding_cells

Specifies a list of padding cells to replace liner cell and fill up the horizontal gaps.

-vertical_padding_cells

Specifies a list of padding cells to replace liner cell and fill up the vertical gaps.

-die_offset

Specifies the horizontal and vertical enclosure from die boundary to the corner liner cell. The default value is {0 0}.

-macro_offset

Specifies the minimum horizontal and vertical spacing from macro boundary to the corner liner cell. The default value is {0 0}.

-core_offset

Specifies the minimum horizontal and vertical spacing from core edge to the corner liner cell if '-along_core_edge' is not specified. The default maximum value is twice as x_step and y_step. If '-along_core_edge' is specified, it specifies the exact horizontal and vertical spacing from core edge to the corner liner cell. The default value is {0 0}.

-step

Specifies the pitch of two adjacent liner cells. The x_step and y_step must be equal to or greater than liner cell's width and height. The default value is liner cell's width and height.

-along_core_edge

Specifies whether to insert liner cell along core edge. If not specified, liner cells will be only inserted along die edge (in die area). Otherwise, liner cells will be also inserted along core edge (outside core area).

DESCRIPTION

This command creates liner cells by keep specified spacing to die edge, macro and core edge and inserts horizontal and vertical padding cells when necessary.

EXAMPLES

The following example shows creating liner cells along both die edge and core edge with potential horiontal and vertical padding cells.

```
create_liner_cells -lib_cell LC -horizontal_padding_cells {HPC1 HPC2 HPC3} -vertical_padding_cells {VPC1 VPC2} -step {3 4} -di
```

SEE ALSO

create_logic_net

Creates a logic net

SYNTAX

status **create_logic_net**
net_name

Data Types

net_name string

ARGUMENTS

net_name

Specifies the name of the net to create.

DESCRIPTION

The create_logic_net command creates a logic net in the current scope.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

create_net(2)

create_logic_port

Creates a logic port

SYNTAX

string **create_logic_port**
port_name
[-direction in | out | inout]

Data Types

port_name string

ARGUMENTS

port_name

Specifies the name of the port to create.

-direction in | out | inout

Specifies the direction of the port. The default is **in**.

DESCRIPTION

The create_logic_port command creates a logic port in the current scope. Logic ports should be created before corresponding isolation and level-shifting strategies are applied so any isolation or level-shifting strategy defined for a power domain may apply to logic ports created on the boundary of that power domain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

create_port(2)

create_macro_array

Arranges macros into an array.

SYNTAX

collection **create_macro_array**
-num_rows *rows*
-num_cols *columns*
[-horizontal_channel_height *list_of_numbers*]
[-vertical_channel_width *list_of_numbers*]
[-align *align_mode*]
[-orientation *list_of_orientations*]
[-flip_alternate_rows]
[-flip_alternate_cols]
[-create_group true | false]
[-name *edit_group_name*]
[-fill_pattern by_row | by_col | by_row_snake_pattern | by_col_snake_pattern]
macros

Data Types

rows integer
columns integer
list_of_numbers list
align_mode string
list_of_orientations list
edit_group_name string
macros collection

ARGUMENTS

-num_rows *rows*

Specifies the number of rows in the array.

-num_cols *columns*

Specifies the number of columns in the array.

-horizontal_channel_height *list_of_numbers*

Specifies the height of each horizontal channel. The height for each macro is set based on its position in the list. If there are fewer elements in the list than there are channels, the remaining channel heights are set to the first element of the list. In particular, if only one number is specified, all heights are set to that number. The default for all heights is 0. Note that heights are calculated from macro edges; keepout margins are not considered.

-vertical_channel_width *list_of_numbers*

Specifies the width of each vertical channel. The width for each macro is set based on its position in the list. If there are fewer elements in the list than there are channels, the remaining channel widths are set to the first element of the list. In particular, if only one number is specified, all widths are set to that number. The default is for all widths is 0. Note that the widths are calculated from macro edges; keepout margins are not considered.

-align *align_mode*

Specifies the edge or corner of each macro to which to align for non-homogeneous macro arrays. The valid values are **center**, **top**, **bottom**, **right**, **left**, **top_left**, **bottom_left**, **top_right**, and **bottom_right**.

The default is **center**.

-orientation *list_of_orientations*

Specifies the orientation for each macro in the array, based on its position in the list. If there are fewer elements in the list than there are macros, the remaining macro orientations are set to the first element of the list. In particular, if only one orientation is specified, all macro orientations are set to that value. The default is for all orientations to be unchanged from the current value.

Legal orientation values are: N, FN, S, FS, E, FE, W, and FW

- N - specifies an R0 orientation
- FN - specifies an MY orientation
- S - specifies an R180 orientation
- FS - specifies an MX orientation
- E - specifies an R270 orientation
- FE - specifies an MYR90 orientation
- W - specifies an R90 orientation
- FW - specifies an MXR90 orientation

-flip_alternate_rows

Flip macros in every other row. By default, macros are not flipped.

-flip_alternate_cols

Flip macros in every other column. By default, macros are not flipped.

-create_group true | false

Specifies whether to create an edit group for the macro array. The default is true.

-name *edit_group_name*

Specifies the name of edit group to create. This option is valid only if **-create_group true** is specified. If **-name** is not specified and -create_group is true, a unique default name, MACRO_ARRAY_#, is used to name the macro. If **-name** is specified and the specified name already exists in another edit group, the command issues an error message.

-fill_pattern by_row | by_col | by_row_snake_pattern | by_col_snake_pattern

Specifies how macros are placed in the array. by_row places macros starting from the first column; new rows are started from the first column. by_row_snake_pattern creates the array row-by-row, but with each row starting where the previous row ended, thus creating a snake pattern.

by_col and by_col_snake_pattern are similar, but place macros column-by-column rather than row-by-row The default fill pattern

is by_row.

macros

Specifies a list of macros to place in the array.

DESCRIPTION

This command arranges a list of macros in an array and optionally creates an edit group for the array. If an edit group is created, the command returns it; otherwise a collection equal to the list_of_objects argument is returned.

EXAMPLES

The following example creates an array from the selected macros.

```
prompt> create_macro_array -num_rows 2 -num_cols 2 [get_selection] -name my_edit_group
```

The following example creates an array from the selected macros and specifies their channels widths, and heights. The orientation for each macro in the array is N.

```
prompt> create_macro_array -num_rows 4 \
  -num_cols 3 [get_selection] -orientation { N } \
  -horizontal_channel_height 10 \
  -vertical_channel_width { 10 20 }
```

The following example creates an array from the selected macros and specifies their orientations, channels widths, and heights.

```
prompt> create_macro_array -num_rows 4 \
  -num_cols 3 [get_selection] -orientation { N S N S } \
  -horizontal_channel_height 10 \
  -vertical_channel_width { 10 20 }
```

The following example returns all macro arrays (edit groups that begin with "MACRO_ARRAY_") and deletes them.

```
prompt> set macro_arrays [get_edit_groups -filter name=~MACRO_ARRAY_*]
{MACRO_ARRAY_0}
prompt> remove_edit_groups $macro_arrays
1
```

SEE ALSO

create_edit_group(2)
get_edit_groups(2)
remove_edit_groups(2)

create_macro_groups

Create macro groups.

SYNTAX

collection_of_macro_group **create_macro_groups**
-method auto | by_hierarchy | by_connectivity | by_pattern | by_index_pattern | by_macros
[-names string]
[-pattern pattern_string]
[-index_pattern index_pattern_string]
[-macros list_of_macros]
[-preview]

Data Types

pattern_string Regular expression
index_pattern_string Index pattern expression
list_of_macros collectionP of macros

ARGUMENTS

-method auto | by_hierarchy | by_connectivity | by_pattern | by_index_pattern | by_macros

Specifies method to create macro group. There are five modes to create macro groups. They are auto, by_hierarchy, by_connectivity, by_pattern, by_index_pattern, and by_macros.

auto is the default method. This method is the same as default grouping method of **create_placement -floorplan** command. It groups macros based on combinations of hierarchy, connectivity, and coarse placement result.

by_hierarchy is the same grouping by hiererachy method of **create_placement -floorplan** command. It groups macros purely based on hierarchy infomration.

by_connectivity is the same grouping by connectivity of **create_placement -floorplan** command. It groups macros based on conneectivity between macros and sequential cells.

by_pattern method groups macros based on name pattern. Parameter -pattern must be specified to use this method. Pattern is a regular expression string. Macros which match the pattern and belong to same placeable area will be grouped together. For example, assume there are four macros

HIER1/MEM_1_1
HIER1/MEM_1_2
HIER1/MEM_1_3
HIER1/MEM_1_4

and they belong to same block.

```
prompt> create_macro_groups -method by_pattern \
   -pattern HIER1/MEM_1*
```

This command will create a macro group which contains these four macros. If one macro belongs to another macro group before this command, the command will remove it from its previous macro group and assign it to the new macro group.

by_index_pattern method group macros based on index pattern. Parameter -index_pattern must be specified to use this method. Index pattern is comprised of fixed text and index. Index has two types, fixed and auto. Fixed index is represent as ?, fixed index is represet as *. Fixed index is used to group macros of same placeable area together. For example, assuming there are following macros

```
HIER/MEM_1_1
HIER/MEM_1_2
HIER/MEM_2_1
HIER/MEM_2_2
```

and they belong to same placeable area.

```
prompt> create_macro_groups -method by_index_pattern \
  -index_pattern HIER/MEM_?_*
```

This command spcifies index pattern as HIER/MEM_?_*. Question mark (?) is fixed index, and star (*) is auto index. The command will first find all macros which match the pattern, i.e, macros with name HIER_MEM_number1_number2. Since the index pattern indicates the first number is fixed, and second is auto, the command will group macros with same first number together. So, in the end, the command will create two groups:

```
HIER/MEM_1_1
HIER/MEM_1_2

and

HIER/MEM_2_1
HIER/MEM_2_2
```

Following command uses a different index_pattern.

```
prompt> create_macro_groups -method by_index_pattern \
   -index_pattern HIER/MEM_*_?
```

The index pattern indicates the first number is auto, and the second number is fixed. The command will create two groups and they are

```
HIER/MEM_1_1
HIER/MEM_2_1

and

HIER/MEM_1_2
HIER/MEM_2_2
```

by_macros method creates macro group based on given macros. Paramenter -macros must be specified to use this method. The command will create a macro group which contains macros in the list.

-names

Specifies group names. The command **create_macro_groups** can create multiple groups. This parametre specify names for each group. It is a list of string. Each item is a group name. If the number of names specified in this parameter is more than macro groups created by the command, additional names will be discarded. If the number of names specified in this parametre is less than macro groups created by the command, the command will create default names for additional macro groups. If any name is already used by other macro group, the command will give a warning message and pick a default name.

-pattern regular_expression_pattern

Specifies regular expression name pattern of macros. This parameter must be used together with parametre -method set as by_pattern.

-index_pattern index_pattern_string

Specifies index pattern of macros. This parameter must be used together with parametre -method set as by_index_pattern.

-preview

With -preview parameter, the command **create_macro_groups** will return a list of collections, and each collection is a macro group which will be created if parameter -preview is not specified.

DESCRIPTION

This command creates macro groups. It is one of command of macro placement assistant flow. Macro placement assistant flow helps user to group and pack macros semi-automatically. This is different from command **create_placement -floorplan**, where the grouping and packing of macros are done automatically.A typical macro placement assistant flow is as following:

\n+[step]. Place macros. Macros can be placed by i**create_placement -floorplan**
command automatically, or by user manually.
\n+[step]. Use **create_macro_groups** command to create macro groups. User
can use different methods to create macro groups. Macros of same macro
groups should be placed together.
\n+[step]. Create contour of macro groups using command set_macro_group_shape.
\n+[step]. Pack macros using command pack_macro_group.

User can undo the change at any step if he or she is not satisfied with the result. in NDM model, macro group is a sub-class of movebound. It contains a group of macros and contour. All macros of one macro group must belong to the same macro group. A placeable area can be a movebound, a voltgage area, or a block. When a macro group is first created, its contour will be placed outside of block area. Use command set_macro_group_shape to modify the contour.

EXAMPLES

The following command creates macro groups with auto method

prompt> **create_macro_groups** -method auto

The following ocmmand creates macro group with give macros

prompt> **create_macro_groups** -method by_macros \
-macros [get_cells {M1 M2 M3 M4}]

The following command print macro groups which will be created by method by_pattern.

prompt> **create_macro_groups** -method by_pattern \

```
    -pattern  I_ORCA_TOP/I_CONTEXT_MEM/I_CONTEXT_RAM_* \
    -preview
```

create_macro_relative_location_placement

Performs macro placement based on the relative location placement constraints.

SYNTAX

status **create_macro_relative_location_placement**
[-hierarchical]

ARGUMENTS

-hierarchical

Performs macro relative location placement in the top-level design and in the child blocks. By default, the command performs macro relative location placement in the current block.

DESCRIPTION

This command performs macro relative location placement based on the constraints for current block. If the **-hierarchical** option is specified, the command places the macros in the current block and the macros in child blocks.

EXAMPLES

The following example performs relative location placement on current block.

```
prompt> create_macro_relative_location_placement
1
```

The following example performs relative location placement on the top-level block and in the child blocks.

```
prompt> create_macro_relative_location_placement -hierarchical
1
```

SEE ALSO

report_macro_relative_location(2)
set_macro_relative_location(2)

create_marker_layers

Populates a set of shape objects in the marker layers in the given design.

SYNTAX

collection **create_marker_layers**
[-design *design*]
[-cells *cells*]
[-references *references*]
[-horizontal_extension *hextension*]
[-vertical_extension *vextension*]
[-horizontal_offset_from_cell *hoffset*]
[-vertical_offset_from_cell *voffset*]
[-exclude { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]

Data Types

design collection
cells collection
references string
hextension string
vextension string
hoffset string
voffset string
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection

ARGUMENTS

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

-cells *cells*

Specifies the collection of cells which are to be excluded for generating the shapes in the marker layers.

-references *references*

Specifies the names of the IPS which are to be excluded for generating the shapes in the marker layers.

-horizontal_extension *hextension*

Specifies the horizontal extension for marker layers where the tracks are vertical. The input is a list of layername and extension pairs. The extension value can be positive or negative.

-vertical_extension *vextension*

Specifies the vertical extension for marker layers where the tracks are horizontal. The input is a list of layername and extension pairs. The extension value can be positive or negative.

-horizontal_offset_from_cell *hoffset*

Specifies the horizontal offset from excluded cells or references for generating the shapes of the marker layers.The input is a list of layername and offset pairs. The offset value can be positive or negative.

-vertical_offset_from_cell *voffset*

Specifies the vertical offset from excluded cells or references for generating the shapes of the marker layers.The input is a list of layername and offset pairs. The offset value can be positive or negative.

-exclude { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the objects to be excluded from the marker layers. The object list can be a heterogeneous collection of poly_rect, geo_mask, shape, layer, and other physical objects.

DESCRIPTION

This command creates a collection of new rectangles and polygons on the marker layers and returns a collection that contains the new shape.

EXAMPLES

The following example creates shapes on the marker layers.

```
prompt> create_marker_layers -references {IP1 IP3} -cells u1 \
  -horizontal_extension {{{M2_P48 10} {M3_P48 20}}}
```

The following example creates shapes on the marker layers where offset from cells and references are specified.

```
prompt> create_marker_layers -references {IP1 IP3} -cells u1 \
  -horizontal_extension {{{M2_P48 10} {M3_P48 20}}}
  -horizontal_offset_from_cell {{{M2_P48 6} {M3_P48 8}}}
```

SEE ALSO

remove_shapes(2)

create_mask_constraint_routing_blockages

Creates routing blockages around the terminals and boundaries in the current top-level design, or around the block pins and inside the block instance boundaries on the layers that have mask constraints defined.

SYNTAX

status **create_mask_constraint_routing_blockages**
[-cells *cells*]
[-create_placement_blockages]
[-self]

Data Types

cells collection

ARGUMENTS

-cells *cells*

Specifies a list of block instances in which to create the mask constraint routing blockages. If this option is omitted, the command creates mask constraint routing blockages inside each of the block instances within the current top-level design.

The command places mask constraint routing blockages inside the specified block instances (or all of the block instances if omitted). The blockages surround the block pins on the layers where mask constraints are defined.

-create_placement_blockages

Creates placement blockages in addition to routing blockages. The shapes and locations of the placement blockages are the union of the mask constraint routing blockages.

-self

Specifies that the mask constraint routing blockages are created at top-level design. The mask constraint routing blockages are created in the top-level design and surround the top-level terminals on layers where mask constraints are defined. This option is mutually exclusive with the **-cells** option.

When this option is omitted, mask constraints routing blockages are created inside the block instances within the current top-level design.

DESCRIPTION

This command creates mask constraint routing blockages, and optionally creates placement blockages. If the technology file for the

current top-level design defines mask constraint rules on one or more layers, this command creates routing blockages. If the **-self** option is specified, routing blockages are created around the terminals and boundaries of the top-level design. If the **-self** option is not specified, the command creates routing blockages around the block pins and inside the block instances specified by the **-cells** option. If both **-self** and **-cells** options are omitted, the command creates routing blockages inside all of block instances. Blockages are created on the layers that have the mask constraint rules defined. The **set_editability** can enable/disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled by **set_editability**.

Routing blockages prevent the router from accessing those terminals or the block pins on the same layers within a certain distance of the boundaries and avoid creating mask constraint violations.

The routing blockages created by this command use the naming style __DPT_ROUTING_BLOCKAGE_x__, where x is a nonnegative integer. If the design already contains a routing blockage with the same naming style, the tool deletes the blockage automatically.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates double-patterning routing blockages for the current top-level design.

```
prompt> create_mask_constraint_routing_blockages
```

SEE ALSO

create_routing_blockage(2)
set_editability(2)

create_matching_type

Creates a matching type in the current block.

SYNTAX

collection **create_matching_type**
-name *matching_type_name*
[-uniquify *count*]
[*object_list*]

Data Types

matching_type_name string
count int
object_list list

ARGUMENTS

-name *matching_type_name*

Specifies the name of the matching type. The name must be unique among all matching types in the block.

-uniquify *count*

Specifies how bump cells are assigned to pad pins within the same matching type. This is optional. If specified, the valid value range is [-4, 8]. If the value is > 0, the value indicates the number of pad pins that can be assigned to a single bump cell, and no two bump cells can be assigned to the same pad pin. If the value is < 0, the absolute value indicates the number of bump cells that must be assigned to each pad pin, and no two pad pins can be associated to the same bump cell. If the value = 0, only 1 bump cell is assigned to all pad pins.

object_list

Specifies a list of cells, pins, and terminals to add to the matching type. The list can contain names, patterns, or collections. This list is optional. You can create an empty matching type without specifying any object list. It is an error to add an object which is already in another matching type. Each object can exist in at most one matching type in the block.

DESCRIPTION

This command defines a matching type constraint. A matching type specifies which bump cells are to be connected to which pad pins through its list of objects. It also optionally specifies how this is done through its uniquify number. If the matching type contains only bumps or no bumps, no bump assignment will be performed on its list of objects.

When I/O placement is performed, objects can be connected only to other objects with the same matching type. The matching type exists only in the block in which it was created, but its containing objects can span into subblocks. This means that the current block's matching types can apply to objects in subblocks when performing I/O placement from the current block, but matching types created in other blocks are not visible from the current block.

A pin is a RDL pin if it contains at least a single terminal with class attribute equal to bump. When a pad is in a matching type, all its RDL pins are in the matching type. When a RDL pin with multiple terminals with class attribute equal to bump is included in a matching type, only a single terminal will be selected for bump assignment and RDL routing. To force the tool to connect all, users need to create a matching type with all terminals explicitly described. Bumps and the uniquify number must also be set accordingly.

EXAMPLES

The following example creates a matching type named "myMatchingType1" with cell "bump" and pin "padCell/padio".

```
prompt> create_matching_type -name "myMatchingType1" -uniquify 0 \
  [list [get_cells bump] [get_pins padCell/padio]
```

report_matching_types(2)

create_mim_capacitor_array

Places Metal-Insulator-Metal (MIM) capacitor cells in the design in an array style. When inserting MIM capacitor cells, the command ignores placement blockages, macros, standard cells and PG network routes.

SYNTAX

status **create_mim_capacitor_array**
-lib_cell *lib_cell*
-x_increment *distance*
-y_increment *distance*
[-prefix *prefix*]
[-orientation R0|R90|R180|R270|MX|MY|MXR90|MYR90]
[-boundary *polygon*]

Data Types

lib_cell	string
distance	float
prefix	string
polygon	list

ARGUMENTS

-lib_cell *lib_cell*

Specifies the MIM capacitor library cell explicitly. This option is required.

-x_increment *distance*

Specifies the horizontal distance between the centers of two cells.

-y_increment *distance*

Specifies the vertical distance between centers of two cells.

-prefix *prefix*

Specifies the prefix added to the MIM capacitor cell name.

-orientation R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of the MIM capacitor cells placed by this command. The orientation can be R0, R90, R180, R270, MX, MY, MXR90, MYR90. If not specified, the default orientation is R0.

-boundary *polygon*

Specifies the area in which to place MIM capacitor cells.

DESCRIPTION

This command places the cells into the design in an array style.

EXAMPLES

The following example places MIM capacitor cells.

```
prompt> create_mim_capacitor_array -lib_cell my_lib/mim_ref_cell \
  -x_increment 20 -y_increment 20
```

SEE ALSO

create_cell(2)

create_mismatch_config

Creates a new config.

SYNTAX

status **create_mismatch_config**
config_name
[-ref_config *name*]

Data Types

config_name string
name string

ARGUMENTS

config_name

Specifies the config name to be created.

-ref_config *name*

Specifies the reference config to be used for creating new config. If no ref_config is passed, then the most restrictive config will be used, i.e. **default**. Pre-defined configs available are: auto_fix and default. One config among pre-defined configs or user defined configs can be used as a reference config.

DESCRIPTION

This command creates a new config. It uses the ref_config to create the new config if passed any. If no ref_config is passed, most restictive config which is **default** is used to create the new config. Pre-defined configs are: default and auto_fix. auto_fix being permissive and default being restrictive.

If the new named config already exists, or reference config does not exists, proper messaging is given. The **report_mismatch_configs** can be used to list all the available configs in a session. So, once **create_mismatch_config** succeeds for a config, **report_mismatch_configs** will report this config too.

The **set_current_mismatch_config** command can be used to set the newly created config as current config of a session.

EXAMPLES

The following example creates new config:

```
prompt> create_mismatch_config user-def
1
prompt> create_mismatch_config user-def
Error: Mismatch config 'user-def' already exists. (DMM-016)
0
```

The following example creates a new config based on a ref config:

```
prompt> create_mismatch_config user-def1 -ref_config auto_fix
1
```

The following example creates a new config using a user defined config:

```
prompt> create_mismatch_config user-def
1
prompt> create_mismatch_config user-def1 -ref_config user-def
1
prompt> create_mismatch_config user-def3 -ref_config user-def10
Error: Mismatch config 'user-def10' do not exists. (DMM-015)
0
```

create_mode

Creates a mode in the current design.

SYNTAX

string **create_mode**
mode_name

Data Types

mode_name string

ARGUMENTS

mode_name

Specifies the name of the mode being created.

DESCRIPTION

Creates a mode in the current design. Modes are used to contain a set of constraints environment for the design. Unique modes are often used for different combinations of operating modes and power schemes. Modes are used together with corners, which contain operating condition and parasitics parameters. Timing analysis is actually done for various mode/corner combinations, as configured by the **set_scenario_status** command.

Constraints are contained in the current mode. When the design is linked, a single mode named "default" is automatically created and set to be the current mode. If the **create_mode** command is used, the current_mode is set to the newly-created mode. You can set the current mode to a different mode with the **current_mode** command.

To create a collection of modes matching a pattern and optionally matching filter criteria, use the **get_modes** command. To get a collection of all modes in the design, use the **all_modes** command.

To undo **create_mode**, use the **remove_modes** command.

EXAMPLES

The following example creates a mode named "Mission5" and sets it to be the current mode.

```
prompt> create_mode Mission5
```

SEE ALSO

all_modes(2)
current_mode(2)
get_modes(2)
remove_modes(2)
create_corner(2)
set_scenario_status(2)

create_module

Creates one or more modules within a design.

SYNTAX

collection **create_module**
[-design *design*]
modules

Data Types

design collection
modules list

ARGUMENTS

-design *design*

Specifies the design to create the modules in. If no design is specified, the modules are created in the *current_design*.

modules

Specifies the names of the modules to be created in the design. Each module name must be unique.

DESCRIPTION

This command creates new modules in the current design. A module is a definition of logical hierarchy within a physical design block. The newly created modules are empty, they have no ports or cells. Instances of these modules may then be created with the **create_cell** command.

Unused modules may be deleted with the **remove_modules** command.

EXAMPLES

The following example creates a module named FOO.

```
prompt> create_module FOO
```

The following example creates modules named *MOD1*, *MOD2*, and *MOD3*.

```
prompt> create_module {MOD1 MOD2 MOD3}
```

SEE ALSO

create_cell(2)
current_design(2)
remove_modules(2)

create_multibit

Creates a multibit cell from a list of single-bit cells.

SYNTAX

status **create_multibit**
object_list
[-name *multibit_cell_name*]
-lib_cell *library_name/lib_cell_name*

Data Types

object_list list
multibit_cell_name string
library_name/lib_cell_name string

ARGUMENTS

object_list

Specifies a list of single-bit registers or latches or mv cells in the current design from which a multibit cell is created. The specified cells are removed from the netlist and replaced by the multibit cell. The order in which the cells are listed determines the order in which the nets are connected to the inserted cell.

-name *multibit_cell_name*

Specifies the name of the new multibit cell. If this option is omitted, the command derives a name by concatenating the names of *object_list*.

-lib_cell *library_name/lib_cell_name*

Specifies the name of the library reference cell used for the new cell. The bit-width of the specified library cell must be at least as large as the total bit-width of the cells specified in the *object_list*. You can specify only one library cell name. Specifying the library name along with the cell name (for example, my_lib/my_cell) is mandatory.

DESCRIPTION

The **create_multibit** command creates a new multibit cell from a list of registers or latches or mv cells in the current design. All the single-bit cells in *object_list* are replaced by one multi-bit cell.

The command verifies that the cells in the *object_list* exist in the design and have valid locations, and do not have a "dont_touch" or "fixed" attribute.

The order of the specified cells determines the pin connection order of the new multi-bit cell. For example, a net connected to the third specified cell in the *object_list* will be connected to the third bit of the multibit cell inserted by the command.

If the multi-bit library cell has a larger bit-width than the total bit-width of the specified cells, the pins of the unused bits of the cell are left dangling. If a pin of a specified cell does not have a corresponding pin in the multibit library cell, the tool disconnects the pin and issues a warning message.

To automatically generate a script containing **create_multibit** commands, use the **identify_multibit** command.

EXAMPLES

The following example creates a multibit register cell from 4 single-bit registers:

```
prompt> create_multibit -name group0_0 \
  {reg_1 reg_2 reg_3 reg_4} -lib_cell REG_4_BIT
```

SEE ALSO

identify_multibit(2)
split_multibit(2)

create_multisource_clock_sink_group

Defines sink groups for multisource clock tap assignment

SYNTAX

status **create_multisource_clock_sink_group**
-name *name*
-sinks *pins_or_ports*
[-driver_object *pins_or_ports_or_nets*]
-type exclusive | non_exclusive

Data Types

name	string
pins_or_ports	collection
pins_or_ports_or_nets	collection

ARGUMENTS

-name *name*

Specifies a name for the sink group. This option is required. The name can be used to refer to the sink group for reporting, removal, or modifications. Names have to be unique for all defined sink groups.

-sinks *pins_or_ports*

Specifies a list of clock sinks that should get assigned to the same tap driver as specified with the **-driver_object** option. If the **-driver_object** option is not specified the tool will assign the sinks to the closest tap driver available. A sink can only be assigned once to a sink group. Trying to assign a sink to multiple sink groups results in an error. The clock sinks have to be endpoints of the clock that gets assigned to the driver object using the **set_multisource_clock_tap_options** command.

-driver_object *pins_or_ports_or_nets*

This optional option specifies a driver object to which the sinks shall get assigned during tap assignment using the **synthesize_multisource_clock_taps** command. A driver object can either be a pin or port. If a net name is used, then the driver pin or port of that net is inferred as the driver object. Without using this option the group of sinks is assigned to the closest available tap driver.

-type exclusive | non_exclusive

Specifies the type of the sink group. The type can be either exclusive or non_exclusive. Exclusive means that no other sink which is not in that sink group can be assigned to the tap driver of that sink group. A non-exclusive sink group allows other sinks to get assigned to the tap driver of the sink group as well.

DESCRIPTION

The **create_multisource_clock_sink_group** command is used to define clock sinks to tap drivers. The assignment itself and the required netlist modifications are performed using the **synthesize_multisource_clock_taps** command. The sink group definition will only take effect if the driver object has also been assigned to a clock using the **set_multisource_clock_tap_options** command. Multiple sink groups can be assigned to the same driver object as long as they are non-exclusive.

An error is issued if a particular sink group with the given name has already been defined.

The **remove_multisource_clock_sink_groups** command can be used to remove sink groups that have been created with this command.

The **report_multisource_clock_sink_groups** command can be used to report sink groups created with this command.

The **get_multisource_clock_sink_groups** command can be used to obtain a collection of sink groups.

The **add_to_multisource_clock_sink_group** command can be used to add additional sinks to an existing sink group.

The **remove_from_multisource_clock_sink_group** command can be used to remove sinks from an existing sink group.

Attributes

Four attributes are defined on sink groups:

- name: a read-only attribute that returns the name of a sink group.
- sinks: a read-only attribute that returns the collection of sinks of a sink group.
- type: attribute that corresponds to the type (exclusive or non-exclusive) of a sink group. The attribute is read-write.
- driver_object: The driver of the sink group. The attribute is read-write.

The **get_attribute**, **set_attribute**, and **report_attributes** commands can be used to access these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

This example creates an exclusive sink group of two sinks.

```
create_multisource_clock_sink_group -name sink_group1
 -type exclusive
 -driver_object [get_pins {tap_driver1/Z}]
 -sinks [get_pins {reg1/CK reg2/CK}]
```

This example creates a non-exclusive sink group.

```
prompt> create_multisource_clock_sink_group -name sink_group1 \
  -type non_exclusive \
  -driver_object [get_pins {tap_driver2/Z}] \
  -sinks [get_pins {reg*/CK}]
```

This example creates a non-exclusive sink group without an explicit driver object.

```
prompt> create_multisource_clock_sink_group -name sink_group1 \
  -type non_exclusive \
  -sinks [get_pins {reg*/CK}]
```

create_mv_cells

Create power management cells including repeater, isolation and level shifter cells in the design based on UPF strategies.

SYNTAX

status **create_mv_cells**
[-isolation]
[-level_shifter]
[-map_ao_block]
[-mapped]
[-all]
[-generate_strategy level_shifter]
[-strategy_output *output_filename*]
[-all_blocks | -blocks *block_designs*]
[-host_options *host_option_name*]
[-verbose]

Data Types

output_filename string
block_designs collection
host_option_name string

ARGUMENTS

-all

Inserts repeater, isolation and level shifter cells in the design based on repeater, isolation and level shifter strategy settings. When the design has single rail cells without explicit connect_supply_net in AO Block Domain, the tool will remap such cells into dual rail cells.

-all_blocks

Create MV cells for all the child blocks in the current design and the current design itself. This option is mutually exclusive with *-blocks*. Only one of them can be specified at a time.

-blocks *block_designs*

Specifies the list of child block designs to create MV cells. This option is mutually exclusive with *-all_blocks*. Only one of them can be specified at a time.

-host_options *host_option_name*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

-isolation

Inserts isolation cells in the design based on isolation strategy settings. If there is no user isolation strategy, isolation cells will not be inserted. The tool automatically triggers repeater insertion based on repeater strategy settings.

-level_shifter

Inserts level shifter cells in the design based on level shifter strategy settings. The tool automatically triggers repeater insertion based on repeater strategy settings.

-map_ao_block

When the design has single rail cells without explicit connect_supply_net in AO Block Domain, the tool will remap the cells into dual rail cells.

-mapped

By default, tool will insert new repeater, level shifter and isolation cells from GTECH library only. When -mapped option is specified, tool will insert new repeater, level shifter and isolation cells from user libraries only. Existing GTECH repeater, level shifter and isolation cells in the design will be updated to user library cells.

-generate_strategy level_shifter

If no level shifter strategy is loaded in the UPF, the tool can generate general level shifter strategies based on domain supply voltage shifting status. If there is no voltage shifting among all domain supplies, no strategy is generated. The **-generate_strategy** option only supports the *level_shifter* keyword.

This option can be combined with the **-strategy_output** option. If **-strategy_output** specifies an output file, strategies generated will be written out to the output file only and the tool will not perform level shifter cell insertion based on the strategy. If **-strategy_output** is not specified, the tool continues to do automatic level shifter insertion based on the strategy generated internally. The strategies can be written out in the UPF derived session.

-strategy_output *output_filename*

If the **-generate_strategy level_shifter** option is specified together with **-strategy_output output_filename**, the tool generates general level shifter strategies based on domain supply voltage shifting status and writes out all strategies to the specified file. You can modify the strategies and reload them into the tool.

-verbose

Prints out additional debug messages when inserting power management cells. Currently the verbose messages only include debugging information for level shifter cell insertion.

DESCRIPTION

This command creates power management cells in the design based on UPF strategies.

In addition, this command applies optimization restrictions (dont-touhces) on the nets between isolation, level shifter, repeaters cells and their corresponding power domain boundaries. Buffers might be inserted on these nets to prevent them from being over-constrained.

EXAMPLES

The following example inserts repeater, isolation and level shifter cells in the design based on UPF strategies:

```
prompt> create_mv_cells -all
Information: Total 20 repeater cells have been inserted. (MV-054)
Information: Total 51 isolation cells have been inserted. (MV-054)
Information: Total 51 isolation cells have been associated. (MV-021)
Information: Total 30 level shifter cells have been inserted. (MV-054)
Information: Total 0 MV restriction buffer cells have been inserted. (MV-054)
1
```

set_level_shifter(2)

create_net

Creates one or more power, ground, tie, or signal nets.

SYNTAX

collection **create_net**
[-design *design*]
[-power | -ground | -tie_high | -tie_low]
[-cell *cell*]
net_names

Data Types

design collection
cell collection
net_names list

ARGUMENTS

-design *design*

Specifies the design in which to create the nets. If no design is specified, the nets are created in the current design.

-power

Specifies that power nets should be created.

-ground

Specifies that ground nets should be created.

-tie_high

Specifies that tie-high nets should be created.

-tie_low

Specifies that tie-low nets show be created.

net_names

Specifies the names of the nets to be created in the design. Each net name must be unique.

-cell cell

Specifies the cell where the net is to be added. The net is created in the cell's reference module. The cell must not reference a library cell, unless this command is executed in the library manager. In the library manager, nets may be created in library cells.

When not specified, the net is created in the current module.

DESCRIPTION

This command creates new nets in the current design (unless otherwise specified by -design). It creates only scalar (single-bit) nets. One net is created for each of the names listed.

This command can create PG, tie, or signal nets. If no net type is specified, the command creates signal nets.

Nets connect ports and pins in a design. The **create_net** command creates nets, but does not connect the nets. To establish this connection, use the **connect_net** or **connect_pg_net** commands.

EXAMPLES

The following example creates signal nets named *N1*, *N2*, *N3*, and *N4*.

```
prompt> create_net {N1, N2, N3, N4}
```

The following example creates a power net named *VDD*.

```
prompt> create_net -power VDD
```

SEE ALSO

remove_nets(2)

create_net_bus

Creates a net bus.

SYNTAX

collection **create_net_bus**
[-design *design*]
[-block *block*]
[-cell *cell*]
[-create_nets]
net_bus_name

Data Types

design collection
block collection
cell collection
net_bus_name string

ARGUMENTS

-design *design*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

-block *block*

Specifies the block where the net bus is to be added. If specified, **create_net_bus** has the same effect as **edit_module** in which the module is changed and changes are applied to all module occurrences.

-cell *cell*

Specifies the cell where the net bus is to be added. The net bus is created on the cell's reference module. **create_net_bus** first uniquifies the reference if needed, then creates the net bus. When not specified, the net bus is created on the current module.

-create_nets

Creates net bus members if they do not exist.

net_bus_name

Specifies the net bus name and its range using the **name [start: end]** format. Specify a net bus named busA with net from 1 *to* 5 as **busA[1:5]**. Specify a net bus named busB with net from 5 *downto* as **busB [5:1]**.

DESCRIPTION

This command creates a net bus, collects or creates net bus members, and puts them into the net bus created.This supports creating n-dimensional bus.

The command returns the created net_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates net bus named *bus1* from net 1 to 5 as bus[1], bus[2], bus[3], bus[4], bus[5]

```
prompt> create_net_bus bus1[1:5]
{"bus1"}
```

The following example first creates nets, then creates a net bus named *bus2* from the created net with indexes 5 downto 1 as bus2[5], bus2[4], bus2[3], bus2[2], bus2[1]

```
prompt> create_net_bus bus2[5:1] -create_nets
{"bus2"}
```

create_net_priority

Creates an analog constraint group with net_priority intent in the current design.

SYNTAX

collection **create_net_priority**
[*constraint_group_name*]
-for *objects*
[-priority *int*]
[-force]

Data Types

constraint_group_name string
objects collection
int integer

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group. If not specified then a system generated name is assigned.

-for *objects*

Specifies the objects - can be nets, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

-priority *int*

Specifies the priority of routing for the constituent objects. Objects with higher priority will be routed first. Priority values can be given from -128 to 128. Default is zero.

-force

Specifies force deletion of existing constraint group by the same name as specified and recreation of new constraint group. Default is false where the command exits with error if same name is encountered.

DESCRIPTION

The **create_net_priority** command enables you to create a constraint group for a collection of nets, bundles, and topology_edges with net_priority intent. The constraint is used by Custom Router. All the constituent objects will be routed with same priority and will

be routed before other objects that have lower priority.

EXAMPLES

The following example creates a constraint group named 'abc' for nets and bundles matching the pattern 'pr*' with net_priority intent and priority of 15. The 'pr*' nets are routed with Custom Router.

```
prompt> create_net_priority abc -for pr* -priority 15 {abc}
```

SEE ALSO

get_constraint_groups(2)
remove_constraint_groups(2)
report_constraint_groups(2)

create_net_shielding

Creates an analog constraint group with shielding intent in the current block.

SYNTAX

collection **create_net_shielding**
[*constraint_group_name*]
-for *objects*
[-shield_net *net*]
[-shield_net_2 *net*]
[-gap *distance*]
[-width *distance*]
[-max_gap *distance*]
[-min_segment *distance*]
[-sharing true | false | unset]
[-enclose_pins true | false | unset]
[-enclose_vias true | false | unset]
[-via_defs *via_defs*]
[-disabled_layers *layers*]
[-layer_widths *widths*]
[-layer_gaps *gaps*]
[-layer_max_gaps *gaps*]
[-group_shield]
[-force]

Data Types

constraint_group_name string
objects collection
net collection
distance float
via_defs string
layers string
widths list
gaps list

ARGUMENTS

constraint_group_name

Specifies the name of the constraint group.

By default, the command generates a unique constraint group named shielding_*n*, where *n* is a unique, monotonically increasing integer value.

-for *objects*

Specifies the objects that constitute the analog constraint group. The objects can be nets, bundles, or topology_edges. You can specify the objects as a list of object names or as a collection of objects.

-shield_net *net*

Specifies the net to connect to shield material. For single signal routing, the tool uses this net for the left and bottom shields.

-shield_net_2 *net*

Specifies the net to connect to secondary shield. For single signal routing, the tool uses this net for the top and right shields.

-gap *distance*

Specifies the layer-independent spacing between route objects and shield objects.

The default is 0.

-width *distance*

Specifies the layer-independent width for shielding material.

The default is 0.

-max_gap *distance*

Specifies the layer-independent maximum spacing between route objects and shield objects.

The default is 0.

-min_segment *distance*

Specifies the minimum length of wiring to shield.

The default is 0.

-sharing true | **false** | **unset**

Specifies whether shielding can be shared between constituent objects of the constraint group.

Allowed values are **false**, **true**, and **unset**.

The default is **unset**.

-enclose_pins true | **false** | **unset**

Specifies whether pins are enclosed by the shield. This option is mutually exclusive with *-group_shield* option.

Allowed values are **false**, **true**, and **unset**.

The default is **unset**.

-enclose_vias true | **false** | **unset**

Specifies whether vias are enclosed by the shield.

Allowed values are **false**, **true**, and **unset**.

The default is **unset**.

-via_defs *via_defs*

Specifies the via definition names to be used to connect to the shield.

By default, all via definitions can be used.

-disabled_layers ***layers***

Specifies the layer names that are not to be used for shielding.

-layer_widths ***widths***

Specifies the width of a layer used for shielding.

This is a list of alternating layer and width values, where the layer is a string and the width is a floating point number. For example, {M1 5.0 M2 6.0}.

-layer_gaps ***gaps***

Specifies the gap of shielding material from wiring material.

This is a list of alternating layer and gap values, where the layer is a string and the gap is a floating point number. For example, {M1 5.0 M2 6.0}.

-layer_max_gaps ***gaps***

Specifies the maximum gap of shielding material from wiring material.

This is a list of alternating layer and maximum gap values, where the layer is a string and the maximum gap is a floating point number. For example, {M1 5.0 M2 6.0}.

-group_shield

Specifies whether a single set of shield shapes can be used to shield all nets of the constraint group. This option is mutually exclusive with *-enclose_pins* option.

-force

Forces the deletion of an existing constraint group if the name matches the specified *constraint_group_name* argument.

By default, the command exits with an error if the name already exists.

DESCRIPTION

Some signal nets require isolation or shielding to allow the circuit to function correctly. Whether it is to reduce crosstalk or parasitic effects, some nets must be shielded.

The **create_net_shielding** command creates a constraint group for a collection of nets, bundles, and topology_edges with shielding intent to achieve the necessary shielding. The constraint is used by the Custom Router tool.

Each of the constituent objects are shielded separately as per the requirements specified in the constraint group. Use this constraint to specify which layers to constrain and any layer-specific requirements.

EXAMPLES

The following example creates a constraint group with a system-generated name that describes the shielding intent for nets whose name starts with "pr". A gap of 3 is used for the M2 layer and a gap of 5 is used for the M3 layer. All constituent objects can share the shield and the M5 and M6 layers cannot be used for shielding. The 'pr*' nets are routed with the Custom Router tool.

```
prompt> create_net_shielding -for pr* -disabled_layers {M5 M6} \
  -sharing true -layer_gaps {M2 3 M3 5}
{shielding_4}
```

create_pad_rings

Creates pad rings with simplified options control.

SYNTAX

status **create_pad_rings**
[-create *create_opt*]
[-nets *netname_list*]
-route_pins_on_layer *layer_opt*
[-min_target_layer *layer_opt*]
[-max_target_layer *layer_opt*]
[-drc *drc_opt*]
[-sides *side_opt*]
[-undo]

Data Types

create_opt specification
netname_list list
layer_opt specification
drc_opt specification
side_opt specification

ARGUMENTS

-create all | pg | specified_net

Creates pad rings for all pad pins, all pg pins, or pins with the specified nets. If the **-nets** options is specified, *all* and *pg* will be ignored. This argument is optional.

-nets *netname_list*

Specifies a list of nets on which to create pad rings. This argument is optional.

-route_pins_on_layer *layer_opt*

Creates pad rings on the specified metal layers. This argument is required.

-min_target_layer *layer_opt*

Specifies the lowest metal layer to create via for. This argument is optional.

-max_target_layer *layer_opt*

Specifies the highest metal layer to create via for. This argument is optional.

-drc no_check | check_but_no_fix

Specifies the DRC option for PG pad ring creation. The argument following **-drc** must be either *no_check* or *check_but_no_fix*. *no_check* specifies that no DRC check is performed. *check_but_no_fix* specifies that DRC check is performed and DRC errors are reported, but no DRC fixing is performed. By default, DRC is checked and fixed for the PG pad ring creation.

-sides *side_opt*

Specifies the side option for PG pad ring creation to support connections on aligned pins between neighboring pad cells. The syntax of the *side_opt* argument is *{{side start end} {side start end} ...}* where *side* is one of the following keywords: *left*|*right*|*top*|*bottom*. For *left* and *right* sides, the connection will be vertical and for *top* and *bottom* sides the connection will be horizontal. *start* and *end* denote the coordinate ranges to search for pad cells. It can be inside the core area as well. For *left* and *right* sides they are x coordinates and y for *top* and *bottom* sides.

-undo

Removes pad rings and corresponding vias created by this command and restores the shapes to their original condition before running the **create_pad_rings** command.

DESCRIPTION

This command creates PG pad rings and provides a simple user interface. This command automatically calculates the required information to create pad rings and provides a simpler user interface than the **create_pg_ring_pattern** command.

EXAMPLES

The following example performs PG pad ring creation on metal layer M8 for all PG nets.

```
prompt> create_pad_rings -create pg -route_pins_on_layer {M8}
```

The following command performs PG pad ring creation on metal layer M8 for nets VDD and VSS without checking for DRC violations.

```
prompt> create_pad_rings -nets {VDD VSS} \
   -route_pins_on_layer {M8} -drc no_check
```

The following command connects horizontally aligned pins of adjacent pad cells whose y coordinates fall between 0um and 700 um and between 1000um and 1700um.

```
prompt> create_pad_rings -create all  \
   -route_pins_on_layer {M4 M5} -sides {{bottom 0 700} {top 1000 1700}}
```

set_pg_strategy(2)

create_pg_composite_pattern

Creates a power ground composite pattern. This composite pattern can be defined hierarchically based on low-level patterns such as the basic wire patterns, or other composite patterns.

The composite pattern can be instantiated in a design by the **set_pg_strategy** command to create a power ground mesh.

SYNTAX

status **create_pg_composite_pattern**
pattern_name
[-nets *net_list*]
[-parameters *var_list*]
-add_patterns *pattern_expr*
[-via_rule *via_rule_spec*]

Data Types

pattern_name string
net_list list
var_list list
pattern_expr specification
via_rule_spec specification

ARGUMENTS

pattern_name

Specifies the name of the composite pattern.

-nets *net_list*

Specifies power and ground net names used in this composite pattern. The net names are symbolic names and are mapped from net names specified from a high-level command, that is, either from the symbolic net names in another **create_pg_composite_pattern** command or from the real net names in the **set_pg_strategy** command.

The net mapping is by position. For example, the first net name in a high-level command maps to the first net name in the low-level command, the second net name in a high-level command maps to the second net name in the low-level command, and so on.

If this option is not specified, the list of nets from its high-level command is mapped to its low-level patterns in the same order. If the low-level patterns have different orders or net names, you must specify this option, and specify the order of net names in **-add_patterns** option. If net-based via rules are needed in this composite pattern, net names should also be provided using this option for filtering purpose.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and passed into the low-level patterns used by this composite pattern. This allows the pattern to be programmed and reused by specifying different parameters for different situations. Each parameter *var* in the list *var_list* is a string. The "@" character is used as a prefix keyword to evaluate the parameter, for example, @*var*. Refer to the example section for more details.

-add_patterns *pattern_expr*

Specifies the low-level patterns for this composite pattern. Each low-level pattern is either a wire pattern created by the **create_pg_wire_pattern** command, or a composite pattern created by the **create_pg_composite_pattern** command. The low-level pattern cannot be the current composite pattern or contain the current composite pattern as its low-level pattern, that is, you must not create a recursive definition. Each pattern is specified by a pattern expression *pattern_expr* in the following syntax:

{name: *child_pattern_name*}
{nets: *sub_net_list*}
{parameters: *sub_var_list*}
{offset: {*x_offset y_offset*}}
{pitch: {*x_pitch y_pitch*}}
{repeat {*x_num y_num*}}

The **name** keyword followed by *child_pattern_name* specifies the low-level pattern name to add to the current composite pattern.

The **nets** keyword followed by *sub_net_list* specifies the net name list to map into the symbolic list of nets in *child_pattern_name*. Each net name in *sub_net_list* must be one of the net names specified in **-nets** in the current composite pattern. The index of the *i_th* net in *sub_net_list* is *i*. If not specified, the list of nets from the current composite pattern is used for mapping.

The **parameters** keyword followed by *sub_var_list* specifies the parameter list to pass into the low-level pattern *child_pattern_name*. Each parameter can be either a value, such as 0.5 for wire width, or a variable evaluation, such as "@w" for wire width. "w" should be a parameter specified in **-parameters** in the current composite pattern.

The **offset** keyword followed by {*x_offset y_offset*} specifies the horizontal and vertical offsets when applying the low-level pattern *child_pattern_name* in the current composite pattern. The offset is applied to the origin of the low-level pattern *child_pattern_name*. The offset value is relative to the current composite pattern origin. By default, the offset is 0 for both horizontal and vertical offsets, and the origin of low-level pattern is the same as the current composite pattern origin.

The **pitch** keyword followed by {*x_pitch y_pitch*} specifies the horizontal and vertical pitches when applying and repeating the low-level pattern *child_pattern_name* in the current composite pattern. The pitch is the distance between two adjacent low-level *child_pattern_name* patterns. By default, the pitch is 0 for both horizontal and vertical pitches and the low-level pattern is not repeated.

The **repeat** keyword followed by {*x_num y_num*} specifies the horizontal and vertical repeating numbers when duplicating the low-level pattern *child_pattern_name* in the current composite pattern. By default, the low-level pattern *child_pattern_name* is repeated horizontally and vertically by the specified pitches until the pattern reaches the routing area boundary.

You can specify multiple pattern expressions and separate them by curly brace pairs. For example, one pattern expression per low-level pattern is within a pair of curly braces. The index of the *i_th* low-level pattern added into this composite pattern is *i*.

-via_rule *via_rule_spec*

Specifies the via rule *via_rule_spec* between wires in this composite pattern. The via rule defines the intersection locations and the via at the locations. The rule will only apply between layers of composite pattern, but won't apply between layer of composite pattern and layer of other pattern. Users must define using set_pg_strategy_via_rule if control is needed between layer of composite pattern and layer of other pattern.

There are several methods to define the intersection locations in the *via_rule_spec* specification, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules

The first method is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any two orthogonal wires on any different layer.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword and **adjacent** refers to all intersections between any two orthogonal wires only between adjacent layers.

The third method is to define the intersections based on two sets of wire shapes using *list_of_filter_rules*. The rules contain a list of filtering rules. Each filtering rule is defined inside a curly brace pair. The syntax of each filtering rule is as follows:

{{*set_1*}{*filter_1*}} {{*set_2*} {*filter_2*}} {*via_def*} |
{**intersection** : undefined} {*via_def*}

where *set_1* refers to the first set of wire shapes and *filter_1* refers to the filtering operations for this set. *set_2* and *filter_2* refer to the second set of wire shapes and the filtering operations for the second set, respectively. *set_1* or *set_2* is defined as below:

{**pattern** : *pattern_name*}

where **pattern** is the keyword and *pattern_name* refers to one of the low-level patterns added to the current composite pattern by the **-add_patterns** option.

You can perform filtering operations on the set of wire shapes to obtained a subset of shapes. The filters are *filter_1* and *filter_2* in the previous example. The filtering operation is defined as follows:

{**net_id** : *n_id*} |
{**nets** : *net_list*} {**layers** : *layer_list*}
{**width** : {*lower_w upper_w*}

where **net_id** is the keyword and *n_id* refers to the ID of the specified low-level pattern. The index of the *i_th* net in *sub_net_list* is *i* when specifying the low-level pattern. The subset of wire shapes contains the wires with the specified *n_id*. Net ID is useful when there are multiple nets with the same names within the list of nets in the low-level pattern. Alternatively, **nets**, **layers**, **width** keywords can be used to specify the wire net names by *net_list*, wire layer names by *layer_list*, or a width range by {*lower_w upper_w*}. Only the wire shapes in the lower-level pattern which also satisfy the filtering categories form a subset of wire shapes. Here, *net_list* contains a list of net names, *layer_list* contains a list of layer names, and {*lower_w upper_w*} defines the lower and upper range of the wire width. By specifying two sets of wires by pattern names or pattern IDs and certain filtering operations by net IDs, net names, layer names or wire width ranges, the via locations are the intersections between these two sets of wire shapes. For those intersections which do not belong to any filtering rule, the via definition can be specified by

{**intersection** : undefined}{*via_def*}

where the **intersection** keyword followed by **undefined** refers to the remaining intersections which do not belong to any filtering rules. By default, the tool does not create vias at the intersections which do not belong to any filtering rules, unless specified. Multiple via filtering rules, such as intersection location and via definition, can be defined and separated by curly braces where each filter rule is in one curly brace pair.

With the intersection definition, the via specification {*via_def*} is in the following format:

{**via_master** : *via_master_list*}

where the **via_master** keyword followed by *via_master_list* specifies the list of via masters. Via masters include the via contact code defined in the technology file, or user-defined via cells. The **via_master** keyword followed by *via_rule_list* specifies a list of via master rules. Via master rules are defined by **set_pg_via_master_rule** command. **NIL** can be used as a keyword indicate that no via should be created. **default** can be used to describe the default vias in the specified location. For each specified intersection, vias are created based on the specified via masters or via master rules. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection of orthogonal wires in different layers.

DESCRIPTION

Creates a power ground composite pattern. This composite pattern can be defined hierarchically based on other low-level patterns such as the basic wire patterns using **create_pg_wire_pattern**, or other composite patterns using this command.

The via rules can also be defined between any wire shapes in this composite pattern. Each via rule contains the intersection location and the via definition by via master or via cell.

The composite pattern can be instantiated in a design by the **set_pg_strategy** command to create a power ground mesh.

EXAMPLES

The following example creates a composite pattern, checker_board, with one horizontal wire pattern hor_wire, one vertical wire pattern ver_wire, and the checker board via rule between two wire patterns. Note that net_id is used to specify the checker board via rule.

```
prompt> create_pg_composite_pattern checker_board -nets {VDD} \
  -parameters {ver_layer hor_layer ver_width hor_width ver_pitch hor_pitch} \
  -add_patterns { \
    {{name:ver_wire}{nets: {VDD VDD}} \
      {parameters: {@ver_layer @ver_width}}\
      {pitch: {0 @ver_pitch}} } \
    {{name:hor_wire}{nets: {VDD VDD}} \
      {parameters: {@hor_layer @hor_width}}\
      {pitch: {@hor_pitch 0}} } \
  } \
  -via_rule { \
    {{{pattern: ver_wire}{net_id: 1}} \
     {{pattern: hor_wire}{net_id: 1}}\
       {via_master: default}} \
    {{{pattern: ver_wire}{net_id: 2}}
     {{pattern: hor_wire}{net_id: 2}} \
       {via_master: default}} \
    {{{pattern: ver_wire}{net_id: 1}} \
     {{pattern: hor_wire}{net_id: 2}} \
       {via_master: NIL}} \
    {{{pattern: ver_wire}{net_id: 2}} \
     {{pattern: hor_wire}{net_id: 1}} \
       {via_master: NIL}} \
  }
```

The following example creates a composite pattern which contains wire pattern from layer M3 to M8, strap3, strap4, strap5, strap6 strap7 and strap8. The nets of the composite pattern is pwr and gnd, which are symbolic. The nets for each low-level wire pattern are in different order. The via rule is specified as adjacent, that is, the default via is created at each intersection between any orthogonal wires in adjacent layers.

```
prompt> create_pg_composite_pattern m3_to_m8 -nets {pwr gnd} \
  -add_patterns { \
    {{name:strap3}{nets:{gnd gnd pwr pwr}}{pitch:6.6} \
      {offset:{1.02 0}}}\
```

```
    {{name:strap4}{nets:{pwr gnd}}{pitch:{0 7.8}} \
      {offset:{0 5.9}}} \
    {{name:strap5}{nets:{gnd pwr}}{pitch:{6.6 0}} \
      {offset:{1.8 0}}} \
    {{name:strap6}{nets:{pwr gnd}}{pitch:{0 7.8}} \
      {offset:{0 5.9}}} \
    {{name:strap7}{nets:{gnd pwr}}{pitch:{14 0}}  \
      {offset:{1.8 0}}} \
    {{name:strap8}{nets:{gnd pwr}}{pitch:{0 9.6}} \
      {offset:{0 6.6}}} \
  } \
  -via_rule {{intersection: adjacent}{via_master: default}}
```

The following example creates a composite pattern composed of two wire patterns on layers M3 and M5. Vias with the via master Via_via35 are added between parallel wires M3 and M5.

```
set_pg_via_master_rule Via_via35 -contact_code {via3_CUST via4_CUST} \
  -via_array_dimension {2 1} \
  -allow_multiple {2.508 0.48} -cut_spacing {0.054 0.090}
create_pg_wire_pattern pg_wire -layer @l -direction @d -width @w \
  -pitch @p -spacing @s -parameters {l d w p s}
create_pg_composite_pattern pg_pat -nets VSS \
  -add_patterns { \
    {{pattern: pg_wire} {nets: VSS}
      {parameters: {M3 vertical {0.19 } 2.508 interleaving}}
      {offset: 02.508}} \
    {{pattern: pg_wire} {nets: VSS} \
      {parameters: {M5 vertical {0.23 } 2.508 interleaving}} \
      {offset: 02.508}} \
  } \
  -via_rule { \
    {{pattern_id: 1} {pattern_id: 2} \
      {via_master: Via_via35} {between_parallel: true}} \
      {{intersection: undefined} {via_master: NIL}} \
  }
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: **gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"**.

create_pg_macro_conn_pattern

Creates a macro power ground connection pattern. Use the **set_pg_strategy** command to instantiate the pattern and connect macros to the power ground network.

SYNTAX

status **create_pg_macro_conn_pattern**
pattern_name
-pin_conn_type long_pin | ring_pin | scattered_pin
[-nets *net_list*]
[-parameters *var_list*]
[-direction horizontal | vertical | @*var*]
[-width *width* | {*hor_width ver_width*} | @*var*]
-layers *layer_name* | {*hor_layer ver_layer*} | @*var*
[-spacing minimum | interleaving | *spacing* |
{*hor_space ver_space*} | @*var*]
[-pitch *pitch* | {*hor_pitch ver_pitch*} | @*var*]
[-number *num* | {*hor_num ver_num*} | @*nvar*]
[-excluded_pins *pin_filter_spec*]
[-via_rule *via_rule_spec*]
[-pin_layers *layer_list* | @*var*]

Data Types

ver_space float
pitch float
hor_pitch float
ver_pitch float
num integer
hor_num integer
ver_num integer
nvar string
pin_filter_spec specification
via_rule_spec specification
layer_list list of string

ARGUMENTS

pattern_name

Specifies the name of the macro pattern.

-pin_conn_type long_pin | ring_pin | scattered_pin

Specifies the macro pin and connection types. This is a required option and you must specify the **long_pin**, **ring_pin** or **scattered_pin** keyword. The long_pin keyword refers to long pins in the macro; orthogonal straps will be created for connection. The ring_pin keyword refers to internal ring pins inside the macro; finger connections will be created to connect the ring pin to a strap or external macro ring in the external power network. The scattered_pin keyword refers to the irregular pin shapes scattered inside the macro; extension straps will be created to connect scattered pins to the external power network.

-nets *net_list*

Specifies power and ground net names used in this macro connection pattern. The net names are symbolic names and will be mapped from net names specified by using real net names in the **set_pg_strategy** command.

The net mapping is by position, that is, the *i_th* net name in **set_pg_strategy** command maps to the net name in the same position in this command. This option is not required and is needed when pin filtering based on net name is required. For example, use this option if certain nets can be skipped or pin connections in different nets have different via rules.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used by other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string and the at character (@) is used as a prefix to evaluate the parameter, such as *@var*. See the example section for more details.

-direction horizontal | vertical | *@var*

Specifies the direction of macro long pin connection straps. This option is required when you specify **-pin_conn_type long_pin**, otherwise, this option is ignored. This option specifies the direction for connection straps, not macro pins. The direction could be "horizontal", or "vertical", or specified by evaluating the variable *var* in the **-parameters** option. For parameters, the at character (@) is used as a prefix to evaluate the variable.

-width *width* | {*hor_width ver_width*} | *@var*

Specifies the width of the macro pin connection straps. If you specify **-pin_conn_type long_pin**, only one width value is required. Otherwise, the horizontal width and vertical width must be specified with *hor_width* and *ver_width*, respectively. The unit is defined in the technology file.

The width can also be specified by evaluating the variable *var* in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum width defined in the technology file is used if this option is not specified.

-layers *layer_name* | {*hor_layer ver_layer*} | *@var*

Specifies the layer of the macro pin connection straps. This is a required option. If you specify **-pin_conn_type long_pin**, only one layer *layer_name* is required. Otherwise, the horizontal and vertical layers must be specified with *hor_layer* and *ver_layer*, respectively.

The layer names can be also specified by evaluating the variable *var* in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable.

-spacing minimum | interleaving | *value* | {*hor_space ver_space*} | *@var*

Specifies the spacing between macro connection straps in the pattern. This option only applies if you specify **-pin_conn_type long_pin** or **-pin_conn_type ring_pin**. If you specify **-pin_conn_type scattered_pin**, this option is ignored.

minimum keyword refers to the minimum spacing between connection straps defined in the technology file, based on the wire width. **interleaving** keyword means that the distance between adjacent center lines of connection straps is equal.

Specific values can also be used for spacing. If you specify **-pin_conn_type long_pin**, only one *value* is required. If you specify **-pin_conn_type ring_pin**, the horizontal and vertical spacing values must be specified with *hor_space* and *ver_space*, respectively.

The spacing can also be specified by evaluating the variable *var* in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum spacing is used if this option is not specified.

-pitch *pitch* | {*hor_pitch ver_pitch*} | @*var*

Specifies the pitch of macro connection straps in the pattern. The pitch only applies if you specify **-pin_conn_type long_pin** or **-pin_conn_type ring_pin**. If the connection type is **scattered_pin**, the pitch is ignored.

If the connection type is **long_pin** or **ring_pin**, at least one of the **-pitch** or **-number** options must be specified. If both options are specified, both options are honored. Otherwise, one value is derived from another by evenly distributing the connection straps in the macro.

If the pin connection type is **long_pin**, one *value* must be specified for the pitch value. If the type is **ring_pin**, horizontal and vertical pitch values must be specified by *hor_pitch* and *ver_pitch*, respectively. The unit is defined in the technology file. The pitch values can also be specified by evaluating the variable *var* in the **-parameters** option. The at character (@) is used as a prefix to evaluate the variable.

-number *num* | {*hor_num ver_num*} | @*var*

Specifies the repeating number of macro connection straps in the pattern. It only applies if you specified **-pin_conn_type long_pin** or **-pin_conn_type ring_pin**. If the connection type is **scattered_pin**, the number is ignored.

If the connection type is **long_pin** or **ring_pin**, at least one of **-pitch** or **-number** option must be specified. If both are specified, both are honored. Otherwise, one value is derived from another by evenly distributing the connection straps in the macro.

If the pin connection type is **long_pin**, one *num* must be specified for the repeating pattern. If the type is **ring_pin**, horizontal and vertical numbers must be specified by *hor_num* and *ver_num*, respectively. The repeating number can also be specified by evaluating the variable *var* in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable.

-excluded_pins *pin_filter_spec*

This option is not required. This option only applies when you specify **-pin_conn_type scattered_pin**.

For **scattered_pin** connection type, certain pin shapes that satisfy the *pin_filter_spec* specification can be excluded for connection. The *pin_filter_spec* specification uses the following format:

{**layers** : *layer_list*}

where **layers** is the keyword for pin layers. *layer_list* is a list of strings which contains a list of layer names. The pin shapes which satisfy the above criteria are excluded from connection. By default, all pin shapes are connected if this option is not specified.

-via_rule *via_rule_spec*

Specifies the via rule *via_rule_spec* between connection straps and macro pins in this macro connection pattern. The via rule defines the intersection locations and the via at the locations.

There are several ways to define the intersection locations in the specification *via_rule_spec*, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |

list_of_filter_rules |

The first method is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any two connection strap and macro pin across any layers.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword and **adjacent** refers to all intersections between any two connection strap and macro pin only in adjacent layers.

With the intersection definition, the via specification {*via_def*} uses the following format:

{**via_master** : *via_master_list*}

where **via_master** is the keyword for via masters including via contact code defined in the technology file or user-define via cells, or the PG via rules defined by **set_pg_via_master_rule** command. The *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or replication is needed, via rules specified by **set_pg_via_master_rule** command can be used. The *via_master_list* can also contain a list of PG via rules. **NIL** can be used as a keyword to indicate that no via is created. **default** can be used to describe the default vias in the specified location. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection of orthogonal connection straps and macro pins in different layers.

-pin_layers ***layer_list*** | ***@var***

Specifies a list of layers for allowed pin connections. Only pins on the specified layers can be used for a PG connection. If not specified, pins on all layers will be considered for a PG connection.

DESCRIPTION

Creates a macro power ground connection pattern. This pattern can be instantiated in a design with the **set_pg_strategy** command to connect macros to the power ground network. There are three types of macro connections: **long_pin**, **ring_pin** and **scattered_pin**. This pattern can be also applied to power pad connection.

EXAMPLES

The following example creates a macro connection pattern with long pin type. The pattern name is long_pin_pattern, the connection strap direction is horizontal, the layer is M5, symbolic net names are pwr and gnd respectively and width, spacing, pitch are specified through parameters w, s and p respectively. Default vias are created at all intersections between connection straps and macro pins.

```
prompt> create_pg_macro_conn_pattern long_pin_pattern \
  -pin_conn_type long_pin -nets {pwr gnd} \
  -direction horizontal -width @w \
  -layers M5 -spacing @s -pitch @p \
  -parameters {w s p}
```

The following example creates a macro connection pattern with ring pin type. The pattern name is ring_pin_pattern. The horizontal and vertical layers are M5 and M6 respectively. Width, spacing, pitch are specified by parameters.

```
prompt> create_pg_macro_conn_pattern ring_pin_pattern \
  -pin_conn_type ring_pin \
  -width {@hor_w @ver_w} -layers {M5 M6} \
```

```
    -spacing {@hor_s @ver_s} -pitch {@hor_p @ver_p} \
    -parameters {hor_w ver_w hor_s ver_s hor_p ver_p}
```

The following example creates a macro connection pattern with scattered pin connection type. The pattern name is scatter_pin_pattern. The connection strap width is specified with parameters. Horizontal and vertical layers are M5 and M6 respectively. Default vias are created between macro pins and connection straps.

```
prompt> create_pg_macro_conn_pattern scatter_pin_pattern \
  -pin_conn_type scattered_pin -nets {pwr gnd} \
  -width {@hor_w @ver_w} -layers {M5 M6} \
  -parameters {hor_w ver_w}
```

MORE EXAMPLES

create_pg_mesh_pattern

Creates a power ground mesh pattern. The mesh pattern can be instantiated in a design by **set_pg_strategy** command to create power ground mesh.

SYNTAX

status **create_pg_mesh_pattern**
pattern_name
-layers *layer_expr*
[-parameters *var_list*]
[-via_rule *via_rule_spec*]

Data Types

pattern_name string
layer_expr specification
var_list list
via_rule_spec specification

ARGUMENTS

pattern_name

Specifies the name of the mesh pattern.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used by other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string and the at character (@) is used as a prefix to evaluate the parameter, such as *@var*. See the example section for more details.

-layers *layer_expr*

Specifies the layer configuration for this mesh pattern. Each layer is specified by a *layer_expr* expression in the following syntax:

{horizontal_layer | vertical_layer: *layer_name* | *@var*}
{width: minimum | *value_list* | *@var*}
{spacing: interleaving | minimum | *value_list* | *@var*}
{offset: *offset_value* | *@var*}
{pitch: *pitch_value* | *@var*}
{trim : true | false | *@var*}
{track_alignment : track | half_track | auto | *@var*}
{mask : mask_one | mask_two | mask_three | mask_one_mask_two_alternate |
mask_two_mask_one_alternate | *@var*}

{mask_constraint : *constraint_name*}

where the specification contains several keywords, **horizontal_layer** or **vertical_layer**, **width**, **offset**, **pitch**, **spacing**, **trim**, **mask** and **mask_constraint**.

The **horizontal_layer** or **vertical_layer** keyword specifies the layer name for this layer. Only one of **horizontal_layer** and **vertical_layer** can be specified within one layer. The layer name is specified by *layer_name* or by evaluating the variable *var* in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. The layer name is a required option in the layer spec.

The **width** keyword specifies the width of this layer. "minimum" refers to the minimum wire width defined in the technology file. *value_list* contains a list of width values, where the width value is a float-type value with units defined in the technology file. If the number of width values is smaller than the number of nets from the **set_pg_strategy** command, the last width value is assumed for the extra nets. The width can also be specified by evaluating the *var* variable in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum width is used if this option is not specified.

The **offset** keyword specifies the offset value. *offset_value* is the offset applied to the center line of the first wire to the boundary of the routing region or a specified absolute coordinate in **set_pg_strategy** command. By default, the offset is 0. The offset can also be specified by evaluating the *var* variable in **-parameters** option.

The **pitch** keyword specifies the pitch value. *pitch_value* specifies the pitch of the wires in this layer. The pitch can also be specified by evaluating the *var* variable in **-parameters** option. This pitch is a required option in the layer spec.

The **spacing** keyword specifies the spacing between wires in this layer. **minimum** refers to the minimum spacing between wires defined in the technology file based on the wire width. *value_list* contains a list of spacing values, where the spacing value is a float-type value with unit defined in the technology file. Each spacing value specifies the spacing between the adjacent wires in the pattern. For example, the first spacing value specifies the spacing between the first and the second wires, and so on. The number of wires in this pattern is specified by the **set_pg_strategy** command. If the number of spacing values is smaller than the number of nets minus one, the last spacing value is assumed for the extra nets. **interleaving** keyword means that distance between adjacent center lines of wires is equal. The spacing can also be specified by evaluating the *var* variable in **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the minimum spacing is used if this option is not specified.

The **trim** keyword specifies the trim option for wires in this layer. Valid values are true, false or a value specified by evaluating the *var* variable in **-parameters** option. By default, the trim option is true.

The **track_alignment** keyword specifies the track alignment option for wires in this layer. The option can be track, half_track, or auto. When auto is specified, tool choose the alignment method with smaller number of used tracks. It can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are created at the specified location and no alignment is performed.

The **mask** keyword specifies the mask option for wires in this layer. The mask can be specified by one of the keywords, mask_one, mask_two, mask_three, mask_one_mask_two_alternate or mask_two_mask_one_alternate. It can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are not colored with mask if not specified.

The **mask_constraint** keyword specifies the mask constraint option for wires in this layer. The mask constraint is defined by the **set_pg_mask_constraint** command. It can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are not checked against mask constraint.

Multiple layer expressions can be specified and separated by brace pairs, that is, one layer expression per layer is within a pair of braces.

-via_rule ***via_rule_spec***

Specifies the *via_rule_spec* via rule between wires in this mesh pattern. The via rule defines the intersection locations and the via at the locations. The rule will only apply between layers of mesh pattern, but won't apply between layer of mesh pattern and layer of other pattern. You must define via rules with the **set_pg_strategy_via_rule** command if control is needed between layer of mesh pattern and layer of other pattern.

There are several ways to define the intersection locations in the *via_rule_spec* specification, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules |

The first method is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any two orthogonal wires in any different layers.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword, and **adjacent** refers to all intersections between any two orthogonal wires only in adjacent layers.

The third method is to define the intersections based on two sets of wire shapes using *list_of_filter_rules*, which contains a list of filtering rule. Each filtering rule is inside a brace pair. The syntax of each filtering rule is as follows:

{*filter_1*}{*filter_2*}{*via_def*} |
{**intersection** : undefined}{*via_def*}

where *filter_1* refers to the first filtering operation and *filter_2* refer to the second filtering operation. The intersection is defined between the first set and second set of wires based on the filtering rules. The second filtering rule is optional, that is, the intersection is defined based on the first set of wires to all other wires in this mesh.

The filtering operation is defined as follows:

{**layers** : *layer_list*} {**width** : {*lower_w upper_w*}}

where the **layers** and **width** keywords can be used to specify the wire layer names by *layer_list* or width range by {*lower_w upper_w*}. Here, *layer_list* contains a list of layer names, and {*lower_w upper_w*} is the lower/upper range of wire width. For those intersections which do not belong to any filtering rule, the via definition can be specified as follows:

{**intersection** : undefined}{*via_def*}

where **intersection** is the keyword and **undefined** refers to the remaining intersections which do not belong to any filtering rules. By default, vias are only created at the intersections which belong to a filtering rule. Multiple via filtering rules for intersection location and via definition can be defined and separated by braces where each filter rule is in one brace pair.

With the intersection definition, the via specification {*via_def*} uses the following format:

{**via_master** : *via_master_list* | *via_rule_list*}

where **via_master** is the keyword for via masters including via contact code defined in the technology file or user-defined via cells, The PG via rules defined by **set_pg_via_master_rule** command can be also specified in the list. *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or specific array dimension is needed, via rules specified by **set_pg_via_master_rule** command can be used. *via_rule_list* is a list of PG via rules. **NIL** can be used as a keyword indicate that no via would be created. **default** can be used to describe the default vias in the specified location. Multiple via rules can be specified and separated by brace pairs. If **NIL** is not specified in the list, default contact code will be used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file will be created at each intersection of orthogonal wires in different layers.

DESCRIPTION

Creates a power ground mesh pattern. This mesh pattern can be used to create PG mesh with the **set_pg_strategy** command.

The via rules can also be defined based on intersection or filtering rules. Each via rule contains the intersection location and the via definition by contact code or via master rule.

EXAMPLES

The following example creates a mesh pattern with three layers. Parameters are used for width and offset. The vias between adjacent layers are specified in the via rule. **set_pg_strategy** and **compile_pg** are used to create the mesh.

```
prompt> create_pg_mesh_pattern mesh \
  -parameters {w1 w2 w3 f} \
  -layers { \
    {{vertical_layer: M8}{width: @w1} \
       {spacing: interleaving}{pitch: 20} {offset: @f}} \
    {{horizontal_layer: M7}{width: @w2} \
       {spacing: interleaving} {pitch: 20} {offset: @f}} \
    {{vertical_layer: M6}{width: @w3} \
       {spacing: interleaving}{pitch: 20} {offset: @f}} \
  } \
  -via_rule { \
    {{layers: M8}{layers: M7}{via_master: VIA78}} \
    {{layers: M7}{layers: M6}{via_master: VIA67}} \
  }

prompt> set_pg_strategy smesh \
  -pattern { \
    {pattern: mesh}{nets: VDD VSS} \
       {parameters: 5 3 1 3}} \
  -core

prompt> compile_pg
```

The following example creates a mesh pattern with layers with same direction. Parameters are used for width and offset. The vias between parallel layers M8 and M6 are specified in the via rule.

```
prompt> create_pg_mesh_pattern mesh \
  -parameters {w1 w3 f} \
  -layers { \
    {{vertical_layer: M8}{width: @w1} \
       {spacing: interleaving}{pitch: 20} {offset: @f}} \
    {{vertical_layer: M6}{width: @w3} \
       {spacing: interleaving}{pitch: 20} {offset: @f}} \
  } \
  -via_rule { \
    {{layers: M8}{layers: M6} \
      {via_master: VIA78 VIA67}{between_parallel: true}} \
  }
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: **gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"**.

create_pg_ml_data

Create ML training files based on created ML training data in memory.

SYNTAX

status **create_pg_ml_data**
[-output_directory *directory_name*]

Data Types

directory_name string

ARGUMENTS

-output_directory *directory_name*

Specify directory name for created ML training file. The option is required.

DESCRIPTION

This command creates ML training files based on created ML training data in memory.

EXAMPLES

The following example creates ML training data in memory, output training data to files in directory pg_data_1, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

prompt> **compile_pg -create_ml_data**
prompt> **create_pg_ml_data -output_directory pg_data_1**
prompt> **train_pg_ml_model -input_directory {pg_data_1}**

SEE ALSO

create_pg_pattern_shapes

Creates power ground wire shapes in pattern-based. Vias will not be created in the command.

SYNTAX

status **create_pg_pattern_shapes**
-layer *layer_name*
-net *net_name*
-width *value*
-low_end *value*
-high_end *value*
-start *value*
-direction horizontal | vertical
[-max_array_size *number*]
[-within_bbox { {*llx lly*} {*urx ury*} }]
[-xPitch *value*]
[-yPitch *value*]
[-ignore_drc]
[-mark_as *pg_type*]
[-tag *tag_name*]
[-mask mask_one | mask_two | mask_three]
[-mask_pattern uniform | alternate_row | alternate_column]
[-blockage {*blockage_spec*}]

Data Types

layer_name string
net_name string
value float
number integer
llx float
lly float
urx float
ury float
tag_name string
pg_type specification
blockage_spec specification

ARGUMENTS

-layer *layer_name*

Specifies the layer name on which to create the PG pattern shapes. This is a required option.

-net *net_name*

Specifies net name of the PG pattern shapes by the string *net_name*. This is a required option.

-width *value*

Specifies the width of repeating PG shapes in the PG patterns shapes. This is a required option. *value* is a float value with um as the unit.

-low_end *value*

Specifies the low end coordinate of lower-left PG shapes in the PG patterns shapes. It could be specified as a fixed *value* with um as the unit. This is a required option.

-high_end *value*

Specifies the high end coordinate of lower-left PG shapes in the PG patterns. It could be specified as a fixed *value* with um as the unit. This is a required option.

-start *value*

Specifies the starting position of center-line of repeating PG shapes in the PG patterns shapes. This is a required option. *value* is a float value with um as the unit.

-direction horizontal | vertical

Specifies the direction of repeating PG shapes in the PG patterns shapes. This is a required option. Legal directions are "horizontal" and "vertical".

-max_array_size *number*

Specifies the max array size of of one PG pattern shapes. The number limit max repeated size in both two dimension. This option is not required. If not specified, the default value is 1000.

-within_bbox { {*llx lly*} {*urx ury*} }

Specifies the region that pattern shapes should be created. This option is not required. If not specified, pattern shapes will be created in corea area.

-xPitch *value*

Specifies the pitch in X axis. It will be x pitch in one pattern shapes. It could be specified as a fixed *value* with um as the unit. This option is not required. If the option is not specified, shape will not be repeated horizontally.

-yPitch *value*

Specifies the pitch in Y axis. It will be y pitch in one pattern shapes. It could be specified as a fixed *value* with um as the unit. This option is not required. If the option is not specified, shape will not be repeated vertically.

-ignore_drc

Specifies this option for PG pattern shapes creation. If speficied, DRC will be ignored. The PG pattern shapes will be created, based on the specification when this option is used. By default, DRC is activated and fixed for the PG pattern shapes.

-mark_as *pg_type*

Specifies the type of the PG pattern shapes to be created. The argument must by on of these keywords: stripe, ring, lib_cell_pin_connect, macro_pin_connect, user_route and follow_pin. These types refer to stripe, ring, standard cell connection, macro connection, user_route and follow_pin respectively. By default, the stripe type is used.

-tag *tag_name*

Specifies a tag name to assign to all new shapes created by this command. This tag name is used as contents of an user attribute tag for filtering ollections at later stages (see the example in the EXAMPLES section). By default, no tags are assigned.

-mask mask_one | mask_two | mask_three

Specifies the mask option for the PG pattern shapes. By default, the PG pattern shapes is not colored with a mask identifier. The type of mask can be specified by one of the keywords, mask_one, mask_two, mask_three.

-mask_pattern uniform | alternate_row | alternate_column

Specifies the mask option for the PG pattern shapes. By default, the PG pattern shapes mask pattern is uniform. The type of mask can be specified by one of the keywords, uniform, alternate_row, alternate_column.

-blockage {*blockage_spec*}

Specifies the routing blockage in the power ground network. You can specify multiple blockages within the braces, one blockage per group. Blockages are separated by braces and contain the keywords **nets:**, **layers:**, and a target specification as follows:

{{nets: *nets*} {layers: *layers*} {*target*}

where *target* is a voltage area, block, macro, macro with hard keep-out-margin (KOM), PG region, hard placement blockage, or polygon that is specified as follows:

{voltage_areas : *voltage_areas* | macros : *macro_names* |
macros_with_keepout : *macro_names* | placement_blockages : all |
polygon : {*polygon_area*} | blocks : *blocks* |
pg_regions : *region_list* }

The net names following the *nets* keyword are a subset of the nets specified by **-nets** in *pattern_expr* from **-pattern** option. If you do not specify the **nets** keyword, the blockage applies to all the nets in the strategy. The layer names following the **layers** keyword are the routing layers on which power or ground straps are blocked. If you do not specify the **layers** keyword, the blockage applies to all routing layers. Use one of the **voltage_areas**, **macros**, **polygon**, **blocks** or **pg_regions** keywords to represent the blockage area. *polygon_area* is specified as a list of coordinate points.

DESCRIPTION

Creates power ground wire shapes in pattern-based. Vias will not be created in the command. The command will create one shape pattern object that can represent repeating PG shapes based on user specified spec. DRC engine will check each element in pattern shapes. Fixing engine will modify the shape by cutting or remove single wire shape. For the fixed wire shapes, the geometry will not be the same as input. It will generate non-repeating PG shapes. Non-repeating PG shapes will be created as normal wire shapes.

EXAMPLES

The following example creates a VDD PG pattern shapes on layer M3, center at 0.993(X-axis), width as 0.037um, low end at 1(Y-axis), high end at 1.3(Y-axis) and vertical direction. Each wires shapes repeated every 4.959 um in x direction. -yPitch is not specified, so will created one row of vertical wire shapes. The shapes in the pattern will mask lower-left shape as mask one. The color will alternate every other column.

```
prompt> create_pg_pattern_shapes \
  -width 0.037 \
  -net VDD \
```

```
-low_end 1 -high_end 1.3 \
-start 0.993 -xPitch 4.959 \
-direction vertical \
-layer M3 \
-mark_as stripe \
-mask_pattern alternate_column -mask {mask_one}
```

create_pg_region

Defines a PG region used to create a power ground network. The region can be used as a routing region or a blockage constraint for PG creation.

SYNTAX

status **create_pg_region**
region_name
[-core | -design_boundary |
-group_of_macros *macro_cells* |
-group_of_ios *io_cells* |

notch_spec specification

ARGUMENTS

region_name

Specifies the name of the power ground region. This option is required.

-core

Defines the power ground region as the core area boundary. The command saves the region with the name *region_name*.

-design_boundary

Defines the power ground region as the design boundary. The command saves the region with the name *region_name*.

-group_of_macros {*macro_cells*}

Defines the power ground region as the contour around the specified macros. The command saves the region with the name *region_name*.

-group_of_ios {*io_cells*}

Defines the power ground region as the contour around the specified ios. The command saves the region with the name *region_name*.

-block *block*

Defines the power ground region as the contour around the specified soft macro block. You can specify a single block only. The command saves the region with the name *region_name*.

-polygon { {*llx lly*} {*urx ury*} } | {{*x y*} {*x y*} {*x y*} {*x y*}...} | *geometric_objects*

Defines the power ground region as the specified polygon area. The command saves the region with the name *region_name*.

The polygon area may be specified as a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

A polygon may also be specified as the combined area of a heterogenous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the polygon area as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

-voltage_area *voltage_area*

Defines the power ground region as the specified voltage area. You can specify a single voltage area only. The command saves the region with the name *region_name*.

-join_regions *region_list*

Defines the power ground region as the union of the contours of the specified regions. If the regions do not touch or overlap, the command expands the new region to form a contiguous boundary. The command saves the region with the name *region_name*.

-update *old_name*

Copies the power plan region *old_name* and modifies it by applying operations specified by other options. The command saves the new region with the name *region_name*.

The options **-core**, **-design_boundary**, **-voltage_area**, **-polygon**, **-block**, **-group_of_macros**, **-join_regions**, and **-update** are mutually exclusive. You can specify only one of these options.

You can perform operations on the defined region, including expanding or shrinking by horizontal and vertical offsets, excluding certain macros with offset, excluding a list of previously defined power ground regions, smoothing out narrow channels between macros, and so on. Not all operations are supported for all regions.

If you specify more than one modification operation, the tool applies the operations in the following sequence: expand the region, exclude regions, exclude macros, remove notches and jogs. You can change this order by running multiple **create_pg_region -update** commands and specifying one modification at a time.

-expand {*h_offset v_offset*}

Specifies the horizontal and vertical expansion offsets for the region. The offset unit is um. *h_offset* is applied to horizontal edges and *v_offset* is applied to vertical edges. You can specify negative offsets to shrink the region. By default, the offset is 0 and no region adjustment is performed.

-expand_by_edge *edge_offset_spec*

Specifies the expansion option for edges. Edge could be specified by either direction or an index. The supported directions are left, right, top, bottom, leftmost, rightmost, topmost, and bottommost. When edges are specified by index, each edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there are more than one leftmost edges, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction. *edge_offset_spec* specifies the offset for each edge as a pair of **edge_id** and **offset** keywords. An example is as follows:

{{side: *edge_id*}{offset: *edge_offset*}}

where *edge_id* and *edge_offset* specify the edge id and edge offset respectively. The offset unit is um. You can specify negative offsets to shrink the region. If you do not specify offsets for all edges, the offset for the remaining edges is either 0 or the uniform offset for all edges set by the **-expand** option. By default, the offset is 0 for all edges and no region adjustment is performed.

-exclude_regions *region_list*

Specifies a list of power ground region names to exclude from the current region. You can use the **-exclude_regions** option together with the **-core**, **-voltage_area**, **-polygon**, **-group_of_macros** and **-update** options. You cannot use **-exclude_regions** together with the **-join_regions** options. By default, no regions are excluded.

If you use the **-expand** or **-expand_by_edge** and **-exclude_regions** options together, the tool first expands the region, then excludes regions by default. To change the default execution order, use the **-update** option with one option at a time.

-exclude_macros *macro_cells*

Specifies a list or collection of hard macros to exclude from the power ground region. You can use the **-exclude_macros** option together with the **-core**, **-voltage_area**, **-polygon**, **-join_regions** and **-update** options. You cannot use **-exclude_macros** together with the **-group_of_macros** options. By default, no hard macros are excluded.

If you use the **-expand** or **-expand_by_edge** and **-exclude_macros** options together, the tool first expands the region, then excludes macros by default to honor the offset specified for the macros. To change the execution order of macro expansion and exclusion, use the **-update** option with one option at a time.

-macro_offset {*x_offset y_offset*}

Specifies the horizontal and vertical edge offsets for the list or collection of hard macros to be excluded from the region. This option only takes effect when used together with the **-exclude_macros** option or the **-group_of_macros** option. The offset is uniformly applied to all specified hard macros. The offset unit is um. By default, the offset is 0.

-io_offset {*x_offset y_offset*}

Specifies the horizontal and vertical edge offsets for the list or collection of ios to be excluded from the region. This option only takes effect when used together with **-group_of_ios** option. The offset is uniformly applied to all specified ios. The offset unit is um. By default, the offset is 0.

-remove_jog *jog_spec*

Specifies the method used to remove jogs and jog threshold. The **expand** keyword specifies that the region is expanded to remove jogs. The **shrink** keyword specifies that the region is shrunk to remove jogs. Any jog edge in the region shorter than the threshold specified by the *threshold* value is removed by expanding or shrinking the current region. The syntax of *jog_spec* is as follows:

{**expand** | **shrink** : *threshold*}

where only one of **expand** and **shrink** can be specified and *threshold* is a floating value with unit as um. If you specify the **-group_of_macros** or **-join_regions** option, the tool removes jogs by expanding the region automatically. If you specify the **-exclude_macros** or **-exclude_regions** option, the tool removes jogs by shrinking the region automatically. Otherwise, you must specify the removal method by using the one of **expand** and **shrink** keywords.

-remove_notch *notch_spec*

Specifies the notch type to be removed from the region and the notch threshold. The **convex** keyword specifies that the tool removes **convex** notches inside the region. The **concave** keyword specifies that the tool removes concave notches outside the region. The tool removes convex notches by shrinking the region, and removes concave notches by expanding the region. The tool only removes any convex or concave notches with a width smaller than the specified *threshold*. The syntax of *notch_spec* is as follows:

{**convex** | **concave** : *threshold*}

where only one of **convex** and **concave** can be specified and *threshold* is a floating value in um. If you also specify the **-group_of_macros** or **-join_regions** option, the tool removes concave notches by expanding the region automatically. If you specify the **-exclude_macros** or **-exclude_regions** option, the tool removes convex notches by shrinking the region automatically. Otherwise, you must specify the notch type by using one of **convex** and **concave** keywords.

DESCRIPTION

This command defines the regions used to create the power ground network. The region can be used as a routing region or a blockage for power mesh or ring creation.

You can specify the region by core area, by voltage area boundary, by polygon area, by contour of the macro groups, by contour from joining a list of previously defined power ground regions, or by incrementally modifying a previous defined region. You can perform operations on the defined region, including expanding or shrinking by horizontal and vertical offsets, excluding certain macros with offset, excluding a list of previously defined power ground regions, smoothing out narrow channels between macros, and so on. Not all operations are supported for all regions.

If you specify more than one operation, the tool runs the operations in a specific sequence. The tool begins by expanding the region, followed by excluding regions, excluding macros, and notch or jog removal is the last step. You can change the order by specifying the **-update** option with one operation at a time.

The power ground region only supports simple polygons and does not support donut-shape, self-cut or disjoint polygons.

EXAMPLES

The following example defines a power ground region with the name pp_region1. The region is specified with the coordinates {{1200 952} {1200 650} {1400 650} {1400 952}}.

```
prompt> create_pg_region pp_region1 \
  -polygon {{1200 952} {1200 650} {1400 650} {1400 952}}
```

The following example defines a region with the name *pp_region2* based on the core area boundary. The core area is first shrunk by 50 um. The $macro1 and $macro2 hard macros are excluded from the region. A horizontal edge offset of 20 um and vertical edge offset of 30 um are applied to both hard macros. Any notch areas inside the region with width smaller than 30 um are removed.

```
prompt> create_pg_region pp_region2 \
  -core -expand -50 \
  -exclude_macros "$macro1 $macro2" \
  -macro_offset {20 30} \
  -remove_notch 30
```

The following example defines a region named *new_region* that is copied from the previously defined region *old_region*. The *old_region* region is copied and expanded by 200 um to create the new region. The concave notches outside the region with width smaller than 10 um are removed by expanding the region. The jog edges shorter than 10 um are removed by expanding the region.

```
prompt> create_pg_region new_region \
  -update old_region -expand 200 \
  -remove_notch {concave: 10} \
  -remove_jog {expand: 10}
```

The following example defines a region named *pp_region3* that is based on the contour of the three macros $macro1, $macro2 and $macro3. The uniform horizontal and vertical offset applied to both hard macros is 20 um. The notches outside the region with width smaller than 30 um are removed by expanding the region. The jog edges shorter than 10 um are removed as well.

```
prompt> create_pg_region pp_region3 \
  -group_of_macros "$macro1 $macro2 $macro3" \
  -macro_offset {20 20} \
  -remove_notch 30 -remove_jog 10
```

The following example defines a region with the name *pp_region4* based on the voltage area boundary of va_top and expanded by 30 um horizontally and 20 um vertically.

```
prompt> create_pg_region pp_region4 \
  -voltage_area va_top -expand {30 20}
```

The following example defines a region with the name *pp_region5* based on core area and expanded by 10 um, 20 um, 30 um, and 40 um for the four edges assuming that the core is a rectangle.

```
prompt> create_pg_region pp_region5 \
  -core \
  -expand_by_edge { \
    {{side: 1}{offset: 10}} {{side: 2}{offset: 20}} \
    {{side: 3}{offset: 30}} {{side: 4}{offset: 40}} \
  }
```

The following example defines a region with the name *pp_region5* based on core area and expanded by 10 um, 20 um, 30 um, and 40 um for edges at left, top, right, and bottom.

```
prompt> create_pg_region pp_region6 \
```

```
-core \
-expand_by_edge { \
  {{side: left}{offset: 10}} {{side: top}{offset: 20}} \
  {{side: right}{offset: 30}} {{side: bottom}{offset: 40}} \
}
```

MORE EXAMPLES

create_pg_ring_pattern

Creates a power ground (PG) ring pattern. The pattern created by this command is associated with a region or area of the design by using the **set_pg_strategy** command. The actual ring is inserted into the design by the **compile_pg** command.

SYNTAX

status **create_pg_ring_pattern**
pattern_name
[-nets *net_list*]
[-horizontal_width *width_list*]
[-vertical_width *width_list*]
[-horizontal_spacing *spacing_list*]
[-vertical_spacing *spacing_list*]

[-side_spacing *spacing_spec*]
[-side_layer *layer_spec*]
[-corner_bridge true | false | @*param*}]
[-track_alignment track | half_track |@*var*]
[-parameters *var_list*]
[-via_rule *via_rule_spec*]

Data Types

pattern_name string
net_list list
width_list list
spacing_list list
layer string
width_spec specification
spacing_spec specification
layer_spec specification
param string
var_list list
via_rule_spec specification

ARGUMENTS

pattern_name

Specifies the name of the ring pattern.

-nets *net_list*

Specifies power and ground net names used in this ring pattern. The net names are symbolic names and are mapped to actual net names by the **set_pg_strategy** command.

The net name mapping is by position, where the first net name in the *net_list* list corresponds to the first net name specified by the **set_pg_strategy** command, and so on. This option is required when you specify a net-based via rule, as each net can have a different via requirement. Otherwise, this option is not required.

-horizontal_width *width_list*

Specifies the horizontal ring width. *width_list* specifies the list of horizontal widths, where the first width in the list is the width of the first net, and so on. The unit is um. Each value can also be specified by evaluating the variable in the **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter and directs the command to replace the value with the value specified by the **set_pg_strategy** command. If this option is not specified, the minimum width defined in the technology file is used for the horizontal width.

-vertical_width *width_list*

Specifies the vertical ring width. *width_list* specifies the list of vertical widths, where the first width in the list is the width of the first net, and so on. The unit is um. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. If this option is not specified, the minimum width defined in the technology file is used for the vertical width.

-horizontal_spacing *spacing_list*

Specifies the spacing between horizontal ring segments. *spacing_list* specifies the list of horizontal spacing values, where the first value in the list is the spacing of the first net, and so on. The unit is um. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. If this option is not specified, the minimum spacing defined in the technology file is used for horizontal spacing.

-vertical_spacing *spacing_list*

Specifies the spacing between vertical ring segments. *spacing_list* specifies the list of vertical spacing values. The first value in the list is the spacing of the first net, and so on. The unit is um. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. If this option is not specified, the minimum spacing defined in the technology file is used for vertical spacing.

-horizontal_layer *layer*

Specifies the horizontal layer name. The layer name can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. If this option is not specified, the topmost metal layers in the preferred routing direction defined in the technology file is used.

-vertical_layer *layer*

Specifies the horizontal layer name. The layer name can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. If this option is not specified, the topmost metal layers in the preferred routing direction defined in the technology file is used.

-side_width *width_spec*

Specifies the ring segment width per side. The *width_spec* is defined as follows:

{{**side** : *id_list*}
{**width** : *width_list*}}

where **side** is the keyword to create a side specification. Side contains a list of edge IDs. Each ring edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there is more than one leftmost edge, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction.

width is the keyword to create a ring width specification for that side. *width_list* specifies the width list for each net. The unit is um. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix

symbol to specify a parameter.

You can create multiple specifications, where each spec is contained within a brace pair.

The side width specified in this option has a higher priority than the horizontal or vertical width.

-side_spacing *spacing_spec*

Specifies the ring segment spacing per side. The *spacing_spec* is defined as follows:

{{**side** : *id_list*}
{**spacing**: *spacing_list*}}

where **side** is the keyword for side. Side contains a list of edge IDs. Each ring edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there are more than one leftmost edges, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction.

spacing is the keyword for ring spacing of that side. *spacing_list* specifies the spacing list between nets. The unit is defined in the technology file. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter.

You can create multiple specifications, where each spec is contained within a brace pair.

The side spacing specified in this option has a higher priority than the horizontal or vertical spacing.

-side_layer *layer_spec*

Specifies the ring segment layer per side. The *layer_spec* is defined as follows:

{{**side** : *id_list*}
{**layer**: *layer_name*}}

where **side** is the keyword for side. Side contains a list of edge IDs. Each ring edge is indexed by a unique number. Edge numbering starts from 1 at the leftmost vertical edge. If there are more than one leftmost edges, the bottommost edge is the starting edge. The edge number increases by 1 as you proceed around the shape in the clockwise direction.

layer is the keyword for ring layer of that side. *layer_name* specifies the layer name for each net. Each value can also be specified by evaluating the variable in **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter.

You can create multiple specifications, where each spec is contained within a brace pair.

The side layer specified in this option has a higher priority than the horizontal or vertical layer.

-corner_bridge true | false | @*param*

Specifies whether the pattern creates a corner bridge. You can specify the setting by evaluating the variable *param* in the **-parameters** option. The at character (@) is used as a prefix symbol to specify a parameter. The "true" setting creates bridge connection at all ring corners and connects inner and outer rings of the same net. If this option is not specified, no bridge connection is created for the ring pattern.

-track_alignment track | half_track |@*var*

Specifies the track alignment option of this wire pattern. It can be specified by track or half_track. It can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable.

-parameters *var_list*

Specifies the list of parameters for this pattern. Each parameter can be evaluated and used as the argument for other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string. Parameter strings in *var_list* for the **-parameters** option do not contain the at character (@), but the at character is used as a prefix symbol for parameters when used with the other command options.

Parameter values are specified by the **set_pg_strategy** command. See the example section for more details.

-via_rule ***via_rule_spec***

Specifies the via rule for creating vias between horizontal and vertical ring segments. The via rule defines the intersection locations and the via at the locations.

There are several ways to define the intersection locations in the *via_rule_spec* specification. The syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules |

The first way is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any ring segments in different directions and different layers.

The second way is "{**intersection** : adjacent}", where **intersection** is the keyword, and **adjacent** refers to all intersections between any two ring segments in different directions only in adjacent layers.

The third way is to define the intersections based on two sets of shapes using *list_of_filter_rules*, which contains a list of filtering rules. Each filtering rule is specified inside a brace pair. The syntax of each filtering rule is as follows:

{{*set_1*} {*filter_1*}} {{*set_2*} {*filter_2*}} {*via_def*} |
{**intersection** : undefined} {*via_def*}

where the two sets are the set of ring segments. Each set can be further filtered to obtain a subset of selected shapes. *set_1* and *set_2* are defined as follows:

{**side** : *id_list*}

where **side** is the keyword for ring side, which contains a list of edge IDs *id_list*.

The filtering operations for ring segments are defined as follows:

{**nets** : *net_list*}
{**layers** : *layer_list*}
{**width** : {*lower_w upper_w*}}

nets, **layers**, **width** keywords can be used to specify the wire net names by *net_list*, wire layer names by *layer_list* or width range by {*lower_w upper_w*}. Ring segments which satisfy the above criteria form a subset of shapes.

For those intersections which do not belong to any filtering rule, the via definition can be specified by

{**intersection** : undefined}{*via_def*}

where **intersection** is the keyword, **undefined** refers to the remaining intersections which do not belong to any filtering rules. By default, vias are not created at the intersections if they do not belong to a filtering rule, unless otherwise specified. Multiple via filtering rules, such as intersection location and via definition, can be defined and separated by braces, where each filter rule is in one brace pair.

With the intersection definition, the via specification {*via_def*} is in the following format:

{**via_master** : *via_master_list* | *via_rule_list*}

where **via_master** is the keyword for both via masters and via master rules. *via_master_list* specifies the list of via masters. Via masters include via contact code defined in the technology file or user-defined via cells. *via_rule_list* is a list of PG via rules. Via master rules are defined by the **set_pg_via_master_rule** command. **NIL** can be used as a keyword to indicate that no via is created. **default** can be used to apply the default vias in the specified location. For each specified intersection, vias are created based on the specified via masters or via master rules. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via when a DRC error occurs.

By default, the default via defined in the technology file is created at each intersection of orthogonal ring segments, where the ring segments are on different layers.

DESCRIPTION

Creates a power ground (PG) ring pattern. The pattern created by this command is associated with a region or area of the design by using the **set_pg_strategy** command, and is inserted into the design by the **compile_pg** command.

The ring pattern specifies the horizontal and vertical ring width values, layer names, spacing values and corner bridge options. The values can be either fixed values or set by using parameters. Via rules between horizontal and vertical ring segments can also be specified.

The ring contour shape, offset to the ring contour and vias between this ring pattern and any other shapes can be specified by **set_pg_strategy** command when associating this pattern to a routing area in the design.

EXAMPLES

The following example creates a ring pattern ring1 for layers M3 and M4. The spacing values are 1 and 2, the width is 5 for horizontal and vertical segments except for side 1 with width 6, the corner bridge option is defined by parameter @flag, and the via master rule via34_2x2, i.e. between layer M3 and M4 with array size 2 by 2.

```
prompt> create_pg_ring_pattern ring1 \
  -parameters {flag} \
  -horizontal_layer M3 -vertical_layer M4 \
  -horizontal_width 5 -vertical_width 5 \
  -horizontal_spacing 1 -vertical_spacing 2 \
  -side_width {{side: 1} {width: 6}} \
  -corner_bridge @flag \
  -via_rule {{intersection: all} {via_master: VIA34}}
```

The following example creates a ring pattern ring2, where the width list {1 2 3} is applied to sides {1 3} and width list {3 4 5} is applied to sides {2 4}. For sides 1 and 3, the innermost ring width is 1, middle ring width is 2 and outermost ring width is 3. For sides 2 and 4, the innermost ring width is 3, middle ring width is 4 and outermost ring width is 5.

```
prompt> create_pg_ring_pattern ring2 \
  -side_width { \
    {{side: 1 3} {width: 1 2 3}} \
    {{side: 2 4} {width: 3 4 5}} \
  }
```

The following example creates a ring pattern ring3, where the width list {1 2 3} is applied to sides {1 2 3 4}. For sides 1, 2, 3 and 4, the innermost ring width is 1, the middle ring width is 2 and the outermost ring width is 3.

```
prompt> create_pg_ring_pattern ring3 \
  -side_width { \
    {side: 1 2 3 4} {width: 1 2 3} \
  }
```

MORE EXAMPLES

For more example, please start GUI and invoke the following command. **gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"**.

create_pg_special_pattern

Creates a power ground special pattern. This pattern can be instantiated by **set_pg_strategy** command to create power ground shapes inside the specified routing area.

SYNTAX

status **create_pg_special_pattern**
pattern_name
[-insert_channel_straps *spec*]
[-insert_terminal_alignment_straps *spec*]
[-terminal_alignment_via_rule *via_rule_spec*]
[-insert_power_switch_alignment_straps *spec*]
[-insert_physical_cell_alignment_straps *spec*]
[-honor_max_stdcell_strap_distance *spec*]
[-parameters *var_list*]

Data Types

pattern_name collection
spec specification
via_rule_spec specification
var_list specification

ARGUMENTS

pattern_name

Specifies the name of the special pattern.

-insert_channel_straps *spec*

Specifies the channel strap insertion option specification. Channel straps are inserted inside channels formed by objects if no existing straps are inside the channels. The *spec* specification is as follows:

{
{**layer** : *layer_name*}
{**direction** : horizontal | vertical}
{**width** : *width_value*}
{**spacing** : *spacing_value*}
{**offset** : *offset*}
{**reference** : *offset_reference*}
{**channel_threshold** : *threshold*}
{**track_alignment** : *track* | *half_track*}
{**channel_between_objects** :
macro | placement_blockage | voltage_area |

macro_with_keepout | region_boundary | block}
{**check_one_layer** : true | false}
}

The **layer** keyword followed by the *layer_name* layer specifies the layer for channel strap insertion; this setting is required. The **direction** keyword followed by horizontal or vertical specifies the channel direction; the default is vertical. The **width** keyword followed by *width_value* specifies the channel strap width; the default is the minimum width. The **spacing** keyword followed by *spacing_value* specifies the spacing between channel straps; the default is the minimum spacing. The **offset** keyword followed by *offset* specifies the offset from **reference** to the center of the first strap. The **reference** keyword followed by *offset_reference* specifies the offset reference. The offset_reference could be either left or center. Left means channel left boundary. Center means the centerline of the channel. The default is left. However, if the offset is 0, the reference will be changed to center. The **channel_threshold** keyword followed by *threshold* specifies the lower width bound for narrow channels. Any channels with width smaller than the threshold are not considered for insertion. The default threshold is 0. The **track_alignment** keyword followed by track or half_track specifies how straps align to the track.

The **channel_between_objects** keyword followed by the object name specifies the objects considered for channels such as macros, hard placement blockages, voltage areas, macros with hard keepout, routing area boundary, and blocks. When **macro_with_keepout** is specified, if a hard keepout is not defined for a certain macro, the macro boundary is used for channel detection. When **voltage_area** is specified, channels between embedded voltage areas and disjoint voltage areas are supported, while channels between partially overlapped voltage areas are not supported. If no object is specified using the **channel_between_objects** keyword, by default the tool considers only macros for channels.

The **check_one_layer** keyword followed by true or false specifies when the tool inserts straps in the channel. If **check_one_layer** is false, channel straps are not inserted if any straps at any layers are inside the channel. If **check_one_layer** is true, channel straps are not inserted only if any straps at the specified layer are inside the channel. By default, **check_one_layer** is false.

-insert_terminal_alignment_straps *spec*

Specifies how terminal alignment straps are inserted. If *spec* is "on", terminal alignment straps will be inserted for all terminals at all layers. By default, the terminal alignment straps are created at all layers. Terminal straps are trimmed and snapped to shapes in different directions when cut by blockages or DRCs. If dangling wires are preferred, you can turn off the trim option. If specific layers are preferred, layers can be specified in the spec. The *spec* for trim is described as follows:

{**trim** : true | false}
{**layers** : layerList}

When **trim** is false, terminal alignment straps are not trimmed. **layers** is the keyword for layers and layerList specifies the list of layers for terminal alignment strap insertion.

-terminal_alignment_via_rule *via_rule_spec*

Specifies the via rule *via_rule_spec* between terminal alignment straps. The via rule defines the intersection locations and the via inserted at the locations. This option can be applied only for terminal alignment pattern.

There are several ways to define the intersection locations in the *via_rule_spec* specification, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules |

The first method is "{**intersection** : all}", where **intersection** is the keyword and **all** refers to all intersections between any two orthogonal wires in any different layers.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword and **adjacent** refers to all intersections between any two orthogonal wires only in adjacent layers.

The third method is to define the intersections based on two sets of wire shapes using *list_of_filter_rules*, which contains a list of filtering rules. Each filtering rule is specified inside a curly brace pair. The syntax of each filtering rule is as follows:

{*filter_1*}{*filter_2*}{*via_def*} |
{**intersection** : undefined}{*via_def*}

where *filter_1* refers to the first filtering operation and *filter_2* refer to the second filtering operation. The intersection is defined between the first set and second set of wires based on the filtering rules. The second filtering rule is optional, and the intersection is defined based on the first set of wires to all other terminal alignment straps.

The filtering operation is defined as follows:

{**layers** : *layer_list*} {**width** : {*lower_w upper_w*}}

where the **layers** keyword followed by *layer_list* specifies the wire layer names. The **width** keyword and {*lower_w upper_w*} setting specifies the lower and upper range of possible wire widths. For those intersections which do not belong to any filtering rule, the via definition can be specified as follows:

{**intersection** : undefined}{*via_def*}

where **intersection** is the keyword and **undefined** refers to the remaining intersections which do not belong to any filtering rules. By default, no via is created at the intersections which do not belong to any filtering rules unless specified. Multiple via filtering rules, such as intersection location and via definition, can be defined and separated by curly braces where each filter rule is in one brace pair.

With the intersection definition, the via specification {*via_def*} is in the following format:

{**via_master** : *via_master_list* | *via_rule_list*}

where **via_master** is the keyword for via masters including via contact code defined in the technology file or user-defined via cells. The PG via rules defined by **set_pg_via_master_rule** command can be specified in the list. *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or specific array dimension is needed, via rules specified by **set_pg_via_master_rule** command can be used. *via_rule_list* is a list of PG via rules. **NIL** can be used as a keyword indicate that no via would be created. **default** can be used to describe the default vias in the specified location. Multiple via rules can be specified and separated by brace pairs. If **NIL** is not specified in the list, default contact code will be used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file will be created at each intersection of orthogonal terminal alignment straps in different layers.

-insert_power_switch_alignment_straps ***spec***

Specifies the power switch alignment strap insertion option. The alignment straps are inserted to align with power switch primary power input pins. The *spec* is defined as follows:

{
{**lib_cells** : *lib_cell_name_list*}
{**layer** : *layer_name*}
{**width** : *width_value*}
{**direction** : horizontal | vertical}
{**offset** : *offset_value*}
{**pitch** : *pitch_value*}
{**track_alignment** : *track* | *half_track*}
{**number** : *number*}
{**pin_layers** : *layer_name_list*}
{**via_master** : *via_master_list*}
}

The **lib_cells** keyword followed by *lib_cell_name_list* specifies the lib cell name list for power switch cells; this option is required. The **layer** keyword followed by *layer_name* specifies the layer for strap insertion, this option is required. The **width** keyword followed by *width_value* specifies the strap width; this option is optional. By default, the pin width is used. The **direction** option followed by horizontal or vertical specifies the alignment strap direction, the default is vertical. The **offset** keyword followed by *offset_value* specifies the offset between strap center and pin shape center. By default, the offset is 0. The **pitch** keyword followed

by *pitch_value* specifies the pitch between alignment strap center. The **track_alignment** keyword followed by track or half_track specifies how straps align track. The **number** keyword followed by *number* specifies the number of alignment straps for each pin shape. By default, the number is 1. The **pin_layers** keyword followed by *layer_name_list* specifies a list of layer names. Only pin shapes on the specified layers are aligned. By default, pins on all layers are aligned. The **via_master** keyword followed by *via_master_list* specifies the via masters used for via creation between the alignment straps and pins. *via_master_list* can include contact codes or design vias defined in the technology file, or via master rule defined by **set_pg_via_master_rule** command. It can also include **default** or **NIL** keywords. By default, the default contact codes are used for via creation.

-insert_physical_cell_alignment_straps *spec*

Specifies the physical cell alignment strap insertion option. Supported cell types include physical_only, well_tap, and filler. The alignment straps are inserted to align with physical cell pins. The *spec* is defined as follows:

{
{**lib_cells** : *lib_cell_name_list*}
{**layer** : *layer_name*}
{**width** : *width_value*}
{**direction** : horizontal | vertical}
{**offset** : *offset_value*}
{**track_alignment** : *track* | *half_track*}
{**number** : *number*}
{**pin_names** : *pin_name_list*}
{**pin_layers** : *layer_name_list*}
{**via_master** : *via_master_list*}
}

The **lib_cells** keyword followed by *lib_cell_name_list* specifies the lib cell name list for physical cells. The **layer** keyword followed by *layer_name* specifies the layer to use for strap insertion; this setting is required. The **width** keyword followed by *width_value* specifies the strap width. This setting is optional. By default, the tool uses the pin width. The **direction** option followed by horizontal or vertical specifies the alignment strap direction. By default, the direction is vertical. The **offset** keyword followed by *offset_value* specifies the offset between strap center and pin shape center, by default, the offset is 0. The **track_alignment** keyword followed by track or half_track specifies how straps align track. The **number** keyword followed by *number* specifies the number of alignment straps for each pin shape. By default, the number is 1. The **pin_names** keyword followed by *pin_name_list* specifies a list of pin names for alignment. By default all pins are considered for alignment. The **pin_layers** keyword followed by *layer_name_list* specifies a list of layer names and only pin shapes on the specified layers are aligned. By default, pins on all layers are aligned. The **via_master** keyword followed by *via_master_list* specifies the via masters used for via creation between the alignment straps and pins. *via_master_list* can include contact codes or design vias defined in the technology file, or via master rule defined by **set_pg_via_master_rule** command. It can also include **default** or **NIL** keywords. By default, the default contact codes are used for via creation.

-honor_max_stdcell_strap_distance *spec*

Specifies the extra strap insertion to honor maximum standard cell rail tail distance option. Extra vertical straps are inserted for rail tails longer than the specified maximum distance. The *spec* is defined as follows:

{
{**layer** : *layer_name*}
{**width** : *width_value*}
{**max_distance** : *threshold*}
{**offset** : *offset_list*}
{**check_layers** : *layer_name*}
}

The **layer** keyword followed by *layer_name* specifies the layer for strap insertion; this setting is required. The **max_distance** keyword followed by *threshold* specifies the maximum length of standard cell rail tails; this setting is required. The **width** keyword followed by *width_value* specifies the strap width. This setting is optional; by default, the tool uses the minimum width for the layer. The **check_layers** keyword followed by *layer_name* specifies target layers for standard cell rail tails distance calculation. User can spefify one or multiple layers. This is an optional setting. By default, it will check all layers.

The **offset** keyword followed by *offset_list* specifies a list of offset values. This setting is optional. By default, extra straps are inserted such that the distance between the inserted strap center and the nearest strap center is *threshold*. If *offset_list* is specified, the largest value from *offset_list* is used to calculate the extra strap distance such that the extra strap is within the rail tail range.

-parameters *var_list*

Specifies the list of parameters for this pattern. Each parameter can be evaluated and used as the argument for other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string. Parameter strings in *var_list* for the **-parameters** option do not contain the at character (@), but the at character is used as a prefix symbol for parameters when used with the other command options. Parameter values are specified by the **set_pg_strategy** command.

DESCRIPTION

Creates a power ground special pattern. This pattern can be instantiated by the **set_pg_strategy** command to create special power ground shapes inside the specified routing area.

The special pattern can specify channel strap insertion, terminal alignment strap insertion, or extra strap insertion to honor maximum standard cell rail tail distance. Only one type can be specified for one special pattern.

EXAMPLES

The following example creates a special pattern for channel strap insertion. Vertical channels straps are inserted on layer M8 with width 1.0um. Macros, voltage areas and placement blockages are considered for channels.

```
prompt> create_pg_special_pattern channelPattern \
  -insert_channel_straps { \
    {layer: M7}{direction: vertical}{width: 1} \
    {channel_between_objects: {macro placement_blockage voltage_area}} \
  }
```

The following example creates a special pattern for terminal alignment strap insertion. The vias between adjacent layers are specified in the terminal alignment via rule.

```
prompt> create_pg_special_pattern terminalPattern \
  -insert_terminal_alignment_straps on \
  -terminal_alignment_via_rule { \
    {{layers: M8}{layers: M7}{via_master: VIA78}} \
    {{layers: M7}{layers: M6}{via_master: VIA67}} \
  }
```

The following example creates a special pattern for power switch cell pin alignment strap insertion. The alignment straps are inserted on layer M4 for power switches with lib cell name HEAD16DM.

```
prompt> create_pg_special_pattern pwrSwitchAlignmentPattern \
  -insert_power_switch_alignment_straps { \
    {lib_cells: HEAD16DM} {layer: M4} \
  }
```

The following example creates a special pattern for physical cell pin alignment strap insertion. The alignment straps are inserted on

layer M4 for tap cells with lib cell names TAP_REF1 and TAP_REF2.

```
prompt> create_pg_special_pattern \
   phyCellAlignmentPattern \
   -insert_physical_cell_alignment_straps { \
        {lib_cells: TAP_REF1 TAP_REF2} {layer: M4} \
   }
```

The following example creates a special pattern for extra strap insertion to honor maximum standard cell rail tail distance. The tool inserts extra straps of width 2um on layer M8, the rail tail maximum length is 20um, the location is decided by offset value list {20 10}.

```
prompt> create_pg_special_pattern \
   extraStrapPattern \
   -honor_max_stdcell_strap_distance { \
        {layer: M8}{max_distance: 20}{width: 2}{offset: {20 10}} \
   }
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: **gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"**.

create_pg_stapling_vias

Creates PG stapling vias for the specified PG nets between parallel PG straps.

SYNTAX

status **create_pg_stapling_vias**
-nets *netname_list*
-from_shapes *shape_collection*
-from_layer *layer*
-to_shapes *shape_collection*
-to_layer *layer*
[-align_track top_layer|bottom_layer]
[-contact_code *contact_code_list*]
[-via_masters *via_rule_list*]
[-ignore_drc]
[-mask mask_one | mask_two | auto]
[-mark_as strap | ring | std_conn | macro_conn]
[-max_array_size integer]
[-no_effect_of_pg_nets_on_each_other]
[-offset *coordinate*]
[-pitch *coordinate*]
[-regions *bbox | bbox_list*]
[-tag *tag_name*]
[-create_via_matrix]

Data Types

netname_list list
shape_collection collection
layer string
contact_code_list list
via_rule_list list
coordinate {float, float}
bbox list
bbox_list list
tag_name string

ARGUMENTS

-nets *net_list*

Specifies a list of PG nets on which to create vias. This is a required option.

-from_shapes *shape_collection*

Specifies the collection of PG shapes to create stapling vias. This option is required.

-from_layer *layer*

Specifies the layer name for PG shapes. This option is required. from_layer and to_layer must be adjacent metal layers.

-to_shapes *shape_collection*

Specifies the collection of PG shapes to create stapling vias. This option is required.

-to_layer *layer*

Specifies the layer name for PG shapes. This option is required. from_layer and to_layer must be adjacent metal layers.

-align_track top_layer | bottom_layer

Specifies the track alignment option for stapling via creation. The argument must be either **top_layer** or **bottom_layer**. If **top_layer** is specified, stapling cuts will be aligned to the routing tracks of the top enclosure layer. If **bottom_layer** is specified, stapling cuts will be aligned to the routing tracks of the bottom enclosure layer. By default, no track alignment is applied.

-contact_code *contact_code_list*

Specifies a list of contact codes to be used during via creation. Contact code names are defined in the technology file. If not specified, the default contact code is used. The option is mutually exclusive with -via_masters.

-via_masters *via_rule_list*

Specifies a list of PG via master rules to be used during via creation. PG via master rules are defined using set_pg_via_master_rule command. The option is mutually exclusive with -contact_code.

-ignore_drc

Specifies the DRC option for stapling via creation. If specified, no drc check is applied for via creation. By default, DRC is checked and fixed for all stapling vias.

-no_effect_of_pg_nets_on_each_other

Specifies if stapling vias of one PG net may cause DRC of another PG net in a list on adjacent rows. By default the tool assumes that one net may affect another, and created stapling vias are loaded into DRC checking engine. This may impact runtime, and if the user is sure that stapling vias with their medtal enclosures have absolutely no effect on adjacent rows, this option will help with runtime.

-mask mask_one | mask_two | auto

Specifies the mask option for stapling via creation. The argument must be one of: **mask_one**, **mask_two**, **auto**. If **mask_one** is specified, mask of all cuts will be assigned as mask_one. If **mask_two** is specified, mask of all cuts will be assigned as mask_two. If **auto** is specified, the tool will automatically assign either mask_one or mask_two to cuts to achieve best stapling rate. By default, no mask is assigned to cuts.

-mark_as strap | ring | std_conn | macro_conn

Specifies the type of the stapling vias to be created. The argument must be one of: **strap**, **ring**, **std_conn** and **macro_conn**. These types refer to strap, ring, standard cell connection and macro connection respectively. By default, **std_conn** is used.

-max_array_size integer

Specifies the maximum via array size for stapling vias. For example, if -max_array_size is specified as 20, then all stapling via arrays created will be 1x20 or smaller. By default, array size is not limited.

-offset coordinate

Specifies the offset in both x and y direction. For stapling vias in horizontal direction, x offset means shrink the intersection area

by specified amount; y offset means shift the vias in y direction by certain amount. For example, for horizontal direction stapling, -offset {1.0, 0.1} means that in y axis, the cuts are moved up by 0.1um; while in x axis, all the intersections will be shrank by 1.0um from both ends.

-pitch coordinate

Specifies the stapling via pitch in both x and y direction. By default, minimum cut spacing will be used as spacing between cuts. Only horizontal pitch is honored.

-regions *bbox* | *bbox_list*

Specifies a bounding box or a list of bounding boxes within which to create PG vias. The vias are created at the power strap intersections within this bounding box. If not specified, the design boundary is used as the bounding box.

-tag *tag_name*

Specifies a tag name to assign to all new vias created by this command. This tag name is used as contents of an user attribute tag for filtering collections at later stages (see the example in the EXAMPLES section). By default, no tags are assigned.

-create_via_matrix

If specified, the stapling vias will be stored as via matrixes.

DESCRIPTION

This command is used for stapling via creation between parallel straps on adjacent as well as non-adjacent layers, usually between standard cell rails on M1/M2. Only stapling vias in the horizontal direction are supported. By default the command will check DRC against std cells and signal/clock nets. All created vias will be assigned attribute is_via_staple true. It does not honor app options plan.pgrouter.honor_signal_route_drc and plan.pgroute.honor_std_cell_drc.

EXAMPLES

The following example creates PG stapling vias for net VDD between M1/M2 horizontal shapes. The mask of cuts is automatically assigned, and the maximum array size is 20.

```
prompt> create_pg_stapling_vias \
   -nets VDD \
   -from_layer M1 \
   -to_layer M2 \
   -from_shapes [get_shapes -of_objects VDD -filter "layer_name == M1"] \
   -to_shapes [get_shapes -of_objects VDD -filter "layer_name == M2"] \
   -mask auto \
   -max_array_size 20
```

The following example creates collections of vias that are tagged with the name pg1.

```
prompt> create_pg_stapling_vias \
   -nets VDD \
   -from_layer M1 \
   -to_layer M2 \
   -from_shapes [get_shapes -of_objects VDD -filter "layer_name == M1"] \
   -to_shapes [get_shapes -of_objects VDD -filter "layer_name == M2"] \
```

```
    -mask auto \
    -max_array_size 20 \
    -tag pg1
prompt> set vias [get_vias -filter tag==pg1]
```

The following example creates PG stapling vias for net VDD between non-adjacent M0/M2 horizontal shapes. It then checks number of vias with attribute is_via_staple==true

```
prompt> create_pg_stapling_vias \
    -nets VDD \
    -from_layer M0 \
    -to_layer M2 \
    -from_shapes [get_shapes -of_objects VDD -filter "layer_name == M0"] \
    -to_shapes [get_shapes -of_objects VDD -filter "layer_name == M2"]
prompt> sizeof_collection [get_vias -filter is_via_staple==true]
```

top_width float
var1 string
bottom_width float
var2 string
top_shift string
bottom_shift string
layers list
var string
var_list list
top_mask string (mask_one|mask_two|mask_three|follow_pin)
bottom_mask string (mask_one|mask_two|mask_three|follow_pin)

ARGUMENTS

pattern_name

Specifies the name of the standard cell rail connection pattern.

-rail_width {*top_width* | *@var1 bottom_width* | *@var2*}

Specifies the top cell row rail width and bottom cell row width. This option is optional. By default, the tool uses the longest PG pin width. The units are defined in the technology file. Each width can also be specified by evaluating the *var1* and *var2* variables in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. If only one width is specified, it is applied to both top and bottom width values. If rail width is not specified, the standard cell pin width is used by default. This option is required when a design does not contain any standard cells.

-rail_shift {*top_shift* | *@var1 bottom_shift* | *@var2*}

Specifies the shift distance of rails. The units are defined in the technology file. The rail shift can also be specified by evaluating the *var1* and *var2* variables in the **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. A positive distance shifts the bottom and top rails into the cell rows. A negative distance shifts the bottom and top rails out from the cell rows. If only one shift value is specified, it is applied to both top and bottom shift values. The shift value is applied to the center of rail with respect to the row boundary, that is, a shift value of 0 can align the center of rail with the row boundary. By default, the rails are aligned with standard cell pins.

-rail_mask {*top_mask* | *@var1 bottom_mask* | *@var2*}

Specifies the top cell row rail mask and bottom cell row mask. This option is optional. By default, the rail is not colored with any mask. Each mask can also be specified by evaluating the *var1* and *var2* variables in **-parameters** option. The at character (@) is used as a prefix to evaluate the variable. If only one mask is specified, it is applied to both top and bottom masks. The valid keyword for rail mask is one of mask_one, mask_two, mask_three and follow_pin. "follow_pin" refers to assigning same mask of std cell pins to std rails. Report command **report_pg_patterns** reports the rail mask in the same order, i.e. top and bottom masks.

-layers *layers* | *@var*

Specifies the list of layer names for standard cell connection. By default, the standard cell power ground pin layer is used for connection. The list of layers can be specified by evaluating the variable *@var*. The variable *var* is specified in **-parameters** option. The at character (@) is used as a prefix keyword to evaluate the variable. If layers are not specified, the standard cell pin layer is used for rail creation. This option is required when a design does not contain any standard cells.

-check_std_cell_drc true | false | *@var*

Specifies the option to check DRCs between the rail and the standard cells. For example, if standard cells are not placed, the DRCs between standard cell pins and PG rails can be ignored. This option can be set to "true", "false" or by evaluating the *var* variable in the **-parameters** option. The at character (@) is used as a prefix keyword to evaluate the variable. By default, the option is "false", and DRCs between rails and standard cells are ignored for faster runtime.

-mark_as_follow_pin true | false | *@var*

Specifies the output shape_use of the generated rails. If set the option false, the generated rail will have "lib_cell_pin_connect" attribute in shape_use. If it is true, it will be "follow_pin". The at character (@) is used as a prefix keyword to evaluate the variable. By default, the option is "false".

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used by other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string and the at character (@) is used as a prefix to evaluate the parameter, such as *@var*. See the example section for more details.

DESCRIPTION

Creates a standard cell connection pattern. This pattern can be instantiated in a design by the **set_pg_strategy** command to create standard cell connections. For standard cell rails, macro and pad pins are not connected and floating segments are always kept.

EXAMPLES

The following example creates a standard cell connection pattern std_pattern_1 at layer M1.

```
prompt> create_pg_std_cell_conn_pattern \
  std_pattern_1 \
  -layers {M1}
```

The following example creates a standard cell connection pattern named std_pattern_2 at a programmable layer by using the parameter **my_metal2**. The rail width and shift distance are also specified by parameters, **w** and **dist**, respectively. When referring to this pattern with the **set_pg_strategy** command, you can program the actual layer name for the metal layer, for example "Metal2" or "M2". Parameters allow this pattern to be reused by designs with different technologies.

```
prompt> create_pg_std_cell_conn_pattern \
  std_pattern_2 \
  -parameters {my_metal2 w dist} \
  -layers {@my_metal2} \
  -rail_width {@w @w} \
  -rail_shift {@dist}
prompt> set_pg_strategy \
  s1 \
  -core \
  -pattern {{name: std_pattern_2}{nets: VDD}{parameters: {M2 2 10}}} \
  -extension {{stop: 10} {layers: M2}}
```

MORE EXAMPLES

For more example, please start GUI and invoke the following command. **gui_show_task -task "Design Planning:PG Planning->Examples->Overview"**

create_pg_strap

Creates power ground straps. Vias are also created between the new strap shapes and existing shapes.

SYNTAX

status **create_pg_strap**
-layer *layer_name*
-direction horizontal | vertical
-width *value*
-net *net_name*
[-start *value*]
[-stop *value*]
[-pitch *value*]
[-low_end *value*]
[-high_end *value*]
[-extend_low *ext_type*]
[-extend_high *ext_type*]
[-via_rule *via_rule_spec*]
[-drc no_check | check_but_no_fix]
[-show_phantom]
[-tag *tag_name*]
[-mark_as *pg_type*]
[-mask mask_one | mask_two | mask_three]
[-mask_constraint *constraint_name*]

Data Types

layer_name string
value float
net_name string
ext_type specification
via_rule_spec specification
tag_name string
pg_type specification
constraint_name string

ARGUMENTS

-layer *layer_name*

Specifies the layer name on which to create the PG strap. This is a required option.

-direction horizontal | vertical

Specifies the direction of the PG strap. This is a required option. Legal directions are "horizontal" and "vertical".

-width *value*

Specifies the width of the PG strap. This is a required option. *value* is a float value with um as the unit.

-net *net_name*

Specifies net name of the PG strap by the string *net_name*. This is a required option.

-start *value*

Specifies the starting position of the PG strap. This is a required option. *value* is a float value with um as the unit.

-stop *value*

Specifies the stopping point of the PG strap. This option works with **-pitch** option to create multiple PG straps.

-pitch *value*

Specifies the pitch of the PG straps. This option works with **-stop** option to create multiple PG straps.

-low_end *value*

Specifies the low end coordinate of the PG strap. It could be specified as a fixed *value* with um as the unit. This option is not required. By default, the strap is extended to the core area boundary.

-high_end *value*

Specifies the high end coordinate of the PG strap. It could be specified as a fixed *value* with um as the unit. This option is not required. By default, the strap is extended to the core area boundary.

-extend_low *ext_type*

Specifies the extension type for the low end of PG strap. *ext_type* should be one of **core**, **design_boundary**, **design_boundary_and_generate_pin**, **first_target**, **innermost_ring**, **outermost_ring** or **pad_ring**.

If **-low_end** is not specified, by default the low end of PG strap is extended to the core area boundary. If **-low_end** is specified, by default the low end of PG strap stops at the value specified by **-low_end** and no extension is performed. If both **-extend_low** and **-low_end** are specified, the extension is perform based on the value specified by **-low_end**.

-extend_high *ext_type*

Specifies the extension type for the high end of PG strap. *ext_type* should be one of **core**, **design_boundary**, **design_boundary_and_generate_pin**, **first_target**, **innermost_ring**, **outermost_ring** or **pad_ring**.

If **-high_end** is not specified, by default the high end of PG strap is extended to the core area boundary. If **-high_end** is specified, by default the high end of PG strap stops at the value specified by **-high_end** and no extension is performed. If both **-extend_high** and **-high_end** is specified, the extension is perform based on the value specified by **-high_end**.

-via_rule *via_rule_spec*

Specifies the via rule *via_rule_spec* between the new PG strap and existing shapes including existing PG shapes, macro pins and terminals (top-level block pins). The via rule defines the intersection locations and the via at the locations.

There are three methods to define the intersection locations in the specification *via_rule_spec*, where the syntax is defined as follows:

{**intersection** : all} {*via_def*} |
{**intersection** : adjacent} {*via_def*} |
list_of_filter_rules

The first method is "{**intersection** : all}", where **intersection** is the keyword, and **all** refers to all intersections between the PG strap and any orthogonal existing shapes in any different layers. Existing shapes include PG shapes such as straps, rings, standard cell rails and macro connections, as well as macro pins and terminals.

The second method is "{**intersection** : adjacent}", where **intersection** is the keyword, and **adjacent** refers to all intersections between the PG strap and any orthogonal existing shapes only in adjacent layers.

The third method is to define the intersections based on the PG strap and a set of shapes using *list_of_filter_rules*, which contains a list of filtering rule. Each filtering rule is inside a curly brace pair. The syntax of each filtering rule is as below:

{{*set*}{*filter*}}{*via_def*} |
{**intersection** : undefined}{*via_def*}

where *set* refers to the set of shapes and *filter* refers to the filtering operations for this set. *set* is defined as follows:

{**existing** : *shape_type*} |
{**macro_pins** | **terminals** : all | *pin_names*}

where **existing** is the keyword for existing PG wires, **macro_pins** is the keyword for macro pins and **terminals** is the keyword for terminals. Existing wires are specified by shape type *shape_type*, which could be ring, strap, macro_conn and std_conn.

The keywords ring, strap, std_conn, and macro_conn specify ring, strap, standard cell, and macro pin connection types. Macro pins or terminals could be specified by the all keyword, or by a list of pin names in *pin_names*. The filtering operations of the set of existing shapes are defined as follows:

{**nets** : *net_list*}
{**layers** : *layer_list*}
{**width** : {*lower_w upper_w*}}

nets, **layers**, **width** keywords can be used to specify the net names by *net_list*, wire layer names by *layer_list* or width range by {*lower_w upper_w*}.

By specifying the set of shapes certain filtering operations by net names, layer names, wire width ranges or types, the via locations are the intersections between the subset of shapes and the PG strap. For those intersections which do not belong to any filtering rule, the via definition can be specified by

{**intersection** : undefined}{*via_def*}

where **intersection** is the keyword, **undefined** refers to the remaining intersections which do not belong to any filtering rules. By default, vias are created only if the intersection matches one or more filtering rules. Multiple via filtering rules, that is, intersection location and via definition, can be defined and separated by curly braces where each filter rule is in one curly brace pair.

With the intersection definition, the via specification {*via_def*} uses the following format:

{**via_master** : *via_master_list* | *via_rule_list*}

where **via_master** is the keyword for via masters including via contact code defined in the technology file or user-defined via cells, as well as the PG via rules defined by **set_pg_via_master_rule** command. The *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or multiplication is needed, via rules specified by **set_pg_via_master_rule** command can be used. *via_rule_list* is a list of PG via rules. **NIL** can be used as a keyword indicate that no via is created. **default** can be used to describe the default vias in the specified location. If **NIL** is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection between the PG strap and any orthogonal shapes in different layers.

-drc no_check | check_but_no_fix

Specifies the DRC option for PG strap creation. The argument following **-drc** must be either no_check or check_but_no_fix. no_check means that no DRC check is performed. check_but_no_fix means that DRC check is performed, DRC errors are reported, but no DRC fixing is performed. The PG strap and associated vias are created, based on the specification when this

option is used. By default, DRC is checked and fixed for the PG strap.

-show_phantom

Generates report for wires/vias that should be created but failed due to fixing DRC violation. Detailed information will be displayed in error browser. The report includes two parts, phantom wire and phantom via. Wire information and DRC violation are included in one phantom wire. Only DRC violations that cut part of wire shape while fixing will be included in phantom wire. Abutted phantom wires will be merged and reported together. Via information and DRC violation are included in one phantom via. Via information includes top/bottom wire information, via def, net name. DRC violation shows initial violation before fixing. If **-drc** no_check or check_but_no_fix is specified, phantom via will not be generated.

-tag *tag_name*

Specifies a tag name to assign to all new vias and shapes created by this command. This tag name is used as contents of an user attribute tag for filtering collections at later stages (see the example in the EXAMPLES section). By default, no tags are assigned.

-mark_as strap | ring | std_conn | macro_conn

Specifies the type of the PG strap and associated vias to be created. The argument must by on of these keywords: strap, ring, std_conn and macro_conn. These types refer to strap, ring, standard cell connection and macro connection respectively. By default, the strap type is used.

-mask mask_one | mask_two | mask_three

Specifies the mask option for the PG strap. By default, the PG strap is not colored with a mask identifier if not specified. The type of mask can be specified by one of the keywords, mask_one, mask_two, mask_three.

-mask_constraint *constraint_name*

Specifies the mask constraint for the PG strap. The PG mask constraint is defined by **set_pg_mask_constraint** command. The PG strap will be checked against the specified constraint. If the constraint is not satisfied, the strap will not be created with error message issued. By default, PG mask constraint is not checked.

DESCRIPTION

Creates one or more power ground straps. Vias are also created between the new strap shape and existing shapes. The command is used to create one or multiple straps in special cases where pattern-based PG cannot create power ground straps.

EXAMPLES

The following example creates a VDD PG strap on layer M3, center at 100um, width as 3um, and horizontal direction. Both ends are extended to core area boundary by default.

```
prompt> create_pg_strap \
  -layer M3 \
  -direction horizontal \
  -width 3 \
  -net VDD \
  -start 100
```

The following example creates VDD PG strap on layer M3, starting at 100um and stopping at 150um with pitch 20um, width as 3um,

and horizontal direction. Both ends are extended to core area boundary by default.

```
prompt> create_pg_strap \
  -layer M3 \
  -direction horizontal \
  -width 3 \
  -net VDD \
  -start 100 \
  -stop 150 \
  -pitch 20
```

The following example creates a VDD PG strap on layer M3, center at 100um, width as 3um, horizontal direction, low end at 50um and high end 300um. DRC is checked but not fixed. All the new shapes are marked as macro connection.

The low end is extended to the innermost ring. The high end is extended to the design boundary with pin generated. Vias are created between the PG strap and rings using a specified rule, but not for macro pins. Default vias are inserted at any remaining intersections.

```
prompt> create_pg_strap \
      -layer M3 \
      -direction horizontal \
      -width 3 \
      -net VDD \
      -start 100 \
      -low_end 50 \
      -high_end 300 \
      -extend_low innermost_ring \
      -extend_high design_boundary_and_generate_pin \
      -drc check_but_no_fix \
      -via_rule { \
            {{existing: ring} {via_master: VIA34}} \
            {{macro_pins: all} {via_master: nil}} \
            {{intersection: undefined} {via_master: default}} \
      }
```

The following example creates a VDD PG strap on layer M3, starts at 100um, ends at 300um, pitch as 10um, width as 3um, and horizontal direction. Both ends are extended to core area boundary by default.

```
prompt> create_pg_strap \
  -layer M3 \
  -direction horizontal \
  -width 3 \
  -net VDD \
  -start 100 \
  -stop  300 \
  -pitch 10 \
```

The following example creates collections of wires and vias that are tagged with the name pg1.

```
prompt> create_pg_strap \
  -layer M3 \
  -direction horizontal \
  -width 3 \
  -net VDD \
  -start 100 \
  -stop  300 \
  -pitch 10 \
```

```
  -tag pg1
prompt> set wires [get_shapes -filter tag==pg1]
prompt> set vias [get_vias -filter tag==pg1]
```

via_master_list list
usage_type string
tag_name string
shape_list list
pin_name_list string
pin_collection collection
coordinate_list list
blockage_spec specification

ARGUMENTS

-nets ***netname_list***

Specifies a list of PG nets on which to create vias. This is a required option.

-within_bbox ***bboxes***

Specifies a bounding box or a list of bounding boxes within which to create PG vias. The vias are created at the power strap intersections within this bounding box. By default, design boundaries are used.

-from_types ***type_list***

Specifies a list of PG object types. The PG types should include one or more of the following keywords: **ring**, **stripe**, **lib_cell_pin_connect**, **macro_pin_connect**,**follow_pin**, **core_wire**, **macro_pin**, **shield_route**, **pwrswitch_pin**, **user_route**, and **terminal**. These types are for PG rings, PG straps, standard cell pin connections, macro pin connections, macro pins, power switch pins, user routes and terminals respectively. This option is not required. By default, all of these types are considered for via creation.

-from_layers ***layer_list***

Specifies the layer names for the PG objects. *layer_list* is a list containing layer names. This option is not required. By default, objects on all layers are considered for via creation.

-to_types ***type_list***

Specifies a list of PG object types. The PG types should include one or more of the following keywords: **ring**, **stripe**, **lib_cell_pin_connect**, **macro_pin_connect**, **follow_pin**, **core_wire**, **macro_pin**, **shield_route**, **pwrswitch_pin**, **user_route**, and **terminal**. These types are for PG rings, PG straps, standard cell pin connections, macro pin connections, macro pins, power switch pins, user routes and terminals respectively. This option is not required. By default, all of these types are considered for via creation.

-to_layers ***layer_list***

Specifies the layer names of PG objects. *layer_list* is a list of layer names. This option is not required. When not specified, objects on all layers are considered for via creation.

-via_masters ***via_master_list***

Specifies the list of via masters to be used during via creation. Contact code names defined in the technology file, custom via definitions, via rule names defined by **set_pg_via_master_rule**, and the **default** keyword can be used in the list. Given one intersection, the feasible via rules are tried for via creation, followed by the feasible specified custom via contact definitions if all via rules do not apply to this intersection, followed by the specified contact codes in technology file, followed by any feasible contact codes or custom via definitions if none of the previous conditions apply to the intersection. If **-via_masters** is not specified, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable. By default, the first DRC-clean default contact code is used for via insertion for each intersection.

-allow_parallel_objects

Specifies that vias are created between parallel objects. By default, vias are only created between orthogonal objects.

-insert_additional_vias

Specifies that vias are created between intersections with existing vias. By default, additional vias are not created for one intersection where existing vias are present for that intersection.

-drc no_check | **check_but_no_fix**

Specifies the DRC option for PG via creation. The argument following **-drc** must be either no_check or check_but_no_fix. no_check means that no DRC check is performed. check_but_no_fix means that DRC check is performed, DRC errors are reported, but no DRC fixing is performed. By default, DRC is checked and fixed for the PG via.

-show_phantom

Generates report for vias that should be created but failed due to unfixed DRC violation. Detailed information will be displayed in error browser. Via information and DRC violation are included in one phantom via. Via information includes top/bottom wire information, via def, net name. DRC violation shows initial violation before fixing. If **-drc** no_check or check_but_no_fix is specified, phantom via will not be generated.

-mark_as *usage_type*

Specifies the type of the created vias. The argument must be one of the following:

- **stripe**: Power strap
- **ring**: Power ring
- **lib_cell_pin_connect**: Standard cell connection
- **macro_pin_connect**: Macro connection
- **user_route**: User route
- **follow_pin**: Standard cell connection
- **shield_route**: Shield route

If you do not specify this option, the tool uses the shape use of the bottom layer shape for the created vias.

-tag *tag_name*

Specifies a tag name to assign to all new vias and shapes created by this command. This tag name is used as a user attribute for filtering collections at later design stages (see the example in the EXAMPLES section). By default, no tags are assigned.

-shapes *shape_list*

Specifies a list of PG shapes for which to create pg vias. If specified, The command will not search for PG shapes inside specified region, but create pg vias at intersections among the specified shapes.

-pins *pin_name_list*

Specifies a list of PG pin name for which to create pg vias. If specified, The command will not search for PG shapes inside specified region, but create pg vias at intersections among the specified pins. This option is mutual exclusive with option **-pin_collection**.

-pin_collection *pin_collection*

Specifies a collection of PG pins for which to create pg vias. If specified, The command will not search for PG shapes inside specified region, but create pg vias at intersections among the specified pins. This option is mutual exclusive with option **-pins**.

-start coordinate_list

Specifies a list of coordinates as the starting points for array based via insertion flow. The number of coordinates specified should be the same as the number of nets specified by -nets option. This option should be specified together with -pitch option. Note that -via_master option is required for this array based flow.

-pitch coordinate_list

Specifies a list of coordinates as the X/Y pitch for array based via insertion flow. The number of coordiantes specified should be no more than the number of coordinates specified by -start option. The last value in the list will be used if the number of pitches is

less than the number of starts. This option should be specified together with -pitch option. Note that -via_master option is required for this array based flow.

-create_via_matrix

If specified, the command will create via matrixes instead of single vias or via arrays. Currently this option is only honored when -start and -pitch options are specified.

-blockage {*blockage_spec*}

Specifies the routing blockage in the power ground network. The option only applys to start/pitch mode. You can specify multiple blockages within the braces, one blockage per group. Blockages are separated by braces and contain the keywords **nets:**, **layers:**, and a target specification as follows:

{{nets: *nets*} {layers: *layers*} {*target*}

where *target* is a voltage area, block, macro, macro with hard keep-out-margin (KOM), PG region, hard placement blockage, or polygon that is specified as follows:

{voltage_areas : *voltage_areas* | macros : *macro_names* |
macros_with_keepout : *macro_names* | placement_blockages : all |
polygon : {*polygon_area*} | blocks : *blocks* |
pg_regions : *region_list* }

The net names following the *nets* keyword are a subset of the nets specified by **-nets** in *pattern_expr* from **-pattern** option. If you do not specify the **nets** keyword, the blockage applies to all the nets in the strategy. The layer names following the **layers** keyword are the routing layers on which power or ground straps are blocked. If you do not specify the **layers** keyword, the blockage applies to all routing layers. Use one of the **voltage_areas**, **macros**, **polygon**, **blocks** or **pg_regions** keywords to represent the blockage area. *polygon_area* is specified as a list of coordinate points.

-create_ml_data

This option enables this command to create training data for training ML model for fixability prediction. When this option is set, the command only creates ML training data, not creating PG wires/vias.

-use_ml_model

This option enables this command to load pre-trained ML model for fixability prediction.

DESCRIPTION

Creates PG vias in the specified bounding box for the specified PG nets. This command is used for via creation in certain corner cases where the pattern-based PG creation cannot handle.

EXAMPLES

The following example creates PG vias for nets VDD and VSS in bounding box {{900um 900um} {1100um 1100um}}.

```
prompt> create_pg_vias \
   -within_bbox {{900 900} {1100 1100}} \
   -nets {VDD VSS}
```

The following example creates PG vias using 4 threads for nets VDD and VSS in bounding box {{900um 900um} {1100um

1100um}}.

```
prompt> set_host_options -max_cores 4
prompt> create_pg_vias \
   -within_bbox {{900 900} {1100 1100}} \
   -nets {VDD VSS}
```

The following example creates PG vias for nets VDD and VSS in bounding box {{900um 900um} {1100um 1100um}}. Vias are created between rings on layer M5 and standard cell connections on layer M1. Additional vias are allowed and DRC is skipped. All the vias are marked as ring type.

```
prompt> create_pg_vias \
   -within_bbox {{900 900} {1100 1100}} \
   -nets {VDD VSS} \
   -from_types ring \
   -from_layers M5 \
   -to_types lib_cell_pin_connect \
   -to_layers M1 \
   -drc no_check \
   -insert_additional_vias \
   -mark_as ring
```

The following example creates collections of vias and wires that are tagged with the name pg1.

```
prompt> create_pg_vias \
   -within_bbox {{900 900} {1100 1100}} \
   -nets {VDD VSS} -tag pg1
prompt> set vias [get_vias -filter tag==pg1]
prompt> set wires [get_shapes -filter tag==pg1]
```

The following example creates an array of vias for net VDD staring from coordinate {5 5} with X-pitch 10 and Y-pitch 10 using contact code VIA1.

```
prompt> create_pg_vias \
   -within_bbox {{0 0} {1100 1100}} \
   -nets {VDD} \
   -start {{5 5}} \
   -pitch {{10 10}} \
   -via_masters VIA1
```

The following example creates ML training data in memory, output training data to files in the directory ./pg_model, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> create_pg_vias -nets {VDD} -create_ml_data
prompt> train_pg_ml_model
```

The following example creates ML training data in memory, output training data to files in directory pg_data_1, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> create_pg_vias -nets {VDD} -create_ml_data
prompt> create_pg_ml_data -output_directory pg_data_1
prompt> train_pg_ml_model -input_directory {pg_data_1}
```

The following example loads pre-trained ML model in the directory ./pg_model for fixability prediction to reduce runtime of PG via

creation.

```
prompt> create_pg_vias -nets {VDD} -use_ml_model
```

create_pg_wire_pattern

Creates a power ground wire pattern. This pattern can be used to create a hierarchical composite pattern with the **create_pg_composite_pattern** command or instantiated in a design with the **set_pg_strategy** command to create a power ground mesh.

SYNTAX

status **create_pg_wire_pattern**
pattern_name
-direction horizontal | vertical | @*var*
-layer *layer_name* | @*var*
[-center *value* | @*var*]
[-low_end_reference_point *value* | @*var*]
[-high_end_reference_point *value* | @*var*]
[-extend_low boundary | first_target | @*var*]
[-extend_high *ext_type* | @*var*]
[-width minimum | *value_list* | @*var*]
[-pitch {*x_value y_value*} | @*var*]
[-spacing interleaving | minimum | *value_list* | @*var*]
[-trim true | false | @*var*]
[-track_alignment track | half_track | @*var*]
[-mask *mask_value*]
[-mask_constraint *constraint_name*]
[-parameters *var_list*]

Data Types

pattern_name string
var string
layer_name string
value float
mask_name string
constraint_name string
ext_type specification
value_list list
x_value float
y_value float
var_list list

ARGUMENTS

pattern_name

Specifies the name of the wire pattern.

-direction horizontal | vertical | @*var*

Specifies the direction of the wire pattern. This is a required option. The direction could be "horizontal", or "vertical", or specified by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable.

-layer *layer_name* | @*var*

Specifies the layer name of the wire pattern. This is a required option. The layer can be specified by using *layer_name* or by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable.

-center *value* | @*var*

Specifies the center of the first wire in this wire pattern. The center coordinate is relative to the pattern origin (0, 0). *value* is a float value with units defined in the technology file. The center is specified as a fixed *value* or by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the center is 0,0.

-low_end_reference_point *value* | @*var*

Specifies the low end coordinate. The coordinate is relative to the pattern origin (0,0). The low end can be specified as a fixed *value* or by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the low end of wire is extended to the left or bottom side of the routing area specified in **set_pg_strategy** command.

-high_end_reference_point *value* | @*var*

Specifies the high end coordinate. The coordinate is relative to the pattern origin (0,0). The high end can be specified as a fixed *value* or specified by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the high end of wire is extended to the right or top side of the routing area specified in **set_pg_strategy** command.

-extend_low boundary | first_target | @*var*

Specifies the extension type for the low end of wire pattern. **boundary** refers to the left or bottom side of routing area boundary. **first_target** refers to other wires within the routing area. The low extent can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. The routing area is specified in **set_pg_strategy** command.

If **-low_end_reference_point** is not specified, by default the low end of wire pattern is extended to routing area boundary. If **-low_end_reference_point** is specified, by default the low end of wire pattern stops at the value specified by **-low_end_reference_point** and no extension is performed. If both **-extend_low** and **-low_end_reference_point** is specified, the **-extend_low** will be ignored.

-extend_high boundary | first_target | @*var*

Specifies the extension type for the high end of wire pattern. **boundary** refers to the right or top side of routing area boundary. **first_target** refers to other wires within the routing area. The high extent can also be specified by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. The routing area is specified in **set_pg_strategy** command.

If **-high_end_reference_point** is not specified, by default the high end of wire pattern is extended to routing area boundary. If **-high_end_reference_point** is specified, by default the high end of wire pattern stops at the value specified by **-high_end_reference_point** and no extension is performed. If both **-extend_high** and **-high_end_reference_point** is specified, the **-extend_high** will be ignored.

-width minimum | *value_list* | @*var*

Specifies the width of the wire pattern. **minimum** refers to the minimum wire width defined in the technology file. *value_list* contains a list of width values, where the width value is a float value with units defined in the technology file. Each width value is for each wire in this wire pattern. The number of wires in this pattern is derived from the number of nets specified in

create_pg_composite_pattern or **set_pg_strategy** command. If the number of width values is smaller than the number of nets, the last width value is assumed for the extra nets. The width can also be specified by evaluating the variable *var* in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the minimum width is used.

-pitch {*x_value y_value*} | *@var*

Specifies the pitch values for the wire pattern. {*x_value y_value*} specifies the horizontal and vertical pitches when applying to a wire pattern. If only one pitch value is specified, the value is applied to both horizontal and vertical pitches if applicable. The pitch value can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the pitch is 0 for both horizontal and vertical pitches, and the wire pattern is not repeated.

-spacing minimum | interleaving | *value_list* | *@var*

Specifies the spacing between wires of the wire pattern. **minimum** refers to the minimum spacing between wires defined in the technology file based on the wire width. **interleaving** keyword means that distance between adjacent center lines of wires is equal. *value_list* contains a list of spacing values, where the spacing value is a float-type value with unit defined in the technology file. Each spacing value is for the adjacent wires in the pattern. For example, the first spacing value is for the first and the second wires. The number of wires in this pattern is derived from the number of nets specified in the **create_pg_composite_pattern** or **set_pg_strategy** command. If the number of spacing values is smaller than the number of nets minus one, the last spacing value is used for the remaining nets. The spacing can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the minimum spacing is used if this option is not specified.

-trim true | false | *@var*

Specifies the trim option for this wire pattern. The "true" keyword means to remove one-end floating or dangling wires while "false" means to keep one-end floating or dangling wires. You can also specify the setting by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable. By default, the value is "false".

-track_alignment track | half_track | *@var*

Specifies the track alignment option of this wire pattern. It can be specified by track or half_track. It can also be specified by evaluating the *var* variable in the **-parameters** option. The at character (@) character is used as a prefix to evaluate the variable.

-mask *mask_value*

Specifies the mask option for this wire pattern. You can specify either a keyword value or evaluate the *var* variable in the **-parameters** option. Valid keywords are **mask_one**, **mask_two**, **mask_three**, **mask_one_mask_two_alternate**, and **mask_two_mask_one_alternate**. To evaluate the *var* variable, use the at character (@) as a prefix to the variable name. The **mask_one_mask_two_alternate** keyword means that wires with an odd index have the mask_one color and wires with an even index have the mask_two color.

By default, the wire pattern is not colored.

-mask_constraint *constraint_name*

Specifies the mask constraint for the wire pattern. The PG mask constraint is defined by **set_pg_mask_constraint** command. The PG wires derived by this pattern will be checked against the specified constraint. It the constraint is not satisfied, the wires will not be created with error message issued. By default, PG mask constraint is not checked.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used as the argument for other options in this command. This allows the pattern to be programmed and reused by passing different parameters in different situations. Each *var* parameter in the *var_list* list is a string. The at character (@) character is used as a prefix to evaluate the parameter, for example, *@var*. See the example section for more details.

DESCRIPTION

Creates a power ground wire pattern. This pattern can be used to create a composite pattern using the **create_pg_composite_pattern** command, or instantiated in a design by the **set_pg_strategy** command to create a power ground mesh.

A wire pattern contains a group of wires. All wires in this pattern share the same layer, direction, trim option, and low end and high end. The center of the first wire can be specified. Width and spacing can be specified for each wire and between adjacent wires, respectively. The number of wires can be derived from the number of nets specified in **create_pg_composite_pattern** or **set_pg_strategy** command. The wire pattern is not repeated while the pitch can be specified in **create_pg_composite_pattern** or **set_pg_strategy** command when using this wire pattern.

EXAMPLES

The following example creates a wire pattern M3_vertical_strap, where layer is M3, direction is vertical, low and high end extension is to routing area boundary. The width and spacing are specified by evaluating variables "width_list" and "spacing_list", respectively.

```
prompt> create_pg_wire_pattern \
   M3_vertical_strap \
   -parameters {width_list spacing_list} \
   -layer M3 \
   -direction vertical \
   -width {@width_list} \
   -spacing {@spacing_list} \
   -extend_low boundary \
   -extend_high boundary
```

The following example creates a wire pattern m5_segment, where the wire is a horizontal segment at layer M5 with width 1, and the length is specified by a variable "len".

```
prompt> create_pg_wire_pattern \
   m5_segment \
   -parameters {len} \
   -layer M5 \
   -direction horizontal \
   -low_end_reference_point 0 \
   -high_end_reference_point {@len} \
   -width 1
```

MORE EXAMPLES

For more example, please start GUI and invoke the following command. **gui_show_task -task "Design Planning:PG Planning->Examples->Overview"**

create_pin

Creates one or more pins on a cell.

SYNTAX

collection **create_pin**
[-design *design*]
[-direction in | out | inout]
pin_names

Data Types

design collection
pin_names list

ARGUMENTS

-design *design*

Specifies the design in which to create the pin(s). If no design is specified, the pin(s) are created in the current design.

-direction in | out | inout

Specifies the direction of the pins. By default, the command creates pins with direction **in**.

pin_names

Specifies the names of the pins to create. Each pin name must be unique.

DESCRIPTION

This command creates pins of cells in the current design (unless otherwise specified by -design). It creates only scalar (single-bit) pins. One pin is created for each of the names listed. If a pin with the specified name already exists on the cell, the command displays an error message.

When the **create_pin** command creates pins, they are not connected. To establish a connection, you can use the **connect_net** command.

EXAMPLES

The following example creates pins named *data1* and *data2* on cell u14.

```
prompt> create_pin -direction in u14/data1
{"u14/data1"}
prompt> create_pin -direction out u14/data2
{"u14/data2"}
```

The following example creates input pins named *xg1* and *xg2* on cell u23/u8/u1.

```
prompt> create_pin {u23/u8/u1/xg1 u23/u8/u1/xg2}
{"u23/u8/u1/xg1", "u23/u8/u1/xg2"}
```

The following example creates pins named *usr1* and *usr2* on cell u5/u7.

```
prompt> current_instance u5/u7
u5/u7
prompt> create_pin -direction in {usr1 usr2}
{"u5/u7/usr1", "u5/u7/usr2"}
```

create_pin_blockage

Creates a pin blockage in the current design.

SYNTAX

int **create_pin_blockage**
-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects
[-layers *layer_list*]
[-name *pin_blockage_name*]
[-cell *cell_name*]
[*object_list*]

Data Types

llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection
layer_list	list
pin_blockage_name	string
cell_name	string or collection
object_list	list

ARGUMENTS

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary coordinates of the pin blockage. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}. A polygon is specified by its points as {*x y*} {*x y*} {*x y*} {*x y*} and so on.

Polygons may also be specified as the combined area of a mixed collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

-layers *layer_list*

Specifies a list of layers for the pin blockage. Pins will not be assigned within the blockage area on these layers. If no layer is specified, the pin blockage applies to all layers and pins will not be assigned within the blockage area on all layers.

-name ***pin_blockage_name***

Specifies the name of the pin blockage.

-cell ***cell_name***

Specifies the physical cell where the pin blockage is to be added. The pin blockage is created in the reference block for the cell using the coordinate system of the cell argument's top block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, pin blockages can be created in library cells. When not specified, the pin blockage is created in the current block.

-feedthrough_only

Specifies that this pin blockage prevents feedthrough pins from being placed in the specified area.

object_list

Specifies a list of physical pins, nets, or ports to associate with this pin blockage. The object list must be homogeneous; it cannot contain a mixture of different object types. Only the specified pins, nets' pins, and ports will avoid this pin blockage. If this option is not specified, all pins and ports will avoid this pin blockage. A pin, net, or port can be associated with multiple pin blockages. Pin assignment will avoid all pin blockages associated with a particular pin, net, or port.

DESCRIPTION

The **create_pin_blockage** command creates a pin blockage with the specified boundary in the current design. The pin blockage can be associated with a list of physical pins, nets, or ports. The list must be homogeneous; it cannot contain a mixture of object types. Each pin, net, and port can be associated to multiple pin blockages.

All associated pins, pins of associated nets, and associated ports must be placed outside of the blockage. If no objects are associated, all pins and ports will be placed outside of the blockage during pin assignment.

EXAMPLES

The following example creates a pin blockage named 'PB_1' with rectangular boundary that applies to all layers.

```
prompt> create_pin_blockage -boundary {{100 100} {200 200}} \
  -name PB_1
```

The following example creates a pin blockage with a rectilinear boundary that applies to the M1 and M2 layers only.

```
prompt> create_pin_blockage -boundary {{0 0} {2000 0} \
  {2000 2000} {1000 2000} {1000 1000} {0 1000}} -layers {M1 M2}
```

The following example creates a pin blockage with a rectangular boundary that is associated with physical pins.

```
prompt> set pins [get_pins -physical_context cell1/pin*]
prompt> create_pin_blockage -boundary {{100 100} {200 200}} $pins
```

get_pin_blockages(2)
remove_from_pin_blockage(2)
remove_pin_blockages(2)
report_pin_blockages(2)

create_pin_bus

Creates one pin_bus.

SYNTAX

collection **create_pin_bus**
[-design *design*]
[-create_pins]
[-block *block*]
-direction in | out | inout
-cell_bus *cell_bus*
pin_bus_names

Data Types

design collection
pin_bus_name string

ARGUMENTS

-design *design*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

-create_pins

Creates pin bus members if they do not exist.

-block *block*

Specifies the block where the pin bus is to be added. If specified, **create_pin_bus** has the same effect as **edit_module** in which the module is changed and changes are applied to all module occurrences.

-direction in | out | inout

Specifies the direction of the pin_bus members.

-cell_bus *cell_bus*

Specifies the cell_bus where the pin bus has to be created.

pin_bus_name

Specifies the pin bus name which has to be created. Doesn't support patterns containing hierarchial separators.

DESCRIPTION

This command creates a pin bus, collects or creates pin bus members, and puts them into the pin bus created.

Width of created pin bus will be same as cell bus on which it is created.

The command returns the created pin_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates pin bus named bus1 from pins 1 to 5 as bus[1]/bus1, bus[2]/bus1, bus[3]/bus1 and so on. The width of the pin bus is the same as the cell bus on which it is created.

```
prompt> create_pin_bus -cell_bus bus bus1
{"bus/bus1"}
```

The following example first creates pins, then creates a pin bus named bus/bus2 from the created pin bus[1]/bus2, bus[2]/bus2, bus[3]/bus2 and so on.

```
prompt> create_pin_bus -cell_bus bus bus2 -create_pins
{"bus/bus2"}
```

SEE ALSO

get_pin_buses(2)
remove_pin_buses(2)
report_pin_buses(2)

create_pin_constraint

Creates individual and bundle pin constraints.

SYNTAX

status **create_pin_constraint**
-type individual | bundle
[-cells *cells*]
[-layers *layers*]
[-pin_spacing_tracks *spacing*]
[-pin_spacing_distance *distance*]
[-allow_feedthroughs true | false]
[-sides *side_numbers*]
[-width *width*]
[-length *length*]

[-nets *nets*]
[-pins *pins*]
[-ports *ports*]
[-exclude_sides *exclude_side_numbers*]
[-offset *offset_distance*]
[-off_edge]
[-location {*x y*}]

[-bundles *bundles*]
[-keep_pins_together true | false]
[-range {*start end*}]
[-bundle_order ordered | increasing | decreasing | equal-distance]
[-self]

Data Types

cells collection cells
layers collection of layers
spacing integer
distance distance
side_numbers collection of integers
width string
length string
nets collection of nets
pins collection of pins
ports collection of ports
offset_distance string
bundles collection of net bundles
range string
x float
y float

ARGUMENTS

Note the first set of arguments applies to both individual and bundle pin constraints. The second set of arguments applies to only individual pin constraints, and the third set of arguments applies only to bundle pin constraints. If the user provides a type-specific argument for the incorrect type the command will return an error.

-type individual | bundle

Specifies the type of pin constraint to create.

-cells *cell_collection*

Limits the constraints to the specified cells. The cells must correspond to sub-levels of physical hierarchy in the top design. When creating individual pin constraints, this argument is only valid when used with **-nets**.

-layers *metal_layers*

Specifies the set of metal layers allowed for pin placement. The argument is a list of metal layer names as returned by the **get_layers** command.

By default, the metal layers from M2 to the maximum metal layer (specified earlier during floorplan flow) are allowed for pin placement. If the maximum metal layer has not been specified, the maximum available metal layer specified in the technology file is used as the default. If the maximum layer specified is beyond the maximum metal layer for the current design, then the maximum layer in the technology file is used.

-pin_spacing_tracks *spacing_number*

Specifies the minimum number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks. The default pin-to-pin spacing is one wire track. The spacing number must be 0 or a positive integer.

This option is mutually exclusive with **-pin_spacing_distance**.

-pin_spacing_distance *spacing_distance*

Specifies the minimum distance between adjacent pins or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks.

This option is mutually exclusive with **-pin_spacing_tracks**.

-allow_feedthroughs true | false

Specifies whether feedthrough ports can be created in pin placement flow. When true, the global router can create feedthrough routing on a block cells for the specified nets. When a feedthrough is created on a top-level net, the net is split into a set of new top-level nets and child-level nets if feedthrough nets are created for the child nets. Directions are assigned for the new feedthrough ports, and the netlist is modified to accommodate the new ports in the block cell.

When used for individual pin constraints, this option can only be specified together with the **-nets** option and cannot be used together with **-cells** option. To set feedthrough constraints on individual block cells for selected nets, create a pin constraints file and use the **read_pin_constraints** command.

This option can also be used to set feedthrough allowance for the push-down into a block of pre-routed nets using **push_down_objects**. That command will check this pin constraint, and if found to be set, and set to true, will create feedthroughs based upon the pre-route multiple crossing of a block's boundary.

For individual pin constraints, this option is only applicable with the **-net** argument. Also, for individual pin constraints, this option is mutually exclusive with the **-cells** argument.

-sides *side_numbers*

Specifies one or more block sides on which the pin must be placed.

A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the left-most vertical edge is the starting edge (side number 1). If there are multiple left-most edges, then the edge 1 is the lowest left-most edge. You cannot specify a value of 0 for this option.

For individual pin constraints, this option is mutually exclusive with **-exclude_sides** option.

-width *pin_width*

Specifies the width of the pin. The width is perpendicular to the layer's preferred routing direction. The syntax can be a single real number to indicate the width is applied to all allowed layers (referred to as common pin width). Or alternatively, the width can be specified as a list of layer-real pairs as the following (referred to as per layer pin width):

-width {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its width should be 0.2 and if on M4 or M5, 0.3. On other layers, use the default width defined by the tech file.

If you first set the pin width to be common pin width, then set the pin width to be per layer width with a second **create_pin_constraint** command, then the width specified in the second command will override the first. Likewise, if you first set the pin width to be per-layer width, then set the pin width to be a common pin width with a second **create_pin_constraint** command, then the width specified in the second command will override the first.

However, if you first set the pin width to be per layer, then in a second command sets the pin width again to be per layer but with different layers or different values, then the combined per layer pin width will be the final constraints. For example, consider the following example:

```
create_pin_constraint -bundles {bundle1} -width 0.3
create_pin_constraint -bundles {bundle1} -width {{M2 0.3} {M3 0.3}}
```

The first common pin width constraint will be overridden by the second per layer pin width. The pin width should be 0.3 on layer M2 or M3, but default width on all other layers.

And for the following example:

```
create_pin_constraint -bundles {bundle1} -width {{M3 0.4} {M4 0.4}}
create_pin_constraint -bundles {bundle1} -width {{M2 0.3} {M3 0.3}}
```

The pin width should be 0.3 on layer M2 or M3, 0.4 on layer M4, and default width on all other layers.

-length *pin_length*

Specifies the length of the pin. The length is in parallel to the layer's preferred routing direction. The syntax can be a single real number to indicate the length is applied to all allowed layers (referred to as common pin length). Or alternatively, the length can be specified as a list of layer-real pairs as the following (referred to as per layer pin length):

-length {{M2 0.2} {M3 0.2} {M4 0.3} {M5 0.3}}

It means that if the pin is to be placed on layer M2 or M3, its length should be 0.2 and if on M4 or M5, 0.3. On unspecified layers, the pin length is derived from the pin width. Refer to the manpage of **place_pins** for details.

-pins *pins*

Specifies the pins that receive the constraints. Specify the full pin name from top-level design.

-nets *nets*

Applies the constraints only to the nets specified in *nets*.

-ports *ports*

Specifies the ports that receive the constraints.

-exclude_sides *exclude_side_numbers*

Specifies the block edges on which pins cannot be placed. The *exclude_side_numbers* argument is a list of positive integers.

A side number is a positive integer that starts at one, and increments by one as you proceed clockwise around each edge in the shape. Given any rectilinear shape, the left-most vertical edge is the starting edge (side number 1). If there are multiple left-most edges, then the edge 1 is the lowest left-most edge. You cannot specify a value of 0 for this option.

When creating individual pin constraints, this option is mutually exclusive with **-sides** option.

-offset *offset_distance*

Specifies the distance in microns between the starting or ending point of a specified edge and the pin's center location. The starting point is the location where the edge begins as you proceed clockwise around the shape. The ending point is the location where the edge end as you proceed clockwise around the shape. The starting point of edge 1 is the lowest point of the edge, the ending point of edge 1 is the highest point of the edge the starting point of edge 2 is the leftmost point of the edge, and so on. Positive value means offset distance calculates from starting point of a specified edge and the pin's center location, vice versa for negative value.

A range can also be specified for this option. Specify range start and range end values within which the pins are allowed to place. The start and end values refer to the distances as measured to the starting point of the edge in microns (or the default unit). Negative value for range refer to the distances as measured to the ending point of the edge in microns (or the default unit). For example,

-offset {10 40}

You must specify the side information together with the offset. However, offset cannot be specified with multiple sides.

-off_edge

Specifies whether the pin is created on the block boundary. This option is mutually exclusive with the **-sides** and **-offset** options.

-location *{x y}*

Specifies the x- and y-location in the top-level design where the pin should be created. This option is mutually exclusive with the **-sides** and **-offset** options. When used together with the **-off_edge** option, the pin is placed on the closest wiretrack to the specified location. Note that in this case there will be no legalization of pin placement for off edge pins, as it is meant to be a basic placement where user is expected to give the legal location. If the location constraint is a hard constraint set by the **set_block_pin_constraints** command, the center of the pin is placed at the exact location specified by this option. If you do not specify the **-off_edge** option, the pins are placed on the edge that is closest to this location.

-bundles *bundles*

Limits the constraints to the specified net bundles. The bundles must be in the top-level of the current design. If not specified, the command applies the constraints to all net bundles.

-keep_pins_together true | false

Specify whether bundle pins are kept together. When this option is true, all bundle pins on the same block are placed on the same layer (hard constraint) and no other pins should be placed between the bundle pins (soft constraint). In certain cases, the command might violate the soft constraint and insert other pins between the bundle pins. The default value is false.

-range {*start end*}

Specifies the range of positions on a side within which the bundle pins must be placed. The positive *start* and *end* values refer to the distances as measured to the starting point of the edge in microns (or the default unit). The negative *start* and *end* values refer to the distances as measured to the ending point of the edge in microns (or the default unit). Postive *start* is the position that is

closest to the edge's starting point, and postive *end* is the position that is farthest to the edge's starting point. Vice versa for negative *start* and *end* positions. The starting point of an edge is the vertex of the edge where the edge begins as you proceed clockwise around the block's boundary from the lowest vertex of the leftmost edge. If there are more than one leftmost edges, then from the lowest one.

The following simple drawing shows an example of how postive *start* and *end* are measured on a rectangular block on each of the sides.

```
 +---start-------end------+
 |                |
 |                start
end                 |
 |                |
 |                end
start               |
 |                |
 +------end-----start-----+
```

The following simple drawing shows an example of how negative *start* and *end* are measured on a rectangular block on each of the sides.

```
 +---end-------start------+
 |                |
 |                end
start               |
 |                |
 |                start
end                 |
 |                |
 +------start-----end-----+
```

-bundle_order ordered | increasing | decreasing | equal-distance

Specifies the relative placement order of the pins connected to the bundle nets. Note that the order refers to the net order in the bundle, not the pins on the block. The bundle order is measured as seen at the current top design. Pin placement considers this option only when option **-keep_pins_together** is set to true. If two or more bundles connecting the same collection of MIB pins but with conflict orders, only one of them can be honored.

- ordered: Pins are ordered according to the net order in the bundle. For vertical block sides, bundle pins can be placed either from bottom to top or from top to bottom. For horizontal sides, bundle pins can be placed either from left to right or from right to left. The orders on each edges are chosen such that for the bundle nets connect the bundle pins from one edge to another edge, there is no net crossing, i.e. river turn style.

  In the following example, bundle pin constraint is specified as *ordered* so that the nets connecting two bundle pins are of the river turn style, i.e. no crossing.

  ```
  prompt> create_pin_constraint -type bundle -layers {M3} -bundles bundle1 \
    -bundle_order ordered -keep_pins_together true
  ```

- increasing: Pins are ordered according to the increasing net order in the bundle. For vertical block sides, bundle pins are placed from bottom to top. For horizontal block sides, bundle pins are placed from left to right.

  In the following example, bundle pin constraint is specified on a rectangular block so that bundle pins are placed on side 2 (horizontal edge) of block. Pins are placed from left to right (Least significant bit is the leftmost; Most significant bit is the right most on side2).

  ```
  prompt> create_pin_constraint -type bundle -bundles bundle1 -sides 2 \
    -bundle_order increasing -keep_pins_together true
  ```

- decreasing: Pins are ordered according to the decreasing net order in the bundle. For vertical block sides, bundle pins are placed from top to bottom. For horizontal block sides, bundle pins are placed from right to left.

  In the following example, bundle pin constraint is specified on a rectangular block so that bundle pins are placed on side 2 (horizontal edge) of block. Pins are placed from right to left (Most significant bit is the leftmost; Least significant bit is the rightmost).

  ```
  prompt> create_pin_constraint -type bundle -bundles bundle1 -sides 2 \
    -bundle_order decreasing -keep_pins_together true
  ```

- equal-distance: Pins are ordered as with **-bundle_order ordered**, but the pin ordering for two edges is chosen to create the same Manhattan distance between each corresponding pair of pins.

  In the following example, bundle pin constraint is specified as *equal-distance* so that the Manhattan distacnes of each bits of the bundle are the same for bundle *bundle1*.

  ```
  prompt> create_pin_constraint -type bundle -layers {M3} -bundles bundle1 \
    -bundle_order equal-distance -keep_pins_together true
  ```

  Note that when setting bundle pin constraints on pins of multiple instantiated blocks (MIB), as the orientation of MIBs can be different, the tool chooses one of the MIBs randomly to honor the constraints. Therefore the bundle constraints could be not honored for the other MIBs.

  When option **-keep_pins_together** is set to true but option **-bundle_order** is not specified, the tool will choose from either **increasing** or **decreasing** based on alignment, abutment and wire length cost. The bundle order might also be decided by already placed or fixed bundle pins on this bundle due to alignment or abutment.

-self

Applies the constraints to the top-level block. You can combine the **-cells** and **-self** options. If both the **-cells** and **-self** options are unspecified, the constraints apply to all block cells.

DESCRIPTION

This command constrains the placement of net bundles, individual pins, individual ports, or individual nets on a physical design block. The pin placement constraints are saved in the design database. The constraints are honored by the **place_pins** command.

The **create_pin_constraint** command is additive. The constraint values set in previous calls are retained, unless they are explicitly overridden by subsequent calls.

The **set_editability** command can enable or disable the **create_pin_constraint** command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the **set_editability** command.

- Global constraints: Constraints apply to all bundles and all block instances.
- Specific bundle constraints: Constraints apply to a specific bundle and all block instances.
- Specific block constraints: Constraints apply to all bundles and a specific block instance. Note that this can apply to the top-level block when you specify the *-self* option.
- Bundle and block pair constraints: Constraints apply to a specific bundle and a specific block instance. Note that this can apply to the top-level block when you specify the *-self* option.

Upon success, the command returns a collection of pin constraints containing the newly created pin constraint.

EXAMPLES

The following example sets the allowed pin layers to METAL2 and METAL3 for bundle BUNDLE_0. This creates a specific bundle constraint.

```
prompt> create_pin_constraint -type bundle -layers [get_layers METAL2 \
  METAL3] -bundles [get_bundles BUNDLE_0]
```

The following example enforces ordering on all bundle pins of cell BLOCK1. This creates a specific block constraint.

```
prompt> create_pin_constraint -type bundle -bundle_order ordered \
  -cells [get_cells BLOCK0] -keep_pins_together true
```

The following example enforces ordering and minimum pin spacing for bundle BUNDLE_0. This creates a specific bundle constraint.

```
prompt> create_pin_constraint -type bundle -bundle_order ordered \
  -pin_spacing_tracks 2 -bundles [get_bundles BUNDLE_0] -keep_pins_together true
```

The following example sets the allowed pin layers for net clk to M2 and M3.

```
prompt> create_pin_constraint -type individual -layers [get_layers {M2 M3}] \
  -nets [get_nets clk]
```

create_pin_guide

Creates a pin guide in the current design.

SYNTAX

int **create_pin_guide**
-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects
[-layers *layer_list*]
[-parents *cell_list*]
[-name *pin_guide_name*]
[-exclusive]
[-pin_spacing *number_of_wire_tracks*]
[-cell *cell*]
object_list

Data Types

llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection
layer_list	list
cell_list	list
pin_guide_name	string
number_of_wire_tracks	int
cell	string or collection
object_list	list

ARGUMENTS

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary coordinates of the pin guide. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates, for example, {*llx lly*} {*urx ury*}. A polygon is specified by its points, for example, {*x y*} {*x y*} {*x y*} {*x y*} and so on.

Polygons can also be specified as the combined area of a mixed collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every

shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

-layers *layer_list*

Specifies a list of layers for the pin guide. Pins will be placed only on these layers. If layers are not specified, pins can be placed on any layer.

-parents *cell_list*

Specifies a list of block cells to which this pin guide applies. If not specified, this pin guide is applied to the current design.

-name *pin_guide_name*

Specifies the name of the pin guide.

-exclusive

Specifies that this pin guide is exclusive. This prevents the placement of terminals within the pin guide, except for pins, pins of nets, and ports associated to this pin guide.

-pin_spacing *number_of_wire_tracks*

Specifies the number of wire tracks between pins within this pin guide. When this option is specified, the pin placement command will place pins, within the pin guide, such that the pin minimum spacing is equivalent to the number of specified wire tracks.

-cell *cell*

Specifies the physical cell where the pin guide is to be added. The pin guide is created in the cell's reference block using the coordinate system of the cell argument's top block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, pin guides can be created in library cells. When not specified, the pin guide is created in the current block.

object_list

Specifies a list of physical pins nets, or bundles of nets to associate with this pin guide if the parents for the pin guide are block cells. Specifies a list of physical ports, nets, or bundles of nets to associate with this pin guide if the parent for the pin guide is the current design. The object list must be homogeneous; it cannot contain a mixture of different object types. During pin assignment, the terminals generated for these objects are constrained to the pin guide bounding box. Currently bundles of supernets is not supported. If bundle of supernets is specified then it will be skipped with a warning message.

DESCRIPTION

The **create_pin_guide** command enables you to create a pin guide with the specified boundary in the current design. The pin guide has one or more parent cells, to which the pin guide is applied. The parents of the pin guide can be the current design or a list of block cells. During pin assignment, the terminals generated for these objects are constrained to the pin guide bounding box.

If the parent of the pin guide is the current design, the pin guide can be associated with a list of physical ports or nets. If the parents of the pin guides are block cells, the pin guide can be associated with a list of physical pins or nets. The list must be homogeneous; it cannot contain a mixture of object types. Each pin, net, and port can be associated to multiple pin guides.

EXAMPLES

The following example creates a pin guide named 'PB_1' with rectangular boundary that applies to all layers of the current design. It is associated with physical ports of the current design.

```
prompt> create_pin_guide -boundary {{100 100} {200 200}} \
  -name PB_1 [get_ports clk*]
```

The following example creates a pin guide with a rectilinear boundary that applies to the M1 and M2 layers only in the current design. It is associated with physical nets in the current design.

```
prompt> create_pin_guide -boundary {{0 0} {2000 0} {2000 2000} \
  {1000 2000} {1000 1000} {0 1000}} -layers {M1 M2} [get_nets n*]
```

The following example creates a pin guide with a rectangular boundary that is associated with physical pins of the macro cell 'macroA'.

```
prompt> set macro macroA
prompt> create_pin_guide -boundary {{100 100} {200 200}} \
  -parents [get_cells $macro] [get_pins $macro/*]
```

create_placement

Performs coarse placement on the current design.

SYNTAX

status **create_placement**
[-floorplan]
[-host_options *host_option_name*]
[-use_seed_locs]
[-effort very_low | low | medium | high]
[-timing_driven]
[-buffering_aware_timing_driven]
[-congestion]
[-congestion_effort low | medium | high]
[-incremental]

Data Types

host_option_name string

ARGUMENTS

-floorplan

Specifies that floorplanning placement should be used. This includes macro placement and special effort levels which are tuned for speed. There are a number of special app option controls for floorplanning. To get a list of them use **report_app_options plan.place.*** and **report_app_options plan.macro.***. One app option which you must be aware of is **plan.place.auto_generate_blockages**. This controls whether soft blockages are automatically created in thin channels between hard macros and block boundary. This is useful for congestion reduction. See man page of this app option for more details.

-host_options *host_option_name*

Specifies that the given host option should be used for distributed processing. Host options are set with the **set_host_options** command. Note that not all operations performed by the **create_placement** command support distributed processing. The effect of this option depends on the design and the other option settings.

-use_seed_locs

Specifies that the current placement should be used as a seed for placement.

-effort very_low | low | medium | high

Specifies the CPU effort level for coarse placement. The default effort level is medium for floorplanning placement, and high for all other cases.

-timing_driven

Enables timing-driven placement. When used with the -floorplan option, you can adjust the behavior of the command with the plan.place.timing_driven_mode application option.

-buffering_aware_timing_driven

Enables timing-driven placement using an approximate timing model that estimates the effects of buffering long nets and high fanout nets later in the flow. The netlist is not changed. Intended for use as an initial placement step that gives a better starting point for later timing optimizations.

-direct_timing

Obsolete. Use the **-timing_driven** option instead.

-congestion

Enables congestion-driven placement mode.
When used with the **-floorplan** option, you can adjust the behavior of the command with the **plan.place.congestion_driven_mode** application option.

-congestion_effort low | **medium** | **high**

Specifies the effort level for congestion mode. The default effort level is medium. Expect a significant increase in runtime for high effort. This option can only be used with the **-congestion** option.

-incremental

Performs incremental placement on the design. Incremental placement tries to keep cells close to their current location. The **-incremental** option automatically enables the **-use_seed_locs** option. By default, the command can move cells far from their current location to improve placement QoR.
When **-incremental** is used in combination with **-floorplan**, the macro placement will be legalized while trying minimizing the macro movements. Also, the standard cell placement will be updated in incremental fashion. When also combined with the **-congestion** option, the command expects that the current placement is legal and that an up-to-date congestion map exists. This congestion map is used to increase the channel sizes between the macros in congested areas. Again, the standard cell placement is updated in an incremental fashion. See also the man page for the **plan.place.congestion_driven_mode** application option.

DESCRIPTION

The **create_placement** command performs coarse placement on the current design. With the **-floorplan** option, this includes the placement of hard macros as well as standard cells. To avoid placing hard macros, mark the hard macros as fixed with the **set_attribute** command.

EXAMPLES

The following example runs the **create_placement** command in timing-driven mode:

```
prompt> create_placement -effort high -timing_driven
```

create_placement_attraction

Advise coarse placer on relative placement of modules

SYNTAX

collection **create_placement_attraction**
[-name *attraction_name*]
[-region coord_list]
[-effort very_low | low | medium | high]
[-exclude_buffers none | edge | all]
[-add_internal_logic false | true]
[*cell_list*]

Data Types

attraction_name string
coord_list list
cell_list list

ARGUMENTS

-name *attraction_name*

Specifies the name of the placement attraction.

-region coord_list

Specifies the region for the placement attraction. The region may be exactly one of the following: unset (floating), point, line, rectangle. The argument takes a coordinate list and parses it to determine the desired region. If the user does not specify a value the region is unset. A coordinate list with one point corresponds to a point region. A coordinate list with two co-linear points that form an axis-parallel line corresponds to an edge region. A coordinate list with two non-co-linear points corresponds to an area region with coordinates specifying the lower left and upper right point of the rectangle. For more details, refer to the description section of this man page.

-effort very_low | low | medium | high

The **-effort** option allows you adjust how strong your attraction suggestion will be. Please see the section on "Setting the effort" below.

-exclude_buffers none | edge | all

The placer will apply a filter to the buffers and inverters in the attraction constraint. If all you specify "all", the placer will exclude all of the specified buffers and inverters from the effect of the attraction. If you specify "edge", the placer will exclude all buffers and inverters that are on timing paths that lead to logic that is outside of the attraction group. This is useful so that you don't overconstrain buffer chains which should not have attraction to a central location. If you specify "none", then the buffers and

inverters will not be excluded from the effect of the attraction. The default setting is "edge".

-add_internal_logic false | true

When specified, the placer will try to work on extra cells, in addition to the cells specified in your attraction. In particular, the placer will include logic cells that occur on timing paths between two flops that are already declared in the attraction. This is useful when you have ungrouped your logic hierarchies and run initial optimization. In general, the instance names of ungrouped logic are not maintained, which makes it difficult to put that logic into an attraction. But since flop names are generally maintained, you can put selected flops in the attraction and use this command option to fill in the intervening random logic. The default value is true.

cell_list

Specifies a list of cells to be included in the attraction constraint. Please see the section on "Specifying your cell list" below. Some or all of the cells in the list may correspond to logic hierarchies in your block. If a logic hierarchy is specified, the all of the leaf cells under that hierarchy are also implicitly included in the attraction constraint.

DESCRIPTION

When placing a block, there is often significant latitude for configuring individual of logic modules within that placement. For example, a particular logic module may be placed on the left or on the right -- with little difference in the overall placement quality. The **create_placement_attraction** command allows you to suggest how modules (or any arbitrary group of cells) should be placed -- both relative to each other and relative to the floorplan.

The **create_placement_attraction** command is a much "softer" placement constraint than the move bound or group bound constraints created by the **create_bound** command. The placement attraction is used to tell the placer about the module relationships that are important, without the need to strongly constrain every cell in each module. In general, the placement attractions will steer the placer in the right direction, but it will also trade off with other considerations like wire length and timing.

The placement_attraction constraint is meant act on modules or big groups of cells. If you are interested in constraining small groups of cells, you should be using the **create_bound** command. The placement_attraction can direct general placement, but it is generally too weak to force the placement of individual cells.

The effect of the **create_placement_attraction** command will be most pronounced in the *first placement* and will have a strong effect on where in a logic modules are placed. This makes placement attraction an excellent tool for "high level" communication with the placer. If you have run the placer and don't like where a module is located, this is how you tell the placer what you would like to see instead.

Placement attractions will not have a strong effect in subsequent (incremental or seed) placements. This is by design, so that the attractions will not block optimization of individual timing paths or congested areas. So if you are want to add new attractions to your block, you should restart your flow from *initial placement*. Note that some flows use a first placement from logic synthesis. If you use this flow, then the attractions should be set before the logic synthesis placement.

The **-region** option allows you to direct a module or group of cells to be near a given point in your floorplan. You can get different behaviors, depending on how you specify the coordinates to this option. If you specify a single point coordinate, cells will be attracted to that point. Unlike a move bound, there is no need to provide a "boundary". The placer will decide how close to the point individual cells should be. Cells with critical timing may drift very far away to improve a difficult path -- if that is appropriate.

If you specify a horizontal or veritical line to **-region**, modules or group of cells will attract near that line in your placement. It is presumed, that the given line will be near the edge of block or a macro, but that is not a requirement. Unlike a move bound, there is no need to provide a "boundary". The placer will decide how close to the line individual cells should be. Cells with critical timing may drift very far away to improve a difficult path -- if that is appropriate.

If you specify a box area to **-region** option, modules or group of cells will attract near that given area in your floorplan. The placer will decide how close to the area individual cells should be. Cells with critical timing may drift very far away to improve a difficult path -- if that is appropriate. Unlike a move bounds, there is no strong force to keep cells inside of the given box, only close. If you want to

force your cells to be mostly inside of box, use the **create_bound** command to create a move bound.

If you do not specify **-region**, then the specified cells will be kept together, but will not be constrained to a particular location in the floorplan. Unlike a group bound from the **create_bound** command, there will not be an overly strong grouping of the objects.

See the section on "Common usage" below for more details.

Setting the effort

The **-effort** option allows you adjust how strong your attraction suggestion will be. Stronger attractions will be given higher weight by the placer, but may result in some amount of over-constraining. For example, if you want to group two modules together, a high effort may hold the modules together too tightly. In general, you will want to use the lowest setting that delivers the desired result. The default setting is "low".

If you find that you need to use high effort to get the desired effect, you might want to think harder about why this is happening. If you need high effort, there is probably some competing constraint that is fighting what you want to do. For example, maybe the floorplan does not have enough space to accommodate what you want, where you want it. Or maybe there are many connections pulling your module in the opposite direction. If even high effort attraction does not work, you probably need to use a move bound to strongly force what you want.

Note that the effort levels of **create_placement_attraction** are not equivalent to those in **create_bound**. Bounds are much stronger.

Specifying your cell list

When creating a placement attraction, you need to specify the standard cells that participate in the attraction constraint. Most often, the cells will be found using the **get_flat_cells** command, with a regular expression that matches cells in a particular module. For example:

```
create_placement_attraction -name abc [get_flat_cells u_abc/*]
```

If you have preserved your logical hierarchy, the get_flat_cells command will give you all of the cells in your module. Alternatively, you can choose to simply put the logic hierarchy cell instance directly in your cell list. All contained leaf cells will be implicitly included along with the parent hierarchy.

If you have flattened some or all of your logical hierarchy, you might only find the sequential elements of a module. It is OK if you do not find all of the cells of your module. Often, setting attraction on only the sequential elements of a module will give the desired effect. The **-add_internal_logic** option (which is true by default) will help find the missing non-sequential cells.

It is often useful to use temporary collections of cells for each module that you want to constrain. The you can refer to the collections in your **create_placement_attraction** command. For example, you can create collections for module abc and module xyz:

```
set abc_cells [get_flat_cells u_abc/*]
set xyz_cells [get_flat_cells u_xyz/*]
```

After you do this you can make attractions between the modules like this:

```
create_placement_attraction -name abc_xyz "$abc_cells $xyz_cells"
```

Note that the same cells may participate in multiple placement attraction constraints. And fixed cells will be ignored.

Common usage

For the most part the placer is very good at placing modules within a block floorplan. The placer considers wire length, timing, and congestion when arranging modules within the floorplan. Placement attraction is best used only to adjust the default placement, not to dictate it. When you are first starting to work on a block, it is suggested that you don't use any placement attraction directives. This will give the placer the maximum flexibility to optimize your design.

As you find placement decisions you want to adjust, you can add attraction directives. But you should only add directives where they are needed to achieve the desired result. You may find that one added attraction on one module may have a "ripple effect" that improves other module placements. So avoid adding too many attractions, unless you absolutely need them. Using fewer attraction constraints will give the placer the maximum flexibility to optimize your design. Also, keep in mind that attractions only work well during the initial placement, not incremental placement. If you add a new attraction, start your placement again from scratch.

There are several ways to use placement attraction. We will describe a few of them below. Please note that there is a theme for the following examples. The placement_attraction constraint is meant act on modules or big groups of cells. If you are interested in constraining small groups of cells, you should be using the **create_bound** command. The placement_attraction can direct general placement, but it is generally too weak to force the placement of individual cells.

You can use **create_placement_attraction** to force the placement of a module in the floorplan. Usually, you would either use **-region** with a single point to direct the module placement to be in a corner or small area, or you would use **-region** with a horizontal or vertical line to direct a module to hug the side of the block or macro. Unlike using a move bound for this purpose, you do not have to mark out the exact boundary of the module -- just the general area.

You can use **create_placement_attraction** to influence the placement of a module near a set of RAMs. Usually, you would use **-region** to mark the area over the RAMs to pull the module close by. This is different than using a move bound from the **create_bound** command, which would tend to force the module on top of and in between the RAMs. For example, if you have a RAM array that occupies the area {{1000 1000} {1500 1500}}, then the following three constraints operate in very different ways:

```
# Place cells in between the RAMs:
create_bound -bound {{1000 1000} {1500 1500}}

# Attract the cells near a point at the center of the RAM array:
create_placement_attraction -region {{1250 1250}}

# Attract cells to be next to the RAM array:
create_placement_attraction -region {{1000 1000} {1500 1500}}
```

You can use **create_placement_attraction** without **-region** a single module to hold it together. Sometimes, when a module is not very "dense", other modules may overlap or come in the middle of your module. The attraction will pull the module together more tightly. Unlike using a group bound for this purpose, the attraction will not unduly squish the module into a particular shape.

You can use **create_placement_attraction** without **-region** to keep two or more modules in close proximity to each other. This is done by putting the cells of both modules into the same attraction group. You can use attractions with varying efforts to make more complicated groupings. For example, you can group an adder and multiplier closely together by using a "medium" effort attraction group. And then group both the adder and multiplier with other ALU units in a "low" effort attraction group.

You can use **create_placement_attraction** to influence the placement optimization of critical timing paths. For example, it is sometimes the case that timing can only be met when entire modules are carefully placed -- near a port, near a macro, or near each other. Using the **-region** options will guide placement near ports or macros. You can use **create_placement_attraction** without **-region** to keep modules together.

EXAMPLES

The following sets the attraction of cells from the "abc" module near a point. Note that two sets of curly brackets are required to make a valid coordinate list.

```
prompt> set abc_cells [get_flat_cells u_abc/*]
prompt> create_placement_attraction -name abc_near_ll \
 -region {{0 0}} $abc_cells
```

The following sets the attraction of cells from the "abc" module near a vertical edge.

```
prompt> set abc_cells [get_flat_cells u_abc/*]
prompt> create_placement_attraction -name abc_on_the_left \
 -region {{0 0} {0 1500}} $abc_cells
```

The following sets the attraction of cells from the "abc" module near the area occupied by L2 RAMs.

```
prompt> set abc_cells [get_flat_cells u_abc/*]
prompt> set l2_rams [get_flat_cells u_l2/* -filter "is_hard_macro==true"]
prompt> set l2_mask [create_geo_mask $l2_rams]
prompt> create_placement_attraction -name abc_near_l2 \
 -region [get_attribute $l2_mask bbox] $abc_cells
```

The following ties the cells from the "abc" to be near the cells of the "mmu" module. The location is not restricted to any particular area of the floorplan.

```
prompt> set abc_cells [get_flat_cells u_abc/*]
prompt> set def_cells [get_flat_cells u_mmu/*]
prompt> create_placement_attraction -name abc_near_mmu \
 "$abc_cells $mmu_cells"
```

The following ties cells of the adder module to be close to cells of the multiplier module, and then more loosely ties all cells of the alu together.

```
prompt> set add_cells [get_flat_cells u_alu/u_add/*]
prompt> set mult_cells [get_flat_cells u_alu/u_mult/*]
prompt> set all_alu [get_flat_cells u_alu/*]
prompt> create_placement_attraction -name add_near_mult \
 "$add_cells $mult_cells"
prompt> create_placement_attraction -name all_alu -effort low \
 $all_alu
```

create_placement_blockage

Creates a new placement blockage.

SYNTAX

collection **create_placement_blockage**
-boundary *boundary_spec*
[-type *blockage_type*]
[-purpose user | system]
[-blocked_percentage *percentage*]
[-name *blockage_name*]
[-category *category_name*]
[-cell *cell*]

Data Types

boundary_spec list
blockage_type string
percentage integer
blockage_name string
category_name string
cell collection

ARGUMENTS

-boundary *boundary_spec*

Specifies the boundary of the placement blockage. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  {{*llx lly*} {*urx ury*}}

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  {{*x1 y1*} {*x2 y2*} ... {*xn yn*}}

- Specify the boundary as a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects.

  In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. In the case of layers, the resulting area includes the area of every shape on the layer.

  When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

-type *blockage_type*

Specifies the type of placement blockage to create.

Valid values are

- **hard** (the default)

  A hard blockage prevents the placement of standard cells in the specified region. It is honored by placement, legalization, optimization, and clock tree synthesis.

- **hard_macro**

  A hard macro blockage prevents the placement of hard macros in the specified region. It is honored by placement, legalization, and optimization. This is the only type of placement blockage that is honored by hard macro placement.

- **soft**

  A soft blockage prevents the placement of standard cells in the specified region. It is honored by coarse placement, but not legalization, optimization, and clock tree synthesis.

- **partial**

  A partial blockage limits the cell density in the specified region. It is honored by coarse placement, but not legalization, optimization, and clock tree synthesis.

  When you create a partial blockage, you must specify the blocked percentage value by using the **-blocked_percentage** option.

- **category**

  A category blockage is a partial blockage that also prevents the placement of a specific category of cells in the specified region. It is honored by coarse placement, but not legalization, optimization, or clock tree synthesis.

  The cell categories are identified by a category name attribute. When you create a category blockage, you must specify the category name by using the **-category** option and the blocked percentage value by using the **-blocked_percentage** option.

- **rp_group**

  A relative placement group blockage is a partial blockage that also prevents the placement of relative placement groups in the specified region. It is honored by coarse placement, but not legalization, optimization, or clock tree synthesis.

  When you create a relative placement group blockage, you must specify the blocked percentage value by using the **-blocked_percentage** option.

- **allow_buffer_only**

  An allow-buffer-only blockage allows only buffers and inverters to be placed in the specified region. The cell density is limited to the specified percentage of the blockage area. It is honored by coarse placement, but not legalization, optimization, or clock tree synthesis.

  When you create an allow-buffer-only blockage, you must specify the blocked percentage value by using the **-blocked_percentage** option.

- **allow_rp_only**

  An allow-relative-placement-only blockage allows only relative placement groups to be placed in the specified region; however, hard macros can overlap with the specified region. the cell density is limited to the specified percentage of the blockage area. It is honored by coarse placement, but not legalization, optimization, or clock tree synthesis.

  When you create an allow-relative-placement-only blockage, you must specify the blocked percentage value by using the **-blocked_percentage** option.

- **register**

  A register blockage is a partial blockage that also prevents the placement of registers in the specified region. It is honored by coarse placement, but not legalization, optimization, or clock tree synthesis.

  When you create a register blockage, you must specify the blocked percentage value by using the **-blocked_percentage** option.

-purpose user | **system**

Specifies the purpose of the blockage to be created.

Valid values are:

- **user** (the default)

  This should be used by all user-created blockages and ensures that any automated tools will not remove the blockage.

- **system**

  A system blockage can be removed by tools that create and manipulate blockages. Create a blockage with this purpose only when it can be removed by an automatic tool.

-blocked_percentage ***percentage***

Specifies the percentage blockage for a partial blockage.

This option can only be used with **partial**, **category**, **rp_group**, **allow_buffer_only**, **allow_rp_only**, and **register** blockage types.

-name ***blockage_name***

Specifies the optional name of the blockage. If you specify a name for the blockage, you can get the blockage by name later in the flow.

-category ***category_name***

Specifies the category name for a category blockage.

This option can only be used with the **category** blockage type.

-cell ***cell***

Specifies the physical cell in which to add the placement blockage.

The placement blockage is created in the cell's reference block using the coordinate system of the cell's top-level block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, placement blockages can be created in library cells.

By default, the placement blockage is created in the current block.

DESCRIPTION

This command creates a new placement blockage that is used to control the placement of cells in a specified boundary.

Snapping to the bounding box is done automatically using the global snap settings.

See the description of the **-type** option for more information about the supported placement blockage types and how they are supported by the various engines.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a soft placement blockage.

```
prompt> create_placement_blockage -type soft \
  -boundary {{0 0} {0 100} {100 100} {100 0}}
```

The following example creates a hard placement blockage.

```
prompt> create_placement_blockage -type hard \
  -boundary [get_shapes POLYGON_0]
```

SEE ALSO

create_routing_guide(2)
create_routing_blockage(2)

create_poly_rect

Creates a collection of poly_rect objects.

SYNTAX

collection **create_poly_rect**
-boundary {*boundary_spec*}
[-layers {*layer_list*}]

Data Types

boundary_spec list
layer_list list

ARGUMENTS

-boundary {*boundary_spec*}

A list of rectangles or polygons that specify the boundaries of the poly_rect objects.

Specify each rectangle with the coordinates of its lower-left and upper-right corners: {{*llx lly*} {*urx ury*}}. Specify each polygon with the coordinates of its points: {{*x y*} {*x y*} {*x y*} {*x y*}...}.

This is a required option.

-layers *layer_list*

Specifies a list of layers to associate with each poly_rect in the result. By default, poly_rects are not associated with any layer. This option will associate each poly_rect in the result collection to the respective layer in *layer_list*. To enable this one-to-one correspondence between poly_rects and their respective layers, *layer_list* must have the same length as the list of boundaries.

DESCRIPTION

This command creates a new poly-rectangular object for each rectangle or polygon in the specified list of boundaries, and returns a collection that contains the new objects.

You must specify the boundary of the object, as either a rectangle or a polygon. You may optionally specify a list of layers to associate with each object in the result collection.

EXAMPLES

The following example creates a rectangular poly_rect.

```
prompt> create_poly_rect -boundary {{0 0} {200 100}}
```

The following example creates an L-shaped poly_rect and a rectangular poly_rect.

```
prompt> create_poly_rect -boundary {{{0 0} {0 100} {100 100} \
  {100 200} {200 200} {200 0}} {{0 300} {100 400}}}
```

The following example creates two rectangular poly_rects, and associates the first with layer M1 and the second with layer M2.

```
prompt> create_poly_rect \
  -boundary {{{0 300} {100 400}} {{100 400} {200 500}}} -layers {M1 M2}
```

compute_polygons(2)
resize_polygons(2)
split_polygons(2)
compute_area(2)
transform_polygons(2)

create_port

Creates one or more top-level ports.

SYNTAX

collection **create_port**
[-design *design*]
[-direction in | out | inout]
[-cell *cell*]
[-port_type *port_type*]
port_names

Data Types

cell collection
port_type string
port_names list

ARGUMENTS

-design *design*

Specifies the design in which to create the port(s). If no design is specified, the port(s) are created in the current design.

-direction in | out | inout

Specifies the direction of the ports. By default, the command creates ports with direction **in**.

-port_type *port_type*

Specifies the port_type of the created port. Allowed values are analog_ground, analog_power, analog_signal, clock, deep_nwell, deep_pwell, ground, nwell, power, pwell, reset, scan, signal, tie_high, tie_low and unset. Default port_type is unset which gets treated as signal.

port_names

Specifies the names of the ports to create. Each port name must be unique.

-cell cell

Specifies the cell where the port is to be added. The port is created on the cell's reference module. The cell must not reference a library cell, unless this command is executed in the library manager. In the library manager, ports may be created on library cells. When not specified, the port is created on the current module.

DESCRIPTION

This command creates top-level ports on the current design (unless otherwise specified by -design). It creates only scalar (single-bit) ports. One port is created for each of the names listed. If a port with the specified name already exists, the command displays an error message.

When the **create_port** command creates ports, they are not connected. To establish a connection, you can use the **connect_net** command.

EXAMPLES

The following example creates ports named *data1* and *data2*.

```
prompt> create_port -direction in data1
{"data1"}
prompt> create_port -direction out data2
{"data2"}
```

SEE ALSO

connect_net(2)
disconnect_net(2)
get_ports(2)
remove_ports(2)

create_port_bus

Creates a port bus.

SYNTAX

collection **create_port_bus**
[-design *design*]
[-block *block*]
[-cell *cell*]
[-direction in | out | inout]
[-create_ports]
port_bus_name

Data Types

design collection
block collection
cell collection
port_bus_name string

ARGUMENTS

-design *design*

Specifies the design in which to create the port bus. If no design is specifed, the port bus is created in the current design.

-block *block*

Specifies the block where the port bus is to be added. If specified, **create_port_bus** has the same effect as **edit_module** in which the module is changed and changes are applied to all module occurrences.

-cell *cell*

Specifies the cell where the port bus is to be added. The port bus is created on the cell's reference module. **create_port_bus** first uniquifies the reference if needed, then creates the port bus. When not specified, the port bus is created on the current module.

-direction in | out | inout

Specifies the direction of the ports in port bus. It will not change direction of existing ports. If direction provided in option is not same as existing port direction then port bus will not be created.

-create_ports

Creates port bus members if they do not exist.

port_bus_name

Specifies the port bus name and its range using the **name [start: end]** format. Specify a port bus named busA with port from 1 *to* 5 as **busA[1:5]**. Specify a port bus named busB with port from 5 *downto* as **busB [5:1]**.

DESCRIPTION

This command creates a port bus, collects or creates port bus members, and puts them into the port bus created. This supports creating n-dimensional bus.

The command returns the created port_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

EXAMPLES

The following example creates port bus named *bus1* from port 1 to 5 as bus[1], bus[2], bus[3], bus[4], bus[5]

```
prompt> create_port_bus bus1[1:5]
{"bus1"}
```

The following example first creates ports, then creates a port bus named *bus2* from the created port with indexes 5 downto 1 as bus2[5], bus2[4], bus2[3], bus2[2], bus2[1]

```
prompt> create_port_bus bus2[5:1] -create_ports
{"bus2"}
```

SEE ALSO

remove_from_port_bus(2)
remove_port_buses(2)
report_port_buses(2)

create_power_domain

Creates or updates a power domain, which provides a power supply distribution network.

SYNTAX

string **create_power_domain**
domain_name
[-elements *list*]
[-exclude_elements *list*]
[-include_scope]
[-supply {*supply_set_handle_name supply_set_name*}*]
[-available_supplies *list*]
[-scope *instance_name*]
[-update]

Data Types

domain_name string
list list
supply_set_handle_name string
supply_set_name string
instance_name string

ARGUMENTS

domain_name

Specifies the name of the power domain to be created. The name should be a simple (non-hierarchical) name.

The power domain cannot be created if there is a power domain with the same name in the specified scope or if there is a hierarchical or leaf cell instance or port with the same name in the specified scope.

An exception to this rule is when you use the **-update** option. In this case the power domain name must be same as an existing power domain in the same scope.

-elements *list*

Specifies a collection of cells (hierarchical or leaf) that are added as an extent of the power domain. Specified cells cannot be added in other power domains of the same scope. The special element **"."** has the same meaning as **-include_scope**, which includes the scope of the power domain in the extent of the domain.

If you do not use either the **-elements** or the **-include_scope** option, the power domain consists of the current scope and any of its children not specified as elements in another **create_power_domain** command.

-exclude_elements *list*

Specifies a collection of cells (hierarchical or leaf) that should not be considered as part of this power domain. Specified cells should also appear in **-elements** list of this power domain and another power domain that the cells should be included.

-include_scope

Includes the scope of the power domain in the extent of the power domain. This means all elements within the current scope get the same supply as the power domain, but they are not explicitly added to it.

-supply {*supply_set_handle_name supply_set_name*}*

Specifies the supply sets that need to be associated with the corresponding supply set handles of the power domain. This option can be specified multiple times.

If the *-supply* is not specified, implicit supply sets are created automatically for each handle of the power domain.

The valid names of the supply set handles are *primary*, *main_rail*, *default_retention* and *default_isolation*.

Specifying the **main_rail** keyword implies that the given domain will be treated as an Always-On Block Synthesis Domain, meaning it will be synthesized with dual-rail cells with primary PG pin connected to the *main_rail* supply and backup PG pin connected to the primary supply of the domain.

Additional handles that can be used apart from the above mentioned ones are **extra_supplies** and **extra_supplies_#**, where **#** represents a unique numeral.

Specifying the **extra_supplies_#** keyword restricts the supply sets that are available for the power domain for usage. The supply sets that are specified with **extra_supplies_#** are made available for the power domain for use in level shifter insertion and always-on synthesis.

Specifying the **extra_supplies** keyword indicates that the power domain does not use any extra supplies.

The **extra_supplies** or **extra_supplies_#** keywords are mutually exclusive with **-update** option.

Using user-defined names for handles is supported.

-available_supplies *list*

Specifies a list of additional supply sets that are available for use in the power domain.

The supply sets that are specified with **-available_supplies** are made available in the power domain for use in level shifter insertion and always-on synthesis. If an empty string argument is specified, only the locally available supplies are available for use by tools to power cells inserted into the power domain.

This option is mutually exclusive with **extra_supplies** or **extra_supplies_#** keywords specified in **-supply** option.

-scope *instance_name*

Specifies in which scope the power domain is to be created. The instance name is the name of a hierarchical cell.

By default, the power domain is created in the current scope.

-update

Instructs the tool to add elements, supply sets and available supplies to an existing power domain. It is an error if the power domain specified does not exist.

If your update is not successful, the tool issues an error message. You can continue to update the functionality, until your update is successful.

DESCRIPTION

This command creates a power domain in the specified scope. A power_domain is a collection of design elements that share a primary power and ground power net. The logic hierarchy level where a power domain is created is called the scope of the power domain. The set of design elements that belong to a power domain are called the "extent" of that power domain. A hierarchical cell is an example of an element. Although a design element can be in the scope of several power domains, it can be in the extent of only one power domain.

A power domain can have several supply nets, which are connected to a power domain via a supply port. A power switch of a power_domain can be used to turn on and off the power supply of part or all of the power domain. You can create a supply net, supply port, and power switch by using the **create_supply_net**, **create_supply_port** and **create_power_switch**, respectively.

When this command succeeds, it returns the full name of the power domain (from the current scope). When it fails, it raises a Tcl error.

EXAMPLES

The following example creates two power domains in the scope named INST1.

```
prompt> create_power_domain PD1 -elements INST1/SUB_INST -scope INST1
INST1/PD1
prompt> create_power_domain PD2 -scope INST1 -include_scope
INST1/PD2
```

The following example creates a power domain with the **-supply** argument using a supply set at the top level scope.

```
prompt> create_power_domain PD_MID -scope mid1 -supply {primary all_primary}
mid1/PD_MID
```

SEE ALSO

create_supply_set(2)
report_power_domains(2)

create_power_state_group

Creates a power state group under current scope.

SYNTAX

string **create_power_state_group**
power_state_group_name

Data Types

power_state_group_name string

ARGUMENTS

power_state_group_name

Specifies the name of the power state group to be created. The name should be a simple (non-hierarchical) name.

The power state group cannot be created if there is a power state group with the same name in the specified scope.

DESCRIPTION

This command creates a power state group in the specified scope. A power_state_group is used to collect related power states defined by add_power_state. The legal power states of a group define the legal combinations power states of other objects in this scope or the descendant subtree. i.e. those combinations of states of those objects that can be active at the same time during operation of the design.

A power_state_group may be used to represent a virtual component made up of more than one instance. Power states defined for the group can represent the legal power states of the virtual component without having to change the design hierarchy to create a single instance for that component.

EXAMPLES

The following example creates a power state group in the scope named SUB1.

```
prompt> set_scope ./SUB1
prompt> create_power_state_group SUB1_GROUP
```

SEE ALSO

add_power_state(2)

create_power_switch

Creates a power switch in the specified power domain.

SYNTAX

string **create_power_switch**
switch_name
-domain *domain_name*
-output_supply_port {*port_name supply_net_name*}
-input_supply_port {*port_name supply_net_name*}
-control_port {*port_name net_name*}
[-ack_port {*port_name net_name* [{*boolean_function*}]}]
[-ack_delay {*port_name delay*}]
-on_state {*state_name input_supply_port* {*boolean_function*}}
[-on_partial_state {*state_name input_supply_port* {*boolean_function*}}]
[-off_state {*state_name* {*boolean_function*}}]
[-supply_set {*supply_set_name*}]
[-error_state {*state_name* {*boolean_function*}}]

Data Types

switch_name string
domain_name string
port_name string
supply_net_name string
net_name string
boolean_function list
delay string
state_name string
input_supply_port string

ARGUMENTS

switch_name

Specifies the name of the power switch to be created. The name should be a simple, non-hierarchical name. If a power switch with the same name already exists in the specified power domain, the power switch cannot be created.

This is a required option.

-domain *domain_name*

Specifies the power domain that contains the power switch. If the power domain with the specified name does not exist in the current scope, the command fails.

This is a required option.

-output_supply_port {*port_name supply_net_name*}

Specifies the name of the output port of the power switch and the supply net to which the port connects. On the power switch, if a port with the same name exists, the command fails. In the current scope, if there is no supply net with the same name, the command fails.

This is a required option.

-input_supply_port {*port_name supply_net_name*}

Specifies the name of the input port of the power switch and the supply net to which the port connects. On the power switch, if a port exists with the same name, the command fails. In the current scope, if there is no supply net with the same name, the command fails.

This is a required option and can be specified more than one time. One power switch can have multiple input supply ports.

-control_port {*port_name net_name*}

Specifies the name of the control port of the power switch and the logical net to which this port connects. If a port with the specified name already exists on the power switch, the command fails. If a net with the specified name does not exist, the command fails.

This is a required option and can be specified more than one time. One power switch can have multiple control ports.

-ack_port {*port_name net_name* {*boolean_function*}}

Specifies the name of the acknowledge port of the power switch and the logical net to which this port connects. If a port with the specified name already exists on the power switch, the command fails. If a net with the specified name does not exist, the command fails.

If this option is not specified, the power switch will not have an acknowledge port. Optionally, you can specify a Boolean function. The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-ack_delay {*port_name delay*}

Specifies the acknowledge port on the switch and the corresponding acknowledge delay.

This option can be specified multiple times.

-on_state {*state_name input_supply_port* {*boolean_function*}}

Specifies the on-state name, the relevant input supply port, and its Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-on_partial_state {*state_name input_supply_port* {*boolean_function*}}

Specifies a named on-partial-state, the relevant input supply port, and its Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-off_state {*state_name*, {*boolean_function*}}

Specifies the off-state name and its relevant Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-supply_set {*supply_set_name*}

Specifies the supply set that should be used to find the related supply net for control and ack pins. If supply set is not available in the domain, it will be made available if this option is used.

-error_state {*state_name* {*boolean_function*}}

Specifies a named error state and its relevant Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

DESCRIPTION

The *create_power_switch* command creates a power switch at the specified power domain. The switch is created within the scope of the power domain. Each power switch must be connected to an input supply net and an output supply net. The power switch can be connected with an acknowledge (logical) net and several control (logical) nets. Each net is connected with a power switch via a switch port. The switch ports are automatically created if the power switch is created successfully.

On success, this command returns the full name of the power switch (from the current scope). The command returns a null string upon failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates power switch SW1 within the power domain PD1:

```
prompt> create_power_switch SW1 -domain PD1 \
    -output_supply_port {vout VNO2} \
    -input_supply_port {vin1 VNI1} \
    -input_supply_port {vin2 VNI2} \
    -control_port {ctrl_small ON1} \
    -control_port {ctrl_large ON2} \
    -ack_port {ack_p ACKN {ctrl_small & !ctrl_large}} \
    -ack_delay {ack_p 1} \
    -on_state {full_s vin1 {ctr_small}} \
    -off_state {off_s {!ctr_small}}
```

SEE ALSO

create_power_domain(2)
create_power_switch_array(2)
create_power_switch_ring(2)

create_power_switch_array

Places power-switch cells in the design in an array style. Power switches will be automatically snapped to FinFET grid if FinFET grid exists.

Power switches can be placed before or after compiling the power ground (PG) network. If power switches are placed after generating the PG network, use the **connect_pg_net** and **create_pg_vias** commands after the **create_power_switch_array** command to connect power switch pins to the existing PG network. User can specify -pattern to activate patten flow. It will provide a group of cells placed in a pattern.

SYNTAX

status **create_power_switch_array**
-power_switch *power_switch_strategy*

pattern_name string
polygon list
pg_strategy_spec string
pg_straps collection or string
number integer

ARGUMENTS

-power_switch *power_switch_strategy*

Specifies the power switch strategy name *power_switch_strategy* defined in the UPF file. If **-lib_cell** is not specified, the first library cell that is mapped to the specified power switch is inserted. The **-power_switch** option is not required if the **-lib_cell** option is used. If **-power_switch** is not used, you must ensure that the supply net information is derived correctly for the power switches. This can be achieved by successful power switch associations or by manual associations.

-lib_cell *lib_cell*

Specifies the library cell explicitly. The specified library cell must be mapped to the power switch. This options is required if **-power_switch** is not being used.

-voltage_area *voltage_area*

Specifies the voltage area as the area in which to insert power switches. If not specified, the primary voltage area associated with the power switch is used. The **-voltage_area** option is mutually exclusive with the **-voltage_area_shape** option.

-voltage_area_shape *voltage_area_shape*

Specifies the voltage area shape as the area in which to insert power switches. The **-voltage_area_shape** option is mutually exclusive with the **-voltage_area** option.

-x_pitch *distance*

Specifies the horizontal distance between the centers of two power switches or power switch patterns. If the *distance* is zero, only one column of power switches is inserted. If **-pg_strategy** or **-pg_straps** is specified, power switches are aligned to each vertical power strap when **-x_pitch** is not specified. If **-x_pitch** is also specified, power switches are placed according to pitch, then snapped to the closest power strap.

-y_pitch *distance*

Specifies the vertical distance between centers of two power switches or power switch patterns. If *distance* value is zero, only one power switch row is inserted. **-y_pitch** is mutually exclusive with **-siterow_pitch**.

-x_offset *distance*

Specifies the horizontal offset from the placement region boundary. If *distance* is negative, the tool honors the negative offset, but omits switch cells which would be placed outside the placement boundary.

-y_offset *distance*

Specifies the vertical offset from the placement region boundary. If *distance* is negative, the tool honors the negative offset, but switch cells to be placed outside the placement boundary are dropped. This option is mutually exclusive with **-siterow_offset**.

-siterow_pitch *rowcount*

Specifies the vertical distance, in site rows, between the lower-left corners of two power switches or power switch patterns. **-siterow_pitch** is mutually exclusive with **-y_pitch**.

-siterow_offset *rowcount*

Specifies the vertical offset, in site rows, from the placement region boundary. **-siterow_offset** is mutually exclusive with **-y_offset**.

-prefix *prefix*

Specifies the prefix added to the power switch names. If this option is not specified or the *prefix* is empty, the default prefix *headerfooter* is used.

-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of the power switch placed at the lower-left corner of the array. The orient can be R0, R90, R180, R270, MX, MY, MXR90, MYR90. If user specified -pattern, it will activate a pattern flow. Only R0 and MX is supported in pattern flow. If not specified, the default orientation is the same as the site row orientation if **-snap_to_site_row** is true. Otherwise, the default orientation is R0.

-checkerboard even | odd

Inserts switch cells in a checkerboard fashion. There are two types of checkerboard: even or odd. By default, the cells are inserted as a normal array.

The even checkerboard type specifies that a switch cell is placed at the lower-left corner. The odd checkerboard type specifies that a blank space is placed at the lower-left corner.

```
x x x x      x x x
 x x x      x x x x
x x x x      x x x
 x x x      x x x x
x x x x      x x x
  even         odd
```

-offset_start {*x y*}

Specifies the startpoint of a uniform power switch grid for disjoint voltage area regions.

-pattern *pattern_name*

Specifies the pattern to be placed. The pattern is defined by the **set_power_switch_placement_pattern** command.

-boundary *polygon*

Specifies the boundary in which to place power switches. The power switches are inserted only in the overlapping area of specified polygon and voltage area or voltage area shape.

-snap_to_site_row true | false

Specifies if the power switches are snapped to site rows. The default value is true.

-pg_strategy *pg_strategy_spec*

Specifies the PG wires with which to align power switches. *pg_strategy_spec* is the strategy name or a triplet that contains the strategy name, net name, and metal layer name. If only the strategy name is specified, power switches are aligned with its input supply net wires on all vertical layers. For example, the **-pg_strategy strategy1** option aligns power switches with both M6 and M8 VDD wires, if the input supply net of the power switch is VDD, and the M6 and M8 VDD wires are generated by strategy1.

If the *pg_strategy_spec* contains the strategy name, net name, and metal layer name, power switches are aligned with those specified wires. For example, the **-pg_strategy {strategy1 VDD M8}** option aligns the power switches with the M8 VDD wires created by using strategy1. Note that the metal layer direction should be vertical. This option is mutually exclusive with **-pg_straps**.

-pg_straps *pg_straps*

Specifies a collection of wires with which to align power switches. You can only specify vertical wires of same PG nets. This option is mutually exclusive with **-pg_strategy**.

-align_marker *distance*

Specifies the marker on the power switch library cell to align with the power straps. The marker is defined as the horizontal offset that refers to the lower-left corner of the library cell. If this option is not specified, the center of the largest rectangular shape of the corresponding pin is the default marker.

-switch_number *number*

Specifies the maximum number of switch cells to be inserted. The switch cell insertion still honors the user-specified offset and pitch. The process stops when the total number of switch cell reach the specified value.

-fine_grid_pitch {*x y*}

Specifies the value to set up a search pitch when power switch cannot be inserted in orginal location. It will search nearby location, it the new location can place power switch successfully. It will stop searching. The option should be used with -search_range.

-search_range {*number number*}

Specifies a pair of integer to set up a search region. The first value is for the number of X-direction pitches. The second is for Y-direction. The option should be used with -fine_grid_pitch.

DESCRIPTION

This command places power-switch cells into the design in an array style. The command also associates the placed cell instances with their power intention as defined in UPF.

Power switch insertion honors placement blockages, keepout margin, macros, fixed cells and other voltage areas as blockages.

EXAMPLES

The following example places power-switch cells in array inside a voltage area.

```
prompt> create_power_switch_array -power_switch Multiplier/mult_sw \
  -x_pitch 10 -y_pitch 10
Insert 684 power switch cell HEAD16DM successfully.
```

prefix string

pattern_name string
integer integer

ARGUMENTS

-power_switch *power_switch_strategy*

Specifies the power switch strategy name *power_switch_strategy* defined in the UPF file. If **-lib_cell** is not specified, the first library cell that is mapped to the specified power switch is inserted. **-power_switch** is optional as long as **-lib_cell** is used. If not using **-power_switch**, you must ensure that the supply net information is correctly derived for the power switches. This can be achieved by successful power switch associations or by manual associations.

-lib_cell *lib_cell*

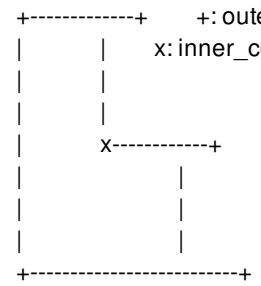
Specifies the library cell explicitly. The specified library cell must be mapped to the power switch. This options is required if **-power_switch** is not being used.

-vertical_lib_cell *lib_cell*

Specifies the library cell to be inserted along vertical edges explicitly. The specified library cell must be mapped to the power switch.

-inner_corner_cell *lib_cell*

Specifies the library cell to be placed at the inner (concave) corners of the region. If not specified, inner corner cell will be the same as cells placed along the edges.



-outer_corner_cell *lib_cell*

Specifies the library cell to be placed at the outer (convex) corners of the region. If not specified, no cell is placed at the outer corners.

-filler_cells *lib_cell_list*

Specifies the list of filler cells to be placed into gaps in the power switch ring. This option can only be used when **-snap_to_site_row** is false. If multiple filler cells are specified, the tool tries to use the filler cells in a descending order of cell size.

-vertical_filler_cells *lib_cell_list*

Specifies the list of filler cells to be placed into gaps in the power switch ring of the vertical edges. This option can only be used when **-snap_to_site_row** is false. If multiple filler cells are specified the tool tries to use the filler cells in a descending order of cell size.

-voltage_area *voltage_area*

Specifies the voltage area as the area in which to insert power switches. If **-voltage_area** is not specified, the primary voltage area associated with the power switch will be used. **-voltage_area** is mutually exclusive with **-voltage_area_shape**, **-**

through_points and **-boundary**.

-voltage_area_shape ***voltage_area_shape***

Specifies the voltage area shape as the area to insert power switches. **-voltage_area_shape** is mutually exclusive with **-voltage_area**, **-through_points** and **-boundary**.

-x_pitch ***distance***

Specifies the horizontal distance between the centers of two power switches or power switch patterns. If *distance* is zero, the pitch set to the width of the switch cell.

-y_pitch ***distance***

Specifies the vertical distance between centers of two power switches or power switch patterns. If *distance* is zero, the pitch is set to the height of the switch cell.

-x_offset ***distance***

Specifies the horizontal offset from the placement region boundary.

-y_offset ***distance***

Specifies the vertical offset from the placement region boundary.

-snap_to_site_row true | **false**

Specifies whether the power switch cells should be snapped to site rows. If **-snap_to_site_row** is true, the cell orientation is flipped when the site row orientation is flipped. If **-snap_to_site_row** is false, cell orientation is rotated along the edges. See the **-orient** option for more information. By default, this option is true.

-start_point {*x y*}

Specifies the startpoint of the partial ring. If the startpoint is not on the edges of the region, it is projected to the closest edge or corner. If the offset value is set, the edges of the expanded or shrunk region are used. This option must be used together with **-end_point**.

-end_point {*x y*}

Specifies the endpoint of the partial ring. If the endpoint is not on the edges of the region, it is projected to the closest edge or corner. If the offset value is set, the edges of the expanded or shrunk region are used. This option must be used together with **-start_point**.

-boundary ***polygon***

Specifies a polygon as the area to insert power switches. The inserted switch cells are associated with the primary voltage area of the power switch strategy. **-boundary** is mutually exclusive with **-voltage_area**, **-voltage_area_shape** and **-through_points**.

-through_points ***coordinate_list***

Specifies a list of points as the edges to insert power switches. The inserted switch cells are associated with the primary voltage area of the power switch strategy. **-through_points** is mutually exclusive with **-voltage_area**, **-voltage_area_shape** and **-boundary**.

-prefix ***prefix***

Specifies the prefix added to power switch names. If this option is not specified or the specified string is empty, the default prefix *headerfooter* is used.

-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of the power switch placed along the bottom-most and left-most edge. Legal orientation values are: R0,

R90, R180, R270, MX, MY, MXR90, and MYR90. The default orientation is R0. Cell orientation along other edges are rotated accordingly. If **-snap_to_site_row** is true, cell orientation is flipped when site row orientation is flipped. If **-snap_to_site_row** is false, the rotation rules are: O_RIGHT = R90(O_BOTTOM); O_TOP = MX(O_BOTTOM); O_LEFT = MXR90(O_BOTTOM). O_BOTTOM, O_RIGHT, O_LEFT, O_TOP are cell orientations along bottom, right, left, and top edges, respectively.

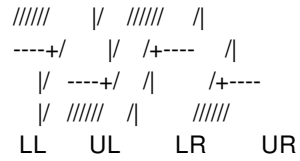
-vertical_lib_cell_orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of the power switch placed along the right-most edges. Legal orientation values are: R0, R90, R180, R270, MX, MY, MXR90, and MYR90. The default orientation is R0. Cell orientation along other edges are rotated accordingly. If **-snap_to_site_row** is true, cell orientation is flipped when site row orientation is flipped. If **-snap_to_site_row** is false, the rotation rules are: O_LEFT = MY(O_RIGHT). O_RIGHT and O_LEFT are cell orientations along right and left edges, respectively.

-inner_corner_cell_orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of power switch placed at the lower-left corner. Legal orientation values are: R0, R90, R180, R270, MX, MY, MXR90, and MYR90. The default orientation is R0. The orientation of other corners are rotated accordingly. The rules are: O_UL = MX(O_LL); O_LR = MY(O_LL); O_UR = R180(O_LL). O_LL, O_UL, O_LR, and O_UR are the orientations of LL, UL, LR, UR corners, respectively.

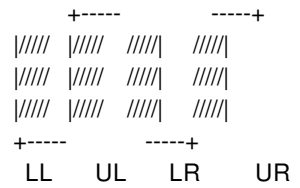
The inner corner types are:



-outer_corner_cell_orient R0|R90|R180|R270|MX|MY|MXR90|MYR90

Specifies the orientation of power switch placed at the LL corner. Legal orientation values are: R0, R90, R180, R270, MX, MY, MXR90, and MYR90. The default orientation is R0. The orientations of other corners are rotated accordingly. The rules are: O_UL = MX(O_LL); O_LR = MY(O_LL); O_UR = R180(O_LL). O_LL, O_UL, O_LR, and O_UR are the orientations of LL, UL, LR, UR corners, respectively.

The outer corner types are:



-pattern *pattern_name*

Specifies the pattern name to be inserted. The pattern is defined by the **set_power_switch_placement_pattern** command. When **-pattern** is specified, the **-x_pitch** and **-y_pitch** options are ignored. This option can only be used when **-snap_to_site_row** is false.

-continue_pattern

Specifies that the pattern should restart on adjacent edges. By default, a pattern restarts on the next adjacent edge. If **-continue_pattern** is specified, the current pattern continues. This option is ignored if **-pattern** is not specified.

-switch_number *integer*

Specifies the total number of power switches to be inserted. If offset and pitch is specified, the insertion will follow the pitch and stop when the number of inserted cells reaches the specified value. If **-pitch** is not specified, the tool derives the pitch to evenly distribute the required number of switch cells along the ring.

DESCRIPTION

This command places power switch cells into a power switch ring. The command also associates the placed cell instances with their power intention as defined in UPF.

Power switch insertion honors placement blockages, keepout margin, macros, fixed cells and other voltage areas as blockages.

EXAMPLES

The following example places power switch cells along the boundary of the prime voltage area of the power switch strategy.

```
prompt> create_power_switch_ring -power_switch Multiplier/mult_sw \
  -x_pitch 10 -y_pitch 10

Insert 64 power switch cell HEAD16DM successfully.
```

SEE ALSO

create_power_switch_array(2)
map_power_switch(2)
report_power_switch_placement_patterns(2)
set_power_switch_placement_pattern(2)

create_pr_rule

Creates a cell row spacing rule (pr_rule) in the specified technology object.

SYNTAX

collection **create_pr_rule**
[-tech *tech_object*]
[-library *library*]
-row_spacing *distance_list*
-abut_table *abut_table*

Data Types

tech_object collection
library collection
distance_list list
abut_table list

ARGUMENTS

-tech *tech_object*

Specifies the technology object in which to create the cell row spacing rule.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

-library *library*

Specifies the library in which to create the cell row spacing rule. The command creates the rule in the technology object associated with the specified library. In an implementation tool, the library is a design library. In the library manager, the library is a cell library. You can specify the library using the library's name or a collection that contains the library.

The **-tech** and **-library** options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

-row_spacing *distance_list*

Specifies the row spacing distances. Use the following syntax to specify the distances, where each value is a floating point number that represents the spacing in microns:

{*top_top top_bottom bottom_bottom*}

- The *top_top* argument represents the spacing between the top edges when you are using double-back cell rows in your floorplan.

- The *top_bottom* argument represents the spacing between the top edge and the bottom edge when you are not using double-back cell rows in your floorplan.
- The *bottom_bottom* argument represents the spacing between the bottom edges when you are using double-back cell rows in your floorplan.

-abut_table *abut_table*

Specifies whether the edges can be abutted. Use the following syntax to specify the *abut_table* argument, where each value is either **true** (allows abutment) or **false** (does not allow abutment):

{*top_top top_bottom bottom_bottom*}

- The *top_top* argument specifies whether the two top edges can be abutted when you are using double-back cell rows in your floorplan.
- The *top_bottom* argument specifies whether the top edge and the bottom edge can be abutted when you are not using double-back cell rows in your floorplan.
- The *bottom_bottom* specifies whether the two bottom edges can be abutted when you are using double-back cell rows in your floorplan.

DESCRIPTION

This command creates a new cell row spacing rule (pr_rule) in the specified technology object. The tool treats the rule the same as a rule defined in the PRRule section of the technology file. For more information about defining cell spacing rules, see the "PRRule Section" in the *Synopsys Technology File and Routing Rules Reference Manual*.

If the command is successful, it returns a collection that contains the created rule; otherwise, it returns an empty string. If there is a command syntax error, it returns a TCL_ERROR.

EXAMPLES

The following example creates a cell row spacing rule in the technology object of the current library.

```
prompt> create_pr_rule -row_spacing {1.0 1.1 1.2} \
  -abut_table {false true false}
```

SEE ALSO

get_pr_rules(2)
remove_pr_rules(2)
report_pr_rules(2)

create_pst

Creates a UPF power state table (PST), assigns a name to the table, and lists the supply ports or nets in a specific order.

SYNTAX

string **create_pst**
table_name
-supplies *list*

Data Types

table_name string
list list

ARGUMENTS

table_name

Specifies the name of the power state table.

-supplies *list*

Specifies a list of supply nets or supply ports to include in the power state table. Hierarchical names are allowed.

DESCRIPTION

The **create_pst** command creates a new UPF power state table, assigns a name to the table, and lists the supply ports or supply nets in a specific order. After you use this command, use the **add_port_state** command to specify the names and voltages of the possible states for each supply port, and the **add_pst_state** command to specify the allowed combinations of supply states.

The following script demonstrates the power state definition flow:

```
# Create power state table, specify supply ports for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_port_state PN1     -state {sLO 0.88}
add_port_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_port_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
```

```
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the **create_pst** command.

The **create_pst** command can only be used at the top-level scope. Power switch supply ports are considered supply ports because they are connected by supply nets, so they can be listed as supply nets in the **create_pst** command.

A supply port and a supply net can have the same name, even when they are unconnected. If such a name is listed in the **create_pst** command, it is assumed to represent the supply port and not the supply net.

The **create_pst** command returns the name of the power state table if the table is created successfully, or the null string otherwise.

You can use multiple power state tables to specify the states within a particular scope. The tool expands the specified tables to cover all possible combinations of states.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command creates a power state table named MyPST and specifies a list of three supplies to be included in the table:

```
prompt> create_pst MyPST -supplies {PN1 PN2 SOC/PN3}
```

SEE ALSO

add_port_state(2)
add_pst_state(2)
report_pst(2)

create_purpose

Creates a purpose in the given tech object.

SYNTAX

collection **create_purpose**
[-tech *tech_object*]
-name *purpose_name*
-number *purpose_number*
[-force]

Data Types

tech_object collection
purpose_name string
purpose_number int

ARGUMENTS

-tech *tech_object*

Purpose will be created in this tech object. If not specified then tech object of current library will be used.

-name *purpose_name*

Specifies the name of the purpose to be created.

-number *purpose_number*

Specifies the number of the purpose to be created.

-force

If specified, it overwrites an existing purpose of the same name.

DESCRIPTION

create_purpose command creates a purpose in the given technology. The purpose creation requires a name and a number for the new purpose.

If the command is successful, it returns the newly-created purpose as a single-element collection. If the command fails, it returns TCL_ERROR with appropriate error message. If there is a syntax error, it returns a TCL_ERROR.

EXAMPLE

The following example creates a purpose in the technology of the current design.

```
prompt> create_purpose -tech [get_techs [current_lib]] -name test_purpose -number 100
{test_purpose}
```

The following example creates the same purpose without -tech option.

```
prompt> create_purpose -name test_purpose -number 100
{test_purpose}
```

SEE ALSO

get_techs(2)
remove_tech(2)

create_qor_snapshot

Generates a quality-of-results report for specified modes/corners/scenarios and stores the report into a set of files under location designated by application option **time.snapshot_storage_location**.

SYNTAX

status **create_qor_snapshot**
-name *name*
[-power]
[-significant_digits *digits*]
[-zero_wire_load]
[-max_paths *number*]
[-nworst *number*]
[-scenarios *list_of_scenarios*]
[-nosplit]

Data Types

name string
digits integer
number integer
list_of_scenarios list

ARGUMENTS

-name *name*

Specifies the name of the QoR snapshot, which can be used to identify a particular snapshot. The name should start with a letter.

-power

Records dynamic and static power.

-significant_digits *digits*

Specifies the number of significant digits for the values generated in the reports.

-zero_wire_load

Uses zero wire load models for timing reporting.

-max_paths *number*

Specifies the maximum number of paths for the **report_timing** command to report per path group.

-nworst *number*

Specifies the maximum number of worst paths for the **report_timing** command to report per timing endpoint.

-scenarios *list_of_scenarios*

Specifies the list of active scenarios to get a QoR snapshot. The default behavior is to report all active scenarios.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **create_qor_snapshot** command generates a quality-of-results report for given scenarios of the current design and stores the report into a set of files. A QoR snapshot contains information about quality metrics such as timing, area, DRC, clocks, power.

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the **-scenarios** option or the **-corners** and **-modes** options.

EXAMPLES

The following command creates a QoR snapshot named "preroute" from the current design and saves the snapshot files under the "snapshot" directory under the current working directory.

```
prompt> create_qor_snapshot -name preroute
```

The following example shows how the number of significant digits can affect the output of the Timing.

```
prompt> create_qor_snapshot -name atest -significant_digits 4
 ...
**************************************************

create_rdl_power_extension

Creates RDL power extensions.

SYNTAX

status **create_rdl_power_extension**
-layer *tech_layer_name*
[-mode new | remove]
[-power_net *net_name*]
[-ground_net *net_name*]
[-bbox { {*llx lly*} {*urx ury*} }]
[-width_variation { *variation distance*}]
[-remove_nets *nets*]
[-from_previous_extension true | false]

Data Types

tech_layer_name string
net_name string
llx float
lly float
urx float
ury float
variation float
distance float
nets collection

ARGUMENTS

-layer *tech_layer_name*

Specifies the metal layer on which to optimize the RDL wires. You specify the metal layer by using its technology file layer name. This option is required.

Use the **create_routing_rule** command to specify the required spacing of the thin nets before using this command.

-mode new | remove

Specifies the action to perform: add new extensions or remove existing extensions. The **-mode new** option creates new RDL extensions for power and ground straps. If a net was previously extended, even partially, no new RDL extensions are created for that net.

The **-mode remove** option removes existing RDL extensions. This option can remove only those RDL extensions that were created with the **create_rdl_power_extension** command. Wires created by other means, such as a third-party tool, might not have full association information and must be removed by using the **remove_routes** command. If the tool cannot find any RDL

extensions, no action is performed.

-power_net ***net_name***

Specifies which power net to extend wires. By default, the command automatically finds power net to extend wires. If the design contains multiple power nets, you must use this option to specify the power net.

-ground_net ***net_name***

Specifies which ground net to extend wires. By default, the command automatically finds ground net to extend wires. If the design contains multiple ground nets, you must use this option to specify the ground net.

-bbox { {*llx lly*} {*urx ury*} }

Specifies the bounding box of a rectangular routing area. The engine will only extend power and ground nets inside the area. The format {{*llx lly*} {*urx ury*}} specifies the lower-left and upper-right corners of the rectangle.

-width_variation { *variation distance*}

Specifies the width variation of the extension wires. Inside each distance, the difference of wire widths from small to large (the direction is from startpoint to endpoint) will be equal or smaller than the variation. If the variation is zero, it means the wire width will become equal or smaller only. The unit for variation and distance is microns.

-remove_nets ***collection_of_nets***

Specifies a list of net names to remove extension.

-from_previous_extension true | false

Create extension from previous extension (default false).

DESCRIPTION

This command extends power straps from the core area to the I/O region. The routing widths of the RDL extensions are made as wide as possible while still meeting DRC rules. Before running this command, you must first create power straps. The command searches for starting points from power straps that are within a search distance to the bumps. The search distance is the average distance between the flip chip bumps. To efficiently use available RDL routing space, you should run the **optimize_rdl_routes -reserve_power_resources true** command to reserve resources. You can use the **create_routing_rule** command to change the internal application of DRC rules. The maximum wire width can be controlled by the maxWidth value setting in the technology file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates RDL power extensions on the METAL9 layer.

```
prompt> create_rdl_power_extension -layer METAL9
```

The following example first reserves resources, then creates RDL power extensions on the METAL7 layer.

```
prompt> optimize_rdl_routes -reserve_power_resources true -layer METAL7
```

```
prompt> create_rdl_power_extension -layer METAL9
```

The following example removes the RDL power extensions created by the **create_rdl_power_extension** command.

```
prompt> create_rdl_power_extension -mode remove
```

SEE ALSO

create_pg_strap(2)
create_routing_rule(2)
optimize_rdl_routes(2)

create_rdl_routing_guides

Creates routing guides for RDL routing at block corners to honor special spacing rules.

SYNTAX

collection **create_rdl_routing_guides**
-layer *layer*
-check_overlap_layer *layer*
-corner_distance *distance*
-boundary_distance *distance*
[-spacing *distance*]
[-name_prefix *name_prefix*]

Data Types

layer list
distance double
name_prefix string

ARGUMENTS

-layer *layer*

Specifies the layer on which to set the rdl routing guide.

-check_overlap_layer *layer*

Specifies the layer to check whether there are shapes in the corner regions. Only if there are shapes in the corner regions on the check_overlap_layer, then the rdl routing guide at these corner regions are created.

-corner_distance *distance*

Specifies the distance from the block corner. This distance is the length of two sides of the pentagonal routing guides.

-boundary_distance *distance*

Specifies the distance from the block boundary. This distance is the length of two sides of the pentagonal routing guides.

-spacing *distance*

Specifies the spacing for RDL router to honor inside the routing guides. The **spacing** value must be larger than the **minSpacing** specified in the tech file. If this option is not specified, use the value of **nonDefaultRDLRegionMinSpacing** defined in the technology file as spacing.

-name_prefix *name_prefix*

Specifies the prefix of the name of the created routing guides.

DESCRIPTION

This command creates several new rdl type routing guides and returns a collection that contains the created routing guide.

First, the command removes all existing rdl type routing guides. Then, it checks the pentagon regions at four boundary corner to see if there is any geometry on the **-check_overlap_layer** in these regions. The pentagon regions are calculated by the values of **-corner_distance** and **-boundary_distance**. Then, it creates rdl type routing_guides only in the corner regions which has overlapped geometries on the **-check_overlap_layer**. Finally, the command associates the routing guides with the **nonDefaultRDLRegionMinSpacing** value (defined in technology file) as the special spacing. If some corner regions do not contain geometries on the **-check_overlap_layer**, no rdl type routing guides are created for those corners. You can also use **-spacing** to specify the spacing value for the rdl routing guides.

The lower-left corner pentagon region is calculated as follows:

If the boundary bounding box of the block is *(ll_x, ll_y) (ur_x, ur_y)*, and the **-corner_distance** is *c_dist*, **-boundary_distance** is *b_dist*, then the boundary of the lower-left corner pentagon region is

(ll_x, ll_y) (ll_x + c_dist, ll_y) (ll_x + c_dist, ll_y + b_dist) (ll_x + b_dist, ll_y + c_dist) (ll_x, ll_y + c_dist)

The other three pentagon regions are calculated symmetrically in the corresponding corners.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates rdl routing guides on layer M8. Two rdl routing guides are created, since geometries on AP layer only exist at these two block corners.

```
prompt> create_rdl_routing_guides -layer {M8} -check_overlap_layer AP -boundary_distance 600 -corner_distance 750 -sp
```

```
Information: Remove existing RDL routing guide before creating new one. (RT-305)
{RDL_0 RDL_1}
```

SEE ALSO

create_routing_guide(2)

create_rdl_shields

Performs automatic shield routing on RDL nets.

SYNTAX

status **create_rdl_shields**
-layers *layer_list*
[-mode new | unshield | reshield | tie | report]
[-nets *collection_of_nets* | -nets_in_file *nets_file*]
[-shield_on_bump true | false]
[-shield_via_tie true | false]
[-shield_routing_tie true | false]
[-trim_floating true | false]
[-reference_layer layer]
[-offset offset_value]
[-report_coaxial_shield_ratio_offsets coaxial_shield_layer_offset_list]
[-coordinates bounding_box_list]
[-half_shield off | up | down | left | right]

Data Types

layer_list collection
collection_of_nets collection
nets_file string
offset_value unsigned int
bounding_box_list collection
coaxial_shield_layer_offset_list collection

ARGUMENTS

-layers *layer_list*

Specifies the target layers for creating shielding wires. Use layer names from the technology file.

-mode new | unshield | reshield | tie | report

Selects the action to perform during automatic shielding.

The mode options are defined as follows:

- **new** (default)
  Creates new shielding wires for unshielded RDL nets. If a net is previously shielded, even partially, no new shielding wires are created for that net.

You can specify the power or ground net shielding wires for a net with the **set_app_options {flip_chip.route.shielding_net shielding_net}** command before you run the **create_rdl_shields** command. If the shielding net is unset, the RDL router uses the ground net with maximum number of ports as the shielding net.

- **unshield**
  Removes existing shielding wires that are associated with shielded RDL nets. The command removes all tie-off connections from deleted shielding wires to the power and ground network.

  This command can remove only those shielding wires that were created by using the **create_rdl_shields** command. Shielding wires created by other means, such as a third-party tool, might not have full association information and must be removed with a different command.

  If the tool cannot find any shielding wires associated with shielded RDL nets, no action is performed.

- **reshield**
  Removes existing RDL net shields and creates new shielding wires. The shielding wires are first removed as described in the **-mode unshield**. After removing all existing shielding wires, new shielding wires are added for the specified RDL nets that do not have shielding wires.

  If the design does not contain existing shielding wires, it is more efficient to use **-mode new**, because the tool first checks for existing shielding WIRES and then creates new shielding WIRES.

- **tie**
  Do "tie shielding wires" operation only.

- **report**
  Do "report shield ratio" operation only.

-nets *collection_of_nets*

Specifies the RDL nets to be shielded, unshielded, or reshielded, depending on the specified mode.

-nets_in_file *file_name*

Specifies the name of the file that contains the RDL nets to be shielded, unshielded, or reshielded, depending on the specified mode.

-nets has higher priority than **-nets_in_file**.

If neither **-nets** nor **-nets_in_file** option is specified, the tool processes all RDL nets.

When creating shielding wires, the tool skips specified RDL nets, which have no shielding rules defined in **create_routing_rule**, or the **-shield_widths** defined for the target layer is 0. To define the shielding rules, use the **create_routing_rule** and **set_routing_rule** commands.

-shield_on_bump true | false

Specifies whether to create shielding wires around bump cells. The default is true.

-shield_via_tie true | false

Specifies whether to tie shielding wires with vias. The default is true.

-shield_routing_tie true | false

Specifies whether to tie shielding wires with RDL routes. The default is true.

-trim_floating true | false

Specifies whether to remove floating shielding wires. The default is true.

-reference_layer layer

Specifies the layer of routes which shields are created for. It is designed for coaxial shield.

When -reference_layer is specified, only one layer is allowed in -layers. Coaxial shields are created on the layer specified in -layers.

-offset offset_value

Specifies the offset of coaxial shields to their referenced routes. Default is 0.

- **offset_value = 0, shields are created to align to center line of target routes.**
- **offset_value > 0, shields are created by shifting center line of target routes by offset_value**
- **offset_value < 0, invalid value.**

-report_coaxial_shield_ratio_offsets {{shield_layer1 route_layer1 offset1} {shield_layer2 route_layer2 offset2} ...}

By default, only side wall shield ratio is reported after create_rdl_shields command. With this option specified, the coaxial shield ratio will be also reported. Users can specify a list of layer offset triple {shield_layer route_layer shield_route_offset}. These tripe values are used to determine the layer of shields to report, the layer of route to be shielded, and the effective shield to route distance

-coordinates {bounding_box1 bounding_box2 ..}

Specifies the area that create_rdl_shields command applies. Default value is whole design boundary.

create_rdl_shields creates shields and tie these shields to PG structure. When running on a huge design, for example, an interpose design, it might have performance issue when tie-ing shields due the large number of PG shapes. Users could use this option to improve the run time of create_rdl_shields.

-half_shield {off | up | down| left | right}

Specifies whether to create side-wall shield on one side.

By default, it is off, and create_rdl_shields create side wall shields on two sides.

- **For horizontal nets, create upside side-wall shield when -half_shield is "up", and crate downside side-wall shield when -half_shield is "down".**
- **For vertical nets, create left side-wall shield when -half_shield is "left", and create right side-wall shield when -half_shield is "right".**

DESCRIPTION

The **create_rdl_shields** command shields RDL nets based on the associated shielding rules. Shielding rules are defined by the **create_routing_rule** command. The shielding wires are tied to RDL wires, standard pins, and standard cell rails of shielding net, defined by the **set_app_options {flip_chip.route.shielding_net shielding_net}** command. If no shielding net is defined, the RDL router uses the ground net with maximum number of ports as the shielding net.

RDL nets are nets in flip-chip or 3DIC designs which are routed on the redistribution layer. In a flip-chip design, RDL nets connect a bump cell to driver I/O cells. In a 3DIC or interposer design, RDL nets can connect the following elements:

- A microbump cell and a microbump cell
- A microbump cell and a through silicon via (TSV) cell
- A microbump cell and driver I/O cell

Microbump cells are also called flip-chip pads.

Prerequisites

Before you run this command, you must first define the shielding rules with the **create_routing_rule** command and assign these rules to the RDL nets to be shielded with the **set_net_routing_rule** command. You might need to set a specific power or ground net that shielding wires belong to, by using **set_app_options {flip_chip.route.shielding_net shielding_net}** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines the shielding rules and assigns the shielding rules to CLK_B1 and CLK_B5. It also assigns VSS as shielding net, and routes the CLK_B1 and CLK_B5 nets. Finally, it shields the CLK_B1 and CLK_B5 nets with the VSS ground net, and uses via and RDL routes to tie shielding wires to VSS without trimming any floating shielding wires.

```
prompt> create_routing_rule clock_net_shielding \
  -widths { METAL7 10 METAL8 10 } \
  -spacings { METAL7 2 METAL8 2 } \
  -shield \
  -shield_widths { METAL7 10 METAL8 10 } \
  -shield_spacings { METAL7 2 METAL8 2 } \

prompt> set_routing_rule -rule clock_net_shielding {CLK_B1 CLK_B5}
prompt> set_app_options -block [current_block] {flip_chip.route.shielding_net VSS}
prompt> route_rdl_flip_chip -layers METAL8
prompt> create_rdl_shields -layers METAL8 -nets {CLK_B1 CLK_B5} \
      -shield_routing_tie true -shield_via_tie true -trim_floating false
```

The following example creates METAL7 coaxial shielding wires to shield METAL8 routings. The shield to route centerline offset is 5.

```
prompt> create_rdl_shields -reference_layer METAL8 -layers METAL7 -offset 5\
      -report_coaxial_shield_ratio {{METAL7 METAL8 5}}
```

The following example creates METAL7 shielding wires within the area {100 100} {200 200}.

```
prompt> create_rdl_shields -layers METAL7 -coordinates {{100 100} {200 200}}
```

create_repeater_groups

Groups a list of repeaters or repeaters of supernets.

SYNTAX

status **create_repeater_groups**
-supernets *supernet_list* | -supernet_bundles *supernet_bundle_list*
| -cells *cell_list*
-lib_cells *lib_cell_list*
[-lib_cell_input *lib_pin*]
[-lib_cell_output *lib_pin*]
[-group_pin_spacing *spacing*]
[-ignore_pin_layers]

Data Types

supernet_list	list
supernet_bundle_list	list
cell_list	list
lib_cell_list	list
lib_pin	string
spacing	float

ARGUMENTS

-supernets *supernet_list*

Specifies a list of supernets whose repeaters are grouped. The list might contain supernet names, patterns, or collections. Specify a collection by using the **get_supernets** command.

-supernet_bundles *supernet_bundle_list*

Specifies a list of supernet bundles whose repeaters are grouped. The list might contain supernet bundle names, patterns, or collections. Specify a collection by using the **get_bundles** command. When you use this option, you cannot use the **-group_pin_spacing** and **-ignore_pin_layers** options.

-cells *cell_list*

Specifies a list of cells for grouping. The list might contain cell names, patterns, or collections. Specify a collection by using the **get_cells** command.

-lib_cells *lib_cell_list*

Specifies a list of library cells that enables you to group repeaters whose library cells is in the list specified by the -lib_cells

option. The list might contain library cell names, patterns, or collections. Specify a collection by using the **get_lib_cells** command.

-lib_cell_input ***lib_pin***

Specifies the input pin name of the library cell. By default, the command uses "D" as the input pin name.

-lib_cell_output ***lib_pin***

Specifies the output pin name of the library cell. By default, the command uses "Q" as the output pin name.

-group_pin_spacing ***spacing***

Specifies the distance within which two pins are considered to be in one group. The default is 2.0 um.

-ignore_pin_layers

Pin layers are ignored when grouping pins. With this option, pins in the same group might not be on the same layer.

DESCRIPTION

This command automatically groups a list of repeaters or repeaters of supernets. This command passes in a list of repeaters using **-cells**, a list of supernets using **-supernets** or bundles of supernets using **-supernet_bundles** and return a list of repeater group created by **set_repeater_group**.

To know the number of newly created repeater groups and their group IDs use Tcl variables, crg_num_of_created_group_ids and crg_created_group_ids. To verify each repeater group, use the **report_repeater_groups** command.

-supernets, **-supernet_bundles** and **-cells** are mutual exclusive. When you use **-supernet_bundles**, you are not allowed to set **-group_pin_layers** and **-ignore_pin_layers**.

The command supports both single load and multiple loads supernets.

EXAMPLES

The following examples shows usages of different repeater inputs separately.

prompt> **create_repeater_groups -supernets [get_supernets sNet*] -lib_cells {lib_cell_1 lib_cell_2}**

prompt> **create_repeater_groups -supernet_bundles [get_bundles sBundle*] -lib_cells [get_lib_cells libCell*]**

prompt> **create_repeater_groups -cells [get_cells eCell*] -lib_cells lib_cell_1**

The following example uses the **-group_pin_spacing** option to group pins within a specific distance.

prompt> **create_repeater_groups -supernets [get_supernets] -lib_cells {lib_cell_1 lib_cell_2} -group_pin_spacing 5.0**

The following example uses the **-ignore_pin_layers** option to ignore layer difference of pins.

prompt> **create_repeater_groups -cells [get_cells eCell*] -lib_cells {lib_cell_1 lib_cell_2} -ignore_pin_layers**

SEE ALSO

set_repeater_group(2)
report_repeater_groups(2)
place_group_repeaters(2)

create_repelling_group_bound_shapes

Create and associate routing blockages from repelling group bound content.

SYNTAX

string **create_repelling_group_bound_shapes** [-guard_band *distance*] [-name_prefix *routing_blockage_name_prefix*]
-repelling_group_bounds *repelling_group_bounds*

list *distance*
string *routing_blockage_name_prefix*
list *repelling_group_bounds*

ARGUMENTS

-guard_band *distance*

Distance value(s) for guard band in form of {x,y} or {r}. The computed cover shapes are based on a core's internal cells, enlarged by the distance provided here. Additionally routing blockages are associated with a core's internal nets. These routing blockages prevent the internal nets from being routed over hostile cores in the repelling group bound.

-name_prefix *routing_blockage_name_prefix*

Optional name prefix for the routing blockages created by this command.

-repelling_group_bounds *repelling_group_bounds*

This option specifies the repelling group_bounds for which routing blockages are created.

DESCRIPTION

This command produces several routing blockages for each core found in the given repelling group bounds. Blockages are created on all routing layers. Two types of routing blockages are created per core.

The first type of routing blockages represent the cover shape of a core, and their blockage_group_id is associated with the core by the core's attribute called rgb_core_cover_shape. Although these blockages are not explicitly associated with any nets, their shape determines whether internal nets or transit nets are protruding.

The second type of routing blockages confine the routing space of a core's internal nets, and their blockage_group_id is associated with the internal nets and also with the core (by attribute rgb_core_routing_blockages). Their shape for a given core is the union of:

- the complement of this core's cover shape

- the cover shape of the hostile cores in the repelling group bound.

EXAMPLES

The following example creates a repelling group bound containing two cores called dcls1 and dcls2, and based on the current legalized placement, obtains a list of shapes per core.

```
prompt> create_bound -name "MyRGB1" -repelling diamond -dimensions 10 [get_cells {dcls1 dcls2}]
prompt> create_placement
prompt> legalize_placement
prompt> create_repelling_group_bound_shapes -repelling_group_bounds [get_bounds MyRGB] -guard_band 6

create_routing_blockage

Creates a routing blockage on metal, via, or poly layers.

SYNTAX

collection **create_routing_blockage**
-layers *layers*
-boundary *boundary_spec*
[-net_types *net_type_list*]
[-zero_spacing]
[-reserve_for_top_level_routing]
[-boundary_internal]
[-boundary_external]
[-allow_metal_fill_only]
[-cell *cell*]
[-blockage_group_id *group_id_number*]
[-name_prefix *prefix*]
[-allow_via_ladder]

Data Types

layers collection
boundary_spec list
net_type_list list
cell collection
group_id_number integer
prefix string

ARGUMENTS

-layers *layers*

Specifies the layers on which to create the routing blockage. Specify the layers by using a collection or by specifying a list of layer names from the technology file.

If you specify more than one layer, the tool creates multiple routing blockages simultaneously.

This is a required option.

-net_types *net_type_list*

Specifies the net types that must respect the generated routing blockages.

You can specify one or more of the following values: **analog_ground**, **analog_power**, **analog_signal**, **clock**, **deep_nwell**, **deep_pwell**, **ground**, **nwell**, **power**, **pwell**, **reset**, **scan**, **signal**, **tie_high**, and **tie_low**.

The default is all net types.

This option is mutually exclusive with the **-blockage_group_id**, **-boundary_internal**, and **-boundary_external** options.

-boundary *boundary_spec*

Specifies the boundary of the routing blockage. The boundary can be a rectangle or a polygon.

To specify a rectangle, use the following format to specify its lower-left and upper-right coordinates:

{ {*llx lly*} {*urx ury*} }

To specify a polygon, use the following format to specify its coordinates:

{ {*x1 y1*} {*x2 y2*} ... {*xn yn*} }

You can also specify a polygon as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. In the case of layers, the resulting area includes the area of every shape on the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This is a required option.

-zero_spacing

Creates a zero-spacing routing blockage.

A zero-spacing routing blockage disables the minimum spacing rule between the routing blockage boundary and the net shapes. When you use this option, the net shapes can touch, but not overlap, the routing blockage boundary.

This option is mutually exclusive with the **-boundary_internal** and **-boundary_external** options.

-reserve_for_top_level_routing

Creates a routing blockage to reserve area for top-level routing.

Top-level routing uses the area reserved by this kind of routing blockages as a routing channel through the block.

This option is mutually exclusive with the **-boundary_internal**, **-boundary_external** and **-allow_metal_fill_only** options.

-boundary_internal

Creates an internal boundary routing blockage.

This option is mutually exclusive with the **-reserve_for_top_level_routing**, **-boundary_external**, and **-allow_metal_fill_only** options.

-boundary_external

Creates an external boundary routing blockage.

This option is mutually exclusive with the **-reserve_for_top_level_routing**, **-boundary_internal**, and **-allow_metal_fill_only** options.

-allow_metal_fill_only

Creates a routing blockage that allows only metal fill shapes within the routing blockage. No routing shapes are allowed within the blockage.

You must use the **-layers** option with this option to specify the layer on which to create the routing blockage.

This option is mutually exclusive with the **-boundary_internal**, **-boundary_internal**, and **-reserve_for_top_level_routing** options.

-cell ***cell***

Specifies the physical cell in which to add the routing blockage.

The command creates the routing blockage in the cell's reference block using the coordinate system of the cell's top-level block.

The cell must reference a block, not a library cell, unless you run the command in the library manager. In the library manager, you can create routing blockages in library cells.

By default, the routing blockage is created in the current block.

-blockage_group_id ***group_id_number***

Assigns a blockage group identification number to the routing_blockage created by the command. You can assign the same blockage group ID number to Multiple blockages by using multiple **create_routing_blockage** commands. All routing blockages with the same blockage group ID belong to the same group. For block boundary blockages, the group ID number is an integer in the range of 0 to 99. For other routing blockages, the group ID number is an integer in the range from 1 to 99 and defaults to 0 if unspecified.

Each net has an integer attribute named **routing_blockage_group_id**, which lets you specify which blockage group applies to that net. For example, if a net's **routing_blockage_group_id** attribute is set to 3, all routing blockages assigned a blockage group ID of 3 block routing of that net in the layers specified for the routing blockages.

This option is mutually exclusive with the **-net_types** option.

-name_prefix ***prefix***

Specifies a prefix string used for the names of the generated routing blockage.

When you use this option, the tool uses the following naming convention for the generated routing blockages:

prefix_object_id

If you do not use this option, the tool uses the following naming convention for the generated routing blockages:

RB_*object_id*

-allow_via_ladder

Allows via ladders to overlap the routing blockage.

DESCRIPTION

The **create_routing_blockage** command creates metal or via routing blockages on the metal, via, or poly layers. The routing blockages can be either rectangular or rectilinear.

Unlike routing guides, which direct the router to change routing information on nets that go through the routing guide, routing blockages direct the router to avoid routing through these areas.

EXAMPLES

The following example creates a rectangular via routing blockage on the VIA5 layer with its lower-left corner at (0,0) and its upper-right corner at (100,100).

```
prompt> create_routing_blockage -layers VIA5 \
  -boundary {{0 0} {100 100}}
{RB_29440}
```

The following example creates rectilinear metal routing blockages on the M1 and VIA4 layers with boundary points at (0,0), (50,0), (50,50), (100,50), (100,100), and (0,100).

```
prompt> create_routing_blockage -layers {M1 VIA4} \
  -boundary {{0 0} {50 0} {50 50} {100 50} {100 100} {0 100}}
{RB_29696 RB_29697}
```

The following example creates a rectangular metal routing blockage with its lower-left corner at (0,0) and its upper-right corner at (50,50) on each metal layer in the design library:

```
prompt> create_routing_blockage \
  -layers [get_layers  -filter {name=~M*}] \
  -boundary {{0 0} {50 50}}
{RB_29441 RB_29442 RB_29443 RB_29444 RB_29445 RB_29446 RB_29447
RB_29448 RB_29449 RB_29450 RB_29451 RB_29452 RB_29453 RB_29454 RB_29455}
```

The following two commands create two routing blockages belonging to the same routing blockage group with group ID number 3:

```
prompt> set rBlockage1 [create_routing_blockage -layers M3 \
  -boundary {{0 0} {100 100}} -blockage_group_id 3]
{RB_29500}
prompt> set rBlockage2 [create_routing_blockage -layers VIA4 \
  -boundary {{0 0} {100 100}} -blockage_group_id 3]
{RB_29501}
```

The following command specifies group ID number 3 as the routing blockage group associated with net n52, causing blockages rBlockage1 and rBlockage2 to block routing of n52 in the specified blockage layers:

```
prompt> set_attribute -name routing_blockage_group_id \
  -objects [get_nets n52] -value 3
{n52}
```

The following command returns the routing blockages that belong to group ID number 3:

```
prompt> get_routing_blockages -filter "blockage_group_id==3"
{RB_29500 RB_29501}
```

create_routing_corridor

Creates a new routing corridor.

SYNTAX

collection **create_routing_corridor**
[-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]
[-path {{x y} {x y} ... }]
[-width width]
[-start_endcap flush | half_width | full_width]
[-end_endcap flush | half_width | full_width]a
[-min_layer_name min_layer]
[-max_layer_name max_layer]
[-name corridor_name]
[-object objects]
[-cell cell]

Data Types

llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection
width	float
min_layer	collection
max_layer	collection
corridor_name	string
objects	collection
cell	string or collection

ARGUMENTS

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary coordinates of the routing corridor. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogenous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

The **-boundary** and **-path** options are mutually exclusive, you must specify only one.

-path {{*x y*} {*x y*} ... }

Specifies the coordinates for a rectilinear path shape to be added to the routing corridor. A path must have 2 or more points. The **-width** option is required when you specify the **-path** option. The **-boundary** and **-path** options are mutually exclusive, you must specify only one.

-width *width*

Specifies the width of each segment of the path specified for a path shape. The **-path** option is required when you specify the **-width** option.

-start_endcap flush | half_width | full_width

Specifies the endcap for the startpoint of the corridor path. The endcap values are flush, half_width, and full_width. The default is flush.

-end_endcap flush | half_width | full_width

Specifies the endcap for the endpoint of the corridor path. The possible values are flush, half_width, and full width. The default is flush.

-min_layer_name *min_layer*

Specifies the minimum routing layer for the routing corridor shape. Only one layer can be specified. By default, the minimum layer is the min routing layer.

-max_layer_name *max_layer*

Specifies the maximum routing layer for the routing corridor shape. Only one layer can be specified. By default, the maximum layer is the max routing layer.

-name *corridor_name*

Specifies the name of the routing corridor. By default, the tool generates a unique name for the routing corridor by using the format CORRIDOR_objId.

-object *objects*

Specifies the nets and supernets (individual or bundled) to associate with the routing corridor.

-cell *cell*

Specifies the physical cell where the routing corridor is to be added. The routing corridor is created in the cell's reference block using the coordinate system of the cell argument's top block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, routing corridors can be created in library cells. When not specified, the routing corridor is created in the current block.

DESCRIPTION

This command creates a new routing corridor based on the boundary or path you specify. You can associate nets and supernets in the design with a routing corridor of the same design only and restrict their routing to within the routing corridor.

EXAMPLES

The following example creates a routing corridor with one rectangle shape, and associates six nets with the corridor.

```
prompt> create_routing_corridor -name corridor_a \
  -boundary { {35 35} {37 45} } \
  -min_layer_name M1 -max_layer_name M4 \
  -object [get_nets [list N1 N2 N3 N4 N5 N6]]
```

The following example creates a routing corridor with one rectilinear shape, and associates one net and one supernet with the corridor.

```
prompt> create_routing_corridor -name corridor_b \
  -boundary {{35 35} {45 35} {45 40} {40 40} {40 45} {35 45} } \
  -min_layer_name M1 -max_layer_name M4 \
  -object {N3 supernet_1}
```

The following example creates a routing corridor with one path shape, and associates two nets with the corridor.

```
prompt> create_routing_corridor -name corridor_c \
  -path {{35 35} {45 35} {45 40} } -width 0.2 \
  -min_layer_name M1 -max_layer_name M4 \
  -object [get_nets [list N5 N6]]
```

create_routing_corridor_shape

Creates a routing corridor shape on a routing corridor.

SYNTAX

collection **create_routing_corridor_shape**
-routing_corridor *routing_corridor*
[-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects]
[-path {{*x y*} {*x y*} ... }]
[-width *width*]
[-start_endcap flush | half_width | full_width]
[-end_endcap flush | half_width | full_width]
[-min_layer_name *min_layer*]
[-max_layer_name *max_layer*]

Data Types

routing_corridor collection
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection
width float
min_layer collection
max_layer collection

ARGUMENTS

-routing_corridor *routing_corridor*

Specifies the routing corridor to create the routing corridor shape. This is a required option.

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary coordinates of the routing corridor shape. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other

physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must integrate to a single, connected polygon. It is an error to specify a collection of objects with a combined area that integrates into multiple polygons.

The **-boundary** and **-path** options are mutually exclusive, you must specify only one.

-path {{*x y*} {*x y*} ... }

Specifies the coordinates for a rectilinear path shape to be added to the routing corridor. A path must have 2 or more points. The **-width** option is required when you specify the **-path** option. The **-boundary** and **-path** options are mutually exclusive, you must specify only one.

-width *width*

Specifies the width of each segment of the path specified for a path shape. The **-path** option is required when you specify the **-width** option.

-start_endcap flush | half_width | full_width

Specifies the endcap for the starting point of the corridor path. The endcap values are flush, half_width, and full_width. The default is flush.

-end_endcap flush | half_width | full_width

Specifies the endcap for the end point of the corridor path. The possible values are flush, half_width, and full width. The default is flush.

-min_layer_name *min_layer*

Specifies the minimum routing layer for the routing corridor shape. Only one layer can be specified.

-max_layer_name *max_layer*

Specifies the maximum routing layer for the routing corridor shape. Only one layer can be specified.

DESCRIPTION

This command creates a routing corridor shape and adds it to the specified routing corridor. The names of the routing corridor shapes are automatically generated.

The **-boundary** and **-path** options are mutually exclusive, you must specify only one of these options.

EXAMPLES

The following example adds a rectangle routing corridor shape to the routing corridor named CORRIDOR_1.

```
prompt> create_routing_corridor_shape -routing_corridor CORRIDOR_1 \
  -boundary { {35 35} {37 45} } \
  -min_layer_name M1 -max_layer_name M4
{"CORRIDOR_SHAPE_2"}
```

The following example adds a rectilinear routing corridor shape to the routing corridor named CORRIDOR_1.

```
prompt> create_routing_corridor_shape -routing_corridor CORRIDOR_1 \
  -boundary {{35 35} {45 35} {45 40} {40 40} {40 45} {35 45} }  \
  -min_layer_name M1 -max_layer_name M4
{"CORRIDOR_SHAPE_3"}
```

The following example adds a path routing corridor shape to the routing corridor named CORRIDOR_1.

```
prompt> create_routing_corridor_shape -routing_corridor CORRIDOR_1 \
  -path {{35 35} {45 35} {45 40} } -width 0.2 \
  -min_layer_name M1 -max_layer_name M4
{"CORRIDOR_SHAPE_4"}
```

create_routing_guide

Creates a new routing guide.

SYNTAX

collection **create_routing_guide**
-boundary *list_of_points*
[-layers *layers*]
[-horizontal_track_utilization *percentage*]
[-vertical_track_utilization *percentage*]
[-name *guide_name*]
[-cell *cell*]
[-river_routing]
[-switched_direction_only]
[-max_patterns *pattern_string*]
[-access_preference *access_preference*]
[-metal_cut_allowed]
[-forbidden_preferred_grid_extension]
[-design_boundary_blockage]
[-pin_access]
[-standard_cell_region]
[-single_row_via_ladder_pattern_must_join_allowed]
[-rdl_routing *spacing*]
[-preferred_direction_only]
[-switch_preferred_direction]

Data Types

list_of_points integer
layers list
percentage integer
guide_name string
cell collection
pattern_string string
access_preference string
spacing double

ARGUMENTS

-boundary *list_of_points*

Specifies the coordinates of the bounding box of the routing guide. The coordinate unit is specified in the technology file.

This option is required.

-layers *layers*

Specifies the layers on which to set the routing guide.

This option is required with the **-river_routing**, **-switched_direction_only**, and **-max_patterns** options. This option is not required when using other options.

The direction of the track utilization is determined from the preferred direction of the specified layers. If the preferred direction of a specified layer is horizontal, the horizontal track utilization is set on that layer. If you specify more than one utilization in the same area, the router uses the minimum utilization.

-horizontal_track_utilization *percentage*

Specifies the horizontal track utilization for the routing guide.

You must specify an integer value between 0 and 100 for the *percentage* argument. If you do not specify this option or if you specify a value greater than 100, it is set to 100.

Note that a utilization routing guide is a soft constraint for the router. It does not impact the capacity analysis in global routing. Also, for the overlapping area of multiple routing guides, the lowest utilization value of the routing guides is honored in the overlapping area.

-vertical_track_utilization *percentage*

Specifies the vertical track utilization for the routing guide.

You must specify an integer value between 0 and 100 for the *percentage* argument. If you do not specify this option or if you specify a value greater than 100, it is set to 100.

Note that a utilization routing guide is a soft constraint for the router. It does not impact the capacity analysis in global routing. Also, for the overlapping area of multiple routing guides, the lowest utilization value of the routing guides is honored in the overlapping area.

-name *guide_name*

Specifies the name of the created routing guide.

If you do not specify this option, the tool assigns a name to the routing guide using the naming convention RG#x, where x is an integer value.

-cell *cell*

Specifies the physical cell where the routing guide needs to be added. When you use this command in an implementation tool, the cell must reference a block, not a library cell. When you run this command in the library manager, the cell can reference a library cell.

The routing guide is created in the cell's reference block using the coordinate system of the cell argument's top block.

If you do not specify this option, the routing guide is created in the current block.

-river_routing

Specifies that the type of route guide is **river_routing**.

River routing refers to the routing of many nonshorting routes in roughly the same direction when routing is already restricted to just one or two layers.

When you use this option, you must also use the **-layers** option to specify the layers on which river routing is encouraged.

This option is mutually exclusive to **-switched_direction_only**, **-max_patterns**, and **-access_preference** options.

-switched_direction_only

Specifies that the type of route guide is **switched_direction_only**.

When you use this option, you must also use the **-layers** option to specify the affected layers.

This option is mutually exclusive to **-river_routing**, **-max_patterns**, and **-access_preference** options.

-max_patterns ***pattern_string***

Specifies that the type of route guide is **max_patterns**.

When you use this option, you must also use the **-layers** option to specify the affected layers.

This option is mutually exclusive to **-river_routing**,**-switched_direction_only**, and**-access_preference** options.

-access_preference ***access_preference***

Specifies that the type of route guide is **access_preference**

Use the following syntax to specify the access preference areas for the routing guide:

{*layer* {*access_preference_type* { {*x1 y1*} {*x2 y2*} } *strength*}}

Where *access_preference_type* is either **wire_access_preference** or **via_access_preference**, *x1* and *y1* are the coordinates of the lower-left corner of the access preference area, *x2* and *y2* are the upper-right coordinates of the access preference area and *strength* is a value between 0 and 1. If access preference areas overlap, the stronger access preference area takes precedence over the weaker access preference area. To require routing in a specific access preference area, use a strength value of 1. When you define access preference areas with a strength of 1, all access preference areas with a strength less than 1 are ignored and Zroute treats the access preference routing guide as a hard constraint.

This option is mutually exclusive to **-river_routing**, **-switched_direction_only**, and **-max_patterns** options.

-metal_cut_allowed

Specifies that the type of route guide is **metal_cut_allowed**.

-forbidden_preferred_grid_extension

Specifies that the type of route guide is **forbidden_preferred_grid_extension**.

-design_boundary_blockage

Specifies that the type of route guide is **design_boundary_blockage**.

-pin_access

Specifies that the type of route guide is **pin_access**.

-standard_cell_region

Specifies that the type of route guide is **standard_cell_region**.

-single_row_via_ladder_pattern_must_join_allowed

Specifies that the type of route guide is **single_row_via_ladder_pattern_must_join_allowed**.

-rdl_routing ***spacing***

Specifies that the type of route guide is **rdl_routing**, with the spacing as specified. The **spacing** value must be larger than the **minSpacing** specified in the tech file.

-preferred_direction_only

Creates a preferred-direction-only routing guide.

If you use the **-layers** option, the setting applies only to the specified layers; otherwise, it applies to all layers within the route guide boundary.

-switch_preferred_direction

Creates a switch-preferred-direction routing guide.

If you use the **-layers** option, the setting applies only to the specified layers; otherwise, it applies to all layers within the route guide boundary.

DESCRIPTION

This command creates a new routing guide and returns a collection that contains the created routing guide.

The tool uses the global snap settings to snap the bounding box of the routing guide.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a routing guide.

```
prompt> create_routing_guide -boundary {{0.0 0.0} {100.0 100.0}} \
    -layers {M3 M4} \
    -river_routing \
    -horizontal_track_utilization 50 -vertical_track_utilization 30
```

cut_name	string
distance	float
layer_name	string
mask_name	string
num_of_cuts	integer
num_of_layers	integer

ref_rule_name string
rule_name string
spacing float
spacing_multiplier float
width float
width_multiplier float
rule_name string

ARGUMENTS

-default_reference_rule

Specifies that the default routing rule (from the tech) is used as the reference rule when initializing the width and shielding constraints. See the **-widths** and **-shield** options.

The **-default_reference_rule**, **-reference_rule_name**, and **-no_reference_rule** options are mutually exclusive; you may use only one. By default, the command uses the default routing rule as the reference rule when none of these options are specified.

-reference_rule_name *ref_rule_name*

Specifies the name of the reference (source) rule to use. The created routing rule is initialized with the values from the reference rule.

The **-default_reference_rule**, **-reference_rule_name**, and **-no_reference_rule** options are mutually exclusive; you may use only one. By default, the command uses the default routing rule as the reference rule when none of these options are specified.

-no_reference_rule

Specifies that no reference rule should be used. The created routing rule will not be initialized with values from any reference rule. See the **-widths** and **-shield** options.

The **-default_reference_rule**, **-reference_rule_name**, and **-no_reference_rule** options are mutually exclusive; you may use only one. By default, the command uses the default routing rule as the reference rule when none of these options are specified.

-widths {*layer_name width* ...}

Specifies the routing width for each named routing layer. Each entry in the list is comprised of a routing layer name and its width separated by a space. The width portion of the pair is a floating point number. You can specify only a single width per layer.

If you do not specify the width for a layer, the tool copies the width from the reference rule if a reference rule is specified. See the **-default_reference_rule**, **-reference_rule_name**, and **-no_reference_rule** options.

-shield

Defines shielding in the non-default routing rule using the default spacing and width. No shielding constraints are defined in the routing rule if the **-no_reference_rule** option is specified.

-shield_widths {*layer_name width* ...}

Specifies the shielding width for each named routing layer. Each entry in the list is comprised of a routing layer name and its shielding width separated by a space. The shielding width portion of the pair is a floating point number. You can specify only a single width per layer.

If you do not specify the shielding width for a layer, the tool copies the shielding width from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the shielding width defaults to unspecified for the layer.

-shield_spacings {*layer_name spacing* ...}

Specifies the minimum shield spacing allowed between wires for each named routing layer. Each entry in the list is comprised of a routing layer name and its shield spacing separated by a space. The shield spacing portion of the pair is a floating point number. You can specify only a single spacing per layer.

If you do not specify the shield spacing for a layer, the tool copies the shield spacing from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the shield spacing defaults to unspecified for the layer.

-snap_to_track

Snaps shielding wires to the nearest routing track.

-vias {{*via_definition_name site_spec rotation_spec*} ...}

Creates vias automatically during routing, using this via pattern. Each entry in the via_pattern_list argument consists of the routable via definition name, its horizontal and vertical site count numbers, and its rotation setting, separated by spaces. The via definition name can be found as one of the simple via_def names. To obtain a list of simple via_defs, call the following command:

```
get_via_defs -filter "via_def_type==simple_via_def"
```

The via_defs are generated from the Technology File's ContactCode, DEF VIAS definitions, and the **create_via_def** command. The site count portion of the triplet is in the format mxn, where m is the horizontal site count (i.e., the number of columns in the via) and n is the vertical site count (i.e., the number of rows in the via), separated by the x character. The rotation portion of the triplet is specified by r or nr, where r indicates a rotated via and nr indicates an unrotated via. The rotation portion of the triplet is specified by r or nr, where r indicates a rotated via and nr indicates an unrotated via. Only those modes and rotations that are explicitly specified are allowed by the non-default routing rule. For example, to allow all via array modes (swapped and unswapped) and rotations (rotated and unrotated) for a 1x2 via array named VIAHH, you must specify the following definition:

```
-vias {{VIAHH 1x2 NR} {VIAHH 1x2 R} {VIAHH 2x1 NR} {VIAHH 2x1 R}}
```

When you define a via array, e.g. {VIAHH 2x2 R}, the 2x2 via array is constructed by rotating VIAHH instances. The rotation portion of the triplets should be specified on the cuts of the via array, not on the via array itself.

The **-vias** and **-cuts** options are mutually exclusive; you can specify only one.

-cuts {{*cut_layer_name* {*cut_name num_of_cuts*} ...} ...}

Creates vias automatically during routing using the general cut definitions.

Each entry in the option value consists of the cut layer name and the cut pair lists, separated by spaces. Each cut pair consists of the cut name and the number of cuts, separated by spaces. The cut name is defined in the Layer section of the technology file along with the width and height information for the cut. The **create_routing_rule** command searches for proper {via, rowXcolumn, rotation} solutions (the description for the **-via** option for more information) without violating any non-default rules or technology file rules.

The solutions must satisfy the following conditions:

1. The cut sizes of the vias match the width and height of the specified cut name.
2. The solutions are a subset of the contact codes defined in the fatTblFatContactNumber attribute in the Layer section of the technology file required by the metal width and number of cuts.
3. The cut number is the larger of the number defined in the non-default routing rule and the number defined in the fatTblFatContactMinCuts attribute in the Layer section of the technology file.

For example, assume the following information is defined in the technology file:

```
Layer "VIA1" {
  fatTblThreshold        = ( 0, 0.181, 0.411 )
  fatTblFatContactNumber  = ( "2,3,4,5,6", "5,6,20", "5,6,20" )
  fatTblFatContactMinCuts = ( "1,1,1,1,1", "1,1,1",  "2,2,2" )
```

```
    cutNameTbl          = ( Vsq, Vrect )
    cutWidthTbl         = ( 0.05, 0.05 )
    cutHeightTbl        = ( 0.05, 0.13 )
    ...
  }
```

To specify all cuts that match the size requirement of Vrect, meet the fat table rules according to the upper and lower metal widths, and the cut number is at least 1, enter the following definition:

```
create_routing_rule ruleA -widths { M1 0.2 M2 0.25 } -cuts {{VIA1 {Vrect 1}}}
```

The **create_routing_rule** command automatically populates all cuts that meet the requirements.

The **-vias** and **-cuts** options are mutually exclusive; you can specify only one.

-taper_distance *distance*

Specifies the taper distance for all routing layers. If you do not specify the taper distance, the tool copies the taper distance from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the taper distance defaults to unspecified, and Signal router will use 10 times the mean number of tracks as the tapering distance for all routing layers and the default tapering wire width is the default width for the respective layer.

-driver_taper_distance *distance*

Specifies the driver taper distance for all routing layers. If you do not specify the driver taper distance, the tool copies the driver taper distance from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, the the driver taper distance defaults to unspecified, and Signal router will use 10 times the mean number of tracks as the driver tapering distance for all routing layers and the default tapering wire width is the default width for the respective layer.

-taper_over_pin_layers *num_of_layers*

Specifies the number of routing layers over the pin layer that the router may use for tapering, and enables layer-based pin tapering.

Values must be greater or equal to 0. If both the **-taper_over_pin_layers** and **-taper_under_pin_layers** options are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

If this option is not specified for this rule, the tool copies it from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the taper over pin layers defaults to unspecified, and the router will apply tapering up to 2 layers over the pin layer. The default is 2.

If any of the layer-based tapering options is specified, distance-based tapering options (i.e. **-taper_distance** and **-driver_taper_distance**) are ignored.

-taper_under_pin_layers *num_of_layers*

Specifies the number of routing layers under the pin layer that the router may use for tapering, and enables layer-based pin tapering.

Values must be greater or equal to 0. If both the **-taper_over_pin_layers** and **-taper_under_pin_layers** options are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

If this option is not specified for this rule, the tool copies it from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the taper under pin layers defaults to unspecified, and the router will apply tapering down to 2 layers under the pin layer. The default is 2.

If any of the layer-based tapering options is specified, distance-based tapering options (i.e. -taper_distance and -driver_taper_distance) are ignored.

-driver_taper_over_pin_layers num_of_layers *num_of_layers*

Specifies the number of routing layers over the output pin layer that the router may use for tapering, and enables layer-based pin tapering.

Values must be greater or equal to 0. If both the **-driver_taper_over_pin_layers** and **-driver_taper_under_pin_layers** options are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

If this option is not specified for this rule, the tool copies it from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the driver taper over pin layers defaults to unspecified, and the tool copies the value from **-taper_over_pin_layers**.

-driver_taper_under_pin_layers num_of_layers ***num_of_layers***

Specifies the number of routing layers under the output pin layer that the router may use for tapering, and enables layer-based pin tapering.

Values must be greater or equal to 0. If both the **-driver_taper_over_pin_layers** and **-driver_taper_under_pin_layers** options are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

If this option is not specified for this rule, the tool copies it from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the driver taper under pin layers defaults to unspecified, and the tool copies the value from **-taper_over_under_layers**.

-spacings {*layer_name* **{***spacing* **...} ...}**

Specifies the minimum different-net spacing allowed between wires for each named routing layer. Each entry in the list is comprised of a routing layer name and its spacing separated by a space. The spacing portion of the pair is a list of floating point numbers. If you specify more than one spacing, you must specify the **-spacing_weight_levels** option. The spacing values in the **-spacings** argument and the weight values in the **-spacing_weight_levels** argument must have a one-to-one correspondence.

If you do not specify the minimum spacing for a layer, the tool copies the minimum spacing from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, then the minimum spacing defaults to unspecified for the layer.

-spacing_weight_levels {*layer_name* **{***low***|***medium***|***high***|***hard* **...} ...}**

Sets the weight for the corresponding spacing that is specified in the **-spacings** option. Each entry in the list is comprised of a routing layer name and its weight level separated by a space. Each weight value must be either of low, medium, high or hard. Following values are used for conversion: low = 0.3, medium = 0.5, high = 0.7, hard = 1. There can be maximum one hard spacing rule per routing layer.

-spacing_length_thresholds {*layer_name* **{***spacing_length_threshold* **...} ...}**

Sets the length threshold for the corresponding spacing that is specified in the **-spacings** option. Each entry in the list is comprised of a routing layer name and its length threshold list in microns, separated by a space. The length threshold portion of the pair is a list of floating point numbers.

The length threshold values in the **-spacing_length_thresholds** argument and the spacing values in the **-spacings** argument must have a one-to-one correspondence.

Router reports and tries to fix only those DRC violations where the parallel length of the metal involved in the violation over- laps by at least the specified threshold. Router calculates the parallel length using a shape-based formulation. The purpose of this option is to increase the flexibility of DRC convergence but not hurt crosstalk in a significant way.

The default threshold value is 0.

-multiplier_width ***width_multiplier***

Specifies the multiplier to apply to the layer widths in this routing rule. For layer widths specified by the **-widths** option, the widths are multiplied by width_multiplier. For each layer not specified in the **-widths** option, the default routing rule's layer width (i.e., the layer's default width in the tech file) is multiplied by width_multiplier and set as the layer width in this routing rule. You do not

need to know the units or layer width currently defined in the default routing rule. For example, to define double width, specify **-multiplier_width 2.0**.

-multiplier_spacing ***spacing_multiplier***

Specifies the multiplier to apply to the layer spacings in this routing rule. For layer spacings specified by the **-spacings** option, the spacings are multiplied by spacing_multiplier. For each layer not specified in the **-spacings** option, the default routing rule's layer spacing (i.e., the layer's minimum spacing in the tech file) is multiplied by spacing_multiplier and set as the layer spacing in this routing rule. You do not need to know the units or layer spacing currently defined in the default route rule. For example, to define double spacing, specify **-multiplier_spacing 2.0**.

Each multiplied spacing is assigned a hard weight level. The spacing_multiplier is only applied to hard rules. So if a layer is specified in the spacing_weight_levels option with a non-hard weight, the spacing_multiplier is not applied to any of that particular layer's spacings, because the spacing_multiplier cannot be applied to soft rules.

-single_side_spacing

Applies the spacing rule to only one side of the net, instead of both sides of the net.

-ignore_spacing_to_pg true|false

Indicates whether or not the router should ignore this routing rule's spacing constraints when considering the distance to power and ground nets. If not specified, the router uses the setting specified by the **route.common.ignore_var_spacing_to_pg** application option.

-ignore_spacing_to_blockage true|false

Indicates whether or not the router should ignore this routing rule's spacing constraints when considering the distance to blockages. If not specified, the router uses the setting specified by the **route.common.ignore_var_spacing_to_blockage** application option.

-ignore_spacing_to_shield true|false

Indicates whether or not the router should ignore this routing rule's spacing constraints when considering the distance to shield nets. If not specified, the router uses the setting specified by the **route.common.ignore_var_spacing_to_shield** application option.

-single_connection_to_pin true|false

Indicates whether or not the router must connect to a pin only once. If true, the router must connect to a pin only once. This applies to all pins connected to nets with this routing rule. If false, the router is allowed to connect to a pin any number of times. If this option is unspecified, the default is false except for nets using a nondefault width routing rule. For those nets, the value is always true. This option takes precedence over the global app option "route.common.single_connection_to_pins".

-rdl_taper_distances {*layer_name distance* **...}**

Specifies the maximum length in microns for tapering wires in the redistribution layer. The default is 0 and the wires are not tapered. This option is supported only by the flip-chip router.

-rdl_taper_widths {*layer_name width* **...}**

Specifies the tapering width for each redistribution layer. If you do not specify this option, the flip-chip router uses the size of the via or pin as the wire width. This option is supported only by the flip-chip router.

-mask_constraints {{*layer_name mask_name* **fixed} ...}**

Specifies the mask constraint for each routing layer. Each entry in the option value consists of the routing layer name, its mask constraint, and the optional **fixed** keyword. The **fixed** keyword is specified if and only if the mask constraint is fixed on the layer (i.e., it is a hard constraint). If the "fixed" keyword is not specified, the mask constraint is not fixed on the layer (i.e., it is a soft constraint). The supported masks are mask_one, mask_two, and same_mask.

If you do not specify the mask constraint for a routing layer, the tool copies the mask constraint from the reference rule specified by **-reference_rule_name**. If **-reference_rule_name** is not specified, there is no default value.

-via_spacings {{*layer_name layer_name spacing*} ...}

Specifies the via spacing between two via layers. The two via layers can be the same layer or different layers. Only one via spacing may be specified for each pair of via layers.

The minimum spacing between vias on any layer combinations not specified in this option is determined from the technology file. For vias on the same layer, the router uses the minimum spacing defined in the Layer section for the via layer. For vias on different layers, the router uses the minimum spacing defined in the DesignRule section for the via layer combination.

-parallel_wire {*layer_name* ...}

Specifies a list of layers on which to create fat wires for parallel wire purpose. Layers must be interconnect or via_cut layers.

rule_name

Specifies the name for the new non-default routing rule. This is a required argument.

DESCRIPTION

This command defines non-default routing rules in the design.

Use the **create_routing_rule** command to define width, shielding, tapering, and spacing rules.

Use the **set_routing_rule** command to set the minimum and maximum routing layers, and to assign non-default routing rules to specific nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines a non-default routing rule named new_rule that uses the default routing rules as the reference rule:

```
prompt> create_routing_rule new_rule -default_reference_rule \
  -widths {m1 0.8 m4 0.9} -spacings {m1 1.0 m4 1.0}
```

The following example reports the non-default rule named new_rule:

```
prompt> create_routing_rule new_rule
prompt> report_routing_rules new_rule
```

The following example defines a non-default rule named new_rule that specifies spacings, spacing weights, and spacing length thresholds:

```
prompt> create_routing_rule new_rule \
  -spacings {m1 {0.09 0.15 0.2} m2 {0.09 0.15 0.2} m3 {0.09 0.15 0.2}} \
  -spacing_weight_levels {m1 {high medium low} m2 {high medium low} \
            m3 {high medium low}} \
  -spacing_length_thresholds {m1 {0.01 0 0} m2 {0.01 0 0} m3 {0.01 0 0}}
```

The following example defines a non-default rule named new_rule that specifies multiple via pattern with both rotated and unrotated vias for certain layers.

```
prompt> create_routing_rule new_rule \
  -vias {{VIA1_HH 2x1 NR} {VIA1_HH 2x1 R} {VIA1_HV 2x1 R} {VIA1_HV 2x1 R}}
```

The following example defines a non-default rule named new_rule that specifies layer-based tapering options.

```
prompt> create_routing_rule new_rule -taper_over_pin_layers 1 -taper_under_pin_layers 3
```

create_rp_group

Creates a relative placement group in the given design.

SYNTAX

collection **create_rp_group**
-name *rp_group_name*
[-rows number_of_rows]
[-columns number_of_columns]
[-design *design*]

Data Types

rp_group_name string
number_of_rows integer
number_of_columns integer
design collection

ARGUMENTS

-name *rp_group_name*

Specifies the name of the relative placement group.

-rows *number_of_rows*

Specifies the number of rows into which objects can subsequently be added, relative to each other. The default value for the option is 1.

-columns *number_of_columns*

Specifies the number of columns into which objects can subsequently be added, relative to each other. The default value for the option is 1.

-design *design*

Specifies the top design for creating relative placement group. If this is not specified then relative placement group will be created in the current design.

DESCRIPTION

The **create_rp_group** command creates new relative placement group. This command returns a collection containing the created relative placement group. If no objects are created, the empty string is returned.

The created group is empty and contains no objects. The objects to relative placement group can be added using the **add_to_rp_group** command.

Relative placement groups provide for explicit user control of placement for a group of cells. A relative placement group is placed as a whole while maintaining the relative placement (or tiling) of the cells within the group as specified with the **add_to_rp_group** command. Relative placement is also known as "structured placement."

When placing a relative placement group, the placer automatically chooses the orientation for the group. For example, if the placer chooses the north orientation for a relative placement group, the first column of that relative placement group is placed first, and subsequent columns are placed toward the right. If the placer chooses the flip-north orientation then last column will be placed first and other columns towards the right.

EXAMPLES

The following example creates a relative placement group named "top_rp", with 3 rows and 4 columns.

```
prompt> create_rp_group -name top_rp -rows 3 -columns 4
```

create_sadp_track_rule

Creates a self-aligned double patterning (SADP) track rule.

SYNTAX

status **create_sadp_track_rule**
-name *track_pattern_rule*
-pattern *pattern*
-sadp_spacing *spacing*

Data Types

track_pattern_rule string
pattern list
spacing float

ARGUMENTS

-name *track_pattern_rule*

Defines the name of the track rule. As multiple *track_pattern_rules* can be created for the track plan, the rule name should be unique in the current library.

-pattern *pattern*

Defines the inter-leaving wide tracks which can be used either for specific PG nets or left without any net assignments. If no nets are assigned, those wide tracks can be used later by nets with nondefault routing rules for wide metal routing. The following are example pattern specifications:

{{width1 count1 netname1} {{width2 count2 netname2} ... }
{{width1 count1 netname1} {{width2 count2 } ... }

The fields used in the pattern specification are:

- width - The width of the track used by netname.
- count - The number of default width tracks allowed until the next wide track defined by width.
- netname - Net which can be routed over this track. This field is optional. If specified unrouted_net with name netname should exist in the block where sadp_tracks will be created.

-sadp_spacing *spacing*

Defines the minimum spacing between the adjacent tracks created by this track rule. This spacing along with default or minimum width of the route is used to calculate the track position of the default width tracks between width1, width2, and so on.

DESCRIPTION

This command defines a self-aligned double patterning (SADP) track rule by specifying SADP constraints. The SADP rules are used to create SADP tracks. These rules are persistent across sessions and are saved in the current library.

EXAMPLES

The following example creates a self-aligned double patterning (SADP) track rule named tr1. For net VDD, the track width is 1 and the track count is 1. For net VSS, the track width is 2 and the track count is 1. The minimum spacing between adjacent tracks is 0.50.

```
prompt> create_sadp_track_rule -name tr1 \
  -pattern {{1 1 "VDD"} {2 1 "VSS"}} -sadp_spacing 0.50
```

The following example creates a self-aligned double patterning (SADP) track rule named tr2 for net VSS and other unassigned nets. For VSS, the track width is 2 and the track count is 1. For other nets, the track width is 2 and the track count is 1. The minimum spacing between adjacent tracks is 0.50.

```
prompt> create_sadp_track_rule -name tr2 -pattern {{2 1 "VSS"} {2 1}} \
  -sadp_spacing 0.50
```

create_safety_register_group

Creates one safety_register_group object

SYNTAX

status **create_safety_register_group**
-rule *safety_register_rule*
[-name *group_name*]
[-registers *objects*]
[-logic *cells*]
[-taps *cells*]
[-split_pins *pins*]

Data Types

safety_register_rule object
group_name string
objects collection
cells collection
pins collection

ARGUMENTS

-rule *safety_register_rule*

Specifies the safety registery rule based on which this redundancy group was created

-name *group_name*

Name of the new safety_register_group object. If not specified, the name will be automatically generated by the tool

-registers *objects*

Specifies the collection of registers or register output pins which should be part of this register redundancy group.

-logic *cells*

Specifies the collection of logic cells which form a part of the voting logic circuit. These must be combinational cells.

-taps *cells*

Specifies the collection of tap cells for the registers in this group.

-split_pins *pins*

Specifies the set of pins which should be split so as to be a part of different branches of high-fanout tree.

DESCRIPTION

This command creates one safety_register_group object based on the given parameters. It stores the reference to the original safety register rule which was honored to create it.

EXAMPLES

The following example creates a safety_register_group object consisting of 3 registers and some voting logic combinational cells.

```
prompt> create_safety_register_group -rule rule1 \
   -registers {flop1 flop2 flop3} \
   -logic {land1 land2 lxor1} \
   -name group1
```

The following example creates a safety_register_group object consisting of 3 register output pins and tap cells

```
prompt> create_safety_register_group -rule rule2 \
   -registers {flop1/Q flop2/Q flop3/Q} \
   -taps {TAP1 TAP2} \
   -name group2
```

SEE ALSO

get_safety_register_groups(2)
remove_safety_register_groups(2)
report_safety_register_groups(2)
write_safety_register_script(2)

create_safety_register_rule

Creates one safety_register_rule object

SYNTAX

status **create_safety_register_rule**
-type *rule_type*
[-name *rule_name*]
[-distance *values*]
[-register_mapping *lib_cell_list*]
[-logic_module *reference*]
[-tap_mapping *lib_cell_list*]
[-split_pin_types *pin_type_list*]

Data Types

rule_type	string
reference	object
values	list
lib_cell_list	list
pin_type_list	list

ARGUMENTS

-type *rule_type*

Specifies whether the register should be mapped to another fault-tolerant variant, or should be replaced by a group of redundant flops (redundancy group). Valid values are "fault_tolerant", "dual_mode" and "triple_mode"

In case of redundancy group, it specifies the module that the register should be replaced by.

-name *rule_name*

Optionally specifies the name of the rule to be created. If not specified, a name will be automatically generated and assigned.

-distance *values*

Specifies the distance values for repelling bound constraint for redundancy group. It could be either in the form of an {x y} pair or a single number denoting radial distance. The values are in user units. The values cannot be negative. The distances are measured edge-to-edge, or in other words, from the boundary of one register to the closest boundary of another. For *-type dual_mode or triple_mode*, this option must be specified. For *-type fault_tolerant*, this option is unnecessary and will be ignored.

Specifying the {x y} distance pair means that either "x" or "y" separation must be honored. In other words, each pair of registers in the group should be either "x" distance apart measured on X-axis, or "y" distance apart measured on Y-axis. This will effectively create a rectangular keep-out region around each register, in which it is forbidden to place another register of the same group. It

is allowed to specify a distance of zero for "x" or "y", but not for both simultaneously.

Specifying the single "r" value means that the Manhattan distance between each pair of registers in the group should be at least "r". The Manhattan distance between two redundancy registers is defined as the sum of the vertical distance and horizontal distance between their closest edges. Specifying a radial distance thus creates an octagonal keep-out region around each register, wherein another register of the same group must not be placed. For cells in the same column, the horizontal distance is 0. For cells in the same row, the vertical distance is 0. This "r" value cannot be zero.

-register_mapping *lib_cell_list*

Specifies one or more lib_cells that should be considered for safety registers of type fault tolerant. When this option is provided, synthesis will map the original register to an appropriate lib_cell from the given values.

This option cannot be specified with *-type dual_mode* or *triple_mode*. This option cannot be specified along with *-logic_module*.

-logic_module *reference*

Specifies the module containing the combinational logic which follows the duplicated or triplicated registers after the safety register group is created based on the given rule. For example, in case of triple-mode redundancy, this could be a majority circuit with three inputs and one output.

This option cannot be specified with *-type fault_tolerant*. This option cannot be specified along with *-register_mapping*.

-tap_mapping *lib_cell_list*

The list of lib cells, out of which the appropriate one will be used for instantiating tap cells for the safety registers.

-split_pin_types *pin_type_list*

The pin types which should be considered for splitting so as to be a part of different branches of clock tree or high fanout net trees. Allowed values are *clock*, *reset* and *scan*. List of one or more such types can be specified.

DESCRIPTION

This command creates a new safety_register_rule object based on the options specified. This rule can be then applied to safety-critical registers. The rule can specify replacement of the register either to another fault-tolerant register, or by a group of redundant registers. In latter case, the minimum separations between the redundant registers can be specified which can be considered by the placement engine. If the pins of the redundant registers should be split to different branches of trees, the types to be considered can also be specified.

EXAMPLES

The following example creates a safety_register_rule object.

```
prompt> create_safety_register_rule -type fault_tolerant \
   -distance {20 30} \
   -split_pin_types {scan clock} \
   -name rule1
```

The following example defines a rule that requires redundancy registers to be separated by at least 20u horizontally, or, at least 5u vertically.

```
prompt> create_safety_register_rule -type triple_mode
```

-name RULE1 -distance {20 5}

Assuming that the width of current block is smaller than 2000u, following rule states that redundancy registers must be placed into separate rows. Because the specified y distance is zero, adjacent rows are allowed.

```
prompt> create_safety_register_rule -type triple_mode\
  -name RULE2 -distance {2000 0}
```

Assuming that the width of current block is smaller than 2000u, following rule states that redundancy registers must be placed into separate rows. The vertical between the two redundancy registers must be at least 10u.

```
prompt> create_safety_register_rule -type dual_mode\
  -name RULE3 -distance {2000 10}
```

The following rule defines a required Manhattan distance of 8u between the redundancy registers that should follow this rule.

```
prompt> create_safety_register_rule -type triple_mode -name RULE4 -distance 8
```

Note: All examples above assume the length unit to be microns.

create_scan_chain

Creates a scan chain in the current design.

SYNTAX

collection **create_scan_chain**
-name *name*
[-availabe_bits *number_of_bits*]
[*stub_chains*]

Data Types

name string
number_of_bits integer
stub_chains collection

ARGUMENTS

-name *name*

Name of the scan_chain

-partition *name*

Scan partition name

-available_bits *number_of_bits*

Number of bits available with respect to the expected bit length of this scan_chain

stub_chains

Ordered collection of stub_chain objects to be added into the new scan_chain

DESCRIPTION

This command creates a new scan chain and returns a collection containing the new scan chain.

EXAMPLES

The following example creates a scan chain with name scan1 and available_bits 8

```
prompt> create_scan_chain -name scan1 -available_bits
```

The following example creates a scan chain with name scan2 and stub_chains {stub1 stub2}

```
prompt> create_scan_chain -name scan2 {stub1 stub2}
```

SEE ALSO

get_scan_chains(2)
remove_scan_chains(2)

create_scenario

Creates a scenario in the current design.

SYNTAX

collection **create_scenario**
-mode *mode*
-corner *corner*
[-name *name*]
[-init_from *corner_or_scenario*]

Data Types

mode	collection
corner	collection
name	string
corner_or_scenario	collection

ARGUMENTS

-mode *mode*

Specifies the mode of the new scenario. This option is required. The mode must already exist.

-corner *corner*

Specifies the corner of the new scenario. This option is required. The corner must already exist.

-name *name*

Specifies the name of the new scenario. If this option is not given, a unique name will be synthesized from the mode and corner names.

-init_from *corner_or_scenario*

Specifies an existing scenario or corner object. If given, this object will be used to initialize the new scenario's constraints and analysis flags. If a scenario is given, it must have the same mode as the scenario being created. If a corner is given, there must be an existing scenario with that corner and the mode of the scenario being created.

DESCRIPTION

Creates a scenario in the current design, and sets it active for all analysis types except cell and signal EM. If any of these analysis

types are not needed, this command should be followed by the **set_scenario_status** command. If a scenario already exists for the given mode and corner, the command will fail. If a scenario with the given name already exists, the command will fail. If a scenario is successfully created, its mode will become the current mode, and its corner will become the current corner. This means that the new scenario will be the current scenario.

The **-init_from** option allows you to duplicate all the constraints and settings of an existing scenario onto a new scenario. If an existing scenario is given with **-init_from**, it will be used as the source. If a corner is given, it will be used (along with the mode given by the **-mode** option) to search for an existing scenario to serve as the source. In either case, the source scenario must have the same mode as the new scenario.

If successful, the command returns a collection containing the new scenario.

Multicorner-Multimode Support

By default, this command uses the current mode and current corner. To specify a different mode, use the **-mode** option. To specify a different corner, use the **-corner** option.

EXAMPLES

The following command creates a scenario named m1@c1 using corner c1 and mode m2.

```
prompt> create_scenario -name m1@c1 -mode m1 -corner c1
```

create_secondary_pg_placement_constraints

Create secondary pg placement constraints that will allow dual rail cells to be inserted into specific regions.

SYNTAX

status **create_secondary_pg_placement_constraints**
[-name *constraint_name*]
[-supply *supply_net_name*]
[-exclude_supply *exclude_supply_net_name*]
[-voltage_areas *voltage_area_list*]
[-layers *layer_list*]
[-margin *distance*]
[-region *region_list*]

Data Types

constraint_name string
supply_net_name string
exclude_supply_net_name string
voltage_area_list collection
layer_list list of strings
distance distance in user units
region_list list of coord

ARGUMENTS

-name

Specifies the name of this pg constraint. The name of the constraint should be unique for the design. No two secondary pg constraints should have the same name.

-supply

This is optional and specifies the supply net name. Either this option or -exclude_supply should be specified, but not both.

-exlude_supply

This is optional and specifies the excluded supply net name. Either this option or -supply should be specified, but not both.

-voltage_areas

Specifies the list of voltage areas (VA) that this pg constraint will be applied to. When -voltage_areas is not specified, this pg constraint will be applied to all voltage areas in the current block, even if the same supply has restricted physical availability in another VA. PG straps in a foreign VA that is not included in the list of VAs in the constraint for the same supply will not be used for buffering, even if the strap in the foreign VA is available within the specified margin of the VA listed in the constraint.

-layers

Specifies the list of layers. The physical shapes where the dual rail cells should be inserted into are derived based on the pg straps on the specified layers with shape_use of "stripe". This optional should not be specified with -exclude_supply, or an error will be issued.

-margin

This is optional and specifies the margin distance when -layers is used, which is a floating point number specifying the maximum distance between the outer edge of a strap and the furthest edge of a dual-rail cell in the distance unit of the design. The cells will be placed such that no part of it will be outside the margin. We recommend the margin be large enough such that when each edge of each strap is expanded by the margin amount, neighboring expanded straps should touch or overlap, resulting in a continuous region for dual rail cell placement. The default margin is 0. When margin is specified and has a none zero value, -layers must be specified, or an error will be issued. This optional should not be specified with -exclude_supply, or an error will be issued.

-region

Specifies the rectanges or rectilinear polygons where the dual rail cells should be inserted. This use model can be used even if power network synthesis has not been completed. If -margin or -layers or -voltage_area is specified with -region, a warning will be issued and the -margin/-layers/-voltage_areas options will all be ignored. This optional should not be specified with -exclude_supply, or an error will be issued.

Each region can be one of the following objects:

- Rectangle
  Each rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}).
- Polygon
  Each polygon is specified by its points as {*x1 y1*} {*x2 y2*} {*x3 y3*} {*x4 y4*} and so on.
- Geometric object A geometric object is the combined area of a mixed collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area include the areas of each object. In the case of layers, the resulting area includes the area of every shape on the layer. Overlapping areas are preserved and not merged.

The specified regions can overlap or be disjoint.

DESCRIPTION

This command creates a secondary pg constraint. When there is a secondary pg constraint with -supply being defined for certain supplies, this implies that these supplies will not be available everywhere in the voltage area/power domain as what UPF specified. Instead, they will only be available within specific regions which the secondary pg constraint specified. When there is a secondary pg constraint with -exclude_supply being defined for certain supplies, this implies that these supplies will not be available for implementation in the voltage areas specified even though these supplies are indicated as available in UPF.

When a secondary pg constraint with -supply is creatd, the requirement to place the dual-rail cells in the regions with the power straps is a hard constraint. If regions with straps are not available where needed, nets can remain unbuffered (logical design rule check issues such as transition violations, or timing violations). Dual-rail cells including buffers, inverters, isolation and level shifters are considered to honor the constraint. Power switch cells are not considered. This constraint is for cases where PG straps are available in some region of a VA.

When a secondary pg constraint with -exclude_supply is created, the tool should not insert any cells that require the excluded supply in the specified voltage area/power domains. This is also a hard constraints. This constraint is for cases where supplies are available in UPF, but there are no PG straps planned and implemented in the corresponding voltage areas.

This feature supports the flat flow with VAs in the current_design. Hierarchical flows with restricted secondary PG straps in VAs that are in linked physical blocks are not supported. Only the advanced legalizer is supported with this feature. It must be enabled to use this feature. For optimization, only the default "advanced buffering" is supported.

This feature uses VA shapes to implement the placement constraints under the hood. VA shapes will be generated based on the secondary PG strap location so that dual-rail cells can be placed in the strap region. The VA shapes created by the user can be modified in number and size. There are attributes to distinguish VA shapes created as a result of secondary PG placement constraints from regular VA shapes. Each generated VA shape represents a region where straps for one or more supplies are available. Do not alter or remove the VA shapes related to the secondary PG placement constraints.

Exactly one of either -layers or -region must be specified if -supply is specified. If multiple calls of create_secondary_pg_placement_constraints for the same supply and voltage area are issued, the union of the locations is considered.

The constraint is saved with the design in the nlib.

EXAMPLES

The following example creates a secondary pg constraint named pg_cstr0 that defines supply VDD2 being available only within a margin of 1 from the VDD2 straps in voltage area VA on layer M7 and M8 after commit_secondary_pg_placement_constraints is issued.

```
prompt> create_secondary_pg_placement_constraints -name pg_cstr0 \
  -supply VDD2 -voltage_areas VA -margin 1 -layers {M7 M8}
prompt> commit_secondary_pg_placement_constraints
```

The following example creates a secondary pg constraint named pg_cstr1 that defines supply VDD1 being available only within region {{120 30 } {250 70}} after commit_secondary_pg_placement_constraints is issued.

```
prompt> create_secondary_pg_placement_constraints \
  -name pg_cstr1 -supply VDD1 -region {{120 30 } {250 70}}
prompt> commit_secondary_pg_placement_constraints
```

The following example creates a secondary pg constraint named pg_cstr2 that defines supply VDD1 to be excluded from implementation usage in all voltage areas after commit_secondary_pg_placement_constraints is issued.

```
prompt> create_secondary_pg_placement_constraints \
  -name pg_cstr2 -_exclude_supply VDD1
prompt> commit_secondary_pg_placement_constraints
```

[-end_endcap *endcap_type*]
[-start_extension *extension*]
[-end_extension *extension*]
[-origin *point*]
[-height *height*]
[-orientation *orientation*]
[-justification *justification*]
[-text *text_string*]
[-fill_cell *fill_cell*]

Data Types

layer collection
use string
llx float
lly float
urx float
ury float
x float
y float
geometric_objects collection
width float
endcap string
extension float
height float
orientation string
justification string
text_string string
net collection
port collection
fill_cell collection

ARGUMENTS

-shape_type rect | **polygon** | **path** | **text**

Specifies the type of shape to create.

This is a required option.

-layer ***layer***

Specifies the layer on which to create the shape. You must specify a single layer using either the layer name from the technology file or a collection containing exactly one layer.

This is a required option.

-shape_use ***use***

Specifies the usage of the shape.

Valid values are

- **area_fill**
  A fill shape that does not require optical proximity correction (OPC). Fill shapes are created inside the top level **fill_cell** for the design, unless a **fill_cell** is specified using **-fill_cell** option.
- **core_wire**
  A shape that connects the endpoints of a follow-pin to its target.
- **detail_route** (the default)
  A shape used for detail routed signal nets.
- **follow_pin**
  A shape that connects a standard cell to a power structure.
- **global_route**
  A shape used for global routed signal nets.
- **lib_cell_pin_connect**
  A shape that connects to a pin of a standard cell.
- **macro_pin_connect**
  A shape that connects to a pin of an I/O pad cell or macro cell.
- **opc**
  A fill shape that requires optical proximity correction (OPC).
- **pg_augmentation**
  A shape added post route to the power and ground structures.
- **ring**
  A shape that belongs to a power ring.
- **shield_route**
  A shape used for shielding route shapes.
- **stripe**
  A shape that belongs to a power strap.

- **user_route**
  A shape used for user-entered route shapes.
- **zero_skew**
  A shape used for zero-skew route shapes.

This option is valid only for rectangle, polygon, and path shapes; the tool issues an error if you use it for text shapes.

-net ***net***

Specifies the net that owns this shape. If the net is power or ground, the shape rule_type attribute is automatically set to "none". Otherwise it is set to "default".

This option is valid only for rectangle, polygon, and path shapes; the tool issues an error if you use it for text shapes.

The **-net** and **-port** options are mutually exclusive; you can specify neither option (for unassigned shapes) or one of them.

-port ***port***

Specifies the port that owns this shape.

When you assign a shape to a port, the tool creates a new terminal named TM_*n*, where *n* is a unique integer in the block. The new terminal is owned by the port, owns the shape, and has the default access direction (all).

This option is valid only for rectangle, polygon, and path shapes; the tool issues an error if you use it for text shapes.

The **-net** and **-port** options are mutually exclusive; you can specify neither option (for unassigned shapes) or one of them.

-boundary ***list_of_points***

Specifies the boundary of a rectangle, polygon or path shape. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This option is required for rectangle and polygon shapes. It is an error to use this option with other shape types.

-path {{*x y*} {*x y*} ...}

Specifies the centerline points of a path shape. You must specify at least two points.

If you use this option with other shape types, the tool issues an error.

-width ***width***

Specifies the width of a path shape. The value must be non-negative.

If you use this option with other shape types, the tool issues an error.

-start_endcap ***endcap_type***

Specifies the type of the start endcap of a path shape.

The valid values are

- **flush** (the default)

Creates an endcap with square ends and no extension.

- **full_width**
  Creates an endcap with square ends that is extended by the path width.
- **half_width**
  Creates an endcap with square ends that is extended by half the path width.
- **octagon**
  Creates an endcap with octagonal ends and no extension.
- **variable**
  Creates an endcap with square ends that is extended by the value specified in the **-start_extension** option. When you specify this setting, the **-start_extension** option is required.

This option is valid only for path shapes; the tool issues an error if you use it for other shape types.

-end_endcap *endcap*

Specifies the type of the end endcap of a path shape.

The valid values are

- **flush** (the default)
  Creates an endcap with square ends and no extension.
- **full_width**
  Creates an endcap with square ends that is extended by the path width.
- **half_width**
  Creates an endcap with square ends that is extended by half the path width.
- **octagon**
  Creates an endcap with octagonal ends and no extension.
- **variable**
  Creates an endcap with square ends that is extended by the value specified in the **-start_extension** option. When you specify this setting, the **-start_extension** option is required.

This option is valid only for path shapes; the tool issues an error if you use it for other shape types.

-start_extension *extension*

Specifies the start extension of a path shape with variable endcaps. The value must be non-negative.

This option is required when you use the **-start_endcap variable** option. If you use this option with other shape types, the tool issues an error.

-end_extension *extension*

Specifies the end extension of a path shape with variable endcaps. The value must be non-negative.

This option is required when you use the **-end_endcap variable** option. If you use this option with other shape types, the tool issues an error.

-origin {*x y*}

Specifies the placement location of the text shape's origin. The origin is determined by the text's justification, as specified with the **-justification** option.

This option is required for text shapes. If you use this option with other shape types, the tool issues an error.

-height *height*

Specifies the height of a text shape. The value must be non-negative.

This option is required for text shapes. If you use this option with other shape types, the tool issues an error.

-orientation *orientation*

Specifies the orientation of a text shape.

Valid values are

- **MX** (mirror around the X-axis)
- **MXR90** (mirror around the X-axis and rotate 90 degrees)
- **MY** (mirror around the Y-axis)
- **MYR90** (mirror around the Y-axis and rotate 90 degrees)
- **R0** (no rotation, which is the default)
- **R90** (rotate 90 degrees)
- **R180** (rotate 180 degrees)
- **R270** (rotate 270 degrees)

This option is valid only for text shapes; the tool issues an error if you use it for other shape types.

-justification *justification*

Specifies the justification of a text shape. Text is justified with respect to the untransformed bounding box (the bounding box before applying the orientation rotation).

Valid values are

- **C** (center)
- **CB** (center-bottom)
- **CT** (center-top)
- **LB** (left-bottom, which is the default)
- **LC** (left-center)
- **LT** (left-top)
- **RB** (right-bottom)
- **RC** (right-center)
- **RT** (right-top)

This option is valid only for text shapes; the tool issues an error if you use it for other shape types.

-text *text_string*

Specifies the text string to display in a text shape.

This option is required for text shapes. If you use this option with other shape types, the tool issues an error.

-fill_cell *fill_cell*

Specifies the *fill_cell* to create the shape in. The shapes are created as fill shapes even if **-shape_use** is not specified as **area_fill**

DESCRIPTION

This command creates a new rectangle, polygon, path, or text shape and returns a collection that contains the new shape.

For rectangle (**-shape_type rect**) and polygon (**-shape_type polygon**) shapes, you must specify the layer (**-layer**) and boundary (**-boundary**). You can also specify the use (**-shape_use**) and ownership (**-net** or **-port**) for the shape.

For path (**-shape_type path**) shapes, you must specify the layer (**-layer**) with either combination of path (**-path**) and width (**-width**) or boundary (**-boundary**) with points that form rectangle. You can also specify the use (**-shape_use**), ownership (**-net** or **-port**), start endcap (**-start_endcap**), and end endcap (**-end_endcap**) for the shape. If you specify the **-start_endcap variable** option, you must also specify the **-start_extension** option. If you specify the **-end_endcap variable** option, you must also specify the **-end_extension** option.

For text (**-shape_type text**) shapes, you must specify the layer (**-layer**), origin (**-origin**), height (**-height**), and text string (**-text**). You can also specify the orientation (**-orientation**) and justification (**-justification**) for the shape.

EXAMPLES

The following example creates a rectangle shape on the port named Clk.

```
prompt> create_shape -shape_type rect -layer METAL \
  -boundary {{0 0} {1000 1000}} -port Clk
```

The following example creates a polygon shape that is not associated with any net or port.

```
prompt> create_shape -shape_type polygon -layer METAL \
  -boundary {{0 0} {0 1000} {500 1000} {500 0}}
```

The following example creates a path shape on the net named Clk.

```
prompt> create_shape -shape_type path -layer METAL \
  -path {{0 0} {0 1000}} -width 50 -net Clk
```

The following example creates a path shape.

```
prompt> create_shape -shape_type path -layer METAL \
  -boundary {{0 0} {0 1000}}
```

The following example creates a text shape that contains the string "hello world".

```
prompt> create_shape -shape_type text -layer METAL \
  -origin {100 100} -height 100 -orientation R0 -justification LB \
  -text "hello world"
```

uniform_mask { mask [fixed] }
mask_list { mask1 mask2 ... }

ARGUMENTS

-shape_pattern_type rect_pattern | polygon_pattern | path_pattern

Specifies the type of shape_pattern to create.

This is a required option.

-layer *layer*

Specifies the layer on which to create the shape_pattern. You must specify a single layer using either the layer name from the technology file or a collection containing exactly one layer.

This is a required option.

-net *net*

Specifies the power/ground net that owns the shapes of this shape_pattern.

The shape_pattern rule_type attribute is automatically set to "none" by default as the owner is power or ground net.

This is a required option for shape_patterns with shape_pattern_type "rect_pattern", "polygon_pattern" or "path_pattern".

-shape_use *use*

Specifies the usage of the shapes in this pattern.

Valid values are

- **area_fill**
  A fill shape that does not require optical proximity correction (OPC). Fill shapes are created inside the top level **fill_cell** for the design, unless a **fill_cell** is specified using **-fill_cell** option.
- **core_wire**
  A shape that connects the endpoints of a follow-pin to its target.
- **detail_route**
  A shape used for detail routed signal nets.
- **follow_pin**
  A shape that connects a standard cell to a power structure.
- **global_route**

A shape used for global routed signal nets.

- **lib_cell_pin_connect**
  A shape that connects to a pin of a standard cell.
- **macro_pin_connect**
  A shape that connects to a pin of an I/O pad cell or macro cell.
- **opc**
  A fill shape that requires optical proximity correction (OPC).
- **pg_augmentation**
  A shape added post route to the power and ground structures.
- **ring**
  A shape that belongs to a power ring.
- **shield_route**
  A shape used for shielding route shapes.
- **stripe** (the default)
  A shape that belongs to a power strap.
- **user_route**
  A shape used for user-entered route shapes.
- **zero_skew**
  A shape used for zero-skew route shapes.

This option is valid only for shape_patterns with shape_pattern_type "rect_pattern", "polygon_pattern" or "path_pattern".

-base_boundary *list_of_points*

Specifies the boundary of a rectangle, polygon or path type base shape. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons may also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This option is required for rectangle and polygon shapes.

-base_path {{*x y*} {*x y*} ...}

Specifies the centerline points of a path type base shape. You must specify at least two points.

If you use this option with other shape types, the tool issues an error.

-base_width *width*

Specifies the width of a path type base shape. The value must be non-negative.

If you use this option with other shape types, the tool issues an error.

-base_start_endcap *endcap*

Specifies the type of the start endcap of a path type base shape.

The valid values are

- **flush** (the default)
  Creates an endcap with square ends and no extension.
- **full_width**
  Creates an endcap with square ends that is extended by the path width.
- **half_width**
  Creates an endcap with square ends that is extended by half the path width.
- **octagon**
  Creates an endcap with octagonal ends and no extension.
- **variable**
  Creates an endcap with square ends that is extended by the value specified in the **-base_start_extension** option. When you specify this setting, the **-base_start_extension** option is required.

This option is valid only for path shapes; the tool issues an error if you use it for other shape types.

-base_end_endcap ***endcap***

Specifies the type of the end endcap of a path type base shape.

The valid values are

- **flush** (the default)
  Creates an endcap with square ends and no extension.
- **full_width**
  Creates an endcap with square ends that is extended by the path width.
- **half_width**
  Creates an endcap with square ends that is extended by half the path width.
- **octagon**
  Creates an endcap with octagonal ends and no extension.
- **variable**
  Creates an endcap with square ends that is extended by the value specified in the **-base_start_extension** option. When you specify this setting, the **-base_start_extension** option is required.

This option is valid only for path shapes; the tool issues an error if you use it for other shape types.

-base_start_extension ***extension***

Specifies the start extension of a path type base shape with variable endcaps. The value must be non-negative.

This option is required when you use the **-base_start_endcap variable** option. If you use this option with other shape types, the tool issues an error.

-base_end_extension ***extension***

Specifies the end extension of a path type base shape with variable endcaps. The value must be non-negative.

This option is required when you use the **-base_end_endcap variable** option. If you use this option with other shape types, the tool issues an error.

-m_dimension ***dimension***

Specifies the number of repetitions in first dimension. The value must be greater than zero. If this option is not specified, the default value is 1.

At least one of *-m_dimension* or *-n_dimension* option must be specified with value greater than 1 to have multiple shapes in the repetition.

-n_dimension *dimension*

Specifies the number of repetitions in second dimension. The value must be greater than zero. If this option is not specified, the default value is 1.

At least one of *-m_dimension* or *-n_dimension* option must be specified with value greater than 1 to have multiple shapes in the repetition.

-m_displacement *delta*

Specifies the uniform offset in first dimension.

This option cannot be specified when *m_dimension* is 1.

This option is mutually exclusive with *-displacements* option. At least one of *-m_displacement*, *-n_displacement* or *-displacements* option must be specified, but all these options cannot be specified together.

-n_displacement *delta*

Specifies the uniform offset in second dimension.

This option cannot be specified when *n_dimension* is 1.

This option is mutually exclusive with *-displacements* option. At least one of *-m_displacement*, *-n_displacement* or *-displacements* option must be specified, but all these options cannot be specified together.

-displacements *delta_list*

Specifies the list of arbitrary offsets for a single dimension.

This option is mutually exclusive with *-m_displacement* and *-n_displacement* options. At least one of *-m_displacement*, *-n_displacement* or *-displacements* option must be specified, but all these options cannot be specified together.

Exactly {m_dimension - 1} or {n_dimension - 1} offsets must be specified for the single dimension {M x 1} or {1 x N} shape_pattern.

-grid_size *gridSize*

Specifies the offset multiplier. The value must be greater than zero. If this option is not specified, the default value is 1.

-occupancy_pattern *occupancy_pattern*

Specifies the occupancy matrix of the shape_pattern. The occupancy_pattern defines a MxN bit pattern of base shape existence. If the occupancy_pattern is smaller than the shape_pattern size, it is replicated in the mDimension-major order. Excess bits in the occupancy_pattern are ignored. The occupancy_pattern is formatted as a space delimited string of equal length substrings (e.g., "1010 0101 1011" is a 3x4 pattern). Each substring must consist of only 1s and 0s, representing a mDimension in the MxN shape_pattern, starting with the first mDimension in the shape_pattern. A 1 means the base-shape is included. A 0 means the base-shape is omitted. If not specified, all the base-shapes are included.

-mask_pattern *mask_pattern*

Specifies the mask-pattern. If the specified value is any one of *alternating*, *alternate_n_dimensions* or *alternate_m_dimensions* then the *-alternating_mask_constraints* option must be specified.

-uniform_mask_constraint *uniform_mask*

Specifies the uniform mask and mask-fixed to use for uniform mask-pattern.

This option is mutually exclusive with *-alternating_mask_constraints* option.

This option may be used when the -mask_pattern option is specified as *uniform*. The default uniform mask is mask_none and it is not fixed.

-alternating_mask_constraints *mask_list*

Specifies the mDimension-major ordered list of masks to use for *alternating*, *alternate_n_dimensions* or *alternate_m_dimensions* mask-pattern.

This option is mutually exclusive with *-uniform_mask_constraint* option.

This option is required when any one of *alternating*, *alternate_n_dimensions* or *alternate_m_dimensions* is specified as the *-mask_pattern* option.

-is_uniform_mask_fixed *true* | *false*

Specifies the uniform mask-fixed to use for all shapes in this shape_pattern.

This option is mutually exclusive with *-uniform_mask_constraint* option.

The default uniform mask is not fixed.

DESCRIPTION

This command creates a new shape_pattern with rectangle, polygon or path type base shape and returns a collection that contains the new shape_pattern.

For a shape_pattern, you must specify the layer (**-layer**) and ownership (**-net**) to a power/ground net.

For rectangle type base shape (**-shape_pattern_type rect_pattern**) and polygon type base shape (**-shape_pattern_type polygon_pattern**), you must specify the boundary (**-base_boundary**). You can also specify the use (**-shape_use**) for the shapes of this shape_pattern.

For path type base shape (**-shape_type path_pattern**), you must specify either combination of path (**-base_path**) and width (**-base_width**) or boundary (**-base_boundary**) with points that form rectangle. You can also specify the use (**-shape_use**), start endcap (**-base_start_endcap**), and end endcap (**-base_end_endcap**) for the shapes of this shape_pattern. If you specify the **-base_start_endcap variable** option, you must also specify the **-base_start_extension** option. If you specify the **-base_end_endcap variable** option, you must also specify the **-base_end_extension** option.

EXAMPLES

The following example creates a 5x4 shape_pattern to repeat the base rectangle {{0 0} {100 100}} on PG net named VDD, but omits the rectanges on the third nDimension of each mDimension.

```
prompt> create_shape_pattern \
        -shape_pattern_type rect_pattern -layer METAL1 \
        -base_boundary {{0 0} {100 100}} -net VDD \
        -m_dimension 5 -n_dimension 4 \
        -m_displacement 150:east -n_displacement 250:north \
        -occupancy_pattern "1101" \
        -mask_pattern alternate_m_dimensions \
        -alternating_mask_constraints \
                {mask_two mask_one mask_three}
```

The following example creates a 3x1 shape_pattern to repeat the base polygon {{0 0} {0 100} {50 100} {50 0}} on PG net named VDD.

```
prompt> create_shape_pattern \
        -shape_pattern_type polygon_pattern -layer METAL1 \
        -base_boundary {{0 0} {0 100} {50 100} {50 0}} \
        -net VDD -m_dimension 3 \
        -displacements {{200:east 300:north} 200:east} \
        -mask_pattern alternating \
        -alternating_mask_constraints \
                {mask_one mask_three mask_two}
```

SEE ALSO

remove_shape_patterns(2)

create_shaping_blockage

Creates a new shaping blockage.

SYNTAX

collection **create_shaping_blockage**
-boundary { { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } } |
geometric_objects
[-purpose user | system]
[-name *blockage_name*]
[-cell *cell*]

Data Types

llx	float
lly	float
urx	float
ury	float
x	float
y	float
blockage_name	string
cell	string or collection

ARGUMENTS

-boundary { {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} {*x y*} {*x y*}...} } | geometric_objects

Specifies the boundary coordinates of the shaping blockage. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates, for example, {*llx lly*} {*urx ury*}. A polygon is specified by its points, for example, {*x y*} {*x y*} {*x y*} {*x y*}, and so on.

Polygons may also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This is a required option.

-purpose user | system

Specifies the purpose of the blockage to be created.

Valid values are:

- **user** This should be used by all user-created blockages and ensures that any automated tools will not remove the blockage. This is the default.
- **system** A system blockage can be removed by tools that create and manipulate blockages. You should only create a blockage with this purpose when it may be removed by an automatic tool.

-name *blockage_name*

Specifies the optional name of the blockage. If you specify a name for the blockage, you can get the blockage by the name later in the flow.

-cell *cell*

Specifies the physical cell where the shaping blockage is to be added. The shaping blockage is created in the reference block for the cell by using the coordinate system of the cell argument's top block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, shaping blockages may be created in library cells. When not specified, the shaping blockage is created in the current block.

DESCRIPTION

The **create_shaping_blockage** command creates a shaping blockage. This blockage directs the block shaping commands to avoid areas covered by the blockage.

You can create either rectangular shaping blockages or rectilinear shaping blockages by using the **-boundary** option.

When the tool creates shaping blockages, it automatically assigns a name of SB_*object_id* to each shaping blockage.

EXAMPLES

The following example creates a rectangular shaping blockage with its lower-left corner at (0,0) and its upper-right corner at (100,100).

```
prompt> create_shaping_blockage -boundary {{0 0} {100 100}}
{SB_29440}
```

The following example creates a rectilinear shaping blockage with boundary points at (0,0), (50,0), (50,50), (100,50), (100,100), and (0,100).

```
prompt> create_shaping_blockage \
  -boundary {{0 0} {50 0} {50 50} {100 50} {100 100} {0 100}}
{SB_29696}
```

SEE ALSO

get_shaping_blockages(2)

create_shaping_channel

Creates a single channel in the current block.

SYNTAX

channel **create_shaping_channel**
[-left_min *distance*]
[-left_max *distance*]
[-bottom_min *distance*]
[-bottom_max *distance*]
[-right_min *distance*]
[-right_max *distance*]
[-top_min *distance*]
[-top_max *distance*]
[-neighbor *object*]

Data Types

distance float
object string or collection

ARGUMENTS

-left_min *distance*

Specifies the minimum channel spacing along the left side of an object.

-left_max *distance*

Specifies the maximum channel spacing along the left side of an object.

-bottom_min *distance*

Specifies the minimum channel spacing along the bottom of an object.

-bottom_max *distance*

Specifies the maximum channel spacing along the bottom of an object.

-right_min *distance*

Specifies the minimum channel spacing along the right side of an object.

-right_max *distance*

Specifies the maximum channel spacing along the right side of an object.

-top_min ***distance***

Specifies the minimum channel spacing along the top of an object.

-top_max ***distance***

Specifies the maximum channel spacing along the top of an object.

-neighbor ***object***

Specifies a shapeable object relative to which the given channel spacing applies.

DESCRIPTION

The command creates a single channel object in the current block with the specified channel spacing. A channel object must have at least one valid spacing value, so you must specify at least one of the **-left_min**, **-left_max**, **-bottom_min**, **-bottom_max**, **-right_min**, **-right_max**, **-top_min**, or **-top_max** options.

Any number of generic and neighbor channel objects may exist, so this command always creates a new channel object in the block (until the channel capacity in the block is reached).

When you create a neighbor channel by using the **-neighbor** option, you assign the channel constraint to an object by specifying the **create_shaping_constraint -neighbor_channel** command. Channels created without the **-neighbor** option are assigned to an object by specifying the **create_shaping_constraint** command without the **-neighbor_channel** option.

EXAMPLES

The following command creates a generic channel object.

```
prompt> create_shaping_channel -left_max 4
```

The following command creates a neighbor channel object.

```
prompt> create_shaping_channel -top_min 2 -top_max 4 -neighbor my_neighbor
```

The following example creates channel constraints for a boundary channel and a neighbor channel. The boundary channel has a minimum width of 50 microns. The **create_shaping_constraint -boundary_channel** command applies this constraint to the TOP block. The neighbor channel has a minimum width of 200 microns and a maximum width of 250 microns on the top, bottom, left, and right sides of block u3. The **create_shaping_constraint -neighbor_channel** command is used to apply this constraint to the u1 block; any other blocks do not honor this constraint.

```
prompt> set boundary_channel_50_100 \
      [create_shaping_channel -left_min 50 -right_min 50 \
                  -top_min 50 -bottom_min 50]
prompt> create_shaping_constraint [get_block TOP] -type boundary_channel \
  -object_channel $boundary_channel_50_100

prompt> set neighbor_channel [create_shaping_channel -left_min 200 -left_max 250 \
  -right_min 200 -right_max 250 -top_min 200 -top_max 250 \
  -bottom_min 200 -bottom_max 250 -neighbor [get_cells u3]]
prompt> create_shaping_constraint [get_cells {u1}] \
  -type external_channels -neighbor_channel $neighbor_channel
```

get_shaping_channels(2)
channel(3)

create_shaping_constraint

Creates a single shaping_constraint object of a given type.

SYNTAX

shaping_constraint **create_shaping_constraints**
-type *type*
[-object_channel *channel*]
[-neighbor_channels *channels*]
[-relative_x *coord*]
[-relative_y *coord*]
[-min_ratio *ratio*]
[-target_ratio *ratio*]
[-max_ratio *ratio*]
[-min_util *util*]
[-target_util *util*]
[-max_util *util*]
[-min_area *area*]
[-target_area *area*]
[-max_area *area*]
[-reference_object *object*]
[-array_layout north | east | south | west]
[-allowable_orientation set of R0, R180, MX, MY]
[-is_rigid_boundary false | true]
object

Data Types

type string
channel collection
channels collection
coord float
ratio float
util float
area float
object collection

ARGUMENTS

-type *type*

Specifies the type of shaping_constraint object to create. Valid values are **external_channels**, **child_default_channels**, **boundary_channels**, **target_location**, **reference_region**, **alignment_point**, **parent_object**, **aspect_ratio**, **boundary_area**, **child_default_utilization**, **utilization**, **array_layout**, **allowable_orientation**, and **is_rigid_boundary**.

-object_channel *channel*

Specifies the channel object to assign as the generic object channel for channels of type boundary_channels, child_default_channels, and external_channels.

-neighbor_channels *channels*

Specifies the set of channel objects to assign as the neighbor channels for channel valued constraints.

-relative_x *coord*

Specifies the x-coordinate for relative location constraints. Relative location constraints use a float valued pair with values between 0 and 1 to describe a position with the bounding box of a given object. A relative location of {0 0} corresponds to the lower-left bounding box corner, and a relative location of {1 1} corresponds to the upper-right bounding box corner.

-relative_y *coord*

Specifies the y-coordinate for relative location constraints. Relative location constraints use a float valued pair with values between 0 and 1 to describe a position with the bounding box of a given object. A relative location of {0 0} corresponds to the lower-left bounding box corner, and a relative location of {1 1} corresponds to the upper-right bounding box corner.

-min_ratio *ratio*

Specifies the desired minimum value for aspect ratio shaping constraints.

-target_ratio *ratio*

Specifies the desired target value for aspect ratio shaping constraints.

-max_ratio *ratio*

Specifies the desired maximum value for aspect ratio shaping constraints.

-min_util *util*

Specifies the desired minimum value for utilization constraints.

-target_util *util*

Specifies the desired target value for utilization constraints.

-max_util *util*

Specifies the desired maximum value for utilization constraints.

-min_area *area*

Specifies the desired minimum value for area constraints.

-target_area *area*

Specifies the desired target value for area constraints.

-max_area *area*

Specifies the desired maximum value for area constraints.

-reference_object *object*

Specifies one of a voltage area, move bound, shaping group, or block for object valued constraints.

-array_layout north | **east** | **south** | **west**

Specifies the layout direction of objects within the constrained object's boundary.

- north : Objects are arranged from bottom to top
- east : Objects are arranged from left to right
- south : Objects are arranged from top to bottom
- west : Objects are arranged from right to left

-allowable_orientation set of R0, R180, MX, MY

Specifies the allowed orientations of the constrained object. The constraint can be any subset of the orientation values R0, R180, MX, and MY.

-is_rigid_boundary false | true

Specifies the rigidity of the constrained object's boundary. The boundary_status of a constrained object derives from this value as well as the object's physical status.

object

The object for which to create the shaping constraint.

DESCRIPTION

The **create_shaping_constraint** command creates a single shaping constraint of a given type for a given constrainable object. A constrainable object can be a voltage area, move bound, cell, shaping group, or block. Each constrainable object has a certain subset of shaping constraint types that apply to it. For each applicable type, exactly one shaping_constraint object of that type can exist for the given object. Therefore, the **create_shaping_constraint** command either creates a new constraint if one did not previously exist or replaces an existing constraint of the same type.

Each shaping constraint type has a different data value, so the option chosen for the **-type** argument impacts which other arguments are necessary and valid. For example, the parent_object type is object valued, and thus specifying **-type parent_object** requires that you also provide a **-reference_object** argument and restricts you from giving any other data arguments. A complete list of which data arguments are valid for which types is given below. The types are grouped by data value.

Type	Valid options for this type
allowable_orientation	-allowable_orientation
alignment_point target_location	-relative_x, -relative_y
array_layout	-array_layout
aspect_ratio	-min_ratio, -target_ratio, -max_ratio
child_default_utilization utilization	-min_util, -target_util, -max_util
boundary_area	-min_area, -target_area, -max_area
boundary_channels	-object_channel
child_default_channels	-object_channel, -neighbor_channels

external_channels

is_rigid_boundary -is_rigid_boundary

parent_object -reference_object
reference_region

EXAMPLES

The following command creates an alignment_point shaping constraint that applies to a move bound.

```
prompt> create_shaping_constraint -type alignment_point \
  -relative_x 0 -relative_y 0 my_move_bound
```

The following example creates a block shaping constraint. Cells u1, u2, u3, u4, and u5 are grouped into the LEFT_COLUMN group, arranged into a column and placed from bottom to top. Cells u6, u7, u8, u9, and u10 are grouped into the RIGHT_COLUMN group, arranged into a column and placed from top to bottom. The two groups are placed side-by-side with the LEFT_COLUMN group on the left and the RIGHT_COLUMN group on the right.

```
prompt> create_group -name LEFT_COLUMN -shaping [get_cells {u1 u2 u3 u4 u5}]
prompt> create_group -name RIGHT_COLUMN -shaping [get_cells {u6 u7 u8 u9 u10}]
prompt> create_group -name LEFT_AND_RIGHT \
  -shaping [get_groups -shaping {LEFT_COLUMN RIGHT_COLUMN}]
prompt> create_shaping_constraint [get_groups -shaping LEFT_COLUMN] \
  -type array_layout -array_layout north
prompt> create_shaping_constraint [get_groups -shaping RIGHT_COLUMN] \
  -type array_layout -array_layout south
prompt> create_shaping_constraint [get_groups -shaping LEFT_AND_RIGHT ] \
  -type array_layout -array_layout east
prompt> shape_blocks
```

[-coaxial_above_user_spacing *spacing*]]]
[-pg_via_tie_effort_level low | medium | high]
[-shield_via_tie_effort_level low | medium | high]
[-include_adjacent_layers true | false]

Data Types

net_name string
collection_of_nets collection
number_of_tracks int
layer_name_and_number_of_tracks_pairs list

ARGUMENTS

-shielding_mode new | unshield | reshield

Controls which action to perform during automatic shielding.

The definition for each mode is

- **new** (default)
  Creates new shielding for unshielded nets. If a net is previously shielded, even partially, no new shielding is created for that net.
- **unshield**
  Removes existing shielding wires that are associated with shielded nets. All tie-off connections from deleted shielding to the

power and ground network are also deleted to prevent dangling power or ground (PG) nets. The remaining shielding is reconnected to the power and ground network, if needed.

This command can remove only those shielding wires that were created by using the **create_shields** command. Shielding wires created by other means, such as a third-party tool, might not have full association information and must be removed by using the **remove_routes -shield_route** command.

If the tool cannot find any shielding wires associated with shielded nets, no action is performed.

In unshield mode, only the **-nets** option is considered; all other options are ignored.

- **reshield**
  Creates new shielding after unshielding the nets. The shielding is first removed by using the process described for the **unshield** mode. After moving any existing shielding, new shielding is added for the specified nets that do not have shielding.

  Options which used to create shielding will be automatically stored during shield creation and used during reshielding.

  If the design does not contain existing shielding, it is more efficient to use new mode, rather than reshield mode, because in reshield mode the tool first checks for existing shielding and then creates new shielding.

-nets ***collection_of_nets***

Specifies the nets to be shielded, unshielded, or reshielded, depending on the specified mode.

When creating shielding, if the specified nets do not have shielding rules defined, the tool uses the default width and minimum spacing for the layer as defined in the technology file.

By default, this command works on all nets with defined shielding rules. To define the shielding rules, use the **create_routing_rule** and **set_routing_rule** commands.

-with_ground ***net_name***

Specifies which power or ground net to tie the shielding wires to.

By default, the shielding wires are tied to the ground net. If the design contains multiple ground nets, you must use this option to specify the ground net.

-preferred_direction_only true | false

Controls whether the shielding wires are created in the preferred layer direction only.

By default (false), this command creates shielding wires in both preferred and nonpreferred directions, which surround the shielded routing shape.

If this option is true and the shielding wires are created only in the preferred layer direction, the shielding wires might not be connected to each other, in which case more effort is needed to connect these shielding wires to the power and ground nets. Any shielding wires that are not connected to a power or ground net (floating shielding) are deleted. Note that for shielding wires, router does not honor route guides to switch the preferred layer direction.

-align_to_shape_end true | false

Controls whether the shielding wires are aligned to the shielded routing wire ends.

By default (false), this command creates shielding wires that surround the shielded routing shape.

If this option is true, the shielding wires are cut at the shielded wire end points, which might create shielding wires that are not connected to each other, in which case more effort is needed to connect these shielding wires to the power and ground nets. Any shielding wires that are not connected to a power or ground net (floating shielding) are deleted.

-ignore_shielding_net_pins true | false

Controls whether the shielding wires are connected to the standard cell power or ground (PG) pins.

By default (false), this command connects the shielding wires to the standard cell PG pins.

-ignore_shielding_net_rails true | **false**

Controls whether the shielding wires are connected to the standard cell rails.

By default (false), this command connects the shielding wires to the standard cell rails.

-coaxial_skip_tracks_on_layers {*layer_name_and_number_of_tracks_pairs*}

Controls the metal layers on which to perform coaxial shielding for shielded nets and the number of tracks left open between coaxial shielding segments on the specified layers.

You specify the metal layers by using the layer name from the technology file. The number of tracks is an integer value between -1 and 7 that specifies the number of tracks to leave open between coaxial shielding segments.

If the number of tracks is -1 for a layer (the default), this command does not create coaxial shielding on that layer. Otherwise, it skips the specified number of tracks between coaxial shielding segements on that layer.

You cannot combine this option with the non-layer-based method for specifying coaxial shielding (the **-coaxial_below**, **-coaxial_above**, **-coaxial_below_skip_tracks**, **-coaxial_above_skip_tracks**, **-coaxial_below_user_spacing**, and **-coaxial_above_user_spacing** options).

-coaxial_below true | **false**

Controls whether coaxial shielding is created below the shielded net segment layer.

By default (false), this command does not perform coaxial shielding below the shielded net segment layer.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** option).

-coaxial_above true | **false**

Controls whether coaxial shielding is created above the shielded net segment layer.

By default (false), this command does not perform coaxial shielding above the shielded net segment layer.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** option).

-coaxial_below_skip_tracks *number_of_tracks*

Controls the number of tracks to be left open between coaxial shielding segments created below the shielded net segment layer.

You can specify an integer value between 0 and 7. The default is 1, which spaces the coaxial shielding segments such that they leave at least one signal routing resource on the layer. To disallow signal routing below the shielded net segment layer, specify 0.

This option is used only when **-coaxial_below** is true.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** and **-coaxial_below_user_spacing** options).

-coaxial_above_skip_tracks *number_of_tracks*

Controls the number of tracks to be left open between coaxial shielding segments created above the shielded net segment layer.

You can specify an integer value between 0 and 7. The default is 1, which spaces the coaxial shielding segments such that they leave at least one signal routing resource on the layer. To disallow signal routing above the shielded net segment layer, specify

0.

This option is used only when **-coaxial_above** is true.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** and **-coaxial_above_user_spacing** options).

-coaxial_below_user_spacing ***spacing***

Controls the spacing between coaxial shielding segments created below the shielded net segment layer.

This option is used only when **-coaxial_below** is true. This option doesn't support incremental shielding, this setting will be ignored during incremental shielding.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** and **coaxial_below_skip_tracks** options).

-coaxial_above_user_spacing ***spacing***

Controls the spacing between coaxial shielding segments created above the shielded net segment layer.

This option is used only when **-coaxial_above** is true. This option doesn't support incremental shielding, this setting will be ignored during incremental shielding.

You cannot combine this option with the layer-based method for specifying coaxial shielding (the **-coaxial_skip_tracks_on_layers** and **coaxial_above_skip_tracks** options).

-include_adjacent_layers true | **false**

Controls whether the shielding wires are created on adjacent (above and below) layers of the shielded net segment layer. This command creates shielding wires with the same preferred direction as the shielded net segments, therefore, the created shielding wires may be in non-preferred layer direction.

By default (false), this command creates same-layer shielding only and does not create shielding wires on adjacent (above and below) layers of the shielded net segment layer.

This option doesn't support incremental shielding, this setting will be ignored during incremental shielding.

-pg_via_tie_effort_level low | **medium** | **high**

Specifies the effort level used to tie the shielding wires to the power and ground network with vias. This option affects the via connections from the shielding wires to PG pins and wires (straps, rails, and rings) that cross shielding wires on adjacent layers.

Valid values for this option are:

- **low**
  Creates a single via or via array connection regardless of the number of intersections between the shielding structure and a PG net on an adjacent layer. Use low effort to speed up the command.
- **medium** (default)
  Creates a via or via array for each intersection between an unconnected wire in the shielding structure and a PG net on an adjacent layer; however, it avoids creating vias or via arrays in the immediate vicinity of already connected shielding wires.
- **high**
  Creates a via or via array connection for each intersection between a shielding wire and a PG net on an adjacent layer. There is a runtime cost associated with using high effort.

-shield_via_tie_effort_level low | **medium** | **high**

Specifies the effort level used to tie the shielding wires to each other with vias. This option affects the via connections between the shielding wires that cross on adjacent layers.

Valid values for this option are:

- **low**
  Does not create via connections between intersecting shielding wires. Use low effort if your design has an enormous number of intersecting shielding wires on adjacent layers, such as when you shield bus nets, which creates a fine grid on adjacent layers. To ensure a high shielding ratio, you should provide a structured power and ground mesh to connect shielding wires to.
- **medium**
  Creates a via or via array connection for each intersection between shielding wires that are associated with the same shielded net.
- **high** (default)
  Creates a via or via array connection for each intersection between shielding wires.

DESCRIPTION

The **create_shields** command shields nets based on the associated shielding rules.

By default, the command performs same-layer shielding on all nets with predefined shielding rules. The router routes shielding wires based on the shielding widths and spacing defined in the shielding rules. The shielding wires are tied to the ground net, standard cell ground pins, and standard cell rails.

To explicitly specify the nets on which to perform shielding, use the **-nets** option. To tie the shielding wires to a named power or ground net, use the **-with_ground** option. To prevent connections to the standard cell PG pins, use the **-ignore_shielding_net_pins** option. To prevent connections to the standard cell rails, use the **-ignore_shielding_net_rails** option.

By default, the command does not perform coaxial shielding. To perform coaxial shielding above the shielded net segment layer, use the **-coaxial_above true** option. To perform coaxial shielding below the shielded net segment layer, use the **-coaxial_below true** option. When the tool performs coaxial shielding, the coaxial shielding segments

- Are routed in the preferred layer direction
- Use the defaultWidth layer attribute from the technology file.
- Are spaced as specified by the **-coaxial_above_skip_tracks** option for coaxial shielding above the shielded net segment layer and as specified by the **-coaxial_below_skip_tracks** option for coaxial shielding below the shielded net segment layer

To remove existing shielding on specified nets, use the **-shielding_mode unshield** option. To remove existing shielding on the whole design, you should use the **remove_routes -shield_route** command.

Prerequisites

Before you run this command, you must first define the shielding rules with the **create_routing_rule** command and assign these rules to the nets to be shielded with the **set_routing_rule** command.

This requirement applies when you do not specify the **-nets** option, you want to use a nondefault width or minimum spacing, you want to snap the shielding segments to the grid, or you want to reserve space for future postroute shielding during signal routing.

Limitations

There might be a discrepancy between DRC violations reported by the **create_shields** and **check_routes** commands. The **create_shields** command works only with shielding shapes and therefore reports only violations for shielding shapes and not for other signal net routing. To get an accurate DRC violations report for all nets, run the **check_routes** command after running the **create_shields** command.

In addition, there might be a slight difference in the shield ratios reported by the **create_shields** and **report_shields** commands. This is due to graph connectivity differences between the two commands. When the reported values differ, use the values reported by the **report_shields** command. The difference in reported values is typically less than three percent, but can be up to five percent.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines the shielding rules; assigns these shielding rules to all clock nets; and then shields the CLK_B1 and CLK_B5 clock nets with the VSS ground net, the CLK_B2 clock net with the GND ground net, and the CLK_B3 and CLK_B4 clock nets with the VDD power net. The shielding wires are not connected to the standard cell PG pins. The CLK_B5 net also has coaxial shielding above and below the shielded net segment layers and no signal routing resources are left between the coaxial shielding segments.

```
prompt> create_routing_rule clock_net_shielding \
  -default_reference_rule -taper_distance 0 -snap_to_track \
  -widths { METAL1 0.16 METAL2 0.2 METAL3 0.2 METAL4 0.2 } \
  -spacings { METAL1 0.18 METAL2 0.21 METAL3 0.21 METAL4 0.21 } \
  -shield_width { METAL1 0.16 METAL2 0.2 METAL3 0.2 METAL4 0.2 } \
  -shield_spacing { METAL1 0.18 METAL2 0.21 METAL3 0.21 METAL4 0.21 } \
  -vias { {via1 1X1 NR} {via2 1X1 NR} {via3 1X1 NR} }

prompt> set clock_nets [get_nets -filter "net_type == Clock" -hier]

prompt> set_routing_rule -rule clock_net_shielding $clock_nets

prompt> create_shields -with_ground VSS -nets {CLK_B1} \
  -ignore_shielding_net_pins true

prompt> create_shields -with_ground GND -nets {CLK_B2} \
  -ignore_shielding_net_pins true

prompt> create_shields -with_ground VDD -nets {CLK_B3 CLK_B4} \
  -ignore_shielding_net_pins true

prompt> create_shields -with_ground VSS -nets {CLK_B5} \
  -coaxial_below true -coaxial_below_skip_tracks 0 \
  -coaxial_above true -coaxial_above_skip_tracks 0 \
  -ignore_shielding_net_pins true
```

The following example adds coaxial shielding for the CLK_B5 net on the M5, M6, and M7 layers. It does not skip tracks on the M5 layer but skips one track on the M6 layer and two tracks on the M7 layer. Other metal layers do not have coaxial shielding.

```
prompt> create_shields -nets {CLK_B5} \
  -coaxial_skip_tracks_on_layers {M5 0 M6 1 M7 2}
```

xy_distance float
site_array string or collection
left float
bottom float

right float
top float
row_cycle_list *collection of integers*
row_offset_list *collection of integers*

ARGUMENTS

-name *site_array_name*

Specifies the name of the site array. If not specified, the tool generates a name for the site array.

-site *site_names*

Specifies the site definitions to use when creating the site array. By default, the default site definition is used if available, otherwise an error is issued. User can specify count after ':' of site_name. This will be useful to create hybrid site-rows i.e. site array with multiple site names.

-boundary {{*llx lly*} {*urx ury*}} | {{*x y*} {*x y*} ...} | *geometric_objects*

Specifies the boundary coordinates of the site array. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates, for example, {*llx lly*} {*urx ury*}. A polygon is specified by its points, for example, {*x y*} {*x y*} {*x y*} {*x y*} and so on.

Polygons can also be specified as the combined area of a mixed collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This option is mutually exclusive with **-voltage_area**.

-voltage_area *voltage_area*

Specifies the name or voltage area object based on whose boundary the site array will be created. The site array is associated with this voltage area and is automatically updated when there are changes to this voltage area boundary. When this voltage area is deleted, then the associated site array are also deleted. This option is mutually exclusive with **-boundary** and **-default**.

-flip_first_row *true* | *false*

Specifies whether the first site row of the site array will be flipped or not. By default, this option is true.

-flip_alternate_row *true* | *false*

Specifies whether alternate site rows of the site array will be flipped or not. Along with **-flip_first_row** this can specify whether even numbered rows are flipped or odd numbered. By default, this option is true.

-transparent true | false

Specifies whether a site array is transparent or opaque. When site arrays are stacked together, this option defines how one site array can affect another. An opaque site array affects the effective site row area for all site arrays that are beneath the opaque site array. By default, this option is false and the site array is opaque. Default site array can't be transparent and this option is ignored for default site array.

-direction horizontal | vertical

Specifies whether a site array is horizontal or vertical. By default, the site array is horizontal.

-x_margin *distance*

Specifies the x-offset between sites within a site row of the site array. By default, the *distance* is zero.

-y_margin *distance_list*

Specifies the y-offset between site rows of the site array. By default, the *distance* is zero. For Hybrid site-rows, specifies the list of y-offset corresponding to site name. If list has less elements as compare to site names then y-offset will be zero for trailing site names and if list has more elements as compare to site names then trailing y-offset will be ignored.

-core_offset *xy_distance* | {*x_distance y_distance*}

Creates an offset to the site grid. Use this option to create offsets from the block origin for aligned site arrays and from the lower left of site array bounding box for unaligned site arrays. The offset values are normalized with respect to site width and height. If one value is specified, the value applies to both x- and y-coordinates of reference point. When two values are specified, the first value is x-coordinate and second is the y-coordinate. By default, the offset values are zero.

-above *site_array*

Places the new site array above *site_array*. This option is mutually exclusive with the **-below**, **-top** and **-bottom** options. By default, the site array is always placed at the top, except for the default site array, which is placed at the bottom.

-below *site_array*

Places the new site array below *site_array*. If the default site array is specified as *site_array*, the new site array will be placed above the default site array. This option is mutually exclusive with **-above**, **-top** and **-bottom**. By default, the site array is always placed at the top, except for the default site array, which is placed at the bottom.

-top

Places the new site array at the top. By default, the site array is always placed at the top, except for the default site array, which will be placed at the bottom. This option is mutually exclusive with **-above**, **-below** and **-bottom**.

-bottom

Places the new site array at the bottom. By default, the site array is always placed at the top, except for the default site array, which will be placed at the bottom. If a default site array already exists, the site array will be placed above the default site array. This option is mutually exclusive with the **-above**, **-below** and **-top** options.

-default

Specifies that the newly created site array will be the default site array. This option is useful when default site array must be created with an input boundary. Use this option to specify if the site array created with input boundary should be default or not. This option is mutually exclusive with **-voltage_area**.

-aligned true | false

Specifies the site array to be aligned or unaligned. By default, this option is true. Default site array can't be unaligned and this option is ignored for default site array.

-inner_margin {*left bottom right top*}

Specifies the inner margin to be applied to shape of site array. This is to shrink the shape of site array for effective region of its site rows. It is helpful to maintain a no site row region for site arrays derived from voltage areas.

-row_cycles *row_cycle_list*

Specifies one or more value of cycle for rows of site-array. Cycle will be assigned to site-rows in order as specifed in command

option. Value of cycle on first site-row will depend upon **-aligned** option.

-row_offsets ***row_offset_list***

Specifies one or more value of offset for rows of site-array. Offset will be assigned to site-rows in order as specified in command option. Value of offset on first site-row will depend upon **-aligned** option.

DESCRIPTION

The **create_site_array** command creates a site array with the specified boundary in the current design. Site arrays can be stacked together and their transparency dictates the effective area available for site row creation for each of the stacked site arrays. Some of the properties, such as flipping first site row or alternate site rows, describes how they are going to appear in the design. The site rows of a site array can be made horizontal or vertical. They have a name and are based on a basic site definition or multiple site definition. In case of multiple site definitions i.e. hybrid site-array, User can give count followed by ':' after site name like {unit1:2 unit2:3}. Count will used to create number of site-rows of corresponding site name before site row creation of next site name.

There can be a default site array inside a block. When no reference boundary, either through **-boundary** or **-voltage_area**, is provided, or a boundary with **-boundary** is provided along with **-default** option, then a default site array is created in the current block. The site array tracks the boundary of the block and is placed at the bottom of the stack as an opaque and aligned site array.

The region for the default site array is calculated by shrinking the block boundary by the block hard keepout margin and inner margin if applicable, and taking the common area with any input boundary provided by the user. If the block boundary changes or the hard keepout margin for the block changes, then the site array also changes accordingly.

The nondefault site array considers block hard keepout margins and inner margins if applicable for its effective site rows calculation. If any part of nondefault site array falls within a hard keepout margin region, that portion is removed from any effective site rows calculation. If the block boundary changes or the hard keepout margin for the block changes, then the nondefault site arrays also change.

A site array can be associated with a voltage area. In this case, the site array tracks the boundary of voltage area and changes according to any changes in the voltage area boundary. Removing such a voltage area will cause removal of the associated site array. Since the voltage area can have multiple regions, this will result in multiple site arrays stacked on top of each other.

The site arrays have two flavors, aligned and unaligned. Aligned site arrays have their site rows aligned to a virtual site grid passing through the block's origin plus any offset specified. The **-flip_first_row** value applies to the first site row starting at block's origin plus any offset specified. As a result, the first site row within the site array might be flipped or not, depending on the location of site array on the virtual site grid. Unaligned site arrays have their site rows directly based on site array boundary starting at lower-left corner of site array bounding box, taking into account any offset specified. So first site row within unaligned site array will be based on **-flip_first_row** value.

Cycle and offset will be assigned to site-rows in same order in which they specified but cycle/offset on first site-row will depend upon **-aligned** option. If **-aligned** is false then first site-row will have first value specified as command option **-row_cycles**/**-row_offsets**.

EXAMPLES

The following example creates an unaligned site array named SA1 with a rectangular boundary. SA1 is opaque with horizontal rows. Odd numbered rows are flipped and are at the top of the stack.

```
prompt> create_site_array -name SA1 -site unit -boundary \
  {{100 100} {200 200}} -aligned false
```

The following example creates an aligned site array named SA2 with its boundary copied from the voltage area DEFAULT_VA. SA2

is opaque with vertical rows. The site array is placed above the existing site array SA1. This may cause the effective area of SA1 to change and therefore change in its site rows, since SA2 is opaque.

```
prompt> create_site_array -name SA2 -site unit -voltage_area DEFAULT_VA \
  -above SA1 -direction vertical
```

The following example creates a default site array named SA1 with its boundary as the boundary of the block shrunk by hard keepout margin. When the block boundary changes, or its hard keepout margin changes, the boundary of SA1 (and therefore its site rows) will also change. SA1 is opaque with horizontal rows and will be at the bottom of the stack.

```
prompt> create_site_array -name SA1 -site unit
```

The following example creates a default site array with a system-generated name with a rectangular boundary. When the block boundary changes, or its hard keepout margin changes, the default site array boundary (and therefore its site rows) might also change depending on input boundary. The default site array is opaque with horizontal rows and will be at the bottom of the stack.

```
prompt> create_site_array -boundary {{100 100} {200 200}} -default
```

The following example creates aligned site array named SA1 with its boundary copied from the voltage area VA1 and has an inner margin. Boundary of VA1 will be shrunk by specified inner margin. SA1 is opaque with vertical rows.

```
prompt> set voltage_area VA1
prompt> create_site_array -name SA1 -site unit -voltage_area $voltage_area \
  -inner_margin {10 20 10 20}
```

The following example creates an site array named SA1 with a rectangular boundary. SA1 will have 3 site-rows of site name 'unit' followed by 2 site-rows of site name 'punit'. Similar pattern will follow after that. y-offset between site-rows of site name 'unit' will be 0.5 and y-offset between site-rows of site name 'punit' will be 1.

```
prompt> create_site_array -name SA1 -site {unit:3 punit:2} -boundary \
  {{100 100} {200 200}} -y_margin {0.5 1}
```

SEE ALSO

get_site_arrays(2)
remove_site_arrays(2)

create_site_def

Creates a site def using the technology of the current or the specified library.

SYNTAX

collection **create_site_def**
-name *site_def_name*
-height *distance*
-width *distance*
[-is_default]
[-library *library*]
[-tech *tech_object*]
[-type *type*]
[-symmetry *symmetry*]

Data Types

site_def_name string
distance float
library collection
tech_object collection
type string
symmetry string

ARGUMENTS

-name *site_def_name*

Specifies the name of the site_def to be created.

-height *distance*

Specifies the height of the site_def to be created.

-width *distance*

Specifies the width of the site_def to be created.

-is_default

Specifies the site definition as default. Creates a default site_def for the specified tech unless the default already exists. Results in error and returns NULL if the default site_def of the specified tech already exists.

-library *library*

Site definition will be created in the technology of this library. Default is current library's tech. This is mutually exclusive with **-tech**

option.

-tech ***tech_object***

Site definition will be created in this technology. Default is current library's tech. This is mutually exclusive with **-library** option.

-type ***type***

Specifies the type of the site definition as core/pad. Default is core.

-symmetry ***symmetry***

Specifies if the site definition is symmetrical about X and/or Y and/or 90 degree rotation. By default there is no symmetry.

Valid symmetry is a set or combination of the following values

- **X** (symmetrical about the X-axis)
- **Y** (symmetrical about the Y-axis)
- **R90** (symmetrical for 90 degrees rotation)

DESCRIPTION

The **create_site_def** command enables you to create a site def in the tech of the current or specified library. A tech can have at-most one default site definition. The use of "-is_default" option would result in error if the tech already has a default site definition.

EXAMPLES

The following example creates a core type site def named 'SD1' with height 0.15 and width 0.25 in the tech of current library. SD1 will be symmetrical about both horizontal and vertical axes.

```
prompt> create_site_def -name SD1 -height 0.15 -width 0.25 \
  -symmetry { X Y }
```

The following example creates a pad type site def named 'SD2' with height 1.5 and width 0.15 in the tech of library r4000. SD1 will be symmetrical about X and Y and 90 degree rotation.

```
prompt> create_site_def -library r4000 -name SD2 -height 1.5 \
  -width 0.15 -type pad -symmetry { X Y R90 }
```

create_site_row

Creates a site row in the current design.

SYNTAX

collection **create_site_row**
-name *site_row_name*
-site *site_name*
-origin {*x y*}
-site_count *count*
[-orientation *orientation*]
[-site_orientation *orientation*]
[-x_margin *distance*]

Data Types

site_row_name string
site_name string
x y point
count int
orientation string
distance float

ARGUMENTS

-name *site_row_name*

Specifies the name of the site row.

-site *site_name*

Specifies the name of the site based on which the site row will be created.

-origin {*x y*}

Creates a site row at the specified x- and y-coordinate. The coordinate is relative to the die origin.

-site_count *count*

Specifies the number of sites to be put in the site row. This determines the bbox of the site row and core area of the block.

-orientation *orientation*

Specifies the orientation of a site row. The default orientation is R0.

Valid values are

- **MX** (mirror around the x-axis)
- **MXR90** (mirror around the x-axis and rotate 90 degrees)
- **MY** (mirror around the y-axis)
- **MYR90** (mirror around the y-axis and rotate 90 degrees)
- **R0** (no rotation, which is the default)
- **R90** (rotate 90 degrees)
- **R180** (rotate 180 degrees)
- **R270** (rotate 270 degrees)

-site_orientation *orientation*

Specifies the orientation of sites within a site row. The orientation is relative to the orientation for the site row. By default, the orientation is R0.

Valid values are

- **MX** (mirror around the x-axis)
- **MXR90** (mirror around the x-axis and rotate 90 degrees)
- **MY** (mirror around the y-axis)
- **MYR90** (mirror around the y-axis and rotate 90 degrees)
- **R0** (no rotation, which is the default)
- **R90** (rotate 90 degrees)
- **R180** (rotate 180 degrees)
- **R270** (rotate 270 degrees)

-x_margin *distance*

Specifies the x-offset between sites within a site row. By default, the offset is zero.

DESCRIPTION

The **create_site_row** command creates a site row in the current design, at the specified origin with specified number of sites. The site rows have a name and are based on a basic site definition. The number of sites determine the bounding box of a site row and the core area of the block. The created site row cannot overlap any existing site arrays.

EXAMPLES

The following example creates a site row named SR1 with 1000 sites at location 0,100. SR1 will be horizontal with horizontal sites in it.

```
prompt> create_site_row -name SR1 -site unit -origin \
  {0 100} -site_count 1000
```

The following example creates a site row named SR1 with 1000 sites at location 0,100. SR1 will be vertical with relative horizontal sites in it.

```
prompt> create_site_row -name SR1 -site unit -origin \
  {0 100} -site_count 1000 -orientation R90
```

SEE ALSO

get_site_rows(2)

create_stdcell_fillers

Fills empty spaces in standard cell rows with filler cells.

SYNTAX

status **create_stdcell_fillers**
-lib_cells *lib_cells*
[-one_fin_lib_cells *lib_cells*]
[-post_eco]
[-ignore_hard_blockages]
[-prefix *prefix*]
[-bboxes *rectangle*]
[-voltage_area *voltage_areas*]
[-rules *rule_list*]
[-continue_on_error]
[-utilization *float_value*]
[-smallest_cell_size *int_value*]
[-type_utilization *lib_cells_utilization_pairs*]
[-fill_remaining]
[-leakage_vt_order *vt_layer_list*]
[-leakage_vt_check]
[-flip]
[-prefer_type_ordering]

Data Types

lib_cells	collection
prefix	string
rectangle	rectangle
voltage_areas	collection
rule_list	list
float_value	float
int_value	int
lib_cells_utilization_pairs	list
vt_layer_list	list

ARGUMENTS

-lib_cells *lib_cells*

Specifies the filler cells to use.

By default, the tool adds the filler cells in the order that you specify. For best results, specify the cells from largest to smallest; this is a requirement when the no_1x rule or advanced rules are used.

-one_fin_lib_cells *lib_cells*

Specifies the one-fin filler cells to use. The specified cells must not exist in the list specified by the **-lib_cells** option.

The command minimizes the usage of one-fin filler cells; these cells are used only when none of the filler cells specified in the **-lib_cells** option can be legally inserted.

This option applies only when the advanced legalizer is enabled by setting the **place.legalize.enable_advanced_legalizer** application option to **true**.

-post_eco

Marks new filler cells so the **remove_stdcell_fillers_with_violation** command can identify them in the post-ECO flow.

-ignore_hard_blockages

Creates filler cells in areas that have hard placement blockages.

-prefix *prefix*

Adds the specified prefix to the instance names of the filler cells inserted by this command. You can later use the prefix to identify the filler cell instances.

-bboxes *rectangle*

Specifies the rectangular region (in microns) in which to insert filler cells. To specify the rectangular region, use the following syntax to specify the coordinates of the lower-left and upper-right corners of the region:

{ {*llx lly*} {*urx ury*} }

By default, filler cells are inserted throughout the entire chip.

-voltage_area *voltage_areas*

Specifies the voltage areas in which to insert filler cells.

By default, the tool inserts filler cells in all voltage areas.

-rules *rule_list*

Specifies the special rules to follow during filler cell insertion.

You can specify one or more of the following keywords:

- **no_1x**
  Prevents the command from placing filler cells such that it would leave a 1x gap.
- **color_safe**
  Ensures color correctness for multiple-patterning designs. This rule applies only when color-aware placement is enabled by setting the **place.legalize.enable_color_aware_placement** application option to **true**.
- **check_pnet**
  Enables power net checking for the filler cells. By default, power net checking is disabled to save runtime.

-continue_on_error

Skips unfillable cell locations and continues to the next gap.

This option applies only when advanced rules are used. Use this option only when the list of filler cells specified by the **-lib_cells** option does not have all the necessary filler cells to fill all possible gaps. For example, use this option when you are performing decoupling capacitor insertion but do not have smaller decoupling capacitors to fill all possible gaps. In this case, the remaining gaps must be filled during nonmetal filler cell insertion.

When you specify this option, it is assumed that you will fill the remaining cell locations later. The tool avoids trying all possible cell combinations to save runtime and leaves fillable gaps unfilled.

-utilization ***float_value***

Specifies the maximum percentage of free space to fill with filler cells. The default is 100.

-smallest_cell_size ***int_value***

Specifies the smallest cell size for the design, which must be an integer between 1 and 11. The default is 1.

If the design has no 1x cells, use either **-rules {no_1x}** or **-smallest_cell_size 2**. Do not use both.

-type_utilization ***lib_cells_utilization_pairs***

Controls different target area percentages for one or more of the library cells specified in the **-lib_cells** option. Specify the argument as a list of pairs in the following format:

{{*lib_cells*} *utilization* ...}

For example, the following option specifies that total area percentage for the lib_A1 and lib_A2 library cells is 20 percent and the total area percentage for the lib_B1 library cell is 30 percent:

```
-type_utilization { {lib_A1 lib_A2} 20 lib_B1 30 }
```

As with the **-lib_cells** option, the library cells in each pair should be specified in descending order by cell size. You can use the * wildcard character to specify the library cell names. The percentage specification must be greater than 0 and less than or equal to 100. The sum of all the percentages must be less than or equal to 100.

-fill_remaining

Uses the cells specified in the **-lib_cells** option but not in the **-type_utilization** option to fill the design.

When you specify this option, the command fills all empty space. The command fails if you specify this option but all library cells have been specified in the **-type_utilization** option and there are no remaining library cells available to fill the rest of the design.

You can use this option only when the **-type_utilization** option is specified.

-flip

Only works with advanced legalizer. Normally filler insertion will not try flipping when the violation is due to pin color alignement. If you use this option and filler insertion encounter pin color alignment violation, it will try inserting with flipped orientation as well.

-prefer_type_ordering

When this option is specified, it will insert lib cells lists specified in **-type_utilization** one by one from the left to right. User can use this option to improve the real utilization of those lib cells difficult to be inserted due to legalization rule or lib cell size compared with normal type utilization mode. But it may increase the runtime compared with normal type utilization mode. This option must be used together with **-type_utilization** option. Otherwise, it will error out.

This option applies only when the advanced legalizer is enabled by setting the **place.legalize.enable_advanced_legalizer** application option to **true**.

-leakage_vt_order ***vt_layer_list***

Specifies the threshold voltage layers in order of decreasing leakage current. The command uses this information to reduce the leakage current by selecting the filler cells with the lowest leakage current.

The specified threshold voltage layers must include all layers used by the filler cells specified in the **-lib_cells** option.

This option applies only when the advanced legalizer is enabled by setting the **place.legalize.enable_advanced_legalizer** application option to **true**.

-leakage_vt_check

Checks if the current filler cell insertion result has the lowest leakage power when using the filler cells specified in the **-lib_cells** option.

By default, the command reports a maximum of 100 violations. To change the maximum number of reported violations, set the **chf.create_stdcell_fillers.max_leakage_vt_order_violations** application option.

When you use this option, the command ignores the **-bboxes** and **-voltage_areas** options.

You can use this option only when the **-leakage_vt_order** and **-lib_cells** options are specified.

DESCRIPTION

This command fills empty spaces in standard cell rows with instances of reference filler cells from the library. You should perform placement (and clock tree synthesis, if applicable) before adding filler cells.

A typical flow is

1. Use the **create_stdcell_fillers** command to insert decoupling capacitors.
2. Update the PG connections by using the **connect_pg_net -automatic** command.
3. Use the **remove_stdcell_fillers_with_violation** command to remove the decoupling capacitors with violations.
4. Use the **create_stdcell_fillers** command to insert non-metal filler cells.
5. Update the PG connections by using the **connect_pg_net -automatic** command.

After filler cell insertion, use the **check_legality** command to verify the filler cell placement legality.

EXAMPLES

The following example fills empty spaces with filler cells from the mylib reference library named FILL_4X, FILL_2X, and FILL_1X in the specified order. If the sizes of the filler cells are such that FILL_4X > FILL_2X > FILL_1X, this ordering minimizes the number of filler cells added by using the larger filler cells first.

```
prompt> create_stdcell_fillers \
  -lib_cells {mylib/FILL_4X mylib/FILL_2X mylib/FILL_1X}
```

create_stub_chain

Creates a stub chain in the current design.

SYNTAX

collection **create_stub_chain**
-name *name*
[-partition *name*]
[-max_bits *number_of_bitsl*]
[-startpoint *port_or_pin*]
[-endpoint *port_or_pin*]
[-floating_elements *elements_lists*]
[-ordered_elements *elements_lists*]

Data Types

name string
number_of_bits integer
port_or_pin collection
elements_list list

ARGUMENTS

-name *name*

Name of the scan_chain

-partition *name*

Scan partition name

-max_bits *number_of_bits*

Maximum bit length of the stub_chain

-startpoint *port_or_pin*

Starting physical port or pin

-endpoint *port_or_pin*

Ending physical port or pin

-floating_elements *elements_lists*

Floating element lists to add to the new stub_chain. The scan-in and scan-out pin of each triplet must be from the same scan cell. List Format: {{{ scan_in_pin_name scan_out_pin_name bit_length } ... } ... }

-ordered_elements elements_list

Ordered element lists to add to the new stub_chain. The scan-in and scan-out pin of each triplet must be from the same scan cell. List Format: {{{ scan_in_pin_name scan_out_pin_name bit_length } ... } ... }

DESCRIPTION

This command creates a new stub chain and returns a collection containing the new stub chain.

EXAMPLES

The following example creates a stub chain with port1 as the startpoint and port2 as the endpoint.

```
prompt> create_stub_chain -name stub1 -startpoint port1 -endpoint port2
```

The following example creates a stub chain with floating and ordered_elements.

```
prompt> create_stub_chain -name stub2 -floating_elements {{{u1/pin1 u1/pin2 4} {u1/pin3 u1/pin4}} {{u2/pin1 u2/pin2 4}}}
-ordered_elements {{{u3/pin1 u3/pin2 4}}}
```

SEE ALSO

get_stub_chains(2)
remove_stub_chains(2)

create_supernet

Creates a new supernet.

SYNTAX

collection **create_supernet**
pin_or_port
[-design *design*]
[-name *supernet_name*]
[-start *supernet_start_pin_or_port*]
[-stop *supernet_stop_pin_or_port*]

Data Types

pin_or_port collection
design collection
supernet_name string
supernet_start_pin_or_port pin_port_object
supernet_stop_pin_or_port pin_port_object

ARGUMENTS

pin_or_port

Specifies the anchor object for the supernet. It is an error if a supernet already exists on that anchor.

This is a required argument.

-design *design*

Specifies the block in which to create the supernet.

By default, the supernet is created in the current block.

-name *supernet_name*

Specifies the name of the supernet.

By default, the name is the name of the anchor object, possibly with a numerical postfix to make it unique.

-start *supernet_start_pin_or_port*

Specifies the pin or port which is start anchor of the supernet. It is an error if a supernet already exists on start.

This is a required argument if pin_or_port is not specified.

-stop *supernet_stop_pin_or_port*

Specifies the pin or port which is stop anchor of the supernet.

This is a required argument if pin_or_port is not specified and -start is specified.

DESCRIPTION

This command creates a new supernet with the specified name and anchor object. The new supernet is returned as a collection. If -start and -stop is specified then it will create a supernet between start to stop and return an supernet.

start and stop anchor must be on block-boundaries and both in same physical hierarchy only.

This command marks cells and pins as being transparent for supernets from the design.

The set of nets assigned to a particular supernet are automatically derived by transparently tracing in both directions through repeaters (and cells explicitly specified by the user) from the specified anchor point defined for the supernet. In case of supernet created using start and stop, set of nets are nets from start to stop. If no path exists from start to stop then it will not return any get. If multiple paths exists from start to stop then supernet is set of all the nets between start to stop from all paths.

By default tracing will see through repeaters (buffers and inverters only) only. Non-repeater cells can be marked as transparent for supernet tracing using the set_supernet_exceptions command. Also, user can disable certain repeater cells for supernet tracing by marking them non-transparent using set_supernet_exceptions command. These supernet exceptions have to be defined prior to the creation of supernets.

EXAMPLES

The following example creates a supernet on pin instA/01 and names it IF1.

prompt> **create_supernet [get_pins instA/O1] -name IF1**

The following example creates a supernet between i1 to o1 and names it S1.

prompt> **create_supernet -start i1 -stop o1 -name S1**

create_supply_net

Creates a supply net for the specified power domain. The supply net is created in the logic hierarchy at the same scope as the specified power domain.

SYNTAX

string **create_supply_net**
[-domain *domain_name*]
[-reuse]
[-resolve unresolved | parallel | one_hot | parallel_one_hot]
supply_net_name

Data Types

domain_name string
supply_net_name string

ARGUMENTS

supply_net_name

Specifies the name of the supply net to be created. The name should be a simple (non-hierarchical) name.

In the scope of specified power domain, if there is a supply net or logical hierarchical net with the same name, the supply net cannot be created. An exception to this rule is when you use the **-reuse** option. In this case the net name must be same as an existing supply net in the same scope; name; check is not performed.

This argument is required.

-domain *domain_name*

Specifies the power domain for which this supply net is defined. The power domain must exist.

This argument is optional. If -domain is not specified, the supply net will be available for all power domains at the current scope and below.

-reuse

Reuses an existing supply net instead of creating a new one. One supply net can be associated with several power domains. If this option is used, the specified supply net must already exist.

-resolve unresolved | parallel | one_hot | parallel_one_hot

Specifies how the state and voltage of the supply net are resolved when the supply net is driven by a power switch or multiple power switches. Specifying *unresolved* means that this supply net allows only a single driver. Specifying *parallel* means that this supply net can be driven by multiple power switches. When the supply net is connected to the output of multiple power switches,

any number of outputs may be ON at the same time, as long as the voltage value is same. Specifying *one_hot* means multiple supply sources, each having a unique driver, may be connected to the supply net. Specifying *parallel_one_hot* allows resolution of a supply net that has multiple root supply drivers where each driver may have more than one path through supply sources to the supply net.

Users can specify their own custom resolution functions, defined during simulation. The resolution function thus defined can be used as the value to the -resolve option. Custom resolutions allows for multiple drivers.

The default is **unresolved**.

DESCRIPTION

The **create_supply_net** command enables you to create a supply net defined in the specified power domain. A supply net presents the intention of the power supply in the power domains. A supply net connects supply ports and, or pins.

Each power domain has a primary power supply net and a primary ground supply net, and could have several other supply nets. If the command succeeds, a supply net is created in the scope of the power domain. The new supply net is neither a primary power net nor a primary ground net of the power domain. Use the **set_domain_supply_net** command to set the supply net as the primary power or ground net.

On success this command returns the full name of the supply net (from the current scope). On failure, it returns a null string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a supply net named A_VDD in the power domain PD1, and recreates supply net A_DD in the power domain PD2 using the **-reuse** option:

```
prompt> create_power_domain PD1 -element INST1
PD1

prompt> create_power_domain PD2 -element INST2
PD2

prompt> create_supply_net A_VDD -domain PD1
A_VDD

prompt> create_supply_net A_VDD -domain PD2 -reuse
A_VDD
```

SEE ALSO

report_supply_nets(2)

create_supply_port

Creates a supply port in the specified power domain. If a power domain is not specified, creates the port in the current scope.

SYNTAX

string **create_supply_port**
supply_port_name
[-domain *domain_name*]
[-direction in | out | inout]

Data Types

supply_port_name string
domain_name string

ARGUMENTS

supply_port_name

This is a required argument.

Specifies the name of the supply port to be created. The name should be a simple (non-hierarchical) name. This argument can be used with the **-domain** option to avoid hierarchical names.

If a supply port with same name exists, this command will result in an error. If a design port with same name exists, this command will continue to create a supply port without any warning, error. Especially, if this existing port is signal type, then it will be treated as a PG (with direct tie with the signal pins), let resolve_pg_net handle it.

-domain *domain_name*

Specifies the power domain where this port defines a supply net connection point. If the specified power domain does not exist in the current scope, the command fails.

-direction in | **out** | **inout**

Defines how the state information is propagated through the supply network when connected to the port. If the port is an input port, the state information of the external supply net connected to the port is propagated into the domain. Similarly, for an output port, the state information of the internal supply net connected to the port is propagated outside the domain.

The default value of this option is **in**.

DESCRIPTION

The *create_supply_port* command creates a supply port at the scope of the specified power domain or at the current scope. A supply port provides a connection point for the supply net.

On success, the command returns the full name of the supply port (from the current scope). Otherwise, returns a null string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates the supply port *VN1* at the scope of power domain *PD1*:

```
prompt> create_power_domain PD1 -element INST1
PD1

prompt> create_supply_port VN1 -domain PD1
VN1
```

SEE ALSO

report_supply_ports(2)

create_supply_set

Creates or updates a set of supplies that can be used to define the power network. A supply set is created in the current logic hierarchy.

SYNTAX

string **create_supply_set**
[-function {function_name supply_net_name}*]
[-update]
supply_set_name

Data Types

supply_set_name string
function_name string
supply_net_name string

ARGUMENTS

supply_set_name

Specifies the name of the supply set to be created. The name should be a simple (non-hierarchical) name.

If a supply set with the same name exists in the current scope, the supply set is not created.

An exception to this rule is when you use the **-update** option. In this case the supply set name must be same as an existing supply set in the same scope.

This argument is required.

-function {*function_name supply_net_name*}*

Specifies the functionality to which an actual supply net named **supply_net_name** should be associated.

This argument takes two parameters as input. First is the name of the functionality, which is either **power** or **ground**. Second parameter is the name of the supply net that is in the same hierarchical scope of the supply set.

This argument is required when the **-update** argument is used. Optional otherwise.

-update

Instructs the tool to associate an actual supply net to the **power** and **ground** functionalities of an existing supply set. It is an error if the supply set specified does not exist. Only one update is allowed for each functionality of the supply set. If your update is not successful, the tool issues an error message. You can continue to update the functionality, until your update is successful.

This argument is optional. When the **-update** argument is used, the **-function** argument must also be used.

DESCRIPTION

The **create_supply_set** command creates a supply set in the current scope. A supply set eliminates the requirement of a supply net and supply ports in the design in the frontend tool. However, actual supply nets must be associated with the supply sets later on in the flow before physical synthesis is done.

A supply set supports the use of the following functions in the design:

a) Power

b) Ground

These functions, when unassociated with any supply net, can be used as supply nets for any purpose. They can be accessed by referencing them through the name of the supply set. To access the **power** function, you must specify *supply_set_name.power* and to access the **ground** function, you must specify *supply_set_name.ground*.

The functions of a supply set can be used just as any other supply net in the UPF design, with no domain restrictions. However, domain restrictions are applicable when an **-update** is called. This means that the actual supply nets, being associated with a supply set, will be checked for their definitions in the domains where the supply set functions have been used.

Calling an update on an existing supply set means replacing the supply set functions with actual supply nets. After doing an **-update**, the actual supply net can be referenced through the supply set or by its actual name.

EXAMPLES

The following example creates a supply set named primary_sset in the current logical hierarchy.

```
prompt> create_supply_set primary_sset
primary_sset
```

The following example illustrates how a supply set function can be used.

```
prompt> create_supply_set primary_sset
primary_sset

prompt> create_power_domain PD_TOP
PD_TOP

prompt> set_domain_supply_net PD_TOP A \
        -primary_power_net primary_sset.power \
        -primary_ground_net primary_sset.ground \
1
prompt> set_retention ret_cstr -domain PD_TOP \
        -retention_power_net primary_sset.power \
        -retention_ground_net primary_sset.ground
1
prompt> set_isolation iso_cstr -domain PD_TOP \
        -isolation_power_net primary_sset.power \
        -isolation_ground_net primary_sset.ground \
1
```

The following example illustrates how a supply set can be associated with actual supply nets.

```
prompt> create_supply_set primary_sset
primary_sset

prompt> create_power_domain PD_TOP
PD_TOP

prompt> set_domain_supply_net PD_TOP \
        -primary_power_net primary_sset.power \
        -primary_ground_net primary_sset.ground
1
prompt> set_retention ret_cstr -domain PD_TOP \
        -retention_power_net primary_sset.power \
        -retention_ground_net primary_sset.ground
1
prompt> set_isolation iso_cstr -domain PD_TOP \
        -isolation_power_net primary_sset.power \
        -isolation_ground_net primary_sset.ground \
1
prompt> create_supply_net TOP_VDD -domain PD_TOP
TOP_VDD
prompt> create_supply_net TOP_VSS -domain PD_TOP
TOP_VSS
prompt> create_supply_set primary_sset \
       -function {power TOP_VDD} \
       -function {ground TOP_VSS} \
       -update
1
```

create_supply_net(2)
set_domain_supply_net(2)
set_retention(2)
set_isolation(2)

create_tap_cells

Inserts tap cells in the current block to form a two-dimensional array structure to ensure that all standard cells placed subsequently comply with the maximum diffusion-to-tap distance limit.

SYNTAX

status **create_tap_cells**
-lib_cell *cell_name* | -multiple_tap_cells *table*
[-mirrored_row_lib_cell *cell_name*]
-distance *tap_distance*
[-voltage_area *voltage_areas*]
[-offset *distance*]
[-pattern every_row | every_other_row | stagger]
[-insert_into_blocks]
[-skip_fixed_cells]
[-prefix *cell_prefix*]
[-separator *cell_separator*]
[-at_distance_only]
[-enable_prerouted_net_check]
[-min_horizontal_periphery_spacing *number_of_unit_tiles*]
[-row_end_tap_bypass]
[-preserve_distance_continuity *lib_cells*]
[-min_row_edge_distance_layer_override *layerMinRowPair*]
[-other_cells_with_well_taps *table*]
[-cells_not_breaking_well_continuity *cell_names*]
[-cells_breaking_nwell_continuity *cell_names*]
[-cells_breaking_pwell_continuity *cell_names*]

Data Types

cell_name string
cell_names string
tap_distance float
voltage_areas collection
distance float
cell_prefix string
cell_separator string
number_of_unit_tiles integer
lib_cells collection
table string

ARGUMENTS

-lib_cell *cell_name*

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

-mirrored_row_lib_cell *cell_name*

Specifies the library reference cell to be used as a tap cell on mirrored rows. Mirrored rows are rows whose row orientation is set to MX rather than R0. You can only specify a single library cell.

If you do not use this option, the command uses the cell specified with the **-lib_cell** option on the mirrored rows.

-distance *tap_distance*

Specifies the distance in microns between two tap cells in a row. This distance is referred to as the tap distance. This is a required option.

-voltage_area *voltage_areas*

Specifies the voltage areas in which to create tap cells.

By default, the command creates tap cells in all voltage areas.

-offset *distance*

Specifies the distance in microns that the tap pattern should be shifted to the right.

If the offset distance is a multiple of the tap distance, the effective offset is 0. For example, if the tap distance is 10 microns and the offset is 32 microns, the effective offset is 2 (32 - 3x10).

The default is 0.

-pattern every_row | every_other_row | stagger

Specifies the tap cell insertion pattern. The supported patterns are as follows:

- **every_row** (the default)
  The command adds tap cells to every row using the specified tap distance. The tap distance specified for this pattern should be approximately twice the design rule distance limit.
- **every_other_row**
  The command adds tap cells to every other row for odd rows only. This reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately twice the design rule distance limit.
- **stagger**
  The command adds tap cells to every row. The tap cells on even rows are offset with half the tap distance relative to the odd rows, producing a checkerboard-like pattern. This pattern also reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately four times the design rule distance limit.

-insert_into_blocks

Inserts tap cells inside the child blocks.

-skip_fixed_cells

Prevents the command from inserting tap cells in locations that are occupied by fixed cells.

When you use this option, the tool treats a fixed cell like a blockage, which breaks the row and might cause a tap cell to be inserted on each side of the fixed cell. To prevent the insertion of tap cells that overlap fixed cells without breaking the row, use the **-preserve_distance_continuity** option with the **-skip_fixed_cells** option.

By default, the command inserts a tap cell in each calculated tap location, even if it is occupied by a fixed cell.

-prefix *cell_prefix*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

tapfiller!*cell_prefix*!*lib_cell*!*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

tapfiller!*lib_cell*!*number*

-separator *cell_separator*

Specifies the separator character that is used when composing the instance name of the tap cell.

The default is "!".

-at_distance_only

Creates tap cells only at the specified distance, distance/2, or distance/4 (stagger mode). Note that using this option can cause DRC violations.

-enable_prerouted_net_check

When this option is turned on prerouted net checking is performed for tap-boundary cells. Prerouted net checking is not performed on other boundary cells whether or not this option is specified.

-min_horizontal_periphery_spacing *number_of_unit_tiles*

Specifies the minimum horizontal spacing measured in unit tiles from a tap cell that is directly above or below a blocked area to the beginning or end of that placeable row. This option requires the **-skip_fixed_cells** option.

-no_abutment

When this option is specified vertical abutment is enforced during tap cell creation. This means that tap cells are created in a manner where the top or bottom of the tap cells do not overlap with other tap cells or other cells specified by the **-no_abutment_cells** option. Additionally, when this option is specified no abutment horizontal spacing and corner spacing rules are also enforced with the parameters specified to the **-no_abutment_horizontal** and **-no_abutment_corner_spacing** options respectively.

-no_abutment_horizontal_spacing *number_of_unit_tiles*

This options requires the **-no_abutment** option and specifies the minimum horizontal spacing between two different tap cells that are on the same row or a tap cell and another cell specified by the **-no_abutment_cells** option. The default value for this option is 1, which means there must be at least a distance of one unit tile measured horizontally between the cells.

-no_abutment_corner_spacing *number_of_unit_tiles*

This options requires the **-no_abutment** option and specifies the minimum horizontal corner spacing between two different tap cells that are on adjacent rows row or a tap cell and another cell specified by the **-no_abutment_cells** option. The default value for this option is 0, which means that the corners of the cells may touch. For example, if this option is set to 2, it means that there must be at least a distance of two unit tile measured horizontally between the corners of cells in vertically adjacent rows.

-no_abutment_cells *lib_cells*

This options requires the **-no_abutment** option. When this option is specified, tap cell are created so that instead of just complying with no abutment rules with other tap cells, the created tap cells also comply with no abutment rules with other cells that use the library cell passed to this option. This option applies to all three no abutment rules, the no vertical abutment, no abutment horizontal spacing and the no abutment corner spacing rules.

-row_end_tap_bypass

Specifies that the boundary cells have taps.

Note that the command does not check if the boundary cells contain taps nor does it check if the boundary cells exist. It assumes that taps are available at both ends of each row and inserts the tap cells accordingly.

-preserve_distance_continuity *lib_cells*

Ensures that the tap distance is maintained even when a tap cell cannot be placed in a certain location due to fixed instances of the specified library cells.

When you use this option, the command checks if the calculated tap location is occupied by a fixed instance of the specified library cells. If so, the command shifts the tap cell to the left of the fixed cell instance, if possible. Otherwise, it shifts the tap cell to the right of the fixed cell instance. Only the affected tap cell is shifted; the next tap cell remains at its original tap location. To prevent DRC violations, you might need to specify a smaller tap distance when you use this option.

This option affects tap cell insertion only when used with the **-skip_fixed_cells** option.

-multiple_tap_cells

Specifies the tap cells to be used for insertion and the properties of those tap cells, including latch-up coverage distance, the minimum required to the edge of the row, type of left side coverage and right side coverage. The syntax is follows:

-multiple_tap_cells { {tap1 tapCoverageDist1 minRowEdgeDist1 leftCoverage1 rightCoverage1} {tap2 tapCoverageDist2 minRowEdgeDist2 leftCoverage2 rightCoverage2} }

The left side coverage option specifies whether the coverage is provided for the left nwell and pwell half of the cell and can be any of one the following strings: left_full, left_nwell_only, left_pwell_only, left_none.

The right side coverage option specifies whether the coverage is provided for the right nwell and pwell half of the cell and can be any of one the following strings: right_full, right_nwell_only, right_pwell_only, right_none.

-min_row_edge_distance_layer_override *layerMinRowPair*

This option takes a set of layer and distance pairs. When this option is specified the minimum row edge distance is set to the distance value for all rows where the beginning or end of the row is covered by the specified layer.This option requires the **-multiple_tap_cells** option.

This option should be used for all processes that have requirements for cells being within a minimum distance of the edge of the row. This option does not require multiple tap cells to be used. The option can be run with only one tap library cell.

-other_cells_with_well_taps *table*

Specifies cells that are not tap cells that provide latch-up protection and the properties of those cells, including latch-up coverage distance, the minimum required to the edge of the row, type of left side coverage and right side coverage. The syntax is the same as for the -multiple_tap_cells option.

-cells_not_breaking_well_continuity *cell_names*

Specifies the library reference cells that do break the continuity of either nwell or the pwell half of the specified cell.

-cells_breaking_nwell_continuity *cell_names*

Specifies the library reference cells that break the continuity of the half of the cell that is covered by the nwell. Cells specified by this option allow tap cell coverage to propagate through the half of the cell that is covered by the pwell but not the nwell.

-cells_breaking_pwell_continuity *cell_names*

Specifies the library reference cells that break the continuity of the half of the cell that is covered by the pwell. Cells specified by this option allow tap cell coverage to propagate through the half of the cell that is covered by the nwell but not the pwell.

DESCRIPTION

This command adds tap cells to the design. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cell in the library contain no substrate or well taps.

The design rules typically specify a distance limit from every transistor of a standard cell to a well or substrate tie. This command is used to create tap cells before global placement so that all standard cells that are subsequently placed can satisfy the distance limit because of the created tap cells.

You should specify the tap distance and offset based on your specific design rule's distance limit. The command has no knowledge of the design rule's distance limit. A visual check is recommended after running this command to ensure that all standard cell placement areas are properly protected by tap cells.

You can select several tap cell placement patterns. In the following situations, the tap cells are shifted from their calculated tap locations:

- If the **place.legalize.enable_pin_color_alignment_check** application option is **true** (its default is **false**) and the calculated tap location would violate the double-patterning spacing rules.
- If the **-skip_fixed_cells** and **-preserve_distance_continuity** options are used and the tap location is occupied by a fixed instance of the specified library cells.

In these situations, you should reduce the tap distance slightly to avoid signoff DRC errors due to the shifting.

EXAMPLES

The following example creates tap cells. The tap cell array will contain instances of the Cell1 cell in every row. The distance between tap cells is 30 microns.

```
prompt> create_tap_cells -lib_cell myLib/Cell1 \
  -distance 30 -pattern every_row
```

SEE ALSO

create_boundary_cells(2)
create_stdcell_fillers(2)
place.legalize.enable_pin_color_alignment_check(3)

create_tap_meshes

Creates a tap mesh in the specified region.

SYNTAX

status **create_tap_meshes**
-lib_cell *cell_name*
-bbox *coordinates*"
-mesh_window *array_spec*
[-prefix *cell_prefix*]
[-orientation *cell_orientation*]

Data Types

cell_name string
coordinates rectangle
array_spec list
cell_prefix string
cell_orientation string

ARGUMENTS

-lib_cell *cell_name*

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

-bbox *coordinates*

Specifies the rectangular tap insertion region in microns. Specify the rectangle as a list of four coordinates, {{llx lly} {urx ury}}, which represents the lower-left and upper-right corners of the rectangle.

This is a required option.

-mesh_window *array_spec*

Specifies x-pitch and y-pitch for the tap cell insertion. This is a required option.

-prefix *cell_prefix*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

<*cell_prefix*>__<*lib_cell*>_R#_C#_*number*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

headerfooter__<*lib_cell*>_R#_C#_*number*

-orientation ***cell_orientation***

Specifies the orientation of the placement of the tap cells. The valid values are: R0, R90, R180, R270, MX, MXR90, MY, MYR90.

The default is R0.

DESCRIPTION

This command creates a tap mesh, which is a two-dimensional array of tap cells with a tap cell in each mesh window. A tap mesh is typically inserted outside of a place and route block.

When inserting the tap mesh, the command does not honor the standard cell rows or sites. It places a tap cell in the lower-left corner of each mesh window. If that location is blocked, the command uses the closest available location, which is measured as the Manhattan distance to the lower-left corner of the mesh window. If there is no available location, the command issues a warning and does not place a tap cell in that mesh window.

EXAMPLES

The following example places tap cells in a mesh window that has an x-pitch of 10 and a y-pitch of 20.

```
prompt> create_tap_meshes -lib_cell myLib/Cell1 \
  -bbox {{0 0} {100 100}} -mesh_window {10 20}
```

create_interior_tap_walls(2)
create_tap_cells(2)

create_taps

Creates voltage source objects (taps) to be used in the rail analysis.

SYNTAX

status **create_taps**
[-top_pg]
[-of_objects *object_list*]
[-import *file_name*]
[-point {*X-coord Y-coord*}]
[-layer *number_or_name*]
[-supply_net *supply_nets*]
[-nocheck]
[-snap_distance *snap_distance*]
[-region {{*left top*} {*right bottom*}}]
[-xpitch *X-pitch*]
[-ypitch *Y-pitch*]
[-xoffset *X-offset*]
[-yoffset *Y-offset*]
[-direction all | v | h]

Data Types

object_list list
file_name string
X-coord real
Y-coord real
number_or_name string
file_name string
supply_nets list
snap_distance real

ARGUMENTS

-top_pg

Indicates that tap points are to be created for all top-level supply (power or ground) pins of the design. This option cannot be used with the **-of_objects**, **-import**, **-point**, or **-snap_distance** option. The **-layer**, **-supply_net**, and **-nocheck** options are ignored if the **-top_pg** option is specified.

-of_objects *object_list*

Creates tap points on the specified object which can be either cell or lib_cell. By default, taps are created on all supply power and ground pins of the object from *object_list*. The **-supply_net** option can be used to determine only which supply power or ground

pins can be put on the taps. If the **-point**, **-layer**, and **-supply_net** options are specified at the same time, one tap is created at the specified physical location; the power of the tap is specified by the **-supply_net** option, relative to the origin of each object. Object names are used as tap names, in the format net_name:cell_name:pin_name.

This option cannot be used with the **-top_pg**, **-import**, or **-snap_distance** option. The **-nocheck** option is ignored if the **-of_objects** option is specified.

-import ***file_name***

Reads in the information from a tap file that defines tap XY locations, layer numbers and supply nets, and so on.

The supported tap file format is as follows:

<net_name> <layer_number> <X-coord> <Y-coord> [*R(<R_in_Ohm>)*] [*L(<L_in_Henry>)*] [*C(<C_in_Farad>)*]

This option cannot be used with the **-top_pg**, **-of_objects**, **-point**, **-layer**, or **-supply_net** option.

-point {*X-coord Y-coord*}

Defines the location where the tap is to be created, in terms of the *X-coord* and *Y-coord* location on the XY plane. When the **-of_objects** option is specified also, then XY location is relative to the origin of the specified objects. Otherwise, XY location is relative to the origin of the current top-level design. Moreover, this option must be accompanied by the **-layer** and **-supply_net** options to define a physical location associated with a given supply net in the three-dimensional space at which the tap is to be created. This option cannot be used with the **-top_pg** or **-import** option. If a tap point is defined in a location where another tap already exists, the tool issues a warning message and replaces the old tap with new one.

-layer ***number_or_name***

Defines the layer at which the tap point is to be created. The layer can be specified as either a layer number or a layer name. This option must be accompanied by the **-point** and **-supply_net** options to define a physical location associated with a given supply net in the three-dimensional space at which the tap is to be created. In addition, this option cannot be used with the **-import** option.

-supply_net ***supply_nets***

Specifies the supply net with which this tap point is associated. If both the **-point** and **-layer** options are used, this option is required and only one supply net should be specified. If there are more than one supply net, then only the first supply net is used with the tool warning message. If the **-of_objects** option is used, then a collection of supply nets is acceptable. This option cannot be used with the **-import** option.

-nocheck

Specifies that tap points are not checked to see if they touch any cross-hierarchy (including soft or hard macros) geometry. This option cannot be used with the **-snap_distance** option. In addition, this option is ignored when you specify the **-top_pg** or **-of_objects** option.

-snap_distance ***snap_distance***

Defines the snap distance in microns. When a given tap location does not touch a layout geometry of a supply net, the tool searches for legal locations within the specified distance by expanding to the left, right, bottom and top corners. This option cannot be used with the **-top_pg**, **-of_objects**, or **-nocheck** option.

-region {{*left top*} {*right bottom*}}

Defines a region to place pitched taps. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

-xpitch ***X-pitch***

Defines a fixed interval along the X-axis to place pitched taps. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

-ypitch ***Y-pitch***

Defines a fixed interval along the Y-axis to place pitched taps. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

-xoffset ***X-offset***

Defines an offset on the X-axis to begin placing pitched taps. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

-yoffset ***Y-offset***

Defines an offset on the the Y-axis to begin placing pitched taps. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

-direction ***all*** | ***v*** | ***h***

Defines a wire direction for which shapes pitched taps can be placed upon. This option requires both the **-xpitch** and **-ypitch** options and cannot be used with the **-snap_distance** option.

DESCRIPTION

The **create_taps** command creates tap objects which are considered as part of supply network during rail analysis.

Taps are used to model the external voltage source environment in which the device under analysis (DUA) operates. They are not part of the design itself, but can be thought of as virtual models of voltage sources. For some analysis types, taps are treated only as sources of ideal voltage. For other analysis types, taps represent the package in which the DUA is contained. In these cases the electrical behavior can be significantly more complex than a simple ideal voltage source.

When a physical location for a tap object is specified via the **-point** and **-layer** options, the tap is virtually connected to the design at that location. If there is no supply (or supply pin) net or via shape at the specified location, which means there is no conductive path to the supply network, the tap has no rail effect.

By default, cross-hierarchy (including soft and hard macros) geometry-touch checking is always performed during tap creation. The checking result is updated to the *is_valid_location* attribute of the tap object from an initial unknown status. Note that the tool drops taps with invalid locations. To disable this checking, use the **-nocheck** option.

If a tap already exists at a location when the **create_taps** command is executed, the new tap will be dropped with a warning message.

Two or more tap points might be created close to one another. This can occur when you run the **create_taps** command multiple times to specify taps in different ways. If taps are placed too close to one another, the effective resistance between them might be too small to have an impact on the rail result. This means these taps effectively act as one single tap point. For example, if the taps are sufficiently separated at opposite ends of a relatively long segment of a net shape, there is non-trivial resistance between them, which alters the rail results more substantially.

When a *lib_cell* is provided within the *object_list* parameter, the tap points are created on all instances of that *lib_cell* used in the design.

If you have an ASCII file that describes tap information, use the **-import** option to read in this file and create taps accordingly. The format of the file is shown in the **-import** option description.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

EXAMPLES

The following example imports taps from a tap file.

```
prompt> sh cat tap_file

VDD 31 269.900 409.740
VSS 31 218.500 409.740

prompt> create_taps -import tap_file
prompt> report_taps

Name     Net  Point          Layer  Is_valid
-------------------------------------------------
Tap_24   VDD  269.900 409.740  31     true
Tap_25   VSS  218.500 409.740  31     true
```

The following example creates two taps by specifying their layers, locations, and associated supply nets.

```
prompt> create_taps -point {269.900 409.740} -layer 31 -supply_net VDD
prompt> create_taps -point {319.500 409.740} -layer METAL4 \
  -supply_net VSS
```

The following example creates taps at all top-level supply pins.

```
prompt> create_taps -top_pg
```

The following example create taps by objects which could be cells or lib_cells.

```
prompt> create_taps -of_objects [get_cell U5]
prompt> create_taps -of_objects [get_cell U5] -supply_net VDD
prompt> create_taps -of_objects [get_cell U5] -point {2.8000 1.8000} \
  -layer 31 -supply_net VDD
prompt> create_taps -of_objects [get_lib_cell */EDF]
prompt> create_taps -of_objects [get_lib_cell */EDF] -supply_net VDD
prompt> create_taps -of_objects [get_lib_cell */EDF] \
  -point {2.8000 1.8000} -layer 31 -supply_net VDD
```

The following example creates pitched taps within the region {{23.285 10.63} {23.285 11.39}} spaced by an interval of 0.38 length units along the X-axis and Y-axis and touching horizontal net shapes of the supply net VDD and the layer 32. Since an offset is not specified, the pitched taps have their intervals begin at the origin.

```
prompt> create_taps -region {{23.285 10.63} {23.285 11.39}} \
  -xpitch 0.38 -ypitch 0.38 -supply_net VDD -layer 32 \
  -direction h
```

[-mirror_right_inside_horizontal_abutment_cell]
[-tap_distance *distance*]
[-top_tap_cell *lib_cell_name*]
[-bottom_tap_cell *lib_cell_name*]

Data Types

target_objects list
boundary_cell_prefix string
boundary_cell_separator string
lib_cell_name string
orientation orientation in DEF syntax
distance float

ARGUMENTS

-target_objects {*target_objects*}

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified. This option is a required option.

-include_touching_placement_blockages

Specifies that when boundary cells are created and placed, placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

-ignore_row_orientation

Specifies that when flipping between top and bottom.

-prefix *boundary_cell_prefix*

Specifies the prefix for the created boundary cells. By default, no prefix is added.

-separator *boundary_cell_separator*

Specifies the separator character that is used when composing the instance name of the boundary cell. The boundary cell instance name consists of a prefix, the library reference cell name and an incrementing number. For example, the instance name "boundarycell!MY_CELL!25" has the boundary cell prefix, the MY_CELL library reference cell name, the incrementing number 25, and the boundary cell separator !. This naming convention allows you to do pattern matching selection of the boundary cells. The default is "!".

-left_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the beginning of each cell row.

-right_boundary_cell *lib_cell_name*

Specifies the library cell to be placed at the end of each cell row.

-bottom_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the bottom object boundaries. In a double-back design, adjacent rows are flipped; the bottom boundary cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_boundary_cells *lib_cell_name*

Specifies the library cells to be placed along the top of object boundaries. In a double-back design, adjacent rows are flipped; the top boundary cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-left outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-bottom_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at bottom-right outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

-top_left_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-left outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-top_right_outside_corner_cell *lib_cell_name*

Specifies the library cell to be placed at top-right outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

-bottom_left_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-bottom_right_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the bottom-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-top_left_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the top-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

-top_right_inside_corner_cells *lib_cell_name*

Specifies the library cell to be placed at the top-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

-mirror_left_outside_corner_cell

Places left outside corner cells in a mirrored orientation.

-mirror_right_outside_corner_cell

Places right outside corner cells in a mirrored orientation.

-mirror_left_inside_corner_cell

Places left inside corner cells in a mirrored orientation.

-mirror_right_inside_corner_cell

Places right inside corner cells in a mirrored orientation.

-mirror_left_boundary_cell

Places left boundary cells in a mirrored orientation.

-mirror_right_boundary_cell

Places right boundary cells in a mirrored orientation.

-mirror_left_inside_horizontal_abutment_cell

Places left inside horizontal abutment cells in a mirrored orientation.

-mirror_right_inside_horizontal_abutment_cell

Places right inside horizontal abutment cells in a mirrored orientation.

-tap_distance *distance*

Specifies the distance in microns between tap cells.

-top_tap_cell *lib_cell_name*

Specifies the tap cell to be placed at the top boundary. The tool inserts this tap cell at the specified interval on top boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the top tap cell is used on unflipped top boundary rows and on flipped bottom boundary rows. This option must be used with the **-tap_distance** option.

-bottom_tap_cell *lib_cell_name*

Specifies the tap cell to be placed at the bottom boundary. The tool inserts this tap cell at the specified interval on bottom boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the bottom tap cell is used on unflipped bottom boundary rows and on flipped top boundary rows. This option must be used with the **-tap_distance** option.

DESCRIPTION

This command adds boundary cells around the boundaries of target objects, such as voltage areas, macros, blockages, and the core area.

EXAMPLES

The following example creates boundary cells around target placement blockages on both the left and the right edges of boundaries.

```
prompt> create_targeted_boundary_cells -target_objects {PB_7 PB_8} \
        -left_boundary_cell myLib/CellLeft -right_boundary_cell myLib/CellRight
```

create_tech

Creates a technology in the given library

SYNTAX

collection **create_tech**
[-library]
[-force]
name

Data Types

name string

ARGUMENTS

-library

Technology will be created in this library. If not specified then current library will be used.

-force

By default if a library already has a tech then create_tech will return error. But with this option, create_tech will replace the existing tech with new one.

name

Name of the technology.

DESCRIPTION

create_tech command creates a "tech object", the object to contain all technology related data. Typically the tech object is created from a tech file. This command provides a user interface to create the tech object directly from the Tcl interface.

The tech object can be created for a specific library, that can be sepecified as an option to this command. If the library is not specified with this command, the current library is used for tech object creation. If there is no current library set and no library specified with this command, the command will return an error.

create_tech fails if the tech already exists for the given library, however tech object creation can be forced by using -force option.

If the command is successful, it returns the newly-created tech as a single-element collection. If the command fails, it returns TCL_ERROR with appropriate error message. If there is a syntax error, it returns a TCL_ERROR.

EXAMPLE

The following example creates a technology object in the given library

```
prompt> create_tech -library r4000 tcbn90g
{r4000}
prompt> get_techs -of_objects [get_libs r4000]
{tcbn90g}
```

The following example replaces the existing technology object by creating a new technology object in the current library.

```
prompt> create_tech -force tcbn90g
{tcbn90g}
prompt> get_techs -of_objects [current_lib]
{tcbn90g}
```

SEE ALSO

remove_tech(2)
get_techs(2)

create_terminal

Creates a terminal on a port in the current design.

SYNTAX

collection **create_terminal**
-port *port*
-of_objects shapes_and_via_shapes
[-object *shape_or_via*]
[-direction *access_dir*]
[-eeq_class *eeq_class_value*]
[-name *terminal_name*]

Data Types

port collection
shapes_and_via_shapes collection
shape_or_via collection
access_dir list
eeq_class_value integer
terminal_name string

ARGUMENTS

-port *port*

Specifies the port on which to create the terminal. The option "-port" and "-object" should be specified together.

-object *shape_or_via*

Specifies the shape or via assigned to the terminal. This shape or via is owned by the terminal and defines its geometry. It is an error to include a shape or via which has already been assigned to another terminal. Text shapes may not be assigned to a terminal. The option "-port" and "-object" should be specified together.

-of_objects *shapes_and_via_shapes*

Specifies the net shapes and vias which are to be duplicated as terminal shapes. These copied net shapes and via geometries are owned by the terminals and defines their geometry. The shapes and the via geometries should have a valid net id assigned, otherwise they will be ignored. Text shapes may not be assigned to a terminal. This option is mutually exclusive with option "-port". The options "-eeq_class" and "-name" are ignored when used with "-of_objects" option.

-direction *access_dir*

Specifies the list of terminal access directions. Possible values are none, all, or one or more of: left, right, bottom, top. Default value is all.

-eeq_class *eeq_class_value*

Specify value for eeq_class attribute for the terminal. Value range is 0-65535.

-name *terminal_name*

Specifies the name of the terminal. If not specified, the name will be automatically generated.

DESCRIPTION

This command creates a new terminal and returns a collection containing the new terminal. Each shape or via may belong to one and only one terminal. A single rect, polygon, path, simple via, simple array via, or custom via may belong to the terminal. A text shape may not belong any terminal.

EXAMPLES

The following example creates a terminal with a shape.

```
prompt> create_terminal -port port1 -object [get_shapes PATH_16_40] -direction "all"
```

The following example creates a terminal with a via.

```
prompt> create_terminal -port port1 -object [get_vias VIA_S_1] -direction "all"
```

The following example creates terminals from net shapes and via.

```
prompt> create_terminal -of_objects {PATH_28_1393 PATH_18_2008  VIA_S_5491}
{TM_129 TM_130 TM_131}
```

SEE ALSO

create_terminals_for_pins

Create terminals for pins based on user constraints.

SYNTAX

status **create_terminals_for_pins**
[-pins *pins*]
[-nets *nets*]
[-ports *ports*]
[-bundles *bundles*]

Data Types

pins	collection
nets	collection
ports	collection
bundles	collection

ARGUMENTS

-pins *pins*

Specifies a list of pins for creating terminals.

-nets *nets*

Specifies a list of nets for creating terminals.

-ports *ports*

Specifies a list of ports for creating terminals.

-bundles *bundles*

Specifies a list of bundles for creating terminals.

DESCRIPTION

This command does quick pin assignment based on user constraints without doing global route and no feedthrough creation. For the pins to be created, they at least should have a side constraint. If possible, user should also consider providing offset or range constraints, in conjunction with layer constraints. During the pin creation, the command starts from the center of the constrained

region and search for the leagl pin location. The finer the constraints are, the fast the pin creation runtime will be.

The command honors user provided individual, bundle, block pin constraints, NDR rules, and recognize PG mesh and pin blockages. It also honors the spacing rules and size rules defined in technology files that the command **place_pins** honors. If multiple pin constraints are provide but are conflict to each other, the prioritiy from the highest to the lowest is NDR, individual pin constraints, bundle pin constraints, block pin constraints. If the user provided constraints conflict with technology rules, the values defined by the technology rules are honored.

The command does not consider alignment or abutment during pin creation. Its main purpose is to create physical pins as closest as possible to the constrained region, i.e. the shortest distance to the constrained region is the objective function. The intended usage of this command is to quickly create a collection of pins, interactively update them from GUI if desired, then fix them. These fixed pins will act as anchor points for later global route based pin creation to create feedthroughs. It is not intended to replace the command **place_pins**, nor a different flavor of **place_pins -nets_to_exclude_from_routing**.

The command will not re-create pins for fixed pins.

EXAMPLES

The following example creates terminals for pins

```
prompt> create_terminals_for_pins -pins [get_pins ]
1
```

SEE ALSO

place_pins(2)

create_test_protocol

Creates a test protocol based on user specifications.

SYNTAX

<return_value> **create_test_protocol**

ARGUMENTS

The create_test_protocol command has no arguments.

DESCRIPTION

The create_test_protocol command creates a test protocol for the cur- rent design based on user specifications issued prior to running this command. The specifications are made using commands such as set_dft_signal.

This command removes any protocol that is present in memory due to a previous execution of create_test_protocol. However, if the protocol is present in memory due to a previous execution of read_test_protocol, it issues a warning and does not create a new test protocol.

This command checks whether the user-specified values are consistent with each other. If they are not, it issues an error and does not generate a protocol.

EXAMPLES

The following example creates a test protocol in memory for the current design:

```
prompt> create_test_protocol
```

set_dft_signal(2)
insert_dft(2)

create_topological_constraint

Creates a new topological pin feedthrough constraint.

SYNTAX

create_topological_constraint
[-start_sides *side_numbers*]
[-start_offset *offset*]
[-start_offset_range *offset_range*]
[-start_layers *layers*]
[-end_sides *side_numbers*]
[-end_offset *offset*]
[-end_offset_range *offset_range*]
[-end_layers *layers*]
-start_object *object*
-end_object *object*
owner

Data Types

side_numbers list
offset float
offset_range float
layers collection
object collection
owner collection

ARGUMENTS

-start_sides *side_numbers*

Specifies the allowed side numbers on the start object for the pin-connection to go through. For a rectangular or rectilinear shape, the leftmost edge is the side number 1. If there are multiple leftmost edges, then edge 1 is the lowest leftmost edge. Numbering continues from the leftmost edge in the clockwise direction. This option is applicable only if the start object is of type cell, voltage-area or voltage-area-region. This is an optional option. When not specified the pin may be placed on any side.

-start_offset *offset*

Specifies the offset distance from the edge's starting point. The starting point is the first point on the edge in the clockwise direction. This is an optional option and can be specified only when the *-start_sides* option is specified.

-start_offset_range *offset_range*

Specifies the distance from the offset that a pin may be placed. This is an optional option and can be specified only when the *-start_offset* option is specified. When specified, the pin can be placed anywhere between (offset-range) and (offset+range).

-start_layers *layers*

Specifies the routing layers on which the pins may be created. This is an optional option. When no layers are specified then any layer may be used for pin placement.

-end_sides *side_numbers*

Specifies the allowed side numbers on the end object for the pin-connection to go through. For a rectangular or rectilinear shape, the leftmost edge is the side number 1. If there are multiple leftmost edges, then edge 1 is the lowest leftmost edge. Numbering continues from the leftmost edge in the clockwise direction. This option is applicable only if the start object is of type cell, voltage-area or voltage-area-region. This is an optional option. When not specified the pin may be placed on any side.

-end_offset *offset*

Specifies the offset distance from the edge's starting point. The starting point is the first point on the edge in the clockwise direction. This is an optional option and can be specified only when the *-end_sides* option is specified.

-end_offset_range *offset_range*

Specifies the distance from the offset that a pin may be placed. This is an optional option and can be specified only when the *-end_offset* option is specified. When specified, the pin can be placed anywhere between (offset-range) and (offset+range).

-end_layers *layers*

Specifies the routing layers on which the pins may be created. This is an optional option. When no layers are specified then any layer may be used for pin placement.

-start_object *object*

Specifies the object that forms the start of the connection. Valid object include an object of a cell, a voltage-area, a voltage-area-region, a port or a pin. Unless the object is of type cell, the values in the *-start_object* and *-end_object* should be different. If the object is of type port or pin, then it must be logically connected to the owner object (net or bundle).

-end_object *object*

Specifies the object that forms the end of the connection. Valid object include an object of a cell, a voltage-area, a voltage-area-region, a port or a pin. Unless the object is of type cell, the values in the *-end_object* and *-start_object* should be different. If the object is of type port or pin, then it must be logically connected to the owner object (net or bundle).

owner

Specifies the objects that will own a copy of the newly created constraint. Valid objects include a homogenous or heterogeneous collection of nets or bundles.

DESCRIPTION

The **create_topological_constraint** command creates topological pin feedthrough constraint with the specified parameters in the current block.

The topological constraints owned by a net or a bundle should be unique. If a topological constraint similar to the one being created is already owned by the net or the bundle, then the command errors out reporting the same.

EXAMPLES

The following example creates a topological pin feedthrough constraint with the cell1 and cell2 cells as the start and end object respectively. The topological constraint are owned by the net named net1.

```
prompt> create_topological_constraint net1 \
  -start_object cell1 -end_object cell2
```

The following example creates a topological pin feedthrough constraint with port "port1" and pin "pin1" as start and end object respectively. The topological constraint will be owned by the bundle bundle1. The topological constraint also specifies the start and end routing layers:

```
prompt> create_topological_constraint bundle1 \
  -start_object port1 -end_object pin1 \
  -start_layers {METAL1} -end_layers {METAL2 METAL3}
```

The following example creates a topological pin feedthrough constraint with cell "cell1" and voltage-area-shape VOLTAGE_AREA_SHAPE_0, owned by the net named net1. The topological constraint also specifies the side numbers, the offset, and the offset range to be used:

```
prompt> create_topological_constraint net1 \
  -start_object cell1 -end_object VOLTAGE_AREA_SHAPE_0 \
  -start_sides {1 2} -end_sides {1 2 3 4} \
  -start_offset 1.2 -end_offset 2.3 \
  -start_offset_range 0.5 -end_offset_range 0.5
```

SEE ALSO

create_topology_edge

Creates a topology edge.

SYNTAX

collection **create_topology_edge**
[-name *topology_edge_name*]
[-plan *topology_plan*]
[-nodes *node_list*]
[-objects *object_list*]
[-net_estimation_rule *rule_name*]
[-shape_layers *layer_length_width_list*]
[-allow_feedthrough none | select_on | select_off | all]
[-allow_feedthrough_type pure | mixed | any]
[-allow_feedthrough_select *object_list*]
[-allow_flyover none | select_on | select_off | all]
[-allow_flyover_select *object_list*]
[-constraint_groups *constraint_group_list*]
[-group_master *edge_list*]

Data Types

topology_edge_name string
topology_plan collection
node_list collection
object_list collection
rule_name string
layer_length_width_list list of {layer_name length_or_percentage distance} triplets
constraint_group_list collection
edge_list collection

ARGUMENTS

-name *topology_edge_name*

Specifies the name of the topology_edge. The name may not contain the special characters '~' or '/'. If unspecified, the command will generate a name automatically using the prefix "TOPOLOGY_EDGE" with a system-generated number appended.

-plan *topology_plan*

Specifies the topology_plan that will own the topology_edge. If unspecified, the topology_edge will be created in the current topology_plan.

-nodes *node_list*

Specifies a path of topology_nodes on which to create topology_edges, such that if there are N nodes in the list, then (N-1) edges will be created with the specified nodes as endpoints.

-objects *object_list*

Specifies the set of objects to be associated with the topology_edge. The objects may be hierarchical. Allowed object types are pins, ports, nets, supernets, and bundles.

-net_estimation_rule *rule_name*

Specifies the name of the net_estimation_rule of the topology_edge.

-shape_layers *layer_length_width_list*

Specifies the shape_layers of the topology_edge, in the form of a list of {layer_name distance_or_percentage distance} triplets. The second element, "distance_or_percentage", can either be an absolute length for that segment of the edge, or it can be a percentage, in which case it must be appended with the percent symbol. The third element is a distance value representing the width of the edge on that segment.

-allow_feedthrough none | select_on | select_off | all

Specifies the allow_feedthrough setting of the topology_edge.

"none" indicates that no feedthrough is allowed for the edge.

"select_on" indicates that feedthroughs are only allowed through the objects specified in the *-allow_feedthrough_select* option.

"select_off" indicates that feedthroughs are allowed through all objects except those specified in the *-allow_feedthrough_select* option.

"all" indicates that feedthroughs are allowed through all objects.

-allow_feedthrough_type pure | mixed | any

Specifies the allow_feedthrough_type setting of the topology_edge.

-allow_feedthrough_select *object_list*

Specifies the collection of objects for which the *-allow_feedthrough_select* option is applied.

-allow_flyover none | select_on | select_off | all

Specifies the allow_flyover setting of the topology_edge.

"none" indicates that no flyover is allowed for the edge.

"select_on" indicates that flyover is only allowed over the objects specified in the *-allow_flyover_select* option.

"select_off" indicates that flyover is allowed over all objects except those specified in the *-allow_flyover_select* option.

"all" indicates that flyover is allowed over all objects.

-allow_flyover_select *object_list*

Specifies the collection of objects for which the *-allow_flyover_select* option is applied.

-constraint_groups *constraint_group_list*

Specifies the constraint groups to which to add the topology_edge as a member.

-group_master *edge_list*

Specifies the topology_edge group master edge of this topology_edge. Only one topology_edge may be specified, and it must be

in the same topology_plan as this edge.

A topology_edge group is a group of topology_edges sharing the same (or reversed direction) endpoints and coordinate points, as well as selected other attributes. The "master" edge of the group is the edge that governs the attributes of the other edges in the group (the "members").

If this option is specified, then the following options may not be set, as their values will be governed by the master edge: *-allow_feedthrough*, *-allow_feedthrough_type*, *-allow_feedthrough_select*, *-allow_flyover*, *-allow_flyover_select*.

You may set the *-nodes* option if this option is specified, however it must contain the same node endpoints as the master edge, though they may be reversed in direction. If the *-nodes* option is not set, the new edge will have the same endpoints as the master edge.

You may set the *-shape_layers* option if this option is specified, however the value specified may be automatically modified such that the new edge's *points* attribute matches that of the master edge. If the *-shape_layers* option is not set, the new edge will have the same *shape_layers* attribute as the master edge.

DESCRIPTION

The **create_topology_edge** command creates a graph-like edge in a topology_plan. Each topology_edge has two endpoints, *start_node* and *end_node*, each of which may be connected to a topology node, or may be left unconnected.

The name of a topology_edge must be unique within its topology_plan. If the "-plan" option of the command is not specified, then the edge will be created in the "current" topology_plan. Once created, the edge cannot be moved to a different plan, and if the plan is deleted then the edge will also be deleted.

EXAMPLES

The following example creates a topology_edge in the current topology_plan "curplan":

```
prompt> create_topology_edge
{curplan/TOPOLOGY_EDGE0}
```

The following example creates a topology_edge in the topology_plan "myplan", and sets its objects collection to the nets in cell "mycell"'s ref_block:

```
prompt> create_topology_edge -plan myplan -objects [get_nets mycell/*]
{myplan/TOPOLOGY_EDGE0}
```

The following example creates a topology_edge in the current topology_plan "curplan", and that allows feedthrough through all objects except the cells in cell "mycell"'s ref_block:

```
prompt> create_topology_edge -allow_feedthrough select_off -allow_feedthrough_select [get_cells mycell/*]
{myplan/TOPOLOGY_EDGE0}
```

The following example creates 3 topology_edges in the topology_plan "myplan", with the name prefix "myedge", connecting topology_nodes n0, n1, n2, and n3:

```
prompt> create_topology_edge -plan myplan -name myedge -nodes {n0 n1 n2 n3}
{myplan/myedge myplan/myedge_1 myplan/myedge_2}
```

Data Types

topology_node_name string
topology_plan collection
topology_node collection
cell collection
object_list collection
coord float_pair
edge_list integer_list
dist_or_pct float [+ "%"]
distance float
side_list string

ARGUMENTS

-name *topology_node_name*

Specifies the name of the topology_node. The name may not contain the special character '/'. If unspecified, the command will generate a name automatically using the prefix "TOPOLOGY_NODE" with a system-generated number appended.

-plan *topology_plan*

Specifies the topology_plan that will own the topology_node. If unspecified, the topology_node will be created in the current topology_plan.

-ref_node *topology_node*

Specifies the ref_node of the topology_node. If specified, the topology_node will be in "reference" mode. In reference mode, the topology node will assume the majority of the ref_node's attribute values, and setting those attribute values will result in the values being set on the ref_node.

This option is mutually exclusive with the *-cell* and *-ref_plan* options.

-cell *cell*

Specifies that this topology_node should be in reference mode, and create its ref_node in a new topology_plan in the block referenced by *cell*.

This option is mutually exclusive with the *-ref_node* and *-ref_plan* options.

-ref_plan *topology_plan*

Specifies that this topology_node should be in reference mode, and create its ref_node in *topology_plan*.

This option is mutually exclusive with the *-ref_node* and *-cell* options.

-objects *object_list*

Specifies the set of objects to be associated with the topology_node. The objects may be hierarchical. Allowed object types are pins, ports, cells, voltage_areas, voltage_area_shapes, shapes, placement_blockages, routing_blockages, bounds, and bound_shapes.

-constrained_objects *object_list*

Specifies the set of constrained objects to be associated with the topology_node. The objects may be hierarchical. Allowed object types are pins and ports.

-origin *coord*

Specifies the origin of the topology_node. If unspecified, the origin will be auto-computed based on the other specified options if possible.

-constraint_type origin | edge | side | bbox | tap

Specifies the constraint type of the topology_node.

-edge *edge_list*

Specifies the constraint edge list of the topology_node. Value must be a list of integer values.

-start *dist_or_pct*

Specifies the constraint start of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-end *dist_or_pct*

Specifies the constraint end of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-range *dist_or_pct*

Specifies the constraint range of the topology_node. Value may be either a distance or a percentage - to specify a percentage, append a '%' character to the end of the float value.

-offset *distance*

Specifies the constraint offset of the topolology_node.

-side *side_list*

Specifies the constraint sides of the topolology_node. Value may be a single instance or list of the following: W, N, E, or S.

-alignment left | **right**

Specifies the constraint alignment of the topolology_node.

-bbox_percentage *float_single_or_pair*

Specifies the bbox_percentage of the topology_node. Specify a single value for linear regions, and a float pair for 2D regions.

-corner_type auto | **cross** | **default** | **river**

Specifies the corner_type of the topology_node.

-constraint_source user | **application**

Specifies the constraint_source of the topology_node.

-halo *distance*

Specifies the halo of the topology_node. May only be specified when the *-origin* argument is specified.

DESCRIPTION

The **create_topology_node** command creates a graph-like node or "steiner point" in a topology_plan. topology_nodes serve as endpoints of topology_edges, and have various constraint-related attributes.

The name of a topology_node must be unique within its topology_plan. If the "-plan" option of the command is not specified, then the node will be created in the "current" topology_plan. Once created, the node cannot be moved to a different plan, and if the plan is deleted then the node will also be deleted.

Some topology_nodes may reside in the top level, but reference different nodes, usually at a lower level of hierarchy. A node that references a different node (a "ref_node") is considered to be in "reference mode". When in reference mode, the values of the node's attributes will reflect those of the ref_node. Exceptions are the node's name and the node's edge connectivity-related attributes. When in reference mode, the node's *edges* attribute will report the union of the edges of the node and its ref_node.

EXAMPLES

The following example creates a topology_node in the current topology_plan "curplan":

```
prompt> create_topology_node
{curplan/TOPOLOGY_NODE0}
```

The following example creates a topology_node in the topology_plan "myplan", and sets its objects collection to the cells in cell "mycell"'s ref_block:

```
prompt> create_topology_node -plan myplan -objects [get_cells mycell/*]
{myplan/TOPOLOGY_NODE0}
```

The following example creates a topology_node named "mynode". The node will be in reference mode, and a new topology_node will be created to be its ref_node. The ref_node will be created in a new topology_plan in cell "mycell"'s ref_block:

```
prompt> create_topology_node -name mynode -cell [get_cells mycell]
{curplan/mynode}
```

create_topology_plan

Creates a topology plan in the current block.

SYNTAX

collection **create_topology_plan**
[-name *topology_plan_name*]
[-cell *cell*]
[-objects *object_list*]
[-net_estimation_rule *rule_name*]
[-allow_feedthrough none | select_on | select_off | all]
[-allow_feedthrough_type pure | mixed | any]
[-allow_feedthrough_select *object_list*]
[-allow_flyover none | select_on | select_off | all]
[-allow_flyover_select *object_list*]
[-launch_budget *float*]
[-capture_budget *float*]
[-comment *comment*]

Data Types

topology_plan_name string
cell collection
object_list collection
rule_name string
comment string

ARGUMENTS

-name *topology_plan_name*

Specifies the name of the topology_plan. The name may not contain the special characters '~' or '/'. If unspecified, the command will generate a name automatically using the prefix "TOPOLOGY_PLAN" with a system-generated number appended.

-cell *cell*

Specifies that this topology_plan should be created in the block referenced by *cell*.

-objects *object_list*

Specifies the set of objects to be associated with the topology_plan. The objects may be hierarchical. Allowed object types are pins, ports, nets, supernets, and bundles.

-net_estimation_rule *rule_name*

Specifies the name of the net_estimation_rule of the topology_plan.

-allow_feedthrough none | **select_on** | **select_off** | **all**

Specifies the allow_feedthrough setting of the topology_plan.

"none" indicates that no feedthrough is allowed for the plan.

"select_on" indicates that feedthrough is only allowed through the objects specified in the *-allow_feedthrough_select* option.

"select_off" indicates that feedthrough is allowed through all objects except those specified in the *-allow_feedthrough_select* option.

"all" indicates that feedthrough is allowed through all objects.

-allow_feedthrough_type pure | **mixed** | **any**

Specifies the allow_feedthrough_type setting of the topology_plan.

-allow_feedthrough_select *object_list*

Specifies the collection of objects for which the *-allow_feedthrough_select* option is applied.

-allow_flyover none | **select_on** | **select_off** | **all**

Specifies the allow_flyover setting of the topology_plan.

"none" indicates that no flyover is allowed for the plan.

"select_on" indicates that flyover is only allowed over the objects specified in the *-allow_flyover_select* option.

"select_off" indicates that flyover is allowed over all objects except those specified in the *-allow_flyover_select* option.

"all" indicates that flyover is allowed over all objects.

-allow_flyover_select *object_list*

Specifies the collection of objects for which the *-allow_flyover_select* option is applied.

-launch_budget *float*

Specifies the launch budget of the topology_plan.

-capture_budget *float*

Specifies the capture budget of the topology_plan.

-comment *comment*

Specifies the comment of the topology_plan. This is a general-purpose string that can be used for documentation.

DESCRIPTION

The **create_topology_plan** command creates a new topology_plan in the current block. A topology_plan encapsulates topological planning and constraint data, and owns collections of topology_nodes and topology_edges.

The name of a topology_plan must be unique in the block.

A topology_plan may be set as the "current" topology_plan using the *current_topology_plan* command. Subsequent commands to

create or query topology objects will operate in the context of the current topology_plan.

EXAMPLES

The following example creates a topology_plan in the current block:

```
prompt> create_topology_plan
{TOPOLOGY_PLAN0}
```

The following example creates a topology_plan with name "myplan" and sets its objects collection to the nets in cell "mycell"'s ref_block:

```
prompt> create_topology_plan -name myplan -objects [get_nets mycell/*]
{myplan}
```

The following example creates a topology_plan that allows feedthrough through all objects except the cells in cell "mycell"'s ref_block:

```
prompt> create_topology_plan -allow_feedthrough select_off -allow_feedthrough_select [get_cells mycell/*]
{TOPOLOGY_PLAN0}
```

create_topology_repeater

Creates a topology repeater.

SYNTAX

collection **create_topology_repeater**
-edge *topology_edge*
[-name *topology_repeater_name*]
[-type repeater | sequential]
[-offset *distance*]
[-objects *object_list*]

Data Types

topology_edge collection
topology_repeater_name string
distance float

ARGUMENTS

-edge *topology_edge*

Specifies the topology_edge on which to create the topology_repeater.

-name *topology_repeater_name*

Specifies the name of the topology_repeater. The name may not contain the special characters '~' or '/'. If unspecified, the command will generate a name automatically using the prefix "TOPOLOGY_REPEATER" with a system-generated number appended.

-type repeater | sequential

Specifies the type of the topology_repeater.

-offset *distance*

Specifies the offset of the topology_repeater.

-objects *object_list*

Specifies the set of objects to be associated with the topology_repeater. The objects may be hierarchical. Allowed object types are pins, ports, and cells.

DESCRIPTION

The **create_topology_repeater** command creates a topology_repeater on a topology_edge.

A topology_repeater will always have an owner edge, and once created cannot be transferred to a different edge. If the owner edge is deleted, then the repeaters owned by the edge are also deleted.

EXAMPLES

The following example creates a topology_repeater on the topology_edge "myedge", which itself resides in topology_plan "myplan":

```
prompt> create_topology_repeater -edge myedge
{myplan/myedge/TOPOLOGY_REPEATER0}
```

create_track

Creates the tracks for a routing or poly layer.

SYNTAX

collection **create_track**
-layer *layer*
[-space *track_pitch*]
[-count *number_of_tracks*]
[-coord *offset*]
[-width *wire_width*]
[-dir X | Y]
[-bbox *boundary_spec*]
[-reserved_for_width]
[-cell *cell*]
[-end_grid_low_offset *offset*]
[-end_grid_high_offset *offset*]
[-end_grid_low_steps *list_of_offsets*]
[-end_grid_high_steps *list_of_offsets*]
[-end_grid_relative_to core_area | block_boundary]
[-mask_pattern mask_one | mask_two]
[-relative_to core_area | block_boundary]
[-offset *offset*]

Data Types

layer string
track_pitch float
number_of_tracks integer
offset float
wire_width float
boundary_spec list
cell collection
list_of_offsets list
offset float

ARGUMENTS

-layer *layer*

Specifies the layer for which to create the tracks.

You can specify the layer name, layer number, or a collection that contains one layer object.

-space ***track_pitch***

Specifies the pitch distance between each track. i

The pitch is the center-to-center distance between two routing wires (the router places routes on top of each track). The value specified here is reported in the Pitch column of the **report_tracks** report.

By default, the distance is the same as the routing pitch from the physical library. The unit for the pitch distance is specified in the technology file; usually it is microns.

-count ***number_of_tracks***

Specifies the number of tracks to create.

By default, the tool fills the entire die area with tracks. If you specify the **-bbox** option, the tool fills the specified bounding box with tracks.

-coord ***start_x_or_y***

Specifies the location of the first track.

The x- and y-coordinates depend on the values specified with the **-dir** option. The units for the coordinates are specified in the technology file; usually it is microns.

By default, the track is located at half of the space distance inside of the die area.

-width ***wire_width***

Specifies the associated wire width attribute for rule-based wire tracks.

By default, wire tracks have no width attribute and have no usage constraint. Wire tracks with a width attribute can be used only by shapes whose width matches the track's width attribute.

-dir X | **Y**

Specifies the stepping direction in which the tracks are placed.

The **-dir X** option creates vertical tracks by stepping along the x-axis. The **-dir Y** option creates horizontal tracks by stepping along the y-axis.

By default, the stepping direction is derived from the routing direction of the layer. The stepping direction is X if the routing direction is vertical. The stepping direction is Y if the routing direction is horizontal.

-bbox ***boundary_spec***

Specifies the bounding boxes within which to create tracks.

The bounding box must fit the tracks of a given track object. For horizontal tracks, the first and last tracks must lie on the bottom and top edges of the box. For vertical tracks, the first and last tracks must lie on left and right edges of the box.

You can specify the bounding boxes directly by specifying a list of bounding boxes or you can specify polygons or geometric objects, which are decomposed into one or more bounding boxes.

To specify a list of bounding boxes, use the following syntax to specify the lower-left and upper-right corners of the bounding boxes:

{ {{*llx lly*} {*urx ury*}} ... }

To specify a list of polygons, use the following syntax to specify the vertices of the polygons:../../../../doc/nwtn/man/man2/create_track.2

{ {{*x y*} {*x y*} {*x y*} {*x y*} ...} ... }

The unit for the coordinates are specified in the technology file; usually it is microns.

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. For poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. In the case of layers, the resulting area includes the area of every shape on the layer.

-reserved_for_width

Specifies that the created tracks are reserved tracks. Reserved tracks can be used only by nets with a nondefault rule.

This option must be used with the **-width** option.

-cell *cell*

Specifies the physical cell in which to add the tracks.

The tracks are created in the cell's reference block using the coordinate system of the cell's top block. The cell must reference a block, not a library cell, unless you run this command in the library manager. The library manager can create tracks within library cells.

By default, the tracks are created in the current block.

-end_grid_low_offset *offset*

Specifies the offset from the left or bottom edge to the starting point of the first grid rectangle.

-end_grid_high_offset *offset*

Specifies the offset from the left or bottom edge to the ending point of the first grid rectangle.

-end_grid_low_steps *list_of_offsets*

Specifies a list of steps to use when creating subsequent grid points. Each offset in the list is the distance between the previous starting grid point and the current starting grid point.

-end_grid_high_steps *list_of_offsets*

Specifies a list of steps to use when creating subsequent grid points. Each offset in the list is the distance between the previous ending grid point and the current ending grid point.

-end_grid_relative_to core_area | block_boundary

Specifies that subsequent grid points need to be created with respect to core area bounding box or lower left of block bounding box. This option will also update values of options **-end_grid_low_offset** and **-end_grid_high_offset** as both of these options represent absolute value so providing **-end_grid_relative_to** option will recalculate them.

-mask_pattern mask_one | mask_two

Specifies the mask pattern for the created track.

-relative_to core_area | block_boundary

Specifies the alignment of track line. Based on the option, one of the track line will be aligned to lower boundary of core area bounding box or block bounding box. Although tracks will be created in complete block boundary. This option is mutually exclusive with **-coord** option.

-offset *start_x_or_y*

Specifies the offset of track line with respect to value provided in **-relative_to** option. First track line after start of core area or block boundary bounding box will be on a distance of value provided as part of the option. This option can be used only with **-relative_to** option.

DESCRIPTION

This command creates a group of tracks on the floorplan so the router can use them to perform detail routing. You must specify a routing layer for the tracks. The tracks can be saved in the Design Exchange Format (DEF) file or the design database file.

By default, this command creates a single track object. If the geometry specified by the **-bbox** option decomposes into multiple rectangles, the tool creates one track object per rectangle. The command returns a collection that contains the created track objects.

The **-end_grid_low_offset**, **-end_grid_high_offset**, **-end_grid_low_steps**, and **-end_grid_high_steps** options specify a nonuniform grid of allowed endpoints for wires. The low grid applies to left or bottom edges for horizontal or vertical tracks respectively. The high grid applies to right or top edges.

Wires can pass over these endpoints. If a wire terminates, the end of the wire must be on the grid. Grid points can be left untouched or uncovered by a wire.

For example, the following options describe a nonuniform grid:

```
-end_grid_low_offset 0
-end_grid_high_offset 2
-end_grid_low_steps {3,2}
-end_grid_high_steps {4,3}
```

And form the following grid points:

```
Low grid points are  x = 0, 3, 5, 8, 10, 13, 15
High grid points are x = 2, 6, 9, 13, 16, 20, 23
```

In this example, a wire can have a left edge at x = 10 and a right edge at x = 23. Another wire can have a left edge at x = 0 and a right edge at x = 6. These points form an abstract, nonuniform grid that constrains the router and specifies where wires can start and end.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates routing tracks for the M3 routing layer on the floorplan and reports the newly created routing tracks.

```
prompt> create_track -layer M3
Warning: Direction is not specified. Using the layer preferred
direction. (NDMUI-125)
Warning: Count value is not specified. Covering the bounding box of
track, depending on its space value. (NDMUI-136)
Warning: Coordinate value is not specified. Using coordinate that is
half of the space distance inside of the die area. (NDMUI-122)
Warning: Space is not specified. Using pitch. (NDMUI-124)
{TRACK_28}

prompt> report_tracks -layer M3
...
```

```
Layer        Direction    Start       Tracks   Pitch      Attr
--------------------------------------------------------------------------------
M3           Y            0.152       7333     0.304      default
1
```

The following example creates tracks within a rectilinear bounding box. The tool decomposes the bounding box into two rectangles and creates two track objects.

```
prompt> create_track -layer M3 \
  -bbox {{0 0} {20 0} {20 20} {10 20} {10 10} {0 10}}

prompt> report_tracks -layer M3
...
Layer        Direction    Start       Tracks   Pitch      Attr
--------------------------------------------------------------------------------
M3           Y            10.032      33       0.304      default
M3           Y            0.000       33       0.304      default
1

prompt> get_tracks -filter "layer_name==M3"
{TRACK_0 TRACK_1}
```

The following example uses the **-end_grid_*** options to specify grid points.

```
prompt> create_track -layer M3 -coord 0.96 -space 0.32 -dir Y \
  -width 0.32 -end_grid_low_offset 0.32 -end_grid_high_offset 0.96 \
  -end_grid_low_steps { 1.6 1.6 1.6 1.6 } \
  -end_grid_high_steps { 1.6 1.6 1.6 1.6 }

prompt> report_tracks -layer M3
...
Layer        Direction    Start       Tracks   Pitch
   Attr                   Edge_alignment
Low_offset   High_offset   Low_steps         High_steps
--------------------------------------------------------------------------------
M3           Y            0.960       6966     0.320
   non-reserved, width=0.320
0.320        0.960        1.600,1.600,1.600,1.600
                                1.600,1.600,1.600,1.600
1
```

The following example uses the **-end_grid_*** options along with **-end_grid_relative_to** to specify grid points.

```
prompt> get_attribute [get_core_area ] bbox
{10.5600 21.1200} {78.2000 79.9600}

prompt> create_track -layer M1 -dir Y -mask_pattern mask_one \
  -end_grid_high_steps {3 2 1} -end_grid_low_steps {1.5 2.5 4} \
  -end_grid_high_offset 4 -end_grid_low_offset 5 -end_grid_relative_to core_area

prompt> report_tracks -layer M1
...
Layer        Direction    Start       Tracks   Pitch
   Attr    Mask_pattern              Edge_alignment
Low_offset   High_offset   Low_steps         High_steps
--------------------------------------------------------------------------------
M1           Y            0.140       478      0.280
   default   mask_one
```

```
    7.560       2.560       1.500,2.500,4.000
                                3.000,2.000,1.000
    1
```

Data Types

objects collection
layer collection
width_list list of strings
number integer
percentage float
integer_list list of integers
distance_list list of floating-point numbers
step integer

bounding_box list
distance float
rect_list list of rectangles
transformation string
depth_value integer

ARGUMENTS

-nets *objects*

Specifies the group of nets or bundles for which to create route trunks. Bus bits are expanded left-to-right. The collection order is honored unless **-track_coords** or **-track_numbers** is specified which might force nets to be reordered.

-layer *layer*

Specifies the layer on which to create trunks.

-direction horizontal | vertical

Specifies the routing direction. Valid values are **horizontal** and **vertical**. By default, the direction is the preferred direction for the layer.

-width *width_list* | all

Specifies an unordered list of allowed track widths on which the tool can place a route trunk. Specify **-width all** to place route trunks on a track of any width. Nondefault routing rules take precedence over this option. By default, the command places route trunks only on tracks with the default width; tracks with a nondefault width are skipped.

The format of *width_list* is as follows:

-width width1
-width {width1 width2 ... }

If the *width_list* contains integer values, they are considered to be multiples of the default track width. If the *width_list* contains floating point values, they are considered to be absolute track widths. The following option and argument combinations are equivalent for a default track width of 0.25:

-width {1 2 3 4}
-width {0.25 0.5 0.75 1.0}

-num_wires *number*

Specifies the number of wires to create per net. Valid values are between 1 and 100000. When this option is specified, the command places the specified number of wires next to each other for the same net before proceeding to the next net in the list. By default, the command creates one wire per net.

-gravity driver | load | inout | all | percentage

Specifies the object type to use when aligning the trunks. Valid values are **driver**, **load**, **inout**, **all**, or **percentage**.

- *driver* - Align the trunk with the x- or y-coordinate of the pin of the driving pin
- *load* - Align the trunk with the x- or y-coordinate of the load pin
- *inout* - Align the trunk with the x- or y-coordinate of the inout pin
- *all* - Align the trunk with the center of the bounding box described by all the pins of the specified net

- *percentage* - Align the trunk based on percentage specified by the **-percentage** option. If the **-percentage** option is not specified, the default is 50% and the trunk aligns with the center the net bounding box.

The option is mutually exclusive with the **-track_coords** and **-track_numbers** options.

-percentage *percentage*

Aligns the route trunk based on a percentage of the bounding box for the net, starting from the left or bottom edge. The *percentage* value must be between 0 and 100 inclusive. A value of 0 places the trunk at the bottom or left edge of the bounding box, and a value of 100 places the trunk at the top or right edge of the bounding box. You must specify the **-gravity percentage** option together with the **-percentage** option. By default, the percentage is 50.

-track_numbers *integer_list*

Specifies the starting track number, or a list of specific track numbers, on which to place route trunks. Numbering is relative to the cell boundary origin or the origin of the bounding box specified by the **-track_ref_bbox** option. This option is mutually exclusive with the **-track_coords** and **-gravity** options.

To specify only the starting track, use **-track_numbers** together with a single integer value. For example, specify **-track_numbers 1** to begin placing route trunks at the first track within the boundary.

To specify a list of specific track numbers, use **-track_numbers** together with a list of integers. You must specify one integer value per net name as assigned by the **-nets** option. For example, specify **-track_numbers {1 3 5 7}** to place the route trunk on the first, third, fifth, and seventh tracks within the boundary when four nets are specified with the **-nets** option. If you specify the track numbers not in increasing order, the tool creates the route trunks but issues a LED-110 warning message.

-track_coords *distance_list*

Specifies a single x- or y-coordinate, or a list of x- or y-coordinates, on which to start placing the route trunk. The list must contain one value per net name as assigned by the **-nets** option. The trunk is snapped to the closest track unless **-do_not_snap_to_track** is specified. The option is mutually exclusive with the **-track_numbers** option. The option can be used with the **-track_step** option and the list should contain only one element that specifies the starting coordinate.

If the track is obstructed, the command issues an LED-110 warning message, skips the net, and does not create a route trunk in the obstructed track.

-track_step *step*

Specifies the step to use when placing routes for the remaining nets. The first track is placed as specified by the **-track_numbers** option or the **-track_coords** option. Successive tracks are placed according to the *step* value. You can specify a negative value to place successive tracks in the opposite direction. By default, the step is one and vertical routes are placed in consecutive tracks to the right of the first route trunk and horizontal routes are placed in consecutive tracks above the first route trunk.

-track_ref_bbox *bounding_box*

Specifies the bounding box on which to start track counting. If the bounding box is too small to contain all the route trunks, the tool issues an LED-110 message, skips the nets outside the boundary, and does not create the routes for those nets.

-hierarchical

Traces the net through the hierarchy and uses connections of all traced nets to determine the bounding box for the net for the user-specified topology.

-shield_type full | low | high | cap_shield

Specifies shielding types. Valid values are **full**, **low**, **high**, **cap_shield** as follows:

- *full* : Shield each net on both sides
- *low* : Shield each net on low side

- *high* : Shield each net on high side
- *cap_shield* : Shield first net on low side and last net on high side

-shield_nets *objects*

Specifies the shielding net pattern. The nets in shielding pattern are used cyclically.

-shield_pullback *distance*

Specifies the value in microns to cut or extend the shield ends.

-avoid_obstructions

Finds the next available, unobstructed routing track to create the trunk. The command issues a warning message if the trunk is placed outside the net bounding box. Use the **-track_freedom** option to expand the region where trunks can be shifted without warnings.

By default, if an obstruction is found, the command issues an LED-110 warning message, skips the net, and does not create a route trunk in the obstructed track.

-do_not_check_shorts

Creates route trunks that might create a short circuit with an existing route and overlap route obstructions. Use this option for a quick estimation and preview of route trunk placement without checking for shorts and obstructions.

-do_not_snap_to_track

Avoids snapping to a legal track. By default, route trunks are snapped to tracks.

-track_freedom *distance*

Expands the region where trunks could be shifted without issuing a warning message. This option allows route trunks to be created outside the boundary specified by the **-track_ref_bbox** option or the bounding box defined by the pin connections for the specified nets. You must specify the **-avoid_obstructions** option together with the **-track_freedom** option. By default, tracks are placed within the boundary.

-start_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the starting point derived from net bbox (left or bottom). The positive *distance* value will shorten the segment, while the negative *distance* value will extend the segment.

-stop_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the stop point derived from net bbox (right or top). The positive *distance* value will shorten the segment, while the negative *distance* value will extend the segment.

-net_bbox_override *rect_list*

Specifies the net bounding box to use when creating the trunk. The actual bounding box for the net is ignored. The bounding box specified by this option is applied to all nets.

-of_cells *cells*

Specifies the cells to use to calculate the net bounding box. The option can be used in multi-fanout scenarios to cut unnecessary branches.

-exclude_cells *cells*

Excludes the specified cells when calculating the net bounding box. This option can be used on nets with multiple fanouts to remove unnecessary branches.

-create_obstruction

Creates a routing blockage instead of creating a route shape. The routing blockage is similar to a blockage created with the Create Routing Blockage tool or the **create_routing_blockage** command.

-transform *transformation*

Applies the transformation expression to the route trunks. The transformation expression is one or two transformation steps that are applied to the route trunk. A transformation step is a move by a specific x- and y-distance or an orientation change. The command honors routing obstructions in the new location.

To create the route trunk and move it, specify **-transform {x y}** where x and y are the x- and y-distances in microns to move the trunks. To change the orientation of the route trunk, specify **-transform {orientation}**, where orientation is one of MX, MXR90, MY, MYR90, R0, R180, R270, and R90.

To combine two transformations, specify the delta and orientation transformations in the same list. For example, to specify that the route trunk is rotated 270 degrees and moved to the right by 10 microns, specify **-transform {{R270} {10 0}}**.

-skip_lib_cells

Do not descend into library cells to search for obstructions. This option must be used together with the **-avoid_obstructions** option. By default, the command checks for obstructions within library cells.

-depth *depth_value*

Limits the level of hierarchy to search for obstructions. Specify a *depth_value* of zero to search only the top level. This option must be used together with the **-avoid_obstructions** option. By default, all levels of hierarchy are searched.

-verbose

Prints detailed information about warning and errors.

-quiet

Suppresses all warning messages.

DESCRIPTION

This command creates trunks for the specified nets on a single layer in one direction. The command can be used for straight connections for critical signals where traditional routers might struggle. Although it is not a router in classical terms, the command can still ensure clean routing by shifting the routes.

The command supports the following operational modes:

- **Skip** mode (default): The trunks that cannot be routed are skipped and reported using **-verbose** option.
- **Dirty** mode: No checking on trunks which create violations with existing routes. Specify this mode with the **-do_not_check_shorts** option.
- **Clean** mode: In this case, no trunks should violate spacing. Specify this mode with the **-avoid_obstruction** option.

The command supports the following track snapping modes:

- Default tracks: Trunks should always snap to tracks and avoid overlaps with existing routes. If an overlap occurs, snap to the next available track by spreading the wires.
- Nondefault tracks: Specify this mode with the **-width** option.

- Trackless: Tracks are ignored and routes are created within the minimum spacing distance. Specify this mode with the **-do_not_snap_to_track** option.

The width of a given route trunk is width of the track on which it is placed, or the default track width if the **-do_not_snap_to_track** option is specified. If a net has a non-default routing rule (NDR) that requires a particular width on the layer, the route width is the NDR width and the NDR width takes precedence over the width specified by the **-width** argument. The spacing between route trunks can also be adjusted using NDR spacing. To adjust shielding, set the NDR shielding width and spacing.

The command supports multiple levels of physical hierarchy, can operate on a net within any block,and can create the corresponding routes within that block.

EXAMPLES

The following example creates trunks on vertical layer M2 starting from coordinate 8.4 with step of 2 and uses nonuniform track widths 0.4 and 0.6.

```
prompt> create_trunk -nets bus1 -layer M2 -track_coords {8.4} \
  -track_step 2 -width {0.4 0.6}
```

The following example creates route trunks on the M3 horizontal layer for four nets. The net1 net is placed on the third track above the bounding box defined by the **-track_ref_bbox** option. Successive route trunks are placed on every other track.

```
prompt> create_trunk -nets {net1 net2 net3 net4} -layer M3 -track_numbers 3 \
  -track_step 2 -track_ref_bbox {{100 100} {500 500}}
```

The following example creates route trunks on the M3 horizontal layer and moves them 40 microns in the x-direction and 10 microns in the y-direction. If obstructions exist in the new location, the route trunks are placed on the next available routing track.

```
prompt> create_trunk -nets {net1 net2 net3 net4} -layer M3 \
  -transform {40 10} -avoid_obstructions
```

[-verbose]
[-quiet]

Data Types

objects collection
layer_list list of strings
distance_list list of floating point numbers
distance float
rect_list list of rectangles
depth_value int

ARGUMENTS

-nets *objects*

Specifies the group of nets or bundles. The collection order is honored unless **-order** is specified which forces nets to be reordered.

-layer_legs *layer_list* | all

Specifies the layers for which to create segments. The tracks with default width are used by default. You can specify the list of track widths on which to place routes by using the following syntax:

-layer_legs {{{<layer1> {<width1> <width2> ... }} ... }

To use all tracks on a layer, specify **all** as follows:

-layer_legs {{{<layer1> all} ... }

-extensions *list*

Specifies the distance which to extend each segment. Extensions can be specified as a fraction of the net bounding box, a percentage of the net bounding box, in microns, or as user-defined units. The extensions list corresponds to a list of layer segments.

-start_from low_x | low_y | high_x | high_y

Specifies the relative pin location to start from. Segment lengths or percentages specified by the **-extensions** option are applied from the starting pin. Valid values are **low_y**, **low_x**, **high_y**, **high_x** as follows:

- **low_y** : Start from the bottommost pin (default)
- **low_x** : Start from the leftmost pin
- **high_y** : Start from the topmost pin
- **high_x** : Start from the rightmost pin

-order ascending | descending

Specifies the route ordering used when creating new orthogonal route segments. Valid values are **ascending** or **descending** as follows:

- **ascending** : Sort nets in ascending order at the turn based on the startpoint coordinates
- **descending** : Sort nets in descending order at the turn based on the startpoint coordinates

By default, the user-specified net or bundle order is preserved.

-hierarchical

Traces the net through the hierarchy and uses connections of all traced nets to determine the bounding box for the net for the user-specified topology.

-shield_type low | high | full | cap_shield

Specifies the shielding type. Valid values are **full**, **low**, **high**, **cap_shield** as follows:

- **low** : Shield each net on the low side
- **high** : Shield each net on the high side
- **full** : Shield each net on the both sides
- **cap_shield** : Shield the first net on the low side and last net on the high side

-shield_nets *objects*

Specifies the shielding net pattern. The nets in the shielding pattern are used cyclically.

-shield_pullback *distance*

Specifies the micron value to cut or extend the shield ends.

-avoid_obstructions

Finds the next free, unobstructed routing track to create the trunk. The command issues a warning message if the trunk is placed outside the net bounding box. Use the **-horizontal_freedom** and **-vertical_freedom** options expand the region where trunks could be shifted without creating a warning message.

By default, if an obstruction is found, the command skips the net and issues an LED-110 warning message.

-do_not_check_shorts

Avoids searching for obstructions. The option can be used for quick estimation and preview.

-do_not_snap_to_track

Avoids snapping the trunks to legal tracks.

-do_not_add_vias

Avoids adding vias. The option can be used if you are planning to insert clean vias using some other command as at the moment **create_trunk_pin_to_pin** does not check cut to cut via spacings. Please note that via metal enclosures are included in all spacing checks performed on trunks.

-horizontal_freedom *distance*

Expands the region horizontally where trunks could be shifted without issuing a warning message. The *distance* is in microns. This option allows route trunks to be created outside the boundary specified by the **-net_bbox_override** option. By default, the *distance* is zero, routes are created within the boundary, and nets are skipped if they do not fit in the bounding box.

-vertical_freedom *distance*

Expands the region vertically where trunks could be shifted without issuing a warning message. The *distance* is in microns. This option allows route trunks to be created outside the boundary specified by the **-net_bbox_override** option. By default, the *distance* is zero, routes are created within the boundary, and nets are skipped if they do not fit in the bounding box.

-start_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the starting pin. Specify a positive *distance* value to shorten the segment and prevent it from connecting to the pin. Specify a negative *distance* value to extend the segment beyond the pin.

-stop_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the ending pin. Specify a positive *distance* value to shorten the segment and prevent it from connecting to the pin. Specify a negative *distance* value to extend the segment beyond the pin.

-net_bbox_override *rect_list*

Specifies the net bounding box to use when creating the trunk. The actual bounding box for the net is ignored. The bounding box specified by this option is applied to all nets.

-of_cells *objects*

Specifies the cells to use to calculate the net bounding box. The option can be used in multi-fanout scenarios to cut unnecessary branches.

-exclude_cells *objects*

Excludes the specified cells when calculating the net bounding box. The option can be used in multi-fanout scenarios to cut unnecessary branches.

-create_obstruction

Creates a routing obstruction instead of path objects.

-skip_lib_cells

Do not descend into library cells to search for obstructions. This option must be used together with the **-avoid_obstructions** option.

-depth *depth_value*

Specifies the hierarchy depth to search for obstructions. By default, all levels of hierarchy are searched. This option must be used together with the **-avoid_obstructions** option.

-verbose

Print detailed information about warning and errors.

-quiet

Suppress all warnings

DESCRIPTION

This command creates trunks from one pin to another pin. The net can have one or more fanouts. The command can be used to create a straight connection for critical signals where traditional routers might struggle. Although it is not a router in classical terms, it can still ensure clean routing by shifting the routes. The command supports different routing topologies such as L, Z, U, and so on. Specify the topologies with the **-layer_legs** and **-extensions** options. The routing or wiring directions are determined primarily by the **-start_from** option.

The command supports the following operational modes:

- **Skip** mode (default): The trunks that cannot be routed are skipped and reported using **-verbose** option.
- **Dirty** mode: No checking on trunks which create violations with existing routes. Specify this mode with the **-do_not_check_shorts** option.
- **Clean** mode: In this case, no trunks should violate spacing. Specify this mode with the **-avoid_obstruction** option.

The command supports the following track snapping modes:

- Default tracks: Trunks should always snap to tracks without overlapping, if an overlap would occur, snap to the next available track by spreading the wires.
- Non default tracks: Specify this mode with the **-layer_legs {{{<layer1> {<width1> <width2> ... }} ... }** option.
- Trackless: Tracks are ignored and routes are created within the minimum spacing distance. Specify this mode with the **-do_not_snap_to_track** option.

The trunk routes derive width from underlying tracks or use the default width if **-do_not_snap_to_track** is specified. If the net has a non-default routing rule (NDR) that requires a width on the layer, the route width is set according NDR width and that width takes precedence over a **-layer_legs** argument for track lookup. The spacing between trunk routes can also be adjusted using NDR spacing. To adjust shielding user can set NDR shielding width and spacing.

The command supports multiple levels of physical hierarchy and can operate on a net within any block of a design and create the

corresponding routes within that block.

The command also supports cross-hierarchy routing for top-down flows. When the **-hierarchical** option is specified, the command traces the net across the hierarchy and uses connections of all traced nets to determine the bounding box for the net for the user-specified topology. All routes created would belong to a single top-level net. To finalize the routing, you must use the **push_down_objects** command to push the top-level routing into blocks the route intersects.

EXAMPLES

The following example creates an L-topology that connects pins on vertical layer M2 and horizontal layer M3. Each segment extends to fill 100% of net bounding box.

```
prompt> create_trunk_pin_to_pin -layer_legs {M2 M3} \
  -extensions {1 1}
```

The following example create the same route as the previous example but uses percentages to specify the extensions.

```
prompt> create_trunk_pin_to_pin -nets bus1 -layer_legs {M2 M3} \
  -extensions {100% 100%}
```

The following example uses an alternate syntax to specify absolute distances with either **u** or **d** suffixes:

```
prompt> create_trunk_pin_to_pin -nets bus1 -layer_legs {M2 M3} \
  -extensions {25.00u 25.00d}
```

The following example creates an L-topology route with track widths of 0.4 and 0.6 on layer M2. Routes on layer M3 can be created on tracks of any width.

```
prompt> create_trunk_pin_to_pin -nets bus1 \
  -layer_legs {{{M2 {0.4 0.6}} {M3 all}} -extensions {1 1}
```

SEE ALSO

Data Types

objects collection
layer collection
width collection
distance float
depth_value integer

ARGUMENTS

-nets *objects*

Specifies the group of nets or bundles to connect to pins and ports. The collection order is honored.

-layer *layer*

Specifies the layer for which to create trunks. If this option is omitted, the trunk layers are derived from pins and ports.

-direction horizontal | vertical

Specifies the routing direction. Valid values are **horizontal** and **vertical**. By default, the direction is the preferred direction for the layer.

-width *width*

Specifies the width of the routes to create. A float value specifies the absolute width of the routes. An integer value is multiplied by the pin width to determine the route width.

-min_layer *layer*

Specifies the minimum layer on which pin and port trunks can be routed. By default, the terminal layer is used unless it is lower than minimum layer.

-cluster_proximity *distance*

Specifies the range in microns within which to group individual pin-to-trunk route shapes to a single route shape. The command creates the route segment from the trunk, but might not complete the connection to the pin. By default, the *distance* is zero and the command connects each pin on the net to the trunk by its own route shape.

Pins are clustered together if the following conditions are met:

- Pins can be connected with the same wire
- Pins are located on the same side relative to the wire
- Pin projections to the wire is within the specified threshold distance

-hierarchical

Traces the net through the hierarchy and uses connections to all traced nets to determine the bounding box for the net for the user-specified topology.

-shield_type full | low | high | cap_shield

Specifies shielding types. Valid values are **full**, **low**, **high**, **cap_shield** as follows:

- **full** : shield each net on both sides
- **low** : shield each net on low side
- **high** : shield each net on high side
- **cap_shield** : shield first net on low side and last net on high side

-shield_nets *objects*

Specifies the shielding net pattern. The nets in shielding pattern are used cyclically.

-shield_pullback *distance*

Specifies the value in microns to cut or extend the shield ends.

-avoid_obstructions

Finds the next available, unobstructed routing track to create the trunk. The command issues a warning message if the trunk is placed outside the net bounding box. Use the **-horizontal_freedom** and **-vertical_freedom** options to expand the region where the command can shift trunks without issuing a warning message.

By default, if an obstruction is found, the command issues an LED-110 warning message, skips the net, and does not create a route trunk in the obstructed track.

-do_not_check_shorts

Ignores searching for obstructions. The option can be used for quick estimation and preview.

-do_not_snap_to_track

Avoids snapping to a legal track.

-do_not_add_vias

Avoids adding vias. The option can be used if you are planning to insert clean vias using some other command as at the moment **create_trunk_pin_to_trunk** does not check cut to cut via spacings. Please note that via metal enclosures are included in all spacing checks performed on trunks.

-horizontal_freedom *distance*

Expands the region where trunks could be shifted without warnings.

-vertical_freedom *distance*

Expands the region where trunks could be shifted without warnings.

-pullback *distance*

Specifies the distance in microns to cut or extend the trunks from pins and ports.

-of_cells *cells*

Specifies the cells to use to calculate the net bounding box. This option can be used for nets with large fanout to reduce the number of branches.

-exclude_cells *cells*

Excludes the specified cells when calculating the net bounding box. The option can be used for nets with large fanout to reduce the number of branches.

-create_obstruction

Creates a routing blockage instead of creating a route shape. The routing blockage is similar to a blockage created with the Create Routing Blockage tool or the **create_routing_blockage** command.

-skip_lib_cells

Do not descend into library cells to search for obstructions. This option must be used together with the **-avoid_obstructions** option.

-depth *depth_value*

Limits the level of hierarchy to search for obstructions. Specify a *depth_value* of zero to search only the top level. This option must be used together with the **-avoid_obstructions** option. By default, all levels of hierarchy are searched.

-verbose

Prints detailed information about warning and errors.

-quiet

Suppresses all warnings

DESCRIPTION

This command creates trunks for the specified nets on the layers derived from the pin or port shape for the net. The command can be used for straight connections for critical signals where traditional routers might struggle. Although it is not a router in classical terms, the command can still ensure clean routing by shifting the routes.

The command supports the following operational modes:

- **Skip** mode (default): The trunks that cannot be routed are skipped and reported using **-verbose** option.
- **Dirty** mode: No checking on trunks which create violations with existing routes. Specify this mode with the **-do_not_check_shorts** option.
- **Clean** mode: In this case, no trunks should violate spacing. Specify this mode with the **-avoid_obstructions** option.

The command supports the following track snapping modes:

- Default tracks: Trunks should always snap to tracks without overlapping, if an overlap would occur, snap to the next available track by spreading the wires.
- Non default tracks: Specify this mode with the **-width {<width1> <width2> ... }** option.
- Trackless: Tracks are ignored and routes are created within the minimum spacing distance. Specify this mode with the **-do_not_snap_to_track** option.

The width of the trunk routes is derived from the track width or the default width if the **-do_not_snap_to_track** option is specified. If a net has a nondefault routing rule (NDR) that requires a width on the layer, then the route width is set according to the NDR width and the NDR width takes precedence over the **-width** argument when assigning a track for the route. The spacing between trunk routes can also be adjusted using NDR spacing. To adjust shielding, set the NDR shielding width and spacing.

The command supports multiple levels of physical hierarchy and can operate on a net within any block of a design and create the corresponding routes within that block.

EXAMPLES

The following example creates trunks on vertical layer M2 starting from pins/ports of a specified set of nets to existing trunks. It uses nonuniform track widths 0.4 and 0.6.

```
prompt> create_trunk_pin_to_trunk -nets bus1 -layer M2 -width {0.4 0.6}
```

SEE ALSO

create_trunk(2)
create_trunk_pin_to_pin(2)
push_down_objects(2)

create_trunk_shared_track

Creates route trunks for the specified nets on same track in one direction.

SYNTAX

status **create_trunk_shared_track**
-nets *objects*
-layer *layer*
[-direction horizontal | vertical]
[-width *width_list* | all]
[-track_coord *distance*]
[-track_number *integer*]

[-shield_nets *objects*]
[-shield_pullback *distance*]
[-avoid_obstructions]
[-do_not_check_shorts]
[-do_not_snap_to_track]
[-track_freedom *distance*]
[-start_pullback *distance*]
[-stop_pullback *distance*]
[-gap *number*]
[-net_bbox_override *rect_list*]
[-of_cells *objects*]
[-exclude_cells *objects*]
[-create_obstruction]
[-skip_lib_cells]
[-depth *depth_value*]
[-verbose]
[-quiet]

Data Types

objects collection
layer collection
width_list list of strings
number integer
step integer
bounding_box list
distance float
rect_list list of rectangles
depth_value integer

ARGUMENTS

-nets *objects*

Specifies the group of nets for which to share the same track. The collection is reordered automatically based on net bounding boxes. It is assumed that bounding boxes of nets do not overlap or overlap a little. The typical scenario is creation of trunks for a set of net separated by repeaters.

-layer *layer*

Specifies the layer on which to create trunks.

-direction horizontal | vertical

Specifies the routing direction. Valid values are **horizontal** and **vertical**. By default, the direction is the preferred direction for the layer.

-width *width_list* | all

Specifies an unordered list of allowed track widths on which the tool can place a route trunk. Specify **-width all** to place route trunks on a track of any width. Nondefault routing rules take precedence over this option. By default, the command places route trunks only on tracks with the default width; tracks with a nondefault width are skipped.

The format of *width_list* is as follows:

-width width1
-width {width1 width2 ... }

If the *width_list* contains integer values, they are considered to be multiples of the default track width. If the *width_list* contains floating point values, they are considered to be absolute track widths. The following option and argument combinations are equivalent for a default track width of 0.25:

-width {1 2 3 4}
-width {0.25 0.5 0.75 1.0}

-track_coord *distance*

Specifies a single x- or y-coordinate on which to start placing the route trunk. The trunk is snapped to the closest track unless **-do_not_snap_to_track** is specified. The option is mutually exclusive with the **-track_number** option.

If the track is obstructed, the command issues an LED-110 warning message, skips the net, and does not create a route trunk in the obstructed track.

-track_number *number*

Specifies the track number on which to place route trunks. Numbering is relative to the cell boundary origin or the origin of the bounding box specified by the **-track_ref_bbox** option. This option is mutually exclusive with the **-track_coord**.

-track_ref_bbox *bounding_box*

Specifies the bounding box on which to start track counting. If the bounding box is too small to contain all the route trunks, the tool issues an LED-110 message, skips the nets outside the boundary, and does not create the routes for those nets.

-shield_type full | low | high | cap_shield

Specifies shielding types. Valid values are **full**, **low**, **high**, **cap_shield** as follows:

- *full* : Shield each net on both sides

- *low* : Shield each net on low side
- *high* : Shield each net on high side
- *cap_shield* : Shield first net on low side and last net on high side

-shield_nets *objects*

Specifies the shielding net pattern. The nets in shielding pattern are used cyclically.

-shield_pullback *distance*

Specifies the value in microns to cut or extend the shield ends.

-avoid_obstructions

Finds the next available, unobstructed routing track to create the trunk. The command issues a warning message if the trunk is placed outside the net bounding box. Use the **-track_freedom** option to expand the region where trunks can be shifted without warnings.

By default, if an obstruction is found, the command issues an LED-110 warning message, skips the net, and does not create a route trunk in the obstructed track.

-do_not_check_shorts

Creates route trunks that might create a short circuit with an existing route and overlap route obstructions. Use this option for a quick estimation and preview of route trunk placement without checking for shorts and obstructions.

-do_not_snap_to_track

Avoids snapping to a legal track. By default, route trunks are snapped to tracks.

-track_freedom *distance*

Expands the region where trunks could be shifted without issuing a warning message. This option allows route trunks to be created outside the boundary specified by the **-track_ref_bbox** option or the bounding box defined by the pin connections for the specified nets. You must specify the **-avoid_obstructions** option together with the **-track_freedom** option. By default, tracks are placed within the boundary.

-start_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the starting point derived from net bbox (left or bottom). The positive *distance* value will shorten the segment, while the negative *distance* value will extend the segment.

-stop_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the stop point derived from net bbox (right or top). The positive *distance* value will shorten the segment, while the negative *distance* value will extend the segment.

-gap *number*

Specifies spacing multiplier to put a gap between trunks on a track.

-net_bbox_override *rect_list*

Specifies the net bounding box to use when creating the trunk. The actual bounding box for the net is ignored. The bounding box specified by this option is applied to all nets.

-of_cells *cells*

Specifies the cells to use to calculate the net bounding box. The option can be used in multi-fanout scenarios to cut unnecessary branches.

-exclude_cells *cells*

Excludes the specified cells when calculating the net bounding box. This option can be used on nets with multiple fanouts to remove unnecessary branches.

-create_obstruction

Creates a routing blockage instead of creating a route shape. The routing blockage is similar to a blockage created with the Create Routing Blockage tool or the **create_routing_blockage** command.

To create the route trunk and move it, specify **-transform {x y}** where x and y are the x- and y-distances in microns to move the trunks. To change the orientation of the route trunk, specify **-transform {orientation}**, where orientation is one of MX, MXR90, MY, MYR90, R0, R180, R270, and R90.

To combine two transformations, specify the delta and orientation transformations in the same list. For example, to specify that the route trunk is rotated 270 degrees and moved to the right by 10 microns, specify **-transform {{R270} {10 0}}**.

-skip_lib_cells

Do not descend into library cells to search for obstructions. This option must be used together with the **-avoid_obstructions** option. By default, the command checks for obstructions within library cells.

-depth *depth_value*

Limits the level of hierarchy to search for obstructions. Specify a *depth_value* of zero to search only the top level. This option must be used together with the **-avoid_obstructions** option. By default, all levels of hierarchy are searched.

-verbose

Prints detailed information about warning and errors.

-quiet

Suppresses all warning messages.

DESCRIPTION

This command creates trunks for the specified nets on a single layer in one direction. The command can be used for straight connections for critical signals where traditional routers might struggle. Although it is not a router in classical terms, the command can still ensure clean routing by shifting the routes.

The command supports the following operational modes:

- **Skip** mode (default): The trunks that cannot be routed are skipped and reported using **-verbose** option.
- **Dirty** mode: No checking on trunks which create violations with existing routes. Specify this mode with the **-do_not_check_shorts** option.
- **Clean** mode: In this case, no trunks should violate spacing. Specify this mode with the **-avoid_obstruction** option.

The command supports the following track snapping modes:

- Default tracks: Trunks should always snap to tracks and avoid overlaps with existing routes. If an overlap occurs, snap to the next available track by spreading the wires.
- Nondefault tracks: Specify this mode with the **-width** option.
- Trackless: Tracks are ignored and routes are created within the minimum spacing distance. Specify this mode with the **-**

do_not_snap_to_track option.

The width of a given route trunk is width of the track on which it is placed, or the default track width if the **-do_not_snap_to_track** option is specified. If a net has a non-default routing rule (NDR) that requires a particular width on the layer, the route width is the NDR width and the NDR width takes precedence over the width specified by the **-width** argument. The spacing between route trunks can also be adjusted using NDR spacing. To adjust shielding, set the NDR shielding width and spacing.

The command supports multiple levels of physical hierarchy, can operate on a net within any block,and can create the corresponding routes within that block.

EXAMPLES

The following example creates trunks for four nets on vertical layer M2. The trunks are placed on nonuniform track of a given widths (0.4 or 0.6) nearest to coordinate 8.4.

```
prompt> create_trunk_shared_track -nets {net1 net2 net3 net4} \
    -layer M2 -track_coord {8.4} -width {0.4 0.6}
```

create_trunk_topology

Creates trunks from a topology edge.

SYNTAX

status **create_trunk_topology**
[-plan *plan*]
[-edge *edge*]
[-shield_type low | high | full | cap_shield]
[-shield_nets *objects*]
[-shield_pullback *distance*]
[-avoid_obstructions]
[-do_not_check_shorts]
[-do_not_snap_to_track]
[-do_not_add_vias]
[-horizontal_freedom *distance*]
[-vertical_freedom *distance*]
[-start_pullback *distance*]
[-stop_pullback *distance*]
[-skip_lib_cells]
[-verbose]
[-quiet]

Data Types

edge name or collection
objects names or collection
distance float

ARGUMENTS

-plan *object*

Specifies the topology plan name or collection to create trunks for. This option is mutually exclusive with **-edge** option.

-edge *object*

Specifies the topology edge name or collection to create trunks for. This option is mutually exclusive with **-plan** option. There are currently two types of edges that are fully supported.

- Both edge nodes have explicit or implicit associations with pins and **shape_layers** attribute specifies rectilinear path between them.
- One of the nodes is tap node associated with another edge, while other node is associated with pins. Only straight connection is currently possible for such an edge.

-shield_type low | high | full | cap_shield

Specifies the shielding type. Valid values are **full**, **low**, **high**, **cap_shield** as follows:

- **low** : Shield each net on the low side
- **high** : Shield each net on the high side
- **full** : Shield each net on the both sides
- **cap_shield** : Shield the first net on the low side and last net on the high side

-shield_nets *objects*

Specifies the shielding net pattern. The nets in the shielding pattern are used cyclically.

-shield_pullback *distance*

Specifies the micron value to cut or extend the shield ends.

-avoid_obstructions

Finds the next free, unobstructed routing track to create the trunk. The command issues a warning message if the trunk is placed outside the net bounding box. Use the **-horizontal_freedom** and **-vertical_freedom** options expand the region where trunks could be shifted without creating a warning message.

By default, if an obstruction is found, the command skips the net and issues an LED-110 warning message.

-do_not_check_shorts

Avoids searching for obstructions. The option can be used for quick estimation and preview.

-do_not_snap_to_track

Avoids snapping the trunks to legal tracks.

-do_not_add_vias

Avoids adding vias. The option can be used if you are planning to insert clean vias using some other command as at the moment **create_trunk_topology** does not check cut to cut via spacings. Please note that via metal enclosures are included in all spacing checks performed on trunks.

-horizontal_freedom *distance*

Expands the region horizontally where trunks could be shifted without issuing a warning message. The *distance* is in microns. This option allows route trunks to be created outside the boundary specified by the **-net_bbox_override** option. By default, the *distance* is zero, routes are created within the boundary, and nets are skipped if they do not fit in the bounding box.

-vertical_freedom *distance*

Expands the region vertically where trunks could be shifted without issuing a warning message. The *distance* is in microns. This option allows route trunks to be created outside the boundary specified by the **-net_bbox_override** option. By default, the *distance* is zero, routes are created within the boundary, and nets are skipped if they do not fit in the bounding box.

-start_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the starting pin. Specify a positive *distance* value to shorten the segment and prevent it from connecting to the pin. Specify a negative *distance* value to extend the segment beyond the pin.

-stop_pullback *distance*

Specifies the distance in microns to shorten or extend the trunk at the ending pin. Specify a positive *distance* value to shorten the segment and prevent it from connecting to the pin. Specify a negative *distance* value to extend the segment beyond the pin.

-skip_lib_cells

Do not descend into library cells to search for obstructions. This option must be used together with the **-avoid_obstructions** option.

-verbose

Print detailed information about warning and errors.

-quiet

Suppress all warnings

DESCRIPTION

The command creates trunks for a topology edge. It can be used to create a straight connection for critical signals where traditional routers might struggle. Although it is not a router in classical terms, it can still ensure clean routing by shifting the routes. The command supports different routing topologies such as L, Z, U, and so on.

This command is slightly different semantically compared to sibling command **create_trunk_pin_to_pin** as it supports corner styles and specification of reference bit. It also has fewer options as many important arguments are derived from a single **-edge** option. Here is the list of implicitly derived options:

- Nets and supernets or bundles of nets and supernets are derived from a topology edge, topology plan or pins of a start topology node.
- Routing layers and distances have to be specified as topology edge attribute **shape_layers**
- Start and end pins simply correspond to start and end node of a specified edge
- Reference bit alignment is derived from **alignment** attribute of start topology node. By default the alignment is **center** and attribute **alignment** is unset. User can set it to **left** or **right**. It defines routing bit order and shifting directions.
- The bus corner style is derived from **corner_style** attribute of start topology node. By default the corner type is **cross** and it can also be set to **river**

The command supports the following operational modes:

- **Skip** mode (default): The trunks that cannot be routed are skipped and reported using **-verbose** option.
- **Dirty** mode: No checking on trunks which create violations with existing routes. Specify this mode with the **-do_not_check_shorts** option.
- **Clean** mode: In this case, no trunks should violate spacing. Specify this mode with the **-avoid_obstruction** option.

The command supports the following track snapping modes:

- Tracks: Trunks should always snap to tracks without overlapping, if an overlap would occur, snap to the next available track by spreading the wires.
- Trackless: Tracks are ignored and routes are created within the minimum spacing distance. Specify this mode with the **-do_not_snap_to_track** option.

The trunk routes derive width from underlying tracks or use the default width if **-do_not_snap_to_track** is specified. If the net has a non-default routing rule (NDR) that requires a width on the layer, the route width is set according NDR width. The spacing between trunk routes can also be adjusted using NDR spacing. To adjust shielding user can set NDR shielding width and spacing.

The command supports multiple levels of physical hierarchy and can operate on a net within any block of a design and create the

corresponding routes within that block.

The command also supports cross-hierarchy routing for top-down flows. The command traces the net across the hierarchy and uses connections of all traced nets to determine the bounding box for the net for the user-specified topology. All routes created would belong to a single top-level net. To finalize the routing, you must use the **push_down_objects** command to push the top-level routing into blocks the route intersects.

EXAMPLES

The following set of commands create a Z-topology connecting pins using layers M2 and M3.

```
prompt> create_topology_edge -name E12 -plan TP1 -nodes {TP1/N1 TP1/N2} \
      -shape_layers {{METAL3 50% 0} {METAL2 100% 0} {METAL3 50% 0}}
prompt> create_trunk_topology -edge TP1/E12
```

array_name string
llx float
lly float
urx float
ury float
polyrect list
dx float
dy float
columns integer
rows integer
x float
y float

ARGUMENTS

-via_def *TSV_via_def_name*

Specifies the TSV via def. This is a required option.

-name *array_name*

Specifies the TSV array name.

-bbox { {*llx lly*} {*urx ury*} }

Specifies the region in which to place the TSV. This option and the **-boundary** option are mutually exclusive. If neither this option

nor **-boundary** option is used, the entire design area is used.

-boundary ***polyrect***

Specifies a *polyrect* region in which to place the TSV. This option and the **-bbox** option are mutually exclusive. If neither this option nor **-bbox** option is used, the entire design area is used. The *polyrect* is described as a list of location coordinates.

-delta {*dx dy*}

Specifies the horizontal pitch (*dx*) between adjacent columns and the vertical pitch (*dy*) between adjacent rows. Min delta value is {cutWidth+minCutSpacing, cutHeight+minCutSpacing}. This is a required option.

-pattern inline | staggered_1 | staggered_2

Specifies the placement pattern of the TSV. Valid values for this option are: inline, staggered_1, and staggered_2. The inline argument places TSV at every grid point. The staggered_1 argument places TSV only at grid points where the sum of column index and row index is even. The staggered_2 argument places TSV only at grid points where the sum of column index and row index is odd. If this option is not specified, the command creates an inline TSV array.

-repeat {*columns rows*}

Specifies the total number of columns and rows in the TSV array. The command does not create TSV outside of the TSV array bounding box, even if you specify a column or row count beyond the bounding box. If this option is not specified, the command fills the bounding box or design area with TSV.

-origin {*x y*}

Specifies the spacing between the lower-left corner of TSV array bounding box and the lower-left corner of the bounding box of the TSV located at column 0 and row 0. If this option is not specified, the command derives the origin so that the TSV array is centered in the bounding box.

-orientation R0 | R90 | R180 | R270 | MY | MXR90 | MX | MYR90

Specifies the orientation of all TSVs in the array. If this option is not specified, the default orientation is R0.

DESCRIPTION

This command creates an array of TSV.

EXAMPLES

The following example creates a TSV array.

prompt> **create_tsv_array -via_def VIAB1 -delta {25 25} -bbox {{10 10} {120 120}}**

SEE ALSO

assign_3d_interchip_nets(2)
assign_tsv(2)

create_undo_marker

Create a named marker that can be used to undo or redo to.

SYNTAX

string **create_undo_marker**
marker_name

Data Types

marker_name string

ARGUMENTS

marker_name

The user name for the new marker.

DESCRIPTION

This command creates a user-named undo marker. Undo markers identify points in the command execution history that can be undone or redone to. It is an error to specify a name for which a marker already exists.

This command creates a user marker. Markers are also created automatically by the undo system whenever an undoable command is executed. Both user and system markers get an automatically-generated system name (distinct from *marker_name*) of the form *SNPS_MARKER_#*. It is an error to specify a user name that has the same form as system names.

Note that markers may automatically become invalid if the undo history is cleared or truncated. The undo history is cleared whenever a non-undoable command is executed, or if the undo system has been disabled via the *undo.enabled* app option. The undo history is automatically truncated based on the size limits imposed by the *undo.max_levels* and *undo.max_memory* app options, and may be truncated in the redo direction if a state-changing command is executed while not at the latest point in the command history.

EXAMPLES

The following creates a marker named *my_marker*:

```
prompt> create_undo_marker my_marker
my_marker
```

create_upf2hdl_vct

Defines a value conversion table that can be used to convert UPF supply_net_type values into HDL logic values. This command is supported only in UPF mode.

SYNTAX

status **create_upfhdl_vct**
name
-hdl_type {<vhdl | sv> [*typename*]}
-table {{*from_value to_value*}*}

Data Types

vct_name string
typename string
from_value UPF state type
to_value HDL logic

ARGUMENTS

vct_name

The value conversion table name.

-hdl_type *{<vhdl|sv> typename}*

The HDL type for which the value conversions are defined.

-table *{{<from_value> <to_value>}*}*

A list of UPF state type values to map to the values of the HDL type.

DESCRIPTION

The *create_upf2hdl_vct* command defines a value conversion table for *supply_net_type.state* value when that value is propagated from a UPF supply net into a logic port defined in an HDL. It provides a 1:1 conversion for each possible combination of the partially on and on/off states. *create_upf2hdl_vct* does not check that the values are compatible with any HDL port type.

vct_name provides a name for the value conversion table for later use with the *connect_supply_net* command.

-hdl_type specifies the HDL type for which the value conversions are defined. This information allows a tool to provide completeness and compatibility checks.If the typename is not one of the language's predefined types or one of the types specified in

the next paragraph, then it shall be of the form library.pkg.type.

The following HDL types shall be the minimum set of types supported:

a) VHDL

1) Bit, std_[u]logic, Boolean

2) Subtypes of std_[u]logic

b) SystemVerilog reg/wire, Bit, Logic

-table defines the 1:1 conversions from UPF supply net states to an HDL logic value. The values shall be consistent with the HDL type values.

For example:

- When converting to SystemVerilog logic type, the set of legal values is 0, 1, X, and Z.

- When converting to SystemVerilog or VHDL bit, the legal values are 0 or 1.

- When converting to VHDL std_[u]logic, the legal values are U, X, 0, 1, Z, W, L, H, and -.

The conversion values have no semantic meaning in UPF. The meaning of the conversion value is relevant to the power-aware HDL model to which the supply net is connected.

SEE ALSO

create_hdl2upf_vct(2)
connect_supply_net(2)

create_utilization_configuration

Creates a new utilization configuration.

SYNTAX

create_utilization_configuration
[-capacity *capacity_type*]
[-include *object_type*]
[-exclude *object_type*]
[-scope *config_scope*]
[-as_user_default]
[-force]
config_name

Data Types

capacity_type	string
object_type	string
config_scope	string
config_name	string

ARGUMENTS

-capacity *capacity_type*

Utilization to be based on the given type. The supported types are:

core_area
The core area of the given block will be considered as capacity.

boundary
The boundary of the given block will be considered as capacity.

site_array
If a default site-array is defined for the given block that will be considered as capacity. In the absence of a default site array, the bottom-most site-array will be used as capacity.

site_row
The aggregate area of all the site-rows defined in the block will be considered as capacity. The site-rows belonging to site-arrays will also be considered with this option. This is the default capacity type.

-include *object_type*

Types of objects to be included in utilization computation. The inclusion and exclusion object_type categories must be distinct. Any object_type specified with the -include option can not be repeated with the -exclude option of the same command. The supported types are:

hard_macros
macro_keepouts
soft_macros
io_cells
fixed_cells
physical_only_cells
hard_blockages
soft_blockages
pg_straps
spare_cells
flip_chip_bump_cells
cell_spacing
all (all of the above)
none (none of the above)

-exclude *object_type*

Types of objects to be excluded from utilization computation. The exclusion and inclusion object_type categories must be distinct. Any object_type specified with the -exclude option can not be repeated with the -include option of the same command. The supported types are:

hard_macros
macro_keepouts
soft_macros
io_cells
fixed_cells
physical_only_cells
hard_blockages
soft_blockages
pg_straps
spare_cells
flip_chip_bump_cells
cell_spacing
all (all of the above)
none (none of the above)

-scope *config_scope*

Determines the place where the configuration needs to be stored, thereby controlling the scope of the configuration.

The allowed values for the library-manager shell are:

tech
The tech assocaited with the current library in the workspace. The configurations stored in the tech can be accessed from all the libraries, the tech will be associated with. This is also the default value for this option.

lib
The current library in the workspace.

The allowed values for the design shell are:

tech
The tech associated with the current design-library. The configurations

stored in the tech, can be accessed from all the libraries, the tech will be associated with.

lib
The current design-library. The configurations stored in the library can be accessed from all the designs in this library. This is also the default value for this option.

block
The current block.

-as_user_default

Creates user defined default configuration for utilization reporting.

-force

Force overwrite the existing configuration.

config_name

Specify the name of the configuration

DESCRIPTION

This command can be used to create configurations which control the way the utilization will be calculated/reported. The default configuration has capacity type based on block's core-area and no exclusions.

The configurations created with this command can be passed to the utilization reporting command **report_utilization**

If a configuration with same name or capacity and exclusion values already exists, then the command stops reporting a warning. However, the '-force' option can be used to overwrite the existing configurations.

EXAMPLES

The following example creates a configuration by name config1 with default values and stores it in the current design-library.

```
prompt> create_utilization_configuration config1
```

The following example creates a configuration, in the current block, by name config2 for which the utilization of a block, with respect to its default site-array, will be reported by excluding hard and soft placement blockages.

```
prompt> create_utilization_configuration config2 -scope block \
  -capacity site_array -exclude {hard_blockages soft_blockages}
```

report_utilization(2)

create_via

Creates a via in the current design.

SYNTAX

collection **create_via**
-via_def *definition_name*
-origin {*x y*}
[-orientation *orientation*]
[-pitch {*horizontal vertical*}]
[-size {*rows columns*}]
[-cut_pattern *cut_pattern*]
[-shape_use *use*]
[-net *net*]
[-port *port*]
[-lower_mask_constraint *lower_mask*]
[-cut_mask_constraint *cut_mask*]
[-upper_mask_constraint *upper_mask*]

Data Types

definition_name string
x float
y float
orientation string
horizontal float
vertical float
rows integer
columns integer
cut_pattern string
use string
net collection
port collection
lower_mask string
cut_mask string
upper_mask string

ARGUMENTS

-via_def *definition_name*

Specifies the simple or custom via definition from which to create a via.

-origin {*x y*}

Specifies the placement location of the via's origin (i.e., its center).

-orientation *orientation*

Specifies the orientation of the via. Valid values are MX, MXR90, MY, MYR90, R0, R180, R270, and R90. Default orientation is R0.

-pitch {*horizontal vertical*}

Specifies the horizontal and vertical pitch values between cuts of a simple array via. The values must be non-negative. When not specified, the default pitch values are obtained from the via definition.

-size {*rows columns*}

Specifies the number of rows and columns (i.e., cut array size) in a simple array via. The values must be 1 or greater. When not specified, the default cut array size is 1x1. When the size is 1x1, a simple via is created instead of a simple array via.

-cut_pattern *cut_pattern*

Specifies the cut pattern in a simple array via. If specified, this cut pattern overrides the via_def cut pattern. If not specified, the array via inherits the cut pattern from the via_def. The pattern defines a MxN pattern of cuts. If the pattern is smaller than the array via size, the pattern is replicated left-to-right, bottom-to-top in the array via. Excess bits in the pattern are ignored. The pattern is formatted as a space delimited string of equal length substrings (e.g., "1010 0101 1011" is a 3x4 pattern). Each substring must consist of only 1s and 0s, representing a row in the MxN pattern, starting with the bottom row in the pattern. A 1 means the cut is included. A 0 means the cut is omitted.

-shape_use *use*

Specifies the usage of the via. Valid values are area_fill, core_wire, detail_route, follow_pin, global_route, lib_cell_pin_connect, macro_pin_connect, opc, pg_augmentation, ring, shield_route, stripe, user_route, and zero_skew. Default value is detail_route.

-net *net*

Specifies the net that owns this via. If the net is power or ground, the via rule_type attribute is automatically set to "none". Otherwise it is set to "default".

The *-net* and **-port** options are mutually exclusive. A via may be owned by either a net or port, but not both.

-port *port*

Specifies the port that owns this via. The *-net* and **-port** options are mutually exclusive. A via may be owned by either a net or port, but not both.

-lower_mask_constraint *lower_mask*

Specifies the lower mask constraint of the via. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. Default lower mask constraint is no_mask for simple vias. For custom vias, the default lower mask constraint is inherited from the via_def.

-cut_mask_constraint *cut_mask*

Specifies the cut mask constraint of the via. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, mask_five, mask_six, mask_seven, mask_eight, mask_nine, mask_ten, mask_eleven, mask_twelve, mask_thirteen, mask_fourteen, mask_fifteen and same_mask. Default cut mask constraint is no_mask for simple vias. For custom vias, the default cut mask constraint is inherited from the via_def.

-upper_mask_constraint *upper_mask*

Specifies the upper mask constraint of the via. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. Default upper mask constraint is no_mask for simple vias. For custom vias, the default upper mask constraint is

inherited from the via_def.

DESCRIPTION

This command creates a new via and returns a collection containing the new via. Simple, simple array, and custom vias are supported.

A simple via is defined as a single-cut instance of a simple via definition. To create a simple via, specify a simple via definition and origin. The orientation and use may be optionally specified.

A simple array via is defined as a multi-cut instance of a simple via definition. To create a simple array via, specify a simple via definition, origin, and cut array size greater than 1x1. The orientation, pitch values, and use may be optionally specified.

A custom via is defined as an instance of a custom via definition. To create a custom via, specify a custom via definition and origin. The orientation and use may be optionally specified.

A via may be assigned to either a net or port, but not both at the same time. Once assigned, the net or port owns the via. When a via is assigned to a port, a new terminal is created. The new terminal is owned by the port, owns the via, has the default access direction (i.e., all), and has the default auto-generated name.

EXAMPLES

The following example creates a simple via on a net.

```
prompt> create_via -via_def VIA12 -origin {1000.100 200.320} -net Clk
```

The following example creates a simple array via. Its cut pattern is inherited from the via_def.

```
prompt> create_via -via_def VIA12 -origin {1000.100 200.320}
-size {10 10} -pitch {100 200}]
```

The following example creates a custom via on a port.

```
prompt> create_via -via_def CUSTOM_FATVIA12 -origin {3000.100 400.000}
-port Clk
```

The following example creates a 5x5 simple array via with a 2x2 cut pattern. The resulting array via has an alternating cut pattern, in which the lower-left cut is included.

```
prompt> create_via -via_def VIA12 -origin {100 200} -size {5 5}
-pitch {100 200} -cut_pattern "10 01"]
```

The following example creates a 5x5 simple array via with a 5x5 cut pattern, in which the 4 cuts in the upper-right corner of the via is omitted.

```
prompt> create_via -via_def VIA12 -origin {100 200} -size {5 5}
-pitch {100 200} -cut_pattern "11111 11111 11111 11100 11100"]
```

[-redundant_via_insertion_only]

Data Types

definition_name string
design collection
library collection
tech collection
shape_list collection
layer collection
horizontal float
vertical float
rows integer
columns integer
spacing float
cut_pattern string
contact_source_type string
mask_pattern string

upper_mask_pattern string
lower_mask_pattern string

ARGUMENTS

via_def_name *definition_name*

Specifies the name of the simple or custom via_def to create.

-design *design*

Specifies the block in which to create the via_def. If neither a design nor technology file is specified, the via_def is written to the current block.

-library *library*

Specifies the technology library in which to create the via_def. The technology library contained by or referenced by the given library is used. If neither a design nor technology file is specified, the current block is used.

-tech *tech*

Specifies the technology file in which to create the via_def. If neither a design nor technology file is specified, the current block is used.

-force

Forces replacement of an existing via_def of the same name. By default, attempting to create a via_def with an existing name is an error.

-shapes *shape_list*

Specifies a collection of shapes from which to create a custom via_def. The mask constraint is optional and mutual exclusive with the options mask_pattern, -upper_mask_pattern and lower_mask_pattern. The valid values for cut shape are no_mask, mask_one, mask_two, mask_three, mask_four, mask_five, mask_six, mask_seven, mask_eight, mask_nine, mask_ten, mask_eleven, mask_twelve, mask_thirteen, mask_fourteen, mask_fifteen and same_mask, and the default value is no_mask. The valid values for metal shape are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. Default mask constraint is no_mask.This option is mutually exclusive with **-cut_layer** and the other options which parameterize a simple via_def.

-lower_layer *layer*

Specifies the lower layer of a via_def.

This argument is required if creating a through-silicon via ("TSV") def. If specified for other via_def types, it must match what would be automatically determined given the specified cut layer and other arguments. Note that this command creates a through-silicon via_def if and only if its *-tsv_keepout_spacing* argument is specified.

-cut_layer *layer*

Specifies the cut layer of a simple via_def.

-upper_layer *layer*

Specifies the upper layer of a via_def.

This argument is required if creating a through-silicon via ("TSV") def. If specified for other via_def types, it must match what would be automatically determined given the specified cut layer and other arguments. Note that this command creates a through-

silicon via_def if and only if its *-tsv_keepout_spacing* argument is specified.

-cut_size {*horizontal vertical*}

Specifies the cut size of a simple via_def.

-lower_enclosure {*horizontal vertical*}

Specifies the lower enclosure size of a simple via_def.

-upper_enclosure {*horizontal vertical*}

Specifies the upper enclosure size of a simple via_def.

-min_rows *rows*

Specifies the minimum number of rows allowed in an array simple via created with this via_def.

-min_columns *columns*

Specifies the minimum number of columns allowed in an array simple via created with this via_def.

-min_cut_spacing *spacing*

Specifies the minimum cut spacing allowed in an array simple via created with this via_def.

-tsv_keepout_spacing *spacing*

Specifies the TSV keepout spacing allowed in a through-silicon via ("TSV") cell created with this via_def.

Note that this command creates a via_def of type "through_silicon_via_def" if and only if this argument is specified.

-cut_pattern *cut_pattern*

Specifies the default cut pattern on an array via created from this simple via_def. If not specified, the array via has a full array of cuts (i.e., no cuts are omitted). If specified, the pattern defines a MxN pattern of cuts. If the pattern is smaller than the array via size, the pattern is replicated left-to-right, bottom-to-top in the array via. Excess bits in the pattern are ignored. The pattern is formatted as a space delimited string of equal length substrings (e.g., "1010 0101 1011" is a 3x4 pattern). Each substring must consist of only 1s and 0s, representing a row in the MxN pattern, starting with the bottom row in the pattern. A 1 means the cut is included. A 0 means the cut is omitted.

-is_default

Specifies whether this via_def is a default via_def for the given metal layers. Only a simple via_def can be a default via_def.

-source_type *contact_source_type*

Specifies the contact source type for this via_def. Allowed values are generated, generated_for_special_nets, multiple_cut, multiple_cut_fixed, single_cut and single_cut_fixed. The default is single_cut_fixed.

-is_excluded_for_signal_route

Specifies whether this via_def can be used by the router for signal route vias or whether it is restricted for use for power vias.

-mask_pattern *mask_pattern*

Specifies the cut layer mask pattern of via_def in a multiple-patterning technology. Valid values are alternate_columns, alternate_rows, alternating and uniform. The default is uniform, which means adjacent cut shapes are assigned the same color; alternating means that adjacent cut shapes are assigned successive colors; alternate_columns means the cut shapes in alternating columns are assigned same colors and the colors of cut shapes in successive columns are successive; alternate_rows means the cut shapes in alternating rows are assigned same colors and the colors of cut shapes in successive columns are successive.

-upper_mask_pattern ***upper_mask_pattern***

Specifies the upper layer mask pattern of via_def in a multiple-patterning technology. Valid values are alternating and uniform. Default is uniform.

-lower_mask_pattern ***lower_mask_pattern***

Specifies the lower layer mask pattern of via_def in a multiple-patterning technology. Valid values are alternating and uniform. Default is uniform.

-is_excluded_for_signal_route

Specifies whether this via_def can only be used by the router for redundant via insertion.

DESCRIPTION

This command creates a new via_def in either block or a tech and returns a collection containing the new via_def. Simple, simple array and custom via_defs are supported.

A simple via_def defines a single_cut simple via. It is specified by a cut layer and the height and width of the rectangular shapes on its cut and metal layers. The metal layers are inferred from the cut layer using the mask order of the layers in the technology.

A simple array via_def defines a multiple-cut simple via. To create a simple array via_def, one or more of min_columns, min_rows or min_cut_spacing must be specified.

A custom via_def defines a custom via from an arbitrary collection of Manhattan polygons. The cut layers, upper metal layer, lower metal layer and the shape mask constraint of the via_def are inferred from the given collection of shapes.

EXAMPLES

The following example creates a simple via_def in the current block with an alternating cut pattern, in which the lower-left cut is included.

```
prompt> create_via_def VIA12_FAT -cut_layer VIA1 -cut_size {100 100} \
  -upper_enclosure {200 200} -lower_enclosure {200 200} \
  -cut_pattern "10" -is_default
```

The following example creates a simple array via_def with a full cut array.

```
prompt> create_via_def VIA12_FAT -cut_layer VIA1 -cut_size {100 100} \
  -upper_enclosure {200 200} -lower_enclosure {200 200} -is_default \
  -min_rows 2 -min_columns 2 -min_cut_spacing 0.2
```

The following example creates a custom via_def.

```
prompt> create_via_def CUSTOM1 -shapes { {M1 {0 0} {0 1} {1 1} {1 0}} \
  {VIA1 {0.5 0.5} {0.7 0.7}} {M2 {0 0} {1 1}} }
```

The following example creates a custom via_def with shape mask constraints.

```
prompt> create_via_def CUSTOM1 -shapes { {M1 {0 0} {0 1} {1 1} {1 0} mask_one} \
  {VIA1 {0.5 0.5} {0.7 0.7} mask_two} {M2 {0 0} {1 1} mask_two} }
```

SEE ALSO

get_via_defs(2)
report_via_defs(2)

create_via_ladder

Creates a via ladder in the current design.

SYNTAX

collection **create_via_ladder**
-shapes *shape_list*
[-via_rule *via_rule_name*]
[-electromigration *boolean_option*]
[-pattern_must_join *boolean_option*]
[-high_performance *boolean_option*]
[-pin *pin*]

Data Types

shape_list collection
via_rule_name string
boolean_option boolean
pin string

ARGUMENTS

-shapes *shape_list*

Specifies a list of shapes to be added to the via ladder object. The list may contain shape collections, specified using the **get_shapes** command. All the shapes (vias and layer shapes) must be connected to the same net. This is a required option for this command.

-via_rule *via_rule_name*

A string value which represents the via rule name for the created via ladder. It has a default value of empty string.

-electromigration *boolean_option*

A boolean value which represents the type of via ladder. If this is set to true, then the via ladder is of type 'Electromigration'. It has a default value false.

-high_performance *boolean_option*

A boolean value which represents the type of via ladder. If this is set to true, then the via ladder is of type 'High Performance'. It has a default value false.

-pattern_must_join *boolean_option*

A boolean value which represents the type of via ladder. If this is set to true, then the via ladder is of type 'Pattern Must Join'. It has

a default value false.

-pin ***pin***

A string value which represents the pin for the created via ladder. It should be a physical pin.

DESCRIPTION

This command creates a new via ladder object and returns a collection containing the new via ladder.

EXAMPLES

The following example creates a via ladder with list of shapes.

```
prompt> create_via_ladder -shapes {PATH_31_1 VIA_S_70} \
  -via_rule rule_1 -electromigration -pin icc_route2/VDD
{VIA_LADDER_0}
```

The following example creates a via ladder with collection of shapes returned by get_shapes command.

```
prompt> create_via_ladder -shapes [get_shapes *] \
  -via_rule rule_2 -high_performance -pattern_must_join
{VIA_LADDER_1}
```

base_horizontal float

base_vertical float
base_rows integer
base_columns integer

ARGUMENTS

-via_def *definition_name*

Specifies the simple or custom via definition from which to create a via matrix.

-origin {*x y*}

Specifies the placement location of the via matrix's origin (i.e., center of lower-left base via).

-pitch {*horizontal vertical*}

Specifies the horizontal and vertical pitch values between base vias of a via matrix.

-size {*rows columns*}

Specifies the number of rows and columns (i.e., base via array size) in a via matrix. The values must be 1 or greater and at least one of them is greater than 1.

-base_pattern *base_pattern*

Specifies the cut pattern in a base via of the via matrix. If specified, this cut pattern overrides the via_def cut pattern. If not specified, the array via inherits the cut pattern from the via_def. The pattern defines a MxN pattern of cuts. If the pattern is smaller than the array via size, the pattern is replicated left-to-right, bottom-to-top in the base array via. Excess bits in the pattern are ignored. The pattern is formatted as a space delimited string of equal length substrings (e.g., "1010 0101 1011" is a 3x4 pattern). Each substring must consist of only 1s and 0s, representing a row in the MxN pattern, starting with the bottom row in the pattern. A 1 means the cut is included. A 0 means the cut is omitted.

-lower_mask_pattern *lower_mask_pattern*

Specifies the lower layer mask pattern of base vias in the via_matrix in a multiple-patterning technology. Valid values are arbitrary, uniform, alternate_columns and alternate_rows. Default is uniform.

-cut_mask_pattern *cut_mask_pattern*

Specifies the cut layer mask pattern among all base vias in a multiple-patterning technology. Valid values are arbitrary, uniform, alternate_columns and alternate_rows. Default is uniform. which means cut mask values in all base vias of the via matrix are the same. When it is arbitrary, cut masks of the lower left cuts in the base vias are considered independently. The cut mask pattern in a base via is inherited from the via_def of the via matrix.

-upper_mask_pattern *upper_mask_pattern*

Specifies the upper layer mask pattern of base vias in the via_matrix in a multiple-patterning technology. Valid values are arbitrary, uniform, alternate_columns and alternate_rows. Default is uniform.

-pattern *via_pattern*

Specifies the via pattern in a via matrix. The pattern defines a MxN pattern of base vias. If the pattern is smaller than the via matrix size, the pattern is replicated left-to-right, bottom-to-top in the via matrix. Excess bits in the pattern are ignored. The pattern is formatted as a space delimited string of equal length substrings (e.g., "1010 0101 1011" is a 3x4 pattern). Each substring must consist of only 1s and 0s, representing a row in the MxN pattern, starting with the bottom row in the pattern. A 1 means the base via is included. A 0 means the base via is omitted. If not specified, all the base vias are included.

-orientation *orientation*

Specifies the orientation of the via matrix. Valid values are MX, MXR90, MY, MYR90, R0, R180, R270, and R90. Default orientation is R0.

-via_orientation *orientation*

Specifies the orientation of base vias in the via matrix. Valid values are MX, MXR90, MY, MYR90, R0, R180, R270, and R90. Default orientation is R0.

-shape_use *use*

Specifies the usage of the via matrix. Valid values are area_fill, core_wire, detail_route, follow_pin, global_route, lib_cell_pin_connect, macro_pin_connect, opc, ring, shield_route, stripe, user_route, and zero_skew. Default value is stripe.

-net *net*

Specifies the power/ground net that owns this via matrix.

-lower_mask_constraint *lower_mask*

Specifies the lower mask constraint of the via matrix. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. Default lower mask constraint is no_mask. When the mask_pattern is alternate_rows or alternate_columns, and uniform, only the mask of lower-left base via needs to be specified. For alternate_rows or alternate_columns, another mask is specified according to the lower_layer of via_def number_of_masks attribute. If the number_of_masks is zero, alternate_rows or alternate_columns works as in uniform style.

-cut_mask_constraint *cut_mask*

Specifies the cut mask constraint of the via matrix. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, mask_five, mask_six, mask_seven, mask_eight, mask_nine, mask_ten, mask_eleven, mask_twelve, mask_thirteen, mask_fourteen, mask_fifteen and same_mask. Default cut mask constraint is no_mask. When the mask_pattern is alternate_rows or alternate_columns, uniform, only the mask of lower-left base via needs to be specified. For alternate_rows or alternate_columns, another mask is specified according to the cut_layer of via_def number_of_masks attribute. If the number_of_masks is zero, alternate_rows or alternate_columns works as in uniform style.

-upper_mask_constraint *upper_mask*

Specifies the upper mask constraint of the via matrix. Valid values are no_mask, mask_one, mask_two, mask_three, mask_four, and same_mask. Default upper mask constraint is no_mask. When the mask_pattern is alternate_rows or alternate_columns, and uniform, only the mask of lower-left base via needs to be specified. For alternate_rows or alternate_columns, another mask is specified according to the upper_layer of via_def number_of_masks attribute. If the number_of_masks is zero, alternate_rows or alternate_columns works as in uniform style.

-base_pitch {*horizontal vertical*}

Specifies the horizontal and vertical pitch values between cuts in the base vias of a via matrix. The values must be non-negative. When not specified, the default base pitch values are got from the via definition.

-base_size {*rows columns*}

Specifies the number of rows and columns (i.e., cut array size) in a base simple array via of the via matrix. The values must be 1 or greater. When not specified, the default cut array size is 1x1. When the base size is 1x1, a base simple via is created instead of a base simple array via.

DESCRIPTION

This command creates a new via matrix and returns a collection containing the new via matrix. The base via of the via matrix can be one of a simple, simple array, or custom via.

A simple base via is defined as a single-cut instance of a simple via definition. To create a simple base via, specify a simple via definition and origin. The orientation and use may be optionally specified.

A simple array base via is defined as a multi-cut instance of a simple via definition. To create a simple array base via, specify a simple via definition, origin, and cut array size greater than 1x1. The orientation, pitch values, and use may be optionally specified.

A custom base via is defined as an instance of a custom via definition. To create a base custom via, specify a custom via definition and origin. The orientation and use may be optionally specified.

A via matrix may be assigned to either a net. Once assigned, the net owns the via matrix.

Note that the default value for the -shape_use option is "detail_route". This is probably not what you want. The placer will not check for legal DRC in relation to detail_route shapes. The placer's assumption is that the detail route will be moved later. For power vias, the shape_use should be set to "stripe". For clock meshes, you can use "user_route". In both of these cases, the placer will be sure to place cells so that they don't have bad DRC interactions with your via matrix.

EXAMPLES

The following example creates a via matrix with a base simple via on a net.

```
prompt> create_via_matrix -via_def VIA12 -origin {1000.100 200.320} \
  -pitch {10 10} -size {2 3} -net Clk -shape_use user_route
```

The following example creates a via matrix with a base simple array via. Its base pattern is inherited from the via definition.

```
prompt> create_via_matrix -via_def VIA12 -origin {1000.100 200.320} \
  -pitch {10 10} -size {2 3} -base_size {3 4} -net clear
```

The following example creates a via matrix with a base custom via.

```
prompt> create_via_matrix -via_def FATVIA12_230_530_ALL_1_2 \
  -pitch {10 10} -size {20 30} -origin {1000.100 200.320} -net clear
```

The following example creates a 5x5 via matrix with a base simple via with a 2x2 via pattern. The resulting via matrix has an alternating via pattern, in which the lower-left cut via is included.

```
prompt> create_via_matrix -via_def VIA12 -origin {100 200} \
  -size {5 5} -pitch {100 200} -pattern "10 01"
```

The following example creates a 5x5 via matrix with a 5x5 pattern, in which the 4 base vias in the upper-right corner of the via matrix are omitted.

```
prompt> create_via_matrix -via_def VIA12 -origin {100 200} \
  -size {5 5} -pitch {100 200} -pattern "11111 11111 11111 11100 11100" \
  -net VDD -shape_use stripe
```

SEE ALSO

get_via_matrixes(2)

create_via_region

Creates a new via_region in frame block

SYNTAX

collection **create_via_region**
-terminal *terminal*
-via_def *via_defs*
-boundary *coord_list*
[-design *design*]
[-rotate]
[-force]

Data Types

terminal	collection
via_defs	collection
coord_list	collection
design	collection

ARGUMENTS

-terminal *terminal*

Specifies the terminal collection for which to create the via region. The boundary of the via region must be enclosed by the bounding box of the terminal. Otherwise, the command issues an error message.

-via_def *via_defs*

Specifies the via definition of the via that can be used to make connections to the terminal associated with via region.

-boundary *coord_list*

Specifies the bounding box in the form of coordination list {{x0 y0} {x1 y1} {x2 y2} ...}. The points must specify a rectilinear polygon.

-design *design*

Specifies the frame block in which to create the new via_region. By default, the command creates the new via region in current frame block.

-rotate

Specifies whether the router must rotate the vias by 90-degrees for placement in the via region.

-force

Specifies whether the existing via regions for the pin will be removed before creating the new via region. By default, the existing via regions for the pin will not be removed.

DESCRIPTION

This command creates a new via_region for an existing terminal object, and returns a collection containing the new via_region or empty collection if any error.

The via_region should specify the shape and associated a via_def object, and the via_def should be defined in the design or technology file.

EXAMPLES

The following example creates a via_region in the current frame block.

```
prompt> create_via_region -terminal [get_pins "IN"] -via_def VIA12_FAT \
  -boundary {{100 200} {700 900}}
```

SEE ALSO

get_via_regions(2)
report_via_regions(2)

create_via_rule

Creates a via_rule in a block or technology file.

SYNTAX

collection **create_via_rule**
-name *via_rule_name*
[-design *design*]
[-library *library*]
[-tech *tech*]
[-cut_layer_names {*name_list*}]
[-cut_names {*name_list*}]
[-cut_rows {*int_list*}]
[-cuts_per_row {*int_list*}]
[-em_factor *float*]
[-max_num_stagger_tracks_for_top_level_ndr_track_use *int*]

Data Types

via_rule_name string or collection
design collection
library collection
tech collection
name_list list
int_list list of integers
float float
int interger

ARGUMENTS

-name *via_rule_name*

Specifies the name of the via_rule to be created.

-design *design*

Specifies the block in which to create the via_rule. If neither a design nor technology file is specified, the via_rule is created in the current block.

-library *library*

Specifies the technology library in which to create the via_rule. The technology library contained by or referenced by the given library is used. If neither a design nor technology file is specified, the current block is used.

-tech *tech_object*

Specifies the technology in which to create the via rule. The default is the technology for the current library.

-cut_layer_names *name_list*

Defines the cut layer's names. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cut_names *name_list*

Defines the cut table names. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cut_rows *int_list*

Defines the number of cut rows. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cuts_per_row *int_list*

Defines the number of cuts per row. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same for other via_ladder related attributes.

-em_factor *float*

Defines the EM factor of via_ladder rule. This is float type and its value must be positive. This is an optional attribute and may be specified only for via_ladder. If specified then other via_ladder related attributes are mandatory.

-max_num_stagger_tracks_for_top_level_ndr_track_use *int*

Defines the maximum number of stagger tracks for use of top level tracks of via_ladder rule. This is an integer type and its value must be positive. This is an optional attribute and may be specified only for via_ladder. If specified then other via_ladder related attributes are mandatory.

RETURN VALUE

The command returns the created via_rule (as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

DESCRIPTION

This command creates a new via_rule in the specified block or tech.

EXAMPLES

The following example creates a via_rule in the current block.

```
prompt> create_via_rule -name VR1
```

The following example creates a via_rule in the tech of current lib.

```
prompt> create_via_rule -library [current_lib] -name VR1
```

The following example creates a via_ladder type of via_rule.

```
prompt> create_via_rule -name VL1 -cut_layer_names {VIA1 VIA2} \
  -cut_names {cut1 cut2} -cut_rows {2 2} -cuts_per_row {2 2}
```

create_virtual_connection

Creates the virtual connection to the specified pins or ports.

SYNTAX

status **create_virtual_connection**
-name *name*
-pins *pin_port_list*
[-weight *weight*]

Data Types

name	string
pin_port_list	collection
weight	integer

ARGUMENTS

-name *name*

Specifies the name of the virtual connection. The command errors out if the specified virtual connection exists.

-pins *pin_port_list*

Specifies a list of pins and ports to be connected to the newly created virtual connection. The command errors out if any of given pins or ports has been connected to other virtual connection already.

-weight *weight*

Specifies the virtual connection weight. The value is integer type and should be great than or equal to 1. If the option is not used, the default weight for virtual connection is 1.

The net weight represents the spring force between eco cells. The bigger the net weight, the higher the force. Currently the command **place_eco_cells** uses connectivity based coarse placement.

By default, all net weight are same. So the eco cell is placed with even distance to driver and load. You can decide how close the eco cells by changing the net weight.

DESCRIPTION

This command creates the virtual connection to the specified pins or ports. It is used before *place_eco_cells -use_virtual_connection*, that performs placement based on user-defined virtual connection. Please refer to the man page of

place_eco_cells for the flow usage about virtual connection based coarse placement.

User should make sure the virtual connection is valid. That is, the virtual connection has one driver and one load at least. The command place_eco_cells will ignore the invalid connection for eco cell automaticlly during coarse placement.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates the virtual connection.

```
prompt> create_virtual_connection \
  -name SNPS_VC_0 \
  -pins {U1/Y lh1/ff1/A}

prompt> create_virtual_connection \
  -name SNPS_VC_1 \
  -pins {lh1/ff1/Y lh1/ff2/A}

prompt> create_virtual_connection \
  -name SNPS_VC_2 \
  -pins {lh1/ff2/Y lh1/ff3/A}

prompt> create_virtual_connection \
  -name SNPS_VC_3 \
  -pins {lh1/ff3/Y U2/A U3/A}
```

create_voltage_area

Creates a voltage area in the current block.

SYNTAX

status **create_voltage_area**
-power_domains *domain_list*
[-power *supply_net*]
[-ground *supply_net*]
[-nwell *supply_net*]
[-pwell *supply_net*]
[-cells *cell_list*]
[-region *region_list*
[-guard_band *width_list*]
[-is_fixed]
[-merge_regions]
[-target_utilization *utilization*]
[-name *voltage_area_name*]
[-cell *cell_name*]

Data Types

domain_list	list
supply_net	string
cell_list	collection
region_list	list
width_list	list
utilization	float
voltage_area_name	string
cell_name	string or collection

ARGUMENTS

-power_domains *domain_list*

Specifies the power domains to associate with this voltage area. All power domains must be associated with the current block and have the same primary supply net.

-power *supply_net*

Specifies the power supply net for voltage area. The net must match one of the available power supply nets on the power domains.

This option is required for a gas-station type voltage area.

-ground *supply_net*

Specifies the ground supply net for the voltage area. The net must match one of the available ground supply nets on the power domains.

This option is required for a gas-station type voltage area.

-nwell *supply_net*

Specifies the nwell supply net for the voltage area. The net must match one of the available power supply nets on the power domains.

-pwell *supply_net*

Specifies the pwell supply net for the voltage area. The net must match one of the available ground supply nets on the power domains.

-cells *cell_list*

Specifies the cells to be included in the voltage area. This option is used to create a gas-station type voltage area. All cells must be in the same physical hierarchy as the current block. Cells can be physical leaf cells or hierarchical cells. When you specify hierarchical cells, the cells are expanded into the set of physical leaf cells that reside under them. If cells are later added or removed from this hierarchical cell, the cell membership of the voltage area is not automatically updated. Note that one hierarchical cell can expand into multiple physical leaf cells. If the hierarchical cell is purely logical (it corresponds to a local module that has no physical representation), the cell maps to an empty set of physical leaf cells, and the tool issues a warning message.

The specified cells cannot already be explicitly or implicitly associated with another voltage area. When used with the **-power_domains** option, the specified cells must also belong to one of the power domains. If any of the power domains already have an associated voltage area with implicit cell membership (whose **use_power_domain_cells** attribute is **true**), the cells are excluded from the implicit cell list. This ensures that each cell is associated with only one voltage area.

-region *region_list*

Specifies the rectangles or rectilinear polygons of the voltage area.

Each region can be one of the following objects:

- Rectangle
  Each rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}).
- Polygon
  Each polygon is specified by its points as {*x1 y1*} {*x2 y2*} {*x3 y3*} {*x4 y4*} and so on.
- Geometric object A geometric object is the combined area of a mixed collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area include the areas of each object. In the case of layers, the resulting area includes the area of every shape on the layer. Overlapping areas are preserved and not merged.

Each region defines a target placement area for the objects in the voltage area. The specified regions can overlap or be disjoint. The coordinates are relative to the chip origin.

This option is required for a gas-station type voltage area.

-guard_band *width_list*

Specifies the horizontal and vertical guard band widths for the voltage area regions.

A guard band is the space along the boundary of a voltage area shape where cells cannot be placed. A guard band expands outward from the region.

If you do not specify this option, the guard band width is zero and the voltage areas do not have guard bands.

If you specify this option, the specified values must be positive floating point numbers. You must specify a pair of horizontal and vertical guard band widths for each region specified in the **-region** option, except when the specified regions abut or overlap and you also specify the **-merge_regions** option. In this case, you must specify the guard bands for each resulting region.

This option can be used only with the **-region** option.

This option is valid only for primary voltage areas. It is not allowed on gas-station type voltage areas because gas-stations cannot have guard bands.

-is_fixed

Specifies whether the voltage area is at a fixed location. This option can be used only with the **-region** option.

-merge_regions

Merges all abutted and overlapping shapes of this voltage area into the shape with the highest stacking order. This option can be used only with the **-region** option.

-target_utilization *utilization*

Specifies the target utilization for this voltage area during shaping. The *utilization* value must be between 0.1 and 1.0.

If you do not specify this option, the tool uses the target utilization for the block, whether that value is valid or not. The target utilization of the voltage area is not automatically updated when the design's target utilization is changed later on.

This option can be used only with the **-region** option.

This option is valid only for primary voltage areas. It is not allowed on gas-station type voltage areas.

-name *voltage_area_name*

Specifies the name of the voltage area. The name cannot conflict with any existing voltage areas in the current block. This option is required unless the **-power_domains** option is used and a single power domain not already associated with a voltage area is specified. In that case, the name of the voltage area is the full hierarchical name of the power domain.

The DEFAULT_VA name is reserved for the automatically generated default voltage area and cannot be used. If you specify a power domain named DEFAULT_VA, the tool issues a warning message and adds a numeric suffix to the name to avoid conflict, for example, DEFAULT_VA_1.

-cell *cell_name*

Specifies the physical cell in which to add the voltage area. The voltage area is created in the cell's reference block using the coordinate system of the cell argument's top block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, voltage areas can be created in library cells. When not specified, the voltage area is created in the current block.

DESCRIPTION

This command creates a voltage area with the specified geometry on the core area of the chip. A voltage area is associated with a power domain. The placer treats the voltage area as an exclusive, hard move bound and tries to place all the cells associated with the voltage area within the voltage area's region and all the cells not associated with the voltage area outside of it.

The voltage area's region contains one or more rectilinear polygons and rectangles. These shapes can overlap to form a single region, or be disjoint to form multiple regions. There is a single unique voltage area at any given location on the chip. Voltage areas can be physically nested. A voltage area region can exist completely inside another voltage area's region. A voltage area region

can also exist partially inside another voltage area's region, creating two abutted voltage areas. The order of creation determines the precedence of the overlapping regions. The voltage area that was created last has the highest precedence. The effective region of the voltage area with higher precedence preserves its original shape while the voltage area with lower precedence gets its effective shape by subtracting the overlapping region. Shape precedence is decided by an explicit stacking order that is initially the same as the order of creation, with the most recently created voltage area shape having the highest precedence. You can adjust the stacking order by using the **set_voltage_area_shape** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a voltage area from the INST power domain at the rectangle with its lower-left corner at 215,215 and its upper-right corner at 350,350. The x- and y-guard band widths are 1 and 2:

```
prompt> create_voltage_area -power_domains INST -region {{215 215} {350 350}} \
  -guard_band {{1 2}}
{INST}
```

The following example creates a voltage area from the INST1 power domain at the polygon with coordinates {100 100}, {300 100}, {300 200}, {200 200}, {200 300}, and {100 300}.

```
prompt> create_voltage_area -power_domains INST1 \
-region {{{100 100} {300 100} {300 200} {200 200} {200 300} {100 300} {100 100}}}
{INST1}
```

create_voltage_area_rule

Creates rules for non-native net routing across voltage areas in the current block.

SYNTAX

status **create_voltage_area_rule**
[-name *rule_name*]
[-allow_pass_through true | false]
[-allow_buffering true | false]
[-allow_physical_feedthrough true | false]
[-allow_logical_feedthrough true | false]
[-include_logical_feedthrough_hierarchy *cell_list*]
[-exclude_logical_feedthrough_hierarchy *cell_list*]
-default_rule
-voltage_areas *voltage_areas*

Data Types

rule_name string
cell_list collection
voltage_areas collection

ARGUMENTS

-name *rule_name*

Specifies the name of the voltage area rule. This option must be specified if the **-voltage_areas** option is specified. This option cannot be specified if the **-default_rule** option is specified.

-allow_pass_through true | false

Specifies whether nets can pass through the voltage area. After the rule is created, this property can be modified by calling **set_attribute** on the **is_pass_through_allowed** attribute. By default, this option is true.

-allow_buffering true | false

Specifies whether buffering is allowed in the voltage area. After the rule is created, this property can be modified by calling **set_attribute** on the **is_buffering_allowed** attribute. By default, this option is true.

-allow_physical_feedthrough true | false

Specifies whether physical feedthrough buffering is allowed through the voltage areas. If physical feedthrough buffering is allowed, you must also specify **-allow_pass_through true** and **-allow_buffering true**. It is an error to allow physical feedthroughs, but disallow pass throughs and buffering. After the rule is created, this property can be modified by calling **set_attribute** on the **is_physical_feedthrough_allowed** attribute. The default is false.

-allow_logical_feedthrough true | false

Specifies whether logical feedthrough buffering is allowed through the voltage areas. If logical feedthrough buffering is allowed, you must also specify **-allow_pass_through true** and **-allow_buffering true**. It is an error to allow logical feedthroughs, but disallow pass throughs and buffering. After the rule is created, this property can be modified by calling **set_attribute** on the **is_logical_feedthrough_allowed** attribute. The default is false.

-include_logical_feedthrough_hierarchy *cell_list*

Specifies the hierarchies in which the tool may insert logical feedthrough buffers. Hierarchies are specified by listing logical hierarchical cells to the option. Specify the top-level of hierarchy with the "." character. The specified cells and top-level of hierarchy must be roots of the specified voltage area's power domain. If this option is specified, the **-allow_logical_feedthrough true** option value must be specified and exactly one voltage area must be specified through the **-voltage_areas** option.

The **-include_logical_feedthrough_hierarchy** and **-exclude_logical_feedthrough_hierarchy** options are mutually exclusive. Only one may be specified. If neither are specified, then the **-allow_logical_feedthrough** option applies to all hierarchies.

-exclude_logical_feedthrough_hierarchy *cell_list*

Specifies the hierarchies in which the tool may not insert logical feedthrough buffers. Hierarchies are specified by listing logical hierarchical cells to the option. Specify the top-level of hierarchy with the "." character. The specified cells and top-level of hierarchy must be roots of the specified voltage area's power domain. If this option is specified, the **-allow_logical_feedthrough true** option value must be specified and exactly one voltage area must be specified through the **-voltage_areas** option.

The **-include_logical_feedthrough_hierarchy** and **-exclude_logical_feedthrough_hierarchy** options are mutually exclusive. Only one may be specified. If neither are specified, then the **-allow_logical_feedthrough** option applies to all hierarchies.

-default_rule

Creates the default rule with the name "DEFAULT_RULE".

The **-default_rule** and **-voltage_areas** options are mutually exclusive. One of them must be specified.

-voltage_areas *voltage_areas*

Specifies the voltage areas on which to apply the rule in the current block. More than one voltage area can be specified, and the rule will apply to each one. This command can also be called incrementally with new voltage areas on a previously defined rule. In this case, the rule is added to those voltage areas and retained on previous voltage areas. If a voltage area previously had a voltage area rule defined, and a different one is then applied, then the new rule overrides the old rule.

The **-default_rule** and **-voltage_areas** options are mutually exclusive. One of them must be specified.

DESCRIPTION

This command creates a voltage area rule in the current block. The rule can be either the default rule or a voltage area specific rule. The default rule is automatically applied to all voltage area in the block which are not explicitly assigned a rule. A voltage area specific rule applies to a set of one or more voltage areas in the block.

If the **-default_rule** option is specified, the default rule is created and assigned the name "DEFAULT_RULE". If the default rule already exists, this command returns an error and no rule is created or modified.

If the **-voltage_areas** option is specified, a voltage area specific rule is created for the specified voltage_areas. If the specified name, pass through, physical feedthrough, and logical feedthrough values match an existing rule, the existing rule is applied to the specified voltage areas and no new rule is created.

If a voltage_area in the **-voltage_areas** option is already explicitly assigned an existing rule, this new rule overrides the existing rule. If an existing rule is orphaned (no longer constrains any voltage area), it is removed from the block. If a voltage area is removed

from the block which causes a rule to be orphaned, the rule is removed from the block.

Voltage area rules specify whether nonnative net routing is permitted in the voltage areas. The routing behavior (either to allow routing to pass through the voltage area or not) is specified with the **-allow_pass_through** option.

These routing pass through rules do not apply to all nets, only to nets that are nonnative to the voltage area on which the rule is applied. Native routing is unaffected, and can always pass through the native voltage areas. For example, suppose there is a driver in VA1, a load in VA2, and the net connecting them only has segments in the hierarchies belonging to VA1 and VA2. This net is said to be "native" to both VA1 and VA2, and so any voltage area routing rules applied to either VA1 or VA2 do not apply to this net. Now consider an unrelated voltage area VA3 which is physically between VA1 and VA2. It might be desirable to allow this net to pass through VA3 to connect the driver and load, to make a shorter connection. Or, it might be desirable to disallow this pass through routing in VA3 and force the net to detour around, because of congestion or other reasons. A voltage area rule applied on VA3 will control this behavior for this net, because it is nonnative to VA3.

These routing pass through rules are honored by all optimization engines, including both datapath and clock tree synthesis (CTS) buffer tree topology generation, virtual routing, global routing, track routing, and detail routing.

Physical feedthrough (PFT) buffering is the buffering counterpart to the pass through routing concept. PFT buffering is buffering done across voltage areas that are not native to the hierarchy that the buffers logically belong to. PFT buffering is disabled by default, but can be enabled locally by specifying **-allow_physical_feedthrough true** or globally by setting the **opt.common.allow_physical_feedthrough** application option to *true*. PFT buffering can only be controlled globally by this application option. However, buffering cannot be done when routing cannot be done. So, if a voltage area has a rule that disables pass through routing, it also implies that physical feedthrough buffering is disabled for that voltage area.

Logical feedthrough (LFT) buffering is a complementary solution to PFT buffering. While PFT buffering resolves a buffer's mismatched logical and physical hierarchy membership by setting one of the voltage area's power domains directly on the buffer, LFT buffering moves the buffer to a logical hierarchy under one of the voltage area's power domains.

Voltage area rules are data model objects that can be queried with the **get_voltage_area_rules** command. Each voltage area also has a *voltage_area_rules* attribute which stores the defined rules on the voltage area.

Use the **report_voltage_area_rules** command to report the currently applied rules.

Use the **remove_voltage_area_rules** command to remove any defined rules.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a default voltage area rule named "DEFAULT_RULE" that allows pass throughs and regular buffering, but not physical and logical feedthrough buffering.

```
prompt> create_voltage_area_rule -default_rule \
  -allow_pass_through true -allow_buffering true \
  -allow_physical_feedthrough false -allow_physical_feedthrough false
```

The following example creates a voltage area rule named "RULE1" that allows pass throughs, regular buffering, physical feedthrough buffering, and logical feedthrough buffering on voltage area "VA1".

```
prompt> create_voltage_area_rule -name RULE1 \
  -allow_pass_through true -allow_buffering true \
  -allow_physical_feedthrough true -allow_logical_feedthrough true \
  -voltage_areas VA1
```

The following example applies existing voltage area rule "RULE1" to voltage area "VA2". RULE1 still remains applied to VA1.

```
prompt> create_voltage_area_rule -name RULE1 \
  -allow_pass_through true -allow_buffering true \
  -allow_physical_feedthrough true -allow_logical_feedthrough true \
  -voltage_areas VA2
```

The following example creates a voltage area rule named "RULE2" and applies it to voltage area "VA1", overriding its currently assigned rule "RULE1". Now only RULE2 applies to VA1.

```
prompt> create_voltage_area_rule -name RULE2 -allow_pass_through true \
  -allow_physical_feedthrough false -voltage_areas VA1
```

The following example creates a voltage area rule named "RULE7" which allows logical feedthrough buffers in the I_ORCA_TOP/I_SDRAM_IF level of hierarchy.

```
prompt> create_voltage_area_rule -name RULE7 \
  -allow_logical_feedthrough true -voltage_areas PD7 \
  -include_logical_feedthrough_hierarchy {I_ORCA_TOP/I_SDRAM_IF}
```

create_voltage_area_shape

Creates a voltage area shape at the specified region for providing placement constraints for cells associated with the region.

SYNTAX

collection **create_voltage_area_shape**
-voltage_area *voltage_area*
-region { {*llx lly*} {*urx ury*} } |
{ {*x y*} {*x y*} {*x y*} {*x y*} ... } |
geometric_objects
[-guard_band {*x_width y_width*}]
[-target_utilization *utilization*]
[-cells *cell_list*]
[-exclusive]
[-merge_regions]
[-top | -bottom | -above *voltage_area_shape* | -below *voltage_area_shape*]

Data Types

voltage_area	string or collection
llx	float
lly	float
urx	float
ury	float
