Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the waveform integrity constraints compatible with the specified SMS scenarios. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

This command removes the constraint limit for waveform integrity analysis. The *-static* and *-dynamic* options specify which constraint is removed.

If the list of cell input pins are provided, the constraint limit on the specified cell inputs is removed. If there is no list of cell input pins, the design-level constraint value, if any, is removed.

Examples

The following example removes a static constraint on synchronous input pin "DFF/CLK".

```
pt_shell> remove_waveform_integrity_analysis -static 0.3 [get_pins
 DFF/CLK]
```

Feedback

- set_waveform_integrity_analysis

---

remove_wire_load_min_block_size

Removes the minimum block size for automatic wire load selection.

Syntax

int *remove_wire_load_min_block_size*

Arguments

None.

Description

Removes the minimum block area for automatic wire load selection in the current design, set by the *set_wire_load_min_block_size* command.

Examples

The following example removes the previously-set minimum block size.

```
pt_shell> remove_wire_load_min_block_size
```

See Also

- report_wire_load
- set_wire_load_min_block_size
- set_wire_load_selection_group
- auto_wire_load_selection

---

remove_wire_load_model

Removes wire load model from designs, hierarchical cells, or ports.

Syntax

string *remove_wire_load_model*

```
[object_list]
```

Feedback

Data Types

`list object_list`

Arguments

object_list

Lists ports, designs, or hierarchical cells. If this option is not specified, the wire load model is removed from the current instance, or from the current design if current instance is not set.

Description

Removes user-specified wire load model information on designs, ports, or hierarchical cells. The wire load model is used to calculate net capacitance, resistance, and area for designs, which are not placed and routed. You specify wire load models with the *set_wire_load_model* command, or by using automatic wire load selection.

To display wire load model settings for the current design or instance, use *report_wire_load*. To show wire load information for ports, use *report_port -wire_load*.

Examples

The following example removes wire load model settings from the current design and from all hierarchical cells in the design.

```
pt_shell> current_design TOP
pt_shell> remove_wire_load_model
pt_shell> remove_wire_load_model [get_cells -hier * -filter
 "is_hierarchical==true"]
```

The following example removes wire load model settings from port OUT2.

```
pt_shell> remove_wire_load_model [get_ports OUT2]
```

See Also

- report_port
- report_wire_load
- set_wire_load_model
- set_wire_load_selection_group
- report_design
- auto_wire_load_selection

Feedback

remove_wire_load_selection_group

Removes wire load selection_group from current design.

Syntax

status *remove_wire_load_selection_group*

`[object_list]`

Data Types

object_list list

Arguments

object_list

Provides a list of hierarchical cells or designs. If you do not specify the *object_list* option, the wire load selection group is set on the current instance or on the current design if current instance is not set.

Description

This command removes the wire load selection group setting from the current design. Both min and max selection group information is removed. The wire load selection group is specified with *set_wire_load_selection_group*. For more information, see the *set_wire_load_selection_group* man page.

To show the wire load selection group information for a design, use the *report_design* command.

Examples

This example removes the wire load selection group setting from the current design.

```
pt_shell> remove_wire_load_selection_group
```

See Also

- report_design
- set_wire_load_selection_group

rename

Renames or deletes a command.

Syntax

string *rename*

```
old_name
new_name
```

Arguments

old_name

Specifies the current name of the command.

new_name

Specifies the new name of the command.

Description

Renames the *old_name* command so that it is now called *new_name*. If *new_name* is an empty string, then *old_name* is deleted. The *old_name* and *new_name* arguments may include namespace qualifiers (names of containing namespaces). If a command is renamed into a different namespace, future invocations of it will execute in the new namespace. The *rename* command returns an empty string as result.

Note that the *rename* command cannot be used on permanent procedures. Depending on the application, it can be used on all basic builtin commands. In some cases, the application will allow all commands to be renamed.

WARNING: *rename* can have serious consequences if not used correctly. When using *rename* on anything other than a user-defined Tcl procedure, you will be warned. The *rename* command is intended as a means to wrap other commands: that is, the command is replaced by a Tcl procedure which calls the original. Parts of the application are written as Tcl procedures, and these procedures can use any command. Commands like *puts*, *echo*, *open*, *close*, *source* and many others are often used within the application. Use *rename* with extreme care and at your own risk. Consider using *alias*, Tcl procedures, or a private namespace before using *rename*.

Examples

This example renames my_proc to my_proc2:

```
prompt> proc my_proc {} {echo "Hello"}
prompt> rename my_proc my_proc2
prompt> my_proc2
Hello
prompt> my_proc
Error: unknown command 'my_proc' (CMD-005).
```

See Also

- define_proc_attributes

Feedback

rename_cell

Changes the name of a cell.

Syntax

int *rename_cell*

```
cell
new_name
```

Data Types

cell	list
new_name	string

Arguments

cell

Specifies one cell to be renamed.

new_name

Specifies the new name for *cell*.

Description

The *rename_cell* command changes the name of a cell. Either a cell name that matches a single cell, or a collection of one cell, is passed in as the *cell* argument.

The *rename_cell* command fails if any of the following are true:

- PrimeTime cannot find *cell*.
- PrimeTime finds multiple cells that match *cell*.
- PrimeTime finds a leaf cell matching *new_name*.
- *new_name* is not at the same level of hierarchy as *cell*.

The *write_changes* command records the *rename_cell* command.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Feedback

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following examples, a cell is renamed in the current instance.

```
pt_shell> rename_cell cellA cellB
Information: Renamed cell 'cellA' to 'cellB' in design 'top'. (NED-008)
1
```

In the following examples, a cell is renamed at a level below the current instance. Currently, H1 and H1/H2 are instances of designs that have multiple instances. Therefore, they are uniquified as part of the editing operation.

```
pt_shell> rename_cell H1/H2/u1 H1/H2/cellC
Uniquifying 'H1/H2' (low) as 'low_0'.
Uniquifying 'H1' (inter) as 'inter_0'.
```

Feedback

```
Information: Renamed cell 'u1 to 'cellC' in 'top/H1/H2'. (NED-008)
1
```

---

rename_design

Change the name of a design.

Syntax

int *rename_design*

```
design
new_name
```

Data Types

design	list
new_name	string

Arguments

design

Specifies a design to be renamed. Only one design can be specified.

new_name

Specifies the new name for the *design* option.

Description

The *rename_design* command changes the name of a design. Either a design name which matches a single design, or a collection of one design, is passed in as the *design* argument. The command allows only simple design name changes for a single design. You cannot change the association of a design with its source file.

For the *design* to be renamed to *new_name*, there cannot be a design named *new_name* in the same file as *design* (see the Examples). The command may also fail if there are any instances of *design* in a linked design.

Renaming designs in PrimeTime should be done prior to any linking to avoid the case of instantiation conflicts.

Feedback

Note that the *rename_design* command is not recorded for output with the *write_changes* command.

Examples

In the following example, design *top* is successfully renamed to *top2*:

```
pt_shell> list_designs
Design Registry:
 *  top            /home/designs/top.v:top
1
pt_shell> rename_design [get_designs top] top2
Renamed design 'top' to 'top2'
1
pt_shell> list_designs
Design Registry:
 *  top2           /home/designs/top.v:top2
1
```

In the following example, design *fbox* cannot be renamed *mbox* because there is already a design of that name in the same file. An attempt to rename it to *fbox2* fails because *fbox* is instantiated in a linked design.

```
pt_shell> list_designs
Design Registry:
    fbox           /home/designs/top.v:fbox
    mbox           /home/designs/top.v:mbox
 *L top            /home/designs/top.v:top
1
pt_shell> rename_design fbox mbox
Error: Could not rename design 'fbox' to 'mbox':
 design 'mbox' already exists in file
        '/home/ajs/designs/top.v' (NED-020)
0
pt_shell> rename_design fbox fbox2
Error: Could not rename design 'fbox' to 'fbox2':
 design 'fbox' is instantiated in design 'top' (NED-020)
0
```

---

rename_net

Changes the name of a net.

Feedback

Syntax

status *rename_net*

```
net
new_name
```

Data Types

net	list
new_name	string

Arguments

net

Specifies a net to be renamed. Only one net can be specified.

new_name

Specifies the new name for *net*.

Description

The *rename_net* command changes the name of a net. Either a net name that matches a single net or a collection of one net is passed in as the *net* argument.

The *rename_net* command fails if any of the following are true:

- PrimeTime cannot find *net*.
- PrimeTime finds multiple nets that match *net*.
- PrimeTime finds a net, port, or hierarchical pin matching *new_name* in the same hierarchical block as *net*.
- *new_name* is not at the same level of hierarchy as *net*.

The *rename_net* command is recorded for output with the *write_changes* command.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is re-linked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following examples, a net is renamed in the current instance.

```
pt_shell> rename_net netA netB
Information: Renamed net netA' to 'netB' in design 'top'. (NED-009)
1
```

In the following examples, a net is renamed at a level below the current instance. Currently, H1 and H1/H2 are instances of designs that have multiple instances. Therefore, they are uniquified as part of the editing operation.

```
pt_shell> rename_net H1/H2/w1 H1/H2/netC
Uniquifying H1/H2 (low) as 'low_0'.
Uniquifying 'H1' (inter) as 'inter_0'.
Information: Renamed net 'w1' to 'netC' in 'top/H1/H2'. (NED-009)
1
```

---

report_activity_annotation

Reports the activity conflict among different segments of a net in VCD or FSDB file.

Syntax

```
int report_activity_annotation
[-debug_file]
[-verbose]
```

Data Types

net_list	list

Arguments

`-debug_file`

To specify the name of the output file which will be dumped out by the command.

`-verbose`

To print out all net/pin activities including non-conflict activities on the net.

Description

To check and report conflicting activities among different segments of a net in any timestamp in a VCD/FSDB file. You need to read VCD or FSDB file first, and then run the command. There is no need to run update_power.

This command should only be run in time based mode.

The conflict values in each timestamp among different net segments and pins are reported in an output file. The default file name is "activity_annotation_report.rpt".

The *debug_file* option can be used to change the output report file name. The *net_list* option can be used to report specific nets in the design.

Examples

The following example reports conflict on all nets in the design. The command dumps out the conflict output to a default file name "activity_annotation_report.rpt".

Feedback

```
pwr_shell> report_activity_annotation  [get_nets *]
report_activity_annotation [get_nets *]

Information : Activity annotation report 'activity_annotation_report.rpt'
 generated successfully

1
```

The following example reports the activity conflict for net "s1" and creates an output file "debug_s1_report.rpt"

```
pwr_shell> report_activity_annotation [get_net s1]

report_activity_annotation -debug_file debug_s1 [get_net s1]
Information : Activity annotation report 'debug_s1_report.rpt' generated
 successfully
1
```

---

report_activity_derate

Reports the clock activity derating factors for a specified list of instances.

Syntax

```
int report_activity_derate
[-cell_list]
```

Data Types

cell_list	list

Arguments

-cell_list

Reports the *derate_value* currently applied to cell instances specified in the cell list.

Description

Reports the toggle rate derating factors currently set on a cell instance or a list of cells in the current design.

Feedback

Clock activity derating factor affects toggle rate on cells in the clock network. The clock derating factors are used as a scalar multiplicative factor in calculation of toggle rate for output net of cell. If clock derating factors are not specified, the value of 1.0 is assumed.

The *cell_list* option can be used to report specific derating factors on instances (cells) in the design.

Examples

The following example reports clock activity toggle rate derating factor for all cells in the design.

```
pwr_shell> report_activity_derate  [get_cells *]
report_activity_derate [get_cells *]
****************************************
Report : Clock activity derate factors
Version: O-2018.06-ALPHA-20180405
****************************************
Cell     Derate factor
--------------------------------------------------------------------------------

i_ff_2     0.000000
i_ff_3     0.000000

Feedback

report_activity_file_check

Reads an activity file without annotating the switching activity, and reports the proceedings of the mapping.

Syntax

string *report_activity_file_check*

```
[-rtl]
[-format SAIF | VCD | FSDB]
[-pipe_exec pipe]
[-path prefix]
-strip_path strip_path
[-nosplit]
[-find pattern]
file_name
```

Data Types

pipe	string
prefix	string
strip_path	string
pattern	string
file_name	string

Arguments

`-rtl`

Specifies that the name mapping method must be applied during the *time_based* power analysis mode. As the name mapping method is always applied in the averaged power analysis mode, the -rtl option is disabled in the averaged power analysis mode. For more information about specifying name mapping, see the *set_rtl_to_gate_name* man page. *set_rtl_to_gate_name* man page.

`-format SAIF | VCD | FSDB`

Specifies whether the file referenced by the *file_name* argument is a FSDB file or a VCD file or a SAIF file. The *format* argument is not necessary if the format of the *file_name* can be recognized by the file name extension.

`-pipe_exec pipe`

Specifies a shell command used to generate the VCD file using the *file_name* option. This option invokes the shell command and directly pipes the output VCD file to PrimePower. There is no VCD disk file generated at all. You cannot use this option if the value specified with the *format* argument is SAIF.

`-path` *`prefix`*

Specifies a relative path from the current design to the hierarchical low- level design for which the VCD file has been created. By default, the absolute path names are used. Use this option if the VCD file refers to an object in a hierarchy. Do not use this option if the VCD file refers to an absolute path.

`-strip_path` *`strip_path`*

Specifies a path prefix that must be stripped from all the object names read from the VCD or SAIF file. This option is applied to strip the testbench or instance path from the RTL VCD or SAIF file.

`-nosplit`

Prevents line splitting if a column overflows.

`-find` *`pattern`*

Reports only on the activity file objects that match the *pattern* option, so the report can be much shorter and more readable. The pattern is a glob; for example, the pattern "A/B*" matches "A/B1", "A/B2", and "A/B/C/D". Multiple globs can be included with commas, such as {A/B*, C/*/Q}. Only the activity file objects are checked to see if the pattern matches. Any activity file object not matching the pattern is not reported.

`file_name`

Specifies the name of the switching activity file to be read. The specified file can be a SAIF, VCD, VPD, or FSDB file and can be of compressed format. The file name extension can be used to determine the file type. The file names with the ".vcd", ".vcd.gz", ".vcd.Z", ".vcd.bz2", ".vpd" or ".fsdb" extensions are converted to RTL VCD files and read as RTL VCD files; whereas the file names with the ".saif", ".saif.Z", ".saif.gz", or ".saif.bz2" extensions are converted to RTL SAIF files and read as RTL SAIF files.

Description

The *report_activity_file_check* command helps debug the switching activity annotation from simulation. The command processes the activity file in the same way as the *read_saif* or *read_vcd* command would, except that annotation is not applied to the design. This command reports the proceedings of the name mapping. For each hierarchical module (in VCD) or instance (in SAIF), the corresponding hierarchical cell in the design is displayed, if found. For each signal (in VCD) or net (in SAIF), the corresponding net or pin in the design is shown, if any. The exact method (or the combination of methods) used to arrive at the mapping is also reported. In addition, this command also reports information about any logical inversion between the signal in VCD (or net in SAIF) and the net or pin in the design.

Feedback

Using the *report_activity_file_check* command, it is possible to determine where in the design a particular signal in a VCD would be annotated by the *read_vcd* command. To do this, run the *report_activity_file_check* command with the -find option to output only the results matching the signal in question.

When you set the *power_analysis_mode* variable to *time_based*, you cannot use the SAIF files with the *report_activity_file_check* command.

Examples

The following example reports the mapping of a SAIF file to the design. Note that nothing is reported for the signal Ud SAIF file.

```
pt_shell> report_activity_file_check my_file.saif -strip_path tb/dut
 -path top
****************************************

report_activity_waveforms

Reports on activity analysis of VCD.

Syntax

int *report_activity_waveforms*

```
[-nosplit]
```

Feedback

Arguments

`-nosplit`

Specifies that lines with overflow should not be split. This can be useful when the output is read by a script.

Description

After running the *write_activity_waveforms* command, you can use the *report_activity_waveforms* command to summarize the results and give the peak activity times for each block in the VCD file analyzed.

Examples

This example shows the form of the report.

```
pt_shell> write_activity_waveforms -output filename1 -vcd my_vcd.vcd
 -interval 10
pt_shell> report_activity_waveforms

****************************************
Report : Time-Based Switching Activity

---

report_alternative_lib_cells

Generates a report on the timing effects of alternative library cells that can replace an existing cell instance.

Feedback

Syntax

string *report_alternative_lib_cells*

```
[-current_library]
[-libraries lib_spec]
[-delay_type delay_type]
[-all_pins]
[-weighted_design_cost]
[-total_design_cost]
[-significant_digits digits]
[-nosplit]
cell
```

Data Types

lib_spec	list
delay_type	string
digits	integer
cell	string

Arguments

`-current_library`

Restricts the report to new library cells only from the same library as that of the cell being considered for replacement.

`-libraries lib_spec`

Specifies a list of libraries from which to select alternative library cells. You can specify either a list of library names or a collection created by the *get_libs* command. The default is to select from all libraries specified in the *link_path* variable.

`-delay_type delay_type`

Specifies the type timing slack to report: *max* (the default), *min*, *min_max*, *max_rise*, *max_fall*, *min_rise*, or *min_fall*. For the *min* and *max* setting, the worse between rising and falling slacks is reported. For the *min_max* setting, both min and max slacks are reported.

`-all_pins`

Reports the worst slack through each pin of the cell. By default, the command reports only the worst slack of the single worst output pin.

`-weighted_design_cost`

Reports the weighted design cost (negative slack) caused by using each alternative library cell. The value is calculated as a weighted sum over the weighted cost values calculated for all path groups. The reported cost values are the same as those reported by the *report_constraint* command for minimum

delay (costs resulting from hold constraints) and maximum delay (costs resulting from setup constraints).

The minimum delay cost is calculated as follows:

```
weighted min_delay/hold cost = summation over all path groups
( group weight * sum of all nonzero hold costs in group )
```

The maximum delay cost is calculated as follows:

```
weighted max_delay/setup cost = summation over all path groups
( group weight * worst setup cost in group )
```

Maximum cost values are reported by default or when *-delay_type max*, *max_rise*, or *max_fall* is specified.

Minimum cost values are reported when *-delay_type min*, *min_rise*, or *min_fall* is specified.

If *-delay_type min_max* is specified, both minimum and maximum costs are reported.

`-total_design_cost`

Reports the total design cost (negative slack) caused by using each alternative library cell. This option is similar to the *-weighted_design_cost* option, except that the total design cost can change in cases when the weighted maximum delay (setup) cost does not. The total cost can give some indication of the overall improvement in the design timing when the change does not improve the worst setup timing violation.

The total design cost is also computed as a weighted sum of the total costs computed for each path group. Only positive cost values are included in the calculation. It is calculated as follows:

```
total design cost = summation over all path groups
( group weight * group total cost )

group total cost = summation over all group endpoints
having positive cost ( cost value )
```

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point that are reported for slack values. Allowed values are 0-13. The default is determined by the *report_default_significant_digits* variable, default 2.

`-nosplit`

Prevents splitting of long lines in the report.

cell

Specifies a single cell instance in the design. The command reports the timing effects of replacing that cell with alternative cells.

Description

The *report_alternative_lib_cells* command generates a report to help you select an alternative library cell for a given cell instance. The report shows the slack values that would occur by replacing the cell with alternative cells using the *size_cell* command. The command performs the replacement temporarily using each alternative cell and reports the resulting worst timing slack.

By default, the command reports the worst rising or falling max (setup) slack to the single output pin with the worst slack. To report a different type of slack, use the *-delay_type* option. To report the worst slack through each pin of the cell, use the *-all_pins* option.

The command uses the same criteria to find functionally equivalent alternative cells as the *size_cell* and *get_alternative_lib_cells* commands, and searches through the available libraries in the same order. For details, see the *size_cell* man page.

Examples

The following example reports the alternative library cells for cell instance U141 and shows the min and max slacks resulting from each alternative, including the current cell, which is marked with an asterisk.

```
pt_shell> report_alternative_lib_cells -delay_type min_max U141
Information: Invalidating logical update. (PTE-139)
Information: Updating design - Started                (UITE-214)
Information: Updating design -   Calculating delays   (UITE-214)
 ...
Information: Updating design - Completed              (UITE-214)
 ...
*************************************

Alternative        Slack (min:max)
Library Cells
-------------------------------------------------------------------
cb13_max/or02d4    3.752(r):4.178(r)
cb13_max/or02d7    3.150(r):5.101(r)
cb13_max/or02da *  2.935(r):5.386(r)
cb13_max/or02d2    5.006(r):1.596(r)
cb13_max/or02d1    7.674(r):-3.834(r)
cb13_max/or02d0    13.465(r):-15.573(r)

*: The original library cell, not an alternative.
```

The following example generates a report that shows the weighted and total design costs.

```
pt_shell> set libs_in_mem [get_libs *]
```

Feedback

```
pt_shell> report_alternative_lib_cells U155 -libraries $libs_in_mem
              -delay_type max -weighted_design_cost -total_design_cost
 ...
**************************************

Alternative          Slack       Weighted           Total Design Cost
Library Cells                    max_delay/setup
                                 Cost
-------------------------------------------------------------------------
dz13_max/and2_2      1.01(r)     4.03               35.67
dz13_max/and2_1     -1.34(f)     4.03               34.34
dz13_max/and2_0 *   -2.34(r)     4.03               36.78
dz13_max/and2_3     -3.01(f)     4.03               37.88

*: The original library cell, not an alternative.
```

The weighted design cost is not affected by any of the alternatives, but the total cost of the design can be improved by using library cell and2_2 or and2_1 in place of the current library cell and2_0.

---

report_analysis_coverage

Generates a report about the coverage of timing checks.

Syntax

status *report_analysis_coverage*

```
[-status_details status_list]
[-check_type check_type_list]
[-exclude_untested untested_reason_list]
[-sort_by sort_method]
[-significant_digits digits]
[-nosplit]
[-pre_commands pre_command_string]
[-post_commands post_command_string]
[-sms_scenarios sms_scenarios_list]
```

Feedback

Data Types

status_list	list
check_type_list	list
untested_reason_list	list
sort_method	string
digits	integer
pre_command_string	string
post_command_string	string
sms_scenarios_list	collection

Arguments

`-status_details` *status_list*

Specifies a space-delimited list of status names about which to show detail in the report. The allowed values are *untested*, *violated*, and *met*. By default, only summary information is shown. Use this option to see information about individual timing checks.

`-check_type` *check_type_list*

Specifies a list of check types to include in the report. The allowed values are *setup*, *hold*, *recovery*, *removal*, *min_period*, *min_pulse_width*, *clock_separation*, *data_separation*, *max_skew*, *clock_gating_setup*, *clock_gating_hold*, *out_setup*, *out_hold*, and *nochange*.

Check types *out_setup* and *out_hold* refer to the output setup and output hold constraints generated by the *set_output_delay* command.

`-exclude_untested` *untested_reason_list*

Specifies a space-delimited list of reasons to exclude an untested check in the report. A check classified as untested is excluded from the report for any of the reasons specified as values to this argument. Therefore, the coverage statistics are unaffected by these excluded constraints. The following values are allowed:

- *constant_disabled* - Paths to this check are disabled because of case analysis or a logic constant propagated through the design (for example, caused by a signal tied high or low).
- *mode_disabled* - A timing constraint is disabled because it requires a mode to be selected in mode analysis, and that mode is not selected.
- *user_disabled* - The timing check is explicitly disabled by the user.
- *no_paths* - The timing check had no paths found to it and as a result there were no arrival times.
- *false_paths* - All paths were false to a constrained pin.

- *no_endpoint_clock* - The timing check has no destination clock signal to latch the data.
- *no_startpoint_clock* - The timing check has no clock that launches the data at a startpoint latch.
- *no_constrained_clock* - There is no constrained clock for skew or clock separation checks.
- *no_ref_clock* - There is no reference clock for skew or clock separation checks.
- *no_clock* - A minimum pulse width or period width check has no clock.
- *no_min_check* - An external delay was specified with a maximum delay but no minimum delay.
- *no_max_check* - An external delay was specified with a minimum delay but no maximum delay.
- *unknown* - The reason is not listed above.

`-sort_by` *`sort_method`*

Specifies the sorting method for the output of the detailed list. The following values are allowed:

- *slack* (the default) - Sorts by the slack (untested is treated as negative infinity slack), followed by the pin name and check type.
- *name* - Sorts alphabetically by the name of the constrained pin, followed by the slack and check type.
- *check_type* or *check* - Sorts alphabetically by the check type, followed by the slack and pin name.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point that are to be reported. The allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default is 2. Use this option if you want to override the default.

`-nosplit`

Prevents line-splitting when columns overflow.

`-pre_commands` *`pre_command_string`*

This option is available only if you invoke PrimeTime with the *-multi_scenario* option. This option allows you to specify a string of commands to be executed in the worker context before the execution of the merged reporting command.

Feedback

Commands must be grouped using the ";" character. The maximum size of a command is 1000 characters.

`-post_commands` *`post_command_string`*

This option is available only if you invoke PrimeTime with the *-multi_scenario* option. This option allows you to specify a string of commands to be executed in the worker context after the execution of the merged reporting command. Commands are grouped using the ";" character. The maximum size of a command is 1000 characters.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only timing checks compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Generates a report showing information about the coverage of timing checks in the current design, or current instance if it is defined. The default report is a summary of checks by type. For each type of check (for example, *setup*), the report shows the number and percentage of checks meeting and violating constraints, and those that are untested; the report does not show check types for which there are no checks. The report does not show unconstrained output ports; that is, those that have no output delay or max_delay or min_delay; however, the report does show constrained output ports.

For more information about the individual timing checks, use the *-status_details* option, which shows all checks with the corresponding status. Untested checks show information about the reason why they are untested, if the reason can be determined.

By default, the coverage statistics include constraints that have been disabled. Constraints could be disabled because of constant propagation (for logic constants in the design and case analysis), modes that are not enabled, or explicit disabling of timing arcs by the user. Such disabled constraints appear as untested in the coverage statistics. If you want to exclude some of these untested constraints from the coverage statistics, use the *-exclude_untested* option.

Note that the command reports primarily library defined timing checks, in addition to *output_setup* and *output_hold*, which can be set by the *set_output_delay* command. User-defined constraints such as those set by *set_max_delay*/*set_min_delay* commands are not reported by *report_analysis_coverage*.

Examples

The following example shows the summary report.

```
pt_shell> report_analysis_coverage
****************************************
```

```
Report : analysis_coverage
Design : counter
 ...

---

report_annotated_check

Reports back-annotated timing checks.

Feedback

Syntax

string *report_annotated_check*

```
[-setup]
[-hold]
[-recovery]
[-removal]
[-nochange]
[-width]
[-period]
[-max_skew]
[-clock_separation]
[-max_line num]
[-list_annotated]
[-list_not_annotated]
[-list_lib_annotated]
[-constant_arcs]
[-significant_digits digits]
```

Data Types

num int

Arguments

`-setup`

Reports setup timing checks.

`-hold`

Reports hold timing checks.

`-recovery`

Reports recovery timing checks.

`-removal`

Reports removal timing checks.

`-nochange`

Reports nochange timing checks.

`-width`

Reports minimum pulse width timing checks.

`-period`

Reports minimum period timing checks.

`-max_skew`

Reports maximum skew timing checks.

`-clock_separation`

Reports clock separation timing checks.

`-max_line` *num*

Provides maximum number of line for the *-list_** options.

`-list_annotated`

Lists timing arcs that are back-annotated. Use this option if no annotated checks are expected to identify the specified annotated checks.

`-list_not_annotated`

Lists timing arcs that are not back-annotated. Use this option if some annotated checks are missing to identify the missing annotated checks.

`-list_lib_annotated`

Lists library timing arcs that are back-annotated.

`-constant_arcs`

Keeps a separate count for the arcs that are disabled due to logic constants (but not case_analysis). With this option, the *-list_annotated* or *-list_not_annotated* option does not list the arc disabled due to logic constants. The total count at the end of the table includes the constant_arcs count.

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13. If you do not use this option, the number of digits is specified by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

Description

Provides a summary report of how many cell timing checks are annotated in the current design. The purpose of this command is to check if all timing checks of the design are annotated after reading an SDF file. You can use the *-list_not_annotated* option to identify which check timing arcs are not annotated.

Examples

The following are examples of annotated reports.

```
pt_shell> report_annotated_check

****************************
report: annotated_check
****************************

                                |            |            |     NOT     |
```

```
                              |   Total    | Annotated | Annotated |
------------------------------+------------+-----------+-----------+

---

report_annotated_delay

Reports back-annotated delays.

Syntax

string *report_annotated_delay*

```
[-cell]
[-net]
[-from_in_ports]
[-to_out_ports]
[-max_line num]
[-list_annotated]
[-list_not_annotated]
[-constant_arcs]
```

Data Types

```
num     integer
```

Arguments

`-cell`

Reports all data annotated on cells.

`-net`

Reports all data annotated on nets.

`-from_in_ports`

Includes the nets that start from input ports. By default, nets that start at input ports are not included in the list of nets reported for annotated delays. The reason is that SDF format specifies the nets starting at input ports of the design are not part of the SDF file because the delay of this net is dependent on the external environment.

`-to_out_ports`

Includes the nets that end at output ports. By default, nets that end at output ports are not included in the list of nets reported for annotated delays. The reason is that SDF format specifies the nets ending at output ports of the design are not part of the SDF file because the delay of this net is dependent on the external environment.

`-max_line` *num*

Reports the specified maximum number of lines for the *-list_annotated* and *-list_not_annotated* options.

`-list_annotated`

Lists timing arcs that are back-annotated. Use this option to identify the specified annotated delays if no annotated delays are expected. This option lists both connected and unconnected cells.

`-list_not_annotated`

Lists timing arcs that are not back-annotated. Use this option to identify which delay arcs are not annotated. This option lists both connected and unconnected cells.

`-constant_arcs`

Keeps a separate count for the arcs that are disabled due to logic constants (but not case_analysis). With this option, the *-list_annotated* or *-list_not_annotated* option does not list the arc disabled due to logic constants. The total count at the end of the table includes the number of constant arcs.

Description

Provides a summary report of how many cell and net delays are annotated in the current design. The purpose of this command is to check if all delays of the design are annotated after reading an SDF file. By default, net delay starting from input ports or ending at output ports are considered separately.

By default, this command reports annotated data on both cells and nets. To report annotated data on cells or nets only, use the *-cell* or *-net* option, respectively.

Examples

The following is an example of a default report showing annotated delays:

```
pt_shell> report_annotated_delay

****************************
report: annotated_delay
****************************

                             |           |           |    NOT    |
                             |   Total   | Annotated | Annotated |
-----------------------------+-----------+-----------+-----------+
cell arcs                    |        19 |        19 |         0 |
cell arcs (unconnected)      |         1 |         1 |         0 |
internal net arcs            |         3 |         3 |         0 |
net arcs from primary inputs |        11 |        11 |         0 |
net arcs to primary outputs  |         4 |         4 |         0 |
```

```
-----------------------------+-----------+-----------+-----------+
                             |        38 |        38 |         0 |
```

The following is an example of a delay annotation report that includes a separate count for constant arcs.

```
pt_shell> report_annotated_delay -constant_arcs

****************************
report: annotated_delay
****************************

                             |           |           |    NOT    |
                             |   Total   | Annotated | Annotated |
-----------------------------+-----------+-----------+-----------+
cell arcs                    |        19 |        17 |         0 |
cell arcs (unconnected)      |         1 |         1 |         0 |
constant arcs                |           |         2 |         0 |
internal net arcs            |         3 |         3 |         0 |
constant arcs                |           |         0 |         0 |
net arcs from primary inputs |        11 |        11 |         0 |
constant arcs                |           |         0 |         0 |
net arcs to primary outputs  |         4 |         4 |         0 |
constant arcs                |           |         0 |         0 |
-----------------------------+-----------+-----------+-----------+
                             |        38 |        38 |         0 |
```

---

report_annotated_parasitics

Reports net parasitics back-annotated on the current design.

Syntax

string *report_annotated_parasitics*

```
[-check]
[-no_check]
[-internal_nets]
[-boundary_nets]
[-driverless_nets]
[-loadless_nets]
[-pin_to_pin_nets]
```

Feedback

```
[-max_nets num]
[-list_annotated]
[-list_not_annotated]
[-list_lumped]
[-constant_arcs]
[-via]
[-via_verbose]
[net_list]
```

Data Types

```
net_list    list
num         integer
```

Arguments

`-check`

Checks the design to verify that all annotated RC networks are complete. This option causes the *report_annotated_parasitics* command to check that all fanouts of each net connect through the RC network to each driver of the net. An error message reports nets with incomplete RC networks. This option is the default for PrimeTime version C-2009.06 and later.

`-no_check`

Prevents checking of the design to verify that all annotated RC networks are complete.

`-internal_nets`

Reports only parasitics annotated on internal nets (nets connected only to cell pins).

`-boundary_nets`

only parasitics annotated on boundary (port) nets. A connection to any port qualifies a net as a boundary net.

`-driverless_nets`

Reports parasitics annotated on driverless nets (nets that do not have a global driver).

`-loadless_nets`

Reports parasitics annotated on loadless nets (nets that do not have a global load) are reported. Note that if there are nets that neither have a global driver nor a global load, those nets are counted as driverless nets and not as loadless nets for the report.

`-ignore_partially_annotated`

Ignores incomplete RC network annotations considering them as not annotated.

`-pin_to_pin_nets`

Reports parasitics annotated on nets that have at least one global driver and at least one global load pin.

`-max_nets` *num*

Limites reporting to the specified maximum number of nets for the *-list_annotated*, *-list_not_annotated* and *-list_lumped* options.

`-list_annotated`

Lists back-annotated nets. You cannot use this option together with the *-list_not_annotated* or *-list_lumped* options.

`-list_not_annotated`

Lists nets that are not back-annotated. You cannot use this option together with the *-list_annotated* or *-list_lumped* options.

`-list_lumped`

Lists lumped nets. You cannot use this option together with the *-list_annotated* or *-list_not_annotated* options.

`-constant_arcs`

Keeps a separate count for nets connected to pins with arcs that are disabled due to logic constants or case analysis. With this option, the *-list_annotated* or *-list_not_annotated* option does not list the constant nets. The total count at the end of the table includes the count of constant nets, and a count of constant nets suppressed (due to *-max_nets*) is shown separately from the count of ordinary nets suppressed.

`-via`

Report via annotation details.

`-via_verbose`

Report via annotation details in verbose.

net_list

Reports only the specified nets.

Description

This command reports nets annotated with parasitics in the current design. This command can also check the consistency of parasitics after reading ascii or binary parasitics. The report summarizes how many nets are annotated with reduced parasitics (pi models) or detailed parasitics (RC networks).

Feedback

Parasitics are associate with global nets. This report counts nets without considering hierarchical crossings - only one segment per global net is reported.

The report clearly shows how many nets are back-annotated with lumped, pi and detailed RC networks. The nets that are not annotated are shown in a separate column. In addition, nets that do not have a global driver and nets that do not have any global load pins are shown separately. If a net falls into both these categories, that is if a net does not have a driver and does not have a load, it is shown in driver-less nets row.

Details on which nets are annotated or not annotated can be displayed using either the *-list_annotated* or *-list_not_annotated* option. Listing annotated nets show a detailed description of RC networks. Listing unannotated nets show only a list of net names. By default, these reports only show 10 nets. To increase that limit, use the *-max_nets* option.

You can also report parasitics for a specific set of nets by using the *net_list* option. The *-list_annotated* and *-list_not_annotated* options restrict their scope to the nets in *net_list*.

When the *si_enable_analysis* variable is set, a column for coupled networks is added to the summary report that provides the number nets that have coupling capacitors.

If the *-check* option is used, and the command reports nets with incomplete parasitics, you can complete partially annotated nets using the *complete_net_parasitics* command.

Examples

The following is an example of an annotated parasitics report.

```
pt_shell> report_annotated_parasitics -check

Feedback

report_annotated_power

Reports annotated power.

Syntax

status *report_annotated_power*

```
[-list_annotated]
[-rails rail_list]
```

Data Types

rail_list	list

Arguments

`-list_annotated`

Reports a list of cells with power values annotated on them.

`-rails rail_list`

Reports the annotated power for the specified power supply nets (or rails in non-UPF mode). This feature is only valid if the *power_enable_multi_rail_analysis* variable is set to *true*.

Description

This command provides a summary report of annotated powers in the current design.

Examples

The following example shows how power is annotated, removed, and reported.

```
pt_shell> set_annotated_power -internal_power 1 -leakage_power 0.01 u0/*
1
pt_shell> report_annotated_power -list_annotated

****************************************
Report : annotated_power
        -list_annotated
****************************************

Annotated cell powers:
------------------------------
1.  u0/u0  (internal: 1  leakage: 0.01)
2.  u0/u1  (internal: 1  leakage: 0.01)

---

report_aocvm

Reports information about advanced on-chip variation (AOCV) derate tables and coefficients. Also displays details of path-based and graph-based AOCV calculation.

Syntax

```
status report_aocvm
   [-early]
   [-late]
   [-rise]
   [-fall]
   [-clock]
   [-data]
   [-voltage voltage_value]
   [-cell_delay]
   [-net_delay]
   [-list_annotated]
   [-list_not_annotated]
   [-coefficient]
   [-lib_cell]
```

```
   [-nosplit]
   [object_list]
```

Data Types

voltage_value	string
object_list	list

Arguments

`-early`

Displays only the early AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-late`

Displays only the late AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-rise`

Displays only the rise AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-fall`

Displays only the fall AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-clock`

Displays only the clock AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-data`

Displays only the data AOCV derate tables for the objects specified in the *object_list*. This argument can be used with the -list_not_annotated option.

`-voltage` *voltage_value*

Displays only the voltage value-specific AOCV derate tables for the objects specified in the *object_list*.

`-cell_delay`

Indicates that only cell delay AOCV derate tables are shown on the objects specified in the *object_list*.

`-net_delay`

Indicates that only net delay AOCV derate tables are shown on the objects specified in the *object_list*.

`-list_annotated`

Indicates that leaf cells and global nets that are annotated with AOCV derate tables are listed.

`-list_not_annotated`

Indicates that leaf cells and global nets that are not annotated with AOCV derate tables are listed.

`-coefficient`

Indicates that random AOCV coefficients are shown. You can specify a collection of lib_cell, lib_timing_arc, and cell objects in the *object_list* to display coefficients annotated only on those objects.

`-lib_cell`

This option can be used with either the -list_annotated or -list_not_annotated options to report the library cell name instead of the instance name.

`-nosplit`

Do not split lines when columns overflow.

`object_list`

Specifies either timing_path objects for which path-based AOCV metrics are to be reported; or timing arc objects for which graph-based AOCV metrics are to be reported; or design objects on which AOCV derate tables and advanced OCV derate coefficients have been annotated.

Description

This command displays the user-specified advanced on-chip variation (AOCV) information. The type of information displayed depends on the type of AOCV information annotated.

If the design has been annotated with AOCV derate tables using the *read_aocvm* command, the *report_aocvm* command outputs a summary showing the numbers of leaf cells and global nets annotated with AOCV derate tables. Lists of fully annotated, partially annotated, and not annotated leaf cells and global nets can be displayed using the *-list_annotated* and *-list_not_annotated* options. You can specify a collection of the design, library arcs, hierarchical cells, and nets in the *object_list* to display AOCV derate tables annotated only on those objects. The early, late, rise, fall, clock, and data flags can be used with the list_not_annotated option to filter the list of netlist objects reporting only those missing the specified derating types. If a netlist object is specified and the AOCV information has been read from a file, the full path to the file is listed.

If the design has been annotated with AOCV derate coefficients using the *set_aocvm_coefficient* command, the *report_aocvm -coefficient* command displays these

coefficients. You can specify a collection of library cells, library timing arcs, and cells in the *object_list* to display coefficients annotated only on those objects.

If a timing path is specified in the *object_list*, path-based metrics (distance, launch depth, and capture depth) for that path are displayed. Note that the depths shown in the report have been scaled by random AOCV coefficients, if they exist. Timing paths can be obtained using the *get_timing_paths* command. The path passed to *report_aocvm* has to be a path-based analysis path if a graph-based analysis path is specified an error is issued.

If a timing arc is specified in the *object_list*, graph-based metrics for that arc are displayed. Note that the depths shown in the report have been scaled by random AOCV coefficients, if they exist. Timing arcs can be obtained using the *get_timing_arcs* command. Graph-based timing arc metrics are only displayed when graph-based AOCV analysis has been enabled by setting the *timing_aocvm_enable_analysis* variable to *true*.

Examples

In the following example, the design has been annotated with AOCV derate factors using the *read_aocvm* command.

```
pt_shell> report_aocvm

****************************************
Report : aocvm
 ...
****************************************

             |           | Fully     | Partially | Not       |
             | Total     | annotated | annotated | annotated |
 ------------+-----------+-----------+-----------+-----------+
  Leaf cells |         6 |         0 |         4 |         2 |
  Nets       |         7 |         0 |         0 |         7 |
 ------------+-----------+-----------+-----------+-----------+
             |        13 |         0 |         4 |         9 |
```

The following example displays path-based metrics for the timing path specified in the *object_list*, for a design that has been annotated with AOCV deratings.

```
pt_shell> report_aocvm [get_timing_paths -pba_mode path \\
          -path_type full_clock_expanded]

****************************************
Report : aocvm
         object_list
 ...
****************************************

  Startpoint: ffL (rising edge-triggered flip-flop clocked by clk2)
  Endpoint: ffC (rising edge-triggered flip-flop clocked by clk2)
  Path Group: clk2
```

```
  Path metrics         Cell               Net
 ---------------------------------------------
  Distance           575.85            666.41
  Launch depth         2.69              3.07
  Capture depth        1.00              1.09
```

The following example displays graph-based metrics and AOCV derate factors for the timing arc specified in the *object_list*. This report is only displayed when graph-based AOCV is enabled. The arc depth and distance displayed is the most pessimistic depth and distance for all possible paths through this arc.

```
pt_shell> report_aocvm [get_timing_arcs -from u2/A -to u2/Z]

****************************************
Report : aocvm

Feedback

report_app_var

Shows the application variables.

Syntax

string *report_app_var*

```
[-verbose]
[-only_changed_vars]
[pattern]
```

Data Types

pattern	string

Arguments

`-verbose`

Shows detailed information.

`-only_changed_vars`

Reports only changed variables.

pattern

Reports on variables matching the pattern. The default is "*".

Description

The *report_app_var* command prints information about application variables matching the supplied pattern. By default, all descriptive information for the variable is printed, except for the help text.

If no variables match the pattern, an error is returned. Otherwise, this command returns the empty string.

If the *-verbose* option is used, then the command also prints the help text for the variable. This text is printed after the variable name and all lines of the help text are prefixed with "#".

The Constraints column can take the following forms:

{val1 ...}

The valid values must belong to the displayed list.

val \<= a

The value must be less than or equal to "a".

val \>= b

The value must be greater than or equal to "b".

b \<= val \<= a

The value must be greater than or equal to "b", and less than or equal to "a".

Examples

The following are examples of the *report_app_var* command:

```
prompt> report_app_var sh*
Variable                 Value     Type    Default   Constraints
------------------------ --------- ------- ---------
 ---------------------
sh_continue_on_error     false     bool    false
sh_script_stop_severity  none      string  none      {none W E}
 \.\.\.

prompt> report_app_var sh* -verbose
Variable                 Value     Type    Default    Constraints
------------------------ --------- ------- ---------
 ---------------------
sh_continue_on_error     false     bool    false
   # Allows source to continue after an error
sh_script_stop_severity  none      string  none      {none W E}
   # Indicates the error message severity level which would cause
   # a script to stop executing before it completes
 \.\.\.
```

---

report_attribute

Reports the attributes of objects in the design.

Syntax

string *report_attribute*

```
[-class class_name]
[-nosplit]
[-application]
[-attributes attribute_list]
```

Feedback

```
[-summary]
[-format csv]
[-output file_name]
object_list
```

Data Types

```
class_name          string
attribute_list      list
style               string
file_name           string
object_list         list
```

Arguments

`-class class_name`

Specifies the type of object: *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, or *lib_pin*. Use this option only when the *object_list* is specified as a list of names, not as a collection.

`-nosplit`

Prevents the splitting of long lines in the report.

`-application`

Lists application attributes as well as user-defined attributes. Without this option, the command reports only user-defined attributes (those created by the *define_user_attribute* command).

`-attributes attribute_list`

Reports only the specified list of attributes for each object. Without this option, the command reports all user-defined attributes, plus all application attributes if the *-application* option is used.

`-summary`

Generates a summary report in column format showing multiple attributes on each line, one line per object. Without this option, the report uses multiple lines per object. You can use this option only with the *-attributes* option.

`-format csv`

Specifies the reporting format. The only allowed value is *csv*, which generates the report as a comma-separated value list. Without this option, the report is generated in table format. To write out a file that can be read into a spreadsheet, use the *-format csv* option with the *-output* option.

`-output file_name`

Writes out the report to a file instead of the screen.

object_list

Specifies the objects whose attributes are reported, either as a collection gathered by a get_* command (*get_cells*, *get_nets*, and so on) or a list of object names. If you specify a list of names, you must also use the *-class* option to specify the object type.

Description

The *report_attribute* command reports the attribute settings of specified objects in the design. To see a list of object attributes that you can query, use the *list_attributes* command. For descriptions of the attributes, see the man page for the object type, for example, *man cell_attributes* or *man net_attributes*.

By default, the command reports only user-defined attributes (those created by the *define_user_attribute* command). To also report application attributes (predefined by the PrimeTime application), use the *-application* option.

An attribute value can be an integer, floating-point number, Boolean value, text string, or collection. For a collection-type attribute, the *report_attribute* command reports only the name of the first object in the collection. To gather the attribute as a collection, use the *get_attribute* command.

Hierarchical attribute queries (attribute queries of the form: *attribute1.attribute2*) are supported in report_attribute and *-summary* except for collections containing lib (lib_pin, lib_cell etc) object types and also not in distributed hierarchical analysis.

To limit the report to a specific list of attributes, use the *-attributes* option.

Examples

The following example defines an integer attribute num_x for cells, sets the value on two cells, and reports the result.

```
pt_shell> define_user_attribute -type int -class cell num_x
pt_shell> set_user_attribute [get_cells {U137 U138}] num_x 30
Set attribute 'num_x' on 'U137'
Set attribute 'num_x' on 'U138'

pt_shell> report_attribute [get_cells {U137 U138}]
 ...
Design       Object        Type      Attribute Name      Value
-------------------------------------------------------------------
ORCA         U137          int       num_x               30

ORCA         U138          int       num_x               30
```

The following example reports application attributes as well as user-defined attributes.

```
pt_shell> report_attribute -application [get_cells U137]
 ...
```

```
Design       Object        Type      Attribute Name           Value
-------------------------------------------------------------------------
ORCA         U137          int       num_x                    30
ORCA         U137          float     area                     3.500000
ORCA         U137          string    base_name                U137
ORCA         U137          boolean   disable_timing           true
ORCA         U137          float     early_fall_cell_check_derate_factor
                                                              1.000000
ORCA         U137          float     early_fall_clk_cell_derate_factor
                                                              0.900000
 ...         ...           ...       ...                      ...
```

The following example reports details about the timing arcs in a cell.

```
pt_shell> report_attribute [get_timing_arcs -of_objects [get_cells U137]]
 \\
 -attributes {from_pin to_pin is_disabled delay_max_rise delay_min_rise}
 ...
Design      Object        Type      Attribute Name           Value
-------------------------------------------------------------------------
ORCA        arc           collection
                                    from_pin                 U137/A1
ORCA        arc           collection
                                    to_pin                   U137/Z
ORCA        arc           boolean   is_disabled              true
ORCA        arc           float     delay_max_rise           0.000000
ORCA        arc           float     delay_min_rise           0.000000
ORCA        arc           collection
                                    from_pin                 U137/A2
ORCA        arc           collection
                                    to_pin                   U137/Z
ORCA        arc           boolean   is_disabled              false
ORCA        arc           float     delay_max_rise           0.876045
ORCA        arc           float     delay_min_rise           0.876045
```

The following example is the same as the previous one, but in summary format.

```
pt_shell> report_attribute [get_timing_arcs -of_objects [get_cells U137]]
 \\
 -attributes {from_pin to_pin is_disabled delay_max_rise delay_min_rise}
 \\
 -summary
 ...
Object    from_pin    to_pin     is_disabled  delay_max_rise
 delay_min_rise
-------------------------------------------------------------------------
arc       U137/A1     U137/Z     true         0.000000       0.000000
arc       U137/A2     U137/Z     false        0.876045       0.876045
```

The following example is the same as the previous one, but in CSV format.

Feedback

report_bottleneck

Reports timing bottleneck information.

Syntax

string *report_bottleneck*

```
[-cost_type path_count | path_cost | fanout_endpoint_cost]
[-delay_type max | min]
[-slack_lesser_than slack_limit]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-through through_list]
```

Feedback

```
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-max_cells cell_count]
[-max_paths path_count]
[-nworst_paths paths_per_endpoint]
[-group group_name]
[-significant_digits digits]
[-nosplit]
```

Data Types

slack_limit	float
from_list	list
rise_from_list	list
fall_from_list	list
to_list	list
rise_to_list	list
fall_to_list	list
through_list	list
rise_through_list	list
fall_through_list	list
cell_count	int
path_count	int
paths_per_endpoint	int
group_name	list
digits	int

Arguments

`-cost_type path_count | path_cost | fanout_endpoint_cost`

Specifies a cost type to use for computing the bottleneck cost:

- *path_count* (the default) - Uses the number of violating paths through the cell.
- *path_cost* - Uses the total slack of violating paths through the cell.
- *fanout_endpoint_cost* - Uses the total cost of violating endpoints in the fanout of the cell.

`-delay_type max | min`

Specifies whether to compute the bottleneck cost for

- *max* (the default) - Setup analysis.
- *min* - Hold analysis.

`-slack_lesser_than slack_limit`

Considers only those paths with a slack less than *slack_limit* to find bottlenecks.

`-from` *`from_list`*

Considers only paths from the specified pins, ports, nets, or startpoints clocked by named clocks to find bottlenecks.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *`fall_from_list`*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-to` *`to_list`*

Considers only paths to the specified pins, ports, nets, or endpoints clocked by specified clocks.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Same as the *-to* option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-through` *`through_list`*

Considers only paths through the specified pins, ports, nets or cells to find bottlenecks.

You can use multiple *-through*, *-rise_through*, and *-fall_through* options in a single command to specify paths that traverse through multiple points in the design. The tool respects the order in which you specify these options.

The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If you specify more than one object with one *-through*, *-rise_through*, or *-fall_through* option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

`-rise_through` *`rise_through_list`*

Same as the *-through* option, except that the path must rise through the specified objects.

`-fall_through` *`fall_through_list`*

Same as the *-through* option, except that the path must fall through the specified objects.

`-max_cells` *`cell_count`*

Specifies the number of cells to report. The default is 20.

`-max_paths` *`path_count`*

Specifies the number of paths to be considered per path group. Allowed values are 1 to 2000000; the default is to use the *paths_per_endpoint* setting.

`-nworst_paths` *`paths_per_endpoint`*

Specifies the number of paths to be considered per endpoint. Allowed values are 1 to 2000000; the default is 100.

`-group` *`group_name`*

Indicates that only paths in *group_name* are to be considered.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default is 2. Use this option if you want to override the default.

`-nosplit`

Prevents line-splitting and facilitates writing software to extract information from the report output.

Description

This command reports information about timing bottlenecks in the current design. A bottleneck is a common point in the design that contributes to multiple violations.

To report bottlenecks throughout the current design, the arrival totals and slacks must be available on all pins, not just at endpoints. To achieve this, set the

timing_save_pin_arrival_and_slack variable to *true* before using this command. If the *timing_save_pin_arrival_and_slack* variable is set to *false*, this command automatically sets it to *true* and updates the design timing before the command executes.

If you intend to use this command, it is recommended that you set the *timing_save_pin_arrival_and_slack* variable to *true* before the first timing update, therefore preventing the cost of an additional timing update.

Examples

The following example reports the 20 worst bottleneck cells in the design based on the number of paths through the cell with slack less than 0.0.

```
pt_shell> report_bottleneck

****************************************
Report : bottleneck
         -max_cells 20
         -nworst_paths 100
Design : example
 ...
****************************************

Bottleneck Cost = Number of violating paths through cell

                                                  Bottleneck

report_bounding_box

Reports the approximate bounding box of specified nets.

Syntax

status *report_bounding_box*

`[-of_objects nets]`

Data Types

nets	list

Arguments

`-of_objects nets`

A list of one or more nets for which to report bounding-box information. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command reports the approximate bounding box of specified nets. The coordinates of ground capacitor nodes are used for computation.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a bounding box report.

```
pt_shell> report_bounding_box -of_objects {SUM0 B0}
========        ===========    =========    ===========    =========
Net Name        llx            lly          urx            ury
========        ===========    =========    ===========    =========
SUM0            -467.000000    11.000000    -458.000000    82.000000
B0              -497.000000    2.500000     -272.000000    82.000000
```

report_budget

Reports the budget allocation calculations for a selected timing path.

Feedback

Syntax

string *report_budget*

```
-through      pin_name
[-delay_type  delay_type]
[-show_slack]
[-nosplit]
```

Data Types

delay_type	string
pin_name	string

Arguments

`-through` *pin*

Reports the budget allocation of worst timing path through the given pin.

The pin must be a hierarchical pin. The *update_budget* command must be run prior to using this command.

`-delay_type` *delay_type*

Specifies the type of path delay constraint to consider when reporting worst-slack budgeted paths.

Valid values are: *min*, *max*, *min_rise*, *min_fall*, *max_rise*, *max_fall*.

`-show_slack`

Shows slack after budgeting. This option prints the following rows below the budget report:

- "Block slack at pin" - shows the budget-estimated slack for the block-level analysis at the specified *-through* pin, assuming that the budgeted constraints are used.
- "Top segment slack" - shows the budget-estimated slack for the top-level analysis at the specified *-through* pin.

`-nosplit`

Prevents line splitting. This can useful for scripts that extract information from the report. By default, the report generates a new line when the text cannot fit in the alloted space in a column.

Feedback

Examples

The following command reports the budget allocation of the worst path that goes through hierarchical pin mid/i1:

```
pt_shell> report_budget -through mid/i1
 ...

Slack:  -5.23
Required time:   5.00
From clock: clk_v2
To clock: clk_r
Path Type: max fall

Point                          Mode                      Delay     Weight
 Budget
-------------------------------------------------------------------------
-------
i1
mid/i1                         pin_slack                   0.27     0.38
 -1.72
mid/ff1/D                      pin_slack                   0.44     0.62
 -2.79

mid/i1 -> mid/ff1/D
  Budget = delay + slack * weight =   0.44 +  -5.23 *   0.62 =  -2.79
  Input delay margin = slack + delay - budget =  -5.23 +   0.44 -  -2.79
 =  -1.99
  Input budget = context + Input delay margin =   8.28
```

- update_budget

---

report_bus

Reports the bused ports or nets in the current instance or current design.

Syntax

string *report_bus*

```
[-nosplit]
```

Arguments

`-nosplit`

Does not split lines if column overflows.

Feedback

Description

Displays information about buses (pins or nets) in the current instance or current design. If the current instance is set, the report is generated for the design of that instance; otherwise, the report is generated for the current design.

Examples

The following command reports the buses in the design.

```
pt_shell> report_bus

****************************************
Report : bus
Design : new_design
****************************************

Bussed Port      Dir      From     To     Width
------------------------------------------------------------
acnt             out      15       0      16
baddreg          out      15       0      16
bwordreg         out      15       0      16
caddreg          out      15       0      16
```

See Also

---

report_case_analysis

Reports case analysis entries on ports and pins, and the propagation of user-specified case values and logic constant values throughout the netlist.

Syntax

```
status report_case_analysis
  [-all]
  [-nosplit]
  [-to]
  [-from]
  [-sequential_propagation]
  [pin_or_port_list]
```

Data Types

```
pin_or_port_list      list
```

Feedback

Arguments

`-all`

Reports all pins that have set case analysis values and reports the built-in constant pins of the design that are considered for startpoints of logic constant propagation. Logic constant propagation is performed by default from the constant pins of the design, unless the *disable_case_analysis* variable is set to *true*.

`-nosplit`

Prevents line splitting to facilitate parsing of information from the report output.

`-to`

Shows the backward trace of case propagation to each pin or port specified by *pin_or_port_list*. The backward trace expands only to pins or ports with case values that contribute to the case value on the destination pin or port. If the number of pins or ports involved in backward trace exceeds the number specified by *-max_objects*, PrimeTime truncates the trace and prints a message at the end of the trace to indicate an incomplete trace.

`-from`

Shows the forward trace of case propagation from each pin or port specified by *pin_or_port_list*. The forward trace expands only to pins or ports where the case value from the source contributes to the case value on that pin or port. If the number of pins or ports involved in the forward trace exceeds the number specified by *-max_objects*, PrimeTime truncates the trace and prints a message at the end of the trace to indicate an incomplete trace.

`-sequential_propagation`

Reports sequential cell instances and library cells that are enabled for constant propagation. To enable constant propagation on specific sequential cells, set the *case_analysis_sequential_propagation* variable to *never*, and run the *set_case_sequential_propagation* command.

`pin_or_port_list`

Reports the propagated case values on the specified pins or ports.

Description

This command reports case analysis settings on ports and pins that are specified by the *set_case_analysis* command.

If you do not specify *pin_or_port_list*, the report lists all pins and ports on which case analysis is set; this report does not show where the logic constant values are propagated.

Feedback

Examples

The following example specifies that pins U1/U2/A and U1/U3/CI are set to a constant logic I1:

```
pt_shell> set_case_analysis 1 {U1/U2/A U1/U3/CI}
pt_shell> report_case_analysis

****************************************
Report : case_analysis
 ...
****************************************

Pin name                     User case analysis value
-----------------------------------------------------
U1/U2/A                       1
U1/U3/CI                      1
```

The following example displays the fanout trace of the case value on port CL:

```
pt_shell> report_case_analysis -from CL

****************************************
Report : case_analysis
Design : counter
 ...
****************************************
Properties         Value   Pin/Port
----------------------------------------
user case          1       CL

Case fanout report:
Verbose Forward Trace for pin/port CL:

Pin/Port ID  Value  Fanout Pin/Port IDs  Pin/Port
-------------------------------------------------
0            1      1 8                 CL
1            1      3                   p/B
2            1      3                   p/A
3            1      4 5 6 7             p/Z
4            1                          a/D
5            1                          j/D
6            1                          g/D
7            1                          d/D
8            1                          o/A
9            0                          o/B
```

The following example enables sequential propagation on cell instances (FF1, FF2, and FF3), library cells (D_FF, D_FF_R, and D_FF_S) and then prints them using the '-sequential_propagation' option in the report_case_analysis command.

Feedback

```
pt_shell>set_case_sequential_propagation { FF1 FF2 FF3 }

---

report_cell

Reports cell information.

Syntax

status *report_cell*

```
[-connections]
[-verbose]
[-nosplit]
[-significant_digits digits]
[cell_list]
```

Data Types

```
digits        integer
cell_list     list
```

Feedback

Arguments

`-connections`

Displays the pins and the nets to which they connect.

`-verbose`

Displays detailed connection information. For each input pin, displays the net and the driver pins on that net. For each output pin, displays the net and the load pins on that net. Use this option together with the *-connections* option.

`-nosplit`

Prevents line splitting in the report when a field exceeds the column width.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point shown in the report. Allowed values are 0-13. The default is determined by the *report_default_significant_digits* variable, which has a default of 2. Use this option if you want to override the default. Because the tool uses fixed-precision floating-point arithmetic for delay calculation, the actual precision might depend on the platform. For example, on SVR4 UNIX see FLT_DIG in limits.h. The upper bound on a meaningful value of the argument to *-significant_digits* is then FLT_DIG - ceil(log10(fabs(*any_reported_value*))).

`cell_list`

Specifies the cells to report. If you do not specify this option, all cells in the current instance are listed.

Description

This command displays information and statistics about cells in the current instance or current design. If you set for the current instance, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

If any cell uses nondefault operating conditions, the *report_cell* command shows information about the operating conditions for all cells.

Some information, such as whether the cell is in an ideal network or not, is displayed after a timing update (as a result of manually executing the *update_timing* command function or experiencing an implicit timing update as a result of executing other commands). This behavior is intended to help you to obtain information and statistics about cells without incurring the cost of a complete timing update.

Examples

The following example displays a report of the cells in the current design.

```
pt_shell> report_cell

****************************************
Report : cell

    Q                    out_2           i1/low3/n1/B       Input Pin (NR4)
                                         out_2              Output Port
                                         i1/low/n1/B        Input Pin (NR4)
                                         i1/low2/n1/B       Input Pin (NR4)
```

```
    QN                  NET2QNX        i2/low3/n1/B      Input Pin (NR4)
                                       i2/low/n1/B       Input Pin (NR4)
                                       i2/low2/n1/B      Input Pin (NR4)
```

In the following example, cell U2 uses nondefault operating conditions. Therefore, the *report_cell* command shows information about the operating conditions for all cells.

```
pt_shell> report_cell "B/C/u1  B/C/D/E/u2 B/C/D/E/u3 "

report_cell_em_violation

Reports the toggle rate violations for specific cells or pins.

Syntax

status *report_cell_em_violation*

```
[-cell cell_list]
[-pin pin_list]
[-exclude_arc]
[-nworst number]
[-current_type type]
[-verbose]
[-all]
```

Data Types

cell_list	list
pin_list	list
number	integer
type	string

Arguments

`-cell cell_list`

Reports toggle rate violations for the pins of the cells specified in the *cell_list*. The *-cell* and *-pin* options are mutually exclusive.

`-pin pin_list`

Reports toggle rate violations for the pins specified in the *pin_list*. The *-cell* and *-pin* options are mutually exclusive.

`-exclude_arc`

Prevents the use of arc-based data for calculations. If you do not use this option, the command uses all table data (arc-based and non-arc-based) for toggle rate violation calculations.

`-nworst number`

Reports the specified number of cells or pins with the worst toggle rate violations.

Feedback

`-current_type` *type*

Specifies the table to use for toggle rate violation calculations. If the switch is not specified, the command checks all three current types and report the worst one .

`-verbose`

Shows the slew rate and cap values used for toggle rate violation calculations. Also reports errors for missing electromigration data for pins.

`-all`

Shows all pins. If you do not use this option, by default, the command reports only the pins with toggle rate violations.

Description

This command reports the toggle rate violations for the cells or pins in the design.

Examples

The following command reports violations for all pins in the design with toggle rate violations.

```
pt_shell> report_cell_em_violation
```

The following command reports all pins with and without toggle rate violations. Pins with toggle rate violations will have violation metrics.

```
pt_shell> report_cell_em_violation -pin [get_pins] -all
```

The following command reports the violations for all pins with toggle rate violations in the design. Arc-based tables are ignored for the calculations.

```
pt_shell> report_cell_em_violation -pin [get_pins] -exclude_arc
```

See Also

- get_em_max_toggle_rate

---

report_cell_mode

Reports the modes for specified cells.

Syntax

```
status report_cell_mode
   [-nosplit]
   [instance_list]
```

Feedback

Data Types

instance_list list

Arguments

-nosplit

Prevents line splitting when report columns overflow.

instance_list

Specifies a list of instances whose modes are to be reported. By default, the report includes all cells that have modes. This option is only valid for the *-type cell* option.

Description

This command reports cell modes. The report specifies whether the cell mode is enabled or disabled, and one of the following reasons for enabling or disabling the mode:

- cell - Indicates that the cell mode has been set directly using the *set_cell_mode* command.
- design - Indicates that the cell mode has been set due to the activation of a design mode using the *set_mode -type design* command. The design mode must have previously been mapped to the cell mode using the *map_design_mode* command. The report also specifies the name of the activated design mode. To view more details about the design mode, use the *report_mode -type design* command.
- cond - Indicates that the cell mode has been set due to evaluation of the mode condition during constant propagation.
- default - Indicates that the cell mode has not been set by any of the above reasons.

Examples

The following example reports cell mode information for the design top_design. Two cells have modes, Uram1 and Uram2 are instances of the library cell RAM2_core. rw is a cell mode group defined on the library cell RAM2_core. This cell mode group has two cell modes read and write. No modes are currently active so all modes are enabled and the reason is given as default.

```
pt_shell> report_cell_mode

****************************************
Report : mode
Design : top_design
****************************************

Cell                              Mode(Group)       Status      Reason
```

```
------------------------------------------------------------------------
---
Uram1/core(RAM2_core)              read(rw)          ENABLED     default
                                   write(rw)         ENABLED     default
------------------------------------------------------------------------
---
Uram2/core(RAM2_core)              read(rw)          ENABLED     default
                                   write(rw)         ENABLED     default
------------------------------------------------------------------------
---
```

The following example shows a report of modes specified for the two RAMs that have modes in the design. Ram Uram1 is set in mode read, and Ram Uram2 is set in mode write. Thus, all timing arcs of RAM Uram1 associated with mode read are enabled , and all timing arcs associated with mode write are disabled.

```
pt_shell> set_cell_mode read Uram1/core
pt_shell> set_cell_mode write Uram2/core
pt_shell> report_cell_mode

****************************************
Report : mode
Design : top_design
****************************************

Cell                               Mode(Group)     Status          Reason
------------------------------------------------------------------------
---
Uram1/core(RAM2_core)              read(rw)        ENABLED         cell
                                   write(rw)       disabled        cell
------------------------------------------------------------------------
---
Uram2/core(RAM2_core)              read(rw)        disabled        cell
                                   write(rw)       ENABLED         cell
------------------------------------------------------------------------
---
```

Feedback

report_cell_robustness

Runs unified cell sensitivity analysis at the design level and reports a list of critical cells sensitive to specific parameters.

Syntax

integer *report_cell_robustness*

```
[-pba]
[-dvd]
[-verbose]
[-reg_to_reg]
[-max_violators num_cells]
[-nosplit]
[-significant_digits digits]
[-sort_by slack | delay]
[-type variation | voltage | transition | load_cap | wire_cap |
 {analysis_type_list}]
[-voltage_shift value]
[-voltage_shift_ratio value]
[-tran_shift_ratio value]
[-loadcap_shift_ratio value]
[-wirecap_shift_ratio value]
[-slack_lesser_than maximum_robustness_slack]
[-slack_margin margin_value]
[-mim_filter none | logical | timing]
[-cells cell_list]
[-net]
[-delay_type delay_type]
[-plot]
[-prefix string]
[-compare {file1 file2 ...}]
[-title title_string]
```

Data Types

num_cells	integer
digits	integer
analysis_type_list	list
value	float
maximum_robustness_slack	float
margin_value	float
cell_list	list
delay_type	string
file	string
title_string	string

Feedback

Arguments

`-pba`

Performs cell robustness using path-based timing analysis, where on-demand exhaustive path-based analysis (PBA) pin slacks are used to avoid pessimism. Without this option, cell robustness analysis uses graph-based analysis (GBA) and GBA pin slacks are used to evaluate the cell high-sigma failure rate.

`-dvd`

Performs voltage robustness analysis using the dynamic voltage drop (DVD) information read-in previously using the *read_dvd* command. The variable *timing_enable_dvd_analysis* must be set to *true* for the DVD voltage robustness analysis to be performed. An additional column “Delta_V” is reported in the voltage robustness report to show drop in voltage for each cell based on the DvD file. Please note that "-dvd" cannot be used with "-voltage_shift" or "-voltage_shift_ratio" options.

`-verbose`

Shows detailed information on robustness violators in the report.

`-max_violators` *`num_cells`*

Specifies the maximum number of cells to be reported. The default is 10000.

`-nosplit`

Prevents line-splitting to facilitate parsing of information from the report output. With this option, the design information is listed in fixed-width columns. Without this option, if the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point displayed for the values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which is 2 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-reg_to_reg`

Restricts analysis to register-to-register paths. This option is supported for both GBA and PBA analyses.

`-sort_by slack | delay`

Specifies how the reported cells are sorted. The default is *slack*, which sorts by robustness slack. A value of *delay* sorts by delay impact instead. This option does not apply to variation robustness.

`-type variation | voltage | transition | load_cap | wire_cap | {`*`analysis_type_list`*`}`

Specifies the types of robustness analysis to be performed. One or more types from the following can be specified as a list. The default is *variation* (for backward compatibility with previous release). The supported types of analyses are:

- *variation* (the default) -- identify cells with larger POCV variation.
- *voltage* -- identify cells sensitive to voltage rail (IR) drop.

  This option makes *report_cell_robustness -type voltage* to be identical to *report_voltage_robustness* command.
- *transition* -- identify cells sensitive to input transition change.
- *load_cap* -- identify cells sensitive to output pin load capacitance (wire plus pin capacitance) changes.
- *wire_cap* -- identify cells sensitive to net wire capacitance changes (i.e. changes due to net parasitics).

The *analysis_type_list* must include types only from these supported types. When multiple types are specified, the analyses are performed concurrently. Separate reports will be generated for each analysis performed concurrently.

`-voltage_shift` *`value`*

Specifies the voltage drop used for the sensitivity calculation, as an absolute value in volts. The default is a 5% relative drop from each cell's nominal VDD value. This option applies only to voltage robustness.

`-voltage_shift_ratio` *`value`*

Specifies the voltage drop used for the sensitivity calculation, as a relative ratio (such as 0.95) of each cell's nominal VDD value. The default is a 5% relative drop. This option applies only to voltage robustness.

`-tran_shift_ratio` *`value`*

Specifies the transition change used for the sensitivity calculation, as a relative ratio (such as 0.10) of each cell's computed GBA transition time value. The default is a 10% relative increase. This option applies only to transition robustness.

`-loadcap_shift_ratio` *`value`*

Specifies the load cap change used for the sensitivity calculation, as a relative ratio (such as 0.10) of the cap of the net driven by the cell. The default is a 10% relative increase. This option applies only to load_cap robustness.

`-wirecap_shift_ratio` *value*

Specifies the wire cap change used for the sensitivity calculation, as a relative ratio (such as 0.10) of the cap of the net driven by the cell. The default is a 10% relative increase. This option applies only to wire_cap robustness.

`-slack_lesser_than` *maximum_robustness_slack*

Reports only cells with robustness slack less than the specified *maximum_robustness_slack* value; these cells have a negative robustness slack worse than the specified *maximum_robustness_slack* value (or a positive slack that is closer to causing a violation).

The default *maximum_robustness_slack* value for this option is 0.0.

`-slack_margin` *margin_value*

This option can be used to filter cells from the robustness report. The cells whose worst timing slack (GBA or PBA), amongst paths passing through the cell pins, is above the *margin_value* are filtered out from the report.

The default *margin_value* value for this option is infinity (that is, no filtering margin is applied).

`-mim_filter none | logical | timing`

Specifies how the reported cells are filtered out based on multiply intantiated modules (MIMs) grouping. This option can be used to increase the coverage in the report, given a *-max_violators* count. The default value is *none*, that is, no MIM grouping is considered. When *logical* is specified, only the instance with worst robustness slack, amongst all logically shared MIM instances, is included in the report. With *timing*, the worst, amongst all MIM instances that share delays, will be reported.

`-cells` *cell_list*

Specifies a list of one or more cells in the current design to be analyzed. The analysis is performed only on the cells in the list.

`-net`

Shows the net delay impact for wire cap and load cap robustness analyses. This option must be used with the *-verbose* option.

`-delay_type` *delay_type*

Specifies the type of timing and delay constraint to consider for performing the cell robustness analysis:

- *max* (default) -- max delay (setup constraint)
- *min* -- min delay (hold constraint)

`-plot`

Generates Gnuplot data and script file for the visualization of the robustness metrics.

`-prefix` *`string`*

Use with the *-plot* option. If a prefix string is provided using this option, this string is preprended to the generated Gnuplot file names.

`-compare {`*`file1 file2 ...`*`}`

Use only for the comparison of the robustness analysis result files. This option enables the plotting of data from multiple previous runs in a single graph. *file1*, *file2*, …. are robustness data files, that is, the .dat files generated using the *-plot* option, from previous analysis runs.

`-title` *`title_string`*

Use with the *-compare* option. If a title string is provided using this option, this string is used as the plot title for the comparison plot generated by the *-compare* option.

Description

The *report_cell_robustness* command can be used to report a list of cells sensitive to specific parameters. Use the command to run unified robustness analysis. Currently, the supported parameters to evaluate cell sensitivity are variation robustness, voltage robustness, transition robustness, load cap robustness and wire cap robustness. The default is variation analysis, which reports a list of cells with a high-sigma failure rate.

The variation robustness analysis of the *report_cell_robustness* command reports a list of cells with a high-sigma failure rate. The high-sigma failure rate is evaluated when a cell is at high-sigma, while other cells have normal POCV variation. The command supports robustness analysis using either GBA or PBA.

By default, GBA-based robustness analysis is performed and GBA pin slacks are used to evaluate the cell high-sigma failure rate. Using the *-pba* option invokes PBA-based robustness analysis to reduce pessimism, where exhaustive PBA pin slacks are computed on-the-fly and used for cell high-sigma failure rate evaluation.

The variation robustness analysis of the *report_cell_robustness* command is similar to the *report_variation_bottleneck* command, which also reports critical cells with high-sigma failure rate.

The voltage robustness analysis of the *report_cell_robustness* command is identical to the *report_voltage_bottleneck* command. Refer to man page of the *report_voltage_bottleneck* command for details.

Feedback

Transition robustness analysis identifies the cells in the design that are sensitive to transition changes. The *report_cell_robustness -type transition* command performs this transition robustness analysis.

You can specify the transition shift as a relative factor from the computed GBA pin transition. The default is a 10% relative increase from the GBA pin transition time.

To identify cells that are sensitive to capacitance changes, wire cap or load cap analyses can be performed with *report_cell_robustness -type wire_cap* or *report_cell_robustness -type load_cap* options respectively.

- The *report_variation_bottleneck* command requires a path collection and performs variation bottleneck analysis only for cells in the given paths.
- The *report_cell_robustness* command does not need a path collection. It calculates exhaustive PBA slack values on-demand and uses them to calculate the high-sigma failure rate of all critical cells in the design. Only setup slack analysis is supported in this command.

To perform cell robustness analysis, the *ps_enable_analysis* variable must be set to *true*. The *ps_enable_save_timing_slack_data* variable must also be set to *true* before the first timing update.

Examples

The following example shows a cell robustness report for variation analysis.

```
prompt> report_cell_robustness -significant_digits 6
 ...
   Cell      Lib_cell      Variation    Sigma_ratio    HSFR
                                                    (x 1e-3)
   ------------------------------------------------------------
   nd184     ND2D0XPD      1.107004     0.834039     0.031647
   an463     AN2D1XPD      2.319284     0.661067     0.031636
   nd205     ND2D0XPD      2.280516     0.665559     0.031624
   ff197     DFQD0APD      1.785426     0.604753     0.012661
   ff244     DFQD0BPD      1.638114     0.559612     0.008816
   ------------------------------------------------------------
   Total:                                           0.116385
```

The cell robustness report has the following columns:

- *Cell*: The cell instance with a critical high-sigma failure rate.
- *Lib_cell*: The library cell name of the instance.
- *Variation*: The cell delay variation, which is the cell arc POCV corner delay minus the nominal delay.

- *Sigma_ratio*: The ratio of cell delay sigma to pin slack sigma.
- *HSFR*: The high-sigma failure rate.

The end of the report shows the total high-sigma failure rate, which is the sum of the high-sigma failure rates for all cells.

Often a small number of cells contribute to a large part of the total high-sigma failure rate. Therefore, performing timing ECOs on a few cells at the top of the list can improve the overall joint success rate significantly.

The following example shows how to generate a voltage robustness report:

```
## Must save timing and arrival data
pt_shell> set ps_enable_analysis true
pt_shell> set ps_enable_save_timing_slack_data true

pt_shell> define_scaling_lib_group { ... }
pt_shell> set_voltage ...

pt_shell> update_timing -full

pt_shell> report_cell_robustness -type voltage -max_violators 1 \\
           -voltage_shift 0.05 -nosplit
```

The following output is a voltage robustness violation report for the previous example.

```
voltage_robustness
                                Timing    Delay     Robustness
   Cell              Lib_cell   slack     impact    slack
   ---------------------------------------------------------
   uA/uB/U38           NOR2    -3.5523    0.0321    -0.0321
```

The robustness report shows the delay impact and robustness slack for each violator. The report is sorted based on the robustness slack by default.

The "Delay impact" column shows the impact on cell delay when the voltage is shifted by the value specified.

```
Timing slack = slack at nominal VDD
Delay impact = (cell delay at shifted VDD) - (cell delay at nominal VDD)
```

The "Robustness slack" column shows the new slack with the adjusted cell delay.

```
Robustness slack = (slack at nominal VDD) - (Delay impact)
```

If the slack at nominal VDD is negative, then even cells with a small delay impact can be reported with negative robustness slack. This can mask voltage-drop bottleneck cells with high delay impact on marginally passing paths.

To avoid missing any true voltage-drop bottleneck cells in these cases, the tool uses *0* as the slack for negative-slack paths at nominal VDD, for the robustness slack calculation.

The following is an example of a transition robustness analysis report. It is similar to the voltage robustness report, except the parameter varied is the pin transition time.

```
pt_shell> report_cell_robustness -type transition -max_violators 2 \\
          -tran_shift 0.05 -nosplit

transition_robustness
                                 Timing     Delay      Robustness
   Cell              Lib_cell    slack      impact     slack
   ------------------------------------------------------------
   nd2               ND2D3LVT   -0.65076    0.00096    -0.00096
   or1               OR2D1LVT   -1.24974    0.00084    -0.00084
```

The robustness report shows the delay impact and robustness slack for each violator. The report is sorted based on the robustness slack by default.

The "Delay impact" column shows the impact on cell delay when transition is shifted by the value specified. The robustness slack calculation is identical to voltage robustness analysis.

Multiple robustness analyses can be performed concurrently. The report for each analysis is produced separately as if the analyses were run using separate commands. Concurrent analysis is most helpful when used with *-pba* option as the PBA pin slack calculation is performed only once (thereby speeding up the overall analysis as compared to when each analysis type is run separately). For example, the following command runs variaton and transition robustness analyses concurrently:

```
pt_shell> report_cell_robustness -type { variation transition } -pba
 -max_violators 2 \\
          -tran_shift 0.05 -nosplit
```

report_cell_usage

Reports the usage of cells in a design.

Syntax

string *report_cell_usage*

```
[-pattern_priority pattern_list]
[-attribute attribute_name]
[-alternative_lib_cells]
[-show_others]
[-power_attribute power_attribute_name]
```

Data Types

attribute_name	string
pattern_list	list
power_attribute_name	string

Arguments

`-pattern_priority` *pattern_list*

Specifies a list of library cell patterns, from highest to lowest priority.

`-attribute` *attribute_name*

Specifies an attribute name that can be used either to match patterns specified by the *-pattern_priority* option or to specify power attribute of each library cell. When you specify this option together with the *-pattern_priority* option, PrimeTime uses the value of the attribute instead of library cell names for pattern matching. When you specify this option without the *-pattern_priority* option, PrimeTime uses the value of the attribute as power attribute of each library cell.

`-alternative_lib_cells`

Shows alternative library cells. This option will be obsolete in a future release; use the *report_eco_library_cells* command instead.

`-show_others`

Shows library cells that do not match the specified pattern. This option will be obsolete in a future release; use the *report_eco_library_cells* command instead.

`-power_attribute` *power_attribute_name*

Specifies a power attribute set on library cells. If you specify this option, the summary of power attribute value for each cell group is reported in a separate column.

Description

This command reports the summary of cell usage in a design.

In a multi-scenario analysis flow, this command must be used at the worker processes.

This command reports the usage of cells based on the specified pattern when the *-pattern_priority* option is used. If the *-pattern_priority* option is not used, the command reports a summary of cell usage for each cell group.

Cells are categorized into the following groups:

- Combinational - combinational cells
- Sequential - sequential cells such as latches and flip-flops
- Clock - cells in the clock network
- Others - other cells, including I/O pad, memory, and black-box cells

In a HyperScale hierarchical analysis flow, cells within HyperScale blocks are excluded when reporting the cell usage, as their cell counts can vary depending on how the Hyperscale model was abstracted. Thus, the cell usage number reported in a HyperScale analysis can be smaller than the number reported in a full-flat analysis.

Examples

The following example reports HVT and LVT cell counts in the design:

```
pt_shell> report_cell_usage -pattern_priority {HVT LVT}

****************************************
Report : cell_usage
        -pattern_priority { HVT LVT }
Design : design
 ...
****************************************

Pattern   Combinational cell     Sequential cell               Total
--------------------------------------------------------------------------
HVT           1515979 ( 32%)         1291 (  0%)      1517270 ( 32%)
LVT           2474715 ( 53%)       696222 ( 15%)      3170937 ( 68%)
Others           4115 (  0%)          532 (  0%)         4647 (  0%)
```

The following example reports summary of cell count and area for each cell group:

```
pt_shell> report_cell_usage
 ...

Cell Group                    Count                    Area
-----------------------------------------------------------
Combinational             5 ( 71%)            33.16 ( 59%)
Sequential                1 ( 14%)            16.23 ( 29%)
Clock                     1 ( 14%)             6.35 ( 11%)

report_check_ctpm_tolerance

Reports the passing threshold used to report passing rate in *gen_ctpm* and *validate_ctpm*.

Syntax

string *report_check_ctpm_tolerance*

Feedback

Description

The *report_check_ctpm_tolerance* command is used to report tolerance used in *gen_ctpm* and *validate_ctpm* to calculate passing rate. The tolerance is setup by *set_check_ctpm_tolerance* command. If abs(error percentatage) <= rel_tol or abs(error_in_ns)<abs_tol, a data point is considered as passing.

Examples

The following script set delay and slew passing tolerance as 5%/5ps, and report the user-defined tolerance for CTPM checking.

```
set ps_enable_analysis true
set ps_enable_spice2design_analysis true

set_check_ctpm_tolerance -delay {0.05 0.005} -slew {0.05 0.005}
pt_shell> report_check_ctpm_tolerance
  type                          relative_error    absolute_error
  delay                           0.050000            0.005000
  slew                            0.050000            0.005000

---

report_clib

Displays information about timing data of the specified CLIB reference library, which which has been constructed from one or more .db libraries.

Syntax

status *report_clib*

```
[-nosplit]
[-timing_arcs]
```

```
[-power_arcs]
[-verbose]
library
[lib_cell_list]
```

Data Types

```
library          list
lib_cell_list    list
```

Arguments

`-nosplit`

Most of the library information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

`-timing_arcs`

Reports all cell timing arcs from the library.

`-power_arcs`

Reports all cell power arcs from the library.

`-verbose`

Possibly report additional detail.

`library`

Specifies the CLIB reference library to report. This can be either a .db library name or a collection of a single .db library. The CLIB library that contains the specified .db library will be reported.

`lib_cell_list`

Displays a list of library cells about which information is reported. The default is to report information about all cells in the technology library. Each element in this list is either a collection of library cells or a pattern that matches library cells in the *library* option.

Description

The *report_clib* command displays timing information from the specified CLIB reference library, including the PVT parameters and source .db libraries of each pane.

The default timing data includes the power rails, the details for each timing pane, the constituent logic libraries, and the operating conditions. You can also include the cell timing arcs by using the *-timing_arcs* option.

The scaling group and min-lib relationships (if any) of each pane are also reported.

This command exists only in a CLIB-enabled build.

Examples

The following command generates a default report for the my_lib_fast reference library.

```
prompt> report_clib ccs_1.1.db:synop_lib
****************************************
Report : library

report_clock

Reports clock-related information.

Syntax

status *report_clock*

```
[-attributes]
[-skew]
[-groups]
[-map]
[-skip_internal]
[-map_of instance_list]
```

```
[-cells hierarchical_cell_list]
[-include internal | virtual]
[-exclusivity]
[-nosplit]
[-sms_scenarios sms_scenarios_list]
[clock_names]
```

Data Types

```
clock_names                 list
sms_scenarios_list          collection
hierarchical_cell_list      list
instance_list               list
```

Arguments

`-attributes`

Reports the clocks in the design, along with additional information such as source type, signal rise and fall times, and attributes. This report is shown by default.

`-skew`

Reports clock latency (source and network latency) and uncertainty information set on the design by the *set_clock_latency* and *set_clock_uncertainty* commands, respectively.

The latency reported by this option includes propagated latency for generated clocks.

Clock network latency information includes rise latency and fall latency. Clock source latency information includes rise latency and fall latency for early and late arrivals. Clock uncertainty information includes intraclock setup or hold uncertainty and interclock setup or hold uncertainty. This option also reports any fixed clock transitions set by the *set_clock_transition* command. This option reports only active clocks.

`-groups`

Reports the clock groups defined for the design, including the list of active clocks in the current analysis scope and grouping of exclusive clocks and asynchronous clocks defined by using the *set_clock_groups* command.

To query specific clocks or clock relationships, use the *get_clock_relationship* command.

`-map`

Shows the map between top-level clocks and block-level clocks in HyperScale.

`-skip_internal`

Used together with the *-map* option, skips internal clocks in the mapping between top-level clocks and block-level clocks in HyperScale.

`-map_of` *`instance_list`*

Shows the map between top-level clocks and block-level clocks in the specified HyperScale instances. If the *-map_of* option is not used, the *-map* option reports across all HyperScale instances.

`-cells` *`hierarchical_cell_list`*

Shows clocks that physically enter the specified hierarchical cells through certain hierarchical pins of the cells.

`-include internal | virtual`

Used together with the *-cells* option, optionally also shows the internal clocks of the hierarchical cell and virtual clocks that do not physically enter the cell but do launch/capture data to/from the cell. Valid values are *internal* and *virtual*. If *-include internal* is used, the Pins column shows the source pins of the internal clock. If *-include virtual* is used, the Pins column shows the relevant data pins of the virtual clock; the 'Clock type' column shows 'v' to indicate virtual clocks.

`-nosplit`

Specifies not to split lines if a column overflows. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

`-exclusivity`

Reports the clock exclusivity points in the design, whether inferred implicitly from clocks passing through MUX cells (when the *timing_enable_auto_mux_clock_exclusivity* variable is set to *true*) or defined explicitly by the *set_clock_exclusivity* command.

`clock_names`

Specifies the clocks to be reported. The default is all clocks.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only clock information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Feedback

Description

Reports clock-related information. The report contents are controlled by the options used. If you do not specify any options, the command reports all clocks in an *-attributes* report.

When a clock is created, it defaults to being active. Clocks can subsequently be set active/inactive using the *set_active_clocks* command. The default report shows which clocks are active.

If a dynamic component of clock latency has been specified by the *set_clock_latency* command, the *-skew* option can be used to report what values have been set. In this case, all components of clock latency will be reported.

Some information, such as the waveform of a generated clock or propagated skew, is shown only after a timing update (from an explicit *update_timing* command or an implicit timing update caused by another command). This behavior is intended to help you to report clocks without incurring the cost of a complete timing update.

To show the clock mapping used in HyperScale between top and block, use the *report_clock -map* command. Any user-specified mappings from the *set_clock_map* command are annotated with an asterisk (*) in the report.

To obtain a list of all clocks in the design, use the *all_clocks* command.

Examples

Here are some examples of the *report_clock* command:

```
pt_shell> create_clock -period 20.000000 [get_ports {CLK}]
pt_shell> report_clock

report_clock_crossing

Generates a report about paths launched from one clock and captured by another.

Syntax

string *report_clock_crossing*

```
[-from from_list]
[-to to_list]
[-include include_list]
[-format format]
[-output file_name]
[-nosplit]
[-verbose]
[-ignore_invalid]
[-period]
[-edge_relationships]
```

Data Types

```
from_list     list
to_list       list
include_list  list
```

Arguments

`-from from_list`

Specifies a list of clocks to report clock crossing from. If no *-from* argument is given, all from clocks are reported.

`-to to_list`

Specifies a list of clocks to report clock crossing to. If no *-to* argument is given, all to clocks are reported.

Feedback

-include *include_list*

Specifies a list of type of crossing to report. By default, all types are reported.

" valid - If some of the paths are *false* due to the *set_false_path* command, the interaction is still considered valid, but is marked with a '#'. " false - All of the paths are *false* due to the *set_false_path* command. The interaction is marked with an 'F'. " physically_exclusive - All of the paths are *false* due to a physically exclusive clock grouping. The interaction is marked with a 'P'. " logically_exclusive - All of the paths are *false* due to a logically exclusive clock grouping. The interaction is marked with an 'L'. " asynchronous - All of the paths are *false* due to an asynchronous clock grouping. The interaction is marked with an 'A'.

Allowed values are as follows:

• *valid*:
Reports clock interactions where there are valid paths.
If some of the paths are **false**, that is noted with an attribute
of '#'.

• *false*:
Reports clock interactions where all of the paths between the
clocks are
declared as **false**. Only clock interactions that are connected
with paths
that are declared as **false** are reported. If there is a clock
interaction
declared as **false** but the design has no paths connecting those
two clocks, that
interaction is not reported.

• *logically_exclusive*:
Reports clock interactions where all the paths between the clocks
are
declared as logically_exclusive with a **set_clock_groups** command.
Only clock interactions that are connected with paths are
reported.

• *physically_exclusive*:
Reports clock interactions where all the paths between the clocks
are
declared as physically_exclusive with a **set_clock_groups** command.
Only clock interactions that are connected with paths are
reported.

• *asynchronous*:
Reports clock interactions where all the paths between the clocks
are
declared as asynchronous with a **set_clock_groups** command.

```
   Only clock interactions that are connected with paths are
    reported.
```

`-format` *`format`*

Specifies the format of the report. The default for format must be either standard or csv. The default is standard. The default generates a text report. If csv is specified, the report is written out in a comma-separated value format. If csv is specified, the *-verbose* option is implied. This option requires the *-output* option.

`-output` *`file_name`*

Specifies the output file name for the output.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing tools to extract information from the report output.

`-verbose`

Adds more things to the report. One main addition is all pairs of clocks are added with "No paths" for the noninteracting clocks. In addition, the clock waveforms are also printed and minimum edge separation is printed separately when *-edge_relationships* is used.

`-ignore_invalid`

Reports clock group relation between the launch and capture clock pair even if no valid timing path exists between them.

`-period`

Adds the periods of each clock after each clock name and if there is a valid crossing the base period for the clocks is displayed. If there are no valid paths between the clocks, the base period is given as "--". If the base period is more than 101 times the smallest period, the base period is marked with "*". See the following example for more information.

`-edge_relationships`

Shows the most constraining edge relationship between the clocks that have valid crossing along with multicycle path information. This option also forces the *-period* option to be used so that the periods are displayed.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Generates a report showing the clocks that launch datapaths that are capture by a different class. The from clock column gives the launching clock and the attribute column

is blank for only valid paths. The following attributes are given to classify the interactions between the clocks in the row:

```
#     - some paths false
    F     - all paths false
    L     - logically exclusive clock group
    P     - Physically Exclusive Clock Groups
    A     - Asynchronous Clock Groups
    A_MCP - all multicycle paths
    S_MCP - some multicycle paths
    A_MMD - all min-max delay paths
    S_MMD - some min-max delay paths
    MG    - from clock master of to clock
    GM    - to clock master of from clock
    N     - No valid path between the clock pair ( when -verbose option
 added )
    V     - Valid path between the clock pair    ( when -verbose option
 added )
    *     - Base Period Limit Exceeded ( when -period option is
 specified )
```

The Crossing Clocks column gives all of the clocks that capture paths from the "from clock" with the same attribute. The crossing clocks are separated by spaces and are split onto the next line unless the *-nosplit* option is given.

In addition to the default output, the *-format* and the *-output* options can be used to write the clock crossing report to a file in comma-separated value format.

Examples

The following example shows the summary report.

```
pt_shell> report_clock_crossing -nosplit
****************************************
Report : report_clock_crossing
Design : test
Scenario: default
Version: ...
Date   : ...
****************************************

Attributes
    P     - physically exclusive clock groups
    L     - logically exclusive clock groups
    A     - asynchronous clock groups
    F     - all paths false
    #     - some paths false
    A_MCP - all multicycle paths
    S_MCP - some multicycle paths
    A_MMD - all min-max delay paths
    S_MMD - some min-max delay paths
    MG    - from clock master of to clock
```

```
    GM    - to clock master of from clock

From Clock           Attr     Crossing Clocks
-------------------------------------------------------------------------
-------
CLK                  #,MG     GCLK
GCLK                          CLK2
GCLK                 A_MCP,GM CLK
```

The following example shows reporting the crossings from clock GCLK.

```
pt_shell> report_clock_crossing -from GCLK -nosplit
****************************************
Report : report_clock_crossing
Design : test
Scenario: default
Version: ...
Date   : ...
****************************************

---

report_clock_gate_savings

Reports toggle savings on clock gates.

Syntax

string *report_clock_gate_savings*

```
[-by_clock_gate]
[-sequential]
[-hierarchical]
[-nosplit]
[-clocks clock_list]
[-sort_by sort_method]
[object_list]
```

Data Types

clock_list	list
sort_method	string
object_list	list

Arguments

`-by_clock_gate`

With this option two tables are generated. One is a summary table with column of clock name, total registers, stages, number of clock gate per stage, number of gated cells (register + clock gates) and Clock Gating Efficiency of that stage. The other is detailed clock gating structure table which contains clock name, clock gate stage, gating element, fanout, number of registers, number of gate cells, Toggle Savings, Clock Gating Efficiency, List of gate cells.

`-sequential`

Specifies that the report is to report on registers in the design. When the *-sequential* option is applied, the command uses toggle rates to determine the fraction of clock events at registers that result in a toggle on the Q pin. This fraction is a measure of how well clock gated a register is. Values near 25% are near optimal for datapath registers. Lower values indicate there might be more room for clock gating, as the clock is toggling often when the Q pin toggles little.

In addition to the Q/Clk toggle ratio, the Register Gating Efficiency is reported for each register. This measures the ratio between the toggle rate of the local (gated) clock, and the root clock specified with create_clock. High values indicate that most of the toggles from the root clock have been suppressed by clock gates along the clock tree from the root to the register.

When the *-by_clock_gate* and *-sequential* options are used together, the command reports on register banks in the design. Registers are grouped into clusters by the clock gates that drive their clock pins. An additional cluster of ungated registers is also reported included in the report.

`-hierarchical`

Specifies that results are to be aggregated into hierarchical blocks, and each block is to be reported. Without this option, individual clock gates or registers are reported. The data is aggregated by averaging toggle savings over clock gates in a module.

The *-hierarchical* option cannot be used when both the *-by_clock_gate* and *-sequential* options are also used together.

`-nosplit`

Specifies that report lines should not be split when names are longer than the space provided in the report. This option can make it easier for scripts to parse the results, but might make it harder for humans to read the columns.

`-clocks` *`clock_list`*

Specifies that objects not in the clock domain of one of the given clocks should be excluded from the report.

`-sort_by` *`sort_method`*

Specifies the order in which to print design objects. You can specify the *-sort* option with the *-sequential* and *-by_clock_gate* options but not with the *-hierarchical* option. You can specify the following sort methods:

```
-by_clock_gate              -sequential
----------------            --------------
name                        name
clock_gating_stage          clock_gating_stage
```

```
clock_toggle_rate           clock_toggle_rate
toggle_savings              q_clk_ratio
clock_gating_efficiency     q_toggle_rate
                            gating_efficiency
```

object_list

Specifies that the given cells are to be reported on only. If cells in the list are hierarchical, all clock gates (or registers, if the *-sequential* option is used) under the hierarchical cells are reported on. If the *-sequential* option is used without the *-by_clock_gate* option, any leaf cells in the list should be registers. If the *-by_clock_gate* option is used, or if both the *-by_clock_gate* and *-sequential* options are used, any leaf cells should be individual clock gates.

In the default report, the *object_list* option can also contain clocks, in which case only those clocks are reported on.

Description

This command uses toggle rates in the design to report on the toggle savings on the clock tree from clock gating in the design. To use the command, you should first apply switching activities before the command. In the time based mode, this can be done using the *read_vcd* command followed by the *update_power* command.

In the averaged power mode, apply switching activities by using the *read_saif*, *set_switching_activity*, or *read_vcd* command. In the averaged mode, partial switching activity annotation causes the tool to propagate switching activities.

The usefulness of the *report_clock_gate_savings* command is largely dependent on the quality of the switching activities. To be useful, the activities should come from simulation. The testbench used from simulation should be designed to simulate the typical behavior of the design and should cover all modes that are part of the typical behavior. If a mode is left off, some part of the design might not be exercised.

The default report displays overview information about each clock and the registers that the clock drives. You can use this report to summarize the overall effectiveness of clock gating in the design. The report computes the average toggle savings over the registers driven by each clock, where here the toggle savings for a register is defined as the ratio of the toggle rate at the clock pin of the register to the toggle rate of the clock. A 20% toggle savings means that the toggle rate at clock pin of a register is 80% of the toggle rate of the main clock for the clock domain. When a register is in several clock domains, the register is only included with the domain of the faster clock, so that registers are not included twice in the report.

The *-sequential* reports helps to identify registers with many clk events but few Q toggles.

When the Q/Clk ratio for registers is significantly lower than 25%, there can be room to improve the clock gating for these registers by adding clock gating or increasing the

fraction of time that clock gating suppresses clock toggles. A brief explanation of why 25% can be regarded as optimal is below.

In the case of a datapath, during cycles when the datapath is exercised, the clock gating is enabled, and the probability of Q toggling in a cycle is approximately 50%, assuming random and independent data is moving through the datapath. On cycles when the datapath is not being exercised, the clock gating should be disabled. In this idealized situation, the Q/clk toggle ratio should be 25%, since the clk toggles twice in a cycle, and the Q toggles on average one time every other cycle (a 1:4 ratio).

There are some exceptions where registers can have Q/Clk ratios larger than 25%, such as low bits of counters where the Q should toggle every cycle when the counter is active. However, on the whole, most registers in the design should report (using the *-sequential* option) a Q/Clk ratio less than 25%.

More information can be gathered about individual clock gates and their associated registers when the *-by_clock_gate* and *-sequential* options are used together. In this case, Individual clock gates are reported, with each clock gate followed by a list of the registers driven by the clock gate. This report can be more useful than the *-sequential* report alone in helping find register banks with low Q/Clk ratios, where it is possible to disable the clock gate more often. The report can also help find register banks that should be split; it might be that a portion of the registers driven by a clock gate have low Q/Clk ratios, and these registers might be able to have their own separate clock gate, which could allow disabling the clock more often for those registers.

The *-hierarchical* reports (which can be used with either the *-by_clock_gate* or *-sequential* option) can help to identify modules of interest. Since many register banks are too small for clock gating, the hierarchical sequential report might be less useful as the register banks of interest are overwhelmed in the aggregated data by the small register banks which are not clock gated.

USAGE

You can use the default report to view the overall effectiveness of clock gating in the design.

Examples

The following example shows the default report:

report_clock_gating_check

Displays clock-gating check information about specified pins.

Syntax

status *report_clock_gating_check*

```
[-significant_digits digits]
[-nosplit]
[-auto_inferred_only]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

digits	integer
object_list	list
sms_scenarios_list	collection

Arguments

`-significant_digits digits`

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default value is 2. Use this option if you want to override the default.

`-nosplit`

Prevents line splitting and facilitates scripting to extract information from the report output.

`-auto_inferred_only`

Shows only the automatically inferred clock-gating checks.

object_list

Specifies a list of cells, pins, clocks, or design objects to report.

`-sms_scenarios sms_scenarios_list`

Specifies a collection of SMS scenarios to analyze. Only clock-gating checks compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Feedback

Description

The *report_clock_gating_check* command displays the following information for the clock-gating checks. Information displayed about the specified objects: Instance of the cell, enable pin, clock pin, setup/hold time for rise, setup/hold time for fall, user-specified high/low active waveform. The asterisk (*) in the high/low field means that the user-specified high/low overrides what PrimeTime inferred from the logic of the cell.

The following attributes show where the clock-gating check originally was defined:

- I - Automatically inferred by PrimeTime.
- P - Power Compiler inserted the check.
- L - Defined by library cell.

Examples

The following example displays how to report all clock-gating check informations.

```
pt_shell> report_clock_gating_check
****************************************
Report : clock-gating check
Design : flop123
 ...
****************************************

                                    Rise                Fall
Cell      Enable  Clock     Setup     Hold      Setup     Hold    High/Low
 Attr
--------------------------------------------------------------------------
------
mid       A       B         5.00      3.00      5.00      3.00    High
 I
MX        A       S         5.00      3.00      5.00      3.00    High
 I
MX        B       S         5.00      3.00      5.00      3.00    Low (*)
 I

Feedback

report_clock_jitter

Reports clock jitter information previously set by the *set_clock_jitter* command.

Syntax

```
status report_clock_jitter
   [-clock clock_list]
```

Data Types

```
clock_list     list
```

Arguments

-clock *clock_list*

Specifies a list of clocks to report. If you do not use this option, the command reports the clock jitter for all the clocks whose master (or itself) has cycle-to-cycle jitter or duty-cycle jitter.

Description

This command reports the cycle-to-cycle jitter and the duty-cycle jitter of the clock. If the clock is a generated clock, it will report the cycle-to-cycle and the duty-cycle jitter of its primary master clock. For example, if the generated clock G2 is created from the generated clock G1 and the generated clock G1 is created from the primary master clock M, the cycle-to-cycle jitter and the duty-cycle jitter reported for G2 is in fact the cycle-to-cycle jitter and the duty-cycle jitter of its primary master clock, M. The command reports the primary master clock of the generated clock as well. In case the clock is primary master clock, it will print the clock itself.

To set the clock jitter use the *set_clock_jitter* command.

Examples

The following example reports the cycle-to-cycle jitter of 0.5 and duty-cycle jitter of 0.7 specified on the primary master clock mclk, and its generated clock gclk.

```
pt_shell> set_clock_jitter -clock [get_clocks mclk] -cycle 0.5
 -duty_cycle 0.7
pt_shell> report_clock_jitter

****************************************
Report : clock jitter
 ...
****************************************

Clock         Cycle Jitter   Duty Cycle Jitter   Master Clock with Jitter
--------------------------------------------------------------------------
-------
```

Feedback

```
mclk              0.500          0.700              mclk
gclk              0.500          0.700              mclk
```

post_command_string    string
sms_scenarios_list     collection
```

Arguments

`-type report_type`

Specifies the type of report to be generated. You can specify the following values for *report_type*:

- *transition* - Transition time report.
- *latency* - Latency report.
- *skew* - Skew report. You cannot use the *-launch*, *-capture*, *-rise*, *-fall*, and *-lesser_than* options if you specify a skew report, and you can use the *-include_uncertainty_in_skew* option only in a skew, interclock_skew, or summary report.
- *interclock_skew* - Interclock skew report. You cannot use the *-launch*, *-capture*, *-rise*, *-fall*, and *-lesser_than* options if you specify an interclock skew report, and you can use the *-include_uncertainty_in_skew* option only in a skew, interclock_skew or summary report.
- *summary* - Summary report, which shows the worst instances of transition time, latency and skew over the clock networks or subnetworks of interest. If you specify a summary report, you can use only the *-clock*, *-to_list*, *-from_list*, *-include_uncertainty_in_skew*, *-nosplit*, and *-significant_digits* options.

  For nonsummary reports, report entries are ordered with respect to the specified attribute of interest (transition time, latency, or skew). Note that all skews reported are "local" skews. For an explanation of local skew, see the DESCRIPTION section.

`-clock clock_list`

Uses the specified clock networks in the report. A subreport is typically produced for every clock in the *clock_list*, unless you additionally specify the *to_list*, *from_list*, or both options that has no network intersection with a given clock. In that case, PrimeTime drops these clocks from the *clock_list* and also issues a

warning. By default, if you do not specify *clock_list*, all clocks in the design that have associated clock networks are used in the report.

`-from_clock` *`from_clock_list`*

Uses the specified clock networks as from-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report typically considers every clock in *from_clock_list*, unless you additionally specify the *from_list* option that has no network intersection with a given clock. In that case, PrimeTime drops these clocks from the *from_clock_list* and also issues a warning. By default, if you do not specify the *from_clock_list* option, all clocks in the design that have associated clock networks are used as from-clocks in the report.

`-to_clock` *`to_clock_list`*

Uses the specified clock networks as to-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report typically considers every clock in *to_clock_list*, unless you additionally specify a *to_list* that has no network intersection with a given clock. In that case, PrimeTime drops these clocks from the *to_clock_list* and also issues a warning. By default, if you do not specify the *to_clock_list* option, all clocks in the design that have associated clock networks are used as to-clocks in the report.

`-from` *`from_list`*

Considers the specified sequential clock network pins or ports as from-pins in the current report. If any named pin is not the clock pin of a sequential device, PrimeTime replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list and a warning message is issued.

`-to` *`to_list`*

Considers the specified sequential clock network pins or ports as to-pins in the current report. If any named pin is not the clock pin of a sequential device, such as a sink pin, PrimeTime replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list with a warning message.

For skew reports, the from-to skew sense is defined by the pins in the *from_list* and *to_list* options respectively; if the *to_list* option is not specified, by default all sink pins in the given clock networks are used. Thus, specifying the *to_list* option reduces the topological scope of the report. For transition time and latency reports, the *from_list* and *to_list* options are concatenated and treated as a single list; if neither is specified, the *to_list* option is assumed to be populated with all sink pins in the given clock networks.

For skew reports, the from-to skew sense is defined by the pins in the *from_list* and *to_list* options respectively; if the *from_list* option is not specified, by default all sink pins in the given clock networks are used. Thus, specifying the *to_list* option reduces the topological scope of the report. For transition time and latency reports, the *from_list* and *to_list* options are concatenated and treated as a single list; if neither is specified, the *to_list* option is assumed to be populated with all sink pins in the given clock networks.

`-setup`

Uses only the setup data path is to be used in the report. Also, the skews, latencies or transition times reported must correspond to those used by the *report_timing* command in the verification of setup constraints. The *-setup* and *-hold* options are mutually exclusive. If neither option is specified, the *-setup* option is assumed. You cannot use this option in summary reports.

`-hold`

Uses only the hold data path in the report. Also, the skews, latencies, or transition times reported must correspond to those used by the *report_timing* command in the verification of hold constraints. The *-setup* and *-hold* options are mutually exclusive. If neither option is specified, the *-setup* option is assumed. You cannot use this option in summary reports.

`-launch`

Uses only pins that launch data in the report. Also, latencies or transition times reported must correspond to those used by the *report_timing* command for sequential device clock pins that are launching data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and *to_list* arguments. In all other reports, the *-launch* and *-capture* options are mutually exclusive. If neither option is specified, the *-launch* option is assumed. You cannot use this option in summary or skew reports.

`-capture`

Uses only pins that capture data in the report. Also, the latencies or transition times reported must correspond to those used by the *report_timing* command for sequential device clock pins that are capturing data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and *to_list* options. In all other reports, the *-launch* and *-capture* options are mutually exclusive. If neither option is specified, the *-launch* option is assumed. You cannot use this option in summary or skew reports.

`-rise`

Specifies that the active transition is a rising edge for sequential device clock pins in the current report. The *-rise* and *-fall* options are mutually exclusive; if neither option is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself.

This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. You cannot use this option in summary or skew reports.

`-fall`

Specifies that the active transition is a falling edge for sequential device clock pins in the current report. *-rise* and *-fall* are mutually exclusive; if neither is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself. This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. You cannot use this option in summary or skew reports.

`-nworst` *`worst_entries`*

Specifies the number of worst report entries to be reported per clock domain; the default is 1. Entries are sorted with respect to the attribute of interest (transition time, latency or skew) specified with the *-type* option of the *report_type* command.

The worst entries are those most likely to cause a violation. For example, if you request a latency report using *-setup* and *-capture*, the smallest *worst_entries* are listed, sorted in ascending order, because small capture latencies for setup paths are more likely to lead to a violation than large capture latencies. By contrast, for skew reports, the worst entries always correspond to the largest skews over the specified domain. You cannot use this option in summary reports.

`-greater_than` *`lower_limit`*

Shows only those entries with an attribute value (latency, transition time or skew) greater (more positive) than *lower_limit*. You cannot use this option in summary reports.

`-lesser_than` *`upper_limit`*

Shows only those entries with an attribute value (latency, transition time or skew) less (more negative) than *upper_limit*. You cannot use this option in summary or skew reports.

`-slack_lesser_than` *`slack_upper_limit`*

Shows only those entries with a slack value less (more negative) than *slack_upper_limit*. For skew report entries slack is the worst slack over all paths launched by the from-pin and captured by the to-pin. For transition time or latency report entries, slack is defined as the worst slack of all paths either launched by a transition at the sink pin (if the *-launch* option is used) or captured by a transition at the sink pin (if the *-capture* option is used).

Feedback

Note that the use of this filter might greatly increase the runtime of this report. However, when used with the *-capture* option the effect on runtime should be small, since PrimeTime can make use of cached slack values to avoid expensive recomputations. You cannot use this option in summary reports.

`-include_uncertainty_in_skew`

Specifies that the user-defined uncertainty between the sequential devices in a launch/capture pair is to be considered a component of skew. You cannot use this option in summary or skew reports.

`-verbose`

Generates a more detailed report; instead of a single line per pin, verbose reports trace the entire source-to-sink path through a clock network to show how the final reported attribute (skew, latency or transition time) was accumulated over the course of the path. You cannot use this option in summary reports.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point to be displayed for time values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which has a default of 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, PrimeTime uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

`-show_clocks`

Shows the launching and capturing clocks for every interclock skew entry in the report. This is useful if *from_clock_list* or *to_clock_list* contain more than one clock each. You cannot use this option in interclock skew reports.

`-crosstalk_delta`

Shows the delta delay and delta transition time in verbose reports. The deltas are computed during crosstalk signal integrity analysis, or they can be annotated manually using the *set_annotated_delay -delta_only* and *set_annotated_transition -delta_only* commands. Note that the *-crosstalk_delta* option reports only the calculated or annotated deltas, it does not initiate crosstalk analysis. Only deltas on input pins are shown.

`-derate`

Shows the derating factors in the report. By default, derating factors are not displayed. Derating factors are only shown when you specify the *-verbose* option.

`-variation`

Shows variation information. Using this option is allowed only when detailed variation-aware clock analysis is enabled. Without *-variation*, only the quantile or mean value is displayed, as specified using the *variation_derived_scalar_attribute_mode* variable. With *-variation*, the quantile, mean and either the standard deviation (for skew reports) or sensitivity (for latency or transition reports) is displayed for both verbose and non-verbose reports. In verbose reports, additional statistical info regarding individual path increments appear in new columns, namely the sensitivity, mean and increment, where the increment refers either to the quantile or the effective delay depending on the *variation_report_timing_increment_format* variable.

`-sort_by` *`sort_attr`*

Sorts the entries in the report with respect to the specified variational attribute. This option can be used only with the *-summary* option and only when detailed variation-aware clock analysis is enabled. Note that this option only controls the ranking of entries and not their display. You can specify the following values for *sort_attr*:

- *quantile* - Ranks entries using their quantile values.
- *mean* - Ranks entries using their mean values.
- *sensitivity* - Ranks entries using their sensitivity values. This option cannot be used in a *skew* or *interclock_skew* report.

`-clock_crossing`

Indicates that only skews between interacting clock domains (i.e. clocks connected by at least one non-false data path) is included in the report. This option can only be used in interclock_skew reports.

`-include_clock_gating`

Include clock pins of clock-gating checks in the report. By default, only sequential devices that exercise a setup/hold check are reported by report_clock_timing. This option additionally allows clock-gating checks to be reported.

`-nosplit`

Prevents line-splitting and facilitates writing software to extract information from the report output. If this option is not used, most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-pre_commands` *`pre_command_string`*

This option is available only if you invoke PrimeTime with the *-multi_scenario* option. This option allows you to specify a string of commands to be executed in the worker context before the execution of the merged reporting command. Commands must be grouped using the ";" character. The maximum size of a command is 1000 chars.

`-post_commands` *`post_command_string`*

This option is available only if you invoke PrimeTime with the *-multi_scenario* option. This option allows you to specify a string of commands to be executed in the worker context after the execution of the merged reporting commands. Commands are grouped using the ";" character. The maximum size of a command is 1000 chars.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only clock timing compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`-include_hierarchical_pins`

Includes hierarchical pins in the timing report. This option is valid only when -verbose option is set to TRUE.

`-probe`

Specifies that latency reporting should occur directly at the specified clock network pins.

Normally when you perform latency reporting at intermediate clock network pins, the report is generated for all sequential cell clock pins in the transitive fanout of those pins. With the *-probe* option, the latency report is generated directly at the specified intermediate pins instead.

The *-probe* option is supported only for *-type latency* reporting; it is not supported for other reporting types.

Description

This command generates a report of clock timing information for the current design.

There are several reporting types provided, which allow you to examine skew, latency and transition time attributes of a given clock network or subnetwork at various levels of generality. By default, the report displays the values of these attributes only at sink pins (that is, the clock pins of sequential devices) of the clock network. You use the *-verbose* option to display source-to-sink path traces. If you specify several clock domains, the *report_clock_timing* command generates a separate subreport for each clock domain.

At the highest level of abstraction is the summary style report, which provides only a list of maxima and minima of the skew, latency, and transition time attributes over the given networks. At a lower level of abstraction are the transition, latency, and skew type reports, called list style reports, in which you can sort, filter and display the worst set of sink pins in the given network with respect to a single attribute of interest. For skew reports, each report entry is a pair of sink pins and their relative skew. For transition time or latency reports, each entry corresponds to a single sink pin. The lowest level of abstraction is provided by verbose mode, which replaces every sink pin in a list style report by a corresponding source-to-sink path trace.

In both summary and list style reports, the rightmost column is an attributed column. Corresponding to each sink pin, the set of character symbols in this column indicates the following:

```
Symbol    Meaning
------    -------
 r        Rising transition
 f        Falling transition
 p        Propagated clock to this pin
 i        Clock inversion to this pin
 -        Launching transition
 +        Capturing transition
 m        Library clock insertion delay
```

In verbose mode, back-annotations on path elements in the timing path are indicated using a character symbol. For definitions of these character symbols, see the manual page of the *report_timing* command.

Skews reported by *report_clock_timing* are local skews only. Local skew exists from one sink pin to another only if their associated sequential devices are connected via a data path in the appropriate from-to sense. Note that even if all data paths between the sequential devices are false because of user-defined exceptions, the skew still qualifies as local skew if the devices are connected topologically.

If detailed variation-aware clock analysis is enabled using the *variation_analysis_mode* variable, the *report_clock_timing* command evaluates the attributes of latency, transition time and skew as statistical entities. By default, the quantile of these attributes is used for both ranking and display purposes. The ranking can be controlled using the *-sort_by* option, while the display parameter can be changed from quantile to mean using the *variation_derived_scalar_attribute_mode* variable. To augment the display with additional statistical parameters of *report_clock_timing* attributes, see the *-variation* option.

Examples

The following example shows a typical summary style report.

```
pt_shell> report_clock_timing -type summary
****************************************
Report : clock timing
```

```
        -type summary
        -nworst 1
 ...

report_collection

Output a tabular report of attribute values for elements in a collection.

Syntax

report_collection

```
collection
[-type report_type]
[-header header_type]
[-max_rows value_count]
[-nopslit]
[-columns column_specification]

string collection
list report_type (
string header_type
int value_count
list column_specificaton
```

Arguments

collection

Specifies the collection on which to report. The collection may be homogeneous or heterogeneous. The report comprises a header with information about the report such as the application name and version and the date and a tabular report on attribute values for elements of the collection. The tabular report content is determined by the of report requested with the *-type* option. The attributes on which the report is generated is determined by the argument to the *-columns* option.

Feedback

`-type` *report_type*

This option accepts an argument of a list of valid report type names. A report type is one of the following values: "values" | "statistics" | "distribution". If the option is omitted, the default report type is "values". The report types may be combined in a list to output multiple reports in one run. Each invocation of the command produces a single report header output unless it is suppressed with the *-header* option.

The "values" report is a tabular output of attribute values for the collection elements, with one row of values per collection element. The report columns comprises formatted attribute values for the objects.

The "statistics" report type outputs the following statistical data about the attribute values

```
* Minimum, lower quartile, median upper quartile, and maximum
 values for numeric attributes.
* The mean and standard deviation for numeric attributes.
* Number of null attribute values for each attribute.
* Number of valid attribute values for each attribute.
* Number of unique attribute values for each attribute.
```

The "distribution" report type outputs a header section with information about the report, followed by the following statistical values about the data.

```
* Number of null attribute values for each attribute.
* Number of valid attribute values for each attribute.
* Number of unique attribute values for each attribute.
* Distribution of values with number of occurrences of each
 attribute value..
```

If both "statistics" and "distribution" reports are requested, the overlapping portion of the two reports is output only once.

All report types begin with a line displaying the collection composition including the size of the input collection followed by object count by object class type. When "statistcs" or "distribution" type report is included, the object count breakdown by object class type is always provided regardless of the size of the input collection. In a "values" only report, however, breakdown of object count by object class type is provided for a heterogeneous collection only when the collection contains one hundred or fewer items.

`-header` *header_type*

This option accepts one of the following valid argument values: "standard" | "none". If the option is omitted, the default header type is "standard". The "standard" header consists of the report name, command arguments, product name, product version, and the report date.

`-max_rows` *`value_count`*

This option indicates how many rows of data to include in the values and the value distribution tables. If the *collection* is very large, you may want to use the *-max_rows* option to limit the size of your report output. Number of text lines in the report may be greater than the *-max_rows* argument value if some data rows require multiple lines to output. This option value has no impact on the distribution and statistics calculations, for which the entire collection is processed. However, the *-max_rows* value, if given will limit the number of rows output for the value distribution table. If *-max_rows* value is given and truncates either the values or the distribution table output, a line is added to show the number of remaining items that were not shown.

`-nosplit`

This option indicates that the default column formatting used for a value is that is too long for the column width is "none", rather than the default "split". See the -columns option description below for more details.

`-columns` *`column_specification`*

Indicates the set of attributes on which to report and their order in the report. At a minimum, *column_specification* is a list of attribute names of elements of the collection.

The special attribute name "object_class" may be used to include the element object class names, such as "cell" or "net", in the report output.

If the option is omitted, then the object full names and object class (or type) names are output by default.

Each attribute name may be followed by a list of token-value pairs to indicate report column formatting directives. The value tokens for formatting are *width*, *precision*, *justify*, *label*, and *fit*. All column formatting specifications are optional.

width token is followed by a positive integer to value indicate the desired width of the column in number of characters. If not given, then the attribute value is queried for the first 100 elements of the collection and the longest value string determines the width of the column.

precision token is followed by a positive integer to value indicate the desired precision used to display floating point values (digits after the decimal point). If not given then the default precision for the attribute is used. This is ignored for non floating point attributes.

justify is followed by one of "left" or "right" to indicate the value's alignment in the column. If not given, then numeric attributes are justified right and other attributes are justified left.

Feedback

By default, the column headers show the name of the attribute. *label* is followed a string to display in the report column header in place of the attribute name.

fit is followed by one of the following valid argument values: "split" | "none" | "truncate" | "wrap" | "elide_left" | "elide_center" | "elide_right". This option indicates how to format an attribute value that is too long to fit in the column's width. If option is omitted, the default formatting is "split". However, if the option *-nosplit* is given, then the default formatting becomes "none". Explicit *fit* values given in a column specification overrides the default set by *-noSplit*.

The "split" formatting inserts a newline after the value which is too long and continues the tabular row on the next line, justifying the next value to the correct column.

The "none" formatting does nothing to reformat a value that is too long, continuing with the next column value. Therefore, the remainder of the tabular row will not be aligned with column headers.

The "truncate" formatting truncates the value to the width of the column, discarding the remainder of the value.

The "wrap" formatting truncates the value to the column and continues the rest of the tabular row on the same row. The remainder of the value is output on the following line(s), taking as many lines as is needed to finish outputting the rest of the value.

The "elide_left" formatting truncates the beginning of the value and adds the elision string "..." at the beginning of the value.

The "elide_center" formatting omits the middle of the value and inserts the elision string "..." at the center of the value.

The "elide_right" formatting truncates the end of the value and adds the elision string "..." at the end of the value.

Description

This command outputs a tabular report of attribute values for elements of the given collection. The attribute values in the report are determined by the list of attributes given as the *-columns* option argument. The columns in the tabular report will be ordered by order of attributes in the list. The command *list_attributes* may be called to see a list of attributes defined for an object class.

The *-column* option also accepts additional optional column formatting specifications in the attribute list. You may specify the header label and the width for each column, how to justify the value, and how to fit a value in a column when the value is too long to fit within the column width.

If the collection is large, the report size may be limited by indicating a *-max_rows* value. The commands *filter_collection* and *sort_collection* may be called to filter and sort a collection based on some criteria prior to creating a report for the collection elements.

Statistical and value distribution reports on the collection elements may be produced using the *-type* option arguments "statistics" and "distribution", respectively. Report types may be combined in a list.

The report header is followed by a line of report with collection size and object count by object data types. Precise object counts by types are always shown for "statistics" and "distribution" type reports. For "values" report, it is shown if the collection is homogenous or small. If the collection is heterogeneous and large, the object type shown for "values" report is "heterogeneous".

Examples

The following example from IC Compiler II creates a statistical report on a collection of cells along with a value distribution output.

```
icc2_shell> set cells [get_cells -hierarchical *]
icc2_shell> report_collection $cells -type {statistics distribution}
```

The following example, also from IC Compiler II, creates a report on a collection of cells with the full_name, area, and number_of_pins attribute values.

```
icc2_shell> set cells [get_cells U*]
icc2_shell> report_collection $cells -columns {full_name area
 number_of_pins}
```

The next example creates the same report but limits the width of the full_name column to 26 characters, designating "elide_center" formatting for full_name values that are longer than 26 characters.

```
icc2_shell> report_collection $cells -columns \
                              {{full_name {width 26} {fit elide_center}}
 \
                                area number_of_pins}
```

The next examples limits the output to the first 10 objects in the collection.

```
icc2_shell> report_collection $cells -columns \
                              {{full_name {width 26} {fit elide_center}}
 \
                                area number_of_pins} -max_rows 10
```

The next example first sorts the original collection of cells by the area attribute value in descending order, limiting the resulting collection to the top 10 area values. The example then careates a report for the resulting collection.

```
icc2_shell> set sorted_cells [sort_collection -dictionary \
                             $cells {area- full_name} -limit 10]
```

Feedback

```
icc2_shell> report_collection $sorted_cells -columns \
                              {{full_name {width 26} {fit elide_center}}
 \
                                area number_of_pins}
```

The next example reports on a sorted collection as in the above example but further limits the report to the first 10 objects in the collection. Note that this command may produce a report that is different from the above example. Limiting the sort to the first 10 values may have produced a collection with more than 10 objects since multiple objects may share the same area value.

```
icc2_shell> set sorted_cells [sort_collection -dictionary \
                             $cells {area- full_name} -limit 10]
icc2_shell> report_collection $sorted_cells -columns \
                              {{full_name {width 26} {fit elide_center}}
 \
                                area number_of_pins} -max_rows 10
```

report_constraint

Displays constraint-related information about a design.

Syntax

status *report_constraint*

```
[-all_violators]
[-verbose]
[-path_type slack_only | end]
[-ignore_register_feedback feedback_slack_cutoff]
[-max_delay_groups]
[-min_delay_groups]
[-max_capacitance]
[-min_capacitance]
[-max_transition]
[-pulse_clock_max_transition]
[-min_transition]
[-pulse_clock_min_transition]
[-max_fanout]
```

```
[-min_fanout]
[-min_pulse_width]
[-pulse_clock_min_width]
[-pulse_clock_max_width]
[-min_period]
[-recovery_group]
[-removal_group]
[-max_skew]
[-clock_separation]
[-clock_gating_setup_group]
[-clock_gating_hold_group]
[-significant_digits digits]
[-nosplit]
[-connection_class]
[-boundary_check]
[-boundary_check_include boundary_checks]
[-pre_commands pre_command_string]
[-post_commands post_command_string]
[-format style]
[-output file_name]
[-default_scenario_name scen_name]
[-waveform_integrity static | dynamic]
[-pba_mode none | path | exhaustive | ml_exhaustive]
[-include_hierarchical_pins]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

feedback_slack_cutoff	float
digits	integer
boundary_checks	list
pre_command_string	string
post_command_string	string
style	string
file_name	string
scen_name	string
object_list	list
sms_scenarios_list	collection

Arguments

`-all_violators`

Shows a summary of the worst violation per endpoint of each violated design rule constraint in the current design.

`-verbose`

Shows detailed information about each constraint violation. Multiple violations for a given constraint are listed from the largest to the smallest violation. If no objects are specified, the worst single violation is given for each constraint type.

`-path_type slack_only | end`

Specifies one of the following formats for the path report:

- *slack_only* (the default) - Shows only endpoint slacks.
- *end* - Shows the endpoint path total, required time, and slack for each path.

You cannot use the *-path_type* option together with the *-verbose* option.

`-ignore_register_feedback` *`feedback_slack_cutoff`*

Ignores any timing path that starts and ends at the same register and holds a value. This option applies to minimum delay as well as maximum delay reports. Only paths with slack less than the specified *feedback_slack_cutoff* are ignored. This option is applied as a filter to the paths after they are generated. Therefore, the number of paths generated might be less than the number specified with the *-nworst* and *-max_paths* options.

`-max_delay_groups`

Shows only the maximum delay and setup information. In the default report, the worst violation per clock group is displayed.

The maximum delay information shows cost by path group. This includes violations of setup time on registers or ports with output delay as well as violations of *set_max_delay* commands. The total maximum delay cost is the sum of the weighted cost of each group. For information about creating path groups, see the *group_path* man page. To see the current path groups in the design, use the *report_path_group* command.

`-min_delay_groups`

Shows only the minimum delay and hold information. In the default report, the sum of all violations per clock group is displayed.

The minimum delay cost includes violation of hold time on registers or ports with output delay as well as violations of the *set_min_delay* command.

`-max_capacitance`

Shows only the maximum capacitance constraint information. The *max_capacitance* design rule constraint limits the total capacitance on a net. The *-max_capacitance* option displays the *max_capacitance* cost (the sum of all maximum capacitance violations). To see details about the worst violation, use the *-verbose* and *-max_capacitance* options together. To see details about all *max_capacitance* violations, use the *-all_violators*, *-verbose*, and *-max_capacitance* options together. Note that the *max_capacitance* constraint is not checked for load pins.

`-min_capacitance`

Shows only the minimum capacitance constraint information. The *min_capacitance* design rule constraint limits the total capacitance on a net.

`-max_transition`

Shows only the maximum transition constraint information. The *max_transition* design rule constraint limits the transition time on pins and ports. If the library uses the cmos2 delay model, maximum edge rate information is shown instead. If the variable *timing_enable_slew_variation* is set to *true*, variation reporting is enabled for *max_transition*.

`-pulse_clock_max_transition`

Shows only the pulse clock maximum transition constraint information, similar to the *report_pulse_clock_max_transition* command.

`-min_transition`

Shows only the minimum transition constraint information. The *min_transition* design rule constraint specifies the minimum transition time on pins and ports. If the library uses the cmos2 delay model, maximum edge rate information is shown instead.

`-pulse_clock_min_transition`

Shows only the pulse clock minimum transition constraint information, similar to the *report_pulse_clock_min_transition* command.

`-max_fanout`

Shows only the maximum fanout constraint information. The *max_fanout* design rule constraint limits the fanout load on a net.

`-min_fanout`

Shows only the minimum fanout constraint information. The *min_fanout* design rule constraint specifies the minimum fanout load on a net.

`-min_pulse_width`

Shows only the minimum pulse width constraint information, similar to the *report_min_pulse_width* command. The *min_pulse_width* design rule constraint sets a minimum high or low pulse width at a clock pin or at pins or ports in the clock network.

`-pulse_clock_min_width`

Shows only the pulse clock minimum width constraint information. To enable pulse clock constraint checking, set the *timing_enable_pulse_clock_constraints* variable to *true*.

`-pulse_clock_max_width`

Shows only the pulse clock maximum width constraint information, similar to the *report_pulse_clock_max_width* command. To enable pulse clock constraint checking, set the *timing_enable_pulse_clock_constraints* variable to *true*.

`-min_period`

Shows only the minimum period constraint information. The *-min_period* option is a design rule used to set a minimum period on a clock signal.

`-recovery_group`

Shows only the recovery constraint information in default ***async_default*** group. The *recovery* type is a timing constraint used to describe the minimum allowable time between the control pin transition to the inactive state, and the active edge of the synchronous clock signal. This time is from the control signal going inactive to the clock edge that latches data in. The asynchronous control signal must remain constant during this time, or an incorrect value might appear at the outputs. In the default report, the worst violation in the default ***async_default*** group of the design is displayed.

`-removal_group`

Shows only the removal constraint information in default ***async_default*** group. The *removal* type is a timing constraint used to describe the minimum allowable time between the clock pin inactive edge, while the asynchronous pin is active, to the inactive edge of the same asynchronous control pin. In the default report, the sum of all violations in the default ***async_default*** group of the design is displayed.

`-max_skew`

Shows only the maximum skew constraint information. The *-max_skew* option is a timing constraint that checks the maximum separation time allowed between two clock signals.

`-clock_separation`

Shows only the clock separation constraint information.. The *-clock_separation* option is a timing constraint that checks the minimum separation time allowed between two clock signals.

`-clock_gating_setup_group`

Shows only the clock gating setup constraint information in default ***clock_gating_default*** group. The *clock_gating_setup* type is a timing constraint used to set a minimum setup time between a clock and a signal controlling the gating of that clock. In the default report, the worst violation in the default ***clock_gating_default*** group of the design is displayed.

`-clock_gating_hold_group`

Shows only the clock gating hold constraint information in default ***clock_gating_default*** group. The *clock_gating_hold* type is a timing constraint used to set a minimum hold time between a clock and a signal controlling the gating of that clock. In the default report, the sum of all violations in the default ***clock_gating_default*** group of the design is displayed.

`-significant_digits` *`digits`*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which has a default of 2. Use this option if you want to override the default.

`-nosplit`

Prevents line splitting to facilitate parsing of information from the report output.

`-connection_class`

Shows only the connection class constraint information. The connection_class constraint is displayed only if there is a connection_class violation. With the *-verbose* option, net pins and their associated connection class information are also displayed.

`-boundary_check`

Shows only HyperScale boundary constraint information. For more information, see the "Options for the HyperScale Flow" section.

`-boundary_check_include` *`boundary_checks`*

Reports the specified list of boundary checks. For more information, see the "Options for the HyperScale Flow" section.

`-pre_commands` *`pre_command_string`*

Specifies a string of commands to be executed in the worker context before the execution of merged reporting commands. Delimit commands with a semicolon (;). The maximum length of a command is 1000 characters. This option is available only if you invoke PrimeTime with the *-multi_scenario* option.

`-post_commands` *`post_command_string`*

Specifies a string of commands to be executed in the worker context after the execution of merged reporting commands. Delimit commands with a semicolon (;). The maximum length of a command is 1000 characters. This option is available only if you invoke PrimeTime with the *-multi_scenario* option.

`-format` *`style`*

Specifies the reporting format. The only allowed value is *csv*.

`-output file_name`

Specifies the output file name for CSV report.

`-default_scenario_name scen_name`

Specifies a scenario name in the CSV report. This option is valid only with *-format csv* and *-output* options. Note that in DMSA workers, this option overrides the implicit worker scenario name by the provided scenario name, in the CSV reports.

`-waveform_integrity static | dynamic`

Specifies the type of waveform integrity analysis:

- *static* - Available only if advanced waveform propagation is enabled.
- *dynamic* - Available only if signal integrity analysis is enabled.

To specify the constraints for waveform integrity analysis, use the *set_waveform_integrity_analysis* command.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Controls path-based analysis with the following modes:

- *none* (the default) - Path-based analysis is not applied.
- *path* - Path-based analysis is applied over the paths that gave the worst graph-based analysis violation. There is no guarantee that the reported path-based analysis slack over every endpoint is the worst one.
- *exhaustive* - An exhaustive path-based analysis path search algorithm is applied to determine the worst path-based analysis slack violations.
- *ml_exhaustive* - Performs Machine Learning based exhaustive path-based analysis. This mechanism will deploy machine learning techniques to trade runtime vs accuracy during the design flow. Accuracy and runtime will match pba_mode exhaustive as the design approaches signoff.

`-include_hierarchical_pins`

Includes hierarchical pins in the timing report. This option is valid only when -verbose option is set to TRUE.

object_list

Specifies a list of pins, ports, or cells in the current design for which constraint related information is displayed. For the *-max_transition*, *-min_transition*, *-max_capacitance*, *-min_capacitance*, *-max_fanout*, or *-min_fanout* option, only pins and ports can be specified. For the *-boundary_check* option, only hierarchical cells can be specified.

The *-verbose* option can be used to report detailed constraint calculation, and *-all_violators* option can be used to report only violators among the supplied *object_list*. For the *-boundary_check* option, the *-all_violators* option can be used to report on all violating boundary checks in a HyperScale flow for a subset of instances.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only constraints compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

By default, the *report_constraint* command displays the following information about all timing and design rule constraints checks on the current design:

- Whether the constraint is violated or met
- By how much the constraint value is violated (if it is violated).

The *object_list* can be optionally specified only with the *-max_transition*, *-min_transition*, *-max_capacitance*, *-min_capacitance*, *-max_fanout*, *-min_fanout*, and *-boundary_check* options. When an object list is specified, the *-verbose* option reports detailed constraint calculations for the objects, and *-all_violators* option reports only the violators among the objects.

Options for the HyperScale Flow

In a HyperScale flow (when the *hier_enable_analysis* variable is set to *true*), you can report boundary check violations that indicate whether a HyperScale block is used outside its context.

These checks are intended for use in a top-level analysis. They analyze the HyperScale blocks in the current analysis to ensure that the context used by block-level analysis bounds the actual conditions at the instance of that block in the top-level design. (In other words, they ensure that the top-level analysis is not using a block outside of the context it was analyzed at.)

To use these checks, the *timing_enable_hier_boundary_checks* variable must be set to *true* in both the block-level and top-level analysis runs.

The following options allow you to report boundary checks:

-boundary_check

Shows HyperScale boundary constraint differences between top-level and block-level analysis.

HyperScale boundary checks are not reported by the *report_constraint* command by default; this option must be used.

Boundary checks fall into two categories:

- Automatically fixable checks - HyperScale automatically adjusts the block-level boundary context during the next block-level run to resolve violations of these checks.
- Manually fixable checks – Violations of these checks indicate serious problems with the budgeted block-level constraints. HyperScale cannot automatically fix these violations; you must manually adjust the constraints.

In the report, an asterisk (*) next to a check name indicates an automatically fixable check. By default, only manually fixable checks are reported.

The *-all_violators* and *-verbose* options work with *-boundary_check* as follows:

- *-boundary_check* - the total number of check violations summed across all blocks is reported
- *-boundary_check -all_violators* - the total number of check violations for each violating block is reported
- *-boundary_check -verbose* - verbose details of the worst check violation of each type across all blocks is reported
- *-boundary_check -verbose -all_violators* - verbose details of all check violations are reported

-boundary_check_include *boundary_checks*

Changes the set of checks reported by the *-boundary_check* option.

Manually fixable checks can be specified with the following values:

```
boundary_ideal_network
clock_attributes
clock_mapping
clock_relations
clock_uncertainty
env_variables
global_timing_derate
library_mapping
operating_conditions
```

Automatically fixable checks can be specified with the following values:

```
boundary_logic_value
clock_latency
clock_skew_with_uncertainty
```

```
data_arrival
input_slews
```

The following special values include all manually fixable checks, all automatically fixable checks, or all checks:

```
non_auto_fixable
auto_fixable
all
```

If the *-boundary_check_include* option is not specified, only the manually fixable checks (*non_auto_fixable*) are reported.

For more information about a boundary check and how to resolve its violations, see the man page with "_violations" appended to the check name. For example, the following command shows information about *auto_fixable* violations:

```
pt_shell> man auto_fixable_violations
```

Examples

The following example shows brief constraint information for the current design:

```
pt_shell> report_constraint

report_context

Reports the characterized timing context information.

Syntax

string *report_context*

```
[-timing]
[-environment]
[-design_rules]
[-constant_inputs]
[-nosplit]
[-multi_instance_merge_compatibility]
[-list_context_override]
[-margin]
[-include type_list]
[-noise]
object_list
```

Data Types

object_list	list
type_list	list

Arguments

`-timing`

Reports timing information, such as clocks, input and output delays, and timing exceptions.

`-environment`

Reports environment-related information, such as operating conditions (process, temperature, and voltage), wire load model, capacitive loads on input and output pins, and driving cell information on input pins.

`-design_rules`

Reports characterized design rule information, such as *max_capacitance*, *max_transition*, and *max_fanout*.

`-constant_inputs`

Reports logic constants propagated to input pins.

`-nosplit`

Does not split lines if a column overflows.

`-multi_instance_merge_compatibility`

Specifies clustering information within each multi-instance group that satisfies clock compatibility. This option can only be used for the HyperScale Constraint Extractor or characterize context flows. For multi-instance configurations, it checks if the clock constraints of different instances are compatible or not. If the clock constraints are not compatible, this means that those instances should not be put in the same group. It provides clustering information within each group that satisfies clock compatibility within each cluster. When this option is used, this information is printed as part of the report. A new column is added for this option which shows the cluster. A number shows the cluster number for each instance in that group. If the instance is not part of a multi-instance configuration, -1 is show as the cluster.

`-list_context_override`

This option enables reporting of context overriding exceptions in a HyperScale block-level analysis. Automatic override of user-specified I/O budgets in the block constraints with accurate HyperScale top-level context is critical for the HyperScale flow to achive flat-analysis accuracy in a block-level analysis. However, there are multiple reasons why this automatic context overriding process might either be skipped, or only succeed partially, or completely fail.

The primary causes of context override failure are:

- User directives applied by *set_dont_override*
- Error conditions, such as clock mapping errors
- Netlist change on port nets

This report lists all the ports whose context override was not fully successful, along with the reason(s).

If there is no top-level HyperScale context available for the current block-level run, no ports will be automatically overriden, and therefore no ports will be listed by this report. In this case, a message indicating there is no context loaded for the current design is issued.

The 'Not Overridden Reason' column lists the reasons why ports have no context override when there is context available. The reasons include:

- *dont_override_timing* - port with user-applied *set_dont_override* on timing
- *dont_override_noise* - port with user-applied *set_dont_override* on noise

- *net_mismatch* - port with netlist mismatch on port net
- *unresolved* - port context refers to clock(s) with mapping errors

`-margin`

This option enables reporting of context margin set by the *set_context_margin* command. The margin allocation mode annotation is:

- *s* - *pin_slack*: set by *set_context_margin -allocation pin_slack*.
- *c* - *clock_period* - set by *set_context_margin -allocation clock_period*.
- *o* - *usr_override* - set by *set_context_margin -allocation user_override*.

Where different margin settings overlap in scope, the more specific setting is reported.

`-include` *`type_list`*

This option allows you to report only particular types of context information. Specify a list of one or more of the following types:

- *input_delay*: report only the input delay of the context
- *output_delay*: report only the output delay of the context
- *clock_latency*: report only the clock_latency of the context

`-noise`

This option enables reporting of context noise.

`object_list`

Lists cells or pins/ports for which to report the context.

Description

Reports the timing context captured using the *characterize_context* command for the specified list of instances or pins.

This command can also be used to report context data loaded by the *read_context* command. Use *current_design* as the object if reporting all loaded context. Specify port objects to report the context loaded for those ports.

Command options allow you to specify which categories of context information to report. All information categories are reported if no option is specified.

Examples

The following command reports the timing-related context information for instance I1 and I2. The report shows clocks and their waveforms, point-to-point timing exceptions, input external delays, and output external delays.

Feedback

The input and output delay information lists the minimum rise, minimum fall, maximum rise, and maximum fall delays. Input and output delay information lists the clock to which the delay is relative. If "(f)" follows the clock name, the delay is relative to the falling edge of the clock; otherwise the delay is relative to the rising edge. If "(l)" follows the clock name, input delay is considered as coming from a level-sensitive latch, or output delay is considered as going to a level-sensitive latch. The default is that the delay is relative to a rising edge-triggered device.

Multiple output delays are listed for a characterized output port if it has more than one fanout or if the logic it drives terminates in more than one type of latches (that is, edge-triggered (falling or rising clock) or level-sensitive with falling or rising clock).

```
pt_shell> report_context -timing {I1 I2}
```

The following command reports the environment and design rule context information. The report shows design rule checking, wire load models, drive information of input pin, and capacitive load on the input and output pins of I2.

```
pt_shell> report_context -env -design_rules I2
```

The following command reports the context on port "in" loaded by the *read_context* command.

```
pt_shell> report_context in
```

The following command reports all context data loaded by the *read_context* command.

```
pt_shell> report_context [current_design]
```

---

report_coupling_capacitors

Reports the coupling capacitors for specified nets.

Syntax

status *report_coupling_capacitors*

```
[-verbose]
[-of_objects nets]
[-from node1 -to node2]
```

Feedback

Data Types

nets	list
node1	string
node2	string

Arguments

`-verbose`

Provides additional information about the coupling capacitors.

`-of_objects` *nets*

A list of one or more nets for which to report coupling capacitors. At least one net is required. Glob-style wildcards (*) are supported.

This option is mutually exclusive with the *-from* and *-to* options.

`-from` *node1*

Specifies a pin, port, or net internal node. The tool reports the coupling capacitors between this node and the node specified in the *-to* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

`-to` *node2*

Specifies a pin, port, or net internal node. The tool reports the coupling capacitors between this node and the node specified in the *-from* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

Description

This command reports the coupling capacitors for specified nets.

You must use either the *-of_objects* option or both the *-from* and *-to* options.

The default report contains a section for each victim net (the nets specified in the command arguments). The victim net heading lists the total coupling capacitance for the victim net. For each aggressor net, the report lists the total coupling capacitance between the aggressor net and the victim net and its percentage with respect to the total coupling capacitance on the victim net.

The *-verbose* report also contains a section for each victim net. It provides detailed information about the individual coupling capacitances between nodes of the victim net and nodes of the aggressor nets.

This command is supported only for transistor-level GPDs.

Feedback

Examples

The following example shows a default coupling capacitor report.

```
pt_shell> report_coupling_capacitors -of_objects SUM0
================================
Net: SUM0
Total capacitance: 0.013721
Report Type: Aggressors, summary
================================
Total CCAP      %Cc/Ct         Aggressor Net
==========      ======         =============

---

report_crpr

Reports the clock reconvergence pessimism (CRP) calculated between specified register clock pins or ports.

Syntax

string *report_crpr*

```
-from from_latch_clock_pin
-to to_latch_clock_pin
[-from_clock from_clock]
[-to_clock to_clock]
[-setup | -hold]
[-significant_digits digits]
[-sms_scenarios sms_scenarios_list]
```

Feedback

Data Types

from_latch_clock_pin	string
to_latch_clock_pin	string
from_clock	string
to_clock	string
digits	integer
sms_scenarios_list	collection

Arguments

`-from` *from_latch_clock_pin*

Specifies the clock pin of the launching sequential device or clock gating check to be reported. A constrained input port can also be used.

`-to` *to_latch_clock_pin*

Specifies the clock pin of the capturing sequential device or clock gating check to be reported. A constrained output port can also be used.

`-from_clock` *from_clock*

Specifies the clock that fans out to the launching sequential device.

`-to_clock` *to_clock*

Specifies the clock that fans out to the capturing sequential device.

`-setup`

Indicates that the CRP used for a setup data path is to be reported. The *-setup* and *-hold* options are mutually exclusive. If neither option is specified, *-setup* is assumed.

`-hold`

Indicates that the CRP used for a hold data path is to be reported. The *-setup* and *-hold* options are mutually exclusive. If neither option is specified, *-setup* is assumed.

`-significant_digits` *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13.

If this option is not specified, the number of significant digits is determined by the *report_default_significant_digits* variable.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only data compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Feedback

Description

Reports the clock reconvergence pessimism (CRP) calculated between specified register clock pins or ports.

This command displays the following information about the calculation of the CRP between the two specified sequential elements:

- The name of the common pin in the clock network.
- The clock edges (rising or falling) that propagate through the common point to the launching and capturing registers.
- The value of the *timing_crpr_threshold_ps* variable.
- A tabulation of the arrival times for both clock edges at the common point and their associated CRP (crp_rise and crp_fall).
- The CRP used along with the reasoning behind the selection of the particular CRP (crp_rise or crp_fall) used for that report.
- The CRP value used is independent of the CRPR threshold, and, therefore, is referred to as the exact CRP. The *report_timing* and *report_clock_timing* commands report a CRP value that might be pessimistic by up to the value of the CRPR threshold. If the CRP value used by the *report_timing* or *report_clock_timing* command differs from the exact CRP, this value is also reported.

If the *timing_remove_clock_reconvergence_pessimism* variable is set to *false*, CRPR is inactive and this command does not work.

To generate a CRP report for specific clocks, use the *-from_clock* and *-to_clock* options. Otherwise, the tool reports all clocks that fanout to each sequential device.

For each potential common point in the design, the tool calculates

- crp_rise from rising arrival times at the common point
- crp_fall from falling arrival times at the common point

The value of CRP used in the report is dependent on what clock edges propagate through the common point to the clock pins of the launching and capturing devices. The clock edges are included in the CRPR report as "Launching edge at common point", "Capturing edge at common point".

For example, if a rising edge through the common point triggers the launching device and also triggers the capturing device, then a rising CRP value (crp_rise) is used. Similarly, for a falling edge propagating through the common point and subsequently launching and capturing data, a falling CRP value is used (crp_fall).

If a rising edge through the common point launches the data, and a falling edge through the common point captures it, a mismatch in sense occurs. In this case, if the *timing_clock_reconvergence_pessimism* variable is set to

- *normal*, the minimum of crp_rise and crp_fall is used
- *same_transition*, the CRP is reported as zero

This selection process is reported in the selection details section of the report.

If either clock edge is reported as "RISING or FALLING", there is a non-unate path between the common point and that clock pin, such that botch edge directions result in active clock edges at the clock pin.

If dynamic information is enabled, two sets of arrival totals are tabulated. Dynamic information can result from SI delta delays, dynamic clock latencies or dynamic rail voltages. In this case, the two sets of arrival totals tabulated are those computed with and without dynamic information being available. The arrival totals computed without dynamic information are equivalent to those used in a PrimeTime analysis with no dynamic information available.

The additional set of arrivals result in four CRP values from which the CRP value used should be chosen. These four CRP values can be summarized as rise/fall CRP and rise/fall dynamic CRP. The rise/fall decision is made based on clock edges incident at the clock edge as before. The decision over whether or not to use dynamic CRP is based on the temporal separation of launching and capturing clock edges. It is only valid to use dynamic CRP if the clock edge launching and capturing data occurs at the same time.

In the case when the capturing sequential device is a level-sensitive latch, two CRP values are reported. The first corresponding to the opening edge of the latch (this CRP also appears in the timing report) and the other corresponding to the closing edge of the device. The selection details section also reports the decision making process behind both CRP values. Note that in this case, since the opening and closing clock edges at the latch are always different, there is always a mismatch in clock edges for one of them.

Examples

The following example displays how to use the command to report the clock reconvergence pessimism calculated between the sequential elements, ffa and ffd, for a setup data path.

```
pt_shell> report_crpr -from ffa/CP -to ffd/CP -setup

report_crpr -from ffa/CP -to ffd/CP -setup
****************************************
Report : CRP Calculation
Design : counter
 ...
****************************************
```

```
  Startpoint: ffa (rising edge-triggered flip-flop clocked by CLK)
  Endpoint: ffd (rising edge-triggered flip-flop clocked by CLK)

  Common Point: CLK <inside>
  Common Clock: CLK
  Launching edge at common point: RISING
  Capturing edge at common point: RISING
  CRPR threshold: 0.02

  Arrival Times                        Early    Late     CRP
-------------------------------------------------------------
  Rise                                  3.00    19.00    16.00
  Fall                                  5.00    23.00    18.00
-------------------------------------------------------------

  Selection Details
-------------------------------------------------------------
  Edge Match:          Match, using rise CRP
-------------------------------------------------------------
  clock reconvergence pessimism                          16.00
```

The following example displays a report where the launching device is a flip-flop and the capturing device is a latch. Note that in this case the mismatch in clock edges occurs for the CRP corresponding to the closing edge at the latch.

```
pt_shell> report_crpr -from reg1/CP -to lat2/G
****************************************
Report : CRP Calculation
Design : borrow
 ...
****************************************

  Startpoint: reg1 (rising edge-triggered flip-flop clocked by clk)
  Endpoint: lat2 (positive level-sensitive latch clocked by clk)

  Common Point: clk_buf/Z
  Common Clock: clk
  Launching edge at common point: RISING
  Latch open edge at common point: RISING
  CRPR threshold: 0.01

  Arrival Times                        Early    Late     CRP
-------------------------------------------------------------
  Rise                                2.1229   2.6529   0.5300
  Fall                                2.0868   2.7868   0.7000
-------------------------------------------------------------

  Selection Details
-------------------------------------------------------------
  Edge Match (opening): Match, using rise CRP
  Edge Match (closing): Mismatch, using min(rise CRP, fall CRP)
-------------------------------------------------------------
```

```
  clock reconvergence pessimism (open edge)           0.5300
  clock reconvergence pessimism (close edge)          0.5300
```

The following example displays the case when both SI and CRPR are enabled. As outlined in a previous paragraph, two sets of arrival totals are computed in this case (for example, when both CRPR and SI are enabled). One set of arrival totals are computed with no SI information and another are computed considering SI information. To illustrate this, both a setup and hold report are displayed to highlight the case when CRP is calculated from arrival times without delta delays (setup) and the case when CRP is calculated from arrival times including delta delays (hold with the launching and capturing clock edge occurring at the same time).

```
pt_shell> report_crpr -from seg1/u3/CK -to seg1/u9/CK
****************************************
Report : CRP Calculation
 ...
****************************************

  Startpoint: seg1/u3 (rising edge-triggered flip-flop clocked by CLK1)
  Endpoint: seg1/u9 (rising edge-triggered flip-flop clocked by CLK1)

  Common Point: seg1/u17_c/Y
  Common Clock: CLK1
  Launching edge at common point: RISING
  Capturing edge at common point: RISING
  CRPR threshold: 0.02

  Arrival Times (Static)              Early    Late     CRP

report_ctpm

Report the CTPM in current design, for a library, or a certian CTPM file.

Feedback

Syntax

string *report_ctpm*

```
[-ctpm_file ctpm_file]
[-library lib]
[-verbose]
```

Data Types

```
ctpm_file       string
lib             collection
```

Arguments

`-ctpm_file ctpm_file`

Specifies the CTPM file to report. Without the option, CTPM used in current design will be reported.

`-library lib`

Specifies the library to report ML-CTPM.

`-verbose`

Verbose report for flattened per-lib_timing_arc CTPM values for ML-CTPM.

Description

The *report_ctpm* command reports CTPM related information used in PrimeShield SPICE2Design feature. This feature enables analysis for timing and power impact assessment of a given target. This target can be defined through a spice model representing next PDK, spot model, different spice corner.

Through ML, Project Sicily aims to bridge the gap between the base and the target by capturing and gap through spice process parameters placed inside of a Compact Timing Power Model (CTPM) database. When CTPM is consumed in a base STA session, the QoR of this session is shifted such that to match QoR of the target.

Examples

The following script reports CTPM information of a CTPM file.

```
set ps_enable_analysis true
set ps_enable_spice2design_analysis true

pt_shell> report_ctpm -ctpm_file lib1.ctpm -verbose
Information: Load file cwd/lib1.ctpm successfully.
Information: CTPM for base library lib1 START
base_process_label: N/A
base_custom_label: N/A
target_process_label: N/A
target_custom_label: N/A
```

```

report_delay_calculation

Displays the actual calculation of a cell or net timing arc delay value.

Syntax

int *report_delay_calculation*

```
[-min | -max]
[-from from_pin]
[-to to_pin]
[-of_objects objects
[-nosplit]
[-from_rise_transition value]
[-from_fall_transition value]
[-thresholds]
[-crosstalk]
[-derate]
[-sms_scenarios sms_scenarios_list]
[-sensitivity]
```

Feedback

Data Types

from_pin	string
to_pin	string
objects	collection
value	float
sms_scenarios_list	collection

Arguments

`-min`

Shows the minimum delay calculation. The design must be in either min or max mode.

`-max`

Shows the maximum delay calculation. This is the default if neither the *-min* nor *-max* option is specified.

`-from` *from_pin*

Specifies the startpoint of a timing arc within a design. For a cell timing arc, the pins must represent the input and output pins of a common leaf cell that have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. Port names are allowed in place of pin names for net arcs. Use either the *-from* and *-to* options together, or use the *-of_objects* option. However, you cannot set both.

`-to` *to_pin*

Specifies the endpoint of a timing arc within a design. For a cell timing arc, the pins must represent the input and output pins of a common leaf cell that have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. Port names are allowed in place of pin names for net arcs. Use either the *-from* and *-to* options together, or use the *-of_objects* option. However, you cannot set both.

`-of_objects` *objects*

Specifies a collection of timing arcs (created with the *get_timing_arcs* command) on which to report. Arcs in the list are reported in order of from and to pins. Use either the *-from* and *-to* options together, or use the *-of_objects* option. However, you cannot set both.

`-nosplit`

Prevents line-splitting to facilitate parsing of information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-from_rise_transition` *value*

Specifies a value to be used by the delay calculation for the from rise transition.

`-from_fall_transition` *value*

Specifies a value to be used by the delay calculation for the from fall transition.

`-thresholds`

Reports the characterization thresholds that are used for delay calculation.

`-crosstalk`

Reports the crosstalk information for a net arc. The arc is specified with the *-from_pin* and *-to_pin* options. It is not permitted with the *-of_objects* option and the user-chosen transition time *-from_rise_transition* and *-from_fall_transition* options. The crosstalk information is reported from the last *update_timing* command.

`-derate`

Reports derating components and derated delay.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only delay information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`-sensitivity`

Reports sensitivity caused by physical parameter shift from PrimeShield features like SPICE2Design CTPM, PVT explorer condition what-if PPA analysis, device parameter margin, etc).

Description

This command provides detailed timing calculation information about the specified cell or net timing arc. This information is useful for debugging or verifying timing data in a technology library.

Both operating conditions and wire load models are considered when making delay calculations. Timing ranges as affected by the *set_timing_derate* command (similar to the *set_timing_range* dc_shell command) are not considered because they typically apply to an entire path.

The information reported is solely for the input arcs. Even if there are other arcs merging at the to-pin of an input arc, the transition time reported for the to-pin is the transition time that the input arc contributes to the merging point. As a result, the reported transition time might not match the transition time at the to-pin because the final transition time is the result of merging transition times contributed by all the input arcs. To get the final transition

time at the to-pin, either all these input arcs should be reported or an attribute access to the to-pin should be used.

The *-crosstalk* option on net arc, reports the aggressor and victim information for both rise and fall. It prints coupling capacitance, the driving library cell, the clocks reaching the net (both victim and aggressor). The aggressors have "Switching Bump", which is used for prioritizing the aggressors, and also have aggressor attributes. These informations are already available as net or design attributes. For example, "Switching Bump" is available as the net attribute si_xtalk_bumps. Considering the memory usage, only the worst case bumps for the net is stored, even though during the crosstalk delay calculation switching bump per net arc is used. "Switching Bump" is crosstalk delay bump ratio of VDD. The clocks gives insight into the constraints of the coupling cluster. For example, during the normal mode analysis the test clocks are supposed to be quiet. If there is no arrival windows, it reported as "No Arrival". Driving cell gives a idea relative strength of the victim and aggressor drivers. If the ports/pins have no driving cell it is reported as "No Lib Cell".

It also prints the other settings in design that could effect the crosstalk delay calculation, for example, logical correlation, composite aggressor setting, crosstalk delay analysis mode, and crosstalk delay effort level.

Attributes:

```
A - aggressor is Active
  C - aggressor is a composite aggressor
  E - aggressor is screened due to user Exclusion
  I - aggressor has Infinite arrival with respect to the victim
  L - aggressor is screened due to Logical correlation
  N - aggressor does Not overlap for the worst case alignment
  S - aggressor is screened for Small bumps
  U - aggressor/victim RC calculation is skipped.
  X - aggressor is screened due to aggressor eXclusion
```

Active aggressor is an aggressor that contributes to the worst case alignment scenario. It is reported as 'A'.

PrimeTime analyzes the composite effect of a group of weak aggressors (including filtered ones) for better quality of SI analysis. These aggressors are reported as 'C'.

You can exclude an aggressor from the analysis by using the *case_analysis*, *set_si_delay_analysis -exclude* or *set_coupling_separation* command. These aggressors are reported with attribute 'E'.

An aggressor has infinite window when it has no fixed timing relationship with the victim, for example, an aggressor clock is asynchronous to the victim clock. Also, if the victim or aggressor has the *set_si_delay_analysis -ignore_arrival* command, the aggressor gets the infinite window attribute 'I'.

When PrimeTime SI finds that the victim and aggressors cannot switch together due to the logical relationship (for example, the input and output net of a inverter, they cannot

switch in the same direction at the same time), PrimeTime SI chooses the combination of aggressors that can switch together logically and set them to active. The aggressors that cannot switch due to logical relationship are screened with attribute 'L'. The logical relationship could be identified only for buffer/inverter chains.

Due to multiple aggressors and their possible multiple arrival windows there could be multiple alignments which could cause crosstalk delta. PrimeTime SI identifies and reports the crosstalk delta for only the worst case alignment. If the aggressor does not contribute to the worst case alignment scenario, it is screened, and the attribute is set to 'N'.

The switching bumps that are smaller compared to the electrical filtering criteria, are screened. The attribute of these aggressors are set to 'S'. When composite aggressor feature is applied, the SI effect of screened aggressors are considered, and 'S' is replaced by 'C'.

If the aggressor or victim RC calculation is skipped, the attribute is set to 'U'. The common cause of the RC calculation skipping on a net is there is no cell arc driving the net(victim or aggressor) or the driving model could not be created.

The *set_si_aggressor_exclusion* command can set aggressor exclusion relationship among aggressors (for example, the specified aggressors cannot switch in the same direction at the same time), PrimeTime SI chooses the combination of aggressors that can switch together based on alignment and sets them to active. The aggressors that cannot switch due to aggressor exclusion relationship are screened with attribute 'X'.

Examples

The following example shows the output on a cell arc connected to an RC network. RC delay calculation is performed.

   Effective capacitance  =  0.002625    0.002800  (in library unit)
   Output transition time =  0.060388    0.047040  (in library unit)
   Cell delay             =  0.050937    0.045125  (in library unit)
```

The following example shows the report for net arc when the advanced mode of delay calculation is used. You can set the advanced mode for the receiver model by using the

rc_receiver_model_mode variable. No additional option of the *report_delay_calculation* command is necessary to report details of the advanced mode of delay calculation. In addition to the existing information, the pin capacitances of the advanced receiver model and the transition values used to calculate the pin capacitances of the advanced receiver model are also reported.

```
pt_shell> report_delay_calculation -max -thresholds \\
            -from sig_in0 -to cell0/A -nosplit

From port: sig_in0
To pin:   cell0/A

                                Rise        Fall
   ------------------------------------------------------------------
   Net delay                =   0.000024    0.000064  (in library unit)
   Transition time          =   0.059192    0.037599  (in library unit)
   From_pin transition time =   0.059078    0.037666  (in library unit)
```

```
   To_pin transition time    =    0.059192     0.037599  (in library unit)
   Net slew degradation      =    0.000114    -0.000067  (in library unit)
```

The *define_scaling_lib_group* command allows you to define a group of libraries that PrimeTime interpolates between for voltage or temperature scaling. The following example shows the output on a net arc when scaling of the receiver model is done. The report indicates that scaling was done and also reports all the scaling libraries that were used for scaling the model.

```
pt_shell > report_delay_calculation -from I1/Z -to I2/B

From pin: I1/Z
To pin:   I2/B
Main Library Units:  1ns  0.001pF  1000kOhm

arc sense: unate
arc type:  net

   RC network on pin 'I1/Z' :
   -------------------------------------------------
   Number of elements = 2 Capacitances + 1 Resistances
   Total capacitance  = 0.815687 pF
   Total capacitance  = 815.686687 (in library unit)
   Total resistance   = 8.323139 Kohm

report_design

Shows information about the current design.

Syntax

status *report_design*

```
[-nosplit]
```

Feedback

Arguments

`-nosplit`

Prevents line splitting in the report when a field exceeds the column width.

Description

This command shows the following information about the current design:

- Operating conditions
- Wire load
- Design rules
- Timing ranges

Examples

The following example shows a design report.

```
pt_shell> report_design

****************************************
Report : design
Design : counter
 ...
****************************************

Design Attribute                  Value
------------------------------------------------------------------------------
----
Operating Conditions:
  operating_condition_max_name    WCCOM
  process_max                     1.50
  temperature_max                 70.00
  voltage_max                     4.75
  tree_type_max                   worst_case_tree

Wire Load:                        (use report_wire_load for more
 information)
  wire_load_mode                  top
  wire_load_model_max             --
  wire_load_selection_group_max   --
  wire_load_min_block_size        0

Design Rules:
  max_capacitance                 0.5
  min_capacitance                 --
  max_fanout                      5.6

---

report_design_mismatch

Reports all design mismatches found during linking.

Syntax

string *report_design_mismatch*

```
[-class cell | net | pin]
```

Arguments

`-class cell | net | pin`

For any pin that is found to have mismatches (such as instance and reference have different directions on the pin), only the associated objects (cells, nets, pins) that belong to this class are reported. The possible values are "cell", "net" and "pin".

Description

When the *link_allow_design_mismatch* variable is *true*, linking succeeds even when there are mismatches found. This allows you to gather as much useful information as possible even in the early stages of design. This command provides a report of mismatches for the current design.

Common causes of those mismatches include the following (listed in order of increasing priority):

1. A pin has different directions in instance and reference.
2. A pin of instance does not exist in reference.
3. A bus has different widths in instance and reference.

If a cell, pin, or net has a mismatch issue, the *is_design_mismatch* attribute returns *true* for the affected cell, pin, or net object. If the pin with a mismatch is on a bus, all other bits of the bus are also marked with the *is_design_mismatch* attribute.

Feedback

Note that if a cell or net has more than one mismatched issue, only the one with the highest priority is reported.

Examples

The following report example shows that the u1/Z and u2/Z pins have direction mismatches between instance and reference. The b net is connected to both u1/Z and u2/Z.

```
pt_shell> report_design_mismatch

****************************************
Report : report_design_mismatch
  ...
****************************************

pin                mismatch type
-----------------------------------------
u1/Z               Pin direction mismatch
u2/Z               Pin direction mismatch
-----------------------------------------
cell               mismatch type
-----------------------------------------
u1                 Pin direction mismatch
u2                 Pin direction mismatch
-----------------------------------------
net                mismatch type
-----------------------------------------
b                  Pin direction mismatch
```

report_design_variation

report_disable_pg_pins

Report the PG pins which are disabled using set_disable_pg_pins.

Syntax

string *report_disable_pg_pins*

[lib_cells]

Feedback

Data Types

lib_cells collection

Arguments

lib_cells

Specifies set of lib_cells on which disabled PG pins needs to be reported.

Description

The *report_disable_pg_pins* command reports the list of PG pins disabled using set_disable_pg_pins command. If lib cells are specified then, only the PG pins disabled for tat lib cell are reported. If no lib cells is specified all disabled PG pins are reported.

Examples

The following illustrates the report_disable_pg_pins command.

```
pt_shell> set_disable_pg_pins [get_lib_cell XYZ/A] -pg_pins {VDD}
1
pt_shell> report_disable_pg_pins
report_disable_pg_pins
****************************************

---

report_disable_timing

Reports disabled timing arcs in the current design.

Syntax

string *report_disable_timing*

```
[-nosplit]
[cells_or_ports]
```

Feedback

Data Types

cells_or_ports collection

Arguments

-nosplit

Prevents line splitting to facilitate writing software to extract information from the report output. If you do not use this option, the report is shown in fixed-width columns.

cells_or_ports

Limits disabled arc reporting to the specified list of cells or ports. Provides the list or collection of cells or ports as an argument to the command.

Description

This command reports disabled timing arcs in the current design. Timing arcs can be disabled in several ways. You can disable a timing arc by using the *set_disable_timing* command. The following symbols are used to explain why a timing arc is disabled:

```
c : The propagation of case-analysis values

 C : The presence of conditional arcs (arcs that have a when statement
 defined in the library)

 d : The presence of default arcs (when
 the timing_disable_cond_default_arcs variable
 is set to true)

 f : Disabling of false net-arcs

 l : Loop breaking

 L : db inherited loop breaking

 m : Mode

 p : The propagation of constant values

 u : Arcs disabled by using the set_disable_timing command on cell arcs.

 U : Arcs disabled by using the set_disable_timing command on library
 cell arcs.
```

Examples

The following example shows that the timing arc of the n2_i cell from pin A to pin Z is disabled.

```
pt_shell> set_disable_timing {n2_i} -from A -to Z
pt_shell> report_disable_timing

****************************************
Report : disable_timing
 ...
****************************************

Flags :     c  case-analysis
            C  Conditional arc
            d  default conditional arc
            f  false net-arc
            l  loop breaking
            L  db inherited loop breaking
            m  mode
            p  propagated constant
            u  user-defined
            U  User-defined library arcs

report_dominant_layer_in_path

Reports the layers with the most capacitance for specified nets.

Syntax

status *report_dominant_layer_in_path*

```
[-of_objects nets]
[-from node1 -to node2]
```

Feedback

Data Types

nets	list
node1	string
node2	string

Arguments

`-of_objects` *nets*

A list of one or more nets for which to report layer information. At least one net is required. Glob-style wildcards (*) are supported.

This option is mutually exclusive with the *-from* and *-to* options.

`-from` *node1*

Specifies a pin, port, or net internal node. The tool reports the layer information for paths between this node and the node specified in the *-to* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

`-to` *node2*

Specifies a pin, port, or net internal node. The tool reports the layer information for paths between this node and the node specified in the *-from* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

Description

This command reports the layers with the most capacitance for specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a dominant layer report.

```
pt_shell> report_dominant_layer_in_path -of_objects {SUM0 B0}
================================
List of nets in specified timing path:
net1: SUM0
net2: B0
Total number of nets in the timing path: 2

R dominant layer: poly
Total R on poly: 0.568534

C dominant layer: metal1
Total C on metal1: 0.055679
```

Feedback

report_drc_error

Writes out an error report of physical DRC errors from the specified error data. The *report_drc_error* command supports different reporting styles.

Syntax

status *report_drc_error*

```
-error_data    drc_error_data
[-error_type   drc_error_types]
[-of_objects   drc_error_objects]
[-report_type error_type | error_layer | detailed]
[-nosplit]
```

Data Types

```
drc_error_data     collection
drc_error_types    collection
drc_error_objects  collection
```

Arguments

`-error_data` *drc_error_data*

Specifies the error data for finding objects.

`-error_type` *drc_error_types*

Reports errors within the specified *drc_error_types*. An error is included in the output if it matches any one of the *drc_error_types*. Use the *get_drc_error_types* command to specify *drc_error_types*.

`-of_objects` *drc_error_objects*

Reports errors with the specified *drc_error_objects*. In this case, the *drc_error_objects* are error instances. Use the *get_drc_errors* command to specify *drc_error_objects*.

`-report_type error_type | error_layer | detailed`

Writes out the specified report type. Three types are supported: *error_type*, *error_layer*, and *detailed*. You can specify only one report type. By default, if no *report_type* is specified, the report type is *error_type*.

`-nosplit`

Write out the report without splitting long lines. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line splitting and facilitates writing software to extract information from the report output.

Feedback

Description

The *report_drc_error* command prints a collection or summary of physical DRC errors in the specified error data that match certain criteria. The command returns true if any physical DRC errors match the criteria and successfully reported. If no objects match the criteria, the error status will be reported.

There are three types of report supported by the command: *error_type*, *error_layer*, and *detailed*. Use the *-report_type* option to specify the report type. The *error_type* report type writes out a summary of error information in type order. The *error_layer* report type writes out a summary of error information in layer order. The *detailed* report writes out each error instance information one-by-one. The information includes the ID, type, layer, number of errors in this type, description, status and bbox.

The *-error_type* option filters the errors by the specified types. You can specify more than one *error_type* here by enclosing each error type in curly braces: *{{$errType1} {$errType2}}*

The *-of_objects* option filters the errors by the specified error instances. Use the *get_drc_errors* command to specify the instances.

You can specify one or more filtering options to customize the report. If you specify *"Short"* and *"Net"* error type with *"METAL"* and *"METAL2"* layers, you can get errors with *"Short"* and *"METAL"*, with *"Short"* and *"METAL2"*, with *"Net"* and *"METAL"*, with *"Net"* and *"METAL2"*. If you specify the *-of_objects* option, the command writes out only the errors for the specified objects.

For long reports you do not want to write to the console, use the *redirect* command to write the output to a file.

Examples

The following example displays an error_type report of the errors with error type 'Net'.

```
prompt> set type [get_drc_error_types -error_data $data {Net}]
prompt> report_drc_error -error_data $data -error_type $type -report_type
 error_type

report_driver_model

Displays the driver model for a library cell timing arc used to drive annotated parasitics.

Syntax

integer *report_driver_model*

```
-lib_cell lib_cell
-from_pin from_pin
-to_pin to_pin
-rise_slew rise_slew
-fall_slew fall_slew
-capacitance capacitance
```

Data Types

```
lib_cell            string
from_pin            string
to_pin              string
rise_slew           float
fall_slew           float
capacitance         double
```

Arguments

`-lib_cell` *lib_cell*

Specifies the name of the library cell for which the driver model is computed. Specify the name in the *library_name/cell_name* format.

`-from_pin` *from_pin*

Specifies the startpoint of a timing arc through the *lib_cell* value.

`-to_pin` *`to_pin`*

Specifies the endpoint of a timing arc through the *lib_cell* value.

`-rise_slew` *`rise_slew`*

Specifies the rise time in library units on the *from_pin* value.

`-fall_slew` *`fall_slew`*

Specifies the fall time in library units on the *from_pin* value.

`-capacitance` *`capacitance`*

Specifies the load in library units on the *to_pin* value.

Description

The *report_driver_model* command provides both the library data and the resulting driver model parameters for the specified library arc and conditions. This information is useful for validating library data or PrimeTime driver models used in delay calculation with annotated parasitics.

For each timing arc between the specified pins, the delay, slew, and sensitivities (the changes in delay and slew resulting from a small change in load capacitance) are displayed. This information can be compared to simulation results using the same input slew and output load to measure library interpolation errors. If the current design is in min-max mode, data for both operating conditions is displayed.

Slews are displayed without derating (they are shown as the time between the trip-points.).

In addition to the library data, the driver model parameters used in delay calculation with annotated parasitics are displayed. Currently, PrimeTime supports only the simplified driver model (SDM) with three parameters: rd (the drive resistance through which a linear voltage ramp is applied), tz (the ramp start time relative to the arc input threshold time), and dt (the full-swing ramp duration).

The driver model is constructed to match the library delay, slew, and sensitivity for the specified input slew and output load.

Problematic library data can prevent the construction of a driver model altogether. In this case, the driver model parameters displays as zero, and the check shows FAIL. The most common reason for this error is that the library data not indicating an increasing delay or slew for increasing output capacitance; this indicates a nonpositive drive resistance. Another common reason is incorrect trip-point settings.

Examples

The following report shows the output for the driver model for a library cell timing arc.

```
pt_shell> report_driver_model \\
  -lib_cell [get_lib_cell -of_objects I0] \\
```

Feedback

```
  -from_pin A -to_pin Y \\
  -rise_slew 0.0384 -fall_slew 0.0384 -capacitance 0.115194

report_eco_library_cells

Reports alternative library cells considered for PrimeTime ECO commands.

Syntax

string *report_eco_library_cells*

```
[-pattern_priority pattern_list]
[-attribute attribute_name]
[-show_others]
[-current_library]
[-nosplit]
[-power_attribute power_attribute_name]
```

Data Types

pattern_list	list
attribute_name	string
power_attribute_name	string

Arguments

`-pattern_priority` *pattern_list*

Specifies a list of library cell patterns starting from the highest to lowest priority.

`-attribute` *attribute_name*

Specifies an attribute name that can be used to match patterns specified by the *-pattern_priority* option. When you specify this option, PrimeTime uses the value of the attribute instead of library cell names for pattern matching.

`-show_others`

Shows library cells that do not match the specified pattern. This option must be used together with the *-pattern_priority* option.

`-current_library`

Shows alternative library cells within the same library.

`-nosplit`

Prevents line splitting when column overflows to facilitate writing script to extract information from the report output.

`-power_attribute` *power_attribute_name*

Specifies a power attribute set on library cells. If you specify this option, the attribute values are reported in a separate column.

Description

This command reports the alternative library cells of all cells in a design. This command must be used by workers for multi-scenario analysis flow within PrimeTime.

Examples

The following example reports alternative library cells:

```
pt_shell> report_eco_library_cells
```

```
****************************************
Report : eco_library_cells
Design : design
 ...
****************************************

Alternative library cells:

  Attributes:
      u - dont_use or pt_dont_use
      d - dont_touch

Group  Library_Cell                                  Area Attributes

---

report_eco_mim_instances

Reports ECO MIM instances in the current design.

Syntax

string *report_eco_mim_instances*

```
[-summary]
```

Arguments

`-summary`

Generates a summary report that omits the "Sources" column and limits the number of reported instances to 10 per MIM group.

Feedback

Description

This command reports the sets of multiply instantiated module (MIM) instances that can be modified identically by ECO operations. For each ECO MIM group, the report shows the number of instances, the source of the MIM group, the Verilog module name, and the instance names.

The "source" of a MIM group is the type of action that created the MIM group:

- *Parasitics*: By reading a single parasitic data file for multiple instances
- *Physical*: By module grouping in the physical data files (DEF or NDM)
- *User-Defined*: By explicit MIM grouping using the *set_eco_options* command with the *-mim_group* option
- *Netlist Editing*: By uniquification resulting from netlist editing commands like *insert_buffer*, *size_cell*, and *create_net*

Examples

The following is an example of an ECO MIM instances report.

```
pt_shell> report_eco_mim_instances
  ...
ID    # Insts    Sources         Module          Instances
-------------------------------------------------------------------
0     12         Parasitics      MIM_BLOCK       { block_I10 block_I11
 block_I12 block_I13 }

1     2          Physical        MIM_BLOCK_0     { block_I0 block_I1 }

2     2          User-Defined    MIM_BLOCK_1     { block_I2 block_I3 }
```

See Also

- read_parasitics
- set_eco_options

---

report_eco_options

Reports options specified by the *set_eco_options* command.

Syntax

string *report_eco_options*

Arguments

None.

Feedback

Description

The *report_eco_options* command reports all the ECO options specified by the *set_eco_options* command.

Distributed Multi-Scenario Analysis

To execute the *report_eco_options* command in all scenarios, use the *remote_execute* command. For example:

```
remote_execute -verbose {
  report_eco_options
}
```

Note: You cannot execute the *report_eco_options* command in the manager process.

Examples

The following example reports the ECO options previously specified by the *set_eco_options* command.

```
pt_shell> report_eco_options
****************************************
Report : eco_options
Design : DESIGN

report_eco_scenarios

report_eco_wire

Reports ECO wire optimization changes in the design.

Syntax

```
status report_eco_wire
[-verbose]
[net_list]
```

Data Types

```
net_list          list
```

Arguments

`-verbose`

Displays verbose ECO wire optimization information.

net_list

Lists of nets to report the ECO wire optimization changes.

Feedback

Description

This command reports ECO wire optimization changes performed by *fix_eco_wire* or *set_routing_rule* commands. Changes by *set_routing_rule* will be reported by "manual" method.

Examples

The following example reports the ECO wire optimization change to a net named *n43*.

```
prompt> report_eco_wire {n43}
```

See Also

- fix_eco_wire
- reset_eco_wire

---

report_est_power_savings

Generates estimated power saving reports.

Syntax

string *report_est_power_savings*

```
[-type  power_saving_type]
[-min_reg_width  register_width]
[-max_clk_effi   clock_efficiency]
[-min_pwr_savings  power_savings]
[-self_gating_type  gating_type]
[-csv csv_file]
[-prob_based_gating]
[-report_nl_names]
[object_list]
```

Data Types

power_saving_type	string
register_width	integer
clock_efficiency	integer
power_savings	float
gating_type	string
csv_file	string
object_list	list

Feedback

Arguments

`-type` *`power_saving_type`*

Use this option to specify the power saving technique to be used on the registers for estimating the power savings data on them. Currently only "self_gating" value can be specified.

`-min_reg_width` *`register_width`*

Use this option to filter the bundled registers so that the bundled registers having width greater than or equal to "register_width" will be considered for power saving techniques. Default value of *-min_reg_width* is 8.

`-max_clk_effi` *`clock_efficiency`*

Use this this option to filter the registers so that the registers with a domain clock frequency less than or equal to "clock_efficiency" will be considered for power saving techniques. Default value of *-max_clk_effi* is 80.

`-min_pwr_savings` *`power_savings`*

Use this option to report only those registers whose total power saving, after using the power saving techniques, is more than or equal to the "power_savings" value. Default value of *-min_pwr_savings* is 0.0.

`-self_gating_type` *`gating_type`*

Use this option to specify the explicit gate type to be used when using the "self_gating" type power saving technique. Supported gate types are XOR, OR and NAND. This option is only useful when the user does not want to use the *-prob_based_gating* option. Default gate type used is "XOR" when "self_gating" type is used.

`-csv` *`csv_file`*

Use this option to specify the path for the csv file for writing the power savings report in a comma seperated value format. A csv file can be viewed in a spreadsheet reader. With this option the report will not be printed on the shell.

`-prob_based_gating`

Use this option to automatically determine the gate type for "self_gating" based on the static probability of D and Q Pins. This option cannnot be used with *-self_gating_type* option. The possible gate types are selected from OR, NAND or XOR, based on the values of static probability of the registers involved.

`-report_nl_names`

Use this option to report the netlist(gate-level) name of the register. By default, the RTL name or merged RTL name, in case of bus register, is reported for the registers.

object_list

Use this option to apply the power savings techniques on the list of registers. Options *-min_reg_width*, *-max_clk_effi* and *-min_pwr_savings* cannot be supported with this option. Currently only the gate-level register name can be specified.

Description

Use the *report_est_power_savings* command to generate the power savings report after applying the power savings techniques on the register/bus registers in the design. The two important fields that the command prints are the name of registers and the potential power savings that could happen using the given power savings technique. The other fields are : frequency of clock, if the register is gated or not, the register gate efficiency percentage, current power, final power and the gate-type used for the self-gating method type.

Currently only the "self_gating" power saving method is supported.

To use the command, you should first apply the update_power and update_metrics command or apply the compute_metrics command.

Self_Gating power saving technique

In traditional clock gating technique, the clock is gated based on the enable signal. But if the enable signal is not optimal, then the Q/CP ratio of the register could be low. For such scenarios, a self gating technique is generally used involving an XOR gate to improve the Q/CP ratio and hence making clock gating effective for a given register. With XOR self-gating the enable signal is generated by performing an XOR of D and Q pins of the sequential cell, thus the enable will be high only when D dffers from Q.

Register Name in report

The command prints the RTL register name or the merged RTL names in case of bus registers by default. If mapping information does not exist for some registers the gate level name would get printed instead.

To print the gate-level register names instead of the RTL names use the option -report_nl_names.

Examples

The following example shows a list of bundled registers having a width >=32, where the power could be saved by employing XOR self-gating. The registers may have either a gated clock or not.

```
pt_shell> report_est_power_savings -type self_gating -min_reg_width 32

Feedback

The following example shows a list of bundled register having width >=32, where the power could be saved by employing XOR self-gating technique. The registers may have gated clock or not. The use of the option *report_nl_names* has resulted in printing the netlist names of bundled register (gate-level).

```
pt_shell> report_est_power_savings -type self_gating -min_reg_width 32
 -report_nl_names

```

The following example shows a list of bundled registers having width >=32, where the power could be saved using self-gating involving the use of either a XOR, OR, or NAND gate, depending on the values of the static probabilities of register pins. For bus registers, the user can observe "MULTIPLE" gating type which means that some registers in the bus use, different gates for the power savings.

```
pt_shell> report_est_power_savings -type self_gating -min_reg_width 32
 -prob_based_gating

report_etm_arc

Reports the data and clock paths traversed while extracting a particular timing arc.

Syntax

string *report_etm_arc*

```
[-from from_object
   | -rise_from rise_from_object
   | -fall_from fall_from_object]
[-to to_object
   | -rise_to rise_to_object]
   | -fall_to fall_to_object]
[-arc_type arc_type]
[-include path_type_list]
[-context_borrow]
[-latch_level levels]
[-library_cell]
[-etm_report file_name]
[-netlist_report file_name]
[-significant_digits digits]
[-variation]
[-sms_scenarios sms_scenarios_list]
```

Data Types

```
from_object          list
rise_from_object     list
fall_from_object     list
to_object            list
rise_to_object       list
fall_to_object       list
arc_type             list
path_type_list       list
levels               integer
file_name            string
digits               integer
sms_scenarios_list   collection
```

Feedback

Arguments

`-from` *`from_object`*

Specifies a port or clock from which the arc of interest originates. The sense at the starting point can be either rising or falling. Substitute one of the following valid values for *from_object*: *-fall_from*, *-from*, or *-rise_from*.

`-rise_from` *`rise_from_object`*

Specifies a port or clock from which the arc of interest originates. The sense at the startpoint must be rising.

`-fall_from` *`fall_from_object`*

Specifies a port or clock from which the arc of interest originates. The sense at the startpoint must be falling.

`-to` *`to_object`*

Specifies a port or clock at which the arc of interest terminates. The sense at the endpoint can be either rising or falling. Substitute one of the following valid values for *to_object*: *-fall_to*.,*-rise_to*, or *-to*.

`-rise_to` *`rise_to_object`*

Specifies a port or clock at which the arc of interest terminates. The sense at the endpoint must be rising.

`-fall_to` *`fall_to_object`*

Specifies a port or clock at which the arc of interest terminates. The sense at the endpoint must be falling.

`-arc_type` *`arc_type`*

Specifies the type of arc reported between the start and endpoint.

Only a single type can be specified. Valid values are: *setup*, *hold*, *clock_gating_setup*, *clock_gating_hold*, *recovery*, *removal*, *non_seq_setup*, *non_seq_hold*, *max_combo_delay*, *min_combo_delay*, *max_seq_delay*, and *min_seq_delay*.

`-include` *`path_type_list`*

Specifies what types of path information should be reported. The reporting behaviors are:

- default reporting (*-include* not specified)
  - Extracted data path
- *-include {clock_path}*

    - Extracted clock and data paths
- *-include {netlist_path}*
    - Extracted data path
    - Full-netlist data path
- *-include {clock_path netlist_path}*
    - Extracted clock and data paths
    - Full-netlist clock and data paths

where "extracted" refers to the path as viewed by the *extract_model* command, and "full-netlist" refers to the path as viewed by the PrimeTime timing engine in the current full-netlist analysis.

Extracted paths are reported in an "ETM Report" section, while full-netlist reports are reported in a "Netlist Report" section.

`-context_borrow`

Specifies that PrimeTime determines the latches on an interface that borrow, based on input port arrival times and clock definitions specified at the time of model extraction. This option is one of three that specify the model extraction environment in which the debugging is done: *-context_borrow*, *-latch_level*, and *-library_cell*. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-latch_level` *`levels`*

Specifies the number of levels of latch borrowing that occur at the interface of a design. This option is one of three that specify the model extraction environment in which the debugging is done: *-context_borrow*, *-latch_level*, and *-library_cell*. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-library_cell`

Specifies that the model is extracted as a library cell. This option eliminates boundary nets, and the boundary parasitics become part of the model. This option is one of three that specify the model extraction environment in which the debugging is done: *-context_borrow*, *-latch_level*, and *-library_cell*.

`-etm_report` *`file_name`*

Specifies that the ETM report should be written to the specified file.

`-netlist_report` *`file_name`*

Specifies that the full-netlist report should be written to the specified file.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point is displayed for time values in the generated report. Substitute one of the following valid values for *digits*: an integer from 0 to 13. The default is 2. You can use this option to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, PrimeTime uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

`-variation`

Specifies the report to include parametric on-chip variation (POCV) information in columns labeled "Mean" and "Sensit". POCV analysis is enabled by setting the *timing_pocvm_enable_analysis* variable to *true*.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only etm arc data compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_etm_arc* command reports details about the timing paths used to extract a particular timing arc.

It is typically used to debug a discrepancy between an ETM and a netlist reported by the *write_interface_timing* and *compare_interface_timing* model validation commands.

This command is run in the full-netlist analysis. It internally runs the ETM extraction engine on a boundary timing path of interest, then reports the path as viewed by extraction. The extracted path is reported in the usual timing path format, as a sequence of pins with arc delays and cumulative arrivals.

By default, only the data path portion of the extracted timing arc is reported. The *-include* option can be used to include additional path information in the output, such as also including the clock path, or also including the path as viewed by the current full-netlist timing analysis.

To compare ETM paths to full-netlist paths, it is recommended to use the *-include netlist_path* option of this command instead of the *report_timing* command for the following reasons:

- The *report_timing* command might not report the correct path. For example, *report_timing* would report the worst-slack path to an output port, whereas ETM extraction (and thus this command) use the worst-delay path instead.
- Some types of launch and capture paths might be difficult to report with the *report_timing* command, such as for some constraint and check arcs.

Feedback

You must use the same model extraction options and environment variables when generating a model as when debugging the model. This ensures that the same arc is extracted during model extraction and debugging.

Therefore, the values of environment variables used by the *extract_model* command are also valid for the *report_etm_arc* command. The *-context_borrow*, *-latch_level*, and *-library_cell* options specify how to perform extraction.

Examples

The following example generates a *report_etm_arc* command from a discrepancy shown by model validation. If the *compare_interface_timing* command yields a failure as:

```
RBUS_RnotW(r)  ADC_SCLK_IN(r)  setup  17.18  18.24  1.06  FAIL

pt_shell> report_etm_arc -rise_from RBUS_RnotW \\
            -rise_to [get_clock ADC_SCLK_IN] -arc_type setup \\
            -include {clock_path netlist_path}
```

The following example generates a *report_etm_arc* command for a clock to output path. From the following model validation discrepancy:

```
ADC_SCLK_IN(r) ADC_LRCLK_OUT(f)  FALL  2.04  2.71  0.67  FAIL

pt_shell> report_etm_arc \\
            -rise_from [get_clock ADC_SCLK_IN] \\
            -fall_to ADC_LRCLK_OUT -arc_type min_seq_delay \\
            -include {clock_path netlist_path}
```

---

report_exceptions

Reports timing exceptions.

Syntax

status *report_exceptions*

```
[-from from_list]
[-rise_from rise_from_list]
[-fall_from fall_from_list]
[-through through_list]
```

Feedback

```
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list]
[-rise_to rise_to_list]
[-fall_to fall_to_list]
[-ignored]
[-nosplit]
```

Data Types

from_list	list
rise_from_list	list
fall_from_list	list
through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list

Arguments

`-from` *from_list*

Specifies a list of clocks, ports, cells, and pins in the current design. The report includes only paths that start at the objects in the *from_list* value. Using this option limits the report to information that was set using a path-based command (for example, the *set_multicycle_path* command) with the *-from* option. The *-from*, *-rise_from*, and *-fall_from* options are mutually exclusive.

`-rise_from` *rise_from_list*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can only use one of the *-from*, *-rise_from*, and *-fall_from* options.

`-fall_from` *fall_from_list*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can only use one of the *-from*, *-rise_from*, and *-fall_from* options.

`-through` *through_list*

Specifies a list of pins or ports. The report includes only paths that go through the pins or ports on the *through_list* value. Using this option limits the report to information that was set using a path-based command (for example, the

set_multicycle_path command) with the *-through* option. You can use this option more than one time in the same command.

`-rise_through` *`rise_through_list`*

Specifies a list of pins or ports (the same as the *-through* option) except that the paths must have a rising transition at the through points. You can use this option more than one time in the same command.

`-fall_through` *`fall_through_list`*

Specifies a list of pins or ports (the same as the *-through* option) except that the paths must have a falling transition at the through points. You can use this option more than one time in the same command.

`-to` *`to_list`*

Specifies a list of clocks, ports, cells, and pins in the current design. The report is to include only paths that end at the objects in the *to_list* objects. Using this option limits the report to information that was set using a path-based command (for example, the *set_multicycle_path* command) with the *-to* option. The *-to*, *-rise_to*, and *-fall_to* options are mutually exclusive.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can only use one of the *-to*, *-rise_to*, and *-fall_to* options.

`-fall_to` *`fall_to_list`*

Same as the *-to* option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can only use one of the *-to*, *-rise_to*, and *-fall_to* options.

`-ignored`

Indicates that the report lists path timing exceptions that are set on the current design, but are completely ignored. For example, a false path might be specified from port A to port Z1, but if there is no timing path between those points, the path is ignored. Use the *-from* or *-to* options to limit the report to certain paths. Ignored exceptions on objects are also included in the report; for example, an exception placed by the *set_max_time_borrow* command on a cell other than a level-sensitive latch.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. If you do not use this option, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

Description

The *report_exceptions* command reports information about timing exceptions for the current design.

PrimeTime accepts a timing exception if it alters the constraints of the path. If path constraints are different in the absence of a timing exception, the exception alters the path constraint.

The *report_exceptions* command attempts to identify reasons an exception is ignored, fully or partially, and classifies these into one of the following: invalid startpoints, invalid endpoints, non-existent paths, or overridden paths. This is reported as flags in the Ignored column. When the *-ignored* option is used, the reported flags indicates why an exception is fully ignored. Otherwise, the reported flags indicates why a subset of the exception specified paths were ignored.

By default (without the *-ignored* option), *report_exceptions* displays dominant exceptions. An exception only appears in this section if a path exists for which this exception applies. That is, a path exists that

- Matches the exception's topological and setup/hold, rise/fall criteria
- Has a valid startpoint and endpoint
- Satisfies no higher-priority exception

If no such path exists, the exception is reported in the ignored report with explanatory reasons why the exception was ignored. Even if the exception is dominant, some parts of its specification might be unsatisfiable. Consequently, each of the following reason flags can appear beside an exception whether the exception is dominant or ignored.

- p: invalid path

  At least one of the pins in through or to sets is not reachable from any pin in its predecessor (-from or -through) pin set, the specified exception is deemed to have an invalid path specification.

- f: invalid start point

  At least one of the pins in from set does not launch a signal. This flag is shown only if a from set is specified in the exception.

- t: invalid endpoint

At least one of the pins in -to set is not an endpoint in a timing analysis sense. This flag is shown only if a to set is specified in the exception.

- o: overridden exception

  In this case the exception specification is met by some timing path but another exception is applicable to the path (due to a higher exception precedence or more constraining value).

If a path is unconstrained (that is, if it has a required time of infinity), timing exceptions do not change the path constraints. Applying a timing exception to an unconstrained path does not change the path constraint. A path is unconstrained if it has an infinite required time.

To remove timing exceptions from specified paths, use the *reset_path* command. The *reset_design* command removes all attributes from the design, including timing exceptions.

The number of timing exception objects reported in the *from*, *through*, or *to* sets are limited by the value of the *collection_result_display_limit* variable. As in collection result display, setting the variable to a negative value would print the complete set. Any nonnegative value would truncate any set when the size is greater than the value; the truncated output is designated by an ellipsis. Note that for negative settings, the behavior matches object collection query echoing the entire object set. It is recommended to avoid negative settings when reporting large numbers of exceptions with sizable object sets as this can adversely affect the performance of the *report_exceptions* command.

The max_time_borrowed report is generated for global reporting only and not when any of the *-from*, *-through*, or *-to* options are specified with the command.

Examples

The following example lists all timing exceptions set on the design.

```
pt_shell> report_exceptions

****************************************
Report : exceptions
Design : counter
 ...
****************************************

Reasons:
    f - invalid startpoint(s)
    t - invalid endpoint(s)
    p - non-existent paths
    o - overridden paths

From          To         Setup          Hold                Ignored
```

```

---

report_glitch

Reports glitch source information.

Syntax

string *report_glitch*

```
[-rtl]
[-gate]
[-source]
[-fanout_cone]
[-id source_id]
[-display_source_instances]
[-verbose]
[-debug_source]
```

Data Types

id number

Arguments

-rtl

This option specifies to report glitch source information for rtl design.

-gate

This option specifies to report glitch source information for gate level design.

-source

This option reports all the glitch sources in the design as per power impacted by either RTL line or Gate instance. Each source is represented by a unique id. Additional information about the glitch source and its fanout are also reported like the hier cell of the source, type of leaf cells present in the glitch fanout with their count etc.

-fanout_cone

With the *-id* option, this option lists all the leaf level instances that are part of the glitch fanout represented by cone id. This option can only be used after *report_glitch -source* has been run.

-id *source_id*

This option specifies the glitch source id for which report is to be generated. It must be used along with *-fanout_cone* option.

-display_source_instances

This option lists RTL source code cross-reference information and reports all the leaf level source instances that are part of the glitch source for each source ID. This option can only be used with *report_glitch -source* command. It also reports other information like fanout cone glitch power and fanout count which are reported by *report_glitch -source* command.

-verbose

This option provides additional information about the leaf level source instances that are part of glitch source for each source ID. It reports glitch power in fanout cone of each leaf instance, parent instance name and parent cross-reference information of each glitch source. This option can only be used with *report_glitch -source -display_source_instances* command.

-debug_source

This option provides detailed debug information about glitch source for a given source ID. It reports arrival time and path details of glitch source inputs.

It reports logic depth, RTL cross-reference and RTL constructs in min and max paths of fanin cone of glitch source. This option can only be used with *report_glitch -rtl -fanout_cone -id* command.

Description

This command provides various information helpful in debugging glitch sources in the design. The sources are ranked based on glitch power consumption.

To use the command, you should first apply the *update_power* and *update_metrics* command or apply the *compute_metrics* command.

Examples

The following example shows the default report of *-source -rtl* and helps user to report all glitch sources in design along with RTL cross-reference, fanout count and glitch power:

```
pwr_shell> report_glitch -source -rtl

****************************************
Report : report_glitch
      -rtl
      -source
Design : top
****************************************

------------------------------------------------------------

report_global_slack

Displays slack of specified pins or ports.

Syntax

string *report_global_slack*

```
[-significant_digits digits]
[-nosplit]
[-min]
[-max]
[-rise]
[-fall]
[-sms_scenarios sms_scenarios_list]
port_pin_list
```

Data Types

```
digits               integer
port_pin_list        list
sms_scenarios_list   collection
```

Feedback

Arguments

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default is 2. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. *-nosplit* prevents line splitting and facilitates writing software to extract information from the report output.

`-min`

Displays the minimum slack.

`-max`

Displays the maximum slack.

`-rise`

Displays rise slack.

`-fall`

Displays fall slack.

port_pin_list

Specifies a list of pins or ports to report. By default, the report contains all pins and ports in the current design. Pins of hierarchical cells are not reported.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only global slack information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_global_slack* command displays the slack of specified pins and ports. By default, all pins except those of hierarchical cells and ports of the design are reported. The slack shown in the report for a given pin corresponds to the worst slack among all paths traversing that pin. If a pin is both a timing startpoint and endpoint then its slack will be the worst among all paths either starting and ending at the pin.

To report slacks throughout the current design arrival totals and slacks must be available on all pins, not just at endpoints. To achieve this, set the

Feedback

timing_save_pin_arrival_and_slack variable to *true* before issuing the *report_global_slack* command. If the *timing_save_pin_arrival_and_slack* variable has not been set to *true*. the command is set it to *true* and updates the design timing before the command executes.

The default of the variable is *false*. If you intend to use this command, it is recommended that you set the *timing_save_pin_arrival_and_slack* variable to *true* before the first timing update, thus preventing the cost of an additional timing update.

The *-max* and *-min* options are mutually exclusive. The *-rise* and *-fall* options are also mutually exclusive. You can choose any combination from the *-max* or *-min* option and *-rise* or *-fall* option to report a particular slack value.

- If you specify only the *-max* option, but not the *-rise* or *-fall* option, the tool reports both the maximum rise and maximum fall slack values.
- If you specify only the *-min* option, but not the *-rise* or *-fall* option, the tool reports both the minimum rise and minimum fall slack values.
- If you specify only the *-rise* option, but not the *-max* or *-min* option, the tool reports both the maximum rise and minimum rise slack values.
- If you specify only the *-fall* option, but not the *-max* or *-min* option, the tool reports both the maximum fall and minimum fall slack values.
- If you specify neither the *-rise* and *-fall* options nor the *-max* and *-min* options, the tool reports the maximum rise, maximum fall, minimum rise, and minimum fall slack values.

If slack attribute is not available at a pin or port, the tool prints *.

Note that this command expects that the design has already been timed with the *timing_save_pin_arrival_and_slack* variable set to *true*. If the *timing_save_pin_arrival_and_slack* variable is set to its default of *false*, the *report_global_slack* command can potentially take longer during runtime.

Examples

The following example generates a report of all slack violations in the current design.

```
pt_shell> report_global_slack -significant_digits 4 -nosplit
****************************************
Report : report_global_slack
 ...
****************************************

Max_Rise      Max_Fall      Min_Rise      Min_Fall   Point
-------------------------------------------------------------
-1.4869       -1.6330        1.5669        1.7130   ff2/D
-1.4869       -1.6330        1.5669        1.7130   in2/Z
-1.6330       -1.4869        1.7130        1.5669   in2/A
-1.6330       -1.4869        1.7130        1.5669   in1/Z
```

---

report_global_timing

Reports a top-level summary of the design setup and hold timing: WNS, TNS, and number of violations.

Syntax

status *report_global_timing*

```
[-delay_type max | min]
[-group group_list]
[-include include_list]
[-format format_spec]
[-output file_name]
[-enable_multiple_categories_per_endpoint]
[-separate_non_standard_groups]
[-separate_all_groups]
[-significant_digits digits]
[-sms_scenarios sms_scenarios_list]
[-pba_mode none | path | exhaustive | ml_exhaustive]
[-path_type summary | end]
```

Data Types

group_list	list
include_list	list
format_spec	string
file_name	string
digits	integer
sms_scenarios_list	collection

Arguments

`-delay_type max | min`

Specifies the type of delay violations to report. By default, both max (setup) and min (hold) violations are reported.

`-group group_list`

Reports violations only for the specified timing path groups. With the *-group* option, the command collects the worst path endpoint violations for each group

separately, The report therefore is generated using violations whose endpoints are unique to a path group. The same endpoint contributes to the total report for each group in which it has a violating slack. Use the *get_path_groups* command to query the path groups in the design.

`-include` *include_list*

Specifies a list of additional reporting options. The list includes one or more of the following reporting options.

- *inter_clock* - Shows the breakdown of violations for different combinations of launching and capturing clocks. By default, only the worst violating timing path to each endpoint is considered in the report. Use *per_clock_violations* to check violations specific to each clock combination.
- *non_violated* - Includes interclock combinations that have no violations, in addition to those with violations, possibly resulting in a longer report. By default, only the worst violating timing path to each endpoint is considered in the report. If a clock combination shows no violation, it means that there is no violation with a unique endpoint for that clock combination.
- *per_clock_violations* - Takes into account other paths to the same endpoint, differentiated by: timing path type (register-to-register, input-to-register, input-to-output and register-to-output), launch/capture clock combination, and path group. Using this option might lead to a longer runtime. See "Path Uniquification" below for details.
- *scenario_details* - In a distributed multi-scenario analysis (DMSA) manager process, shows the breakdown of violations by scenario in the merged report. Only the worst violating timing path to each endpoint is considered in the merged report. If a scenario sub-report shows no violation, it means that the scenario did not contribute worst violations across all scenarios currently in focus.

`-format` *format_spec*

Specifies the reporting format:

- *narrow* (default) - Generates a report with WNS-TNS-NUM values stacked in a column.
- *wide* - Generates a report with WNS-TNS-NUM values spread across a row.
- *csv* - Generates a comma-separated values (CSV) report file, which can be read into spreadsheet programs. When using this option, specify the output file name with the *-output* option. You can use the *csv* option with *narrow* or *wide* to get both an on-screen report and a CSV file.

The *narrow* and *wide* values are ignored if *-path_type end* is specified.

`-output` *`file_name`*

Specifies the file name for the generated CSV report.

`-enable_multiple_categories_per_endpoint`

Takes into account other paths to the same endpoint, differentiated by timing path type (register-to-register, input-to-register, input-to-output and register-to-output). Each path endpoint contributes the worst violation per a unique combination of timing path types. Using this option may lead to longer runtime. Using this option together with *-include per_clock_violations* does not have any additional effect.

See "Path Uniquification" below for details.

`-separate_non_standard_groups`

This formatting option divides the report into sub-reports, one for all standard path groups combined and one for each of the nonstandard path groups: **default**, **async_default**, and **clock_gating_default**. This option shows the contribution of these path group categories to the total report. If an endpoint has WNS timing path in multiple path groups, the report only takes into account the WNS of the worst path across all path groups.

`-separate_all_groups`

This formatting option divides the report into sub-reports, one for each path group, including each standard and nonstandard path group. By default, only the worst violating timing path to each endpoint is considered in the report. The values of WNS, TNS, and NUM in sub-reports add up to match the summary report for all groups. If a group sub-report shows no violation, it means that there is no violation with a unique endpoint for that path group.

The WNS path reported for each group is the overall worst negative path across all groups applied to that specific group's context. This may not be the WNS path for that specific group. To generate violation data for each group separately, use the *-group group_list* option, which guarantees reporting of the WNS of each path group.

`-significant_digits` *`digits`*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13. If you do not use this option, the number of digits is specified by the *report_default_significant_digits* variable, which is 2 by default.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only timing violations compatible to the specified SMS scenarios collection are reported. This option is available only with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Controls path-based analysis with the following modes:

- *none* (the default) - Path-based analysis is not used.
- *path* - Path-based analysis is applied over the paths that gave the worst graph-based analysis violations. There is no guarantee that the reported path-based analysis slack over every endpoint is the worst one.
- *exhaustive* - An exhaustive path-based analysis path search algorithm is applied to determine the worst path-based analysis slack violations.
- *ml_exhaustive* - Performs machine-learning-based exhaustive path-based analysis. This mechanism deploys machine learning techniques to trade runtime versus accuracy during the design flow. Accuracy and runtime will approach *pba_mode exhaustive* as the design approaches signoff.

`-path_type summary | end`

Specifies how paths are displayed in the report. The default is *summary*, which provides a top-level summary of the timing of the design. A value of *end* provides a per-endpoint breakdown of the paths contributing to the summary report. The summary report is not displayed when a per-endpoint report is printed.

Description

The *report_global_timing* command generates a top-level summary of the timing for the design. The report shows the worst negative slack (WNS), the sum total of all negative slacks (TNS), and a number of violating endpoints (NUM).

By default, each violating endpoint is only counted one time and only one worst slack at each violating endpoint contributes to the total negative slack. With the *-group* option, each endpoint contributes to the worst negative slack and total negative slack of each group in which it has a violating slack.

The summary information is broken down into columns showing the WNS, TNS, and number of violations, both in total and subdivided into register-to-register, input-to-register, register-to-output, and input-to-output categories.

In a distributed multi-scenario analysis (DMSA) manager, the report shows a merged view of violations across all scenarios. Each unique endpoint contributes to the report only once. To see non-merged reports per scenario, use the *remote_execute -verbose {report_global_timing}* command.

If you specify the *-pba_mode exhaustive* option, path-based analysis is used to calculate the violating slack values. This option performs a path search to ensure that the returned slack values are truly the worst. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing

improvement from path-based analysis increases, the runtime for the path search also increases.

Path Uniquification

By default, the *report_global_timing* command considers the single worst path to each endpoint, determines its path type (reg-to-reg and so on), and counts it once in that category only. If there is a subcritical path to the same endpoint of a different path type, it is not counted in that category.

The *-enable_multiple_categories_per_endpoint* option causes the worst path to be counted:

- for each path type (reg-to-reg and so on)
- to each endpoint

In this case, multiple paths to an endpoint can be considered - the worst critical path of each path type is counted in that category.

The *-include {per_clock_violations}* option causes the worst path to be counted:

- for each path type (reg-to-reg and so on)
- for each launch/capture clock combination
- for each path group
- to each endpoint

This allows an endpoint to be considered in every category that it can contribute to.

Note that these options control only how paths are obtained for analysis, not how the resulting report is grouped.

Examples

The following command generates a report of violations in the current design for path groups whose name starts with "CLK".

```
pt_shell> report_global_timing -group [get_path_groups CLK*]
****************************************
Report : global_timing
        -group CLK1 CLK0
 ...
****************************************

Setup violations
-----------------------------------------------------------
         Total  reg->reg   in->reg  reg->out   in->out
-----------------------------------------------------------
WNS     -20.34    -20.34      0.00     -1.19     -0.98
```

```
TNS   -6887.98  -6882.84      0.00     -3.17     -1.96
NUM        398       392         0         4         2
---------------------------------------------------------

Hold violations
---------------------------------------------------------
         Total  reg->reg   in->reg  reg->out   in->out
---------------------------------------------------------
WNS      -3.55     -3.55      0.00      0.00      0.00
TNS    -561.17   -561.17      0.00      0.00      0.00
NUM        418       418         0         0         0
---------------------------------------------------------
```

The following command generates an interclock report showing the timing summary for each combination of launch clock and capture clock. Each sub-report starts with a "C2C" (clock-to-clock) line that identifies the launch clock -> capture clock combination. The asterisk character "*" means any clock.

```
pt_shell> report_global_timing -include {inter_clock}
****************************************
Report : global_timing
        -include {inter_clock}
 ...
****************************************

Setup violations
---------------------------------------------------------
         Total  reg->reg   in->reg  reg->out   in->out
---------------------------------------------------------

report_gpd_config

Reports the original or modified GPD configuration options for reading parasitic data from a specified GPD directory.

Syntax

string *report_gpd_config*

```
[-type type]
[-include_starrc_options]
[-nosplit]
-gpd gpd_directory
```

Feedback

Data Types

type	string
gpd_directory	string

Arguments

`-type` *type*

Specifies the type of GPD configuration to report:

- *original* -- The original configuration of the GPD directory, as written out by the StarRC tool
- *user_defined* -- The GPD configuration specified by the *set_gpd_config* command
- *active* (default) -- The currently active GPD configuration, which is the same as the *user_defined* configuration if you have used the *set_gpd_config* command, or same as the original configuration if you have not used the *set_gpd_config* or after you have used the *reset_gpd_config* command

`-include_starrc_options`

Includes StarRC GPD configuration options in the report. This includes options not considered by the PrimeTime tool.

`-nosplit`

Prevents splitting of long lines in the report.

`-gpd` *gpd_directory*

Specifies the absolute or relative path to the GPD directory.

Description

The *report_gpd_config* command reports the configuration options for a specified Galaxy Parasitic Database (GPD) directory. The configuration options affect the reading of parasitic data from the GPD directory. You can set these options with the *set_gpd_config* command.

Examples

The following commands set and then report the current and original GPD configuration options for the GPD database called my_design1.gpd.

```
pt_shell> set_gpd_config -gpd my_design1.gpd \\
  -absolute_coupling_threshold 0.005 \\
  -relative_coupling_threshold 0.05
 1
pt_shell> report_gpd_config -gpd my_design1.gpd
 ...
```

Feedback

```
pt_shell> report_gpd_config -gpd my_design1.gpd -type original
  ...
```

- set_gpd_config
- reset_gpd_config

---

report_gpd_properties

Reports the layers, parasitic corners, and other information about parasitic data stored in a GPD disk directory.

Syntax

string *report_gpd_properties*

```
[-all]
[-layers]
[-parasitic_corners]
-gpd gpd_directory
[-nosplit]
```

Data Types

gpd_directory	string

Arguments

`-all`

Reports all types of information about the parasitic data stored in the specified Galaxy Parasitic Database (GPD) directory, including a summary, the layers, and the parasitic corners. By default, only the GPD summary is reported.

`-layers`

Reports only the layers of the GPD directory, in a format consistent with the layer ID number reported by the *get_ground_capacitors*, *get_coupling_capacitors*, and *get_resistors* commands.

`-parasitic_corners`

Reports only the parasitic corners of the GPD directory, whether a single corner or multiple corners.

`-gpd gpd_directory`

Specifies the absolute or relative path to the GPD directory.

Feedback

-nosplit

Prevents splitting of long lines of the report into multiple lines.

Description

This command reports the properties of parasitic data stored in a Galaxy Parasitics Database (GPD) directory. You can query the database without reading it into the PrimeTime tool.

You must specify the relative or absolute path the GPD directory. You can optionally specify whether to report a GPD summary (the default), the list of layers and their properties, the list of parasitic corners and their properties, or all of these types of information.

Examples

The following command reports a summary about the parasitic data stored in the GPD directory named mydesign.gpd in the current working directory.

```
pt_shell> report_gpd_properties -gpd mydesign.gpd
 ...
GPD Summary:
Properties                          Value
-------------------------------------------------
 ...                                 ...
number_of_nets                      288930
number_of_cells                     234730
number_of_ports                     1560
is_gpd_complete                     Yes
has_via_ladder                      No
 ...                                 ...
```

The following command reports only the layers stored in the GPD directory.

```
pt_shell> report_gpd_properties -layers -gpd mydesign.gpd
 ...
Layer information:
Name                  Properties            Value
-----------------------------------------------------------
SUBSTRATE             id                    0
SUBSTRATE             is_via                No
poly                  id                    1
poly                  is_via                No
M1                    id                    2
M1                    is_via                No
M2                    id                    3
M2                    is_via                No
 ...                   ...                   ...
```

The following command reports only the parasitic corners of the GPD directory.

Feedback

```
pt_shell> report_gpd_properties -gpd mydesign.gpd
 ...
Corner information:
Name                Properties              Value
-------------------------------------------------------------------
CMINW125            process_name            /mydata/mypara/grd.min
CMINW125            temperature             125
CMINW125            global_temperature      25
CMINB40             process_name            /mydata/mypara/grd.min
CMINB40             temperature             -40
CMINB40             global_temperature      25
CMINN25             process_name            /mydata/mypara/grd.min
CMINN25             temperature             25
CMINN25             global_temperature      25
CMAXW125            process_name            /mydata/mypara/grd.max
CMAXW125            temperature             125
CMAXW125            global_temperature      25
```

The following command reports all of the above types of data: GPD summary, parasitic corners, and layers.

```
pt_shell> report_gpd_properties -all -gpd mydesign.gpd
 ...
```

---

report_ground_capacitors

Reports the ground capacitors for specified nets.

Syntax

status *report_ground_capacitors*

```
[-of_objects nets]
[-from node1 -to node2]
```

Feedback

Data Types

nets	list
node1	string
node2	string

Arguments

`-of_objects` *nets*

A list of one or more nets for which to report ground capacitors. At least one net is required. Glob-style wildcards (*) are supported.

This option is mutually exclusive with the *-from* and *-to* options.

`-from` *node1*

Specifies a pin, port, or net internal node. The tool reports the layer information for paths between this node and the node specified in the *-to* option. Both nodes must belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

`-to` *node2*

Specifies a pin, port, or net internal node. The tool reports the layer information for paths between this node and the node specified in the *-from* option. Both nodes must belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

Description

This command reports the ground capacitors for specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a ground capacitor report.

```
pt_shell> report_ground_capacitors -of_objects {SUM0 B0}
================================
Net: SUM0
Total capacitance: 0.013721
Report Type: Ground Capacitors

```

---

report_gui_stroke_bindings

Print a report on the dictionaries and the stroke-command bindings they contain..

Syntax

report_gui_stroke_bindings

`[-dictionary` *`dictionary_name`*`]`

Arguments

`-dictionary` *`dictionary_name`*

Specify which dictionary should have its bindings reported. If not specified then all dictionaries will be reported.

Description

This command takes the data returned by get_gui_stroke_bindings and formats it into a report that is human-readable. The report prints out the stroke-to-command bindings for all dictionaries.

This command is defined as a part of the strokes Tcl package, and the command is automatically imported into the global namespace when the package is loaded.

Examples

```
ca_shell> report_gui_stroke_bindings

Dictionary: Graphics

stroke        cmdType       cmd
------        -------       ---
5             builtin       Pan_Center_Rect
852           builtin       Zoom_Full
258           builtin       Zoom_Full
159           builtin       Zoom_Out_Rect
357           builtin       Zoom_Out_Rect
```

```
753          builtin      Zoom_In_Rect
951          builtin      Zoom_In_Rect
654          builtin      Pan_Center_Rect
456          builtin      Pan_Center_Rect
123698741    builtin      Zoom_In_Rect
147896321    builtin      Zoom_In_Rect
s:14789      tcl_cmd      myTclCmd
14789        tcl_cmd      myTclCmd %rect
```

See Also

- set_gui_stroke_preferences
- set_gui_stroke_binding
- report_gui_stroke_builtins

---

report_gui_stroke_builtins

Print a report on the non-Tcl commands available for stroke bindings..

Syntax

report_gui_stroke_builtinss

`[-dictionary` *`dictionary_name`*`]`

Arguments

`-dictionary` *`dictionary_name`*

Specify which dictionary should have its builtins reported. If not specified then only the global builtins will be printed.

Description

This command takes the data returned by get_gui_stroke_bindings and formats it into a report that is human-readable. The report prints out the non-Tcl commands that can be used in stroke bindings.

This command is defined as a part of the strokes Tcl package, and the command is automatically imported into the global namespace when the package is loaded.

Examples

```
ca_shell> report_gui_stroke_builtins

Built-In Commands:

name
----
Zoom_In_Rect
```

Feedback

```
Zoom_Out
Pan_Center_Rect
Zoom_Out_Rect
Zoom_Full
Zoom_In
```

---

report_hier_analysis

Reports the HyperScale configuration set by the *set_hier_config* command, or port abstractions set by the *set_port_abstraction* command.

Syntax

status *report_hier_analysis*

```
[-config]
[-port_abstraction]
[-parasitics]
[-nosplit]
[-verbose]
```

Arguments

`-config`

Reports the HyperScale configuration set by the *set_hier_config* command, including the HyperScale cell names, timestampw, and directory paths. This is the default report type when the *report_hier_analysis* command is used without options.

`-port_abstraction`

Reports any port abstraction overrides that have been applied to the ports of the HyperScale blocks by the *set_port_abstraction* command. "Port abstraction" refers to the removal of part or all of the logic fanin or fanout of a port.

`-parasitics`

Reports information about the parasitics files associated with the different levels of hierarchical analysis.

`-nosplit`

Prevents splitting of long lines of text in the report.

`-verbose`

Reports more detailed messages.

Description

The *report_hier_analysis* command reports HyperScale configuration information.

There are three reporting options available:

- *-config*
- *-port_abstraction*
- *-parasitics*

You can specify any combination of these options to report the desired information. If no option is specified, a configuration report (*-config*) is given.

The following sections describe the reports generated by these options.

HyperScale Block Configuration

A block configuration report shows the cell names, creation timestamps, and directory paths of the HyperScale blocks in the design, as defined by the *set_hier_config* command.

Port Abstraction

A port abstraction report shows the block ports that have been abstracted and the reason for each abstraction. When a port is abstracted in a HyperScale block, some portion of the port's fanout or fanin logic cone is made invisible at higher levels of hierarchy.

For example, each clock port is abstracted by default. In this case, the logic in the fanout cone that leads only to internal registers of the block is not visible at higher levels of hierarchical analysis. Internal registers are registers that cannot be reached from a non-abstracted port through combinational logic.

If you need timing data for an object that is not visible due to block-level port abstraction, you can either access that data during block-level analysis, or you can use the *set_port_abstraction* command to override the default behavior and prevent abstraction of the port for higher-level analysis.

Parasitics Check

A parasitic check report shows information about the parasitics files associated with the different levels of hierarchical analysis, such as the file names, corner names, operating temperatures, program names and versions, and parasitics tech files.

Feedback

Examples

The following command reports the HyperScale block configuration:

```
pt_shell> report_hier_analysis -config
 ...
 Cell            Name     Timestamp           HyperScale path
 ------------------------------------------------------------------
 blkA            default  2017-03-02 10:42:31 /disk1/blkA/HS_DATA/
 <design>        default  2017-03-02 10:44:38 /disk1/TOP/HS_DATA/
```

The following command reports the HyperScale port abstractions:

```
pt_shell> report_hier_analysis -port_abstraction
 ...
 Abstraction codes:
   clk  Clock port
   lfi  Large fanout input port

 Port            Abstraction code
 ------------------------------------------------
 pclk            clk
 scan_en         lfi
 sdr_clk         clk
 sys_clk         clk
```

The following command reports all parasitics file information:

```
pt_shell> report_hier_analysis -parasitics
 ...
 SPEF file  Corner name  Operating temp  Program name   Program version
 Parasitics Tech file
 ------------------------------------------------------------------------
---------------------
 top.spef   RCworstt     -90             TOP_TOOL_NAME  2000.10-DEV
  /grd/file/filet.nxtrg
 blk.spef   RCworstb     -80             BLK_TOOL_NAME  P-2019.03-SP3
  /grd/file/fileb.nxtrg
 ...
```

---

report_hierarchy

Reports the reference hierarchy of the current instance or current design.

Feedback

Syntax

string *report_hierarchy*

```
[-full]
[-noleaf]
[-nosplit]
```

Arguments

`-full`

Displays the full hierarchy. By default, components of submodules in multiple locations in an hierarchy are listed only once. An ellipsis (...) indicates the contents of a previously displayed module.

`-noleaf`

Does not display the leaf library cells.

`-nosplit`

Does not split lines if column overflows.

Description

Displays the indented reference hierarchy of the current instance or the current design. If the current instance is set, the report is generated relative to that instance; otherwise, the report is generated for the current design.

Examples

The following command reports the full hierarchy of the design.

```
pt_shell> report_hierarchy -full

****************************************
Report : hierarchy
Design : middle
****************************************

     FD2                              tech_lib
     ND2                              tech_lib
     inter
          low
              NR4                     tech_lib
     low
          NR4                         tech_lib
```

Feedback

report_host_usage

Creates a detailed report that describes all host options that you have created.

Syntax

status *report_host_usage*

```
[-verbose]
[-nosplit]
[host_option_names]
```

Data Types

host_option_names	list

Arguments

`-verbose`

Generates a more detailed report.

`-nosplit`

Does not split lines if columns overflow.

host_option_names

Reports the specified list of host options, which were previously defined by the *set_hosts_options* command. If you do not specify a list of host options, the command reports all host options by default.

Description

The *report_host_usage* command reports information about the specified sets of host options. The command also reports peak memory and CPU usage for the local process and all online distributed processes.

Running the *report_host_usage* command before starting any hosts reports the following basic information:

- Options Name - The name of the host options set.
- Host Name - The host on which the processes are to be launched. If the processes are to be launched on a managed compute resource, the string "farm" is shown.
- Num Processes - The number of processes to be launched.
- Protocol - The type of the communication protocol specified by the *-protocol* option of the *set_host_options* command. The default value of the protocol is *auto*.

The *-verbose* option reports the following additional information:

- Action and Command - The actions and associated commands that you can perform for the host options. SUBMIT indicates the command to submit a process for execution. TERMINATE indicates the command to terminate a job that has not started.
- Protocol - The type of the communication protocol that is actually used to communicate between the manager process and remote hosts.
- # - The internal instance number of the process. When each worker instance is launched by the *start_hosts* command it is assigned an instance number. This is to allow you to relate the process to the output of the *start_hosts* command.
- Host Name - The name of the actual host on which the process is running.
- Job ID - If the options specified access a managed resource, such as LSF or SGE, this is the ID of the job submitted to the farm. If this value is -1, the job ID either cannot be determined or the process was shutdown in which case the ID is no longer valid. For non-managed resources, a symbol "-" is shown.
- Process ID - The ID of the worker PrimeTime process. If this value is -1, the process ID either could not be determined or the process was shutdown in which case the ID is no longer valid.
- Status - The status of the worker process. The possible values are

```
LAUNCHED      : The process is launched but not ready for use yet.
ONLINE        : The process is online and ready for use.
SHUTDOWN      : The process was shut down.
FATALed       : The process abnormally terminated.
MISSALIGNED   : The manager and worker processes are different
 versions
                of PrimeTime and the worker process is not usable.
SHUTTING_DOWN : The process is shutting down.
```

Usage Limits (Cores)

This section of the report shows details about the cores usage limits applied to each set of host options. The first entry in this table describes the limits on the current local process. The cores limits columns are

- Effective

  This is the effective cores usage limit to be honored by PrimeTime. This value is computed given the user and hardware limits.

If you use the *-verbose* option, the following columns are also shown:

- User-set - The *max_cores* that you set in the corresponding *set_host_options* command.
- Hardware - The number of logical cores on the target hardware.

Memory Usage

This section of the report shows details about the peak memory usage of all online processes. The first entry in this table describes the current local process. The memory usage columns are

- Memory (MB) - The peak memory (in megabytes) usage of the local and all distributed pt_shell processes currently online.

Performance

This section of the report shows details the CPU and Elapsed time measurements (in seconds) of all online processes. The first entry in this table describes the current local process. The performance columns are

- CPU Time (s) - This shows the total CPU time usage for each online process.
- Elapsed Time (s) - This shows the total elapsed time for each online process.

Examples

In the following example, PrimeTime is launched onto a 16-core machine. Initially, reporting usage shows that the user-specified local process is effectively limited to 4 cores even though no user limit is set. The subsequent *set_host_options* command increases the number of cores to 8.

```

report_ideal_network

Displays information about ports, pins, nets, and cells on ideal networks in the current design.

Syntax

status *report_ideal_network*

```
[-net]
[-cell]
[-load_pin]
[-timing]
[object_list]
```

Data Types

object_list list

Arguments

`-net`

Displays all nets in the specified ideal networks. By default, nets are displayed for all ideal networks.

`-cell`

Displays all cells in the specified ideal networks. By default, cells are displayed for all ideal networks.

`-load_pin`

Specifies to display load pins (boundary pins) of the specified ideal networks along with any ideal timing set on them using the *set_ideal_latency* and *set_ideal_transition* commands. By default, load pins are displayed for all ideal networks.

`-timing`

Specifies to display all internal pins (non-source and non-boundary pins) in the specified ideal networks that have ideal timing set on them using the *set_ideal_latency* and *set_ideal_transition* commands. By default, internal pins with timing are displayed for all ideal networks.

object_list

Defines a list of source ports or source pins of the specified ideal networks to be displayed. By default, the source pins and source ports for all ideal networks in the current design are displayed.

Description

Displays information about the ideal networks in the current design. If no arguments are specified, all ideal network sources in the current design are displayed. If you specify a list of source pins or ports, the command displays information about the ideal networks emanating from these objects.

The "Latency" and "Transition" columns show the minimum and maximum values set for both rising and falling edges. Set these values with the *set_ideal_latency* and *set_ideal_transition* commands.

Examples

The following example sets up an ideal network, applies ideal latency and ideal transition values and shows the output of the ideal network report.

```
pt_shell> set_ideal_network {p_in in1}
pt_shell> set_ideal_latency    -min  1.12 in1
pt_shell> set_ideal_transition -max  9.87 in1
pt_shell> set_ideal_latency    -min  1.34 n0_i/Z
pt_shell> set_ideal_transition -rise 5.62 n3_i/B
pt_shell> report_ideal_network -timing -load_pin -cell -net

report_implement_options

Reports options specified by the *set_implement_options* command.

Syntax

string *report_implement_options*

Arguments

None

Feedback

Description

The *report_implement_options* command reports all PrimeECO options specified by the *set_implement_options* command to configure physical signoff ECO flow using IC Compiler II and StarRC.

Examples

The following example reports the ECO options previously specified by the *set_implement_options* command.

```
prompt> report_implement_options
Implementation Options
------------------------------------------------------------
ICC2 executable          : /path/to/icc2_shell
StarRC executable        : /path/to/StarXtract
StarRC mode              : full
Working directory        : ./dcs_work_dir
Physical ICC2 library    : ./design.nlib
Physical ICC2 block      : pre_eco_block
Current working block    : ecoBlock_pid6163

1

---

report_instances

Creates a collection of the instances (cells) associated with one or more nets.

Syntax

status *report_instances*

```
[-filter expression]
```

Feedback

Data Types

expression	list

Arguments

`-filter` *expression*

A list of one or more nets for which to report cells. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command creates a collection of the instances (cells) associated with one or more nets.

The command reports all attributes of the instances with the same format as the instance section of a SPEF file. It reports instances with their name, pin or port names, model name, and their properties. It also provides the location information of a device at the end of the report, if the device location is available.

This command is supported only for transistor-level GPDs.

Examples

The following examples shows the *report_instances* command report:

```
pt_shell> report_instances -filter {name==0\\/33\\/M1} _se14
****************************************
Report : Instances summary
Design : add4
Version: R-2020.09

 PD=32u PS=32u
```

report_ivm

Reports via variation tables previously read in by the *read_ivm* command.

Syntax

```
status report_ivm
   [-layer_name string]
   [-summary]
```

Feedback

Data Types

string string

Arguments

-layer_name

Reports variation tables only for the specified layer. By default, the command reports all layers.

-summary

Reports a summary of the all the variation tables that have been read in by the *read_ivm* command.

Description

The *report_ivm* command displays the user-specified via variation information previously read in by the *read_ivm* command. The report format is similar that of the data file.

Examples

The following command reports the via variation data for only the V2 layer.

```
pt_shell> report_ivm -layer_name V2
 ...
Number of VIA side-file tables: 3

Layer Name: V2
area            : 0.000400 0.000800 0.001600
table_min_sigma : 0.190000 0.159000 0.128000
table_max_sigma : 0.224000 0.208000 0.192000
table_meanshift : 0.000000 0.000000 0.000000
table_stdev     : 0.000000 0.000000 0.000000
```

---

report_latch_loop_groups

Reports on latch data pins involved in loops of transparent latches.

Syntax

string *report_latch_loop_groups*

```
[-of_objects pin_list]
[-loop_breakers_only]
[-path_breakers_only]
[-nosplit]
```

Data Types

pin_list list

Arguments

`-of_objects` *pin_list*

Specifies a collection of data pins of transparent latches. Only pins of loop groups containing the specified pins are reported. By default, the command reports on all latch data pins involved with transparent latch loops, as well as other latch data pins outside loops with the *is_latch_loop_breaker* pin attribute set to *true*.

`-loop_breakers_only`

Specifies that the report should contain only pins that are loop breaker latch data pins and should be pins truly contained in transparent latch loops. By default, all transparent latch data pins within the loop group are reported, along with other latch data pins with the *is_latch_loop_breaker* pin attribute set to *true*.

`-path_breakers_only`

Specifies that the report should contain only pins with the *is_latch_loop_breaker* pin attribute set to *true*. By default, all transparent latch data pins within the loop group are returned in the collections.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing software to extract information from the report output.

Description

When sequential loops of transparent latches exist in a design, a loop group containing all the latch data pins of intersecting loops is formed. The *report_latch_loop_groups* command analyzes the design and reports on latch data pins involved with loops. The report also includes some latch data pins outside loops. Combinational pins are not included in the results.

Latch data pins outside loops can be reported if the latch is being treated by the tool as a latch loop breaker data pin, even if it is not inside a latch loop. This can happen when either the user requests the pin to be treated this way using the *set_latch_loop_breaker* command, or the tool has selected the pin to be treated as a loop breaker data pin to

save runtime. For more information about how this can happen, see the man page of the *timing_through_path_max_segments* variable.

The report lists the name of the latch data pin, a number identifying which latch loop group the pin is part of, and attributes describing if the pin is a loop breaker latch, and why.

The number identifying which latch loop group the pin is part of is an arbitrary number, except that within a report, the latch data pins that are part of the same loop group have the same number. For latch data pins that are not part of a loop group, "NA" is shown instead of a loop group number.

Before using the *report_latch_loop_groups* command, you must set the *timing_enable_through_paths* variable to *true*.

Examples

The following example uses the *report_latch_loop_groups* command to report latch loops in the design:

```
pt_shell> report_latch_loop_groups
****************************************
Report : latch loop groups
 ...
****************************************
Attributes
   b loop breaker d pin
   p long path breaker d pin, but not in a loop
   u user requested to be a loop breaker using set_latch_loop_breaker
   a user requested to avoid with set_latch_loop_breaker

  Latch                                 Latch Loop    Attributes
  D pin                                 Group
-------------------------------------------------------------------
DUT/Latch1/D                            NA            pu
DUT/Latch2/D                            1             b
DUT/Latch3/D                            1
DUT/Latch4/D                            2             bu
DUT/Latch5/D                            2             a
```

report_length_layerwise

Reports the distribution of length with respect to layers for specified nets.

Feedback

Syntax

status *report_length_layerwise*

`-of_objects nets`

Data Types

nets	list

Arguments

`-of_objects nets`

A list of one or more nets for which to report lengths. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command reports the distribution of length with respect to layers for specified nets.

It requires that the original extraction be performed with the *NETLIST_TAIL_COMMENTS: YES* command to save the required information.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a net length report. The report contains a section for each specified net with a list of layers and the length of the specified net on each layer.

```
pt_shell> report_length_layerwise -of_objects {SUM0 B0}
================================
Net: SUM0
Report: Layerwise length of net
================================
metal1 21u
metal2 55.5u
================================
Net: B0
Report: Layerwise length of net
================================
metal1 252.5u
metal2 113u
poly   189u
```

---

report_lib

Reports library information.

Syntax

string *report_lib*

Feedback

```
[-nosplit]
[-timing_arcs]
[-power_arcs]
library
[lib_cell_list]
```

Data Types

```
library              list
lib_cell_list             list
```

Arguments

`-nosplit`

Prevents splitting lines if a column overflows. Some of the information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

`-timing_arcs`

Displays timing arc information. Indicates to list all cell timing arcs.

`-power_arcs`

Displays power arc information. Indicates to list all cell power arcs.

`library`

A pattern matching a single library or a collection containing one library. The library must have been read by using the *read_db* command.

`lib_cell_list`

Displays a list of library cells about which information is reported. The default is to report information about all cells in the technology library. Each element in this list is either a collection of library cells or a pattern that matches library cells in the *library* option.

Description

A library report displays library information including a list of operating conditions, wire load models, and available library cells. The *-timing_arcs* option lists detailed timing arc information for each library cell, while the *-power_arcs* option lists detailed power arc information. Note: Currently, the *-power_arcs* and *-timing_arcs* options are mutually exclusive. The *report_lib* command also indicates if the library is a maximum library in a max/min relationship to a minimum library created by the *set_min_library* command.

To generate a report, the specified library must be loaded into pt_shell.

Feedback

Examples

This example shows the default library report.

```

report_lib_groups

Generates a report of library groups.

Syntax

int *report_lib_groups*

```
-scaling
[-objects]
[-show]
[-nosplit]
[object_list]
[show_list]
```

Data Types

```
object_list       list
show_list       list
```

Arguments

`-scaling`

Reports the list of library groups defined for scaling. Scaling library groups can be defined using the *define_scaling_lib_group* command.

`-objects`

Reports the list of library groups in the *object_list* option. Specify this option if you want to report the library groups of some specific cell, library cell or library.

`-show`

Reports the list of options in the *show_list* option. Specify this option if you want detailed information for the libraries in the scaling group, such as voltage and temperature. If this option is used, you must also specify the *show_list* option.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. If you do not use this option, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`object_list`

Specifies a list of cell, library cell or library. Reports the specific library groups that the specified object list belong.You can use any combination of these type of objects. The *object_list* option cannot be empty. If the *-objects* option is specified, you must also specify a non-empty *object_list*.

`show_list`

Reports the specific options that need to be reported. The *show_list* option can only contain options from the list {temperature, voltage, extended_name}. You can use any combination of these options. The *show_list* option cannot be empty. If the *-show* option is specified, you must also specify a non-empty *show_list*.

Description

Generates a report of the scaling library groups specified in the design.

The *scaling* option allows you to view all the scaling library groups specified using the *define_scaling_lib_group* command.

You can obtain detailed information about the libraries by using the *-show* option. The *-scaling* option is required.

Examples

The following example shows the scaling relationships that exist in the design.

```
pt_shell> report_lib_groups -scaling
****************************************
Report : lib_groups
         -scaling
Design : test
Version: Y-2006.06-Alpha-DEV
Date   : Wed Mar  8 11:22:51 2006
****************************************

Group    Library
------------------------------------------------------------
Group 1
         lib_0.95
         lib_0.85

1
```

The following example shows how you can use the *-show* option to obtain more detailed library information.

```
pt_shell> report_lib_groups -scaling -show {voltage temperature}
****************************************
Report : lib_groups
         -scaling
```

Feedback

```
          -show
Design : test
Version: Y-2006.06
Date   : Wed Mar  8 11:50:28 2006
****************************************

Group    Library      Temperature   Voltage
--------------------------------------------------------------------
Group 1
          lib_0.95     125.00        0.95
          lib_0.85     125.00        0.85

1
```

The following example shows how you can use the *-objects* option to obtain more detailed library information.

```
pt_shell> report_lib_groups -scaling -objects {tc300c_1.05} -show
 {process}
****************************************
Report : lib_groups
 -scaling
 -show
 -objects

---

report_license_limit

Reports the currently defined license limits.

Syntax

```
status report_license_limit
   feature_list
```

Feedback

Data Types

feature_list list

Arguments

feature_list

Shows the limits set on the specified features. If you do not use this option, the command lists all features for which limits are set.

Description

The *report_license_limit* command shows the limits on the number of licenses that were previously set by the *set_license_limit* command.

Examples

In the following example, the upper limit on the number of PrimeTime licenses was set to seven and the number of PrimeTime SI licenses was set to four:

```
pt_shell> report_license_limit
****************************************
Report : report_license_limit
 ...
****************************************

License limits set on these features:

Feature name                                Limit
------------------------------------------------------------
PrimeTime-SI                                4
PrimeTime                                   7

1
```

Feedback

report_memory_input_gate_savings

RTL memory input gate savings.

Syntax

string *report_memory_input_gate_savings*

```
[-nosplit]
[-debug_level debug_level]
[cell_list]
```

Data Types

```
debug_level     integer
cell_list       list
```

Arguments

`-nosplit`

Use this option to prevent line-splitting or section-breaking. By default, if the information for a given field exceeds its fixed column width, the next field begins on a new line, starting in the correct column (line-splitting). By default, if the information for one line exceeds the 80 character limit, the report is broken into two sections, each containing part of the information (section-breaking).

`-debug_level` *debug_level*

Use this option to report verbose information about the memory cell and its pins.

`cell_list`

This command expects user to provide memory instance name for analysis. If no instance is specified all memory instances will be analysed.

Description

This command detects memory inputs without data gating logic at RTL level.

The command estimates the power savings when the memory inputs are gated and report such memory instances along with RTL line information.

Power savings will be obtained by reduced activity on the input pins using gating.

The command only works in the average power analysis mode.

The command reports current memory instance power, estimated power using new enable signal and power savings.

Feedback

Examples

The following example shows the output report of *report_memory_input_gate_savings* command.

```

report_memory_redundant_read_cycles

Analyzes input RTL FSDB for memory cells and reports redundant read cycle power.

Syntax

string *report_memory_redundant_read_cycles*

```
[object_list]
```

Data Types

object_list list

Arguments

object_list

This command expects user to provide memory instance name for analysis. If no instance is specified all memory instances will be analysed.

Description

This command analyzes input RTL FSDB or VCD waveform and reports the redundant cycles of Read Enable signal. The command reads the input RTL FSDB and uses cycle power analysis to estimate the time windows in which read address is constant and read data has been valid for clock cycle. So, *Read Enable* signal can be disabled for the subsequent clock cycles, thereby reducing memory instance power.

The command only works in the average power analysis mode.

The command dumps out an output FSDB file which shows original *Read Enable* signal as well as estimated *Read Enable* signal after redundancy analysis. Output FSDB also contains original input and output signals of the memory instances so user can validate and change RTL code.

The command reports current, modified and improvement in Read Access Rate of *Read Enable* signal. Read Access Rate is defined as Static Probability of *Read Enable* input as percentage. The command also dumps modified *Read Enable* Toggle Rate after redundancy analysis. This can be used to validate estimated power of the memory instance using estimated enable signal.

The command reports current memory instance power, estimated power using new enable signal and power savings.

User can use output FSDB and command output report to modify user's RTL and input FSDB for making architecture-level decisions and improving memory power.

Examples

The following example shows the output report of *report_memory_redundant_read_cycles* command.

```
pwr_shell> report_memory_redundant_read_cycles ram_inst1/i_sram_tcbram

Feedback

Description

This command analyzes input RTL FSDB or VCD waveform and reports the redundant cycles of Write Enable signal. The command reads input RTL FSDB and uses cycle power analysis to estimate the time windows in which write address or write data is constant and data has been valid for clock cycle. So, *Write Enable* signal can be disabled for the subsequent clock cycles, thereby reducing memory instance power.

The command only works in the average power analysis mode.

The command dumps out an output FSDB file which shows original *Write Enable* signal as well as estimated *Write Enable* signal after redundancy analysis. Output FSDB also contains original input and output signals of the memory instances so user can validate and change RTL code.

The command reports current, modified and improvement in Write Access Rate of *Write Enable* signal. Write Access Rate is defined as Static Probability of *Write Enable* input as percentage. The command also dumps modified *Write Enable* Toggle Rate after redundancy analysis. This can be used to validate estimated power of the memory instance using estimated enable signal.

The command reports current memory instance power, estimated power using new enable signal and power savings.

User can use output FSDB and command output report to modify user's RTL and input FSDB for making architecture-level decisions and improving memory power.

Examples

The following example shows the output report of *report_memory_redundant_write_cycles* command.

```
pwr_shell> report_memory_redundant_write_cycles ram_inst1/i_sram_tcbram
**************************************
Report : report_memory_redundant_write_cycles
Design : wrapper_tcbram
Version: U-2022.12-SP3
Date   : Tue May 23 14:21:35

report_min_period

Displays minimum-period check information about specified pins or ports.

Syntax

string *report_min_period*

```
[-all_violators]
[-significant_digits digits]
[-nosplit]
[-path_type format]
[-input_pins]
[-derate]
[-variation]
[-nets]
[-crosstalk_delta]
[-transition_time]
[-capacitance]
[-clocks clock_list]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

```
digits               integer
format               string
sms_scenarios_list   collection
port_pin_list        list
```

Feedback

Arguments

`-all_violators`

Reports only violating minimum period checks.

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

`-nosplit`

Prevents line splitting in the report.

`-path_type` *format*

Specifies the format of the path report and how the clock path is displayed. Allowed values are

- *summary* (the default) - Displays one line for each path that shows only the required period, actual period, and slack.
- *short* - Shows only startpoints and endpoints in the clock path.
- *full_clock* - Shows full clock paths.
- *full_clock_expanded* - Shows full clock paths including all master clocks of a generated clock.

`-input_pins`

Reports the input pins. The default is to show only output pins.

`-derate`

Reports the derating factors. The default is to show no derate factors. This also shows the derate factor specified on the required period if one has been specified by the *set_timing_derate* command. Note that this option applies only when the *-path_type* option is set to *full_clock_expanded*.

`-variation`

Includes parametric on-chip variation (POCV) information in the report in columns labeled "Mean" and "Sensit". POCV analysis is enabled by setting the *timing_pocvm_enable_analysis* variable to *true*.

`-nets`

Reports nets. The default is not to show nets.

`-crosstalk_delta`

Reports the annotated delta delay and delta transition time. The deltas are computed during crosstalk signal integrity analysis, or they can be annotated manually using the *set_annotated_delay -delta_only* and *set_annotated_transition -delta_only* commands. Note that the *-crosstalk_delta* option only reports the calculated or annotated deltas; it does not initiate crosstalk analysis. Only deltas on input pins are shown. Delta transition time is shown only with the *-transition_time* option. The *-crosstalk_delta* option automatically sets the *-input_pins* option.

`-transition_time`

Reports the transition time (slew). The default is not to show transition time. For each driver pin or load pin the transition time is displayed in a column preceding incremental path delay.

`-capacitance`

Reports the total (lump) capacitance. The default is not to show capacitance. When the *-nets* option is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins.

`-clocks` *`clock_list`*

Reports minimum pulse width checks only from the specified clocks.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only min period violations compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`port_pin_list`

Reports the specified list of pins or ports. If you do not use this option, the report contains all pins and ports in the current design.

Description

The *report_min_period* command displays the following information for the minimum period check: required period, actual period, and by how much the constraint is violated or met (slack). This information is listed in order of decreasing slack starting with the worst violator.

If the *timing_remove_clock_reconvergence_pessimism* variable is set to *true*, clock reconvergence pessimism is removed from the slack on the reports.

To show more detailed minimum-period calculations, use the *-path_type* and *-input_pins* options.

When used under simultaneous multivoltage analysis (SMVA) analysis mode it will report only the cross-domain paths for minimum period checks.

You can also report minimum-period violations by using the *report_constraint* command with the *-min_period* option.

Examples

The following example generates a report of all minimum-period constraints in the current design.

```
pt_shell> report_min_period
****************************************
Report : min period
         -path_type summary
 ...
****************************************

   sequential_clock_min_period

                             Required        Actual
   Pin                     min period     min period        Slack
   -------------------------------------------------------------------
   b1/dst/CK (CK1 rise)         2.90           1.64          -1.26
 (VIOLATED)
   b1/dst/CK (CK1 fall)         2.90           1.80          -1.10
 (VIOLATED)
   b2/dst/CK (CK2 rise)         2.90           3.60           0.70   (MET)
   b2/dst/CK (CK2 fall)         2.90           3.80           0.90   (MET)
```

The following example generates a report of the minimum-period violation including the full clock path trace and the derate factor for the block1/test/CK pin.

```
pt_shell> report_min_period -path_type full_clock_expanded -derate
 block1/test/CK
****************************************
Report : min period
         -path_type full_clock_expanded
         -derate

report_min_pulse_width

Displays minimum pulse width check information about specified pins or ports.

Syntax

string *report_min_pulse_width*

```
[-all_violators]
[-significant_digits digits]
[-nosplit]
[-path_type format]
[-input_pins]
[-derate]
[-variation]
[-nets]
[-crosstalk_delta]
[-transition_time]
[-capacitance]
[-voltage_swing]
```

Feedback

```
[-clocks clock_list]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

digits	integer
format	string
sms_scenarios_list	collection
port_pin_list	list

Arguments

`-all_violators`

Reports only violating minimum pulse width checks.

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

`-nosplit`

Prevents line splitting in the report.

`-path_type` *format*

Specifies the format of the path report and how the clock path is displayed. Allowed values are:

- *summary* (the default) - Shows one line for each path and only the required pulse width, actual pulse width, and slack
- *short* - Shows only startpoints and endpoints in the clock path
- *full_clock* - Shows full clock paths
- *full_clock_expanded* - Shows full clock paths including all master clocks of a generated clock

`-input_pins`

Indicates that input pins are shown in the path report. The default is to show only output pins.

`-derate`

Indicates that derate factors are shown in the path report. The default is to show no derate factors. This also shows the derate factor specified on the required pulse width if one has been specified by the *set_timing_derate*

command. Note that this option applies only when the *-path_type* option is set to *full_clock_expanded*.

`-variation`

Includes parametric on-chip variation (POCV) information in the report in columns labeled "Mean" and "Sensit". POCV analysis is enabled by setting the *timing_pocvm_enable_analysis* variable to *true*.

`-nets`

Indicates that nets are to be shown in the path report. The default is not to show nets.

`-crosstalk_delta`

Reports the annotated delta delay and delta transition time. The deltas are computed during crosstalk signal integrity analysis, or they can be annotated manually using the *set_annotated_delay -delta_only* and *set_annotated_transition -delta_only* commands. Note that the *-crosstalk_delta* option only reports the calculated or annotated deltas; it does not initiate crosstalk analysis. Only deltas on input pins are shown. Delta transition time is shown only with the *-transition_time* option. The *-crosstalk_delta* option automatically sets the *-input_pins* option.

`-transition_time`

Shows the transition time (slew). The default is not to show transition time. For each driver pin or load pin the transition time is displayed in a column preceding incremental path delay.

`-capacitance`

Shows the total (lump) capacitance. The default is not to show capacitance. When the *-nets* option is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins.

`-voltage_swing`

Specifies that voltage swing check is performed in advanced waveform propagation mode. When computing the swing check, the minimum required width is set to 0.0 and the width measurement is made at a specified fraction of the supply voltage, which is specified by the variable *timing_voltage_swing_high_pulse_threshold* for the high pulse voltage swing computation and by the variable *timing_voltage_swing_low_pulse_threshold* for the low pulse voltage swing computation. Please note that voltage swing analysis should be enabled through the variable *timing_enable_voltage_swing* before invoking the command.

`-clocks` *`clock_list`*

Reports minimum pulse width checks only from the specified clocks.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only min pulse violations compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`port_pin_list`

Reports only the specified list of pins or ports. If you do not use this option, the report shows all pins and ports in the current design.

Description

The *report_min_pulse_width* command displays the following information for the minimum pulse width check: required pulse width, actual pulse width, and by how much the constraint is violated or met (slack). This information is listed in order of decreasing slack starting with the worst violator.

In minimum pulse width checking, by default, the tools measures the width of a pulse where the signal waveform crosses the voltage threshold at 50 percent of the supply voltage. If the *timing_enable_min_pulse_width_waveform_adjustment* variable is set to true, the measurement thresholds can be set to any fraction of the supply voltage between 0.0 and 1.0, through the variables *timing_min_pulse_width_high_pulse_threshold* and *timing_min_pulse_width_low_pulse_threshold* for the high pulse and the low pulse respectively.

If the *timing_remove_clock_reconvergence_pessimism* variable is set to true, clock reconvergence pessimism is removed from the slack on the reports.

More detailed minimum pulse width calculations are shown using the *-path_type* and *-input_pins* options.

Minimum pulse width violations can also be reported with the *report_constraint* command using the *-min_pulse_width* option.

Two types of minimum pulse width checks are performed:

- Clock Pulse Width Check at Sequential Devices: This check is performed on clock pins of sequential elements. This check verifies that a minimum separation exists between the trailing edge and leading edge of the clock that is clocking the sequential elements. The library defines the constraints, which are environmentally scalable. The most restrictive value of pulse width (library-specified or user-asserted) is used. No default value is assumed.
- Clock Tree Pulse Width Check at Logic Circuits: The clock tree pulse width check ensures that the clock pulse is propagated reliably through the logic. This check is performed on the combinational logic circuits through which the clock signals are propagated. No default is assumed for the clock tree pulse width check. The most restrictive value of pulse width (library-specified or user-asserted) is used.

Feedback

Note that if the *timing_enable_pulse_clock_constraints* variable is set to *true* (default value), the *report_min_pulse_width* command does not report pulse width checks in the pulse clock networks. To report pulse width checks in the pulse clock network use the *report_pulse_clock_min_width* command. To check pulse width in the pulse clock network using the *report_min_pulse_width* command, set the *timing_enable_pulse_clock_constraints* variable to *false*.

When used under simultaneous multivoltage analysis (SMVA) analysis mode it will report only the cross-domain paths for minimum pulse width checks.

Examples

The following example generates a report of all minimum pulse width violations in the current design.

```
pt_shell> report_min_pulse_width

---

report_mode

Displays a report of modes for specified cells or design.

Syntax

string *report_mode*

```
[-type cell | design]
[-nosplit]
[instance_list]
```

Data Types

instance_list	list

Arguments

`-type design | cell`

Indicates the type of mode to be reported. This option has the mutually exclusive valid values of either *design* or *cell*.

The *cell* value specifies that cell modes are to be reported. Cell modes are defined on library cells in the library.

The *design* value specifies that design modes are to be reported. Design modes are user-defined using the *define_design_mode_group* and *map_design_mode* commands. If the *-type* option is ommitted from the command, this is equivalent to specifying *-type cell*.

`-nosplit`

Most of the mode information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

instance_list

Specifies a list of instances whose modes are to be reported. By default, the report includes all cells that have modes. This option is only valid if -type has a cell value

Description

This command reports cell modes or design modes. When reporting cell modes, the report specifies whether the cell mode is enabled or disabled, and it also specifies the reason why the mode is enabled or disabled. There are four possible reasons as to why a mode can be enabled or disabled. They are

- cell - Indicates that the cell mode has been set directly using the *set_mode -type cell* command.
- design - Indicates that the cell mode has been set due to the activation of a design mode using the *set_mode -type design* command. The design mode must have previously been mapped to the cell mode using the *map_design_mode* command. The report also specifies the name of the activated design mode. To view more details about the design mode, use the *report_mode -type_design* command.
- cond - Indicates that the cell mode has been set due to evaluation of the mode condition during constant propagation.
- default - Indicates that the cell mode has not been set by any of the above reasons.

When reporting design modes the report displays the design modes specified on the current design and for each design mode, reports the cell modes and moded pins associated with that design mode.

Examples

The following example reports cell mode information for the design top_design. Two cells have modes, Uram1 and Uram2 are instances of the library cell RAM2_core. rw is a cell mode group defined on the library cell RAM2_core. This cell mode group has two cell modes read and write. No modes are currently active so all modes are enabled and the reason is given as default.

```
pt_shell> report_mode

****************************************
Report : mode
Design : top_design
****************************************

Cell                              Mode(Group)        Status      Reason
--------------------------------------------------------------------------------
---
Uram1/core(RAM2_core)             read(rw)           ENABLED     default
                                  write(rw)          ENABLED     default
```

```
------------------------------------------------------------------------
---
Uram2/core(RAM2_core)              read(rw)          ENABLED     default
                                   write(rw)         ENABLED     default
------------------------------------------------------------------------
---
```

The following example shows a report of modes specified for the two RAMs that have modes in the design. Ram Uram1 is set in mode read, and Ram Uram2 is set in mode write. Thus, all timing arcs of RAM Uram1 associated with mode read are enabled , and all timing arcs associated with mode write are disabled.

```
pt_shell> set_mode read Uram1/core
pt_shell> set_mode write Uram2/core
pt_shell> report_mode

****************************************
Report : mode
Design : top_design
****************************************

Cell                               Mode(Group)     Status          Reason
------------------------------------------------------------------------
---
Uram1/core(RAM2_core)              read(rw)        ENABLED         cell
                                   write(rw)       disabled        cell
------------------------------------------------------------------------
---
Uram2/core(RAM2_core)              read(rw)        disabled        cell
                                   write(rw)       ENABLED         cell
------------------------------------------------------------------------
---
```

The following example reports that two design modes have been specified using the *set_mode -type design* command. For each design mode, it reports any mapping of cell modes, as specified by the *map_design_mode* command. The report also displays any paths that are design mode dependent, as specified by the *map_design_mode -from* or *map_design_mode -to* command.

```
pt_shell> map_design_mode  {read,latching} {U2/core,U1/core} read
pt_shell> map_design_mode  -from {INFF1/CLK} -to {INFF3/D}
pt_shell> map_design_mode  -from {INFF1/CLK} -to {INFF4/D}
pt_shell> map_design_mode  {write,transparent} {U2/core,U1/core} write
pt_shell> report_mode -type design

Feedback

report_multi_input_switching_coefficient

Reports delay coefficient for multi-input switching (MIS) analysis.

Syntax

int *report_multi_input_switching_coefficient*

```
[-nosplit]
[-significant_digits num_digits]
[object_list]
```

Data Types

num_digits	integer
object_list	list

Arguments

`-nosplit`

Does not split lines in report when columns overflow.

`-significant_digits num_digits`

Specifies the number of digits displayed in the report.

object_list

Specifies a list of library cells.

Description

This command reports delay coefficient for multi-input switching (MIS) analysis for the specified list of library cells. If you do not specify a list of library cells, the tool reports the coefficients for all library cells.

Examples

The following example reports all coefficients set by set_multi_input_switching_coefficient command:

```
pt_shell> report_multi_input_switching_coefficient
```

See Also

- set_multi_input_switching_coefficient
- reset_multi_input_switching_coefficient
- si_enable_multi_input_switching_analysis
- si_enable_multi_input_switching_timing_window_filter

Feedback

report_multi_input_switching_lib_cells

Reports candidate library cells for advanced multi-input switching (MIS) analysis.

Syntax

int *report_multi_input_switching_lib_cells*

Description

Advanced multi-input switching (MIS) analyzes library cell data, along with actual pin slew, arrival, and waveform information, to estimate multi-input switching (speedup) effects. See the *si_multi_input_switching_analysis_mode* man page for details.

User-defined coefficients are not required, but the following library data is required:

- CCS timing models
- CCS noise models
- All *when* conditions characterized

The following library cell types are supported for advanced MIS analysis:

```
AND2   OR2   NAND2   NOR2   AO211   AOI211   OA211   OAI211
AND3   OR3   NAND3   NOR3   AO21    AOI21    OA21    OAI21
AND4   OR4   NAND4   NOR4   AO22    AOI22    OA22    OAI22
                            AO31    AOI31    OA31    OAI31
```

This command reports the list of library cells that qualify for advanced MIS calculation.

Examples

The following example reports all the library cells that are candidates for advanced MIS analysis:

```
pt_shell> report_multi_input_switching_lib_cells
```

report_multi_scenario_design

Creates a detailed report on user defined multi-scenario objects and attributes.

Syntax

status *report_multi_scenario_design*

```
[-scenario]
[-session]
[-license]
```

Feedback

Arguments

`-scenario`

Reports in detail on the current scenarios that have been defined. Details reported include the name of the scenario, the files used to generate the image for the scenario (i.e. common and specific data files), the scenario used to generate the baseline image for the scenario, the location of the current image, the focus of the scenario and the affinity specification for the scenario. For detailed description of the settings of the focus field, see the description section below.

`-session`

Reports in detail on the current session. This option reports the number of scenarios defined in the current session. Three fields are reported for each scenario in the current session: the command focus of the scenario, the name of the scenario, and the scenario which provides the image to the scenario.

`-license`

Reports in detail on license usage and limits set.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

The *report_multi_scenario_design* command generates a report on user-defined multi-scenario analysis. The level of detail reported depends on the options specified. By selecting no options, the *report_multi_scenario_design* command issues a short summary of current user-defined objects and settings. The summary reports on whether or not a session has been defined. The number of defined scenarios and licenses in use are also reported. The report generated can report in detail on the following topics: scenarios, sessions, and licenses.

The *-scenario* option generates a report on all the scenarios that exist in the manager process. The report shows several pieces of information about each scenario:

- The name of the scenario
- The files used to generate the images for the scenario (i.e. common and specific data files)
- The scenario used to generate the baseline image for the scenario
- The location of the scenario's current image
- The focus of the scenario, which can be one of three possible values

```
-"Out of focus" means the scenario is not in the current_session.
 -"In current session" means the scenario is in the current session
 but
```

```
     it is not in command focus. i.e. It will not receive commands from
    the
     manager.
    -"In current session and command focus" means the scenario is in the
     current session and in command focus. i.e. It will receive commands
     from the manager.
```

- The affinity of the scenario

See the *current_scenario* command for changing command focus.

The *-session* option reports the scenarios defined in the current session. Along with the number of scenarios, some scenario-specific data is reported. The focus field of the scenario shows whether the scenario is in the session (Session), or whether it is also in command focus (Command). Also reported is the scenario which provides the image to each scenario.

The *-license* option shows the numbers of licenses checked out for each feature and the user defined limits for each feature.

Examples

In the following example, several scenarios are created and the current session is set. Then the *report_multi_scenario_design* command is used to examine the multi scenario information available to the manager.

```
pt_shell>create_scenario -name scen1 -common_data {com_s1.tcl} \\
  -specific_data {spec_s1.tcl spec_s2.tcl spec_s3.tcl}
1
pt_shell>create_scenario -name scen2 -common_data {com_s2.tcl}
 -specific_data {spec_s2.tcl}
1
pt_shell>create_scenario -name scen3 -common_data {com_s3.tcl}
 -specific_data {spec_s3.tcl}
1
pt_shell>create_scenario -name scen4 -common_data {com_s3.tcl}
 -specific_data {spec_s3.tcl}
1
pt_shell> current_session {scen1 scen2 scen3}
1
pt_shell> report_multi_scenario_design
1

---

report_multi_user_server

Reports the configuration of the current multi-user server session.

Syntax

status *report_multi_user_server*

Description

The *report_multi_user* command reports information about the current multi-user server session, including all clients that are active.

It reports the following detailed information:

- Server-related information
  - Server Name - The name of the server session.
  - Session ID - A string which uniquely identifies the multi-user session.
  - Server Log - The name of the file which will contain information related to the active multi-user session.
  - Logging Level - Verbose level of information written in log file. Can be changed using the *multi_user_logging_level* variable.
  - Access Group - Name of the UNIX group to restrict access.
  - Client Cores - Number of cores available for use by the multi-user clients.
  - Client Limit - Maximum number of clients allowed in the current session.
  - Active Clients - Number of clients currently active.
- Client-related information

- Client Name - The name of the client session.
- PID - Process ID of the client session.
- Display - DISPLAY environment used by client to run design in interactive mode
- Script File - Name of script file containing commands which will be executed by clients.
- Output Log - File containing output of commands executed by the client.

The *report_multi_user_server* command is supported only in a multi-user server session.

Examples

In the following example, a multi-user server is running with 2 cores, and a client is connected and running in non-interactive mode:

```
pt_shell> report_multi_user_server
  ****************************************
  Report : Multi-User Report
  ****************************************

  Report on current server configuration:
  ---------------------------------------
    Server Name:     user.123
    Session ID:      30:35787
    Server Log:      user.123_multi_user.log
    Logging Level:   low
    Access Group:    synopsys
    Client Cores:    2 (Total)
    Client Limit:    2
    Active Clients:  1

    Report on active clients:
    -----------------------------
    Client Name    PID    Display           Script file      Output log

 ------------------------------------------------------------------------
---
    c1.8748        8748   N/A               ./script_file           ./log
```

Feedback

report_name_mapping

Reports the user-defined name-mapping rules.

Syntax

string *report_name_mapping*

```
[-nosplit]
```

Arguments

`-nosplit`

Prevents the line splitting if column overflows.

Description

The *report_name_mapping* command reports the user-defined name-mapping rules you have set using the *set_rtl_to_gate_name* command.

Examples

In the following example, all the user-defined name-mapping rules are reported.

```
pt_shell> set_rtl_to_gate_name -rtl a_net -gate n272
1
pt_shell> set_rtl_to_gate_name -rtl a_pin -gate U3/D0
1
pt_shell> set_rtl_to_gate_name -rtl a_cell -gate U3

report_net

Generates a report of net information.

Syntax

string *report_net*

```
[-connections]
[-verbose]
[-significant_digits digits]
[-segments]
[-nosplit]
[net_names]
```

Data Types

digits	int
net_names	list

Arguments

`-connections`

Indicates that the report shows net connection information.

`-verbose`

Indicates that the report shows verbose connection information. This must be used with the *-connections* option.

`-significant_digits digits`

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which the default value is 2. Use this option if you want to override the default. Fixed-precision floating-point arithmetics is used for delay calculation; therefore, the actual precision might depend on the platform. For example, on SVR4 UNIX see FLT_DIG in limits.h, the upper bound on a meaningful value of the argument to the *-significant_digits* option is then FLT_DIG - ceil(log10(fabs(*any_reported_value*))).

`-segments`

Indicates that the report shows all global segments for each net requested. Global net segments are all those physically connected across all hierarchical boundaries.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing software to extract information from the report output.

net_names

Specifies a list of nets that is reported. The default is to report all nets in the current instance or current design.

Description

The command displays information about the nets in the design of the current instance, or in the current design. If the *current_instance* command is set, the report generates for the design of that instance; otherwise, the report generates for the current design. Attributes, such as annotated resistance and annotated capacitance, are displayed.

If the *-connections* optin is used, PrimeTime lists the leaf cell pins connected to each net.

Examples

The following example reports all nets in the design.

```
pt_shell> report_net

****************************************
Report : net

report_net_connectivity

Reports the ports, instances, and cells connected to the specified nets.

Syntax

status *report_net_connectivity*

```
        nets
```

Data Types

nets list or collection

Arguments

nets

A list of one or more nets for which to report net connectivity. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command reports the ports, instances, and cells connected to the specified nets.

Examples

The following example shows a detailed connectivity report for nets with escape characters.

Feedback

```
pt_shell> report_net_connectivity [get_nets -exact {net\\[0\\]}]

U87  312600.00         254000.00         319600.00         258950.00
```

Where,

*P report has pin names, direction, and x and y coordinates.

*I report has port names, direction, cell name, and x and y coordinates.

Cell report has cell names, and x and y coordinates of bounding box.

---

report_noise

Reports noise analysis information.

Syntax

int *report_noise*

```
[-above]
[-below]
[-low]
[-high]
[-nworst_pins pin_count]
[-significant_digits digits]
[-verbose]
[-nosplit]
[-slack_lesser_than slack_limit]
[-slack_type height | area | area_percent]
[-all_violators]
[-data_pins]
[-clock_pins]
[-async_pins]
[-sms_scenarios list]
[object_list]
```

Feedback

Data Types

digits	integer
object_list	list
pin_count	integer
slack_limit	float

Arguments

`-above`

Performs the reporting only above the rails. If this option is combined with the *-low* option, it reports the noise bumps above the low rail. If it is combined with the *-high* option, it reports the noise bumps above the high rail. Otherwise, it reports the noise bumps above either rail.

`-below`

Performs the reporting only below the rails. If this option is combined with the *-low* option, it reports the noise bumps below the low rail. If it is combined with the *-high* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps below either rail.

`-low`

Performs the reporting only for the low rail. If this option is combined with the *-above* option, it reports the noise bumps above the low rail. If it is combined with the *-below* option, it reports the noise bumps below the low rail. Otherwise, it reports the noise bumps both below and above the low rail.

`-high`

Performs the reporting only for the high rail. If this option is combined with the *-above* option, it reports the noise bumps above the high rail. If it is combined with the *-below* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps both below and above the high rail.

`-nworst_pins` *pin_count*

Specifies the number of load pins to be reported. Values of 1 or greater are allowed. The default is 1.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point to be displayed for time values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default value is 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, PrimeTime uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

`-verbose`

Shows more details about the calculation of total noise on each load pin, including the individual contribution of each aggressor as well as noise bumps propagated from previous logic stages in the design.

`-nosplit`

If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing software to extract information from the report output.

`-slack_lesser_than` *`slack_limit`*

Indicates that only those pins with a slack less (more negative) than *slack_limit* are to be shown.

`-slack_type area | height | area_percent`

Specifies the type of slack to be used. Valid values are *area*, *height*, and *area_percent*.

The voltage margin is defined by the noise bump height and noise immunity curves or DC noise margin. A *-slack_type* value of *height* reports noise slack as the voltage margin. A *-slack_type* value of *area* reports noise slack as the voltage margin multiplied by the noise bump width. A *-slack_type* value of *area_percent* reports noise slack as the percentage of the noise constraint area. The noise constraint area is computed by multiplying the noise height constraint by the noise bump width.

The default is *height*.

`-all_violators`

Indicates that only violating pins (negative slack) are to be shown. This option cannot be used with the *-slack_lesser_than* option. If this option is used with the *-nworst_pins* option, the number of violating pins will be limited by that value.

`-data_pins`

Indicates that the reporting is to be performed only for data pins of sequential cells. This is similar to passing the results of the *all_registers -data_pins* command to the *report_noise* command.

`-clock_pins`

Indicates that the reporting is to be performed only for clock pins of sequential cells. This is similar to passing the results of the *all_registers -clock_pins* command to the *report_noise* command.

`-async_pins`

Indicates that the reporting is to be performed only for asynchronous pins of sequential cells. This is similar to passing the results of the *all_registers -async_pins* command to the *report_noise* command.

`-sms_scenarios` *`list`*

Specifies SMS scenarios for scenario specific reporting. By default, the worst-case result across all scenarios is reported.

`object_list`

Specifies the load pins for which noise reporting is performed. If no pins are specified, reporting is performed for the entire design.

Description

This command provides a report of noise information for the current design.

It reports the top *-nworst_pins* pins or the pins specified by the *object_list* argument in increasing order of their slack values. By default, the slack values used are based on *-slack_type height*. Using the *-slack_type area* option may result in a different order of pins reported. Pins with positive slack are not reported in any particular order.

By default, a summary report is generated that shows the total crosstalk noise bump height and width on the load pins. If the *-verbose* option is used, the individual contribution of each effective aggressor and the amount of propagated noise is also reported.

Examples

The following command generates a report for the worst total noise bump above the low rail in the current design.

```
pt_shell> report_noise -above -low
```

The following example generates a report for the five worst total noise bumps above the low rail in the current design.

```
pt_shell> report_noise -above -low -nworst_pins 5
```

The following example generates a report for the worst total noise bump above the low rail and also the worst total noise bump below the low rail in the current design.

```
pt_shell> report_noise -low
```

The following example generates a report for the worst total noise bump for each of the four cases of above the low rail, below the low rail, above the high rail, and below the high rail in the current design.

```
pt_shell> report_noise -low -high
```

Feedback

See Also

- update_noise
- report_default_significant_digits

---

report_noise_calculation

Reports the detailed calculation of noise information for the specified net arc.

Syntax

string *report_noise_calculation*

```
[-above]
[-below]
[-low]
[-high]
[-significant_digits digits]
[-nosplit]
-from from_pin
-to to_pin
[-sms_scenarios list]
```

Data Types

digits	integer
from_pin	list
to_pin	list

Arguments

`-above`

Specifies a noise calculation for the above ground or power rails noise analysis region.

`-below`

Specifies a noise calculation for the below ground or power rails noise analysis region.

`-low`

Specifies a noise calculation for ground rail noise.

`-high`

Specifies a noise calculation for power rail noise.

`-significant_digits digits`

Specifies the number of digits after the decimal point displayed for time values in the generated report. Allowed values are 0-13; the default is determined by

the *report_default_significant_digits* variable, which has a default of 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, PrimeTime uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing software to extract information from the report output.

`-from` *`from_pin`*

Specifies the startpoints of a net arc within a design. The *from_pin* value must be a driver pin or port.

`-to` *`to_pin`*

Specifies the endpoints of a net arc within a design. The *to_pin* value must be the load pin or port of the same net.

`-sms_scenarios` *`list`*

Specifies SMS scenarios for scenario specific reporting. By default, reporting is done for all scenarios.

Description

This command reports the detailed calculation of noise information for the specified net arc. This command uses the noise analysis settings for the design set by the *set_noise_parameters* command. If needed, it updates the noise information for the design.

The report shows some general information about the victim, as well as details of noise bump and noise slack calculations.

The general information section includes the victim driver net, pin, noise composite aggressor mode, and any applicable derating factors set by the *set_noise_derate* command.

The noise calculation section includes the total noise bump as well as the estimated noise bumps induced from each of the aggressors. Note that individual aggressor noise bumps are reported only to show their relative contributions. The linear summation of all individual noise bumps might not match the total noise bump due to the nonlinear behavior of the coupled clusters.

The aggressor attribute column shows more details about each of the effective aggressors. Aggressors which are filtered are not included in this report.

The following is the list of possible attributes an aggressor can have:

```
Attributes:
  A - aggressor is active
  C - aggressor is a composite aggressor
  D - aggressor is analyzed with detailed engine
  E - aggressor is screened due to user exclusion
  G - aggressor is analyzed with gate level simulator
  I - aggressor has infinite window
  L - aggressor is screened due to logical correlation
  S - aggressor is screened due to small bump height
  X - aggressor is screened due to aggressor exclusion
```

An active aggressor is an aggressor that contributes to the worst-case alignment scenario of all the aggressors.

A composite aggressor models the combined effect of a group of weak aggressors to improve runtime and memory capacity.

An aggressor can be screened from the analysis if it has no significant impact on the victim. For example, when the aggressor is excluded by using the *case_analysis* or *set_si_delay_analysis* commands, or if the bump height that it induces on the victim is very small.

An aggressor is analyzed using the CCS noise gate-level simulation engine if the amplitude of the total noise glitch is significant compared to the lowest noise immunity of the load cells. In this mode, all aggressor drivers as well as the victim driver are analyzed using CCS noise advanced engine and this attribute 'G' shows up on the total noise line.

An aggressor is infinite-window when it has no fixed timing relationship with the victim. For example, an aggressor driven by a clock asynchronous to the clock that drives the victim is infinite-window.

An aggressor has logical correlation if there is a common point in the transitive fanin of both aggressor and the victim, or two aggressors.

An aggressor can be excluded from the analysis by using the *case_analysis* or *set_si_delay_analysis* commands.

The noise slack calculation section shows the details of how the area slack and height slack are derived for the victim, and also what type of constraint was used to derive the slack. The height slack is the difference of the actual bump height versus the bump height which causes the failure with the same width. The area slack is the area that needs to be added to the actual bump to cause a noise failure.

Feedback

Examples

The following command reports the noise calculation for the driver pin buf2/ZN and load pin buf5/I for below the high rail noise region:

```
pt_shell> report_noise_calculation -below -high -from buf2/ZN -to buf5/I
 ...

Units:  1ns  1pF  1kOhm

report_noise_parameters

Reports status of the noise analysis parameters for the current design.

Syntax

```
int report_noise_parameters
```

Arguments

None.

Description

This command reports status of the parameters that are considered during the noise analysis. If this command is performed, the settings of the parameters for the noise analysis are reported: beyond the rail analysis, arrival times of aggressors and propagation of noise.

Examples

The following example shows the report format:

```
pt_shell> report_noise_parameters
report_noise_parameters
****************************************
Report  : noise_parameters
Design  : top
Version : Y-2006.06-VA-STA-Beta1-DEV
Date    : Thu Jan 26 09:46:43 2006
****************************************

 ignore arrival       : true
```

```
include beyond Rails : true
enable propagation   : true
```

See Also

---

report_noise_violation_sources

Reports noise violation sources for failing endpoints.

Syntax

int *report_noise_violation_sources*

```
[-above]
[-below]
[-low]
[-high]
[-nworst_endpoints pin_count]
[-max_sources_per_endpoint pin_count]
[-significant_digits digits]
[-verbose]
[-nosplit]
[-slack_type slack_type]
[object_list]
```

Data Types

pin_count	integer
digits	integer
slack_type	float
object_list	list

Arguments

`-above`

Performs the reporting only above the rails. If this option is combined with the *-low* option, it reports for the noise bumps above the low rail. If it is combined with the *-high* option, it reports the noise bumps above the high rail. Otherwise, it reports the noise bumps above the high rail and above the low rail.

`-below`

Performs the reporting only below the rails. If this option is combined with the *-low* option, it reports for the noise bumps below the low rail. If it is combined with the *-high* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps below the high rail and below the low rail.

`-low`

Performs the reporting only for the low rail. If this option is combined with the *-above* option, it reports the noise bumps above the low rail. If it is combined with the *-below* option, it reports the noise bumps below the low rail. Otherwise, it reports the noise bumps for both below and above the low rail.

`-high`

Performs the reporting only for the high rail. If this option is combined with the *-above* option, it reports the noise bumps above the high rail. If it is combined with the *-below* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps for both below and above the high rail.

`-nworst_endpoints` *`pin_count`*

Specifies the number of endpoint pins to be reported. Any number greater than 1 is accepted; the default value is 1.

`-max_sources_per_endpoint` *`pin_count`*

Specifies the number of violation source pins per endpoint to be reported. Any number greater than 1 is accepted; the default value is 1.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point to be displayed for time values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default value is 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, PrimeTime uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

`-verbose`

Shows details about pins in fan-in cone of the logic from violation sources to endpoint. Pins are ordered from the endpoint to sources and levelized by the distance from the endpoint. The worst slacks are shown on the top.

`-nosplit`

If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-

splitting and facilitates writing software to extract information from the report output.

`-slack_type` *`slack_type`*

Specifies the type of slack to be used. Valid values are *area*, *height*, and *area_percent*. The voltage margin is defined by the noise bump height and noise immunity curves or DC noise margin. A *slack_type* value of *height* reports noise slack as the voltage margin. This setting is the default. A *slack_type* value of *area* reports noise slack as the voltage margin multiplied by the noise bump width. A *slack_type* value of *area_percent* reports noise slack as the percentage of the noise constraint area. The noise constraint area is computed by multiplying the noise height constraint by the noise bump width.

`object_list`

Specifies the load pins for which the noise reporting is performed. If no pin is specified, reporting is performed on the entire design.

Description

Provides a report of noise violation source information for failing noise endpoints of the current design.

A noise endpoint is one of the followings: - Data pin, clock pin, or asynchronous pin of flip-flops - Input pin of level sensitive latch - Output port - Load pin of gates where noise exceeds the threshold

A failing endpoint is an endpoint with negative slack value. A violation source is the source of violation that causes a failure in the endpoint.

This command reports the violation sources of the specified or the nworst endpoints.

By default, the non verbose report is generated which shows the total crosstalk noise bump height and width as well as slack on the load pins.

Beginning with the F-2011.06 release, the *-slack_type* option defaults to *height* instead of *area* since it is a more direct representation of the noise violation on a pin.

Examples

The following example generates a report for the worst violation source of the worst endpoint above the low rail in the current design.

```
pt_shell> report_noise_violation_sources -above -low
```

The following example generates a report for the worst violation source of five worst endpoints above the low rail in the current design.

```
pt_shell> report_noise_violation_sources -above -low -nworst_pins 5
```

Feedback

The following example generates a report for the worst violation source above the low rail and also the worst violation source below the low rail in the current design.

```
pt_shell> report_noise -low
```

The following example generates a report for the worst violation source for each of the four cases of above the low rail, below the low rail, above the high rail, and below the high rail in the current design.

```
pt_shell> report_noise -low -high
```

---

report_nonphysical_resistors

Reports the nonphysical resistors associated with the specified nets.

Syntax

status *report_nonphysical_resistors*

```
[-verbose]
[-of_objects nets]
[-from node1 -to node2]
```

Data Types

nets	list
node1	string
node2	string

Arguments

`-verbose`

Provides additional information about the coupling capacitors.

`-of_objects nets`

A list of one or more nets for which to report the nonphysical resistors. At least one net is required. Glob-style wildcards (*) are supported.

This option is mutually exclusive with the *-from* and *-to* options.

`-from` *node1*

Specifies a pin, port, or net internal node. The tool reports the nonphysical resistors for paths between this node and the node specified in the *-to* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

`-to` *node2*

Specifies a pin, port, or net internal node. The tool reports the nonphysical resistors for paths between this node and the node specified in the *-from* option. Both nodes must both belong to the same net.

This option is mutually exclusive with the *-of_objects* option.

Description

This command reports the nonphysical resistors associated with the specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a default nonphysical resistor report.

```
pt_shell> report_nonphysical_resistors -of_objects min_lsb[5]

****************************************
Report : Non-Physical Resistors Net Based summary
Design : toprt
Version: Q-2019.12
Date   : Mon Nov 11 17:14:53 2019

---

report_ocvm

Reports information about AOCV or POCV derating tables and coefficients; shows details about path-based and graph-based calculations.

Syntax

```
status report_ocvm
   [-early]
   [-late]
   [-rise]
   [-fall]
   [-clock]
   [-data]
   [-voltage voltage_value]
   [-cell_delay]
   [-net_delay]
   [-lib_cell]
   [-list_annotated]
   [-list_not_annotated]
   [-coefficient]
   -type aocvm | pocvm
   [-nosplit]
   [object_list]
```

Data Types

```
voltage_value     string
object_list       list
```

Feedback

Arguments

`-early`

Shows objects annotated with the AOCV or POCV early deratings.

`-late`

Shows objects annotated with the AOCV or POCV late deratings.

`-rise`

Shows objects annotated with the AOCV or POCV rising deratings.

`-fall`

Shows objects annotated with the AOCV or POCV falling deratings.

`-clock`

Shows objects annotated with the AOCV or POCV clock deratings.

`-data`

Shows objects annotated with the AOCV or POCV data deratings.

`-voltage` *voltage_value*

Shows objects annotated with the AOCV or POCV voltage deratings.

`-cell_delay`

Shows objects annotated with the AOCV or POCV cell deratings.

`-net_delay`

Shows objects annotated with the AOCV or POCV net deratings.

`-lib_cell`

This option can be used with either the -list_annotated or -list_not_annotated options to report the library cell name instead of the instance name.

`-list_annotated`

Lists the leaf cells and global nets that are annotated with AOCV or POCV derating tables.

`-list_not_annotated`

Lists the leaf cells and global nets that are not annotated with AOCV or POCV derating tables.

`-coefficient`

Shows the AOCV or POCV coefficients. You can specify a collection of lib_cell, lib_timing_arc, and cell objects in the *object_list* to display coefficients annotated only on those objects.

Feedback

`-type aocvm | pocvm`

Specifies the OCV type. The allowed values are

- *aocvm* - Shows AOCV information.
- *pocvm* - Shows POCV information.

`-nosplit`

Prevents split lines when columns overflow.

`object_list`

Specifies either timing_path objects for which path-based metrics are to be reported; or timing_arc objects for which graph-based metrics are to be reported; or design objects on which AOCV or POCV derating tables and coefficients have been annotated.

Description

This command displays the user-specified AOCV or POCV information. The type of information displayed by PrimeTime depends on the type of AOCV or POCV information annotated.

- timing_aocvm_enable_analysis
- timing_pocvm_enable_analysis

---

report_odc_power_savings

Generates power saving reports by identifying the Observability Don't Care (ODC) conditions of the registers.

Syntax

string *report_odc_power_savings*

```
[-clock_gate_type      clock_gate_value_type]
[-min_pwr_savings      power_savings]
[-min_reg_width        register_width]
[-csv csv_file]
[-report_nl_names]
[object_list]
```

Feedback

Data Types

clock_gate_value_type	string
power_savings	float
register_width	integer
csv_file	string
object_list	list

Arguments

`-clock_gate_type` *clock_gate_value_type*

Use this option to specify the type of clock which drives the registers. The clock could be gated type, domain type (non-gated) or both. Default value of *-clock_gate_type* is "all" and other supported values are "gated" and "not_gated".

`-min_pwr_savings` *power_savings*

Use this option to report only those registers whose total power saving, after using the ODC power saving technique, is more than or equal to the "power_savings" value. Default value of *-min_pwr_savings* is 0.0.

`-min_reg_width` *register_width*

Use this option to filter the bundled registers so that the bundled registers having width greater than or equal to "register_width" will be considered for power saving estimate. Default value of *-min_reg_width* is 8.

`-csv` *csv_file*

Use this option to specify the path for the csv file for writing the power savings report in a comma seperated value format. A csv file can be viewed in a spreadsheet reader. With this option the report will not be printed on the shell.

`-report_nl_names`

Use this option to report the netlist(gate-level) name of the register. By default, the RTL name or merged RTL name, in case of bus register, is reported for the registers.

object_list

Use this option to apply the ODC power savings techniques on the list of registers. Options *-min_reg_width* and *-min_pwr_savings* cannot be supported with this option. Currently only the gate-level register name can be specified.

Description

Use the *report_odc_power_savings* command to generate the power savings report after applying the ODC power savings techniques on the register/bus registers in the design.

The three important fields that the command prints are the name of registers, potential power savings that could happen using the above technique and the name of Child Registers whose enable values cause this ODC Condition.

The other fields are: width of register bus, frequency of clock, the register is gated or not, the current and final register gate efficiency percentage, current and final enable probability, current power and the final power.

To use the command, you should first apply the update_power and update_metrics command or apply the compute_metrics command.

ODC Power savings Technique

The Observability Don't Care (ODC) technique is one of the sequential clock-gating techniques to find a new enable or strengthen the existing enable for gated registers. When the downstream register is stable (disabled), the data coming to upstream register is not observable at the output. Hence, the upstream registers can be gated to save the clock power. Let us assume that for a given non-gated input register, if children register enable are stable(disabled), then the input register can be gated using the enable of children, avoid the switching activity of its clock and hence saving the power. This could be done at the power overhead of integrated clock gate cell. This command exactly does this and currently it only looks at the ODC condition of the immediate children of the registers/ bus registers and reports them if there is any power savings.

Register Name in report

The command prints the RTL register name or the merged RTL names in case of bus registers by default. If mapping information does not exist for some registers the gate level name would get printed instead.

To print the gate-level register names instead of the RTL names use the option -report_nl_names.

Examples

The following example shows a list of bundled registers having a width >=8, where the power could be saved by employing ODC Techniques. The registers may have either a gated clock or not.

```
pt_shell> report_odc_power_savings -clock_gate_type all

report_parasitics_range

Reports the two factors of both parasitic resistance and capacitance range previously set by set_parasitics_range command.

Syntax

status *report_parasitics_range*

Feedback

Description

The *report_parasitics_range* command reports the two factors of both parasitic resistance and capacitance range previously set by set_parasitics_range.

Examples

The following example reports the parasitic scaling factors.

```
pt_shell> report_parasitics_Range

****************************************
Report : report_parasitics_range

Design : simple1

Version: T-2022.03-SP5-3-DEV-20231025

Date   : Sat Oct 28 10:28:48 2023

Feedback

report_path_group

Reports path_group information.

Syntax

string *report_path_group*

```
[-nosplit]
[path_group_list]
```

Data Types

path_group_list	list

Arguments

`-nosplit`

Does not split lines if a column overflows.

path_group_list

Displays the path group information for the *path_group_list* that is specified.

Description

Produces a report showing information about path groups in the *current_design* command. The report includes path groups automatically created by the *create_clock* command and those manually created with the *group_path* command. Path groups are used to affect the calculation of the Maximum Delay cost during optimization. The cost of each group is displayed using the *report_constraint* command.

Examples

The following command displays all the path groups in the current design.

```
pt_shell> report_path_group

****************************************
Report : path_group
Design : test
Version: A-2007.12-DEV
Date   : Sun Jul 29 12:03:16 2007

report_path_tag_set

Reports timing path tag sets created by the *create_path_tag_set* command.

Syntax

```
status report_path_tag_set
  [-name tag_names]
  [-show_pins]
```

Data Types

```
tag_names  list
```

Arguments

`-name tag_names`

Specifies a list of path tag sets to report. Without this option, the command reports all defined path tag sets.

`-show_pins`

Shows the path endpoint pins of the paths in the reported path tag sets, along with the number of tagged paths that end at each endpoint, listed in order of decreasing number of paths per endpoint.

Description

This command shows a list of the names of the currently defined timing path tag sets, along with the number of paths tagged for each tag name.

Examples

The following example shows that the path tag set named tag1 is associated with 500 timing paths, while the IN1 path tag set is associated with 10 timing paths.

```
pt_shell> report_path_tag_set
****************************************
Report : Path Tag Set
 ...
```

```
****************************************

Tag name                  |  Number of paths
-----------------------------------------
tag1                      |  500
N1                        |  10

1
```

The following example shows the path endpoint pins of the tagged paths along with the number of tagged paths associated with each endpoint.

```
pt_shell> report_path_tag_set -show_pins
 ...
****************************************
Report : Path Signature Count per Endpoint
 ...
****************************************

Number of endpoints: 182

Pin name                     |   Number of paths
-----------------------------------------------
TOP/I_BLDR/s4_reg[14]/D      |  16
TOP/I_BLDR/s4_reg[12]/D      |  16
TOP/I_BLDR/s2_reg[2]/D       |  8
TOP/I_BLDR/s2_reg[2]/D       |  8
pad[0]                       |  1
pad[1]                       |  1
 ...
```

---

report_point_to_point_resistance

Reports the point-to-point resistance (in ohms) for all combinations of pins and instance ports for specified nets.

Syntax

status *report_point_to_point_resistance*

```
-of_objects nets
[-limit no_pairs]
```

Feedback

Data Types

```
nets          list
no_pairs      integer
```

Arguments

`-of_objects` *nets*

A list of one or more nets for which to report point-to-point resistance. At least one net is required. Glob-style wildcards (*) are supported.

`-limit` *no_pairs*

Maximum number of resistances to report for each net. The default is 1000.

Description

This command reports the point-to-point resistance (in ohms) for all combinations of pins and instance ports for the specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a point-to-point resistance report.

```
pt_shell> report_point_to_point_resistance \
            -of_objects min_msb/conv_blk1/n105 -limit 3

************************************************
Report : Point to Point Resistance
Design : toprt
Version: Q-2019.12

min_msb/conv_blk1/U7/X      min_msb/conv_blk1/U14/C     0.024903
```

report_port

Displays port information within the design.

Syntax

string *report_port*

```
[-verbose]
[-design_rule]
[-drive]
[-input_delay]
[-output_delay]
[-wire_load]
[-nosplit]
[-sms_scenarios sms_scenarios_list]
[port_list]
```

Data Types

```
sms_scenarios_list  collection
port_list           list
```

Arguments

`-verbose`

Indicates that the port report includes all port information. By default, only a summary section is displayed that lists all ports and their direction.

`-design_rule`

Reports only port design rule information, including maxCap, manLoad, and maxFanout.

`-drive`

Reports only drive resistance, input transition time, and driving cell information for only input and inout ports.

`-input_delay`

Reports only the port input delay information you set.

`-output_delay`

Reports only the port output delay information you set.

`-wire_load`

Reports only the port wire load information.

`-nosplit`

Prevents line splitting if column overflows. Most design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only port information compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

port_list

Displays information on these ports in the current design. Each element in this list is either a collection of ports or a pattern matching the port names.

Description

Displays information about ports in the current design. By default, the command produces a brief report including all ports in the design.

The input and output delay information lists the minimum rise, minimum fall, maximum rise, maximum fall delays, and the clock to which the delay is relative. If "(f)" follows the clock name, the delay is relative to the falling edge of the clock; otherwise, the delay is relative to the rising edge. If "(l)" follows the clock name, input delay is considered to be coming from a level-sensitive latch, or output delay is considered to be going to a level-sensitive latch. By default, the delay is relative to a rising edge-triggered device.

Some information, such as whether the port is in an ideal network or not, is displayed after a timing update (as a result of manually executing an *update_timing* function or experiencing an implicit timing update as a result of executing other commands). This behavior is intended to help you to obtain information and statistics about ports without incurring the cost of a complete timing update.

Examples

This example shows the default port report.

```
pt_shell> report_port

Arguments

`-net_power`

Use this option to generate the net-based power report.

`-cell_power`

Use this option to generate the cell-based power report.

`-threshold_voltage_group`

Use this option to report the leakage power per voltage threshold group, instead of reporting the number of cells per voltage threshold group using the *report_threshold_voltage_group* command. You can also use this option in conjunction with the standard filtering options such as *-clocks*, *-groups*, and *-rail*.

`-lvth_groups low_vth_list`

Use this option to specify the list of threshold voltage groups to be considered as low threshold voltage. The value of the argument is a list of threshold voltage group identifiers. Each identifier is a non-empty string that might consist of

alphanumeric characters and the underscore character ("_"). If this option is omitted, no low threshold voltage groups are identified with the "L" attribute. This option is valid only with *-threshold_voltage_group* option.

`-leaf`

Use this option to indicate that the power report must traverse the hierarchy and report the nets or cells at lower-levels (as if the design's hierarchy were flat). The default is to report objects at only the current level of hierarchy. When you use this option in combination with the *-levels* option, the lower levels of the design hierarchy are traversed only to the depth you have specified.

`-include_boundary_nets`

Use this option to indicate that the switching power of primary input nets must be counted when generating the power report; the default is to exclude boundary input nets.

`-verbose`

Use this option to report verbose information, mainly in the header of the report, such as operating conditions, wire load models used to calculate power and the power unit information.

`-nworst` *`number`*

Use this option to filter the report so that it displays only the top-most *number* of the nets or cells sorted by a certain type of sort method.

`-sort_by` *`sort_method`*

Use this option to specify the sorting mode for the net or cell order in the power report.

`-nosplit`

Use this option to prevent line-splitting or section-breaking. By default, if the information for a given field exceeds its fixed column width, the next field begins on a new line, starting in the correct column (line-splitting). By default, if the information for one line exceeds the 80 character limit, the report is broken into two sections, each containing part of the information (section-breaking).

`-hierarchy`

Use this option to generate the hierarchy-based power report.

`-levels` *`level`*

Use this option to specify the number of hierarchy levels to be displayed in the hierarchy-based power report. When you use the *-leaf* option, the number of levels to traverse for the net and cell based report is also specified.

`-power_greater_than` *`threshold`*

Use this option to report only the nets or cells with total power value equal to or greater than *threshold* value.

`-clocks` *`clock_list`*

Use this option to report only the nets, cells, or both nets and cells that belong to the clock domains specified by the *clock_list* value.

`-groups` *`group_list`*

Use this option to report only the nets, cells, or both nets and cells that belong to the power groups specified by the *group_list* value.

`-include_estimated_clock_network`

Use this option to include the clock network power estimated by the *estimate_clock_network_power* command in the power report.

`-derate`

Use this option to include the effective power derate factors in the cell reports. It does not affect other types of reports.

`-rails` *`rails_supply_nets_name`*

Use this option to specify a list of supply nets under UPF mode or design rails under rail mapping mode for which the power values are reported.

`-pattern_priority` *`pattern_list`*

Specifies the list of patterns of cell name (or its attribute value) to be processed for generating the threshold voltage group leakage report.

`-attribute` *`attribute_name_for_cell_pattern`*

Specifies the attribute name, whose values are processed based on the pattern_priority list for generating the threshold voltage group leakage report.

`-pst`

Use this option to report power for valid power state combinations defined at the top level design.

`-relative_toggle_rate`

Use this option with *-net_power* option. When this option is used, the toggle rate specifies the relative toggle rate with respect to the related clock for the given design object.

`-significant_digits` *`digits`*

Specifies the number of digits of precision to be displayed by warnings that show floating point numbers. Allowed values are 0-13; the default is 4.

`-include_shutdown_cells`

Use this option to report shutdown cells as well for valid power state combinations defined at the top level design.

`-separate_glitch_power`

Allows the user to report glitch power components of internal and switching power separately . This option works in time_based mode when the variable "power_enable_clock_cycle_based_glitch" is enabled. When this option is enabled , for each cell or power group 2 additional columns are reported for glitch internal and glitch switching power. The regular internal and switching power columns exclude glitch power components.This feaure enabled, for each net 2 additional columns are reported for glitch rate and glitch switching power.

`-separate_glitch_power_component`

This option works in time_based mode when the variable "power_enable_clock_cycle_based_glitch" is enabled. When this option is enabled , for each cell or power group 2 additional columns are reported for glitch inertial and glitch transport power. The regular internal and switching power columns include glitch power components.

`-through_switch`

Use this option along with *-rail* option. Allows the user to report power associated with the supply_net after getting propagated through the switches.

`-include_lib_cells`

Use this option to report library cell name along with the cell names. -cell or -cell_power option is mandatory to be added to the command to use this option.

`-separate_switching_power`

Allows the user to split switching power into wire power and pin power. Generates net-based wire, pin and switching power report.

`-area`

Use this option to report cell area along with the cell-based or hierarchy-based power report. -cell_power or -hierarchy option is mandatory to be added to the command to use this option.

`-exclude_wire_load_info`

Use this option along with *-verbose* option to exclude wire load models from the verbose report.

`-compact_view`

Use this option for compact view of cell and rail based power report.

`-per_clock` *`per_Iclock_list`*

Use this option for design based report of each of the clock domain specified in the *per_clock_list* value. No any other option should be provided with this for reporting.

`-unit` *`power_unit`*

Use this option to specify the power unit to be used in the power report. Supported units are mW, uW, nW and pW.

`object_list`

Use this option to specify a list of cells, nets, or both to be displayed in the cell-based, net-based, or both cell- and net-based power report.

Description

Use the *report_power* command to generate a power report. It can be used in nondistributed power analysis or distributed power analysis. In the distributed power analysis, the command in the manager process has no options and only generates a merged power report for top design. The following description is for the normal distributed power analysis (nondistributed power analysis or usage in workers of distributed power analysis).

Generates power reports for the design or a specific hierarchy. The specific hierarchy is determined by the *current_instance* command. Before generating the report, power information is updated if necessary.

Four types of power reports can be generated: summary report, cell-based report, net-based report, and hierarchy-based report.

Summary Power Report

When none of the *-cell_power*, *-net_power*, or *-hierarchy* options are specified, a summary power report is generated. The summary power report displays internal, leakage, switching, and total power, as well as peak power, peak time, glitching power, and X transition power, if available, for the current instance, or the current design if the current instance is the top hierarchy of the current design. The summary power report also reports power for each power group. By default, all instances are placed in only one power group; so the summation of the power of the predefined groups equals the total power consumption of the design.

There are seven predefined power groups:

- io_pad: Cells defined as part of the pad_cell group in the library.
- memory: Cells defined as part of the memory group in the library.
- black_box: Cells with no functional description in the library.

- clock_network: Cells in the clock_network excluding io_pad cells.
- register: Latches and flip-flops driven by the clock network excluding io_pads and black_boxes.
- combinational: Nonsequential cells with a functional description.
- sequential: Latches and flip-flops clocked by signals other than those in the clock network.

See the Power Group Power Reporting section.

To report the total leakage breakdowns, set the *power_report_leakage_breakdowns* variable to *true*.

Cell-Based Power Report

When you specify the *-cell_power* option, the cell-based power is reported. The cell-based power report has two sections: Section one displays the cell internal power, cell leakage power, switching power of nets driven by the cell, total power, and percentage of total power compared with the overall power of all cells displayed in the report.

Section two reports the peak power, peak time, glitching power, and X transition power. Section two only shows up when there are peak power, glitching power, X transition power, or both.

When you specify the *-nosplit* option, the two sections are merged together. The peak power for a cell is only available if the waveform is created for this cell. For more information, see the *update_power* man page.

By default, only cells (including hierarchical cells) in current hierarchy are displayed. The power information displayed for a hierarchical cell is the total effect of all leaf cells contained by the hierarchical cell.

If the *power_report_leakage_breakdowns* variable is set to *true*, an additional section of leakage breakdowns is also be printed out.

If the *-derate* option is specified along with the *-cell_power* option, effective power derate factors are included in the power reports. The effective power derate factors are the ratio of derated power to underrated power of a cell. Power components with zero power derate factors are excluded from calculating effective power derate factors. In such a case, a 'z' attribute is added to the corresponding cell.

If you use the *set_power_analysis_options* command with the *-sdpd_tracking* option, the report shows an additional attribute flag "s" for those cells whose state-dependent and path-dependent (SDPD) switching activities are tracked.

If the *-include_lib_cells* option is specified along with the *-cell_power* option, library cell names are reported along with the cell name.

Net-Based Power Report

When you specify the *-net_power* option, the net-based power is reported. The net-based power report displays VDD, total net load, static probability, toggle rate, and net switching power.

By default, only nets in the current hierarchy are displayed. If you use the *-leaf* option, the report would traverse down all lower hierarchies and report all nets found in each hierarchy. When you specify the *object_list* option, only the nets in the object_list are reported. If a net has more than one net segment in different hierarchies, only the net segment in the top most hierarchy is listed in the report.

Hierarchy-Based Power Report

When you specify the *-hierarchy* option, the hierarchy-based power is reported. The report would be in a hierarchical format, with power information on a block-by-block basis. The hierarchy is shown through indentations. The *-levels* option specifies the number of levels of hierarchy to be displayed. Hierarchy levels deeper than the ones specified in this option are not shown in the report. If the *-leaf* option is specified, the leaf cell reference names are to be reported.

For each hierarchical block, the switching, internal, and leakage power are reported, as well as the total power and the percentage of total power compared with the overall power of the top hierarchy. The top hierarchy is determined by current_instance. Hierarchy-based report also has a second section to display peak power, peak time, glitching power, and X transition power, when necessary. Similarly, if the *-nosplit* option is specified, the two sections are merged together. Peak power for the hierarchy is only available if the waveform is created for this hierarchy.

For more information, see the *update_power* man page.

Rail and Supply Nets Based Power Reports

When you specify the *-rails* option, only the power reports associated with the specified rails or supply nets are generated. The *-rails* option accepts a list of name strings. Each name string can contain one or more rail or power supply net names separated by space. One power report is generated for each name string if it contains valid rails or supply nets. If the name string contains "all" keyword, a report of all rails is generated. Multiple power reports can be generated by using the *report_power* command with different combinations of rail names in the list. The *-rails* option works with other options of the *report_power* command to generate cell, hierarchical, or group-based power reports. For time-based power analysis, peak power reports are always for all rails, regardless of the rail specification. Currenlty peak power in consolidated reports is the highest peak among all rails.

Feedback

Negative Power Reporting

When you specify the *-power_greater_than* option along with an appropriate negative threshold value with the *-cell_power* option, the leaf cells with negative power are reported.

Sorting and Filtering

When you specify a certain sort mode with the *-sort_by* option, the list of cell and nets in the cell- based or net-based power report can be sorted. The available sorting modes for the *-net_power* or *-cell_power* option as following:

```
-net_power option          -cell_power option
   -----------------          ------------------
   name                       name
   net_static_probability     cell_internal_power
   net_switching_power        cell_leakage_power
   net_toggle_rate            dynamic_power
   total_net_load             total_power
   total_power
```

If both the *-net_power* and *-cell_power* options are specified and a sorting mode is explicitly selected, the selected sorting mode is used for both the cell and nets reports. Therefore, you must select a sorting mode that applies to both the *-net_power* and *-cell_power* options.

When reporting with the *-hierarchical* option, the same sorting modes are available as the *-cell_power* option. The report is first sorted by hierarchy and then sorted by the requested sorting method, preserving the hierarchical structure of the report.

If the sorting mode is not explicitly set, a default is chosen based on the mode of the *report_power* command:

```
Mode                          Implicit default
      ----------                    ------------------
      -net_power                    net_switching_power
      -cell_power                   cell_internal_power
      -net_power -cell_power        dynamic_power
```

The sorted list of the cells and nets in the cell-based and net-based power report can be filtered to display only the top most number of cells or nets specified by the *-nworst* option.

Clock Domain Power Reporting

When you specify the *clock_list* value with the *-clocks* option, a power report is generated for the cells and nets in the specified clock domains.

The cells and nets in the clock tree network of CLK clock are taken as belonging to CLK clock domain. The cells and nets in a timing path launched by the CLK clock are regarded as belonging to CLK clock domain. The cells and nets in a timing path with no launch clock, but captured by the CLK clock are regarded as belonging to the CLK clock domain

as well. If a cell or net belongs to multiple clock domains, it is forced to belong to the clock domain with the fastest clock. If a cell or net belongs to no clock domains, it is forced to belong to the fastest clock domain in the design.

The power for the design or a hierarchy is no longer the total effect of all leaf cells in the design or hierarchy, but instead, the total effect of all leaf cells that are in the design or hierarchy AND belong to the specified clock domains.

Clock domain power reporting supports all of the four types of power report.

Power Group Power Reporting

When you specify the *group_list* value with the *-groups* option, a power report is generated for the cells and nets in the specified clock domains.

Power groups can be created by the *create_power_group* command. The tool has also several predefined power groups. For more information, see the *create_power_group* man page.

The power for the design or a hierarchy is no longer the total effect of all leaf cells in the design or hierarchy, but instead, the total effect of all leaf cells that are in the design or hierarchy AND belong to the specified power groups.

Power group power reporting supports all of the four types of power report. In the summary power report, if the *-groups* option is not specified, all the power groups are reported. For each power group, the cumulative switching, internal, and leakage power of the power group are reported, as well as the total power and the percentage of the total power compared with the overall power of the top hierarchy. The top hierarchy is determined by current_instance. This power group report also has a second section to display the peak power, peak time, glitching power, and X transition power, when necessary.

Similarly, if the *-nosplit* option is specified, the two sections are merged together. Peak power for the power group is only available if the waveform is created for this power group. For more information, see the *update_power* man page.Option *-nosplit* is supported along with option *-significant_digits*.

Clock Tree Power Reporting

Clock tree power and register (driven by the clock tree) power can be reported using the *report_power* command by using the power group power reporting. There are two predefined power groups: clock_network and register. The clock_network power group contains all cells in the clock tree network. The register power group contains all registers driven by the clock tree network.

The *power_clock_network_include_clock_gating_network* and *power_clock_network_include_register_clock_pin_power* variables can affect clock tree power reporting. For more information, see the man pages.

The clock tree power reporting supports all of the four types of power report. By default, the summary power report displays power of the predefined clock_network and register power groups. An attribute label "i" is used to indicate whether the clock_network or register power group includes the register clock pin power. In the cell-based power report, an attribute label "c" is used to indicate that only clock pin internal power is displayed for the register cell; a "d" attribute label is used to indicate that the power displayed for the register cell does not include the register clock pin internal power.

The clock tree power for certain clocks (if not all clocks) can be reported by combining the *-groups* and *-clocks* options.

Estimated Clock Tree Power Reporting

Clock tree power and register (driven by the clock tree) power estimated using the *estimate_clock_network_power* command can be reported using the *-include_estimated_clock_network* option. Estimated clock tree power can only be reported in the Summary Report; therefore, the *-cell_power* and *-net_power* options cannot be specified together with the *-include_estimated_clock_network* option.

The power of the existing clock tree network, if any, is subtracted from the total power, and the power of the estimated clock tree power is added. If the estimated clock tree power includes register power by using the *estimate_clock_network_power -include_registers* command, the power of the existing registers is subtracted from the total power and the power of the estimated register power is added. Accordingly, the power for the power groups "clock_network" and "register" should be affected. These power groups do not include estimated clock network power. However, the power for the existing clock network is subtracted.

A new section in the Summary power report section shows the estimated clock network power for each clock that has been estimated. The *estimate_clock_network_power* command must be used before the *report_power* command. Multiple *estimate_clock_network_power* commands can be used, but only the power from the latest command that estimates clock tree power for a certain clock is reported by the *report_power* command.

The *-clocks* option can be specified together with *-include_estimated_clock_network* option. In this case, only the clock tree power estimated for the specified clocks is included in the power report.

The *-groups* option can be specified together with *-include_estimated_clock_network* option. In this case, only when the *clock_network* and *register* power groups are specified, the estimated clock network power is reported.

Low-Level Hierarchy Power Reporting

Power reports can be generated for the top design and a lower-level hierarchy. The hierarchy can be determined by *current_instance*. The power reports for the top design are special cases, when the current instance is the top-level hierarchy of the design. If the

current instance is not the top design, only the cells or nets under the current instance are targeted for power reporting.

To generate different power reports for each clock domain, power group, and hierarchy, combine the *-clocks* and *-groups* options with using the *current_instance* command.

PST based Power Reports

When you specify the *-pst* option, PST based power analysis reports are generated. It reports power for valid power state combinatios defined at the top level design. This feature requires that the variable *upf_enable_pst* is set to *true* before load_upf. Option *-pst* can be specified with other *report_power* options to generate cell and hierarchical power reports. But it cann't be specified with *-rails* option. These two reportng features are mutually exclusive.

Examples

The following example shows a verbose summary power report.

```
pt_shell> report_power -verbose
****************************************
Report : power
        -verbose
 ...

report_power_analysis_options

Reports the options for power analysis.

Syntax

status *report_power_analysis_options*

Arguments

None.

Description

The *report_power_analysis_options* command reports the default and user settings for power analysis.

The *collection_result_display_limit* variable specifies the number of cells displayed by the *set_power_analysis_options -cell* command.

Examples

The following is an example from the *report_power_analysis_options* command output:

```
pt_shell> report_power_analysis_options

****************************************
Report : Power Analysis Options
 ..
****************************************

Power analysis mode : time_based

  Option Name              Value
-------------------------------------
  include                  top
  waveform_format          fsdb
  waveform_output          ptpx
```

---

report_power_budget

Reports power budget and derived scaling factors for the hierarchical instances in the design.

Syntax

```
int report_power_budget
```

Description

This command is used to report the power budget and derived scaling factor for the hierarchical instances in the design.

Examples

In the following example, power budget have been set on the following hierarchies.

Feedback

```
pt_shell> set_power_budget 8.513e-05 -cell four_mini_inst/two_mini_1/a
pt_shell> set_power_budget 2.338e-04 -cell four_mini_inst/two_mini_1
 -rails four_mini_inst/VDD_MINI_1
pt_shell> set_power_budget 9.354e-05 -cell four_mini_inst/two_mini_1/a
 -rails four_mini_inst/VDD_MINI_1

report_power_calculation

Displays the actual calculation of internal power for a pin, leakage power for a cell, or switching power for a net.

Syntax

integer *report_power_calculation*

```
[-state_condition state]
[-path_sources name_list]
[-rise]
[-fall]
[-verbose]
[-report_output prefix]
[-report_type type]
[-time]
[-sensitivity]
[-exclude_wire_load_info]
object_list
```

Feedback

Data Types

state	string
name_list	string
prefix	string
type	string
object_list	list

Arguments

`-state_condition` *state*

Specifies that the report should be restricted to tables or polynomials with matching state condition. This option can only be specified for objects of type pin or cell. Use the *-state_condition default* option to specify the default state condition. Use the *-state_condition all* option to specify that all states must be considered for reporting.

`-path_sources` *name_list*

Specifies the related input pin that causes the output pin transition. This option can only be specified for objects of type pin. The path information is used not only for picking the internal power table or polynomial, but also for choosing the input transition time for power calculation if the input transition time is one of the variables. Use the *-path_sources default* option to specify the default path source (without related pin). Use the *-path_sources all* option to specify all possible paths.

`-rise`

Specifies that the internal power report should be limited to rise transition only. If not specified, both rise and fall transitions are reported, which is equivalent to specifying both the *-rise* and *-fall* options.

`-fall`

Specifies that the internal power report should be limited to fall transition only. If not specified, both rise and fall transitions are reported, which is equivalent to specifying both the *-rise* and *-fall* options.

`-verbose`

Specify this option to increase the amount of information that is reported for cells or pins. For cells, the leakage power calculation report is appended by an internal power calculation report for all pins and all possible states and path sources of the cells in the object list. For pins, all the possible states and paths are printed, which is equivalent to the *-state_condition all -path_sources all* option.

`-report_output` *`prefix`*

This option is applicable only in time_based mode and it is specifies the prefix of the reports to be generated. By default the report names are ptpx_detailed.rpt and ptpx_summary.rpt .

`-report_type` *`type`*

This option is applicable only in time_based mode and the valid values are 'detailed' , 'summary' and 'both'. If nothing is specified both detailed and summary reports are generated.

`-time`

Specify the time window for which the report is to be generated in time_based mode. If nothing is specified report is generated for the entire simulation time .

`object_list`

Specifies the objects for which the power calculation is reported. The type of power calculation depends on the object type. For a pin, internal power calculation is reported. For a cell, a leakage power calculation report is produced. For a net, a switching power calculation report is produced. In time_based mode , only cell object type is allowed.

`-sensitivity`

Specify this option to control LLE related sensitivity warnings.

`-exclude_wire_load_info`

This option excludes wire load information reported. Used along with *verbose* option.

Description

The *report_power_calculation* command provides detailed power calculation information for the specified pin, cell, or net. You can use this information for debugging or verifying power data in a technology library. Before using this command to display details of internal or leakage power calculation, read the technology library file into the system with the library features attribute, the *report_power_calculation* attribute included in the library - "library_features (report_power_calculation)", which enables the report_power_calculation command for internal, leakage, and net switch- ing power. If the library is missing this feature, then users do not have access to the power table values in library used to calculate power. Therefore, the built-in security mechanism terminates the command. And, details of power calculation information will not be displayed.

In time_based mode this command generates a detailed report on the sequence of events processed for power calculation for the specified list of cells and time window. It also generates a summary report containing the sdpd activites for the specified cells. The

options 'state_condition' , 'rise' , 'fall' and 'path_sources' are not applicable in time_based mode.

PrimePower supports power net based power report feature for multivoltage designs. You can use the *set_current_power_net* command to set the power net of interest. Only the power dissipated on the specified power nets is calculated and reported. By default (unless otherwise specified), all the power nets are included in the power analysis. Use the *get_current_power_net* command to show the current power net setting.

Examples

This example shows the calculation of path dependent internal power from input pin B to output pin Y. The contributions for rise and fall internal power are shown separately.

```
pt_shell> report_power_calculation [get_pin U4/Y] -state default -path B

report_power_capacitance

Displays the total power capacitance including wire cap, sum of all sink pin cap and subtract port cap for the specified nets in design, by default reports all nets in design.

Syntax

integer *report_power_capacitance*

```
[-nets object_list]
[-detailed]
[-verbose]
```

Data Types

object_list	list

Arguments

`-nets object_list`

reports total power capacitance of specified nets in design along with wire cap and sum of all sink pin cap. Also reports cap type for each net.

`-detailed`

Generates detailed report for each net separate wire cap and each of the sink pin cap.

`-verbose`

Generates detailed report for each net separate wire cap and each of the sink pin cap. Also provides calculation details for each pin individual looked up cap pieces c1cn aggregation of cap pieces to calculate the lumped capacitance.

object_list

Specifies the objects for which the power capacitance is reported. Objects includes all nets in design, by default reports all nets in design.

Feedback

Description

The *report_power_capacitance* command to query native power capacitance information for the specified net. You can use this information for debugging or verifying power capacitance.

Examples

This example shows net based power capacitance reporting.

```

report_power_check_attributes

Allows user to see what bit value represented by option pin_propagation_check, pin_qm_propagation_check, internal_power_check, leakage_power_check.

Syntax

```
string report_power_check_attributes
[-pin_propagation_check]
[-pin_qm_propagation_check]
[-internal_power_check]
[-leakage_power_check]
[-all]
```

Arguments

`-pin_propagation_check`

This option must be provided for attribute pin_propagation_check to know which bit represent what value.

`-pin_qm_propagation_check`

This option must be provided for attribute pin_qm_propagation_check to know which bit represent what value.

`-internal_power_check`

This option must be provided for attribute internal_power_check to know which bit represent what value.

`-leakage_power_check`

This option must be provided for attribute leakage_power_check to know which bit represent what value.

`-all`

This option must be provided for attribute pin_propagation_check , pin_qm_propagation_check , internal_power_check and leakage_power_check to know which bit represent what value.

Description

This command enables user to know bit position what they signify from pin_propagation_check, pin_qm_propagation_check , internal_power_check , leakage_power_check or all attributes.

Examples

The following *report_power_check_attributes command dsipaly option pin_propagation_check bit position what it signify.*

```
pt_shell> report_power_check_attributes -pin_propagation_check

bit sequence            type
left to right
-----------------------------------------
0                       unattempted
1                       missing_lib
2                       missing_function
3                       broken_function
4                       missing_statetable
5                       broken_statetable
6                       clean
```

The following *report_power_check_attributes command display option internal_power_check bit position what it signify.*

```
pt_shell> report_power_check_attributes -internal_power_check

bit sequence            type
left to right
-------------------------------------
0                       unattempted
1                       missing_lib
2                       missing_table
3                       broken_table
4                       out_of_range
5                       clean
```

Feedback

report_power_delay_shifted_event_analysis_options

Reports the options for delay shifted event analysis.

Syntax

integer *report_power_delay_shifted_event_analysis_options*

Description

This command is used when *power_enable_delay_shifted_event_analysis* is set to true. The command is used to report the delay shifted event analysis options set by '*set_power_delay_shifted_event_analysis_options*.

Examples

```
pwr_shell> report_power_delay_shifted_event_analysis_options
effort_level              : low
write_activity_file       : my_design_shifted.fsdb
include_external_delay    : false
```

See Also

- power_enable_delay_shifted_event_analysis
- set_power_delay_shifted_event_analysis_options
- reset_power_delay_shifted_event_analysis_options

report_power_derate

Reports power derate factors annotated on the current design.

Syntax

```
int report_power_derate
[-include_inherited]
[-significant_digits digits]
[-nosplit]
[-x_transition]
[-pin_switching]
[-cnod]
object_list
```

DATA TYPES

```
object_list          list
digits               int
```

Feedback

Arguments

`-include_inherited`

Indicates that the power derating factors reported on each object should also include those set by other objects in the design.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point to be displayed for values in the report. Allowed values are 0-12; the default is determined by the report_default_significant_digits variable. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The -nosplit option prevents line-splitting and facilitates writing software to extract information from the report output.

`-x_transition`

Reports representative nets and pins having x-transition power derating factors along with their derate values.

`-cnod`

Reports derate factors applied in context leakage power calculations.

`-pin_switching`

Reports representative pins having pin switching power derating factors along with their derate values.

`object_list`

Specifies current design or a list of cells or library cells or nets or pins from which the power derating factors are reported.

Description

This command is used to report the derate factors either on the design, specific cells, library cells, nets or pins contained in the design. If this command is called without any option, a separate report will be invoked for the power derating factors stored on the current design (referred to as global power derating factors) and also for each cell, library cell, pin or net that has power derating factors set on it.

If this command is called with the boolean option *-include_inherited*, each row containing an inherited derating factor will contain a column entry indicating the object from which it was inherited. If the command is called with the *object_list* specified then derate reports will only be issued for the instances specified in the object list.

For significant digits used in power derate report, the *-significant_digits* option can be used. If the option is not specified, the value of the *report_default_significant_digits* variable is applied. By default, the number of significant digits used to display values is 2.

Examples

In the following example, power derating factors have been set globally on the design; therefore, only global derate factors are reported.

```
pt_shell> set_power_derate -switching 0.92
pt_shell> set_power_derate -internal  1.15
pt_shell> set_power_derate -gate_leakage 0.75
pt_shell> set_power_derate -subthreshold 1.26
pt_shell> report_power_derate

pt_shell> report_power_derate
****************************************
Report : power derate

report_power_domain

Reports the specified power domain.

Syntax

integer *report_power_domain*

[*domain_list*]

Data Types

domain_list	list

Arguments

domain_list

Specifies the list of power domains reported. The names in the list should be a simple (nonhierarchical) name.

If there is no such a power domain with the same name in the current scope, the command fails.

If this option is not specified, all power domain in the specified scope is reported.

Description

The *report_power_domain* command enables you to get the detailed information of an existing power domain in the current scope. The information of the power domain includes the full name, scope, element, and primary power and ground net.

The command returns 1 if it succeeds, and returns 0 otherwise.

Examples

Here are examples of the *report_power_domain* output:

```
pt_shell> report_power_domain
****************************************
Report : power domains
Design : top
Version: A-2007.12
Date   : Thu Sep 27 18:59:04 2007

report_power_groups

Report the existing power groups.

Syntax

string *report_power_groups*

```
[group_names]
[-nosplit]
```

Data Types

```
group_names        list
```

Arguments

group_names

Specifies the power group names that are to be reported.

-nosplit

Indicates to prevent line splitting if column overflows.

Description

The *report_power_groups* command reports the power groups that has been created in the earlier stage, including the predefined power groups.

Examples

In the following example, all the existing power groups are reported.

```
pt_shell> create_power_group -name clock_tree [get_clock_network_objects
 -type cell]
```

report_power_network

Reports connectivity in the virtual power network formed by UPF supply nets, ports, and PG pins.

Syntax

string *report_power_network*

```
[-nets nets]
```

Data Types

```
nets      string
```

Arguments

```
-nets nets
```

Reports explicit connectivity of a subset of nets.

Description

This command reports the explicit connectivity of supply nets, ports, and connected power and ground pins.

Examples

The following example shows the explicit connections of the given supply net, VDDI when you specify the *connect_supply_net* command.

```
prompt> report_power_network -nets VDDI

 Supply Net: VDDI
  Explicit Connections:
    Name :              Object Type           Domain

report_power_pin_info

Reports the power pin information for logic library cells or leaf cells.

Syntax

status *report_power_pin_info*

```
        object_list
```

Feedback

Data Types

```
object_list      list
-show_rail_name
```

Arguments

object_list

Specifies a list of logic library cells or a list of leaf cells or ports.

-show_rail_name

this option gives the rail name.

Description

The *report_power_pin_info* command reports the power pin information for logic library cells or leaf level cells in the current design.

If you specify a list of library cells, the name, the types, and the voltage specification of the power pins are reported. All types of PG pins including power, ground, and bias pins are shown.

If you specify a list of leaf cells as the *object_list*, the power net information that are connected to the power pins are also reported. Hierarchical cells are ignored by this command.

Examples

The following example uses the command to report the power pin information.

```
pt_shell> report_power_pin_info [get_cells -hierarchical]

****************************************
Report : power pin info
Design : top
 ...
****************************************

Note: Power connections marked by (*) are exceptional

Cell            Power Pin Name      Type                Voltage   Power
 Net Connected
-------------------------------------------------------------------------
---------------
PD0_INST/I0     PWR                 primary_power        1.0000

report_power_rail_mapping

Reports the current power rail mapping.

Syntax

status *report_power_rail_mapping*

```
[-cells cell_list]
[-verbose]
[-nosplit]
```

Feedback

Data Types

cell_list	list

Arguments

`-cells` *cell_list*

Specifies the instance names or collections of instances. This only takes effect when the *-verbose* option is used. The instance can be hierarchical or leaf instances. For a instance block, only the top instance needs to be specified. All the leaf instances inside such blocks are reported. Without this option, the mapping is reported for the whole design.

`-verbose`

Reports detailed rail mapping for each individual leaf instance. Choose the leaf instances to be reported by using the *-instance* option. When this option is used, PrimePower also checks potential problems in rail mapping done for the instances. The list of checks are:

- Different library rails are mapped to the same design rail in a multirail leaf cell
- No rail specific power table is defined for a library cell with multiple power rails

`-nosplit`

Most of the information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

Description

The *report_power_rail_mapping* command displays all the power rails defined in the library and those existing in the design. The library power rails are the *voltage_map* attributes defined in the library (or the *power_rail* attributes defined in the *power_supply* group). The design power rails are the rails created by the *create_power_rail_mapping* command. If a library does not have rail information, default_rail is shown for its library power rail. If the mapping does not exist, the default design power rail is shown and labeled with *(default)*. During power simulation, those missing cases are actually mapped to the default design power rail. Internally, there is a default rail associated with each library and with the whole design. If the *-verbose* option is used, PrimePower reports the detailed rail mapping for each individual leaf instances and also shows possible rail mapping problems for design.

Examples

Here is an example of the *report_power_rail_mapping* command:

```
pt_shell> report_power_rail_mapping -verbose -cells block1
```

Feedback

See Also

- create_power_rail_mapping

---

report_power_switch

Report all power switches defined in the design.

Syntax

int *report_power_switch*

Arguments

None.

Description

The *report_power_switch* command enables you to get the detail information of all power_switches defined in the design. The power switch information includes:

- full name
- power domain where it is created in
- output supply port
- input supply port
- control port
- on_state statement

The command returns 1 if it succeed; otherwise, it returns 0.

Examples

The following example reports the information of all power_switches defined:

```
pt_shell> report_power_switch

  Power Switch : SW1
----------------------------------------
    Power Domain : PD1
    Output Supply Port : vout VN2
    Input Supply Port : vin VN1
    Control Port : ctrl_small ON1
    Control Port : ctrl_large ON2
    On State : state1 vin { ON1 & ON2 }
----------------------------------------
1
```

See Also

- create_power_switch

Feedback

report_pst

Reports the power state table defined in the current design previously using *add_power_state* command.

Syntax

status *report_pst*

```
[-verbose]
```

Arguments

```
-verbose
```

Also reports the power states defined on supply sets.

Description

This command reports the power state table of the current design. This reflects the power state table defined by user using *add_power_state* and *create_power_state_group* commands.

Examples

The following UPF script defines the power states on the supplies and then the legal power state combinations for the design, and the *report_pst* command reports the resulting power state table.

```
prompt> add_power_state -supply SS1 \\
        -state ON  {-supply_expr {power == {FULL_ON 0.8} && ground ==
 {FULL_ON 0}}}
prompt> add_power_state -supply SS2 \\
        -state ON  {-supply_expr {power == {FULL_ON 0.8} && ground ==
 {FULL_ON 0}}} \\
        -state OFF {-supply_expr {power == {OFF} && ground == {FULL_ON
 0}}}
prompt> create_power_state_group MY_PST_GROUP
prompt> add_power_state -group MY_PST_GROUP \\
        -state RUN   {-logic_expr {SS1 == ON && SS2 == ON}} \\
        -state SLEEP {-logic_expr {SS1 == ON && SS2 == OFF}}

prompt> report_pst
 ...

  Total of 1 power state group defined for design 'mydesign'.

------------------------------------------------------------------------
------
    Power State Group : MY_PST_GROUP
      Scope : <top level>
      Group Members : SS1          SS2
```

```
      Total of 2 power state combinations on this group :
      RUN           : ON           ON
      SLEEP         : ON           OFF

prompt>report_pst -verbose
 ...

  Total of 1 power state group defined for design 'mydesign'.

--------------------------------------------------------------------------
------
    Power State Group : MY_PST_GROUP
      Scope : <top level>
      Group Members : SS1          SS2
      Total of 2 power state combinations on this group :
      RUN           : ON           ON
      SLEEP         : ON           OFF

  Power states defined on supply sets for design 'top'.

--------------------------------------------------------------------------
------
    Supply Set : SS1 has 1 state defined:
      State : ON, power : FULL_ON 0.90, ground : FULL_ON 0.00
--------------------------------------------------------------------------
------
    Supply Set : SS2 has 2 states defined:
      State : ON, power : FULL_ON 0.90, ground : FULL_ON 0.00
      State : OFF, power : OFF, ground : FULL_ON 0.00
```

---

report_pulse_clock_max_transition

Displays maximum transition computation at the input of pulse generator and pulse clock network.

Syntax

int *report_pulse_clock_max_transition*

```
[-all_violators]
[-significant_digits digits]
[-nosplit]
[-rise]
[-fall]
```

Feedback

```
[-transitive_fanout]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

digits	int
port_pin_list	list
sms_scenarios_list	collection

Arguments

`-all_violators`

Specifies that only the pins violating maximum transition constraint are reported.

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line splitting and facilitates writing software to extract information from the report output.

`-rise`

Report slack for rise transition.

`-fall`

Report slack for fall transition.

`-transitive_fanout`

Report transition slack at the transitive fanout of pulse generator cells. If this option is not set, the transition slack is reported at the input of pulse generator cells.

port_pin_list

Specifies a list of pins or ports to report. By default, the report contains all pins with pulse clock maximum transition constraint.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only pulse clock information compatible to the specified SMS scenarios collection is reported. This option

is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_pulse_clock_max_transition* command displays the maximum transition computation of pins and ports. By default, only the input pins of the pulse generators are reported. If rise or fall is not specified, both rise and fall transition slack are reported. To enable pulse clock constraint checking, ensure the *timing_enable_pulse_clock_constraints* variable is set to *true*, which is its default.

Examples

The following example generates a report of all transition slack computation at the input of pulse generators in the current design.

```
pt_shell> report_pulse_clock_max_transition
****************************************
Report : pulse clock max transition
        -rise
        -fall
Design : test

---

report_pulse_clock_max_width

Displays maximum pulse width computation for the pulse clock network.

Syntax

int *report_pulse_clock_max_width*

```
[-all_violators]
[-significant_digits digits]
[-nosplit]
[-path_type format]
[-transitive_fanout]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

```
digits                int
format                string
port_pin_list         list
sms_scenarios_list    collection
```

Feedback

Arguments

`-all_violators`

Specifies that only the pins in the pulse clock network violating the maximum pulse width constraint are reported.

`-significant_digits` *`digits`*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line splitting and facilitates writing software to extract information from the report output.

`-path_type` *`format`*

Specifies the format of the path report and how the clock path is displayed. The allowed values are its default of *summary* and also *short*. The *summary* value generates a report with a column format that shows one line for each path and shows only the required pulse width, actual pulse width and slack; The *short* value displays only startpoints and endpoints in the clock path.

`-transitive_fanout`

Report constraints at the transitive fanout of pulse generators. Currently, specifying or not specifying this option has the same behavior.

`port_pin_list`

Specifies a list of pins or ports to report. By default, the report contains all pins with pulse clock maximum width constraint.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only pulse clock information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_pulse_clock_max_width* command displays the maximum pulse clock width computation of the specified pins and ports. By default all pins with pulse clock width constraint are reported. To enable pulse clock constraint checking, ensure that the *timing_enable_pulse_clock_constraints* variable is set to *true*, which is the default.

Feedback

Examples

The following example generates a report of all maximum pulse width violations in the current design.

```
pt_shell> report_pulse_clock_max_width

report_pulse_clock_min_transition

Displays minimum transition computation at the input of pulse generator.

Syntax

int *report_pulse_clock_min_transition*

```
[-all_violators]
[-significant_digits digits]
```

Feedback

```
[-nosplit]
[-rise]
[-fall]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

```
digits                int
port_pin_list         list
sms_scenarios_list    collection
```

Arguments

`-all_violators`

Specifies that only the input pins of pulse generators violating minimum transition constraint is reported.

`-significant_digits digits`

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which defaults to 2. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line splitting and facilitates writing software to extract information from the report output.

`-rise`

Reports slack for rise transition.

`-fall`

Reports slack for fall transition.

port_pin_list

Specifies a list of pins or ports to report. By default, the report contains all pins with pulse clock minimum transition constraint.

`-sms_scenarios sms_scenarios_list`

Specifies a collection of SMS scenarios to analyze. Only pulse clock information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Feedback

Description

The *report_pulse_clock_min_transition* command displays the minimum transition computation of pins and ports. By default, all pins with pulse clock minimum transition constraint are reported. Similarly, if rise or fall is not specified, then both rise and fall transition slack is reported. To enable pulse clock constraint checking, ensure the *timing_enable_pulse_clock_constraints* variable is set to its default of *true*.

Examples

The following example generates a report of all minimum transition violations in the current design.

```
pt_shell> report_pulse_clock_min_transition
****************************************
Report : pulse clock min transition
         -rise
         -fall
Design : test
****************************************

   pulse_clock_min_transition_rise

---

report_pulse_clock_min_width

Displays minimum pulse width computation for the pulse clock network.

Feedback

Syntax

int *report_pulse_clock_min_width*

```
[-all_violators]
[-significant_digits digits]
[-nosplit]
[-path_type format]
[-transitive_fanout]
[-sms_scenarios sms_scenarios_list]
[port_pin_list]
```

Data Types

digits	int
format	string
port_pin_list	list
sms_scenarios_list	collection

Arguments

`-all_violators`

Specifies that only the pins in the pulse clock network violating the minimum pulse width constraint is reported.

`-significant_digits digits`

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default value is 2. Use this option if you want to override the default.

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line splitting and facilitates writing software to extract information from the report output.

`-path_type format`

Specifies the format of the path report and how the clock path is displayed. Allowed values are *summary* (the default) and *short*. The *summary* value generates a report with a column format that shows one line for each path and shows only the required pulse width, actual pulse width, and slack. The *short* value displays only start and end points in the clock path.

`-transitive_fanout`

Reports constraints at the transitive fanout of pulse generators. In this release, specifying or not specifying this option has the same behavior.

port_pin_list

Specifies a list of pins or ports to report. By default, the report contains all pins with pulse clock minimum width constraint.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only pulse clock information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_pulse_clock_min_width* command displays the minimum pulse clock width computation of the specified pins and ports. By default, all pins with pulse clock width constraint are reported. To enable pulse clock constraint checking, ensure the *timing_enable_pulse_clock_constraints* variable is set to its default of *true*.

Examples

The following example generates a report of all minimum pulse width violations in the current design.

```
pt_shell> report_pulse_clock_min_width
****************************************
Report : pulse clock min width
         -path_type summary
Design : test

report_pvt_explorer_condition

Reports PVT explorer condition set by *set_pvt_explorer_condition*.

Syntax

string *report_pvt_explorer_condition*

Description

The *report_pvt_explorer_condition* command reports PVT explorer condition set by *set_pvt_explorer_condition*, which is used in PrimeShield PVT Explorer what-if analysis. *define_sensitivity_lib_mapping* is required to do the analysis. And *set ps_enable_pvt_explorer_analysis true* is required to use *set_pvt_explorer_condition* or *report_pvt_explorer_condition* command.

Examples

The following script enables PVT Explorer analysis, and report the PVT explorer condition, where "one_cond.txt" file content as follows:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode false
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]

set_pvt_explorer_condition one_cond.txt
update_timing -full
update_power

pt_shell> report_pvt_explorer_condition
Information: PVT Explorer condition =
  param_name  perturbation
================================================
  pmos_lvt_vt    0.02
  nmos_lvt_vt    0.02
```

```
  pmos_lvt_ids0  0.15
  nmos_lvt_ids0  0.15

1
```

The following script enables PVT Explorer what-if analysis for timing path robustness, and report the PVT explroer condition, where "multiple_DoEs.txt" file content as follows:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15 2,0.011,0.011,0.10,0.10

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
update_timing -full  # baseline QoR
set paths [get_timing_paths ...]

set_pvt_explorer_condition multiple_DoEs.txt
#update original path collection with slack shift per DoE
set paths_new [get_timing_paths -pba_mode path $paths]
#generate slack shift per DoE for all paths
puts [get_attr $paths_mew pvt_explorer_slack_shift]

pt_shell> report_pvt_explorer_condition
Information: PVT Explorer condition loaded as follows
index pmos_lvt_vt nmos_lvt_vt pmos_lvt_ids0 nmos_lvt_ids0
============================================================
1  0.02   0.02   0.15  0.15

---

report_qor

Provides an overview of the quality of a design.

Feedback

Syntax

```
status report_qor
[-max]
[-min]
[-significant_digits digits]
[-only_violated]
[-summary]
[-physical]
[-pba_mode none | path | exhaustive | ml_exhaustive]
[-sms_scenarios sms_scenarios_list]
[-drc_violations]
[-area]
[-object_count]
[-timing]
```

Data Types

```
digits                integer
sms_scenarios_list    collection
```

Arguments

`-max`

Indicates that only maximum delay and setup information is to be displayed. If this option is not specified, the report for both min and max delay types is produced.

`-min`

Indicates that only minimum delay and hold information is to be displayed. If this option is not specified, the report for both min and max delay types is produced.

`-significant_digits` *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which has a default of 2. Use this option to override the default.

`-only_violated`

Shows timing path group summaries for only violating path groups. The area, object count, and DRC violation sections will be displayed unless the *-timing* is specified.

`-summary`

Summarizes the worst negative slack (WNS) and total negative slack (TNS) for all path groups. See *timing_report_union_tns* for details of TNS calculation. The area, object count, and DRC violation sections will be displayed unless the *-timing* is specified.

`-physical`

This option has no effect in PrimeTime.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Controls path-based analysis with the following modes:

- *none* (the default) - Path-based analysis is not applied.
- *path* - Path-based analysis is applied over the paths that gave the worst graph-based analysis violation. There is no guarantee that the reported path-based analysis slack over every endpoint is the worst one.
- *exhaustive* - An exhaustive path-based analysis path search algorithm is applied to determine the worst path-based analysis slack violations.
- *ml_exhaustive* - Performs Machine Learning based exhaustive path-based analysis. This mechanism will deploy machine learning techniques to trade runtime vs accuracy during the design flow. Accuracy and runtime will match pba_mode exhaustive as the design approaches signoff.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only QoR information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`-timing`

Print per path group and for setup and hold; the length of the worst path (shown as the "Critical Path Length" in the report, which represents the arrival time of the signal at the path's endpoint) and its slack as well as the the total negative slack.

The area, object count and drc violation sections will not be displayed unless their respective options are also provided.

`-area`

Print the total area summary only

`-object_count`

Print the cell and pin count summary only

`-drc_violations`

Print the summary of design related constraint violations.

Feedback

Description

The *report_qor* command provides an overview of the quality of results (QoR) for a design, including the length of the worst paths (shown as "Critical Path Length" in the report, which represents the arrival time of the signal at the path's endpoint), total negative slack, minimum delay and hold summaries, and a detailed DRC summary. When no options are specified the default output is equivalent to *report_qor -timing -area -object_counts -drc_violations*. Specifying any of *-timing*, *-object_counts*, *-drc_violations*, *-area*, *-summary*, and *-only_violated* options tailors the output to only report those summary sections.

Only *-timing*, *-object_counts*, *-drc_violations*, and *-area* are supported at the manager in distributed analysis mode. All the options are supported with the command, if executed on remote workers as part of the distributed command *remote_execute -partitions*.

If you specify the *-pba_mode exhaustive* option, path-based analysis is used to calculate the slack values. This option requires that a path search be performed to ensure that the returned slack values are truly the worst. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing improvement from path-based analysis increases, the runtime for the path search increases.

Examples

The following example shows detailed QoR information for the current design; some timing path group summaries are omitted for clarity:

```
pt_shell> report_qor

report_qtm_model

Reports quick timing model (QTM) data.

Syntax

string *report_qtm_model*

```
[-global_parameters]
[-ports]
[-arcs]
[-nosplit]
```

Arguments

`-global_parameters`

Reports the global parameters of the current quick timing model.

`-ports`

Reports the ports of the current quick timing model.

`-arcs`

Reports the timing arcs of the current quick timing model.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line starting in the correct column.

Description

The *report_qtm_model* command prints a report of the current quick timing model. By default, the command reports the global parameters, ports, and arcs of the model.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following command reports all the attributes of the currently active quick timing model.

```
pt_shell> report_qtm_model

****************************************
Report : qtm_model
```

```

`-of_objects` *nets*

Data Types

nets	list

Arguments

`-of_objects` *nets*

A list of one or more nets for which to report the RC components. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command reports the RC contributions of the specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows an RC component report. The report contains a section for each specified net.

```
pt_shell> report_rc_components -of_objects min_lsb_led[5]
*********************************

```

Feedback

report_rc_corner_ratios

Reports the nets with the largest ratio of parasitics between corners.

Syntax

status *report_rc_corner_ratios*

```
-parasitic_corners corner1 corner2
[-type object]
[-nworst n1]
[-nbest n2]
```

Data Types

corner1	string
corner2	string
object	string
n1	integer
n2	integer

Arguments

`-parasitic_corners` *corner1 corner2*

Two corners for which to report the nets with the largest capacitance ratio.

`-type` *object*

Specifies the type of parasitic object to compare. Valid values are *ground_capacitor*, *coupling_capacitor*, *resistor*. The default is *ground_capacitor*.

`-nworst` *n1*

Specifies to report the largest ratios and the number of nets to report.

`-nbest` *n2*

Specifies to report the smallest ratios and the number of nets to report.

Description

This command reports the nets with the largest ratio of parasitics between corners.

If neither the *-nbest* or *-nworst* options is specified, the default is *-nworst 100*.

For each net, the ratio is the capacitance (or resistance) for corner 1 divided by the capacitance (or resistance) for corner 2.

This command is supported only for transistor-level GPDs.

Feedback

Examples

The following example shows a coupling capacitance report for corners typ and max, listing the 100 worst ratios.

```
pt_shell> report_rc_corner_ratios -parasitic_corners {typ max}\
            -type coupling_capacitor

```

report_redundant_memory_toggles

Analyzes input RTL FSDB for memory cells and reports redundant toggles.

Syntax

string *report_redundant_memory_toggles*

```
[-mem_state disabled_memory | enabled_write | disabled_write | all]
[cell_list]
```

Data Types

```
cell_list       list
```

Arguments

`-mem_state` *disabled_memory | enabled_write | disabled_write | all*

Use this option to choose the memory state to analyse and report redundant toggles.

`cell_list`

This command expects user to provide memory instance name for analysis. If no instance is specified all memory instances will be analysed.

Description

This command analyzes input RTL FSDB or VCD waveform and reports the redundant toggles for different memory states. The command uses input RTL FSDB and cycle power analysis to detect the time windows in which (a) Read-address/data, write-address/data inputs which are toggling despite disabled memory (b) Read-address inputs which are toggling despite enabled write-access (c) Write-address/data inputs which are toggling despite disabled write-access

The command dumps out an output FSDB file which shows the redundant time windows for each memory state. A value of 1 on the waveform signifies redundant toggles of the read/write data/address lines. Output FSDB also contains original input and output signals of the memory instances so user can validate and change RTL code.

The command reports the percentage of redundant toggles for each memory state.

User can use output FSDB and command output report to modify user's RTL and input FSDB for making architecture-level decisions and improving memory power.

Feedback

Examples

The following example shows the output report of *report_redundant_memory_toggles* command.

```
pwr_shell> report_redundant_memory_toggles
****************************************
Report : redundant_memory_toggles

report_reference

Reports the references in current instance or design.

Feedback

Syntax

string *report_reference*

```
[-nosplit]
```

Arguments

`-nosplit`

Does not split lines if the column overflows.

Description

Displays information about all references in the current instance or current design. If the current instance is set, the report is generated relative to that instance; otherwise, the report is generated for the *current_design*.

Examples

This is an example of the *report_reference* output.

```
pt_shell> report_reference

Feedback

report_routed_nets

Reports the nets routed on specified layers and the total capacitance values of those nets.

Syntax

status *report_routed_nets*

`-layer` *layers*

Data Types

layers	list

Arguments

`-layer` *layers*

A list of one or more layers for which to report the routed nets. At least one layer is required. Glob-style wildcards (*) are supported.

Description

This command reports the nets routed on specified layers and the total capacitance values of those nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a routed net report. The report contains a section for each specified layer with a list of nets, the total capacitance for each net, and the percentage contribution of the layer to the total capacitance.

```
pt_shell> report_routed_nets {metal2 metal3}
==========================================
Total number of nets routed on metal2: 16
==========================================
Net Name   Total Capacitance   metal2 Capacitance   %metal2/Ct

A0         0.092668            0.012534             13.525705
A1         0.092722            0.012547             13.531848
A2         0.092721            0.012547             13.531994
A3         0.092718            0.012544             13.529196
B0         0.089779            0.012808             14.266142
```

report_routing_rules

Reports non-default routing rules in the design.

Feedback

Syntax

status *report_routing_rules*

```
[-verbose]
[-nosplit]
[-significant_digits digits]
[-output file_name]
[-of_objects net_list]
[routing_rule_list]
```

Data Types

digits	int
file_name	string
net_list	list
routing_rule_list	string

Arguments

`-verbose`

Displays verbose non-default rule information.

`-nosplit`

Does not split lines if column overflows.

`-significant_digits digits`

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0-13; the default is 2.

`-output file_name`

Generates a Tcl script that defines the specified routing rules. If the given *file_name* does not end with a .tcl file extension, one will be added. If the *routing_rule_list* option is used, the Tcl script will contain the non-default rule definitions. If *-of_objects net_list* option is used, the Tcl script will contain the net non-default rule assignments.

`-of_objects net_list`

Specifies the nets of which to report non-default rules.

`routing_rule_list`

Specifies the non-default routing rules to report. By default, the tool reports all non-default routing rules in the design.

Description

This command reports the details of the specified non-default routing rules, or the non-default routing rules assigned to the specified nets.

Feedback

Examples

The following example reports on the non-default rule named WideMetal.

```
prompt> report_routing_rules WideMetal
```

[-mod_attributes attribute_list]
[-sort_by single_attribute]
[-reverse_sort_by single_attribute]
[-nworst number]
[-by_hier hier_cell_list]
[-by_cell reg_cell_list]
[-by_mem mem_cell_list]
[-by_op operator_list]
[-by_file rtl_file_list]
[-nosplit]
[-disp_cell]
[-bus_merged_off]
[-report_nl_names]
[-disp_per_line]
[-csv csv_file]
[-filter expression]
[-tag]
[-list_attributes]
[-power_unit unit_type]
[-no_hier_name]
[-report_local_data]
[-report_vth_profile]
[object_list]
```

Feedback

Data Types

view_name	string
attribute_list	list
single_attribute	string
number	number
hier_cell_list	list
reg_cell_list	list
mem_cell_list	list
operator_list	list
rtl_file_list	list
csv_file	string
expression	string
object_list	list
unit_type	string

Arguments

`-view` *view_name*

With this option those views are supported: *hier*, *register*, *clock*, *memory*, *operator*, *rtl_file*.

The *-view hier* option is used to report various power exploration/ optimization attributes per hierarchy block. The supporting attributes are: total_power, total_leakage, total_switch, total_internal, total_sequential, sequential_leakage, sequential_switch, sequential_internal, total_combinational, combinational_leakage, combinational_switching, combinational_internal, total_memory, memory_leakage, memory_switching, memory_internal, sequential_annotation, combinational_annotation, memory_annotation, sequential_toggle, combinational_toggle, memory_toggle, glitch_toggle, average_cg, average_data_aware_cg, average_roade, average_dacgee, sequential_cells, combinational_cells, memory_cells, mbit_cells, icg_cells, gated_registers, inferred_gated_registers, instantiated_gated_registers, both_gated_registers, cell_area. The default display attributes are total_power, total_leakage, total_switching, total_internal, total_sequential, total_combinational, total_memory, average_cg, and cell_name.

The *-view register* option provides various information of registers in the design. The various attributes are: register_width, root_clk_name, root_clk_frequency, root_clk_toggle_rate, total_power, internal_power, leakage_power, switching_power, register_gated, clock_gating_type, clock_pin_toggle_rate, q_pin_toggle_rate, d_pin_toggle_rate, q_p_clk_toggle_rate, register_gating_effi, max_wns, max_tns, ROADE, DACGEE. The default display attributes are root_clk_name, root_clk_frequency, total_power, internal_power, leakage_power, switching_power, clock_gating_type, q_p_clk_toggle_rate, register_gating_effi.

The *-view clock* option is used to show various attributes of clock structure and clock gating cells. The clock structure table with column of clock name, frequency, total registers, total buffers, total inverters and maximum clock gate stage of the clock. The other is detailed clock gating cell table which contains root clock name, gating stage, gating element name, frequency, fanout number, register and clock gating element number, buffer and inverter number, intrinsic and incremental gating efficiency and clock gating efficiency.

The *-view memory* option is used to show various attributes of memory in the design. The various attributes are: cell_name, clock_name, clock_freq, total_power, internal_power, leakage_power, switching_power, ave_data_tr, ave_out_tr, ave_read_addr_tr, ave_write_addr_tr, read_condi_prob, write_condi_prob, read_condi_tr, write_condi_tr, read_condition, write_condition.

The *-view operator* option is used to show various attributes of operator in the design. The various attributes are: module_name, total_power, internal_power, leakage_power, switching_power, glitch_power, xref_location.

The *-view rtl_file* option is used to report various power attributes per rtl file and line. To view the report, you should first apply the *update_xref_file_metric* command. The supporting attributes are: total_power, internal_power, leakage_power, switching_power, glitch_power, total_power_sum, internal_power_sum, leakage_power_sum, switching_power_sum, glitch_power_sum, total_power_max, internal_power_max, leakage_power_max, switching_power_max, glitch_power_max.

`-hier_attributes` *`attribute_list`*

User can specify reporting column of hierarchical attributes table with *-view hier* option. If the user specifies *all*, then all the hierarchical attributes will be displayed.

`-levels` *`number`*

User can specify the maximum depth of the hierarchy in *-view hier* with the *-levels* option. Default is 1.

`-reg_attributes` *`attribute_list`*

User can specify reporting column of register attributes with *-view register* option. If the user specifies *all*, then all the register attributes will be displayed.

`-mem_attributes` *`attribute_list`*

User can specify reporting column of memory attributes with *-view memory* option. If the user specifies *all*, then all the memory attributes will be displayed.

`-op_attributes` *`attribute_list`*

User can specify reporting column of operator attributes with *-view operator* option. If the user specifies *all*, then all the memory attributes will be displayed.

`-rtl_file_attributes` *`attribute_list`*

User can specify reporting column of rtl file attributes with *-view rtl_file* option. If the user specifies *all*, then all the rtl file attributes will be displayed.

`-mod_attributes` *`attribute_list`*

User can specify reporting column of module view attributes with *-view mod_cg_savings* option. If the user specifies *all*, then all the mod view attributes will be displayed.

`-sort_by` *`single_attribute`*

Specifies an attribute for sorting option in each view option.

`-reverse_sort_by` *`single_attribute`*

Specifies an attribute for reverse sorting option in each view option.

`-nworst` *`number`*

Specifies *number* of displayed element which is sorted by the *-sort_by* option.

`-by_hier` *`hier_cell_list`*

With the *-view register* option, this option specifies results of register cells which are to be aggregated from the specified hierarchy blocks.

`-by_cell` *`reg_cell_list`*

With the *-view register* option, this option specifies results of register cells which are specified with the given cell list.

`-by_mem` *`mem_cell_list`*

With the *-view memory* option, this option specifies results of memory cells which are specified with the given cell list.

`-by_op` *`operator_list`*

With the *-view operator* option, this option specifies results of operators which are specified with the given operator_list.

`-by_file` *`rtl_file_list`*

With the *-view rtl_file* option, this option displays results of rtl files which are specified with the given rtl_file_list.

`-nosplit`

This option specifies that report lines should not be split when names are longer than the space provided in the report. The option can make it easier for scripts to parse the result, but might make it harder for human to read the columns.

`-disp_cell`

This option gives detailed cell list report for the *-view operator* option: This option gives operator name, cell counts, each cell's full_name under the operator.

`-bus_merged_off`

With the *-view register* option, this option turn off the bus name merged option.

`-report_nl_names`

With the *-view register* option, this option prints the gate level names of the register in the report. By default the RTL names of the register gets printed in the report.

`-disp_per_line`

This option displays per line report for the *-view rtl_file* option:

`-csv` *`csv_file`*

This option specifies that the report is written out in a comma-separated value format. The *csv_file* specifies the csv file name for the report.

`-filter` *`expression`*

Filters the collection with the *expression* value. For objects the expression is evaluated based on the report columns values. If the expression evaluates to true, the object is included in the report.

`-tag`

This option shows Tag names for each columns of any view mentioned. This option is supported for all views.

`-list_attributes`

This option prints all the attribute names for each columns of all the views, along with the detailed description. This option is supported with the filter option (for view and attribute)

`-power_unit` *`unit_type`*

This option helps to display power numbers in unit types like W(Watts), mW(milliWatt), uW(microWatt), nW(nano Watt) This option is supported for all views.

`-no_hier_name`

This option prints only the register names i.e without their hierarchical path. This option is only supported for Hier View.

`-report_local_data`

This option adds an extra row after each hierarchy reporting the attributes for the leaf cells instantiated in that hierarchy without adding the aggregates from the lower hierarchies. The rows with local data can be identified by the string _local_ appended after the hierarchical path. This option is only supported for Hier View with the application variable power_enable_new_rrm_view set to true.

`-report_vth_profile`

This option adds extra columns for threshold voltage groups at the end of hierarchy view report and prints the number of leaf cells per threshold voltage group present in the hierarchy. The number of cells is counted based on the threshold voltage defined for the corresponding library cells. If the threshold voltage group is not defined on the library cell, the cell is assigned to the default threshold voltage group. Only those leaf cells are considered which contribute to the total power calculated for the hierarchy. Others like logic constant cells and cells without supply nets are ignored. The threshold voltage group names cannot be used as attributes for filtering or sorting the report. This option is only supported for Hier View with the application variable power_enable_new_rrm_view set to true.

Description

This command provides various information in different views to analyze user's RTL for making architecture-level decisions. This information spans from existing design characteristics to tool inferred attributes that will help the user make design decisions.

Mnemonics for NA type in report:

NA_CP0 - Root clock toggle rate is zero

NA_GCP0 - Gated register clock pin toggle rate is zero

NA_Q0 - Gated register Q pin toggle rate is zero

NA_Q>CP - Gated register Q pin toggle rate is greater than clock pin

NA_GC>C - Gated register clock pin toggle rate is greater than root clock toggle rate

NA_NOREG - No registers in the hierarchy

NA - Any other reason

To use the command, you should first apply the *update_power* and *update_metrics* command or apply the *compute_metrics* command.

Feedback

Examples

The following example shows the default report of *-view hier*:

```
pwr_shell> report_rtl_metrics -view hier

****************************************
Report : report_rtl_metrics
      -view hier
Design : top
****************************************

total_power   total_leakage   total_switching   total_internal
 total_sequential   total_combinational   total_memory   average_cg
 cell_name
-----------   -------------   ---------------   --------------
 ----------------   -------------------   ------------   ----------

--------------------------------------------------------------------------------
------------------------
```

B_reg[7:4] and B_reg[3:0] shares same ICG cell. Thus, the command shows bus merged name and related report as above.
To turn off the bus merged option, we provide -bus_merged_off option.
The following example shows the report of **-view register** with **-bus_merged_off**:

Feedback

```
pt_shell> report_rtl_metrics -view register -bus_merged_off

report_scale_parasitics

Reports the parasitic resistance and capacitance scaling factors previously set by the *scale_parasitics* command.

Syntax

status *report_scale_parasitics*

`[net_list]`

Data Types

net_list list

Arguments

net_list

Limits the reporting of net-specific scaling settings to only the listed nets. By default, the command reports all net-specific scaling settings, in addition to the global scaling settings.

Description

The *report_scale_parasitics* command reports the parasitic resistance and capacitance scaling factors previously set by the *scale_parasitics* command. Both the global and net-specific scaling settings are reported.

Examples

The following example reports the parasitic scaling factors.

Feedback

```
pt_shell> report_scale_parasitics
Global factors:
Cap factor      : 1.400000
Res factor      : 1.500000
Coupling factor : 1.350000
Net                    Cap factor   Res factor   Coupling factor
-------------------------------------------------------------------
net_sdram_DQ_in[0]     1.200000     1.500000     1.200000

---

report_sense

Reports user-specified unatenes and sense propagation constraints for data or clock.

Syntax

string *report_sense*

```
[-type clock | data]
[-clocks clock_list]
[-nosplit]
object_list
```

Data Types

```
clock_list       list
object_list      list
```

Arguments

`-type clock | data`

Specifies whether the type of sense applies to clock or data networks. The allowed values are *clock* (the default) and *data*.

`-clocks clock_list`

Reports the specified clock objects. If you do not use the *-clocks* option, the tool reports all clocks passing through the given pin or arc objects.

-nosplit

Prevents line splitting if a column overflows.

object_list

Lists of ports, pins, or cell timing arcs to report.

Description

This command reports the user-defined constraints applied to the senses and unateness propagation of data and clock signals. This reports are distinguished based on whether the sense narrows down the clock waveform, or the sense creates a new clock waveform, as specified by the attributes G for source latency waveform and P for primary clock waveform.

Examples

The following example specifies and reports a stop sense propagation through an arc:

```
pt_shell> set_sense -stop_propagation [get_timing_arcs -from u2/A -to
 u2/Z] \\
          -clock [get_clock clk12]
pt_shell> update_timing
pt_shell> report_sense -type clock

****************************************
Report : sense
         -type clock
Design : simple_2ff
 ...
****************************************

Attributes:

report_sensitivity_lib_mapping

Reports the mapping between base library and sensitivity augmented library.

Syntax

string *report_sensitivity_lib_mapping*

```
[libraries]
```

Data Types

```
libraries                 list
```

Arguments

libraries

Specifies a list of libraries to report mapping of base library and sensitivity agumented library. If this option is omitted, the report covers all of libraries in the current design.

Description

The *report_sensitivity_lib_mapping* command reports mapping between base library and sensitivity augmented library, which is defined in *define_sensitivity_lib_mapping*. *define_sensitivity_lib_mapping* is required in PrimeShield Project Sicily.

Examples

The following script enables Project Sicily Spice2Design flow, defines mapping between base library and sensitivity side-file, then report the mapping.

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
```

Feedback

```
pt_shell> report_sensitivity_lib_mapping orig
  Lib              side_file
================================================
  orig             side.db
================================================

report_sensitivity_power_lib_mapping

Sets the options for sensitivity library check for PrimePower.

Syntax

integer *report_sensitivity_power_lib_mapping*

```
[-output_file_name]
[-dump_sensitivity_leak_tables]
```

Data Types

dump_sensitivity_leak_tables	boolean
output_file_name	string

Arguments

`-dump_sensitivity_leak_tables`

Specifies that all the content of the sensitvity library file needs to be dumped into either the default file i.e *report_s2s_power_content.rpt* or the file specified by output_file_name *argument .*

`-output_file_name`

Specifies the file in which the power sensitivity warnigs is to be written. The default is *report_s2s_power_content.rpt*.

Description

This command runs the following consistency check right after the libraries are loaded and dump the warnings in a file. 1. Warning: 1-1 mapping of leakage power table a. When condition b. Related_pg_pin 2. Warning: 1-1 mapping of rise and fall power table a. When

condition and related_pg_pin are same b. Number of input indices (input slew, output load) are same in nominal and side file 3. Value check (for tables that are a structural match) (Inputs are main library and side-file sensitivity library) a. Range of input indices are same in nominal and side file b. Warning if NLPM nominal value in side-file has larger than 1pJ/1% gap v.s. main library The command should be enabled before *update_power*.

Examples

The following example runs report_sensitivity_power_lib_mapping and logs all the warning in *sample_report.rpt*.

```
pt_shell> report_sensitivity_power_lib_mapping -output_file_name
 sample_report.rpt
Information: Detailed sensitivity report generated successfully in
 sample_report.rpt file

Below is a snippet of the report with the warnings.
Warning: Nominal Values = 0.00100495 is not matching S2S Values = 1234
Warning: Nominal Values = 0.000527413 is not matching S2S Values =
 0.000488281
```

The following example runs report_sensitivity_power_lib_mapping and dumps all the content of side_file. in *report_s2s_power_content.rpt*.

```
pt_shell> report_sensitivity_power_lib_mapping
 -dump_sensitivity_leak_tables
Information: Detailed sensitivity report generated successfully in
 report_s2s_power_content.rpt file

Below is a snippet of the report when sensitivity library file content is
 dumped.

report_si_aggressor_exclusion

Reports the exclusive groups set by the *set_si_aggressor_exclusion* command.

Syntax

status *report_si_aggressor_exclusion*

```
[-rise]
[-fall]
[-nosplit]
[net_list]
```

Data Types

net_list	list

Arguments

`-rise`

Reports all the exclusive groups that have been set as exclusive in the rise direction. If neither the *-rise* nor the *-fall* options are specified, the exclusive groups of the aggressor nets *anets* in both rise and fall directions are reported.

`-fall`

Reports all the exclusive groups that have been set as exclusive in the fall direction. If neither the *-rise* nor the *-fall* options are specified, the exclusive groups of the aggressor nets *anets* in both rise and fall directions are reported.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. If you do not use this option, most of the design information

is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

net_list

Specifies the list of nets for exclusive groups you want reported. You can use this option with either the *-rise* or *-fall* options to specify exclusive groups only in that particular direction.

Description

The *report_si_aggressor_exclusion* command reports all the exclusive groups that have been set by the *set_si_aggressor_exclusion* command.

Examples

The following example shows how the exclusion on nets *SCAN_LOGIC** for rise direction is reported.

```
pt_shell> set_si_aggressor_exclusion [get_nets SCAN_LOGIC*] -rise
1
pt_shell> report_si_aggressor_exclusion
****************************************
  Report : report_si_aggressor_exclusion

report_si_bottleneck

Reports the nets that have the largest crosstalk effects that contribute to timing violations.

Feedback

Syntax

status *report_si_bottleneck*

```
[-cost_type type]
[-slack_lesser_than slack]
[-minimum_active_aggressors active_aggressor_count]
[-delta_delay_threshold threshold]
[-min]
[-max]
[-all_nets]
[-nets list]
[-max_nets number]
[-include_clock_nets]
[-pre_commands pre_command_string]
[-post_commands post_command_string]
[-significant_digits digits]
[-nosplit]
[-sms_scenarios sms_scenarios_list]
```

Data Types

type	float
slack	float
active_aggressor_count	int
threshold	float
list	list
number	int
pre_command_string	string
post_command_string	string
digits	int
sms_scenarios_list	collection

Arguments

`-cost_type` *type*

Sorts nets based on the specified cost types. The following cost types return a list of victim nets:

- *delta_delay* - The worst delta delay on the victim net. This is useful for finding the largest delta delays in the design that contribute to failing paths.
- *delta_delay_ratio* - The worst delta delay ratio (delta delay divided by total stage delay) on the victim net. This is useful for finding the delta delays that result in the largest percentage increase of a stage delay in failing paths.
- *total_victim_delay_bump* - The height of the largest crosstalk bump on the victim net. This is useful for finding the strongest electrical couplings in the design that contribute to failing paths.

The following cost type returns a list of aggressor nets:

- *delay_bump_per_aggressor* - The aggressor net with cross-coupled, slack-qualifying victim nets with the largest sum of bump voltages on those victims induced by the aggressor. This is useful for finding aggressors that result in the largest amount of electrical coupling to victim nets in failing paths.

`-slack_lesser_than` *`slack`*

Applies the cost function only to victim nets with slack less than the specified limit. The default is zero. Specify a positive value to find more bottleneck nets, and vice versa.

`-minimum_active_aggressors` *`active_aggressor_count`*

Specifies the minimum number of active aggressors for the net to be selected. The default is 1.

`-delta_delay_threshold` *`threshold`*

Reports only the victim nets whose delta delay cost exceeds the specified threshold. The threshold must be at least zero. The default is zero. This option applies only if the *-cost_type* option is set to *delta_delay*.

`-min`

Considers only minimum-delay (hold) constraints.

`-max`

Considers only maximum-delay (setup) constraints.

By default, the command considers both min and max constraints.

`-all_nets`

Reports all nets with SI cost that contribute to negative path slacks. By default, the command reports the 20 nets with the worst bottleneck cost.

`-nets` *`list`*

Restricts the bottleneck analysis to only the nets specified in a list or collection of nets. By default, the command considers all nets in the design.

`-max_nets` *`number`*

Specifies the maximum number of nets to report. The default is 20.

`-include_clock_nets`

Includes the clock nets in bottleneck analysis. By default, clock nets are not included.

`-pre_commands` *`pre_command_string`*

Specifies a string of commands to be executed in the worker context before execution of the merged reporting command.

`-post_commands` *`post_command_string`*

Specifies a string of commands to be executed in the worker context after execution of the merged reporting commands.

The *-pre_commands* and *-post_commands* options are valid only for distributed multi-scenario (DMSA) analysis. Commands are grouped using the ";" character. The maximum size of a command is 1000 characters.

`-significant_digits` *`digits`*

Specifies the number of digits to display; the allowed range is 0 to 13. The default is set by the *report_default_significant_digits* variable.

`-nosplit`

Prevents splitting of lines in the report when a column overflows.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only SI bottleneck information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_si_bottleneck* command reports the nets that have the largest crosstalk effects that contribute to timing violations. You can choose any one of the following "cost functions" to consider in the analysis:

- *delta_delay* (the default) -- Reports the victim nets with the worst change in absolute delay
- *delta_delay_ratio* -- Reports the victim nets with the worst change in delay as a fraction of the total stage delay
- *total_victim_delay_bump* -- Reports the victim nets with the largest crosstalk bumps
- *delay_bump_per_aggressor* -- Reports the aggressor nets that produce the largest total bump voltages in victim nets of failing paths

By default, the analysis considers only crosstalk effects that contribute to timing violations. Paths with zero or better slack are ignored. You can change this by using the *-slack_lesser_than option*.

By default, the analysis considers both maximum-delay (setup) and minimum-delay (hold) constraints. To restrict the analysis to only one constraint type, use the *-max* or *-min* option.

To create a collection of victim or aggressor nets reported by the *report_si_bottleneck* command, use the *get_si_bottleneck_nets* command.

If a victim fails to meet the slack criteria only for one of its transition senses (rise or fall), only the timing information for the failing sense is considered.

By default, clock nets are not included in bottleneck victim analysis, as the slack of the clock nets is infinite. However, clock nets can be included as victims in the bottleneck search by using the *-include_clock_nets* option. Even without this option, clock aggressor nets are returned by the *total_victim_delay_bump* cost type.

Crosstalk problems can be caused by one or more of the following factors:

- Large coupling capacitance
- Weak victim net driver or slow victim transition
- Strong aggressor net driver

Depending on the relative victim and aggressor slacks, one of the following repairs could be considered:

- Downsize the aggressor net driver to a weaker driver
- Resize the victim net driver to a stronger driver
- Specify physical decoupling with the *set_coupling_separation* command
- Insert a buffer on the victim net to break up long coupled routes

When sizing cells, it can be useful to use the *get_alternative_lib_cells* command to report equivalent cells, or the *report_alternative_lib_cells* command to evaluate their potential slack improvement.

The aggressor-based cost factor can be useful for finding strong aggressors that attack many failing victim nets. If the aggressor has positive setup slack, it might be preferable to downsize the aggressor driver and weaken its effect over multiple victims, or to separate it from the victims using the *set_coupling_separation* command. When performing such an aggressor downsizing, ensure that the resulting weaker aggressor driver does not violate any library max_capacitance or max_transition DRC requirements.

When many aggressors attack a victim net, you can take advantage of the statistical nature of many aggressors where the chances of all of them switching at the same time are very low. To find the failing victim nets that are attacked by many aggressors, you can use the *-minimum_active_aggressors* option. The number of active aggressors is

defined as the number of effective aggressors that are active for the worst-case aggressor alignment.

For example, a victim net can have ten effective aggressors. However, for any given min/max rise/fall scenario, perhaps no more than five of these ten effective aggressors are active in the worst-case alignment for that sense. Such a victim would not meet a *-minimum_active_aggressors* value higher than five.

To exclude specific crosstalk victim/aggressor interactions from the analysis without changing the parasitics, use the *set_si_delay_analysis -exclude* command.

For bottleneck analysis, crosstalk analysis must be enabled (*si_enable_analysis* set to *true*). Bottleneck analysis automatically sets the *timing_save_pin_arrival_and_slack* variable to *true*.

Examples

The following examples show SI bottleneck reports using the default cost type (*delta_delay*) and alternative cost types.

```
pt_shell> report_si_bottleneck
****************************************
Report : si_bottleneck
        -cost_type delta_delay
        -slack_lesser_than 0
        -max_nets 20
        -significant_digits 4
        -minimum_active_aggressors 1
        -min
        -max
    ...
****************************************

report_si_delay_analysis

Generates a report of user coupling information on nets for crosstalk delay analysis.

Syntax

int *report_si_delay_analysis*

```
[-ignored_arrival]
[-excluded]
[-coupling_separated]
[-disabled_statistical]
[-nosplit]
[nets]
```

Data Types

nets	list

Arguments

`-ignored_arrival`

Reports the list of nets you have specified to be analyzed with infinite window.

`-excluded`

Reports the list of nets excluded by you from crosstalk analysis as victim nets or aggressor nets. Also, specifies the analysis type for which the victim/aggressor nets are excluded. It indicates whether the information is set globally on a victim for all aggressors, or globally on a aggressor for all its victims, or between a particular victim and aggressor net. Indicates the type of analysis - minimum path victim falling, minimum path victim rising, maximum path victim falling and maximum path victim rising analysis. The combination of analysis types for which the net is excluded is reported.

`-coupling_separated`

Reports the list of nets on which you have specified coupling separation constraint. It reports the aggressor nets which are separated from all their victims, the victim nets that are separated from all their aggressors, and separation applied between a particular pair of victim and aggressor net.

`-disabled_statistical`

Reports the nets which you have disabled for statistical analysis when the nets are considered as composite aggressor.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. If you do not use this option, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`nets`

Limits a list of nets in the current design for which the report needs to be generated.

Description

Produces a report showing coupling information specified by you on nets for crosstalk analysis.

The *report_si_delay_analysis* command allows you to view all of the sets of nets on which you have indicated the default crosstalk analysis behavior to be ignored and the behavior specified by you to take precedence. For every pair of nets, the type of behavior and analysis for which the default behavior is ignored, is reported. This command also specifies whether the information is specified for the net as a victim or aggressor.

Any combination of the options can be used to generate the corresponding report information. If no options are specified, the command reports all the information on all the nets.

This command reports the behavior set by the *set_si_delay_analysis*, *remove_si_delay_analysis*, *set_coupling_separation*, *remove_coupling_separation*, *set_si_delay_disable_statistical* and *remove_si_delay_disable_statistical* commands.

Examples

The following example shows how the excluded option can be used to report all the pairs of victims or aggressors that have been excluded from crosstalk analysis.

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets CLK_NET*]
1
pt_shell> set_si_delay_analysis -exclude -agressors [get_nets AGG_NET*]
1
```

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets V_NET]
-aggressors [get_nets A_NET]
1

report_si_double_switching

Reports the double switching violation detected in the design.

Syntax

status *report_si_double_switching*

```
[-clock_network]
[-rise]
[-fall]
[-nosplit]
[nets]
```

Data Types

```
nets     list
```

Feedback

Arguments

`-clock_network`

Reports the double switch violations for the clock network only, even if the *si_xtalk_double_switching_mode* variable is set to *clock_network* or *full_design*.

`-rise`

Reports the double switch violations for the rising victim.

`-fall`

Reports the double switch violations for the falling victim. If you use neither the *-rise* nor *-fall* option, the net is reported only one time with the smallest slack.

`-nosplit`

Suppresses line splitting if the line exceeds 80 characters.

nets

Reports for the specific victim nets. By default, all nets are reported.

Description

This command reports the victim nets with double switching violations. It reports the victim net name, actual bump height, the required bump height, and the double switching slack.

To use this command, you must enable double switching detection by setting the *si_xtalk_double_switching_mode* variable before the *update_timing* command.

Examples

The following example reports all double switching violations in the design for both rise and fall.

```
pt_shell> report_si_double_switching -nosplit -rise -fall

****************************************
Report : si_double_switching
        -nosplit
        -rise
        -fall
 ...
****************************************

  Victim    Switching   Actual        Required      Double Switching
  Net       Direction   Bump Height   Bump Height   Slack
  ------    ---------   -----------   -----------   ----------------
  I2        max_rise    0.69          0.42          -0.26 (VIOLATING)
  I2        max_fall    0.51          0.49          -0.02 (VIOLATING)
```

Feedback

---

report_si_noise_analysis

Generates a report of user coupling information on nets for crosstalk noise analysis.

Syntax

int *report_si_noise_analysis*

```
[-ignored_arrival]
[-excluded]
[-coupling_separated]
[-disabled_statistical]
[-nosplit]
[nets]
```

Data Types

nets	list

Arguments

`-ignored_arrival`

Reports the list of nets you have specified to be analyzed with infinite window for noise analysis.

`-excluded`

Reports the list of nets excluded by you from noise analysis as victim nets or aggressor nets. Also specifies the analysis type for which the victim/aggressor nets are excluded. The analysis type may be above low rail, below low rail, above high rail or below high rail. The combination of analysis types for which the net is excluded is reported. It indicates whether the information is set globally on a victim for all aggressors, or globally on a aggressor for all its victims, or between a particular victim and aggressor net.

`-coupling_separated`

Reports the list of nets on which you have specified coupling separation constraint. It reports the aggressor nets which are separated from all their victims, the victim nets which have been separated from all their aggressors, and coupling separation applied between a particular victim and aggressor net.

`-disabled_statistical`

Reports the nets which you have disabled for statistical analysis when the nets are considered as composite aggressor.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the report output. If you do not use this option, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`nets`

Limits a list of nets in the current design for which the report needs to be generated.

Description

Produces a report showing coupling information specified by you on nets for noise analysis.

The *report_si_noise_analysis* command allows you to view all the set of nets on which you have indicated the default noise analysis behavior to be ignored and the behavior specified by you to take precedence. For every pair of nets, the type of behavior and analysis for which the default behavior is ignored, is reported. This command also specifies whether the information is specified for the net as a victim or aggressor.

Any combination of the options can be used to generate the corresponding report information. If no options are specified, the command reports all the information on all the nets.

This command reports the behavior set by the *set_si_noise_analysis*, *remove_si_noise_analysis*, *set_coupling_separation*, *remove_coupling_separation*, *set_si_noise_disable_statistical* and *remove_si_noise_disable_statistical* commands.

Examples

The following example shows how the excluded option can be used to report all the pairs of victims or aggressors that have been excluded from noise analysis.

```
pt_shell> set_si_noise_analysis -exclude -victims [get_nets CLK_NET*]
1
pt_shell> set_si_noise_analysis -exclude -agressors [get_nets AGG_NET*]

report_signal_em_violation

Reports the electromigration rule violations based on the signal EM analysis result.

Syntax

string *report_signal_em_violation*

```
[nets]
[-clear]
[-verbose]
[-report_ratio]
[-ratio_threshold threshold]
[-violation_type type]
[-sort_violation_type type]
[-sort_by value]
```

Data Types

```
nets      list
threshold float
type      string
value     string
```

Arguments

nets

Specifies a list of signal nets to be reported for electromigration violations. Items within the list can be net name patterns or collections. The default is to report all violation nets in the current *check_signal_em* result.

-verbose

print detail information.

-clear

clear *check_signal_em* result from current PrimePower session to release memory.

-report_ratio

report EM ratio (EM ratio = current / current limit) instead of current value.

-ratio_threshold *threshold*

report violation nets and resistors which EM ratio are larger than threshold. (EM ratio = current / current limit). The report is generated from current *check_signal_em* result. Default value is 1. If *ratio_threshold* is 0, all signal nets and resistors analyzed by *check_signal_em* will be reported. If the value is between 0 and 1, this command reports nets from current *check_signal_em* result. Some nets which don't have EM violations may not be reported, if they are not in *check_signal_em* result or filtered. Please see *check_signal_em -skip_filter* for more net filtering information.

-violation_type *type*

report specified violation type. The valid types are all (default), average, rms, and peak.

-sort_violation_type *type*

report resistors sorted by specified violation type. The valid types are average, rms (default), and peak. The default value sorts resistors by the rms type. This option is valid when *violation_type* is all. If *violation_type* is peak, then *sort_violation_type* will be peak automatically.

-sort_by *value*

report resistors sorted by specified value. The valid values are current (default) and ratio.

Feedback

Description

The command reports the electromigration rule violations for the nets included in the current *check_signal_em* result. You must run the command after the *check_signal_em* command.

Electromigration analysis is used to determine whether the current density at a location in the circuit exceeds the defined electromigration rule limits. The current density limits are intended to control the risk that current-carrying geometries is not degraded by excessive current flow. High current densities damage the wires and damaged current-carrying wires can ultimately lead to shorts and opens within the metal, causing circuit failure. The silicon device foundries set the current density limit rules of their related metallurgy to ensure reliability. See the *read_signal_em_rules* man page for more details.

By default, this command reports violation nets and violation resistors to have a minimum report size.

Examples

The following example reports electromigration violations on the signal net after *check_signal_em* is complete.

```
pr_shell> report_signal_em_violation
```

The following example reports rms electromigration violations.

```
pr_shell> report_signal_em_violation -violation_type rms
```

The following example reports rms electromigration violations and all resistors (includes no-violation resistors)

```
pr_shell> report_signal_em_violation -violation_type rms -verbose
```

The following example reports rms electromigration violations and sorts resistors by EM ratio.

```
pr_shell> report_signal_em_violation -violation_type rms -verbose
 -sort_by
ratio
```

Feedback

report_sim_setup

Report the details of the SimLink setup.

Syntax

status *report_sim_setup*

```
[-library]
[-simulator]
```

Arguments

`-library`

Reports only the current *sim_setup_library* configuration.

`-simulator`

Reports only the current *sim_setup_simulator* configuration.

Description

The *report_sim_setup* command reports the details of the current SimLink configuration.

Configure SimLink by using the *sim_setup_library* and *sim_setup_simulator* commands before running this command.

By default, both the library and simulator configurations are reported. You can use command options to limit the report.

Examples

The following example shows a *report_sim_setup -library* report:

```
pt_shell> report_sim_setup -library
****************************************
Report : report_sim_setup
****************************************

  Library : ncx
    Sub circuit : /WORKING_DIRECTORY/run/subckt_dir_211019183614_453
    File name pattern : ^%s(\..*)?$

 Header : /
u/cltmgr/xtalk/si_lib_gen/unit/lsi_28nm_sch30p/model/header.spi_new_2019
```

The following example shows a *report_sim_setup -simulator* report:

```
pt_shell> report_sim_setup -simulator
****************************************
Report : report_sim_setup
****************************************
```

```
  Simulator : /global/apps/hspice_2018.09-SP2-2/hspice/bin/hspice
  Sim options : .option ingold=2 numdgt=6 measdgt=6 brief statfl=1 acct=0
 autostop runlvl=5
  Work dir : /WORKING_DIRECTORY/run/sim_dir
  Preserve logs : all
  Pre filter : none
```

The following example shows a *report_sim_setup* without any options:

```
pt_shell> report_sim_setup
****************************************
Report : report_sim_setup
****************************************

  Simulator : /global/apps/hspice_2018.09-SP2-2/hspice/bin/hspice
  Sim options : .option ingold=2 numdgt=6 measdgt=6 brief statfl=1 acct=0
 autostop runlvl=5
  Work dir : /WORKING_DIRECTORY/run/sim_dir
  Preserve logs : all
  Pre filter : none

  Library : ncx
    Sub circuit : /WORKING_DIRECTORY/run/subckt_dir_211019183614_453
    File name pattern : ^%s(\..*)?$

 Header : /
u/cltmgr/xtalk/si_lib_gen/unit/lsi_28nm_sch30p/model/header.spi_new_2019
```

report_sms_scenarios

Reports the active status of SMS scenarios for selective SMVA or SMC analysis.

Syntax

string *report_sms_scenarios*

```
[-disabled sms_scenarios_list]
```

Data Types

```
sms_scenarios_list      collection
```

Feedback

Arguments

`-disabled` *sms_scenarios_list*

Specifies the report type. The command reports the disabled SMS scenarios. This option is only available with SMVA or SMC analysis.

Description

The *report_sms_scenarios* command reports the active status of SMS scenarios for selective SMVA or SMC analysis. It reports a summarized status of the SMS scenarios configured using the *configure_sms_scenarios* command. This command is only available with SMVA or SMC analysis.

Examples

The following example specifies 3 voltage reference names {high,low,typ} for each one of the supply groups SN1 and SN2. PrimeTime automatically considers all the relevant combinations of voltage levels, in this case up to nine prior the use of the configure_sms_scenarios command. The example disables all SMS scenarios for which the supply group SN1 is at 'typ' voltage and SN2 is at 'typ' voltage.

```
pt_shell> set_voltage_levels SN1 -reference_names {high low typ}
pt_shell> set_voltage -o SN1 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN1 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN1 -reference_name typ 0.9 -min 1.0
pt_shell> set_voltage_levels SN2 -reference_names {high low typ}
pt_shell> set_voltage -o SN2 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN2 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN2 -reference_name typ 0.9 -min 1.0

pt_shell> report_sms_scenarios -disabled

report_stc_power_savings

Generates power saving reports by identifying the stability conditions (STC) of the registers.

Syntax

string *report_stc_power_savings*

Feedback

```
[-clock_gate_type      clock_gate_value_type]
[-min_pwr_savings      power_savings]
[-min_reg_width        register_width]
[-csv csv_file]
[-report_nl_names]
[object_list]
```

Data Types

clock_gate_value_type	string
power_savings	float
register_width	integer
csv_file	string
object_list	list

Arguments

`-clock_gate_type` *clock_gate_value_type*

Use this option to specify the type of clock which drives the registers. The clock could be gated type, domain type (non-gated) or both. Default value of *-clock_gate_type* is "all" and other supported values are "gated" and "not_gated".

`-min_pwr_savings` *power_savings*

Use this option to report only those registers whose total power saving, after using the STC power saving technique, is more than or equal to the "power_savings" value. Default value of *-min_pwr_savings* is 0.0.

`-min_reg_width` *register_width*

Use this option to filter the bundled registers so that the bundled registers having width greater than or equal to "register_width" will be considered for power saving estimate. Default value of *-min_reg_width* is 8.

`-csv` *csv_file*

Use this option to specify the path for the csv file for writing the power savings report in a comma seperated value format. A csv file can be viewed in a spreadsheet reader. With this option the report will not be printed on the shell.

`-report_nl_names`

Use this option to report the netlist(gate-level) name of the register. By default, the RTL name or merged RTL name, in case of bus register, is reported for the registers.

object_list

Use this option to apply the STC power savings techniques on the list of registers. Options *-min_reg_width* and *-min_pwr_savings* cannot be supported with this option. Currently only the gate-level register name can be specified.

Feedback

Description

Use the *report_stc_power_savings* command to generate the power savings report after applying the STC(Stability Conditions) power savings techniques on the register/bus registers in the design.

The three important fields that the command prints are the name of registers, potential power savings that could happen using the above technique and the name of Parent Registers whose enable values cause this Stability Condition.

The other fields are: width of register bus, frequency of clock, the register is gated or not, the current and final register gate efficiency percentage, current and final enable probability, current power and the final power.

To use the command, you should first apply the update_power and update_metrics command or apply the compute_metrics command.

Stability Conditions(STC) Power savings Technique

The Stability Condition (STC) technique is one of the sequential clock-gating techniques to find a new enable or strengthen an enable for gated registers. When the upstream register is stable (disabled), no new data can comes to the downstream registers. Hence, the downstream registers can be gated to save the clock power. Let us assume that for a given non-gated input register, if its parents register enable are stable(disabled), then the input register can be gated using the enable of parents, avoid the switching activity of its clock and hence saves the power. This could be done at the power overhead of Integrated clock gate cell and the Delay cell. This command exactly does this and currently it only looks the stability condition of the immediate parents of the registers/bus registers and reports them if there is any power savings.

Register Name in report

The command prints the RTL register name or the merged RTL names in case of bus registers by default. If mapping information does not exist for some registers the gate level name would get printed instead.

To print the gate-level register names instead of the RTL names use the option -report_nl_names.

Examples

The following example shows a list of bundled registers having a width >=8, where the power could be saved by employing STC(Stability Conditions) Techniques. The registers may have either a gated clock or not.

```
pt_shell> report_stc_power_savings -clock_gate_type all
****************************************

report_supply_group

Reports existing supply groups.

Syntax

```
status report_supply_group
  [supply_group_list]
```

Data Types

```
supply_group_list           string
```

Arguments

supply_group_list

Specifies supply groups to report.

Description

The *report_supply_group* command reports detailed information about the supply groups, including the name, voltage levels defined by the *set_voltage_levels* command, and voltage values that are set per voltage level by the *set_voltage* command.

Examples

The following example reports the information of all supply groups:

```
prompt> report_supply_group
------------------------------------------------------------------------
------
    Supply group :      SN1
    Voltage level :     k
    Max-delay Voltage : Not assigned yet
    Min-delay Voltage : Not assigned yet
    Voltage level :     l
    Max-delay Voltage : 0.8000
    Min-delay Voltage : 0.9000
    Voltage level :     m
    Max-delay Voltage : Not assigned yet
    Min-delay Voltage : Not assigned yet
```

Feedback

```
------------------------------------------------------------------------
------
    Supply group :      SN2
    Voltage level :     Not assigned yet

1
```

See Also

- get_supply_groups

---

report_supply_net

Reports existing supply nets.

Syntax

```
status report_supply_net
   [-domain domain_name]
   [-scope scope_name]
```

Data Types

```
domain_name           string
scope_name            string
```

Arguments

`-domain domain_name`

Specifies domain-dependent supply nets that exist in a particular power domain. The domain must exist.

`-scope scope_name`

Specifies for which scope you want to define the supply nets that are reported. If this is not specified, the command reports all the power nets in the current scope.

Description

The *report_supply_net* command provides detailed information about all supply nets associated with a specified power domain or scope. If you specify a domain, the report shows only the domain-dependent supply nets that exist in the domain. The information of supply nets include:

- The full name
- All power domains that it is created in

Feedback

- All voltage information that is explicitly set on this net by the *set_voltage* command
- All domains for which the net is the primary power or ground net

Examples

The following example reports the information of all supply nets in the current scope.

```
prompt> report_supply_net
  Total of 1 supply nets defined.
------------------------------------------------------------------------
    Supply Net :        i2/net_i2
    Scope :             i2
    Power Domains :
    Supply Ports  :     N/A
    PG_power_pin  :     N/A
    Max-delay Voltage : 1.08
    Min-delay Voltage : 1.3
    Resolve type :      unresolved
1
```

report_supply_set

Reports all supply sets defined in the design.

Syntax

status *report_supply_set*

Arguments

None.

Description

The *report_supply_set* command reports detailed information about the supply sets defined in the design. The report for a supply set includes the following information: its full

name, the scope in which it was created, and the pairs of function and associated supply net.

This command returns 1 on success, otherwise a 0 returns.

Examples

The following example reports information about the primary_sset supply set created in the current scope.

```
prompt> create_power_domain top_domain
top_domain

prompt> create_supply_set sset \\
          -function {power VDD} \\
          -function {ground VSS}
sset

prompt> report_supply_set

  Total of 2 supply sets defined for design 'top'.

--------------------------------------------------------------------------------
------
    Supply Set : top_domain.primary
    Scope      : <top level>
    Function   : power, supply net association : top_domain.primary.power
    Function   : ground, supply net association :
 top_domain.primary.ground
    Associated : -
--------------------------------------------------------------------------------
------
    Supply Set : sset
    Scope      : <top level>
    Function   : power, supply net association : VDD
    Function   : ground, supply net association : VSS
1
```

report_switching_activity

Reports the statistics on the switching activity annotation and signal probability on the current design or instance.

Syntax

integer *report_switching_activity*

```
[-cells cells_list]
[-list_not_annotated]
[-list_annotated]
[-list_low_activity]
[-list_by_source source]
[-base_clock clk]
[-average_activity]
[-coverage]
[-hierarchy]
[-show_pin]
[-sort_by hier | net_toggle_rate | name]
[-toggle_limit limit]
[-exclude exclusion_group]
[-include_only_user_group  inclusion_user_group]
[-include_only inclusion_group]
[-only_related_clock clock]
[-include_mapping_types]
```

Data Types

cells_list	list
source	string
clk	string
limit	integer
exclusion_group	string
inclusion_user_group	string
inclusion_group	string
clock	clock

Arguments

`-cells` *cells_list*

Indicates that switching activity annotation is to be reported only for the specified *cells_list*.

`-list_not_annotated`

Reports a list of design nets that have no user-defined switching activity annotation. When specified, the report does not include constant value nets (logic one/zero nets). Note that such nets are annotated with the default switching activity if they are not user-annotated.

`-list_annotated`

Reports a list of design nets that do have user-defined switching activity annotation.

`-list_low_activity`

Reports a list of nets in the design with fewer toggles than the value defined using the -toggle_limit option. Use the list report to debug which nets are not being exercised by the simulation test bench.

`-list_by_source` *source*

Reports a list of nets that have switching activity information from a given source.

Possible sources are any of the following:

[annotated, file, propagated, default, set_switching_activity, set_case_analysis, create_clock, implied, no_switching_activity]

Here *annotated* means any annotated (not propagated) source. The *file* source means any source with from an activity file (either VCD or SAIF file).

`-base_clock` *clk*

When the -average_activity option is specified, the average activity over nets is reported. The averaged toggle rates reported are by default with respect to 1ns. When the -base_clock option is used, the reported averaged toggle rates are with respect to the period of the clock *clk*. If the reported toggle rate is 0.5, and the period of the base clock is 3ns, then on average during simulation, there are 0.5 toggles every 3ns, or 1 toggle every 6ns.

`-average_activity`

Produces a report that averages toggle rates over the nets in the design. When combined with the -hierarchy option, the average switching activity is computed for each subblock in the design.

It is possible using the filter options, -exclude or -include_only, to get a report of average toggle rates over a subset of the nets in the design. This can be useful for instances to get the average toggle rate for annotated nets, or even the average toggle rate for annotated nets driven by the sequential cells.

`-coverage`

Creates e a summary report about the nets and the design that have switching activity information, but have few toggles. Coverage is defined as the percentage of nets with more than the value defined by the -toggle_limit *limit* option. You can use this report to verify that the switching activity from simulation or propagation is properly exercising the design. When used with the -hierarchy option, you can use the report to make sure that each block in the design is properly exercised.

`-hierarchy`

Includes the information about subblocks in the design. The flag cannot be used with the list generating options for the command.

`-show_pin`

Specifies that driver pins as well as nets are shown in certain net lists. The lists generated by the -list_not_annotated, -list_annotated, -list_low_activity, and -list_by_source options are affected. Pins are not shown for multidriver nets.

`-sort_by` *`hier | net_toggle_rate | name`*

When used with any of the -hierarchy option with the default report or with the -average_activity or -coverage option, the hierarchical blocks in the report are sorted either by hierarchy (depth first), averaged toggle rate, or name.

When used with any of the list options (that is, the -list_low_activity, -list_by_source, -list_not_annotated, or -list_annotated options), the list is sorted by toggle rates or by names. For the list reports, the -sort_by *hier* option is not accepted.

`-toggle_limit` *`limit`*

Sets the lower limit for what is considered to be few toggles. This limit is used by the -coverage and the -list_low_activity options. The default limit is 1 toggle.

The value of the argument to the -toggle_limit option represents the maximum number of toggles considered to be low activity. The number of toggles on a net is defined to be the toggle rate times the simulation duration. For vector free power analysis (where no SAIF or VCD file has been used), the default simulation duration is 10000 ns. If a SAIF file has been used, the duration is taken from the SAIF file. If a VCD file has been used to annotate activity, the duration is the duration of the VCD simulation.

`-exclude` *`exclusion_group`*

Filters out the nets from consideration before generating any of the reports. Filtering occurs before toggle rate averaging, coverage percentage computations, and list generation. Possible exclusion groups are any of the following:

[*sequential, combinational, primary_inputs, black_boxes, three_state, memory, clock_gate, clock, low_activity, high_activity, rtl*]

A net is defined as sequential if it is driven by a sequential cell, same with combinational, primary_inputs, etc.

The RTL exclusion group refers to the nets driven either by sequential cell outputs, black box outputs, primary inputs, or memories. The RTL group is mainly provided as a shorthand for writing out all of these.

The clock_gate exclusion group refers to ICGs only, not other types of clock gates. Other possible exclusion groups are defined by the source of the activity information:

[*annotated, file, propagated, default, set_switching_activity, set_case_analysis, create_clock, implied, no_switching_activity*]

Here *annotated* means any annotated (not propagated) source. The *file* source means any source from an activity file (usually VCD or SAIF files).

To exclude multiple groups, the *exclusion_group* argument can be a list with multiple groups in the list.

Note: Currently, the "sequential" group should not include the nets driven by clock gates. In the C-2006.12 release, the group included such nets.

`-include_only_user_group` *`inclusion_user_group`*

Includes only the nets under the *inclusion_user_group* or the groups defined by the *report_switching_activity* command.

pt_shell> *report_switching_activity -include_only_user_group {user_group}*

`-include_only` *`inclusion_group`*

Includes the nets under the \inclusion_group when generating any of the reports. Filtering occurs before toggle rate averaging, coverage percentage computations, and list generation.

Possible inclusion groups are any of the following: [*sequential, combinational, primary_inputs, black_boxes, three_state, memory, clock_gate, clock, low_activity, high_activity, rtl*].

A net is defined as sequential if it is driven by a sequential cell, same with combinational, primary_inputs, etc. The clock_gate inclusion group refers to ICGs only, not other types of clock gates.

Other possible inclusion groups are defined by the source of the activity information, such as: [*annotated, file, propagated, default, set_switching_activity, set_case_analysis, create_clock, implied, no_switching_activity*]

Here *annotated* means any annotated (not propagated) source. The *file* source means any source from an activity file (usually a VCD or a SAIF file).

To include multiple groups, use the *inclusion_group* argument to specify multiple groups in the list. In this case, only nets that are in one of the listed groups are included in the report.

To include only the nets that are in several groups, use the *&* operator. This operator has low precedence; lists are or'ed first, then and'ed. For instance, to

include only the nets that are driven by RTL points or three_state buffers and have no switching activity, use the following command:

pt_shell> *report_switching_activity -include_only {rtl, three_state & no_switching_activity}*

To invert the selection, the *!* operator can be used. For example, one way to include only the nets that are driven by RTL points and have switching activity would be the following:

pt_shell> *report_switching_activity -include_only {rtl & !no_switching_activity}*

There may be other ways (possibly using the -exclude option) to get this same set of nets included in the report.

`-only_related_clock` *clock*

If specified, nets that have a base_clock other than *clock* are filtered out before the results of the report are included. This option can affect the overview, coverage, or the average toggle report. Also, this option can affect the output lists. Such reports consider only the nets with the given base_clock.

`-include_mapping_types`

When specified, the "Annotated from File" column in the report is split into three columns: Name mapping file, Exact name mapping, and Build-in name mapping, which list the number of netlist objects mapped using each of the techniques respectively.

Description

The command report the switching activities on the nets in the current design or instance.

The default report generated by the *report_switching_activity* command gives an overview of switching activity information in the current instance. The report lists the percentage of nets with switching activity and signal probability that is user-annotated, default-annotated, and propagated (if any).

Switching activity and signal probability can be annotated by using the *set_switching_activity* and *read_saif* commands, or by using event-simulation data using the the *read_vcd* command. The *create_clock* and *set_case_analysis* commands also affect switching activities.

Note that the *read_vcd* command, when used with a named pipe or the *-pipe* option, does not immediately annotate activities on the design. The annotations happen later during the *update_power* command. Because of this, the *report_switching_activity* command does not report activity change in this situation until the *update_power* command has been run.

During power calculations, PrimePower estimates the switching activity of objects that are not user-annotated by propagating the user or default annotated switching activity

values. These objects are reported as propagated after the *update_power* command has been run, but as not propagated prior to running the *update_power* command. In general, propagated switching activity is less accurate than switching activity on objects derived by simulation, so the percentage values in the user-annotated column of the report generated by the *report_switching_activity* command are an indication of the accuracy of power reports.

If the *power_analysis_mode* command has been set to *averaged* or *leakage_variation* and if a VCD file has been read with the *read_vcd* command without the -pipe option, the tool annotates the activity from the VCD file prior to reporting the switching activity. In addition, unannotated objects where the activity can be derived accurately without random vector simulation (for example, clock nets, Qbar pins where the Q pin is annotated, and constant nets) is reported by the *report_switching_activity* command as having *implied\P activity. Activity propagation for other unannotated nodes does not occur until the update_power command is run.*

If the *power_analysis_mode* has been set to *time_based*, the *get_switching_activity* command does not have access to toggle rate information prior to running the *update_power* command. The command reports whether a net is uninitialized or whether it is annotated from the VCD file, but since the VCD file has not been read yet, the toggle rate and other values are reported as -1.

In some instances, you may have incomplete annotation from simulation. In this case, one or more nets may be unannotated after reading the activity file. Part of the purpose of the *report_switching_activity* command is to help you locate these annotation problems. If possible, you should get complete simulation data. If this is not possible, it can be useful to use the -average_activity option to get average toggle rates in the design for the purpose of patching these annotation problems using the *set_switching_activity* command.

Note that a net is defined as *driverless* if it is not driven by any cell. There is no group defined to report these driverless nets, so added with *combinational* or other groups.

Examples

The following examples report switching accuracy for the current design.

In the following example, the *report_switching_activity* command is used after the *read_saif* command.

```
pt_shell> report_switching_activity

****************************************

In the following example, the *report_switching_activity* command is used with the -list_not_annotated option to find the nets that do not have switching activity information. The nets without activity are listed below the overview report.

```
pt_shell> report_switching_activity -list_not_annotated

```

In the following example, the *report_switching_activity* command is used with the -coverage option to determine whether or not the simulation testbench from which the SAIF file was derived did a good job in exercising each part of the design. In this example, the simulation did a poor job in exercising the counter_high_bits subblock.

```
pt_shell> report_switching_activity -coverage -hierarchy

****************************************
Report : Switching Activity
```

Feedback

```
        -coverage -hierarchy
Design : counter

report_sync_app_vars

Reports application variables synchronized between the manager and worker processes

Syntax

status *report_sync_app_vars*

```
[-skip_header]
[-list_only]
[-nosplit]
[-only_changed_vars]
```

Feedback

Arguments

`-skip_header`

Do not print the report's header.

`-list_only`

Instead of the report, return a list of variables.

`-nosplit`

Prevents line splitting. This can useful for scripts that extract information from the report. By default, the report generates a new line when the text cannot fit in the allotted space in a column.

`-only_changed_vars`

Reports only changed variables.

Description

The *report_sync_app_vars* command reports application variables synchronized between the manager and worker processes.

Distributed Analysis

The command can be executed in the manager process. The command shows the list of variables that will be synchronized from the manager session to worker processes at the start of the next distributed task processing round.

To execute the *report_sync_app_vars* command in all scenarios or partitions, use the *remote_execute* command. For example:

```
remote_execute -verbose {
  report_sync_app_vars
}
```

The report produced by a worker process shows the list of variables and the values that have been set at the start of the current distributed task execution on this worker. Reported values may not match the current values of these variables at the worker if the current task changed values of these variables.

---

report_target_library_subset

Reports the target library subset specifications for the top-level design and hierarchical cells.

Feedback

Syntax

status *report_target_library_subset*

```
[-objects objects]
[-top]
[-nosplit]
```

Data Types

objects	list or collection

Arguments

`-objects` *objects*

Reports the subset specifications applied to the specified hierarchical cells.

If you do not specify this option or the *-top* option, the tool reports all specifications explicitly set by the *set_target_library_subset* command.

`-top`

Reports the subset specifications applied to the top-level design.

If you do not specify this option or the *-top* option, the tool reports all specifications explicitly set by the *set_target_library_subset* command.

`-nosplit`

Does not split lines if column overflows.

Description

This command reports the target library subsets applied in the current design. This command reports only subsets that were explicitly set on objects with the *set_target_library_subset* command. This command does not report subsets that are implicitly inherited from a parent hierarchical cell.

Examples

The following example reports the target library subset for a hierarchical cell.

```
prompt> report_target_library_subset -objects [get_cells top/mid]
```

See Also

- set_target_library_subset
- remove_target_library_subset

Feedback

report_threshold_voltage_group

Reports the number and percentage of cells for each threshold voltage group in the design, including any user-specified low-threshold voltage groups.

Syntax

string *report_threshold_voltage_group*

```
[-lvth_groups groups]
[-nosplit]
[-verbose]
[-pattern_priority pattern_list]
[-attribute attribute_name]
[-area]
[-clocks clock_list]
[-rails rails_supply_nets_name]
[-exact_match]
[cell_list]
```

Data Types

groups	list
pattern_list	list
attribute_name	string
cell_list	list
clock_list	list
rails_supply_nets_name	list

Arguments

`-lvth_groups` *groups*

Specifies a list of threshold voltage groups considered low-threshold for reporting purposes. The argument is a list of threshold voltage group identifiers. Each identifier is a string containing only alphanumeric characters and possibly the underscore character. To associate these group identifiers with library cells, set the user-defined attributes named *default_threshold_voltage_group* at the library level or *threshold_voltage_group* at the library cell level.

If you do not use the *-lvth_groups* option, the report does not identify low-threshold-voltage groups.

`-nosplit`

Prevents splitting of long lines that exceed the specified column width.

`-verbose`

Lists all the cells belonging to each threshold voltage group. Without this option, the default summary report shows only the number and percentage of cells in each power group.

`-pattern_priority` *`pattern_list`*

Specifies the list of patterns of cell name (or its attribute value, if using the *-attribute* option) to process for generating the threshold voltage group report.

`-attribute` *`attribute_name`*

Specifies the name of the cell attribute used to match the name patterns specified by the *-pattern_priority* option.

`-area`

Reports the cell area (instead of number of cells) belonging to each threshold voltage group.

`-clocks` *`clock_list`*

Use this option to report only the cells those belong to the clock domains specified by the *clock_list* value.

`-rails` *`rails_supply_nets_name`*

Use this option to specify a list of supply nets under UPF mode or design rails under rail mapping mode for which the report to be shown.

`cell_list`

Specifies a list of cells to report as threshold voltage groups. If this option is omitted, the report covers all of the current design.

`-exact_match`

Use this option to exactly match the cell name pattern specified by the *-pattern_priority* option.

Description

The *report_threshold_voltage_group* command reports the number and percentage of cells in each power group belonging to different threshold voltage groups, for a given list of cells or the whole design. A PrimePower license is required and power analysis must be enabled.

The command identifies the threshold voltage groups to which the cells belong according to the *default_threshold_voltage_group* lib attribute or the *threshold_voltage_group* lib_cell attribute. The lib_cell attribute has priority over the lib attribute in the grouping process.

Clock Domain Reporting

When you specify the *clock_list* value with the *-clocks* option, a report is generated for the cells in the specified clock domains.

The cells in the clock tree network of CLK clock are taken as belonging to CLK clock domain. The cells in a timing path launched by the CLK clock are regarded as belonging

to CLK clock domain. The cells in a timing path with no launch clock, but captured by the CLK clock are regarded as belonging to the CLK clock domain as well. If a cell belongs to multiple clock domains, it is forced to belong to the clock domain with the fastest clock. If a cell belongs to no clock domains, it is forced to belong to the fastest clock domain in the design.

Rail and Supply Nets Based Reports

When you specify the *-rails* option, only the reports associated with the specified rails or supply nets are generated. The *-rails* option accepts a list of name strings. Each name string can contain one or more rail or power supply net names separated by space. One report is generated for each name string if it contains valid rails or supply nets. If the name string contains "all" keyword, a report of all rails is generated. Multiple reports can be generated by using the *report_threshold_voltage_group* command with different combinations of rail names in the list.

Examples

The following script assigns one library to a threshold voltage group named SVT and another library to a group named LFT. After that, the *report_threshold_voltage_group* command reports the threshold voltage groups in a specified order of priority.

```
define_user_attribute -type string -class lib
 default_threshold_voltage_group
set_user_attribute [get_libs agl90g_od_svt_ss]
 default_threshold_voltage_group SVT
set_user_attribute [get_libs agl90g_od_lvt_ss]
 default_threshold_voltage_group LVT

```

Arguments

`-from` *from_list*

Reports only paths that start from the specified list of pins, ports, nets, or cell instances; or from startpoints clocked by the named clocks. Valid startpoints are clock pins of sequential devices and input ports of the design.

`-rise_from` *rise_from_list*

Same as the *-from* option, except that the path must start with a rising transition. If you specify a clock object, the option selects startpoints clocked by the named clock and launched by a rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *fall_from_list*

Same as the *-rise_from* option, except that the path must start with a falling transition.

`-to` *to_list*

Reports only paths that end at the specified list of pins, ports, nets, or cell instances; or at endpoints clocked by the named clocks. Valid endpoints are data input pins of sequential devices and output ports of the design.

Due to the infrastructure of the timing analyzer, the *-to* option runs more efficiently than the *-from* option. As a result, endpoint-oriented reporting flows (based on using the *-to* option) outperform equivalent startpoint-oriented reporting flows (based on using the *-from* option).

`-rise_to` *`rise_to_list`*

Same as the *-to* option, except that the path data must end with a rising transition. If you specify a clock object, the option selects endpoints clocked by the named clock and captured by a rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Same as the *-rise_to* option, except that the path data must end with a falling transition.

`-through` *`through_list`*

Reports only paths in which the data goes through the named pins, ports, cell instances, or nets. You can use this option multiple times in a command.

When a single *-through* list contains multiple objects, the data path can go through any one of the listed objects. When you use multiple *-through* options, the data path must meet each of the *-through* options in sequence.

For example, the following command reports a path that starts at A1, then passes through either B1 or B2, then passes through C1, and ends at D1.

```
pt_shell> report_timing -from A1 -through {B1 B2} -through C1 -to
 D1
```

If advanced analysis through transparent latches is enabled (*timing_enable_through_paths* set to *true*), and the pins specified in the last *-through* option are latch loop breakers, then the timing paths reported are constrained by the worst of the closing edges at the latch or by a required value computed using logic downstream of the latch loop breaker. The latter constraint is called "time required through endpoint" in the timing report, and the latch is said to be constrained by "downstream required."

`-rise_through` *`rise_through_list`*

Same as the *-through* option, except that it applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

Same as the *-through* option, except that it applies only to paths with a falling transition at the specified objects.

`-exclude` *`exclude_list`*

Excludes all paths in which the data goes from, through, or to the specified list of pins, ports, nets, or cell instances; or excludes all paths belonging to the specified list of path tag sets. This option checks only data paths (not clock paths) for excluded objects.

Feedback

Using the *-exclude* option can result in significantly longer runtimes. To reduce the runtime impact, use this option together with other topological restriction options, such as *-from* and *-through*.

The *-exclude* option does not check borrowing paths considered by the *-trace_latch_borrow* option.

`-rise_exclude` *`rise_exclude_list`*

Same as the *-exclude* option, but applies only to rising transitions at the named pins, ports, nets, or cell instances.

`-fall_exclude` *`fall_exclude_list`*

Same as the *-exclude* option, but applies only to falling transitions at the named pins, ports, nets, or cell instances.

You can use no more than one of the *-exclude*, *-rise_exclude*, or *-fall_exclude* options in a command.

`-delay_type` *`delay_type`*

Specifies the type of path delay constraint to consider for finding and sorting paths with the worst slack:

- *max* (default) -- max delay (setup constraint)
- *min* -- min delay (hold constraint)
- *min_max* -- both min and max delay (reports min first, max second)
- *max_rise* -- max delay, rising at data path endpoint
- *max_fall* -- max delay, falling at data path endpoint
- *min_rise* -- min delay, rising at data path endpoint
- *min_fall* -- min delay, falling at data path endpoint

`-nworst` *`paths_per_endpoint`*

Reports up to the specified number of worst paths per endpoint. The default is 1. A larger value results in a larger report and more runtime. Allowed values are 1 to 2000000.

If you set *-nworst* to any number greater than 1, the command automatically does the following:

- Implicitly sets *-max_paths* equal to the *-nworst* setting if the *-max_paths* option is not used in the command, so that at least one set of multiple paths to an endpoint can be reported.
- Implicitly sets *-slack_lesser_than 0.0* if the *-slack_lesser_than* and *-slack_greater_than* options are not specified, so that only violators are reported.

`-max_paths` *`max_path_count`*

Reports up to the specified maximum total number of paths.

If the *-group* option is specified, the total number of paths reported is at most the specified number of paths per path group.

If the *-group* option is not specified, the total number of paths reported is at most the specified number of paths among all path groups.

The *max_path_count* must be greater than zero. The default *max_path_count* is equal to the *-nworst* setting, or 1 if the *-nworst* option is not specified.

If you set *-max_paths* to a value greater than 1, the command implicitly sets *-slack_lesser_than 0.0* if the *-slack_lesser_than* and *-slack_greater_than* options are not specified, so that only violators are reported.

The *-nworst* option controls the maximum number of paths reported *per endpoint*, whereas the *-max_paths* option controls the *overall total maximum number* of paths reported. The *-max_paths* setting should be at least as large as the *-nworst* setting, so by default the tool implicitly sets *-max_paths* to the same value as *-nworst* if the *-max_paths* option is not specified.

`-group` *`group_name`*

Reports only paths that belong to the specified path groups.

Path groups are created by the *create_clock* and *group_path* commands. Without the *-group* option, the *report_timing* command reports paths without considering path groups. For example, the *report_timing* command alone reports the single worst path in the design, whereas *report_timing -group [get_path_groups]* reports the single worst path *in each path group*.

If the *-sort_by group* option is specified and *-group* is not specified, then an implicit *-group* * specification is used.

`-unique_pins`

Reports only the single worst timing path through any given sequence of pins. No other paths are reported for the same sequence of pins from startpoint to

endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin sequence, then paths starting with a falling edge are not reported for that sequence of pins.

For non-unate logic such as XOR gates, using this option greatly reduces the number of paths reported because of the large number of possible rising/falling edge combinations through each sequence of pins.

Using this option can require longer runtimes when used with the *-nworst* option because many paths must be analyzed to find the worst path through each pin sequence, but only the worst path is reported and counted toward the total number of requested paths.

`-slack_greater_than` *`minimum_slack`*

Reports only paths with slack greater than the specified *minimum_slack* value; these paths have a negative slack better than the specified *minimum_slack* value (or a positive slack that is farther from causing a violation). This option is intended to be used with the *-slack_lesser_than* option to report paths within a specific range of slack.

Unlike the *-slack_lesser_than* option, the *-slack_greater_than* option acts as a post-processing filter to restrict the paths that are reported. As a result, the number of paths reported might be less than the number specified with the *-nworst* and *-max_paths* options.

`-slack_lesser_than` *`maximum_slack`*

Reports only paths with slack less than the specified *maximum_slack* value; these paths have a negative slack worse than the specified *maximum_slack* value (or a positive slack that is closer to causing a violation).

If this option is not specified, the default is computed as follows, highest precedence first:

- If exhaustive PBA is used (*-pba_mode* set to *exhaustive* or *ml_exhaustive*), then the default is 0.0, so that only violators are reported.
- Otherwise, if either *-max_paths* or *-nworst* is set to a value greater than 1, then the default is 0.0, so that only violators are reported.
- Otherwise, the default is "infinity", so that the worst path is reported.

The *-slack_lesser_than* and *-slack_greater_than* options act as filters to restrict the paths that are reported, so the number of paths reported can be fewer than the number specified with the *-nworst* and *-max_paths* options. If no paths meet the slack criteria, no paths are reported.

`-ignore_register_feedback` *`feedback_slack_cutoff`*

Ignores noninverting timing loops that start and end at the same register pin that holds a value. To be ignored, the data-to-output arc and the output-to-data path must be either both inverting or both noninverting. This option applies to minimum delay as well as maximum delay constraints. Paths are ignored only if they have a slack less than the specified *feedback_slack_cutoff* value.

This option acts as a filter to restrict the paths that are reported, so the number of paths reported might be less than the number specified with the *-nworst* and *-max_paths* options.

`-report_ignored_register_feedback`

Displays a list of ignored paths when you use the *-ignore_register_feedback* option.

`-include_hierarchical_pins`

Causes the timing path report to show hierarchical pins as well as leaf pins. The hierarchical pins are shown for informational purposes only; they are reported as having zero incremental delay and they do not affect the timing results.

`-trace_latch_borrow`

Controls the type of report generated for paths that starts at a transparent latch.

If the path startpoint borrows from the previous path segment, using this option causes the report to show the set of borrowing paths that lead up to the borrowing latch, starting with a nonborrowing path or a noninverting sequential loop. Each path segment is reported separately, showing the time borrowed and lent and the endpoints of the path segment.

Without the *-trace_latch_borrow* option, the command does not include upstream borrowing latches when in default latch analysis mode or borrowing latch loop breakers when in advanced latch analysis mode (*timing_enable_through_paths* set to *true*) as path segments in the timing report.

`-trace_latch_forward`

Controls the type of report generated for a path that ends at a transparent latch D pin.

If advanced analysis through transparent latches is enabled (*timing_enable_through_paths* set to *true*) and this transparent latch D pin is constrained by a downstream required time, this option causes the report to show the paths in the fanout of this D pin that led to the downstream required constraint. These paths can include multiple path segments whereby the constraint is the result of propagating through more than one latch constrained by the downstream required time. In this case, each path segment is reported separately, showing the downstream required time for that path segment.

Feedback

Without the *-trace_latch_forward* option, the command does not trace the path beyond the specified endpoint.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Specifies one of the following path-based timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths. To control the ordering of the paths (either by original graph-based slack or recalculated path-based slack), set the *pba_path_mode_sort_by_gba_slack* variable.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode. You cannot use the *exhaustive* mode together with the *-start_end_pair*, *-cover_design*, or *path_collection* options.
- *ml_exhaustive* - Performs Machine Learning based exhaustive path-based analysis. This mechanism deploys machine learning techniques to trade runtime versus accuracy during the analysis. Accuracy and runtime will approach *-pba_mode exhaustive* as the design approaches zero-slack signoff.

In ordinary graph-based (default) timing analysis, the tool considers both the worst arrival time and worst slew among all signals feeding into a path, even when the worst arrival and worst slew come from different signals.

In path-based timing analysis, the tool considers each path in isolation from other paths, which eliminates impossible combinations of worst slew and worst arrival, and similar combinations of effects such as crosstalk and CRPR. As a result, path-based analysis reduces pessimism and increases accuracy at the cost of more runtime.

`-start_end_type` *`from_to_type`*

Restricts the report to one of four classes of paths based on the type of startpoint and endpoint:

- *reg_to_reg* - from register to register
- *reg_to_out* - from register to output port
- *in_to_reg* - from input port to register
- *in_to_out* - from input port to output port

In this description, "register" means any valid startpoint or endpoint that is not an input port, output port, or bidirectional port, even if not a sequential register. For example, a clock-gating check endpoint qualifies as a "register" in the *in_to_reg* from-to type. A bidirectional port qualifies as both an input port and an output port.

`-normalized_slack`

Gathers, sorts, and reports paths using normalized slack instead of absolute slack. Normalized slack is the absolute slack divided by an idealized maximum allowable propagation delay (typically the clock period). To use this option, the *timing_enable_normalized_slack* variable must be set to *true* for the current timing update.

`-start_end_pair`

Reports the worst path for each startpoint-endpoint pair in the design.

If *-slack_lesser_than* is not specified, all violating startpoint-endpoint pairs are reported (an implicit *-slack_lesser_than* value of 0.0). If *-slack_lesser_than* is specified, the violating startpoint-endpoint pairs meeting that requirement are reported. The number of paths reported is limited to 2000000 unless *-max_paths* is used to exceed this.

The following options can be used to control the *-start_end_pair* behavior:

-max_paths
-nworst
-slack_lesser_than
-from / -rise_from / -fall_from
-through / -rise_through / -fall_through
-to / -rise_to / -fall_to
-exclude / -rise_exclude / -fall_exclude

The *-start_end_pair* option can result in very large reports and long runtimes. Use the preceding options thoughtfully to generate the report. For example, you could use the *-slack_lesser_than* option to specify a slack limit that is only slightly greater than the worst slack in the design.

The following options cannot be used with the *-start_end_pair* option:

-cover_design
-slack_greater_than
-unique_pins
-ignore_register_feedback / -report_ignored_register_feedback
-pba_mode exhaustive | ml_exhaustive
path_collection

The *-start_end_pair* option sorts the paths first by endpoint and then by slack, with the paths sharing the same endpoint reported together in order of increasing slack.

`-cover_design`

Reports the worst path through each violating pin in the design, so that the reported paths cover every violating pin in the design. A pin is deemed to be violating if its slack is less than zero, or less than the value specified with the *-slack_lesser_than* option if that option is used. The slack of a pin is the worst slack among all paths that start at, pass through, or end at that pin. There is no limit on the number of reported paths.

The following options can be used to control the *-cover_design* behavior:

-slack_lesser_than
-from / -rise_from / -fall_from
-through / -rise_through / -fall_through
-to / -rise_to / -fall_to
-exclude / -rise_exclude / -fall_exclude

The following options cannot be used with the *-cover_design* option:

-nworst
-max_paths
-start_end_pair
-unique_pins
-ignore_register_feedback / -report_ignored_register_feedback
-pba_mode exhaustive | ml_exhaustive
path_collection

`-cover_through` *through_list*

Reports the single worst violating path through each of the named pins, ports, cell instances, and nets. Only paths with negative slack are reported (or with slack less than the value specified by the *-slack_lesser_than* option, if used).

The number of paths reported is less than or equal to the number of objects in the *through_list*. Fewer paths are reported if there are no violating paths through the objects, or if the worst path through one object is the same as the worst path through another object; duplicate paths are combined into a single path.

The following options cannot be used with the *-cover_through* option:

-nworst
-max_paths
-start_end_pair
-unique_pins
-through / -rise_through / -fall_through
-exclude / -rise_exclude / -fall_exclude
-ignore_register_feedback / -report_ignored_register_feedback

-pba_mode exhaustive | ml_exhaustive
path_collection

-dont_merge_duplicates

Prevents the merging of duplicate paths across multiple scenarios in distributed multi-scenario analysis (DMSA).

By default, when the same path is reported in more than one scenario, the tool reports only the single most critical instance of that path in the merged report and shows its associated scenario.

If you use this option, the tool does not merge duplicate instances of the same path, but instead reports all critical instances of the path from all scenarios. Because the number of paths reported might be limited by *-nworst*, *-max_paths*, or other command options, the resulting merged report might be more focused on a portion of the design that is critical in multiple scenarios, and less evenly spread out across different portions of design.

-pre_commands *pre_command_string*

Specifies a list of commands, separated by semicolons, to be executed in the worker context before execution of the *report_timing* command. This option is available only if you invoke the PrimeTime tool with the *-multi_scenario* option. The maximum size of a command is 1000 characters.

-post_commands *post_command_string*

This option is like the *-pre_commands* option, except that the commands are executed after (instead of before) the *report_timing* command.

-path_type *format*

Specifies the types of path information displayed in the timing report, using one of the following format keywords:

- *summary* -- Displays the path startpoint, path endpoint, and slack.
- *end* -- Displays the path endpoint, path delay, required time, and slack.
- *short* -- Displays a report like the default *full* report but omits the intermediate points between the startpoint and endpoint.
- *full* (the default) -- Displays the full data path, including all intermediate points and their incremental and cumulative delay, together with the launch and capture clock arrival times, data required time, and slack.
- *full_clock* -- Displays a *full* report with the addition of the clock path points from the clock source to the launch and capture points.

- *full_clock_expanded* -- Displays a *full_clock* report with the addition of the clock path points between the primary clock source and its related generated clock source point. This report is different from a *full_clock* report only when the clock is a generated clock.

`-input_pins`

Shows cell input pins as well as cell output pins in the timing path. As a result, the report shows the incremental net and cell delays separately at each point, instead of combined. By default, the report shows only the cell output pins.

`-nets`

Shows nets in the timing path. By default, the report does not show nets.

`-nosplit`

Prevents line splitting. This can useful for scripts that extract information from the report. By default, the report generates a new line when the text cannot fit in the alloted space in a column.

`-transition_time`

Shows the transition time (slew) in the path report for each driver pin and load pin, appearing as an additional column labeled "Trans". By default, the report does not show transition time.

`-capacitance`

Shows the total capacitance in the path report for each net, appearing as an additional column labeled "Cap". By default, the report does not show capacitance.

The reported values consider either the CCS receiver capacitance (the default) or the lumped capacitance for pins, depending on the *report_capacitance_use_ccs_receiver_model* variable setting.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point displayed for time values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which is 2 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-crosstalk_delta`

Reports the annotated delta delay values at cell input pins in a column labeled "Delta". The *-input_pins* option is automatically selected. The delta values are computed during crosstalk signal integrity analysis, or they can be annotated manually by using the *set_annotated_delay -delta_only* and *set_annotated_transition -delta_only* commands. Note that the *-crosstalk_delta*

option only reports previously calculated or annotated delta values; it does not initiate crosstalk analysis. Delta transition times are also shown if you use the *-transition_time* option.

`-derate`

Shows derating factors in a column labeled "Derate". The default is to not show derating factors. Specifying this option automatically sets the *-input_pins* option, so that different net and cell derating values are reported. When you use the *-path_type full_clock_expanded* option, an additional summary report follows the timing report showing the overall effect of derating the path. Derating factors are always shown with at least two significant digits.

`-variation`

Includes parametric on-chip variation (POCV) information in the report in columns labeled "Mean" and "Sensit". POCV analysis is enabled by setting the *timing_pocvm_enable_analysis* variable to *true*.

`-exceptions dominant | overridden | all`

Reports user-specified timing exceptions that are satisfied per timing path being reported.

Specifying *dominant* reports the dominant timing exception in the path. It can be one of the following: false path, minimum and maximum delays, and multicycle paths.

Specifying *overridden* reports all the timing exceptions that were overridden by the dominant timing exception.

The unconstrained paths and their reasons are reported for all three options if *timing_report_unconstrained_paths* variable is set to *true*, otherwise unconstrained paths are not reported.

To get more information about the exceptions that apply to the path, you can create a path collection with the *get_timing_paths* command, then query certain timing path attributes. For details, see the man page for the *get_timing_paths* command.

Note: The additional per-path analysis required by the *-exceptions* option can be significant.

This option cannot be used with the *-path_type short/end/summary* option.

`-voltage`

Reports the operating voltage for each path element in a column labeled "Voltage", allowing you to debug voltage levels in multivoltage designs. The displayed voltage is the voltage used in delay calculation, which is typically the

voltage of the operating condition, related supply net, related power pin, or pin signal.

`-supply_net_group`

Reports the supply group or the supply net name for each path element in a column labeled "Supply-Net-Group". If the supply net group name is not defined, the column shows the word "unconnected". If the supply group is not defined and the supply net name is available, then the supply net name is reported in the column along with the letter "n".

`-physical`

Reports the X-Y coordinates for each path element in a column labeled "Location". The location information must be available from previous usage of the *read_parasitics* command with the *read_parasitics_load_locations* variable set to *true*. If the X-Y coordinate data is not available for some or all of the elements, the report shows the string "unplaced" for the missing data.

`-sort_by slack | group`

Specifies the sorting of the reported paths, either by *slack* or by *group*. Ordering by slack means ordering the path reports strictly by slack, ignoring group membership. Sorting by group means ordering the path reports by group, and within each group, by slack.

The default is to sort by *slack*. However, if *-group* is specified, then the default is to sort by *group*.

`-tag_paths_filtered_by_pba` *`tag_name`*

When used with the *-pba_mode path* option, the *-tag_paths_filtered_by_pba* option causes tagging of all paths originally found by path-based analysis and later discarded by path-based analysis, using the specified tag name. In future *get_timing_paths* and *report_timing* commands, you can exclude the tagged paths from further analysis by specifying the tag name as an argument to the *-exclude* option.

`-imsa_session` *`session_name`*

This option can only be used in IMSA mode, when the *eco_update_path_timing* variable is set to *true*. By default, *report_timing* in IMSA mode covers all in-memory timing path collections. When this option is used, *report_timing* covers the timing paths from the specified session only.

`path_collection`

Specifies a collection of timing paths to report, for example, a collection previously created by *set mypaths [get_timing_paths ...]*. When you use this option with the *-pba_mode path* option, the command performs path-based analysis on the paths in the *path_collection* before they are reported. This option

is mutually exclusive with options that control the selection of paths to report; it is compatible only with options that control the formatting of the report.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only timing paths compatible to the specified SMS scenarios collection are reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

`-domain_crossing` *`domain_crossing_mode`*

Specifies the domain crossing report mode. Allowed values include *all, only_crossing, exclude_crossing*. The default mode is *all*. This option is applied as a reporting filter, ensuring that only paths which satisfy the specified mode are reported. With the default setting of *all*, all paths are considered for reporting, including cross-domain and intra-domain. With the *only_crossing* mode, reports include only cross-domain paths. Using the *exclude_crossing* mode only reports intra-domain paths.

This option is only available with SMVA or SMC analysis.

`-pocv_pruning`

Generates a path collection that contributes to joint success rate. This option prunes away all subcritical paths that have no impact on high sigma failure rate. The returned path collection can be used with the *get_design_variation* command for design variation analysis.

This option requires that the *-pba_mode exhaustive* option also be used. It can significantly reduce runtime and memory of both *get_timing_paths* and *get_design_variation*, so it is recommended for use when generating path collections for design variation analysis.

`-attributes` *`attribute_list`*

Specifies a list of *timing_point* attributes to be printed inline with each timing point row.

`-timing_path_attributes` *`attribute_list`*

Specifies a list of *timing_path* attributes to be printed in the report header of each path (that includes information such as startpoint, endpoint, and the last common pin).

`-vdd_slack`

Shows voltage slack and voltage sensitivity information in the report for path collections generated with *get_timing_paths -vdd_slack_lesser_than* or *get_timing_paths -vdd_slack_greater_than*. The *-vdd_slack* option must be used together with a *path_collection* argument.

`-vdd_slack_lesser_than` *`maximum_vdd_slack`*

Performs voltage slack analysis on the paths and shows voltage slack in the report if the value is less than the specified *maximum_vdd_slack value.*

The following options must also be used with the *-vdd_slack_lesser_than* option:

```
-pba_mode path | exhaustive
-path_type full_clock_expanded
```

`-vdd_slack_greater_than` *`minimum_vdd_slack`*

Performs voltage slack analysis on the paths and shows voltage slack in the report if the value is greater than the specified *minimum_vdd_slack value.*

The following options must also be used with the *-vdd_slack_greater_than* option:

```
-pba_mode path | exhaustive
-path_type full_clock_expanded
```

Description

The *report_timing* command reports the timing paths in the current design that have the worst slack. These are the paths that violate the timing constraints by the largest amounts, or paths with positive slack that come closest to causing a timing violation.

Each path has a startpoint and an endpoint. Data is launched by a clock edge at the path startpoint, propagated through combinational logic in the path, and then captured at the path endpoint by another clock edge. The startpoint can be a register clock pin or an input port. The endpoint can be a register data input pin or an output port.

To restrict the scope of the report to only the paths that start, pass through, or end on specific pins, ports, nets, or cell instances, use the *-from*, *-though*, and *-to* options, and the similar transition-specific options (*-rise_from*, *-fall_to*, and so on). To restrict the report to specific clocks, you can use the same options (for example, *-to [get_clocks CLK1]*) or the *-group* option.

By default, the *report_timing* command without options reports the single path in the design with the worst max delay (setup constraint) violation. To consider constraints other than max delay, use the *-delay_type* option. To control the number of paths reported, use the *-nworst* option, which specifies the maximum number of worst paths reported per endpoint; and the *-max_paths* option, which specifies the overall maximum number of paths reported by the command.

To report paths whose slack values fall within a specific range, use the *-slack_lesser_than* and *-slack_greater_than* options in combination with the *-nworst* and *-max_paths* options.

The default timing report shows the point-to-point sequence of cell output pins in the data path, as in the following example:

```
Startpoint: I_ORCA_TOP/I_PCI_CORE/pad_en_reg
              (rising edge-triggered flip-flop clocked by PCI_CLK)
 Endpoint: pad[1] (output port clocked by PCI_CLK)
 Path Group: PCI_CLK
 Path Type: max

 Point                                                  Incr       Path
 -----------------------------------------------------------------------
 clock PCI_CLK (rise edge)                             0.000      0.000
 clock network delay (propagated)                      1.105      1.105
 I_ORCA_TOP/I_PCI_CORE/pad_en_reg/CP (sdcrq1)          0.000      1.105 r
 I_ORCA_TOP/I_PCI_CORE/pad_en_reg/Q (sdcrq1)           0.404 &    1.509 r
 U7/ZN (inv0d1)                                        0.066 &    1.575 f
 U62/ZN (inv0d1)                                       0.042 &    1.617 r
 U63/Z (or02d7)                                        0.269 &    1.887 r
 U63ASTipoInst495/Z (bufbdk)                           0.306 &    2.192 r
 U63ASTipoInst494/Z (bufbda)                           3.798 &    5.991 r
 pad_iopad_1/PAD (pc3b03)                              6.118 H   12.109 r
 pad[1] (inout)                                        0.048     12.157 r
 data arrival time                                               12.157

 clock PCI_CLK (rise edge)                            15.000     15.000
 clock network delay (propagated)                      0.000     15.000
 output external delay                                -4.000     11.000
 data required time                                              11.000
 -----------------------------------------------------------------------
 data required time                                              11.000
 data arrival time                                              -12.157
 -----------------------------------------------------------------------
 slack (VIOLATED)                                                -1.157
```

The report shows the incremental delay contributed by each pin-to-pin segment of the path (Incr column) and the cumulative path delay up to each pin in the timing path (Path column). The table also shows the data launch clock arrival time, the data capture clock arrival time, an accounting of arrival time versus required time, and the resulting timing slack for the path. A negative slack indicates a timing violation.

To calculate the delay contributed by each point along the path, the tool considers any back-annotated RC network or SDF delay information. The types of back-annotated data on path elements in the timing path are indicated by a character symbol in the Incr column:

```
Symbol      Annotation
------      ----------
  H         Hybrid annotation
  ^         Ideal network latency annotation
  *         SDF back-annotation
  &         RC network back-annotation
  $         RC pi back-annotation
  +         Lumped RC
```

```
  @          HyperScale annotation
none         Wire-load model or none
```

Certain annotations dominate others. For example, SDF takes precedence over back-annotated RC parasitics. The symbol displayed in the Incr column indicates the dominant annotation on the path element.

If the *-input_pins* option is used, the report includes the input pins as well as output pins of each cell in the path. In that case, each pin-to-pin delay spans either a net or cell. Without the *-input_pins* option, the delay shown can span both a net and a cell. If the net and cell have the same dominant annotation, the appropriate symbol is shown; otherwise, the "H" symbol indicates that a hybrid of annotation types exists on the corresponding path segment.

The dominant annotation is not necessarily the actual annotation used to calculate the delay. For example, suppose that a back-annotated RC network exists on a net, but the network calculation fails to converge for the driver cell delay. In that case, you get a warning message and a lumped RC model is used instead. However, in the timing report, the "&" symbol still reports the RC network annotation as the dominant annotation. To see the actual pin-to-pin delay calculation in detail, use the *report_delay_calculation* command.

To control the amount of detail provided in the point-to-point timing report, use the following options:

- *-path_type* -- Specifies the report format: *short*, *full*, *full_clock*, ...
- *-input_pins* -- Lists the cell input pins (in addition to output pins) in the path
- *-nets* -- Lists the nets (as well as pins) in the path
- *-transition_time* -- Shows transition time (slew) in a separate column
- *-capacitance* -- Shows capacitance values in a separate column
- *-crosstalk_delta* -- Shows annotated delta delay values in a separate column
- *-derate* -- Shows derating factors in a separate column
- *-variation* -- Shows POCV mean and sensitivity values in separate columns
- *-voltage* -- Shows operating voltages in a separate column
- *-physical* -- Shows XY coordinates a separate column

To invoke path-based analysis, use the *-pba_mode* option. In path-based timing analysis, the tool considers each path in isolation from other paths, which eliminates impossible combinations of worst slew and worst arrival, and similar combinations of effects such as crosstalk and CRPR. As a result, path-based analysis reduces pessimism and increases accuracy at the cost of more runtime.

Feedback

Examples

The following example reports the single path in the design with the worst max-delay (setup) slack:

```
pt_shell> report_timing
****************************************
Report : timing
        -path_type full
        -delay_type max
        -max_paths 1
        -sort_by slack
        ...
****************************************

```

The following example shows a timing report with the *-derate* and *-path_type full_clock_expanded* options. The *-derate* option shows the applicable derating factors in a separate column. The *-path_type full_clock_expanded* option reports the clock path points from the clock source to the launch and capture points, including points from the primary clock and its related generated clock; and also displays a derating summary report at the end.

```
pt_shell> set_timng_derate -late 1.04
1
pt_shell> report_timing -derate -path_type full_clock_expanded
 ...
  Startpoint: I_ORCA_TOP/I_PCI_CORE/pad_en_reg
```

Feedback

report_timing_budget

Reports the budget allocation specifications applied by the *set_timing_budget* command.

Syntax

string *report_timing_budget*

```
-verbose
```

Data Types

verbose	boolean

Arguments

`-verbose`

Reports all the hierarchical pins of a block separately.

Examples

The following command reports the budget allocation specifications applied to the current design:

```
pt_shell> report_timing_budget

Point                Budget Allocation Mode      Path Type       Value
-------------------------------------------------------------------------
<Global Mode>        slack_margin                                 1.00
BLK1/Z               delay_value                 max              3.00
```

See Also

- set_timing_budget
- update_budget

report_timing_derate

Reports derating previously set by the *set_timing_derate* command.

Syntax

status *report_timing_derate*

```

[-min_pulse_width]
```

```
[-significant_digits digits]
[-nosplit]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

```
digits                int
object_list           list
sms_scenarios_list    collection
```

Arguments

`-include_inherited`

Reports the name of the design, ancestor cell, or library cell from which each object inherits its derating settings.

`-aocvm_guardband`

Reports derating previously set by the *set_timing_derate -aocvm_guardband* command.

`-pocvm_guardband`

Reports derating previously set by the *set_timing_derate -pocvm_guardband* command.

`-pocvm_coefficient_scale_factor`

Reports derating previously set by the *set_timing_derate -pocvm_coefficient_scale_factor* command.

`-pocvm_subtract_sigma_factor_from_nominal`

Reports derating previously set by the *set_timing_derate -pocvm_subtract_sigma_factor_from_nominal* command.

`-increment`

Reports incremental derating adjustments previously set by the *set_timing_derate -increment* command.

`-min_period`

Reports min period constraint derating adjustments previously set by the *set_timing_derate -min_period* command.

`-min_pulse_width`

Reports min pulse width constraint derating adjustments previously set by the *set_timing_derate -min_pulse_width* command.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point to be displayed for values in the report. The default is determined by the *report_default_significant_digits* variable.

`-nosplit`

Prevents splitting of long lines of text in the report.

object_list

Reports derating for the given list or collection of cells, library cells, or nets. To report the names of parent objects from which these objects inherit their derating factors, also use the *-include_inherited* option in the command.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios to analyze. Only timing derate information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *report_timing_derate* command reports derating previously set by the *set_timing_derate* command for each object on which derating has been set: the design, cell instances, and nets; or for the objects listed in the *object_list* option. The derating factors are reported in a table format, organized by setting type:

```
pt_shell> report_timing_derate -significant_digits 2
 ...
                           ----- Clock -----              ----- Data -----
                          Rise          Fall            Rise
 Fall

 1.30
```

To report the name of the design, ancestor cell, or library cell from which each object inherits its derating settings, use the *-include_inherited* option in the command. For example, a leaf-level cell might show the name of the ancestor cell or library cell on which derating was set.

Examples

In the following example, derating is set globally (only on the design), so the *report_timing_derate* command reports only global derating factors.

```
pt_shell> set_timing_derate  -data -early 0.92
pt_shell> set_timing_derate  -data  -late 1.14
pt_shell> set_timing_derate -clock -early 0.75
pt_shell> set_timing_derate -clock  -late 1.26
pt_shell> report_timing_derate
 ...
                              ----- Clock ------              ------ Data
 ------
                             Rise            Fall            Rise
   Fall
                         Early    Late   Early    Late   Early    Late
 Early    Late
 ------------------------------------------------------------------------
------------
 design: simple_path
   Net delay static      0.75    1.26    0.75    1.26    0.92    1.14
 0.92    1.14
   Net delay dynamic     0.75    1.26    0.75    1.26    0.92    1.14
 0.92    1.14
   Cell delay            0.75    1.26    0.75    1.26    0.92    1.14
 0.92    1.14
   Cell check             --      --      --      --      --      --
 --      --
```

In the following example, incremental derating is set globally (only on the design), so the *report_timing_derate -increment* command reports only global incremental derating adjustments.

Feedback

```
pt_shell> set_timing_derate  -data -increment -early -0.02
pt_shell> set_timing_derate  -data -increment  -late  0.06
pt_shell> set_timing_derate -clock -increment -early -0.05
pt_shell> set_timing_derate -clock -increment  -late  0.10
pt_shell> report_timing_derate -increment
 ...
                             ----- Clock ------              ------ Data

Feedback

report_total_net_capacitance

Reports the total capacitance of specified nets.

Syntax

status *report_total_net_capacitance*

```
        nets
```

Data Types

nets	list

Arguments

nets

A list of one or more nets for which to report the total capacitance. At least one net is required. Glob-style wildcards (*) are supported.

Description

This command reports the total capacitance of specified nets.

This command is supported only for transistor-level GPDs.

Examples

The following example shows a total net capacitance report.

```
pt_shell> report_total_net_capacitance {SUM0 B0}
************************************
Report : Total Capacitance
Design : toprt
Version: Q-2019.12
Date   : Thu Nov 7 15:50:45 2019
************************************
========    =================
Net Name    Total Capacitance
========    =================
SUM0        0.013721
B0          0.089779
```

report_trace

Produce a report of performance profile metrics collected for traced commands.

Feedback

Syntax

report_trace [-start|-stop|resume] [-profile profile_type] [-command command_name] [-cumulative count] [-top count] [-quiet]

string *profile_type* string *command_name* int *count*

Arguments

`-start`

This option is mutually exclusive with -stop, -resume, -profile, -top, -cumulative, -command. The option starts the collection of performance profile statics for each traced command invocation. If metric collection had previously been stopped with -stop, then previously collected data are deleted before collection starts.

`-stop`

This option is mutually exclusive with -start,-resume, -profile, -top, -cumulative, -command. The option stops the collection of performance profile statics for traced command invocations.

`-resume`

This option is mutually exclusive with -start, -stop, -profile, -top, -cumulative, -command. The option resume the collection of performance profile statics for traced command invocations. Previous gathered statics remain and newly collected metrics are added to pre-existing data. This option may be used after -stop to resume data collection without deleting previously collected data.

`-profile` *`profile_type`*

This option is mutually exclusive with -start, -stop, and -resume. This option selects the profile metrics that are included in the report. Allowed valuesA valid value is a list of permitted values {memory, cpu, time, count}, or the value all to select all metrics. If -profile is given, then the report output contains performance profile data of given types only. If the option is omitted, then it defaults to all.

`-cumulative` *`count`*

This optional option is mutually exclusive with -start, -stop, -resume, and -command. This option limits the number of commands reported for the top resource consumer accumulated over all invocations. However, all commands that share the same usage metric as the minimum consumer included in the count will be shown. If the option is omitted, the report output contains the top 10 consumers.

`-top` *`count`*

This optional option is mutually exclusive with -start, -stop, -resume and -command. This option limits the number of commands reported for the top

resource consumer per single invocation. However, all commands that share the same usage metric as the minimum consumer included in the count will be shown. If the option is omitted, the report output contains the top 10 consumers.

`-command` *`command_name`*

This option is mutually exclusive with -start, -stop, -resume, -top and -cumulative. This option causes a performance profile report to be displayed for the given command. Cumulative and top single invocation metrics are shown. If the command was not invoked, then a message with this information is displayed instead of a report.

`-quiet`

If given, this option causes the command to ignore error conditions such as an attempt to start profile gathering when it has already been started or reporting on a non-existent command. The command will exit quietly when it encounters an error condition.

Description

The *report_trace* command collects performance profile metrics on all traced command invocations since the last -start. Stopping the gathering is not necessary to produce a report. When performance profile collection is started with report_trace -start, each traced command will be measured for the available performance metrics: memory, CPU, wallclock time, and call count. The accumulated profile data can be reported at any time by calling this command

Stopping the metric gathering with -stop freezes the gathered metrics until the next -start. When gathering is restarted, all previously gathered metrics are deleted. Alternatively, metric collection may be restarted without deleting previously collected data using -resume.

The *report_trace* with no options will report the top 10 consumers in both cumulative and single call metrics for all profile types collected thus far.

Examples

The following example starts the collection of performance profile metrics.

```
prompt> report_trace -start
on
```

The following example produces a report of top 10 commands with most usage for all profile types for both cumulative and individual call consumption. 10 is the default number reported for -top and -cumulative when these options are omitted.

```
prompt> report_trace
on
```

The following example produces a report of cumulative and the single most expensive invocation for each profile type for the command update_timing.

```
prompt> report_trace -command update_timing
on
```

The following example produces a report of top 20 consumers for cumulative and single invocation collected thus far.

```
prompt> report_trace -top 20 -cumulative 20
on
```

The following example produces a report of top 5 cumulative consumption of memory.

```
prompt> report_trace -profile memory -cumulative 5
on
```

The following example produces a report of top 15 commands with most invocations.

```
prompt> report_trace -profile count -cumulative 15
on
```

The following example produces a report of top 10 commands with most cpu and wallclock time usage for both cumulative and individual call consumption. 10 is the default number reported for -top and -cumulative when these options are omitted.

```
prompt> report_trace -profile {cpu time}
on
```

---

report_transitive_fanin

Reports logic in fanin of specified objects.

Syntax

string *report_transitive_fanin*

```
[-nosplit]
[-from from_list]
[-through through_list]
```

```
-to to_list
[-trace_arcs timing | enabled | all]
```

Data Types

```
from_list          list
through_list       list
to_list            list
```

Arguments

`-nosplit`

Does not split lines if columns overflow.

`-from from_list`

Specifies a list of pins, ports, and nets in the design to constrain the fanin of *to_list* that is reported. If you specify a net, the effect is same as listing all the load pins on the net.

`-through through_list`

Specifies a list of pins, ports, and nets in the design to constrain the fanin of *to_list* that is reported. If you specify a net, the effect is same as listing all the pins on the net.

`-to to_list`

Specifies a list of pins, ports, or nets in the design, whose transitive fanin is reported. If you specify a net, the effect is the same as listing all driver pins on the net.

`-trace_arcs timing | enabled | all`

Specifies the type of combinational arcs to trace during the traversal. Allowed values are

- *timing* (the default) - Permits tracing of valid timing arcs only -- that is, arcs that are neither disabled nor invalid due to case analysis.
- *enabled* - Permits the tracing of all enabled arcs and disregards case analysis values.
- *all* - Permits the tracing of all combinational arcs regardless of case analysis or arc disabling.

Description

The command produces a report showing the transitive fanin of specified pins, ports, or nets in the design. A pin is considered to be in the transitive fanin of an object if there is a timing path through combinational logic from the pin to that object (also see the *-trace_arcs* option). The fanin report stops at the clock pins of registers (sequential cells).

If the *current_instance* command is set, the report focuses on the fanin within the *current_instance* command. The report stops at the boundaries of the *current_instance* command, and no paths outside the *current_instance* command are reported. The report shows the hierarchical boundary pins on the current instance.

Examples

The following example shows the transitive fanin of a pin in the design.

```
pt_shell> report_transitive_fanin -to FF1/D

****************************************
Report : transitive_fanin
Design : top
 ...
****************************************

Fanin network of sink 'FF1/D':

Driver Pin       Load Pin          Type        Sense
-------------------------------------------------------------
gate1/Y          FF1/D             (net arc)   same

Load Pin         Driver Pin        Type        Sense
-------------------------------------------------------------
gate1/A          gate1/Y           AN2         same
gate1/B          gate1/Y           AN2         same

Driver Pin       Load Pin          Type        Sense
-------------------------------------------------------------
IN1              gate1/A           (net arc)   same
IN2              gate1/B           (net arc)   same
```

See Also

- current_design
- current_instance
- report_clock
- report_timing
- report_transitive_fanout

---

report_transitive_fanout

Reports logic in fanout of specified objects.

Feedback

Syntax

string *report_transitive_fanout*

```
[-nosplit]
[-trace_arcs timing | enabled | all]
-clock_tree
-from from_list
[-through through_list]
[-to to_list]
```

Data Types

```
from_list          list
through_list         list
to_list            list
```

Arguments

`-nosplit`

Does not split lines if columns overflow.

`-trace_arcs timing | enabled | all`

Specifies the type of combinational arcs to trace during the traversal. Allowed values are

- *timing* (the default) - Permits tracing of valid timing arcs only -- that is, arcs that are neither disabled nor invalid due to case analysis.
- *enabled* - Permits the tracing of all enabled arcs and disregards case analysis values.
- *all* - Permits the tracing of all combinational arcs regardless of case analysis or arc disabling.

`-clock_tree`

Reports transitive fanout of all clock sources in the design. When this option is used, the fanout search is constrained to objects in the clock network only.

`-from from_list`

Specifies a list of pins, ports, and nets in the design whose transitive fanout is reported. If you specify a net, the effect is same as listing all the load pins on the net.

`-through through_list`

Specifies a list of pins, ports, and nets in the design to constrain the fanout of *from_list* that is reported. If you specify a net, the effect is same as listing all the pins on the net.

`-to` *to_list*

Specifies a list of pins, ports, and nets in the design to constrain the fanout of *from_list* that is reported. If you specify a net, the effect is same as listing all the driver pins on the net.

Description

Produces a report showing the transitive fanout of specified pins or ports in the design. A pin is considered to be in the transitive fanout of an object if there is a timing path through combinational logic from the object to that pin (also see the *-trace_arcs* option). The fanout report stops at the inputs to registers (sequential cells).

If the *current_instance* command is set, the report focuses on the fanout within the *current_instance* command. The report stops at the boundaries of the *current_instance* command, and no paths outside the *current_instance* command are reported. The report also shows the hierarchical boundary pins on the *current_instance* command.

Examples

The following example shows the transitive fanout of a pin in the design.

```
pt_shell> report_transitive_fanout -from FF1/Q

****************************************
Report : transitive_fanout
Design : top
 ...
****************************************

Fanout network of source 'FF1/Q':

Driver Pin       Load Pin          Type        Sense
-------------------------------------------------------------
FF1/Q            gate5/A           (net arc)   same

Load Pin         Driver Pin        Type        Sense
-------------------------------------------------------------
gate5/A          gate5/Y           AN2         same

Driver Pin       Load Pin          Type        Sense
-------------------------------------------------------------
gate5/Y          OUT2              (net arc)   same
```

The following command shows the transitive fanout of all the clock sources in the design, constrained to the clock network.

```
pt_shell> report_transitive_fanout -clock_tree
```

Feedback

```
****************************************
Report : transitive_fanout
         -clock_tree
Design : top
 ...
****************************************

Fanout network of source 'CLK':

Driver Pin       Load Pin          Type        Sense
-------------------------------------------------------------
CLK              FF3/CLK           (net arc)   same
CLK              FF2/CLK           (net arc)   same
CLK              FF1/CLK           (net arc)   same
```

---

report_units

Reports the unit information.

Syntax

string *report_units*

```
[-nosplit]
```

Arguments

`-nosplit`

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting and facilitates writing software to extract information from the report output.

Description

The *report_units* command displays the units used by the current design. To generate the report, the design should be loaded and linked to a library. The units are always reported

Feedback

in reference to the MKS units such as Farad, Amp, Ohm, Second, and Volt. The resistance unit is inferred from the time and capacitance units. Both time and capacitance units are required for PrimeTime. If either of them is missing, the units are undefined and is reported as "Not specified". The most common cause of this problem occurs when the library is in an old format that needs to be recompiled with the latest Library Compiler.

If power analysis is on, the power units is also reported.

Examples

The following report is an example of the unit information that is reported:

```
pt_shell> report_units

****************************************
Report : units
Design : simple
Version: D-2010.06
Date   : Mon Jun 28 11:55:27 2010
****************************************

Units
------------------------------------------------
Capacitive_load_unit        : 1e-12 Farad
Current_unit                : 0.001 Amp

report_user_def_clock_savings

Generates power saving reports by controlling the enable parameters (toggle rate, static probability) of the registers

Syntax

string *report_user_def_clock_savings*

```
[-clock_gate_type      clock_gate_value_type]
[-enable_def_type      enable_values_type]
[-enable_toggle_rate   toggle_rate_value]
[-enable_sp            static_probability_value]
[-min_pwr_savings      power_savings]
[-min_reg_width        register_width]
```

```
[-report_nl_names]
[object_list]
```

Data Types

clock_gate_value_type	string
enable_values_type	string
toggle_rate_value	float
static_probability_value	float
power_savings	float
register_width	integer
object_list	list

Arguments

`-clock_gate_type` *clock_gate_value_type*

Use this option to specify the type of clock which drives the registers. The clock could be gated type, domain type (non-gated) or both. Default value of *-clock_gate_type* is "all" and other supported values are "gated" and "not_gated".

`-enable_def_type` *enable_values_type*

Use this option to specify the type of activity data to be used. There could be two types of activity data "avg_defs" and "user_defs". In "avg_defs" activity data is the average of design and in "user_defs" activity data is explicitily defined by the user. Default value of *-enable_def_type* is "avg_defs".

`-enable_toggle_rate` *toggle_rate_value*

Use this option to specify the Toggle Rate for the enable Pin. This option is only applicable when *-enable_def_type* is "user_defs". Default value of *-enable_toggle_rate* is 2 and used only for the non-gated registers.

`-enable_sp` *static_probability_value*

Use this this option to specify the Staic Probability for the enable Pin. This option is only applicable when *-enable_def_type* is "user_defs". Default value of *-enable_sp* is 0.5 and used only for the non-gated registers.

`-min_pwr_savings` *power_savings*

Use this option to report only those registers whose total power saving, after using the power saving technique, is more than or equal to the "power_savings" value. Default value of *-min_pwr_savings* is 0.0.

`-min_reg_width` *register_width*

Use this option to filter the bundled registers so that the bundled registers having width greater than or equal to "register_width" will be considered for power saving estimate. Default value of *-min_reg_width* is 8.

`-report_nl_names`

Use this option to report the netlist(gate-level) name of the register. By default, the RTL name or merged RTL name, in case of bus register, is reported for the registers.

`object_list`

Use this option to apply the power savings techniques on the list of registers. Options *-min_reg_width* and *-min_pwr_savings* cannot be supported with this option. Currently only the gate-level register name can be specified.

Description

Use the *report_user_def_clock_savings* command to generate the power savings report after explicitly defining the activity data of Enable of register/bus in the design. Presently, the static probability and toggle rate parameters are defined by the user.

The two important fields that the command prints are the name of registers and the potential power savings that could happen using the above technique. The other fields are: width of register bus, frequency of clock, the register is gated or not, the current and final register gate efficiency percentage, current and final enable probability, current power and the final power.

To use the command, you should first apply the update_power and update_metrics command or apply the compute_metrics command.

Controlling Activity Data on Enable

For clock-gated register, it may happen that the enable signal is not optimal and hence its Q/CP ratio could be low. In order to find the optimal enable signal, the user would like to find its optimum activity data i.e. Toggle Rate and Static Probability. By trying different values of activity data of the enable, a user can find the optimum values where maximum power savings can be achieved for the given registers.

Similarly, for non-gated registers, a user may want to see the amount of power savings achieved by firstly making it clock-gated and then finding the optimum activity data for the enable in the same way as for gated-register.

Average and User-Defined Activity Data

In "avg_defs", the activity data is calculated from the average of activity data values of all the Enable signals existed in the design.

In "user_defs", the activity data values are explicitly defined by the user. The user can either define Toggle Rate or Static Probability or both. If the user defines only one value then the other value will be the: 1. Default value in case of non-gated register. 2. Original value of the signal in case of gated register.

Feedback

Register Name in report

The command prints the RTL register name or the merged RTL names in case of bus registers by default. If mapping information does not exist for some registers the gate level name would get printed instead.

To print the gate-level register names instead of the RTL names use the option -report_nl_names.

Examples

The following example shows a list of bundled registers having a width >=8 (default value) where the power could be saved by setting the average activity data to the enable of registers. The registers may have either a gated clock or not.

```
pt_shell> report_user_def_clock_savings -clock_gate_type all
 -enable_def_type avg_defs

report_variation_bottleneck

Reports a list of cells with large high-sigma failure rate in a *design_variation* object created by the *get_design_variation* command.

Feedback

Syntax

int *report_variation_bottleneck*

```
design_variation_object
[-max_violators num_cells]
[-nosplit]
[-significant_digits digits]
```

Data Types

```
design_variation_object          collection
num_cells              int
digits                 int
```

Arguments

design_variation_object

Specifies a *design_variation* object collection, either an embedded *get_design_variation* command in square braces or a variable previously set to the result of a *get_design_variation* command. The *report_variation_bottleneck* command reports the variation bottleneck cells for this *design_variation* object.

`-max_violators` *num_cells*

Specifies the maximum number of cells to be reported. The default is 1000.

`-nosplit`

Prevents line-splitting to facilitate parsing of information from the report output. Most of the design information is listed in fixed-width columns. Without this option, if the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point displayed for values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which is 2 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

Description

The *report_variation_bottleneck* command reports a list of cells with high-sigma failure rate in a *design_variation* object created by the *get_design_variation* command. The list is sorted from largest to smallest high-sigma failure rate.

You can use this list for robustness ECO fixing. Replacing some of the top cells having the largest high-sigma failure rate with lower-Vt cells can help reduce design high-sigma failure rate significantly.

To perform variation bottleneck analysis, the *ps_enable_analysis* variable must be set to *true*.

Examples

The following example shows the typical usage of *report_variation_bottleneck* command.

```
prompt> set mypaths [get_timing_paths -pba_mode exhaustive \\
          -path_type full_clock_expanded -nworst 10 \\
          -max_paths 10000 -pocv_pruning -slack_lesser_than 1.0]

prompt> set mydvar [get_design_variation -sample_size 100000 $mypaths]

prompt> report_variation_bottleneck -max_violators 10 -nosplit $mydvar \\
          -significant_digits 6

   Cell         Lib_cell    Variation  Sigma_ratio  HSFR
   ------------------------------------------------------

   U20/U17180   AOID2_S     2.257476   0.831172    0.000077
   U16/U16837   AOID3_S     2.240766   0.827820    0.000076
   U11/U640     INVD1_S     1.488405   0.583223    0.000072
   U29/U708     AOID2_L     2.031563   0.796475    0.000069
   U35/U19558   AO2D1_S     2.251250   0.825218    0.000051
   U41/U4909    INVD0_S     1.492606   0.585177    0.000044
   U68/U1090    AOID3_S     1.610532   0.844050    0.000043
```

The variation bottleneck report has five columns:

- *Cell*: The cell instance with critical high-sigma failure rate.
- *Lib_cell*: The library cell name of the instance.
- *Variation*: The cell delay variation, which is the cell arc POCV corner delay minus the nominal delay.
- *Sigma_ratio*: The ratio of cell delay sigma to pin slack sigma.
- *HSFR*: The high-sigma failure rate of the cell instance.

The high-sigma failure rate is evaluated when a cell is at high-sigma while other cells have normal POCV variation. There may be many paths going through this cell. The reported high-sigma failure rate is the accumulated total considering all these paths. The cell list is sorted from largest to smallest high-sigma failure rate.

Often a small number of cells contribute to a large part of the total high-sigma failure rate. Therefore, performing timing ECOs on a few cells at the top of the list can improve overall joint success rate significantly.

report_vcd_hierarchy

Reports the hierarchy in the VCD file.

Syntax

```
status report_vcd_hierarchy
   [-pipe_exec shell_command_string]
   [-full_path]
   [-find pattern_string]
   [file_name]
```

Data Types

```
shell_command_string     string
pattern_string           string
file_name                string
```

Arguments

`-pipe_exec shell_command_string`

Specifies a shell command which is used to generate the VCD file *file_name*. This option invokes the command and directly pipe the output VCD file to PrimePower. In another word, the simulation and power analysis are in parallel run. No VCD disk file is generated at all.

`-full_path`

Displays each scopes in full path format.

`-find pattern_string`

Report only those scopes whose last hierarchy name is matched the specified *pattern*. They are always reported in full path format. Nothing is printed out if not found.

file_name

Specifies a file in VCD format from which the switching activity information is to be read. If file_name ends with .gz, .Z, .vpd and .fsdb, it is read as a gzipped file, a compressed file, a VCD+ file, and a FSDB file, respectively, otherwise it is just read as a normal ASCII VCD file. If the *file_name* is omitted, the name is taken from the *read_vcd* command if it exists; otherwise, an error message is issued.

Description

This command displays the indented hierarchy in the specified VCD file.

To read a gzip VCD file, a compressed VCD file, VCD+ file, or FSDB file, your PATH needs to include gunzip, uncompress, vpd2vcd, and fsdb2vcd. vpd2vcd and fsdb2vcd come with Synopsys VCS and Novas Debussy, respectively.

The pipe option allows PrimePower reading in VCD file directly from simulator, which avoids generating huge VCD file. The VCD file name in this scenario is just served as a pipe name. After running the VCD file does not exist. You don't need to change your existing test bench. Use it just like normal VCD dump (inserting $dumpfile, $dumpvars, etc.) You do not need to invoke the simulator, either. PrimePower automatically runs the simulation and directly read in the VCD output from the simulator.

Examples

The following example shows a VCD hierarchy report.

```
pt_shell> report_vcd_hierarchy vcd.dump.gz
tb
  macinst
    U3
    U4
    U7
    U9
    U10
    U11
    U12
```

report_voltage_robustness

Generates a list of slack-critical or near-critical cells that have higher sensitivity to voltage rail (IR) drop.

Syntax

integer *report_voltage_robustness*

```
[-max_violators count]
[-nosplit]
[-pba]
[-dvd]
[-verbose]
[-reg_to_reg]
[-significant_digits digits]
[-sort_by slack | delay]
[-voltage_shift value]
[-voltage_shift_ratio value]
[-slack_lesser_than maximum_robustness_slack]
[-slack_margin margin_value]
[-mim_filter none | logical | timing]
[-cells cell_list]
[-plot]
[-prefix string]
```

Data Types

count	integer
digits	integer
value	float
maximum_robustness_slack	float
margin_value	float
cell_list	list

Arguments

`-max_violators` *count*

Specifies the maximum number of cells to be reported. The default is 10000.

`-nosplit`

Prevents line-splitting to facilitate the parsing of information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-pba`

Performs voltage robustness using path-based analysis (PBA) timing, where on-demand exhaustive PBA pin slacks are used to avoid pessimism. The default is to use graph-based analysis (GBA) timing.

`-dvd`

Performs voltage robustness using the dynamic voltage drop (DVD) information read-in previously using the *read_dvd* command. The variable *timing_enable_dvd_analysis* must be set to *true* for the DVD voltage robustness analysis to be performed. An additional column “Delta_V” is reported in the voltage robustness report to show drop in voltage for each cell based on the

DvD file. Please note that "-dvd" cannot be used with "-voltage_shift" or "-voltage_shift_ratio" options.

`-verbose`

Shows detailed information on voltage robustness violators in the report.

`-reg_to_reg`

Restricts analysis to register-to-register paths.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point displayed for values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which is 2 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-sort_by slack | delay`

Specifies how the reported cells are sorted. The default is *slack*, which sorts by robustness slack. A value of *delay* sorts by delay impact instead.

`-voltage_shift` *`value`*

Specifies the voltage drop used for the sensitivity calculation, as an absolute value in volts. The default is a 5% relative drop from each cell's nominal VDD value.

`-voltage_shift_ratio` *`value`*

Specifies the voltage drop used for the sensitivity calculation, as a relative ratio (such as 0.95) of each cell's nominal VDD value. The default is a 5% relative drop.

`-slack_lesser_than` *`maximum_robustness_slack`*

Reports only cells with robustness slack less than the specified *maximum_robustness_slack* value; these cells have a negative robustness slack worse than the specified *maximum_robustness_slack* value (or a positive slack that is closer to causing a violation).

The default *maximum_robustness_slack* value for this option is 0.0.

`-slack_margin` *`margin_value`*

This option can be used to filter cells from robustness report. The cells whose worst timing slack (GBA or PBA), amongst paths passing through cell pins, is above the *margin_value* are filtered out from the report.

The default *margin_value* value for this option is infinity (that is, no filtering margin is applied).

`-mim_filter none | logical | timing`

Specifies how the reported cells are filtered out based on multiply intantiated modules (MIMs) grouping. This option can be used to increase the coverage in the report, given a *max_violator* count. The default value is *none*, that is, no MIM grouping is considered. When *logical* is specified, only the instance with worst robustness slack, amongst all logically shared MIM instances, is included in the report. With *timing*, the worst, amongst all MIM instances that share delays, will be reported.

`-cells` *`cell_list`*

Specifies a list of one or more cells in the current design to be analyzed. The analysis is only performed on the cells in the list.

`-plot`

Generates Gnuplot data and script file for the visualization of the robustness metrics.

`-prefix` *`string`*

Use with the *-plot* option. If a prefix string is provided using this option, this string is preprended to the generated Gnuplot file names.

Description

Cells with high voltage sensitivity can cause large timing differences for small changes in voltage, resulting in *Vmin*-critical paths. It is useful to identify these cells early in the design flow.

Voltage robustness analysis identifies the cells in the design that are sensitive to voltage drop. The *report_voltage_robustness* command performs this voltage robustness analysis.

You can specify the voltage shift as an absolute value or a relative drop from the nominal operating voltage. The default is a 5% relative drop from nominal VDD.

Voltage robustness analysis requires the following:

- PrimeShield variation analysis is enabled:

  ```
  prompt> set_app_var ps_enable_analysis true
  ```

- Pin slacks are saved during *update_timing*:

  ```
  prompt> ## set this before update_timing
  prompt> set_app_var ps_enable_save_timing_slack_data true
  ```

- True voltage scaling groups are defined with the *define_scaling_lib_group* command. For details and recommendations, see the *define_scaling_lib_group* command man page.

  The *report_voltage_robustness* command will issue a warning if the shifted voltage value exceeds the scaling range. Cells with exact-match scaling are skipped.

The resulting voltage robustness report shows a "Robustness Slack" value for each cell, which indicates the final slack with the voltage shift applied. The report is sorted based on this robustness slack by default.

Examples

The following example shows how to generate a voltage robustness report.

```
## Must save timing and arrival data
pt_shell> set ps_enable_analysis true
pt_shell> set ps_enable_save_timing_slack_data true

pt_shell> define_scaling_lib_group { ... }
pt_shell> set_voltage ...

pt_shell> update_timing -full

pt_shell> report_voltage_robustness -max_violators 1 \\
           -voltage_shift 0.05 -nosplit
```

The following output is a voltage robustness violation report for the previous example.

```
voltage_robustness
                                Timing     Delay      Robustness
   Cell               Lib_cell  slack      impact     slack
   ---------------------------------------------------------------
   uA/uB/U38            NOR2    -3.5523    0.0321     -0.0321
```

The robustness report shows the delay impact and robustness slack for each violator. The report is sorted based on the robustness slack by default.

The "Delay impact" column shows the impact on cell delay when voltage is shifted by the value specified.

```
Timing slack = slack at nominal VDD
Delay impact = (cell delay at shifted VDD) - (cell delay at nominal VDD)
```

The "Robustness slack" column shows the new slack with the adjusted cell delay.

```
Robustness slack = (slack at nominal VDD) - (Delay impact)
```

If the slack at nominal VDD is negative, then even cells with a small delay impact can be reported with negative robustness slack. This can mask voltage-drop bottleneck cells with high delay impact on marginally passing paths.

To avoid missing any true voltage-drop bottleneck cells in these cases, the tool uses *0* as the slack for negative-slack paths at nominal VDD, for the robustness slack calculation.

```
Robustness slack = 0 - (Delay impact)
```

The preceding report has a negative slack of -3.552 ns. In this case, with delay impact of 0.0321 ns, the robustness slack is calculated as -0.0321 ns.

---

report_waveform_integrity_analysis

Reports static or dynamic constraints for waveform integrity analysis.

Syntax

int *report_waveform_integrity_analysis*

```
[-static]
[-dynamic]
[-nosplit]
[-significant_digits num_digits]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

num_digits	integer
object_list	list
sms_scenarios_list	collection

Feedback

Arguments

`-static`

Reports the static constraint.

`-dynamic`

Reports the dynamic constraint.

`-nosplit`

Prevents line splitting in the report when columns overflow.

`-significant_digits` *`num_digits`*

Specifies the number of digits displayed in the report.

`object_list`

Specifies a list of cell input pins.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only waveform integrity information compatible to the specified SMS scenarios collection is reported. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

This command reports the constraint limit for waveform integrity analysis set by the *set_waveform_integrity_analysis* command.

If the list of cell input pins are provided, the constraint limit on the specified cell inputs is reported. If there is no list of cell input pins, all constraints of both design-level and pin-level are reported.

Examples

The following example shows static constraints for waveform integrity analysis.

```
pt_shell> report_waveform_integrity_analysis -static
  ...

   Cell pins                                                  Tolerance
 ------------------------------------------------------------------------
----
   DFF1/CLK                                                     0.3000
   DFF1/D                                                       0.3000
   DFF2/CLK                                                     0.3000
   DFF2/D                                                       0.3000
```

Feedback

- report_constraint
- set_waveform_integrity_analysis

---

report_wire_load

Reports wire load information.

Syntax

string *report_wire_load*

```
[-nosplit]
[cell_list]
```

Data Types

```
cell_list     list
```

Arguments

`-nosplit`

Does not split lines if the column overflows.

cell_list

Specifies a list of hierarchical cells.

Description

The *report_wire_load* command shows the characteristics of wire load models set on the current design and on cells of the current design. If you do not specify a cell list, by default the command displays the wire load models and wire load mode used in the current design. If you specify a cell list, the command displays the wire load models used in the specified cells.

Examples

This command displays the wire load model in the current design.

```
pt_shell> report_wire_load

****************************************
Report : wire_load
Design : top
 ...
****************************************
```

Feedback

```
Wire Loading Model Mode: segmented

Cell           Design       Wire_model  Library       Selection_type
-------------------------------------------------------------------
               inv_top      WLM1        my_lib        user-specified
cel1           tst          WLM2        my_lib        user-specified

report_yield_bottleneck

This is a synonym for the *report_variation_bottleneck* command.

Syntax

int *report_variation_bottleneck*

```
design_variation_object
[-max_violators num_cells]
[-nosplit]
[-significant_digits digits]
```

See Also

- report_variation_bottleneck

- report_cell_robustness
- report_voltage_robustness

Feedback

reset_activity_derate

Resets the clock activity derating factors for a cell or a specified list of instances.

Syntax

```
int reset_activity_derate
[-cell_list]
```

Data Types

cell_list	list

Arguments

`-cell_list`

the *derate_value* specified should be reset to cell instances specified in the object_list.

Description

Resets toggle rate derating factors currently set on a cell instance or the list of cells in the current design.

Clock activity derating factor affects toggle rate on cells in the clock network. The clock derating factors are used as a scalar multiplicative factor in calculation of toggle rate for output net of cell. If clock derating factors are not specified, the value of 1.0 is assumed.

The *cell_list* option can be used to reset derating factors on specific instances (cells) in the design.

After a reset, the derating factor goes back to the default value (derating factor of 1.0 for every instance in the design).

Examples

The following example resets clock activity toggle rate derating factor on all cells in the design.

```
pwr_shell> reset_activity_derate [get_cells *]
reset_activity_derate [get_cells *]
1
```

The following example resets the derating factor on cell instance "i_and_1" in the design.

```
pwr_shell> reset_activity_derate [get_cell i_and_1]
reset_activity_derate [get_cell i_and_1]
1
```

Feedback

- set_switching_activity
- report_switching_activity

---

reset_aocvm_table_group

The *reset_aocvm_table_group* command removes the association between a named AOCV table set and a hierarchical instance or between a library cell and a AOCV derating group.

Syntax

status *reset_aocvm_table_group*

`[object_list]`

Data Types

object_list list

Arguments

object_list

Specifies the list of design objects.

Description

The *reset_aocvm_table_group* command removes the association between a named AOCV table set and a hierarchical instance or between a library cell and a AOCV derating group, where such an association was previously specified with the *set_aocvm_table_group* command.

Examples

The following example specifies an association between the hierarchical cell H1 and the AOCV table set A1 and then removes this association. After the association is removed, cells (or nets) fully enclosed within H1 derive their AOCV derating from a higher level hierarchical cell that fully encloses H1 and has a named AOCV table set associated with it. If no such hierarchical cell is found, the unnamed AOCV table set is used.

```
pt_shell> set_aocvm_table_group A1 [get_cells H1]

pt_shell> reset_aocvm_table_group [get_cells H1]
```

Feedback

See Also

- get_timing_paths
- read_aocvm
- remove_aocvm
- report_aocvm
- report_timing
- set_aocvm_coefficient
- set_aocvm_table_group
- write_binary_aocvm

---

reset_cell_mode

Resets cell mode groups to the default state.

Syntax

```
status reset_cell_mode
   [instance_list]
```

Data Types

instance_list	list

Arguments

instance_list

Specifies a list of instances for which the specified cell mode groups are to be set to default. If no instance list is specified, all moded cells are considered. This list must only be included with the *-type cell* option. No error occurs if you reset the modes on a cell that has no modes.

Description

This command resets mode groups to the default state of all modes enabled. Cell mode groups are defined in the library. Each library cell can have a set of cell mode groups. Each of these cell mode groups can have two or more cell modes. Each of these cell modes can be mapped to a set of timing arcs of the library cell.

When a cell mode group is set to default for a given instance of the library cell all of its modes are enabled for that cell. All timing arcs of the enabled modes also get enabled with respect to modes for that cell.

Feedback

Cell mode groups can have different states due to the *set_cell_mode*, *set_mode -type design*, and conditional evaluation. When conflict arises the following precedence rule is employed:

- *set_cell_mode*
- *set_mode -type design*
- Evaluation of mode conditions

To reset the state of the cell mode group due to the *set_cell_mode* command, use the *reset_cell_mode* command.

To reset the state of the cell mode group due to the *set_mode -type design* command, use either the *reset_mode -type design* or *remove_design_mode* command.

To reset the state of the cell mode group due to conditional evaluation, use the *remove_case_analysis* command or edit the Verilog netlist to remove logical constants.

You define design modes and design mode groups using the *define_design_group* and *map_design_mode* commands. Design modes can be mapped to a set of cell modes, set of paths, or both cell modes and paths. When a design mode group is reset to default all design modes of that group are enabled. When a design mode is enabled all paths mapped to the design mode are reset and all previous setting of cell modes mapped to the design modes are removed.

Examples

To reset all cell mode group in Uram1/DO, use this command.

```
pt_shell> reset_cell_mode Uram1/D0
```

To reset all cell mode groups in the design, use this command.

```
pt_shell> reset_cell_mode
```

See Also

- define_design_mode_group
- remove_design_mode
- report_mode
- report_cell_mode
- map_design_mode

---

reset_clock_gate_max_power

Reset the vectorless mode for clock gate and memory cells, and reset flag for each of instances

Syntax

```
int reset_clock_gate_max_power
[-instance_list]
```

Data Types

instance_list	list

Description

Find the worst-case internal energy when-condition in the liberty model and set those for each of instances Ignore all propagated TR and SP values to the nets which are part of the when-condition If there is logic conflict with setting it will be ignored. For all other pins which are not part of the selected when-condition use the propagated TR and SP.

- PrimePower will use user defined conditions for power calculation for specific instances • Power calculation – Maximum of weighted sum of states that match the condition specified by user. – No change to toggle rate propagation • User constraint form (UI preliminary subject to change) – Set inst_power_condition <inst_name> {Pin_name bool_value derate_value,…} <related_pin> – inst_name and related_pin is mandatory – Ex: Set inst_power_condition top/blockA/mem1 {RCS 1 0.5, WCS 1 0.5} CLK – User does not need to specify conditions on all the other pins that are not included in the inst_power_condition command – Sum of derate values in an inst_power_condition cannot exceed 1.0 – If multiple inst_power_conditions defined for an instance, then tool will pick last statement one for power analysis for the same inst_name and related_pin

Example1: Single port memory – reset_clock_gate_max_power top/A/InstSp1 {“CS & !WE & !PD & SLEEPB” 1 0.5, “CS & WE & !PD & SLEEPB” 1 0.0} CK – Matching states – S2 = “CS & !WE & !PD & SLEEPB” 1 0.5 with CK S2_derate = 0.5 – S1 = “CS & WE & !PD & SLEEPB” 1 0.0 with CK S1_derate = 0.0 – total_derate_matching_states = 0.5 + 0.0 = 0.5 – Non_matching states – S3 = !CS & !PD & SLEEPB – total_derate_non_matching_states = 1.0 – total_derate_matching_states = 1-0.5=0.5 – Power calculation for supply VCC – matching_state_pwr – S2_pwr*S2_derate + S1_pwr*S1_derate = 40.0*0.5 + 50.0*0.0 = 20 – Non_matching_state_pwr – S3_pwr * total_derate_non_matching_states = 3.0*0.5 = 1.5 – Total_pwr_vcc = matching_state_pwr + non_matching_state_pwr = 20 + 1.5 = 21.5 – Similar calculation will be performed for cvcc – total_power = total_pwr_vcc + total_power_cvcc

Feedback

This command should only be run in average mode. update_power should be used to calculate power and report_power shows the maximum power values used for memory cells.

The *state_condition* option can be used to change the when condition of the state used for derating.

The *target_ts* option can be used to set the derate value to be used for a given state condition.

The *pin* option can be used to specify the input pin which needs to be used for derating and power calculation.

Examples

The following example shows how to set maximum memory power on a single cell in the design. The command dumps out the output in the report_power command.

```
pwr_shell> reset_clock_gate_max_power I_SINGLE_PORT -target_ts 0.5
reset_clock_gate_max_power I_SINGLE_PORT -target_ts 0.5

1
```

The following example sets the derate value of 0.5 for cell "I_TCAM" and creates an output file "debug_s1_report.rpt"

```
pwr_shell> reset_clock_gate_max_power I_TCAM -target_ts 0.5

reset_clock_gate_max_power I_TCAM -target_ts 0.5
1
```

See Also

- update_power
- report_power

reset_ctpm

Read CTPM file into current design for PrimeShield SPICE2Design feature.

Syntax

string *reset_ctpm*

```
[-library baselib_list]
```

Data Types

```
baselib_list            collection
```

Feedback

Arguments

`-library` *`baselib_list`*

Specifies the library list to reset ML-CTPM. Without the option, all CTPMs in design will be reset.

Description

The command *reset_ctpm* is used in PrimeShield SPICE2Design feature to reset any CTPM in design. This feature enables analysis for timing and power impact assessment of a given target. This target can be defined through a spice model representing next PDK, spot model, different spice corner, etc.

Through ML, Project Sicily aims to bridge the gap between the base and the target by capturing and gap through spice process parameters placed inside of a Compact Timing Power Model (CTPM) database. When CTPM is consumed in a base STA session, the QoR of this session is shifted such that to match QoR of the target.

After generating the CTPMs, you can use them in a real design to improve the QoR, by reducing the gap between the base library and the target PDK the CTPM generated from. The *read_ctpm* command reads CTPM generated by *gen_ctpm* into design. If base library QoR is needed after *read_ctpm*, use *reset_ctpm* to reset.

To perform a static timing analysis using a generated CTPM, perform the following steps: 1) Enable the PrimeShield tool for the CTPM generation using the following settings: *set ps_enable_analysis true set ps_enable_spice2design_analysis true* 2) Define the mapping between the base library already loaded in the design and its augmented library. See the following example: *define_sensitivity_lib_mapping [get_lib lib1] -side_lib lib1_side_file.db* 3) Read CTPM generated based on target PDK into the design. See the following example: *read_ctpm lib1.ctpm* 4) Peform complete STA: *update_timing -full*

Examples

The following script uses CTPM generated from target SPICE PDK to improve STA QoR comparing to target PDK, then reset CTPM to revert to original QoR:

```
set link_path orig.db
read_verilog ...
link_design
read_parastics ...
read_sdc ...
update_timing -full
# original STA results corresponding to original SPICE PDK

set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
read_ctpm lib1.ctpm
update_timing -full
# STA results shifted to target SPICE PDK
```

```
reset_ctpm
update_timing -full
# original STA results corresponding to original SPICE PDK
```

See Also

- gen_ctpm
- read_ctpm
- report_ctpm

---

reset_design

Removes user specified information from design.

Syntax

string *reset_design*

```
[-keep_parasitics]
```

Arguments

`-keep_parasitics`

Keeps the parasitics information on the current design.

Description

Removes all attributes from the design. It does not matter whether these attributes are user-defined, command implemented, or read from the design database. Attributes include, but are not limited to, exceptions, input/output delays, and clocks.

Examples

The following command resets the attributes on the current design.

```
pt_shell> reset_design
```

See Also

- current_design
- remove_user_attribute

Feedback

reset_eco_options

Resets options specified by the *set_eco_options* command.

Syntax

status *reset_eco_options*

Arguments

None.

Description

The *reset_eco_options* command removes all the ECO options specified by the *set_eco_options* command.

Distributed Multi-Scenario Analysis

To execute the *reset_eco_options* command in all scenarios, use the *remote_execute* command. For example:

```
remote_execute -verbose {
  reset_eco_options
}
```

Note: You cannot execute the *reset_eco_options* command in the manager process.

Examples

The following example shows how to use the *reset_eco_options* command.

```
pt_shell> reset_eco_options
```

See Also

- report_eco_options
- set_eco_options

reset_eco_scenarios

Reset any forced or ignored violation types set by the *set_eco_scenarios* command from the specified scenarios.

Syntax

```
status reset_eco_scenarios
scenario_name_list
```

Feedback

Data Types

scenario_name_list list

Arguments

scenario_name_list

Specifies one or more scenarios to which the specifications are removed.

Description

The *reset_eco_scenarios* removes any forced or ignored violation types set by the *set_eco_scenarios* command from the specified scenarios.

Note that this command affects only the live and static scenario analysis performed during the *start_eco_scenarios* or *report_eco_scenarios* command; it does not affect what data is used by the *fix_eco_** commands themselves.

Examples

The following example considers only setup timing violations in ss1, ss2, ss3 and ss4 scenarios, and then removes the specification from ss1 and ss2 scenarios.

```
pt_shell> set_eco_scenarios -only -type {setup} {ss1 ss2 ss3 ss4}
pt_shell> reset_eco_scenarios {ss1 ss2}
```

See Also

- set_eco_scenarios
- report_eco_scenarios
- start_eco_scenarios

---

reset_eco_wire

Resets ECO wire optimization changes back to the pre-ECO values.

Syntax

```
integer reset_eco_wire
[-all]
[net_list]
```

Data Types

net_list list

Feedback

Arguments

`-all`

Resets all ECO wire optimization changes back to pre-ECO values.

`net_list`

Lists of nets to reset the ECO wire optimization changes.

Description

This command resets ECO wire optimization changes performed by *fix_eco_wire* or *set_routing_rule* commands.

Examples

The following example resets the ECO wire optimization change to a net named *n43* back to the pre-ECO values.

```
prompt> reset_eco_wire {n43}
```

See Also

- fix_eco_wire
- report_eco_wire

---

reset_emmp_configuration

Specifies the reset configuration options for a hierarchical cell.

Syntax

status *reset_emmp_configuration*

`hier_instance_name`

Data Types

`hier_instance_name`	`string`

Arguments

`hier_instance_name`

To specify the hierarchical cell for which reset emmp config is to be done.

Feedback

Description

The *reset_emmp_configuration* command specifies resets logical memory config for the hierarchy. Which is set previously using *set_emmp_configuration* commands.

Examples

The following examples shows reset memory configuration. Here mem is the hierarchy cell.

```
pt_shell> reset_emmp_configuration mem
```

See Also

- set_emmp_configuration
- estimate_memory_max_power

---

reset_extract_model_indexes

Resets indexes on specified ports for extracted timing model (ETM) generation.

Syntax

```
status reset_extract_model_indexes
```

Arguments

None.

Description

This command replaces all user-specified index values on all ports with automatically-computed index values. The index values are used during model extraction.

See Also

- extract_model
- set_extract_model_indexes

---

reset_gpd_config

Cancels custom GPD configuration options previously set by the *set_gpd_config* command.

Syntax

string *reset_gpd_config*

`-gpd gpd_directory`

Data Types

`gpd_directory` `string`

Arguments

`-gpd gpd_directory`

Specifies that path to the GPD directory.

Description

The *reset_gpd_config* command removes custom GPD configuration options previously set by the *set_gpd_config* command and restores the GPD configuration options to their original states, as defined in the original GPD database generated by the StarRC tool.

Examples

The following session sets a coupling capacitor filtering option for the GPD database, reports the setting, and then resets the configuration back to the original.

```
set_gpd_config -gpd my_design1.gpd -relative_coupling_threshold 0.05
report_gpd_config -gpd my_design1.gpd
 ...
reset_gpd_config -gpd my_design1.gpd
report_gpd_config -gpd my_design1.gpd
```

See Also

- report_gpd_properties
- report_gpd_config
- set_gpd_config

---

reset_hier_resource_limits

Resets constraints specfied by *set_hier_resource_limits* command.

Syntax

status *reset_hier_resource_limits*

Arguments

None.

Feedback

Description

The *reset_hier_resource_limits* command removes all the constraints specified by the *set_hier_resource_limits* command.

```
This should be invoked prior to invocation of report_hier_analysis to
 report
load balanced partitions
```

Examples

The following example shows how to use the *reset_hier_resource_limits* command.

```
pt_shell> reset_hier_resource_limits
pt_shell> report_hier_analysis -explore_partitions
```

See Also

- set_hier_resource_limits
- report_hier_analysis

---

reset_implement_options

Resets options specified by the *set_implement_options* command.

Syntax

```
status reset_implement_options
   [-force]
   [-icc2_pre_legalize_script]
   [-icc2_eco_legalize_script]
   [-icc2_pre_route_script]
   [-icc2_eco_route_script]
   [-icc2_pre_extract_script]
   [-insert_fillers]
```

Arguments

`-force`

Forces the reset, discarding any unsaved pending design changes.

`-icc2_pre_legalize_script`

Removes the option specified by the *-icc2_pre_legalize_script* option of the *set_implement_options* command.

`-icc2_eco_legalize_script`

Removes the option specified by the *-icc2_eco_legalize_script* option of the *set_implement_options* command.

`-icc2_pre_route_script`

Removes the option specified by the *-icc2_pre_route_script* option of the *set_implement_options* command.

`-icc2_eco_route_script`

Removes the option specified by the *-icc2_eco_route_script* option of the *set_implement_options* command.

`-icc2_pre_extract_script`

Removes the option specified by the *-icc2_pre_extract_script* option of the *set_implement_options* command.

`-insert_fillers`

Specifies to reset and stop standard filler cell insertion.

Description

The *reset_implement_options* command removes options specified by the *set_implement_options* command.

If this command is specified with options, only those *set_implement_options* settings are removed.

If this command is specified with no options, all *set_implement_options* settings are removed.

If *reset_implement_options* is invoked after *check_eco* in the PrimeECO flow, it ends the IC Compiler II process.

For more information, see the man pages for the *set_implement_options* and *check_eco* commands.

Feedback

reset_memory_max_power

Reset the worst-case max power for memory cells for each of instances.

Syntax

```
int reset_memory_max_power
[instance_list]
```

Data Types

instance_list	list

Arguments

`instance_list`

To specify the list of memory instances which needs to be reset.

Description

Resets the power set by "estimate_memory_max_power" command for the list of memory instances in the input list.

This command should only be run in average mode. update_power should be used to calculate power and report_power shows the power values is reset for memory cells after running the command.

Examples

The following example shows how to reset maximum memory power on a single cell in the design.

```
pwr_shell> reset_memory_max_power I_SINGLE_PORT
reset_memory_max_power I_SINGLE_PORT
VL flow: For cell: I_SINGLE_PORT Resetting memory cell max power to 0.0
1
```

See Also

- estimate_memory_max_power
- update_power
- report_power

reset_mode

Resets cell mode groups or design mode groups to the default state.

Feedback

Syntax

status *reset_mode*

```
[-type cell | design]
[-group group_list]
[instance_list]
```

Data Types

group_list	list
instance_list	list

Arguments

`-type cell | design`

Indicates the type of mode group to be set to default. This option has the following mutually-exclusive valid values: *design* and *cell*.

- The *cell* value specifies that cell mode groups are to be set to default. Cell mode groups are defined on library cells in the library.
- The *design* value specifies that design mode groups are to be set to default.

Design mode groups are user specified using the *define_design_mode_group* command. If the *-type* option is omitted from the command, this is equivalent to specifying *-type cell*.

`-group group_list`

Specifies a list of mode groups, each of which is to be reset to its default setting. If the *-type* option has a cell value, the *group_list* option must contain only cell mode groups. If the *-type* option has a design value, the *group_list* option must contain only design mode groups.

instance_list

Specifies a list of instances for which the specified cell mode groups are to be set to default. If no instance list is specified, all moded cells are considered. This list must only be included with the *-type cell* option. No error occurs if you reset the modes on a cell that has no modes.

Description

Resets mode groups to the default state of all modes enabled. Cell mode groups are defined in the library. Each library cell can have a set of cell mode groups. Each of these cell mode groups can have two or more cell modes. Each of these cell modes can be mapped to a set of timing arcs of the library cell.

Feedback

When a cell mode group is set to default for a given instance of the library cell all of its modes are enabled for that cell. All timing arcs of the enabled modes also get enabled with respect to modes for that cell.

Cell mode groups can have different states due to the *set_mode -type cell*, *set_mode -type design*, and conditional evaluation. When conflict arises the following precedence rule is employed:

- **set_mode -type cell**
- **set_mode -type_design**
- Evaluation of mode conditions

To reset the state of the cell mode group due to the *set_mode -type cell* command, use the *reset_mode -type cell* command.

To reset the state of the cell mode group due to the *set_mode -type design* command, use either the *reset_mode -type design* or *remove_design_mode* command.

To reset the state of the cell mode group due to conditional evaluation, use the *remove_case_analysis* command or edit the Verilog netlist to remove logical constants.

You define design modes and design mode groups using the *define_design_group* and *map_design_mode* commands. Design modes can be mapped to a set of cell modes, set of paths, or both cell modes and paths. When a design mode group is reset to default all design modes of that group are enabled. When a design mode is enabled all paths mapped to the design mode are reset and all previous setting of cell modes mapped to the design modes are removed.

Examples

In the following example, we have two cell mode groups RW and SH defined on cell Uram1/D0. The first command sets READ as the active mode for RW and EARLY as the active mode for SH.

```
pt_shell> set_mode {EARLY READ} Uram1/D0
```

The following command can be employed to reset the cell mode groups to default.

```
pt_shell> reset_mode -group {RW SH} Uram1/D0
```

To reset all cell mode group in Uram1/DO use the following command

```
pt_shell> reset_mode Uram1/D0
```

To reset all cell mode groups in the design use

```
pt_shell> reset_mode
```

In the following example, the first command defines two design modes, DM1 and DM2. (Since no mode group name was specified, the mode group is named "default".) The second command specifies that for design mode DM1, the READ cell mode is active for the RAM instance Uram1. The third command specifies that for design mode DM2, the WRITE cell mode is active for the RAM instance Uram1. The fourth command maps all paths ending at Uram1/D0 to the design mode DM2. The fifth command sets the design_mode DM1. The sixth command sets READ as the active cell mode and disables the WRITE cell mode.

```
pt_shell> define_design_mode_group {DM1 DM2}
pt_shell> map_design_mode DM1 READ Uram1
pt_shell> map_design_mode DM2 WRITE Uram1
pt_shell> map_design_mode DM2 -to Uram1/D0
pt_shell> set_mode -type design DM1
pt_shell> set_mode -type cell READ Uram1
```

The following example resets the design mode group "default".

```
pt_shell> reset_mode -type design -group default
```

This command enables the design_mode DM2 resulting in the resetting of all paths mapped to Uram1/D0. However the cell mode WRITE on Uram1/D0 does not get enabled since it was also disabled by command 5 above. To reset the cell mode group to default use

```
pt_shell> reset_mode -type cell Uram1
```

The following command is equivalent to the previous command

```
pt_shell> reset_mode Uram1
```

See Also

---

reset_multi_input_switching_coefficient

Resets user-specified multi-input switching (MIS) coefficients.

Feedback

Syntax

int *reset_multi_input_switching_coefficient*

```
-all
object_list
```

Data Types

```
object_list          list
```

Arguments

`-all`

Resets all the library cells specified for multi-input switching analysis. You cannot use this option together with the *object_list* option.

`object_list`

Specifies a list of library cells to be reset. You cannot use this option together with the *-all* option.

Description

This command resets the user-specified base coefficients for multi-input switching (MIS) analysis. If you reset the coefficient of a library cell, then the tool does not perform multi-input switching analysis on that library cell.

Examples

The following example resets the base coefficients of library cell AND2 in the library MY_LIB:

```
pt_shell> reset_multi_input_switching_coefficient [get_lib_cells
 MY_LIB/AND2]
```

See Also

- set_multi_input_switching_coefficient
- report_multi_input_switching_coefficient
- si_enable_multi_input_switching_analysis
- si_enable_multi_input_switching_timing_window_filter

---

reset_noise_parameters

Resets the noise analysis parameters for the current design.

Feedback

Syntax

```
int reset_noise_parameters
```

Arguments

None.

Description

The *reset_noise_parameters* command resets the parameters that are considered during the noise analysis. If this command is used, the default settings are used for the noise analysis: beyond the rail analysis is ignored, arrival times of aggressors are considered and propagation of noise is disabled.

Examples

The following example resets the default noise parameters:

```
pt_shell> reset_noise_parameters
```

See Also

- report_noise
- report_noise_parameters
- set_noise_parameters
- update_noise

---

reset_ocvm_table_group

Resets the association between an AOCV or POCV named table group or a based POCV or AOCV derating group and a list of design objects, where an association has been performed earlier using the *set_ocvm_table_group* command.

Syntax

status *reset_ocvm_table_group*

```
-type aocvm | pocvm
[-table_type coefficient | distance]
[object_list]
```

Data Types

```
object_list     list
```

Feedback

Arguments

`-type aocvm | pocvm`

Specifies AOCV or POCV tables.

`-table_type coefficient | distance`

Specifies coefficient or distance-based POCV tables. The default is *coefficient*. Do not use this option for AOCV.

`object_list`

Specifies a list of design objects.

Description

The *reset_ocvm_table_group* command removes the association between a named AOCV or POCV table set and a hierarchical instance or between a lib_cell and a AOCV or POCV derating group, where such an association has been specified previously using the *set_ocvm_table_group* command.

Examples

In the following example, the *set_ocvm_table_group* command specifies an association between the hierarchical cell H1 and the named POCV coefficient table set A1. The *reset_ocvm_table_group* command that follows removes this association. Cells (or nets) fully enclosed within H1 then derive their POCV coefficients from a higher-level hierarchical cell that fully encloses H1 and has a named POCV coefficient table set associated with it. If no such hierarchical cell is found, the unnamed POCV coefficient table set is used.

```
pt_shell> set_ocvm_table_group -type pocvm -table_type coefficient A1
 [get_cells H1]

pt_shell> reset_ocvm_table_group -type pocvm -table_type coefficient
 [get_cells H1]
```

- report_timing
- set_ocvm_table_group

---

reset_parasitics_range

Resets the parasitic range factors previously set by the set_parasitics_range command.

Feedback

Syntax

status *reset_parasitics_range*

Description

The *reset_parasitics_range* command resets the two factors of parasitic resistance range and two factors of parasitic capacitance range previously set by the set_parasitics_range command.

Examples

The following example resets all parasitic ranges.

```
pt_shell> reset_parasitics_Range

1
```

See Also

- read_parasitics
- set_parasitics_range

---

reset_path

Resets specified paths to single-cycle behavior.

Syntax

status *reset_path*

```
[-setup | -hold]
[-rise | -fall]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
```

Data Types

```
from_list               list
rise_from_list          list
fall_from_list          list
through_list            list
rise_through_list       list
fall_through_list       list
```

Feedback

```
to_list                  list
rise_to_list             list
fall_to_list             list
```

Arguments

`-setup`

Indicates that only setup (maximum delay) evaluation is reset to its default, single-cycle behavior. If neither the *-setup* nor *-hold* options is specified, both setup and hold checking are reset to single-cycle.

`-hold`

Indicates that only hold (minimum delay) evaluation is reset to its default, single-cycle behavior. If neither the *-setup* nor *-hold* options is specified, both setup and hold checking are reset to single-cycle.

`-rise`

Indicates that only rising path delays are reset to single-cycle behavior. If neither the *-rise* nor *-fall* options is specified, both rising and falling delays are reset to single-cycle.

`-fall`

Indicates that only falling path delays are reset to single-cycle behavior. If neither the *-rise* nor *-fall* options is specified, both rising and falling delays are reset to single-cycle.

`-from` *from_list*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected. You can use only one of the following options: *-from*, *-rise_from*, or *-fall_from*.

`-rise_from` *rise_from_list*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the following options: *-from*, *-rise_from*, or *-fall_from*.

`-fall_from` *fall_from_list*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by

the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the following options: *-from*, *-rise_from*, or *-fall_from*.

`-through` *`through_list`*

Specifies a list of pins, ports, and nets through which the paths must pass that are reset. By default, a net is interpreted to imply its driver pins. In case the previous *through_list* includes the driver, the net is interpreted to imply its load pins. If you omit the *-through* option, all timing paths specified using the *-from* and *-to* options are affected.

You can use multiple *-through*, *-rise_through*, and *-fall_through* options in a single command to specify paths that traverse through multiple points in the design. The tool respects the order in which you specify these options.

The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If you specify more than one object with one *-through*, *-rise_through*, or *-fall_through* option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

`-rise_through` *`rise_through_list`*

This option is similar to the *-through* option, but applies only to paths with a rising transition at the through points.

`-fall_through` *`fall_through_list`*

This option is similar to the *-through* option, but applies only to paths with a rising transition at the through points.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of the following options: *-to*, *-rise_to*, or *-fall_to*.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but

only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of the following options: *-to*, *-rise_to*, or *-fall_to*.

`-fall_to` *`fall_to_list`*

Same as the *-to* option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the following options: *-to*, *-rise_to*, or *-fall_to*.

Description

The command restores designated timing paths in the current design to the default single-cycle behavior. Use the *reset_path* command to undo the effect of the *set_multicycle_path*, *set_false_path*, *set_max_delay*, and *set_min_delay* commands. Attributes set by these commands are removed by the *reset_path*. command.

Note that a general *reset_path* command removes the effect of matching general or specific point-to-point exception commands, if there is a matching object in the path specification of the original exception-setting commands. For example, the following command

```
reset_path -from {CLK}
```

resets more specific matching exceptions for the object CLK, such as

```
set_false_path -from {CLK} -to {d/Z}
set_false_path -from {CLK} -to {g/Z}
```

If you do not specify either the *-setup* or *-hold* option, the default behavior is restored to both. The default is a setup relation of one cycle and a hold relation of zero cycles, so that hold is checked one active edge before the setup data at the destination register.

Setup and hold information is different for rising and falling transitions. In most cases, these are reset together. Use the *-rise* or *-fall* options to reset only one or the other. To disable setup or hold calculations for paths, use the *set_false_path* command.

The general and specific constraint options (for example, *-through* and *-rise_through* or *-fall_through*) are treated as different qualifiers. That is, if you issue the *reset_path -fall_through* variable, only those constraints are removed that were set with the *-fall_through* option; any that were set with the *-through* option are not removed. The same applies to the general and specific *-to* and *-from* options. For an example, see the EXAMPLES section.

Feedback

Examples

The following command resets the timing relation between ff1/CP and ff2/D to the default single-cycle behavior.

```
pt_shell> reset_path -from { ff1/CP } -to { ff2/D }
```

The following command resets only the rising delay to single cycle for all paths ending at latch2d.

```
pt_shell> reset_path -rise -to latch2d
```

The following example first sets a specific and a general point-to-point exception, then removes the exceptions.

```
pt_shell> set_multicycle_path 2 -from A -to Z
pt_shell> set_max_delay 15 -to Z
pt_shell> reset_path -to Z
```

In following example, the *reset_path* command removes only the max delay constraints, because the *-to* and *-rise_to* options are treated as different qualifiers and do not match.

```
pt_shell> set_multicycle_path 2 -from A -to Z
pt_shell> set_max_delay 15 -rise_to Z
pt_shell> reset_path -rise_to Z
```

---

reset_power_base_clock

Resets the user specified power_base_clock for a given set of objects.

Syntax

integer *reset_power_base_clock*

```
[object_list]
```

Feedback

Data Types

object_list list

Arguments

object_list

Specify a list of objects in the design. Only nets, pins and ports are supported.

Description

This command resets any user specified power_base_clock on given set of objects. It also resets the activities of the concerned objects annd invalidates the power data on the entire design .

User will need to specifiy activity on the concerned objects and rerun update_power.

---

reset_power_budget

Resets power budget set on the hierarchical instances in the design.

Syntax

int *reset_power_budget*

Description

This command resets power budget set on the hierarchical instances in the design.

Examples

In the following example, power budgets have been set on the following hierarchies and their rail.

```
pt_shell> set_power_budget 8.513e-05 -cell four_mini_inst/two_mini_1/a
pt_shell> set_power_budget 2.338e-04 -cell four_mini_inst/two_mini_1
 -rails four_mini_inst/VDD_MINI_1
pt_shell> set_power_budget 9.354e-05 -cell four_mini_inst/two_mini_1/a
 -rails four_mini_inst/VDD_MINI_1
pt_shell> report_power_budget
****************************************
Report : power budget
Design : top
****************************************

    Cell Name                     Rail                            Power
 Budget        Scale Factor
 ------------------------------------------------------------------------
------------------
    four_mini_inst/two_mini_1     four_mini_inst/VDD_MINI_1
 2.104405e-04        2.50
```

```
    four_mini_inst/two_mini_1/a    --
 8.513000e-05        1.50
    four_mini_inst/two_mini_1/a    four_mini_inst/VDD_MINI_1
 9.354000e-05        2.00
1
```

The following command resets power budgets set on the above hierarchical instances and their rails.

```
pt_shell> reset_power_derate
pt_shell> report_power_budget
****************************************
Report : power budget
Design : top
****************************************

---

reset_power_delay_shifted_event_analysis_options

Resets the options for delay shifted event analysis.

Syntax

integer *reset_power_delay_shifted_event_analysis_options*

Description

This command is used when *power_enable_delay_shifted_event_analysis* is set to true. The command is used to reset the delay shifted event analysis options set by '*set_power_delay_shifted_event_analysis_options*.

See Also

- power_enable_delay_shifted_event_analysis
- set_power_delay_shifted_event_analysis_options
- report_power_delay_shifted_event_analysis_options

Feedback

reset_power_derate

Resets power derating factors set either on a design or on a specified list of instances (cells, library cells, nets or pins).

Syntax

int *reset_power_derate*

```
[-groups group_name_list]
[-rails rail_list]
[-pg_pins pg_pin_list]
object_list
```

Data Types

```
group_name_list     list
rail_list           list
pg_pin_list         list
object_list         list
```

Arguments

`-groups group_name_list`

Specifies the power group or groups in which the derate factors of all the cells are reset.

`-rails rail_list`

Specifies a list of power supply nets in which the derate factors of all the objects are reset.

`-pg_pins pg_pin_list`

Specifies a list of pg_pins on which the derate factors for all the objects are reset.

`object_list`

Specifies current design or a list of cells or library cells on which the power derating factors are reset to 1.0.

Description

Invoke this command with no arguments to reset all derate factors set on the design (to the default of 1.0). This includes both derating factors set globally on the design and those set on specific instances in the design. If the command is called with a list of objects, only the power derating factors on the specified objects are reset. After a *reset_power_derate* command is applied to an object, the power derating factors of all power components, including switching, internal, and leakage power are reset. If the *object_list* variable

contains the current design, then only global power derating factors are reset and instance specific power derating factors remain untouched.

If the *object_list* variable contains any hierarchical cells, then all cells within that hierarchical cell and also all cells of lower hierarchies will have their inherited power derating factors updated accordingly. Note that power derating factors set specifically on an object are not overwritten by a set or reset command on its parent hierarchical cell. To reset the power derating factors set specifically on the child cells, include them in the object list of the command.

The *-groups* options allows to reset the derate factors of cells only in the specified groups.

Heterogeneous collections of objects can be combined and passed to this command.

If the *object_list* variable contains any hierarchical cells, then all cells within that hierarchical cell and also cells of all lower hierarchies will have their inherited derate factors updated accordingly. Note that derate factors set specifically on an object are not overwritten by a set or reset command on its parent hierarchical cell.

The command resets x-transition power derate factors on net or on pin objects if nets or pins are passed in object_list, having x-transition power derate factors.

The command resets pin switching power derate factors on pin objects.

Examples

The following command resets both power derating factors set globally on the design and those set on specific instances in the design.

```
pt_shell> reset_power_derate
```

The following command resets the power derating factors set globally on the design MY_DESIGN only.

```
pt_shell> reset_power_derate [get_design MY_DESIGN]
```

The following example resets the power derating factors set on cell U1.

```
pt_shell> reset_power_derate [get_cell U1]
```

The following command resets the power derating factors set on all cells matching "*".

```
pt_shell> reset_power_derate [add_to_collection [get_cells *]
```

The following example resets the power derating factors set on all instances of library cell IV in the library MY_LIB.

```
pt_shell> reset_power_derate [get_lib_cells MY_LIB/IV]
```

Feedback

Assuming that the hierarchical cell H1 contains a cell U1, then the following command resets the derate factors set on U1. As a result, U1 inherits the derate factors that are set on H1.

```
pt_shell> reset_power_derate [get_cells H1/U1]
```

Assuming that the hierarchical cell H1 also contains a hierarchical cell H2, then the following command resets the power derate factors set on H2. As a result, H2 and all of its cells inherit the power derating factors that are set on H1.

```
pt_shell> reset_power_derate [get_cells H1/H2]
```

Following command will reset the x-transition power derate factors on the given list of nets, assuming nets have x-transition derate factors.

```
pt_shell> reset_power_derate {U0/n5 U0/CP U0/Q U0/n6}
```

---

reset_pvt_explorer_condition

Resets PVT explorer condition for PrimeShield PVT Variation Exploration what-if analysis.

Syntax

string *reset_pvt_explorer_condition*

Description

The *reset_pvt_explorer_condition* command will reset PVT explorer condition specified by *set_pvt_explorer_condition* command, which is used in PrimeShield Power, voltage, and temperature (PVT) parameter variation and exploration.

define_sensitivity_lib_mapping is required in this feature. And *set ps_enable_pvt_explorer_analysis true* is required to use *reset_pvt_explorer_condition* command.

Examples

The following script enables Power, performance, area (PPA) what-if analysis, which enables you to change the design PVT parameters and quickly assess their PPA impact. It allows process sweet-spot exploration and technology option assessment, then reset it.

"one_cond.txt" file content as follows:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15

The timing and power analysis results after *set_pvt_explorer_condition* will reflect the physical parameter shift defined in "one_cond.txt".

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode false
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]

set_pvt_explorer_condition one_cond.txt
update_timing -full
update_power
# timing and power here has impact from device parameter shift impact.

reset_pvt_explorer_condition
update_timing -full
update_power
# timing and power here is without impact from device parameter shift
 impact.
```

You must change the "one_cond.txt" file content to include the device model names and values, based on your PDK or side file. The "one_cond.txt" file includes the delta shift values. In the preceding example, the vt shift provided is +20mV and the idsat shift provided is +15%, from their respective nominal values.

Timing robustness what-if analysis enables you to perform path-based timing analysis with multiple what-if specifications. It allows you to identify paths susceptible to PVT changes, o provide ECO guidance to improve the design robustness.
The following script enables what-if analysis for timing path robustness, where "multiple_DoEs.txt" file content as follows to cover multiple what-if specifications:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15
2,0.011,0.011,0.10,0.10 Then *reset_pvt_explorer_condition* then PBA paths afterwards will not trigger timing robustness what-if analysis.

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
update_timing -full  # baseline QoR
set paths [get_timing_paths ...]

set_pvt_explorer_condition multiple_DoEs.txt
#update original path collection with slack shift per DoE
```

Feedback

```
set paths_new [get_timing_paths -pba_mode path $paths]
#generate slack shift per DoE for all paths
puts [get_attr $paths_mew pvt_explorer_slack_shift]

reset_pvt_explorer_condition multiple_DoEs.txt
set paths_after_reset [get_timing_paths -pba_mode path $paths]
# paths_after_reset doesn't have pvt_explorer_slack_shift attribute and
 slack is same as "paths"
```

---

reset_routing_rule

Resets non-default routing rule changes back to the pre-ECO values.

Syntax

integer *reset_routing_rule*

```
[-all]
[net_list]
```

Data Types

net_list	list

Arguments

`-all`

Resets all routing rule changes back to pre-ECO values.

net_list

Lists of nets to reset the routing rule change.

Description

This command resets routing rule changes performed by *set_routing_rule* command.

Feedback

Examples

The following example resets the routing rule change to a net named *n43* back to the pre-ECO values.

```
prompt> reset_routing_rule {n43}
```

See Also

- set_routing_rule
- report_routing_rules

---

reset_rtl_to_gate_name

Resets all the RTL-to-gate name mapping information.

Syntax

integer *reset_rtl_to_gate_name*

Arguments

None.

Description

The *reset_rtl_to_gate_name* command resets all the RTL-to-gate name mapping information stored previously using the *set_rtl_to_gate_name* and *unset_rtl_to_gate_name* commands.

Examples

The following example provides the resetting of the RTL-to-gate name mapping.

```
pt_shell> reset_rtl_to_gate_name
```

See Also

- set_rtl_to_gate_name
- unset_rtl_to_gate_name

---

reset_scale_parasitics

Resets the parasitic scaling factors previously set by the *scale_parasitics* command.

Syntax

status *reset_scale_parasitics*

```
[net_list]
```

Data Types

```
net_list        list
```

Arguments

net_list

Limits the resetting of parasitic scaling factors to only the listed nets. By default, the command resets all net-specific and global parasitic scaling settings. Using this option, only nets with net-specific scaling factors can be reset.

Description

The *reset_scale_parasitics* command resets the parasitic resistance and capacitance scaling factors previously set by the *scale_parasitics* command. By default, both the global and net-specific scaling factor settings are reset.

You can optionally restrict the resetting to only a specified list of nets that have net-specific scaling factor settings.

Examples

The following example resets all parasitic scaling factors.

```
pt_shell> reset_scale_parasitics
1
```

See Also

- read_parasitics
- report_scale_parasitics
- scale_parasitics

---

reset_sensitivity_lib_mapping

Resets the mapping between base library and sensitivity augmented library.

Syntax

string *reset_sensitivity_lib_mapping*

```
[libraries]
```

Data Types

```
libraries                list
```

Feedback

Arguments

libraries

Specifies a list of libraries to reset mapping of base library and sensitivity agumented library. If this option is omitted, side file for all of libraries will be reset.

Description

The *reset_sensitivity_lib_mapping* command resets mapping between base library and sensitivity augmented library, which is defined in *define_sensitivity_lib_mapping*.

Examples

The following script enables SPICE2Design flow, defines mapping between base library and sensitivity side-file, report the mapping, reset, then report again.

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]

pt_shell> report_sensitivity_lib_mapping orig
  Lib             side_file
================================================
  orig            side.db
================================================
1

reset_sensitivity_lib_mapping
pt_shell> report_sensitivity_lib_mapping
  Lib             side_file
================================================
================================================
1
```

- ps_enable_pvt_explorer_analysis

Feedback

reset_switching_activity

Resets switching activity annotation on nets, pins, ports, and cells of the current design.

Syntax

int *reset_switching_activity*

```
[-static_probability]
[-toggle_rate]
[-state_condition state]
[-path_sources name_list]
[-no_hierarchy]
[object_list]
[-quiet]
```

Data Types

state	string
name_list	string
object_list	list

Arguments

`-static_probability`

Specifies the static probability value to reset for the given design object. The static probability value is internally reset to an invalid number.

`-toggle_rate`

Specifies the toggle rate (rise and fall, if applicable) and glitch rate (rise and fall, if applicable) to reset for the given design object. The toggle and glitch rate values are internally reset to invalid numbers.

`-state_condition` *state*

Specifies the state condition when resetting state-dependent toggle rate and glitch rates on pins or state-dependent static probabilities on cells. State-dependent toggle rate and glitch rate can be annotated when the internal power of the library cell pin is characterized with state-dependent power tables. State-dependent static probabilities can be annotated when the cell leakage power is characterized with state-dependent power tables. The state condition specified with this argument must be logically equivalent to a state condition in the internal/leakage power characterization. The state condition should be enclosed between " ". Moreover, if you want to reset switching activity information for the default state condition, the argument of the *-state* option should be "default". Note that the *-state_condition* option applies only to the leaf level cells.

`-path_sources` *`name_list`*

Specifies the path sources when resetting path-dependent toggle rate and glitch rate on pins. This is used when the library cell pin has path-dependent internal power. The path sources specified with this argument must be the same as those in the internal power characterization. When listing more than one pin in path sources, the pin names should be separated by a space and enclosed between quotes " ". For example, if the pins in path sources are A and B, the argument for the *-path* option looks like "A B". The *-path_sources* argument applies only to the leaf level cells. Note that if the *name_list* option is given using the *-path_sources* argument, the *state* option should also be provided using the *-state_condition* option.

`-no_hierarchy`

This option specifies that only the objects in the hierarchy of the list of instances, specified using the *object_list* option, is reset. If no instance list is specified, then the switching activity on the objects in the same hierarchy of the current instance is reset. If the *-no_hierarchy* option is not specified and the *object_list* option is also not given, the switching activity on all the objects in all the hierarchy of the current instance are reset. Note that if leaf level cells are given using the *object_list* option, the command internally assumes this option is true.

`object_list`

Specifies a list of nets, pins, ports, or instances in the current design on which the static probability, toggle rate, and glitch rate switching activity values are reset.

`-quiet`

Specifies quiet mode and suppresses warnings on design objects for which switching activity could not be reset.

Description

Use this command to reset design nets, ports, pins, and cells with the different kinds of switching activity. These include simple toggle rate, glitch rate, and static probability on nets, ports and pins; state-dependent and path-dependent toggle, and glitch rate on cell pins, and state-dependent static probabilities on cells. Toggle and glitch rates, and static probabilities are reset using the *-toggle_rate* and *-static_probability* options, respectively. You can make the toggle rate, glitch rate, and static probability state-dependent by specifying the *state* option with the *-state_condition* option. You can make the toggle rate and glitch rate path-dependent by specifying the path sources with the *-path_sources* option. The design objects that are reset with switching activity can be specified as a list of objects. You can reset only the objects in the same hierarchy by using the *-no_hierarchy* option.

Most of the above functionality and all the options apply when the *power_analysis_mode* variable is set to the *averaged* or *leakage_variation* option . When the*power_analysis_mode* variable is set to the *time_based* option, the *reset_switching_activity* command has a different meaning. In this mode, the *reset_switching_activity* command removes any VCD or other activity indicated previously with the *read_vcd* command. Because the *time_based* mode is not based on toggle rates, attempting to reset switching activity on individual objects has no effect.

Examples

The following example shows resetting toggle rate, glitch rate, and static probability values only on the current instance of the TOP_MULT design:

```
pt_shell> current_design TOP_MULT

pt_shell> reset_switching_activity -no_hierarchy

pt_shell> reset_switching_activity -no_hierarchy -toggle_rate
 -static_probability

pt_shell> reset_switching_activity -toggle_rate -no_hierarchy

pt_shell> reset_switching_activity -static_probability -no_hierarchy
```

The following example shows resetting the toggle rate, glitch rate, and static probability values on the whole TOP_MULT design:

```
pt_shell> current_design TOP_MULT

pt_shell> reset_switching_activity

pt_shell> reset_switching_activity -toggle_rate -static_probability

pt_shell> reset_switching_activity -toggle_rate

pt_shell> reset_switching_activity -static_probability
```

The following example shows resetting the toggle rate, glitch rate, and static probability values on the list of instances:

```
pt_shell> current_design TOP_MULT

pt_shell> reset_switching_activity {U1 U2}

pt_shell> reset_switching_activity -no_hierarchy {U1 U2}

pt_shell> reset_switching_activity -toggle_rate {U1 U2}

pt_shell> reset_switching_activity -static_probability {U1 U2}

pt_shell> reset_switching_activity -no_hierarchy -toggle_rate {U1 U2}
```

```
pt_shell> reset_switching_activity -no_hierarchy -static_probability
          {U1 U2}
```

The following *reset_switching_activity* command resets simple toggle rate value, glitch rate value, and static probability value on all design input ports:

```
pt_shell> reset_switching_activity -toggle_rate
         -static_probability [get_inputs]

pt_shell> reset_switching_activity [get_inputs]
```

The following example resets different switching activity values on design output ports:

```
pt_shell> reset_switching_activity -toggle_rate [get_outputs]

pt_shell> reset_switching_activity -static_probability
          [get_outputs]

pt_shell> reset_switching_activity -static_probability
         -toggle_rate [get_outputs]
```

The following example resets state-dependent static probabilities on the or1 cell:

```
pt_shell> reset_switching_activity -static_probability
         -state_condition "A & B" [get_cell or1]

pt_shell> reset_switching_activity -state_condition "A & B"
         [get_cell or1]

pt_shell> reset_switching_activity -static_probability
         -state_condition "A & ! B" [get_cell or1]

pt_shell> reset_switching_activity -static_probability
         -state_condition "! A & B" [get_cell or1]

pt_shell> reset_switching_activity -static_probability
         -state_condition "! A & ! B" [get_cell or1]

pt_shell> reset_switching_activity -static_probability
         -state_condition "default" [get_cell or1]
```

The following example resets simple and path sources, dependent toggle rates, and glitch rates on the output pin Y of the cell xor1:

```
pt_shell> reset_switching_activity -toggle_rate [get_pin xor1/Y]

pt_shell> reset_switching_activity -toggle_rate -path_sources "A"
         -state_condition "B" [get_pin xor1/Y]

pt_shell> reset_switching_activity -path_sources "A"
         -state_condition "B" [get_pin xor1/Y]
```

Feedback

```
pt_shell> reset_switching_activity -toggle_rate -path_sources "B"
        -state_condition "A" [get_pin xor1/Y]

pt_shell> reset_switching_activity -toggle_rate -path_sources "A B"
        -state_condition "default" [get_pin xor1/Y]
```

---

reset_timing_derate

Resets the derating previously set by the *set_timing_derate* command.

Syntax

status *reset_timing_derate*

```
[-hierarchical_net_delay]
[-scalar] [-variation]
[-aocvm_guardband] [-pocvm_guardband] [-pocvm_coefficient_scale_factor]
[-pocvm_subtract_sigma_factor_from_nominal]
[-increment]
[-min_period]
[-min_pulse_width]
object_list
```

Data Types

```
object_list      list
```

Arguments

`-hierarchical_net_delay`

Resets net delay derating (as well as cell delay derating) previously set by the *set_timing_derate* command for the hierarchical cells specified in the *object_list*. Without the *-hierarchical_net_delay* option, the *reset_timing_derate ... [get_cells ...]* command resets only the cell delay (not net delay) derating in the hierarchical cells.

`-scalar`

Resets derating previously set by the *set_timing_derate -scalar* ... command. This option should be used only with the PrimeTime VX tool.

`-variation`

Resets derating previously set by the *set_timing_derate -variation* ... command. This option should be used only with the PrimeTime VX tool.

`-aocvm_guardband`

Resets derating previously set by the *set_timing_derate -aocvm_guardband* ... command.

`-pocvm_guardband`

Resets derating previously set by the *set_timing_derate -pocvm_guardband* ... command.

`-pocvm_coefficient_scale_factor`

Resets derating previously set by the *set_timing_derate -pocvm_coefficient_scale_factor* ... command.

`-pocvm_subtract_sigma_factor_from_nominal`

Resets derating previously set by the *set_timing_derate -pocvm_subtract_sigma_factor_from_nominal* ... command.

`-increment`

Resets incremental derating adjustments previously set by the *set_timing_derate -increment* ... command.

`-min_period`

Resets min period derating adjustments previously set by the *set_timing_derate -min_period* ... command.

`-min_pulse_width`

Resets min pulse width derating adjustments previously set by the *set_timing_derate -min_pulse_width* ... command.

`object_list`

Resets the derating previously set for the given list or collection of cells, library cells, or nets.

Description

The *reset_timing_derate* command resets the derating previously set by the *set_timing_derate* command, which effectively changes derating factors back to their

original default values (1.0 for delay or constraint derating, or 0.0 for *-increment* derating adjustments).

To reset all derating, including both global and object-specific derating settings, use the *reset_timing_derate* command by itself, without any options.

To reset only some types of derating, use the same scope-setting options as the original *set_timing_derate* command:

```
-aocvm_guardband
 -pocvm_guardband
 -pocvm_coefficient_scale_factor
 -increment
 object_list
```

By default, using the *reset_timing_derate* command and specifying a hierarchical cell in the *object_list* causes only the cell delay derating to be reset. To also reset the net derating, use the *-hierarchical_net_delay* option in the command.

If the *object_list* option contains a design, only global derating factors are reset, and object-specific derating factors are retained. For example, to reset all global derating but keep derating set on specific cells and nets, use the following command:

```
pt_shell> reset_timing_derate [current_design]
```

To remove the derating on a subset of an existing derating setting, do not use the *reset_timing_derate* command. Instead, set a derating factor of 1.0 on the subset using another *set_timing_derate*, specifying the more narrow condition (*-net_delay*, *-rise*, and so on) or more specific *object_list*.

Examples

The following command resets all derating, including both global and instance-specific settings.

```
pt_shell> reset_timing_derate
```

The following command resets all incremental derating adjustments previously set the *set_timing_derate -increment* ... commands, including both global and instance-specific settings:

```
pt_shell> reset_timing_derate -increment
```

The following command resets all global derating set on the design MY_DESIGN, without affecting the derating set on specific objects in the design (cells, library cells, and nets).

```
pt_shell> reset_timing_derate [get_design MY_DESIGN]
```

The following example resets all derating previously set on cell U1.

```
pt_shell> reset_timing_derate [get_cell U1]
```

Feedback

The following example resets all derating previously set on net n123.

```
pt_shell> reset_timing_derate [get_net n123]
```

The following command resets all derating previously set on cells matching "U2*" and on all nets matching "n1*".

```
pt_shell> reset_timing_derate \\
  [add_to_collection [get_cells U2*] [get_nets n1*]]
```

The following example resets derating previously set on instances of library cell IV1A from the library MY_LIB.

```
pt_shell> reset_timing_derate [get_lib_cells MY_LIB/IV1A]
```

The following command resets the derating previously set on leaf-level cell H1/U1. As a result, cell U1 inherits the derating set on its parent cell, H1.

```
pt_shell> reset_timing_derate [get_cells H1/U1]
```

The following command resets the cell delay derating previously set on hierarchical cell H1/H2. As a result, cell H2 and all of its lower-level cells inherit the cell delay derating set on their parent (or grandparent) cell, H1.

```
pt_shell> reset_timing_derate [get_cells H1/H2]
```

The following command resets the cell *and net* delay derating previously set on hierarchical cell H1/H2. As a result, cell H2 and all of its lower-level cells inherit the cell *and net* delay derating set on their parent (or grandparent) cell, H1.

```
pt_shell> reset_timing_derate -hierarchical_net_delay [get_cells H1/H2]
```

---

reset_vsa_margin_table

Resets the margin table previously set by the *set_vsa_margin_table* command.

Syntax

status *reset_vsa_margin_table*

```
[-cell lib_cell]
```

Feedback

DATA TYPES

lib_cell string

Arguments

`-cell lib_cell`

Specifies the library macro cell instance for which you want to remove the VSA margin table.

Description

The *reset_vsa_marign_table* command resets the margin table, for a specified macro cell instance, previously set by the *set_vsa_margin_table* command.

To reset the margin table for all library macro cells, use the *reset_vsa_marign_table* command by itself, without any option.

Examples

The following command resets the VSA margin table of the library cell, *MACRO*:

```
pt_shell> reset_vsa_margin_table -cell MACRO
```

The following command reset the VSA margin table of all library macro cells:

```
pt_shell> reset_vsa_margin_table
```

See Also

- set_vsa_margin_table

---

restore_session

Restore a PrimeTime session from a directory saved by the *save_session* command.

Syntax

int *restore_session*

```
[-name session_name]
[-partitions instances_or_design_names]
[-program_options save_version | restore_version]
dir_name
```

Data Types

```
session_name          string
dir_name              string
```

Feedback

Arguments

`-name session_name`

This option, if specified when restoring a timing path session, allows assigning a name for the restored path session.

`-partitions instances_or_design_names`

Specifies the block instances to be restored in the distributed analysis flow along with the top-level partition. By default, all partitions are restored. Using the *-partitions* option overrides the default behavior, causing only the listed blocks and top level to be restored.

You can also provide block design names instead of instance names in the list. In this case, any partition whose design name matches the design names in the list will be restored.

`-program_options save_version | restore_version`

This option, if specified will load program settings of save_session or restore_session PrimeTime version. By default, it is save_version.

`dir_name`

Specifies the name of a directory to read the session information from.

Description

Use this command to read a directory that was written by the *save_session* command and restore a PrimeTime session to the same state as the session where the *save_session* command was issued.

When a version-specific session is restored, ensure the version of PrimeTime used to restore a session with the *restore_session* command is the same version used when saving the session with the *save_session* command. Locate the version used to save the session from the README file located in the session directory.

When a version-compatible session is restored, an information message indicates the original version:

```
Information: Restoring the version compatible session saved with
version 'Q-2019.12-SP4'. (SR-048)
```

If there is existing design or library data in memory, it is removed before restoring the session.

The command first tries to grab all licenses that were present at the time of the *save_session* command. If this fails, the command fails.

The design data is restored from data in the session directory. The *restore_session* command reads the library files that are needed to restore the session.

The restore directory contains a text file named 'lib_map'. This file contains the path and leaf name for each logic library needed to restore the session. If necessary, you can edit the path names to reflect the current environment. The leaf names of those files cannot be changed. The logic libraries are assumed to be the same as those used when the *save_session* command was issued.

When a saved session is restored, any variable that existed in the saved image is restored to its saved value. However, any variables that existed in an analysis before the *restore_session* command is issued, which were not defined in the saved image, remain unchanged.

An arbitrary collection of *timing_path* objects generated in a PrimeTime session can be saved using the *-only_timing_paths* option of the *save_session* command. In this case, only the *timing_path* collection and supporting data are saved, not the full design or timing information. Subsequently, multiple path sessions can be loaded into memory in a regular PrimeTime environment using the *restore_session* command. If a design has been instantiated prior to restore of a path session, then an error is generated and the path collection is not loaded. By default, the name of the path collection restored is the same as the name of the session directory and each *timing_path* object within the restored collection inherits the path session name as a read-only application attribute *session_name*. The default path session name can be overwritten by using the *-name* option.

If the session is saved from a distributed analysis flow, then you have the option to restore all or subset of partitions using the *-partitions* option. But, the top-level partition is always restored.

Examples

This example reads a saved PrimeTime session from a directory named state1.

```
pt_shell> restore_session state1
```

The following example restores a collection of timing paths:

```
pt_shell> restore_session path_session_dir -name mypaths
```

The following three examples shows different ways to restore a distributed analysis session.

The first example restores a complete distributed analysis session, including the distributed manager, and recreates the distributed database. It starts the same number of resources that were used to create the session.

```
pt_shell> restore_session da_session
```

The second example restores three partitions: nlkA/hier1, blkB/hier2, and top-level partition. It also restores the distributed manager and creates a distributed system.

```
pt_shell> restore_session -partitions {blkA/hier1 blkB/hier2} da_session
```

The third example only restores a single partition as a standalone PrimeTime session. Here, the tool restores only partition1 of da_session.

```
pt_shell> restore_session da_session/partition1
```

The following example load program settings of restore PT version:

```
pt_shell> restore_session session_dir -program_options restore_version
```

See Also

- save_session

---

restore_timing_paths

Restores a collection of timing paths saved by the *save_timing_paths* command.

Syntax

collection *restore_timing_paths*

```
        dir_name
```

Data Types

dir_name	string

Arguments

dir_name

Specifies the name of the directory from which to read the timing path collection saved by the *save_timing_paths* command.

Description

Use this command to restore a timing path collection stored by the *save_timing_paths* command. The restored path collection is just like a collection created by the *get_timing_paths* command.

The design, constraints, and version of the PrimeTime tool must be exactly the same as when the path collection was saved.

Feedback

Examples

The following example saves a timing path collection named my_paths1 into a directory named paths1, and later restores the path collection:

```
pt_shell> set my_paths [get_timing_paths -nworst 20 -max_paths 500]
 ...
pt_shell> save_timing_paths $my_paths -output paths1
 ...

New session:

pt_shell> set my_paths [restore_timing_paths paths1]
 ...
pt_shell> report_timing $my_paths
 ...
```

The following example saves a timing path collection directly into a directory named paths2, and later restores the path collection and reports its timing:

```
pt_shell> save_timing_paths [get_timing_paths -delay_type min] -output
 paths2
 ...

New session:

pt_shell> report_timing [restore_timing_paths paths2]
 ...
```

See Also

---

rotate_objects

Rotates the specified objects/ cells

Syntax

status *rotate_objects*

```
-orient orient
-angle angle
[-anchor center | ll | lr | ul | ur]
[-pivot {x y}]
[-force]
[-simple]
[object_list]
```

Feedback

Data Types

```
orient       string
angle        string
x            float
y            float
object_list  collection or selection
```

Arguments

object_list

Collection or selection set that contains objects to rotate. If this option is not specified, global selection set is used.

-orient *orient*

Specifies the cell orientation.

The valid values are:

```
N,  W,  S,  E,
FN, FS, FE, FW,
NW, NE, EN, ES,
SE, SW, WN, WS
```

-angle *angle*

Specifies the rotation angle of the objects.

The valid values are:

```
0, 90, 180, 270,
CW90, CW180, CW270, CCW90, CCW180, CCW270
FLIPX, FLIPY
```

The rotation value definitions are:

```
CW90    is 90 degrees clockwise
CW180   and CCW180 are 180 degrees
CW270   is 270 degrees clockwise
CCW90   is 90 degrees counterclockwise
CCW270  is 270 degrees counterclockwise
FLIPX   is the reflection about the x-axis
FLIPY   is the reflection about the y-axis
```

The following values are synonymous:

```
0,   R0
CW90,  90
CW180, 180
CW270, 270,
CCW90,  R90
CCW180, R180
```

CCW270, R270,
FLIPX, MY
FLIPY, MX

`-anchor center | ll | lr | ul | ur`

Specifies anchor point for rotation.

The anchor values are:

center is center
ll is lower left
lr is lower right
ul is upper left
ur is upper right

`-pivot {x y}`

Specifies the rotation pivot point.

The option cannot be specified together with the *-anchor* option.

`-force`

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using *get_edit_setting*.

`-simple`

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using *get_snap_setting*.

Description

This command rotates one or more specified objects by given angle skipping all fixed objects. It can also set selected cell orientation to given value.

Snapping is done automatically using the global snap settings.

Examples

The following example rotates all selected objects by 90 degrees.

```
prompt> rotate_objects -angle 90
```

The alternative syntax uses a collection to specify objects.

```
prompt> rotate_objects [get_selection] -angle 90
```

Feedback

- get_selection
- move_objects
- snap_objects

S

save_block

Saves the current NDM view of a block as a new block.

Syntax

```
status save_block
-as block_name
```

Data Types

```
block_name  string
```

Arguments

`-as block_name`

Specifies the block using a plain block name. Do not include a library name, label name, or view name.

Description

This command saves the current design block, which has been modified by ECO operations, into an IC Compiler II reference design library.

You must use the *-as* argument to specify the destination block name. Specify a plain block name, without any library, label, or view name, and without colon or slash characters.

The block is saved in the library specified by the *set_eco_options -physical_icc2_lib* option command, without a label name, and with the view name ".design".

Examples

The following command saves the block as "CPU_after_eco" in the library specified by the *set_eco_options -physical_icc2_lib* option command.

Feedback

```
prompt> save_block -as CPU_after_eco
Information: Saving 'design.nlib:ecoBlock_pid19.design' to
'design.nlib:CPU_after_eco.design'. (DES-028)
1
```

---

save_drc_error_data

Saves an external DRC error data object to disk.

Syntax

status *save_drc_error_data*

```
drc_error_data
[-as file_name]
```

Data Types

```
drc_error_data      collection
file_name           string
```

Arguments

drc_error_data

Specifies the collection of external physical DRC error data objects to save.

-as *file_name*

Specifies a new file name for the external error data file.

If you do not specify this option, the error data file is saved with its original name.

Feedback

Description

The *save_drc_error_data* command saves the specified external DRC error data object to disk.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example opens the external error data file named my_design_dppinassgn.err, removes fixed errors, and then saves and closes the file.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{my_design_dppinassgn.err}
prompt> remove_drc_errors -error_data $data \\
   [get_drc_errors -error_data $data -filter {status==fixed}]
prompt> save_drc_error_data $data
1
prompt> close_drc_error_data $data
1
```

See Also

- get_drc_error_data
- open_drc_error_data
- remove_drc_error_data

---

save_qtm_model

Saves the current quick timing model (QTM) description.

Syntax

string *save_qtm_model*

```
[-format db | lib]
[-output file_name]
[-library_cell]
```

Data Types

```
file_name     string
```

Feedback

Arguments

`-format db | lib`

Specifies the output format to be used. You can specify *db* (the default) or *lib*.

`-output` *`file_name`*

Specifies the name of the output file. By default, the tool writes the db file to *model_name*_lib.db. If you use the *-output* option, the tool writes the db file to *output_file*_lib.db file.

`-library_cell`

Writes the model as a library cell instead of a wrapper design and core library cell. If you use this option, no wrapper design is written, and the model in the *output_file*_lib.db file is named *model_name*.

If you do not specify this option, a wrapper design is written to the *output_file*.db file, and the model in the *output_file*_lib.db file is named *model_name*_core.

Description

This command saves the quick timing model and indicates that the model definition is complete. You must issue all quick timing model commands between the *create_qtm_model* and *save_qtm_model* commands.

To display information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following example saves a wrapper and core quick timing model as two files:

```
pt_shell> save_qtm_model -format db -output myfile
```

The preceding command generates these files:

- myfile_lib.db - Contains the *model_name*_core library cell
- myfile.db - Contains the *model_name* wrapper design

The following command saves the quick timing model as the *model_name* library cell in the myfile_lib.db file:

```
pt_shell> save_qtm_model -format db -output myfile -library_cell
```

The following example saves the quick timing model as a library cell in .lib format and uses the string "current" for the base file name.

```
pt_shell> save_qtm_model -format lib -output current -library_cell
```

Feedback

See Also

- create_qtm_model
- report_qtm_model

---

save_session

Saves the data of a PrimeTime session in a named directory, which can later be restored with the *restore_session* command.

Syntax

int *save_session*

```
[-include incl_list]
[-only_used_libraries]
[-only_timing_paths path_collection]
[-incremental]
[-name session_name]
[-disable_common_data_sharing]
[-version specific | compatible | both]
dir_name
```

Data Types

```
incl_list               list
path_collection         collection
session_name            string
dir_name                string
```

Arguments

`-version specific | compatible | both`

Specifies whether to save a version-specific or version-compatible session (or both). Allowed values are:

- *specific* Saves the session in a form that can be restored into the same PrimeTime release. Although this is the default, this keyword provides an explicit way to specify the default. A timing update is not needed when restoring the session.
- *compatible* Saves the session in a form that can be restored into the same or later PrimeTime releases. A timing update is always needed when restoring the session.
- *both* Saves a combined version-compatible and version-specific session that can be restored into the same or later releases. A timing update is only needed when restoring the session into a later release.

`-include` *`incl_list`*

Specifies additional data to be included by the *save_session* command. Allowed values are:

- *libraries* - Includes the loaded libraries in the saved session directory. After you restore an image that was saved with the *-include libraries* option, the current session relies on the saved image for its library data, imposing the following restrictions:
  - PrimeTime updates the *search_path* variable to include the library location within the saved image.
  - A subsequent *save_session* command cannot overwrite the saved image containing the libraries of the present session.
  - Any subsequent *save_session* command also includes the libraries.
- *gca_session* - Includes the GCA session in the saved session. This forcefully saves the GCA session. This session is used when running the PrimeTime GCA commands.
- *timing_paths* - Includes timing path collections in the saved session.
- *physical_data* - Includes ECO physical data in a version-compatible saved session. This value is valid only when the *-version compatible* option is set. (Version-specific sessions always save ECO physical data when present.)

  Note: The IC Compiler II reference libraries, specified with the *set_eco_option -physical_icc2_lib* option, are not copied to the session directory. Their original location is stored in the *session_dir*/eco_config file. If needed, edit these paths before restoring the session.

`-only_used_libraries`

By default, the *save_session* command saves references to all loaded logic libraries at the saving of the session. All of these libraries are required to restore the session later. This option saves references to only libraries that are in use, which are needed to restore the session later.

`-disable_common_data_sharing`

By default, a multi-scenario *save_session*, whether issued at the manager or at the workers via *remote_execute*, will share common data between scenarios. This option disables the feature for the present save, and the resulting scenario images contain their own (duplicate) data.

`-only_timing_paths` *`path_collection`*

Saves the given timing path collection to disk in a representation that is independent of timing data and can be subsequently restored along with any

number of other path sessions for analysis. On restore of this type of session, PrimeTime enters into the interactive multi-scenario analysis (IMSA) mode, which has a limited set of enabled commands. You cannot use this option with the *-only_used_libraries* option.

`-incremental`

Incrementally add an additional timing path collection to a saved session that was previously generated with a *save_session* command with the *-only_timing_paths* option or a previous incremental save. You cannot use this option with the *-only_used_libraries* or *-name* options; you must use the *-only_timing_paths* option.

`-name` *`session_name`*

Specifies a name for the saved timing path session, used together with the *-only_timing_paths* option.

`dir_name`

Specifies the directory to save the session to. This option is optional for the HyperScale flow. Otherwise, it is required.

If you are using a flow other than the HyperScale flow, and the named directory does not exist, the *save_session* command attempts to create it. If it already exists, the *save_session* command attempts to delete the directory before recreating it. If PrimeTime is unable to delete the directory due to a lack of write permission, an error is issued and the session is not saved.

Description

Use this command to create a repository of data to save the current PrimeTime session to. Use the *dir_name* option to specify the name of the directory to save the session. If the directory does not exist, a new one is created and the data for the session is written into the directory.

If the directory target save directory already exists, the default behavior is to always overwrite data. Otherwise, a new directory is created to write the data.

The *save_session* command does not perform an implicit *update_timing*; therefore, you can save sessions before using the *update_timing* command. Only a linked design can be saved, so the *save_session* might cause an implicit link to be performed. If there are incremental timing updates pending (the existing timing data is stale), PrimeTime performs an implicit *update_timing* as needed. If noise is to be included, an implicit *update_noise* is also performed as needed.

Note that high-capacity settings are saved and restored. Therefore, restoring a session results in the saved session's high-capacity mode overriding the mode in the session where the *restore_session* command was issued. Additionally, in multicore analysis mode, the distributed multicore analysis settings are saved in the

multicore_compute_resources.tcl file located in the *save_session* directory. During a *restore_session*, this script is sourced to launch the multicore workers.

Note: The tool does not save collections that involve timing objects, Tcl procedures, threaded multicore settings, and warning and informational message suppressions. Also, if there are other designs in PrimeTime memory, other than the linked design, they are not saved. These designs must be separately read into the restored session.

By default, the command saves a version-specific session that must be restored into the same PrimeTime version. The required version is indicated in the README file located in the session directory. Or, use the *-version compatible* option to save a version-compatible session (without timing/noise update data) that can be restored into the same or later version of PrimeTime.

An arbitrary collection of *timing_path* objects generated in a PrimeTime session can be saved using the *-only_timing_paths* option of the *save_session* command. In this case, only the *timing_path* collection and supporting data are saved, not the full design or timing information. Subsequently, multiple path sessions can be loaded into memory in a regular PrimeTime environment using the *restore_session* command.

Distributed Multi-Scenario Analysis

When *save_session* is called in a distributed multi-scenario analysis (DMSA) run, certain data, such as parasitic and physical database information, are stored in a common data directory named common_data. The images saved by each scenario contain softlinks to the data in this common data directory to avoid a duplication of storage of the data that scenarios share in common.

When *save_session* is issued directly to the manager session, the common data directory is created in the specified image directory. When *save_session* is issued to the workers via *remote_execute*, the location of the common data directory is based on whether the image directory specified to the command is relative or absolute:

- For absolute paths, the common data is located in the parent directory of the specified directory. All scenario images should share the same parent directory to maximise sharing.
- For relative paths, the common data directory is located directly under the multi-scenario working directory.

The softlink to common data in the image directory will be in the form of a relative link (a link to ../common_data) where the save session is either issued at the manager (e.g. *save_session session_name*), or if it is remotely executed at the workers and the location is specified by an absolute path (e.g. remote_execute {*save_session /absolute/path/to/session/[current_scenario]}*).

In the case where *save_session* is remotely executed at the workers and the location is specified as a relative path (e.g. *remote_execute {save_session session/*

[current_scenario]}), the softlink to common_data is an absolute path to the common_data directory directly under the DMSA working directory. To execute a multi-scenario *save_session* with common data sharing disabled, use the *-disable_common_data_sharing* option.

Version-Compatible Sessions

When the *-version compatible* option is specified, the session is stored in a format that can be restored into the same or later versions of PrimeTime.

This session format cannot store the in-memory data from a timing update; thus, a timing update is needed to perform analysis after restoring the session. This can result in slight QoR differences, particularly when restoring into a newer version of the tool.

Similarly, in-memory physical data for ECO fixing is not stored and will be reloaded when the *check_eco* command or a *fix_eco_** command is run.

Because the binary timing and ECO data is not included in the session, version-compatible session directories can be smaller than version-specific session directories.

Note: version-compatible session should be saved before any ECO optimization i.e. before fix_eco_* or any manual ECO command gets run, check user guide for flow details.

Examples

The following example saves a PrimeTime session in the state1 directory:

```
pt_shell> save_session state1
```

The following example saves a version-compatible PrimeTime session in the vc_session directory with ECO physical data:

```
pt_shell> save_session -version compatible vc_session \\
            -include {physical_data}
```

The following example generates and saves a collection of timing paths:

```
pt_shell> set paths [get_timing_paths -max 10 -nworst 10]
pt_shell> save_session -only_timing_paths $paths path_session_dir
```

See Also

- restore_session

---

save_timing_paths

Saves a collection of timing paths in a named directory so that you can later restore the collection with the *restore_timing_paths* command.

Feedback

Syntax

int *save_timing_paths*

```
path_collection
-output dir_name
```

Data Types

path_collection	collection
dir_name	string

Arguments

path_collection

Saves the given timing path collection to disk.

-output dir_name

Specifies the directory into which the timing path collection is saved.

Description

Use this command to write a collection of timing paths to a disk directory. You must specify the path collection and the directory in which to save the collection. If the directory already exists, the command overwrites it. Otherwise, the command creates a new directory.

You can later read the timing path collection into the PrimeTime tool using the *restore_timing_paths* command. The design, constraints, and version of the PrimeTime tool must be the same as when the path collection was saved.

Examples

The following example saves a timing path collection named my_paths into a directory named paths1:

```
pt_shell> set my_paths [get_timing_paths -nworst 20 -max_paths 500]
 ...
pt_shell> save_timing_paths $my_paths -output paths1
 ...
```

The following example saves a timing path collection directly into a directory named paths2:

```
pt_shell> save_timing_paths [get_timing_paths -delay_type min] -output
 paths2
 ...
```

Feedback

See Also

- get_timing_paths
- restore_timing_paths

---

save_training_data

Saves training data to a file after PrimeTime learns users' custom sizing operations.

Syntax

```
status save_training_data
   -output file_name
   [-force]
```

Data Types

```
file_name     string
```

Arguments

`-output file_name`

Writes the trianing data to the specified file.

`-force`

Forces overwriting the specified file if the file exists.

Description

The *save_training_data* command saves training data to a file after PrimeTime learns users' custom sizing operations, after the *start_learning* command enables PrimeTime to learn users' custom sizing operations. PrimeTime currently supports only ECO operations performed by one or multiple *size_cell* commands. After the *start_learning* command is executed, PrimeTime is ready to learn optimization that consists of one or multiple size_cell commands.

After PrimeTime learns custom sizing operations, the *save_training_data* command saves the training data for future usage. Later PrimeTime uses the training data to train itself with the training data and applies the learned sizing operations to new designs.

Examples

The example scripts below illustrate how to generate custom optimization training data. First perform the *start_learning* command to get PrimeTime ready for custom sizing operations. Then, apply *size_cell* commands manually or source a file that contains multiple *size_cell* commands. This is useful when a customized ECO script generates a sequence of *size_cell* commands. Once sizing operation is completed, use the *save_training_data* command to save the training data for future ECO operations.

```
pt_shell> start_learning
pt_shell> size_cell U100
pt_shell> source my_eco_changes.tcl
pt_shell> size_cell U200
pt_shell> save_training_data -out my_custom_training.td
```

The following example illustrates the *fix_eco_power* command reads the training data in the example above, trains itself with the training data, and reduces power in the current design using the training data.

```
pt_shell> set training_data_directory ./my_training_data_dir
pt_shell> fix_eco_power -training_data my_custom_training.td
```

See Also

- fix_eco_power
- start_learning
- training_data_directory

---

scale_parasitics

Scales the parasitic resistance and capacitance values in memory by specified factors.

Syntax

status *scale_parasitics*

```
[-resistance_factor r_factor]
[-ground_capacitance_factor c_factor]
[-coupling_capacitance_factor cc_factor]
[-dont_apply_to_annotated]
[net_list]
```

Data Types

```
r_factor          float
c_factor          float
cc_factor         float
net_list          list
```

Arguments

`-resistance_factor r_factor`

The scaling factor for parasitic resistance values, a positive floating-point number. For example, a factor of 1.10 increases the resistor values by 10 percent.

`-ground_capacitance_factor` *`c_factor`*

The scaling factor for net-to-ground capacitance values.

`-coupling_capacitance_factor` *`cc_factor`*

The scaling factor for cross-coupling capacitance values.

`-dont_apply_to_annotated`

Applies the specified global scaling factors only to parasitic data read in after execution of the *scale_parasitics* command, without affecting parasitic data already annotated on the design. By default, global scaling factors apply to both existing and new parasitic data. This option can be used only to specify scaling factors globally, without the *net_list* option.

`net_list`

Applies the scaling only to the specified list of nets.

Description

The *scale_parasitics* command scales parasitic resistance and capacitance values by specified factors. You can perform a single parasitic extraction run and then use this command to scale the parasitic data for variation effects, such as resistance dependence on temperature.

The command works for detailed parasitics as well as pi models. The command works irrespective of the source of the parasitic data (SPEF, GPD, DSPF, RSPF, and so on). Any subsequent delay calculations use the scaled parasitics instead of the original parasitics. If you write out parasitics using the *write_parasitics* command, the scaled parasitics are written out.

You can scale the parasitics for the whole design or just a specific list of nets. A new scaling setting overwrites any previous conflicting setting. If you scale the whole design and then a specific net, the net-specific scaling applies to the original value, not the globally scaled value.

If you read in parasitics again for previously scaled nets, the global scaling factors still apply, but net-specific scaling factors are discarded.

To report or cancel scaling factors, use the *report_scale_parasitics* or *reset_scale_parasitics* command.

Examples

The following example scales the resistance values by a factor 1.1, the ground capacitance values by a factor of 1.3, and the coupling capacitance values by a factor of 0.95. This scaling applies to the whole design and to any new parasitics read in later.

```
pt_shell> scale_parasitics -resistance_factor 1.1 \\
          -ground_capacitance_factor 1.3 \\
          -coupling_capacitance_factor 0.95
```

The following example scales the ground capacitance by a factor of 1.1 and the coupling capacitance by a factor of 0.95 for net n123. This scaling overwrites any previous global or net-specific setting for the net. If you read new parasitics for the net, the net-specific settings are discarded.

```
pt_shell> scale_parasitics -ground_capacitance_factor 1.1 \\
          -coupling_capacitance_factor 0.95 [get_nets n123]
```

See Also

- read_parasitics
- reset_scale_parasitics
- report_scale_parasitics
- write_parasitics

---

sdp

Records session diagnostic data for tool analysis and debugging by the Synopsys product support team.

Syntax

```
status sdp
   [-start]
   [-stop]
```

Data Types

None

Arguments

-start

Starts SDP session diagnostic data recording.

-stop

Stops SDP session diagnostic data recording.

Description

The Synopsys Diagnostic Platform (SDP) utility is for investigating and debugging issues with PrimeTime performance, capacity, long runtime, and crashes.

Execute the *sdp -start* command to start recording tool operating data and *sdp -stop* to stop recording data. When you exit from pt_shell, the tool writes the tool diagnostic data into a compressed tar file. You can then send the file to the Synopsys product support team for analysis and debugging.

The *sdp* command records only tool usage data. The generated tar file does not contain any customer design data, so your design remains confidential. The runtime overhead of using the command is small, typically less than 5 percent.

The *sdp* command is hidden (not displayed by the *help* command). Use the command only at the direction of the Synopsys product support team for tool analysis and debugging purposes. The generated data file can be read and analyzed only by the Synopsys product support team.

The command records the following types of data:

- OS version, CPU model, environment variables, QSC compliance
- CPU, memory, and I/O utilization
- Start/end times, running/idle/waiting status
- Stack trace at regular intervals and on a fatal crash
- CPU profiling information: time spent in each function, ...
- Hardware profiling information: cache misses, FP operations, ...
- Memory profiling information: allocated memory, memory peaks

While the *sdp* command records session data, it writes intermediate data to a directory under the current working directory. The amount of disk space used depends on the session duration, number of processes and threads, and the actions carried out during the session. The intermediate data files and directory are automatically deleted upon exit from pt_shell.

For example, a test run of 10 hours with 10 subprocesses, each having 4 to 8 threads, generated 6 GB of uncompressed data. Upon exit from pt_shell, the tool rewrote out the data in compressed format, producing a 200 MB file.

In a DMSA flow, run the *sdp -start* command at the DMSA master. The operation is queued to be performed at the start of each task executed by a worker process. Similarly, run the *sdp -stop* command at the DMSA master. The *sdp* command works in a similar manner in HyperGrid distributed analysis flows.

Examples

The following command starts SDP data recording:

```
pt_shell> sdp -start
```

Feedback

```
SDP Info: 'stack_tracer' 'crte' 'sst' 'stopwatch' started.
SDP Info: Log folder is located at
 '/remote/my_run_dir/sdp/runid_ig106_20180907_000022068'.
1
pt_shell>
```

The following command stops SDP session data recording:

```
pt_shell> sdp -stop
SDP Info: 'crte' 'sst' 'stack_tracer' 'stopwatch' stopped.
1
```

When you exit pt_shell, the tool reports the data collected by SDP:

```
pt_shell> exit

Timing updates: 4 (2 implicit, 2 explicit) (0 incremental, 4 full, 0
 logical)
Noise updates: 0 (0 implicit, 0 explicit) (0 incremental, 0 full)
Maximum memory usage for this session: 1004.42 MB
CPU usage for this session: 28 seconds
Elapsed time for this session: 2551 seconds
Diagnostics summary: 2 errors, 6 warnings, 291 informationals

Thank you for using pt_shell!

SDP Info: SDP has collected diagnostic data that is useful for analyzing
 the
runtime performance of Synopsys tools. A tar file 'sdp.tgz' is created.
A copy of the file should be sent to the Synopsys support team for
 analysis.
DO NOT MODIFY THIS FILE.

---

set_active_clocks

Sets a group of clocks to be active in the current analysis scope.

Syntax

status *set_active_clocks*

```
active_clock_list
[-all_clocks]
```

Feedback

Data Types

`active_clock_list` list

Arguments

`active_clock_list`

Specifies a list of clocks matching the clock names. The *active_clock_list* and *all_clocks* are mutually exclusive.

`-all_clocks`

Specifies to analyze all clocks simultaneously. The *active_clock_list* and *all_clocks* are mutually exclusive.

Description

Sets a group of clocks to be active in the current analysis scope. Provides capability to perform timing analysis for a particular set of clock domains, but not the entire chip. If a few of the clocks are set as active, the tool performs timing analysis only for these clock domains.

If this command is not specified, the tool analyzes all clocks. The last *set_active_clocks* command always overrides previous ones. If you want to analyze all clocks simultaneously again, use the *set_active_clocks* command with the *active_clock_list* option set to a value of * or use it with the *all_clocks*.

When a clock or a generated clock is created, it is active by default. If a generated clock is active itself, but its master clock is inactive, it is not analyzed. You can use the *is_active* attribute of the clock object to create a collection of active clock objects. Thus, you can freely add or remove individual clocks from this collection.

You can use the *set_active_clocks* and *set_clock_groups* commands together to simultaneously analyze multiple clocks per register without manually specifying false paths. For examples, see the *set_clock_groups* man page.

When the *set_active_clocks* command applied on crosstalk delay analysis, only the victim and aggressors driven by active clocks are considered. Therefore, the nets driven by the non-active aggressor are considered quiet. However, all nets are sensitive to static noise (as victim) even when there is no active clocks driving them. This feature could be used to set test clocks to non-active when the design is in normal or mission mode and vice versa. It is important that you set all active clocks in the design as active, as they can be aggressors to other part of the design.

This command is not supported with the *write_sdc*, *characterize_context*, and *extract_model* commands.

The *set_active_clocks* command is used to speed up update_timing for local analysis, and some global functionalities might not behave as you expect. For example, check_timing reports endpoints as unconstrained if they are captured by inactive clocks.

Examples

The following example sets only two of the existing clocks in the design to be active.

```
pt_shell> set_active_clocks {clk1 clk2}
```

The following example resets all clocks in the design to be active.

```
pt_shell> set_active_clocks [all_clocks]
```

The following example adds *clk3* to the current active clocks list.

```
pt_shell> set het [get_clock * -filter is_active==true]
pt_shell> set newfoo [add_to_collection $het [get_clocks clk3]]
pt_shell> set_active_clocks $newhet
```

The following example removes *clk3* from the current active clocks list.

```
pt_shell> set het [get_clock * -filter is_active==true]
pt_shell> set newfoo [remove_from_collection $het \\
[get_clocks * -filter "is_active==true && full_name == clk3"]]
pt_shell> set_active_clocks $newhet
```

---

set_activity_derate

Sets clock activity derating factors for a specified list of instances or cell types (combinational, integrated clock gating cells).

Feedback

Syntax

```
int set_activity_derate
[-cell_type]
[-derate_factor]
derate_value
object_list
```

Data Types

cell_type	list
derate_value	float
object_list	list

Arguments

`-cell_type`

Indicates that the *derate_value* specified should be applied to combinational, or integrated clock gating cells in the clock network.

derate_value

Specifies the value of the derating factor that is applied to the toggle rate of cells in the clock network.

object_list

Specifies current design or a list of cells to which the specified clock derating factor is applied.

Description

Sets toggle rate derating factors on different cell types in the current design, or a list of cells in the current design. The clock derating factors are used as a scalar multiplicative factor in calculation of toggle rate for output net of cell.

Clock activity derating factor affects toggle rate on cells in the clock network. If clock derating factors are not specified, the value of 1.0 is assumed.

If you use the *set_activity_derate* command with the *-cell_type*, option, the specified activity derating factor is only applied to combinational or integrated clock gating cells accordingly. The derating is not applied to inverters or buffer cells in the clock network. But you can explicitly set derate on buffer/inverter using *cell_list* option.

The *object_list* option can be used to set specific derating factors on instances (cells) in the design. On each instance the *-derate_value* can be used in the same way as previously described to specify exactly how the derating factors should be applied to cell types.

If clock activity derating factors are set multiple times on the same design object or the same cell type, the later value overrides the previous value.

To set derating values back to the default (derating factor of 1.0 for every instance in the design), use the *set_activity_derate* command again with *derate_vale* value of 1.0.

Examples

The following example sets clock activity toggle rate derating factor of value 0.1 on all combinational cells in the design.

```
pwr_shell> set_activity_derate -derate_factor 0.1 -cell_type
 combinational
```

The following example sets clock activity toggle rate derating factor of value 0.1 to all cells in the design.

```
pwr_shell> set_activity_derate -derate_factor 0.1 [get_cells *]
```

The following example sets the toggle derate to 0.1 for all integrated clock gating cells in the design.

```
pwr_shell> set_activity_derate  -derate_factor 0.1 -cell_type
 clock_gating_cells
```

The following example sets a toggle derating factor of 0.1 on cell instance u1 in the design.

```
pwr_shell> set_activity_derate -derate_factor 0.1 [get_cell u1]
```

See Also

- update_power
- set_switching_activity

---

set_advanced_analysis

Turn on advanced analysis mode.

Syntax

string *set_advanced_analysis*

Arguments

None.

Description

This command turns on the advanced analysis mode. In this mode, PrimeTime will perform analysis using enhanced algorithms. In addition, some features will be enabled: the all_path_edges mode will be used in SI window overlap analysis; combined launch and capture depths will be used in AOCV analysis, replacing

separate_launch_capture_depth or separate_data_and_clock_metrics settings. Also, automatic inference of MUX cells for clock exclusivity will be enabled. These additional features can be modified or turned off after the execution of this command. Turning off the aforementioned features after executing this command will still impact the analysis. Potential degradation of runtime and capacity compared to the default mode of analysis is also expected.

It is recommended that this command be executed right before update_timing to prevent potential modification and confliction of related settings. This feature requires PrimeTime SI license.

Examples

The following example shows how to turn on advanced analysis mode:

```
pt_shell> set_advanced_analysis
Information: Checked out license 'PrimeTime-SI' (PT-019)
Changing the following variable settings:
Information: setting si_xtalk_delay_analysis_mode to all_path_edges
Information: setting timing_aocvm_analysis_mode to
 combined_launch_capture_depth
Information: setting timing_enable_auto_mux_clock_exclusivity to true
```

---

set_advanced_multi_input_switching_factor

Sets a derate of advanced multi-input switching (MIS) analysis for a specified list of library cells.

Syntax

int *set_advanced_multi_input_switching_factor*

```
-scale_factor scale factor
[-all]
-reset
[-inverse]
[object_list]
```

Data Types

scale_factor	float
object_list	list

Arguments

`-scale_factor`

Applies a scaling factor to decrease the advanced MIS derate for the specified library cell.

`-all`

Applies the command to all the library cells of the design.

`-reset`

Resets the scaling factor for the specified library cells.

`-inverse`

Applies an inverse scaling factor to increase the advanced MIS derate for the specified library cell.

`object_list`

Specifies a list of library cells for application of the scaling factor.

Description

This command defines a scaling factor that is used to scale the computed advanced MIS coefficients for the specified list of library_cells. The value of the scaling factor must be between 0.0 and 1.0. With the *-inverse* option, the scaling factor is used to increase as opposed to decrease the advanced MIS derate. In case two commands, one with the *-all* option and one with a specific library cell are specified, the library cell specification wins.

Examples

The following example changes the tool computed advanced MIS factor from 0.5 to 0.75 for the NAND2 cell.

```
pt_shell> set_advanced_multi_input_switching_factor -scale_factor 0.5
[get_lib_cell NAND2]
```

The following example changes the tool computed advanced MIS factor from 0.5 to 0.25 for the NAND2 cell.

```
pt_shell> set_advanced_multi_input_switching_factor -inverse
 -scale_factor 0.5
[get_lib_cell NAND2]
```

The following example changes the tool computed advanced MIS factor from 0.5 to 0.25 for all cells in the design.

```
pt_shell> set_advanced_multi_input_switching_factor -all -inverse
 -scale_factor 0.5
```

The following example changes the tool computed advanced MIS factor from 0.5 to 0.75 for the NAND2 library cell and from 0.5 to 0.25 for all other cells in the design.

```
pt_shell> set_advanced_multi_input_switching_factor -scale_factor 0.5
[get_lib_cell NAND2]
pt_shell> set_advanced_multi_input_switching_factor -all -inverse
 -scale_factor 0.5
```

The following example resets the scaling factor for all cells in the design.

```
pt_shell> set_advanced_multi_input_switching_factor -reset -all
```

---

set_annotated_activity_waveform

Allows user to annotate a waveform on design nets or leaf level pins.

Syntax

```
status set_annotated_activity_waveform
[-period period_value]
[-waveform edge_list]
[-value_change change_list]
object_list
```

Data Types

period_value	float
edge_list	list
change_list	list
object_list	list

Arguments

`-period` *period_value*

Defines period value of a symmetric repetitive waveform. It takes float value as input and default unit is ns (nano seconds).

`-waveform` *edge_list*

This option can only be used with -period. Defines the rise and fall transition time within specified period in order of rise transition, fall transition and so on, first edge is always input as rise transition. It can only have even number of edges. If this option is not specified, then rise edge will be assumed at start of period and a fall edge will start from the half- period.

`-value_change` *change_list*

This option is mutually exclusive with -period option. Defines list of time and signal value pair values.. Value can be 0 or 1.

object_list

object_list can be a collection of either nets or leaf level pins.Name of object should be hierarchical. This option accepts wildcard characters.

Description

This command enables user to annotate waveform on nets or leaf level pins. The command overrides annotated waveform from vector file for these pins or signals if present. Annotation type set_annotated_activity_waveform is set for nets or pins on which user has annotated waveform. Toggles specified on the leaf pins of a cell are automatically applied on the nets connected to that pin.

Examples

The following *set_annotated_activity_waveform command generates waveform on d0 net.*

```
pt_shell> set_annotated_activity_waveform -waveform { .25 .75 }
 -period .9 [get_nets d0]
pt_shell> get_switching_activity [get_net d0]
{"u_SDFFW/d0" 2 set_annotated_activity_waveform
 0 set_annotated_activity_waveform 0.571429
 set_annotated_activity_waveform}
```

The following *set_annotated_activity_waveform command generates toggles on d0 net.*

```
pt_shell> set_annotated_activity_waveform -value_change {{3, 1} {3.25,
 0} } [get_nets d0]
```

See Also

- get_switching_activity

---

set_annotated_check

Sets the setup, hold, recovery, removal, or nochange timing check value between two pins.

Syntax

string *set_annotated_check*

```
-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low |
 -width | -period
[-rise]
[-fall]
[-min]
[-max]
[-from from_pins]
[-to to_pins]
[-clock rise | fall]
```

```
[-cond sdf_expression]
[-worst]
[-increment]
[-override_increment]
[comment]
check_value
```

Data Types

```
from_pins           list
to_pins             list
sdf_expression      string
check_value         float
comment    string
```

Arguments

`-setup`

Specifies that data must be stable for the amount of time specified by the *check_value* option before the closing clock edge.

`-hold`

Specifies that data must be stable for the amount of time specified by the *check_value* option after the closing clock edge.

`-recovery`

Specifies that an asynchronous set or clear inactive edge cannot occur within the *check_value* option before the closing clock edge. This is essentially a setup requirement on an asynchronous pin, but only the inactive transition is considered.

`-removal`

Specifies that an asynchronous set or clear inactive edge cannot occur until the *check_value* option time after the closing clock edge. This is essentially a hold requirement on an asynchronous pin, but only the inactive transition is considered.

`-nochange_high`

Specifies that the data must not rise within the *check_value* option time before the clock becomes active, and must not fall until the *check_value* variable time after the clock becomes inactive. A rise data transition corresponds to the check before the activating clock edge. A fall data transition corresponds to the check after the deactivating clock edge. A rise clock transition indicates that the clock is active high. A fall clock transition indicates that the clock is active low.

`-nochange_low`

Specifies that the data must not fall within the *check_value* option time before the clock becomes active, and must not rise until the *check_value* option time after the clock becomes inactive. A fall data transition corresponds to the check before the activating clock edge. A rise data transition corresponds to the check after the deactivating clock edge. A rise clock transition indicates that the clock is active high. A fall clock transition indicates that the clock is active low.

`-width`

Specifies the minimum pulse width constraint for a clock pin. The timing check is defined on the *-from* pin, so the related pin (*-to*) should either be the same or it can be omitted.

`-period`

Specifies the minimum period constraint for a clock pin. The timing check is defined on the *-from* pin, so the related pin (*-to*) should either be the same or it can be omitted.

`-rise`

Specifies that the timing check is for the data rise transition. If you do not specify either the *-rise* or *-fall* options, both values are set.

`-fall`

Specifies that the timing check is for the data fall transition. If you do not specify either the *-rise* or *-fall* options, both values are set.

`-min`

Use this option only if the design is in min_max mode (min and max operating conditions). Specifies the minimum timing check for both data rise and data fall transitions.

`-max`

Use this option only if the design is in min_max mode (min and max operating conditions). Specifies the maximum timing check for both data rise and data fall transitions.

`-from` *`from_pins`*

Specifies a list of leaf cell clock pins that are the startpoints of the timing arcs for which checks are annotated. There must be a corresponding timing arc between the *from_pins* and the *to_pins* options.

`-to` *`to_pins`*

Specifies a list of leaf cell data pins that are the endpoints of the timing arcs for which checks are annotated. There must be a corresponding timing arc between the *from_pins* and the *to_pins* options.

`-clock rise | fall`

Specifies whether the check is for clock rising or falling. By default, checks for both clock rise and fall are set.

`-cond` *`sdf_expression`*

Use this option only if the library has a condition attached to the specified timing check arc; otherwise, an error message is generated. Specifies the condition for which the annotated check is valid. The syntax of the condition must match the condition specified in the library using the sdf_cond construct. The syntax is the same one used in the Standard Delay Format (SDF).

`-worst`

This option is not currently implemented, so it is ignored.

`-increment`

Specifies that the delay value is to be added to the calculated check value of the specified timing arc. If an annotated incremental value already exist, then the new value will be added on the existing one.

`-override_increment`

Overwrite incremental values instead of adding them on the already existing. Applies only for annotating incremental values.

`comment`

Associates a string description with the command for tracking. The comment string must begin and end with double quotation marks ("). Currently, this option is disabled by default. To enable it set pt_enabled_comment_option gvar to true.

`check_value`

Specifies the timing check value between pins on the same cell, in units consistent with the logic library used during optimization. For example, if the logic library specifies delay values in nanoseconds, the *check_value* option must be expressed in nanoseconds. The *check_value* option can be negative.

Description

Annotates a timing check arc between two or more pins on a cell or a net in the current design. This can be appropriate after place and route, for technologies where the timing check value varies for different instances, and the library timing check values do not provide sufficient accuracy.

If the design is not linked, it is linked automatically by the *set_annotated_check* command.

You can use the *set_annotated_check* command for pins at lower levels of the design hierarchy. You can specify pins in the format of *INSTANCE1/INSTANCE2/PIN_NAME*.

To list annotated timing check values, use the *report_annotated_check* command. To remove annotated timing check values from a design, use the *remove_annotated_check* or *reset_design* commands. To see the effect of the *set_annotated_check* command for a specific instance, use the *report_timing* command.

Examples

The following example annotates a setup time of 2.1 units between the CP clock pin of cell instance u1/ff12 and the D data pin of the same cell instance.

```
pt_shell> set_annotated_check -setup 2.1 -from u1/ff12/CP -to u1/ff12/D
```

The following example annotates a check for the maximum value of 3.0 units for a minimum pulse width of a clock signal in 'high' state at the u1/ff12/CP clock pin. The annotation is then reported by *report_annotated_check*:

```
pt_shell> set_annotated_check -width 3.0 -clock rise -max  -from
 u1/ff12/CP
pt_shell> report_annotated_check -width -list_annotated
****************************************
Report : annotated_check
         -width
         -list_annotated
 ...
****************************************

Backannotated cell min_pulse_width check arcs:
-----------------------------------------------
1. u1/ff12/CP -> u1/ff12/CP  (r:0.10/3.00  f:NA  sense:
 clock_pulse_width_high)

                              |           |           |    NOT    |
    Timing check type         |    Total  | Annotated | Annotated |
------------------------------+-----------+-----------+-----------+
cell min pulse width arcs     |       20  |        1  |       19  |
```

The following examples illustrates how the incremental values are annotated and how incremental values are used.

On the example below a value of 1.0 unit is annotated on the setup time between the clock pin and the data pin of a cell instance. After that an incremental setup value of 0.5 units is annotated on the same arc. The final value of the setup constraint on this arcs is 1.5.

```
pt_shell> set_annotated_check -setup -from ff/CP -to ff/D 1.0
pt_shell> set_annotated_check -increment -setup -from ff/CP -to ff/D 0.5
```

Feedback

Continuing the above example, the following command annotates another 0.6 unit on this setup arc. The new setup value for this arc is now 2.1, where 1.0 is the fully annotated value and 1.1 (0.5 + 0.6) is the incremental annotated value.

```
pt_shell> set_annotated_check -increment -setup -from ff/CP -to ff/D 0.6
```

The overriding of the previously annotated incremental values on a timing arc can be achieved with option *-override_increment*. The impact that the following command has on the above example is to override the current increment value of 1.1 with a new one of 0.7. The new setup value is now 1.7 since 1.0 was the initial fully annotated value and 0.7 in the new increment value.

```
pt_shell> set_annotated_check -increment -override_increment -setup -from
 ff/CP -to ff/D 0.7
```

The incremental annotated values equally interacts with fully annotated values and calculated values. They can also be removed with the usage of the *remove_annotated_check* or *reset_design* commands.

---

set_annotated_clock_network_power

Annotate power on clock networks.

Syntax

string *set_annotated_clock_network_power*

```
[-internal_power internal_power]
[-switching_power switching_power]
[-leakage_power leak_power]
[-total_power total_power]
[-clock domain_clock]
```

Feedback

Data Types

internal_power	float
switching_power	float
leak_power	float
total_power	float
domain_clock	string

Arguments

`-internal_power` *internal_power*

Specifies the annotated internal power value on the clock network.

`-switching_power` *switching_power*

Specifies the annotated switching power value on the clock network.

`-leakage_power` *leak_power*

Specifies the annotated leakage power value on the clock network.

`-total_power` *total_power*

Specifies the annotated total power value on the clock network. It is treated as internal power in the reports.

`-clock` *domain_clock*

Specifies the clock in the related clock network on which the power values are annotated.

Description

The *set_annotated_clock_network_power* command provide the capability to annotate the power values on the clock networks in the reports from PrimePower. If this command is used before the *report_power* command, PrimePower uses the annotated clock network power values in the summary report. There is also a separate annotated clock network power report embedded in the regular summary power report. The *clock_network* group power in the summary report excludes the clock network objects whose power values are annotated. An attribute 'e' marks such a situation in the report.

The power values in the unit of Watt are specified by either *-total_power* option of a combination of *-internal_power*, *-switching_power* and *-leakage_power* options, If *-total_power* option is used, the power values are also treated as internal power in the reports to make the results consistent. If the options of *-switching_power*, *-internal_power* and/or *-leakage_power* are used, the values are annotated on internal, switching and/or leakage power respectively. The total power is the sum of these three components. These three options can be used together or separately. But they cannot be used together with the *-total_power* option; otherwise, the CMD-001 error message is issued and the command fails.

By default, the power values aree annotated on the whole clock network in the design. If *-clock* option is used, the power values are annotated on the collection of clock network objects of the corresponding clock domain. Only one clock is allowed for one command. Multiple *set_annotated_clock_network_power* commands can be used to specify annotated power of multiple clock domains separately. The annotated clock network power reports list them separately.

If two *set_annotated_clock_network_power* commands are specified for the same clock domain (or the whole clock network) and the power types (internal, switching, leakage or total) are the same, The power values of the later command overrides the earlier one. If they are not the same power type, both power values are kept and reported.

The *set_annotated_clock_network_power* command can work with *report_power -groups group_list* only when the group_list contains the default 'clock_network' power group; otherwise, an PWR-296 error message is issued and the *report_power* command fails.

The *set_annotated_clock_network_power* command causes the cells in the related clock network not to be reported by *report_power -cell* command. The other options in the *report_power* command are not affected.

The annotated clock network power has higher priority than the estimated clock network power. If both features are invoked in the *report_power* command, a PWR-295 warning message is issued and annotated clock network power values are used in power reports.

To remove the annotated clock network power values already specified for the design, use the *remove_annotated_clock_network_power* command. The *report_power* command reverts back to its original behavior.

Examples

In the following example, the internal, switching power are annotated separately for clock domain CKA and CKB.

```
pt_shell> create_clock -name CKA -period 10 clka
pt_shell> create_clock -name CKB -period 5 clka
pt_shell> set_annotated_clock_network_power -internal 1.0e-03 -switching
 2.0e-03 -clock CKA
pt_shell> set_annotated_clock_network_power -switching 2.0e-03 -clock CKB
pt_shell> report_power
```

The following is the output from the above commands

```
****************************************

---

set_annotated_delay

Sets an annotated net or cell delay value between two pins, or modifies an existing net or cell delay.

Feedback

Syntax

string *set_annotated_delay*

```
-cell | -net
[-rise]
[-fall]
[-min]
[-max]
[-load_delay net | cell]
[-from from_pins]
[-to to_pins]
[-cond sdf_expression]
[-increment]
[-delta_only]
[-worst]
[-of_objects objects]
delay_value
```

Data Types

from_pins	list
to_pins	list
sdf_expression	string
objects	list
delay_value	float

Arguments

`-cell`

Annotates a delay on a cell, from an input to an output of the cell.

`-net`

Annotates a delay on a net, from the output of a cell to the input of another cell.

`-rise`

Applies the delay only to rising transitions.

`-fall`

Applies the delay only to falling transitions.

By default, the delay applies to both rising and falling transitions.

`-min`

Applies the delay only to the minimum operating condition in min-max mode.

`-max`

Applies the delay only to the maximum operating condition in min-max mode.

The min-max mode is enabled by the *set_operating_conditions* command with the *-min* and *-max* options.

`-load_delay net | cell`

Specifies whether load delays are included in *net* delays or *cell* delays. The default is *cell* delays.

Load delay is the portion of cell delay resulting from the capacitive load of the net the cell is driving.

All timing arcs of the same net or of the same cell must be annotated with the same type of load delay setting.

`-from` *`from_pins`*

Specifies a list of leaf-cell pins and top-level ports that are the startpoints of the timing arcs for which delays are annotated.

`-to` *`to_pins`*

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs on which delays are annotated.

You must use the *-from* or *-to* option, or both, to specify the startpoints and endpoints; or the *-of_objects* option to specify a collection of timing arcs on which to annotate the specified delay.

`-cond` *`sdf_expression`*

Specifies the logical condition for which the annotated delay is valid. The syntax of the expression must match the condition specified in the library using the Liberty construct sdf_cond. Use this option only if the library has a condition attached to the specified delay timing arc.

`-increment`

Adds the specified delay value to the existing delay of the timing arc, instead of replacing it.

If the existing timing arc is conditional, you must also use the *-cond* option to specify the condition. Otherwise, the command has no effect. To apply an incremental change to multiple conditional timing arcs, use multiple *set_annotated_delay* commands with different *-cond* option settings.

`-delta_only`

Adds the specified delay value to the existing net delay value calculated by the tool, instead of replacing it. Use this option only with the *-net* option.

`-worst`

This option is accepted as valid syntax but is not used by the PrimeTime tool, so it is ignored.

`-of_objects` *objects*

Specifies a collection of timing arcs created with the *get_timing_arcs* command on which to annotate the delay value. You cannot use this option at the same time as the *-from* or *-to* option.

delay_value

Specifies a new annotated delay value, or an incremental change in the delay value if the *-increment* or *-delta_only* option is used. Specify the value in time units consistent with the logic library.

Description

This command annotates delay values in the design by specifying either a new delay value or an incremental change to an existing delay. You must use the *-cell* or *-net* option to annotate either a cell delay or a net delay.

You must use either the *-from* and *-to* options to specify the startpoints and endpoints of the timing arcs to be annotated or the *-of_objects* option to specify a collection of timing arcs on which to annotate the specified delay. You create a collection of timing arcs using the *get_timing_arcs* command.

Cell delay is the delay from an input pin to an output pin of a leaf-level cell. These delays are defined in the library description of the cell and typically vary with the slew of the input signal and the size of the output load of the cell. Some cell delays are conditional, depending on the logic states of some of the cell inputs.

Net delay is the delay through a net, from an output pin of a leaf-level cell or a top-level input port to an input pin of another leaf-level cell or a top-level output port. The PrimeTime tool calculates net delays from the driver and load characteristics and the RC properties of the net.

To annotate load-dependent delays due to driving cells on input ports, use the *-cell* option, omit the *-from* option, and specify the input ports with the *-to* option.

To see the timing effects of the *set_annotated_delay* command, run the *report_timing* command. In the generated timing reports, annotated delay values are marked with an asterisk (*) character.

To report annotated delay values and locations, use the *report_annotated_delay* command with the *-list_annotated* option.

Load delay, also known as extra source gate delay, is the portion of cell delay caused by the capacitive load of the driven net. Some delay calculators consider load delay part of the cell delay and others consider it part of the net delay.

If your annotated delay values (for either cell or net) assume that load delay is part of the cell delay, use the *-load_delay cell* option. If your delay values assume that load delay is included in the net delay, use the *-load_delay net* option. By default, load delays are assumed to be included in cell delays, so they appear in the *report_timing* path listings.

By default, the specified delay value overrides the calculated cell or net delay value. To add the delay value to the existing delay (instead of overriding), use the *-increment* option. If the timing arc is conditional, you must also use the *-cond* to specify the matching logical condition of the arc.

To add a delay value to a net, use the *-net* option with the *-delta_only* option. After that, if you annotate a net delay again on the same net without the *-delta_only* option, the earlier delta delay setting is ignored, based on the assumption that the latest annotation includes any desired delta delay. If you later remove the annotated full net delay from the net, the delta delay setting again takes effect.

You can use the *set_annotated_delay* command for pins at lower levels of the design hierarchy. Specify these pins using the format INSTANCE1/INSTANCE2/PIN_NAME.

To remove the annotated cell or net delay values from a design, use the *remove_annotated_delay* or *reset_design* command.

Examples

The following example annotates a cell delay of 20 time units between input pin A and output pin Z of cell instance U1/U2/U3. The specified delay value includes the load delay.

```
pt_shell> set_annotated_delay -cell -load_delay cell 20 \\
          -from U1/U2/U3/A -to U1/U2/U3/Z
```

The following example annotates a rise net delay of 1.4 time units between output pin U1/Z and input pin U2/A. The specified delay value for this net does not include load delay.

```
pt_shell> set_annotated_delay -net -rise 1.4 -load_delay cell \\
          -from U1/Z -to U2/A
```

The following example annotates a rise net delay of 12.3 time units between the same output pins. In this example, the net delay value includes load delay.

```
pt_shell> set_annotated_delay -net -rise 12.3 -load_delay net \\
          -from U1/Z -to U2/A
```

The following script creates a collection containing a timing arc and then sets the annotated delay for that timing arc.

```
set my_arc [get_timing_arcs -from I_TOP/I_CORE/U120/Z -to
 I_TOP/I_CORE/reg15/D]
set_annotated_delay -net -of_objects $my_arc 0.123
```

---

set_annotated_power

Annotates power on unresolved black box cells or leaf cells.

Syntax

status *set_annotated_power*

```
[-internal_power internal_value]
[-leakage_power leakage_value]
[-switching_power switching_power_value]
[-rails rail_list]
[-pg_pin pg_pin_list]
[-clock clock_list]
object_list
```

Data Types

internal_value	float
leakage_value	float
switching_power_value	float
rail_list	list
pg_pin_list	list
object_list	list
clock_list	list

Arguments

`-internal_power` *internal_value*

Specifies the internal power (in watts) to be annotated.

`-leakage_power` *leakage_value*

Specifies the leakage power (in watts) to be annotated.

`-switching_power` *switching_power_value*

Specifies the switching power (in watts) to be annotated.

`-rails` *rail_list*

Specifies a list of rails/power supply nets on which power is annotated. This option applies the annotated power values to each power supply net (or rail in non-UPF mode) in the list. This feature is valid only if the *power_enable_multi_rail_analysis* variable is set to *true*.

`-pg_pin` *pg_pin_list*

Specifies a list of pg_pins on which power is annotated. This option applies the annotated power values to each pg_pin in the list. This feature is used in both UPF and non-UPF mode. It is valid only if *power_enable_multi_rail_analysis* variable is set to *true*.

`-clock`

Specifies a clock on which power is annotated. This option applies the annotated power values on clock. This feature is valid only if cell is a hierarchical cell.

object_list

Specifies a list of cells on which to annotate internal_power or leakage_power, or a list of nets on which annotate switching_power.

Description

The *set_annotated_power* command annotates the internal and leakage power on the specified cells and annotates the switching power on the specified nets. The command should be used mostly on unresolved black box cells, where internal and leakage power cannot be estimated. However, the command also works for any leaf cells and hierachical cells, where the annotated internal and leakage power overrides the internally estimated internal and leakage power. The internally estimated power, if available, is overridden by the annotated power number, but is resurrected if the annotated power is removed.

Switching power (power of the nets connected to the output pins of the cell) can be annotated using list of nets.

The annotated power is average power, so it has no effect on power waveforms.

Examples

The following example shows how power is annotated, removed and reported.

```
pt_shell> set_annotated_power -internal_power 0.1 -leakage_power 0.2
 U0/U1
1
pt_shell> set_annotated_power -internal_power 0.3 -leakage_power 0.4 U0
```

Feedback

```
1
pt_shell> set_annotated_power -switching_power .25 out
1
pt_shell> set_annotated_power -switching_power .25  n1

---

set_annotated_transition

Sets the transition time annotated on specified pins in the current design.

Syntax

int *set_annotated_transition*

```
[-rise]
[-fall]
[-min]
[-max]
[-sms_scenarios sms_scenarios_list]
[-delta_only]
slew_value
pin_list
```

Data Types

```
pin_list            list
slew_value          float
sms_scenarios_list  collection
```

Arguments

`-rise`

Indicates that the *slew_value* variable represents the data rise transition time.

`-fall`

Indicates that the *slew_value* variable represents the data fall transition time.

`-min`

Indicates that the *slew_value* variable represents the minimum transition time. Use this option only if the design is in min-max mode (min and max operating conditions).

`-max`

Indicates that the *slew_value* variable represents the maximum transition time. Use this option only if the design is in min-max mode (min and max operating conditions).

`-delta_only`

Indicates that the *slew_value* variable represents a delta transition time that is added to the transition time computed by delay calculation.

`slew_value`

Specifies the transition time of the specified pins or ports, in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, the *slew_value* variable must be expressed in nanoseconds. If used with the *-delta_only* option, the *slew_value* variable can be a negative number.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this transition is applied. When this option is not given the transition applies to all SMS scenarios. This collection is created by *get_sms_scenarios*.

`pin_list`

Specifies a list of pins or ports that is annotated with the transition time *slew_value*.

Description

The *set_annotated_transition* command specifies an annotated transition time value on pins or ports in the design. This transition time value overrides the regular tool-computed transition time value computed at (and propagated from) those objects.

The *set_annotated_transition* command can be used for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To remove annotated transition times, use the *remove_annotated_transition* command.

Examples

The following example annotates a rising transition time of 0.5 units and a falling transition time of 0.7 units on input pin *A* of cell "U1/U2/U3".

```
pt_shell> set_annotated_transition -rise 0.5 [get_pins U1/U2/U3/A]
pt_shell> set_annotated_transition -fall 0.7 [get_pins U1/U2/U3/A]
```

Feedback

---

set_aocvm_coefficient

Specifies the advanced on-chip variation (AOCV) coefficients on library cells, library timing arcs, and cells.

Syntax

status *set_aocvm_coefficient*

```
coefficient
object_list
```

Data Types

```
coefficient     float
object_list     list
```

Arguments

coefficient

Specifies a coefficient value, which should be a floating-point value greater than zero.

object_list

Specifies a list of library cells, library timing arcs, or leaf cells on which the coefficient is set.

Description

Sets AOCV coefficients on library cells, library timing arcs, and leaf cells. Coefficients are used to calculate cell path depths; the default depth increment for a cell arc in a path is 1, but you can specify another coefficient value with this command. AOCV coefficients are not required for an AOCV analysis; however, their use might increase the accuracy of the analysis.

The tool applies the coefficients in the following order of priority for cell arcs (in decreasing order of precedence):

```
1) Cell
2) Library timing arc
```

Feedback

```
3) Library cell
4) 1.0 (default)
```

To display AOCV coefficients, use the *report_aocvm -coefficient* command. To remove AOCV coefficients from a cell, use the *remove_aocvm -coefficient* or the *reset_design* command.

Examples

The following examples specify AOCV coefficients on library cells and library timing arcs.

```
pt_shell> set_aocvm_coefficient 1.2 [get_lib_cells lib/AN2]
pt_shell> set_aocvm_coefficient 2.5 [get_lib_timing_arcs -from lib/AN2/A
 -to lib/AN2/Z]
```

See Also

- read_aocvm
- remove_aocvm
- report_aocvm
- timing_aocvm_analysis_mode

---

set_aocvm_table_group

Associates an AOCV named table group or Liberty-based AOCV derating group with the list of specified design objects.

Syntax

status *set_aocvm_table_group*

```
aocvm_table_group_name
[object_list]
```

Data Types

```
aocvm_table_group_name     string
object_list                list
```

Arguments

aocvm_table_group_name

Specifies the name of the AOCV table set.

object_list

Specifies the list of design objects.

Feedback

Description

The *set_aocvm_table_group* command can operate on either hierarchical cells in the top-level design or on lib_cells.

When operating on hierarchical cells in the top-level design, it sets the association between a named AOCV table group and a hierarchical instance. An AOCV table set is a collection of AOCV tables with the same name. Names are specified using the group_name field in the AOCV table syntax.

When associations are specified between hierarchical cells in the design and named AOCV table sets, a cell (or net) derives its AOCV derating from the table set associated with the hierarchical cell or design that (a) fully contains the cell or net, and (b) is the lowest level (closest ancestor) hierarchical cell or design with an associated AOCV table set. If no such hierarchical cell or design containing the cell or net is found, the unnamed AOCV table set is used.

Note: A net inherits the AOCV derating set of a hierarchical cell (design) that fully contains the net. For example, for nets that cross the boundary between the top level and a block (with an associated AOCV table set), the lowest level hierarchical cell that fully contains the net is not the block. Therefore, the net derating does not come from an AOCV table set that contains the block and fully encloses the net.

When operating on library_cells the *set_aocvm_table_group* command can be used to assign a Liberty-based AOCV table from a Liberty library to the given lib cell. The Liberty AOCV format allows for tables, which are not assigned to any library cell by default, to still be referenced by name. This command provides the ability to setup this reference. The syntax for the P/AOCVM derate group to be referenced follows this pattern:

lib_name/[*lib_cell_name*]/*derate_group_name*

The lib_cell_name is optional and applicable only for lib_cell based table. A lib_cell based can only be assigned to a lib cell of the same name.

Examples

The following example associates the hierarchical cell H1 with the AOCV table set A1.

```
pt_shell> set_aocvm_table_group A1 [get_cells H1]

pt_shell> sh cat test.aocvm

version:        3.0
group_name:     A1
object_type:    lib_cell
rf_type:        rise
delay_type:     cell
derate_type:    late
object_spec:    my_lib/*
voltage:        1.02
```

```
depth:          1 2 3
distance:       100 1000
table:          1.20 1.10 1.08
                1.22 1.15 1.11
```

---

set_app_var

Sets the value of an application variable.

Syntax

string *set_app_var*

```
-default
var
value
```

Data Types

```
var         string
value       string
```

Arguments

`-default`

Resets the variable to its default value.

`var`

Specifies the application variable to set.

`value`

Specifies the value to which the variable is to be set.

Feedback

Description

The *set_app_var* command sets the specified application variable. This command sets the variable to its default value or to a new value you specify.

This command returns the new value of the variable if setting the variable was successful. If the application variable could not be set, then an error is returned indicating the reason for the failure.

Reasons for failure include:

- The specified variable name is not an application variable, unless the application variable *sh_allow_tcl_with_set_app_var* is set to true See the *sh_allow_tcl_with_set_app_var* man page for details.
- The specified application variable is read only.
- The value specified is not a legal value for this application variable

Examples

The following example attempts to set a read-only application variable:

```
prompt> set_app_var synopsys_root /tmp
Error: can't set "synopsys_root": variable is read-only
       Use error_info for more info. (CMD-013)
```

In this example, the application variable name is entered incorrectly, which generates an error message:

```
prompt> set_app_var sh_enabel_page_mode 1
Error: "sh_enabel_page_mode" is not an application variable
        Use error_info for more info. (CMD-013)
```

This example shows the variable name entered correctly:

```
prompt> set_app_var sh_enable_page_mode 1
1
```

This example resets the variable to its default value:

```
prompt> set_app_var sh_enable_page_mode -default
0
```

- report_app_var
- write_app_var

Feedback

set_case_analysis

Specifies a constant logic value or transition type for a list of ports or pins.

Syntax

```
status set_case_analysis
  value
  port_or_pin_list
  comment
```

Data Types

value	string
port_or_pin_list	list
comment	string

Arguments

value

Specifies a constant logic value or a transition type assigned to the given ports or pins. These are the valid values:

- *0* or *zero* - Constant logic 0
- *1* or *one* - Constant logic 1
- *static* - Constant logic 0 or logic 1, no transitions
- *rise* or *rising* - Only rising transitions are considered
- *fall* or *falling* - Only falling transitions are considered

port_or_pin_list

Specifies the ports or pins affected by the case analysis setting.

-comment *comment_string*

Associates a string description with the command for tracking purposes. When writing out SDC, this option is useful for tagging the methodology or tool that originally synthesized the command. You must begin and end the *comment_string* with double quotation marks ("). Currently, this option is disabled as a default. To enable it set *pt_enabled_comment_option* gvar to TRUE.

Description

Case analysis specifies a list of ports or pins that have a constant logic value (*0*, *1*, or *static*) or only one type of transition (*rising* or *falling*). You can use case analysis settings to place the design into a given operating mode without altering the netlist.

When case analysis is specified as a constant value (*0*, *1*, or *static*), this value is propagated through the network where the constant value controls the traversed logic. For example, if you specify a constant value of 0 at an input of a NAND gate, the output of the NAND gate has a constant value of 1. This value is then propagated further to all cells driven by this output.

A net with the *static* logic constant value can be either 0 or 1 but cannot change, and therefore cannot act as an aggressor in crosstalk analysis. If one input of an 2-input AND gate is *static* and the other has a constant logic value of *1*, the output is *static*; or if the other input has a constant logic value of *0*, then the output is a constant logic *0*.

In case of conflicting values, the following rules apply:

- A *set_case_anlaysis* setting has priority over a built-in constant value such as a logic constant in the Verilog netlist.
- A newer *set_case_anlaysis* setting has priority over an older one set on the same port or pin.
- A *set_case_anlaysis* value set directly on a port or pin has priority over a conflicting case analysis value propagated to that port or pin.
- Where propagated case analysis values are in conflict, logic *0* has the highest priority, then the *static* case setting, then logic *1*.

In the case of a leaf pin, the constant is propagated forward only. No backward constant propagation is performed unless a hierarchical driver exists with a conflicting case value.

By default, when a logic constant value is propagated to a net, design rule checking is disabled for that net (for example, *set_max_fanout* and *set_max_capacitance* constraints). To enforce checking of the maximum capacitance rule for these nets, even with case analysis, set the *timing_enable_max_capacitance_set_case_analysis* variable to *true*.

If the case analysis value is either *rising* or *falling*, timing analysis considers only that transition type for the net. The case analysis information is used by all analysis commands.

You can use both case analysis (*set_case_analysis*) and mode analysis (*set_mode*) to fully specify the operating mode of a design. For example, a design might contain at test mode called TESTMODE, enabled by control input. You can specify the TESTMODE operating mode with the *set_mode* command, and also set the control input to a constant value to disable the test circuitry using the *set_case_analysis* command.

In the PrimePower tool, you can use the *set_case_analysis* command for power analysis in both averaged mode and time-based mode. Values set by the *set_case_analysis* command are also used for internal logic simulation to get the switching activity for nonannotated nets. However, the *-rising* and *-falling* options are ignored during power calculation. Simulation results from VCD or SAIF have higher priority than *set_case_analysis* settings.

Feedback

Examples

The following command sets the IN1 port to constant logic 0.

```
pt_shell> set_case_analysis 0 IN1
```

The following command sets the IN1 port to static, which means that it can be either constant logic 0 or constant logic 1. For the connected net, no transitions can occur and DRC rule checking is skipped.

```
pt_shell> set_case_analysis static IN1
```

The following command sets the rising transition case on pins U1/U2/A and U1/U3/CI. Timing analysis considers only rising (not falling) transitions on these pins.

```
pt_shell> set_case_analysis rising {U1/U2/A U1/U3/CI}
```

The following example disables the design mode called TESTMODE and sets the TEST_PORT port to a constant logic value *0*.

```
pt_shell> remove_mode TESTMODE U1/U2
pt_shell> set_case_analysis 0 TEST_PORT
```

Feedback

set_case_sequential_propagation

Specifies sequential cell instances or library cells to be enabled for sequential propagation.

Syntax

```
status set_case_sequential_propagation
  cellinstance_or_libcell_list
```

Data Types

```
cellinstance_or_libcell_list     list
```

Arguments

cellinstance_or_libcell_list

Lists sequential cell instances or library cells to be enabled for sequential propagation.

Description

Selective sequential propagation allows you to specify which cell instances are enabled for sequential propagation. To enable selective sequential propagation, the variable *case_analysis_sequential_propagation* must be set to *never*.

You can specify cell instances or library cells in the same command. If a library cell is specified, all cell instances of the library cell are enabled for sequential propagation. Cell instances and library cells are tracked separately. Therefore, if a cell instance and its library cell have been enabled for sequential propagation, and later you intend to completely disable the cell for sequential propagation, then both its cell instance and library cell must be removed (see *remove_case_sequential_propagation*).

The output of the *write_script* command includes *set_case_sequential_propagation*. However, the output of the *write_sdc* command does not include *set_case_sequential_propagation* because it is not a Synopsys Design Constraints (SDC) command.

Examples

The following example enables one cell instance for sequential propagation. FF1 is the instance name of the sequential cell.

```
pt_shell> set_case_sequential_propagation FF1
pt_shell> report_case_analysis -sequential_propagation
****************************************
Report : case_analysis
        -sequential_propagation
 ...
****************************************
```

```
------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 1
------------------------------------------------------------
Cell Instance : 'FF1'
------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 0
------------------------------------------------------------
```

The following example enables one library cell for sequential propagation. If the library cell is specified, all cell instances in the design with the same library cells are enabled for sequential propagation. To specify a library cell to be enabled for propagation, provide the *library name/library cell* format as shown in the following example.

```
pt_shell> set_case_sequential_propagation snps_test/D_FF
pt_shell> report_case_analysis -sequential_propagation
**************************************
Report : case_analysis
        -sequential_propagation
 ...
**************************************

------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 0
------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 1
------------------------------------------------------------
Lib Cell : 'snps_test/D_FF'
```

The following example enables both a cell instance and a library cell for sequential propagation.

```
pt_shell> set_case_sequential_propagation { FF1 snps_test/D_FF_R }
pt_shell> report_case_analysis -sequential_propagation
**************************************
Report : case_analysis
        -sequential_propagation
 ...
**************************************

------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 1
------------------------------------------------------------
Cell Instance : 'FF1'
------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 1
------------------------------------------------------------
Lib Cell : 'snps_test/D_FF'
```

set_cell_mode

Selects the active mode of cell mode groups

Syntax

```
status set_cell_mode
   [mode_list]
   [instance_list]
```

Data Types

```
mode_list          list
instance_list      list
```

Arguments

mode_list

Specifies a list of cell modes, each of which is to be made the active mode for its mode group.

instance_list

Specifies a list of instances for which the specified cell modes are made active. This list must only be included with the *-type cell* value.

Description

This command selects the active mode for a mode group or for several mode groups and disables modes in the same group as the selected active mode. Mode groups must either have all modes enabled (default setting) or have one of their modes enabled and all others disabled. This command sets either cell modes or design modes depending on the value of the type option.

Cell mode groups are defined in the library. Each library cell can have a set of cell mode groups. Each of these cell mode groups can have two or more cell modes. Each of these cell modes can be mapped to a set of timing arcs of the library cell. When a cell mode is made active for a given instance of the library cell, the cell mode is enabled and all of

its timing arcs are enabled for that cell. All other cell modes are automatically disabled. The timing arcs of the disabled cell modes are then automatically disabled. To view what modes have been enabled or disabled use the *report_cell_mode*. To view what arcs have been disabled, use the *report_disable_timing* command.

In the special case of an arc having multiple cell modes mapped to it, the arc is enabled if any of the modes are enabled.

Cell modes can be made active in three different ways, using the *set_cell_mode* command, using the *set_mode -type design* command or through evaluation of mode conditions.

Examples

This command directly selects the READ cell mode as the active mode for the RAM instance Uram1.

```
pt_shell> set_cell_mode READ Uram1
```

set_check_ctpm_tolerance

Sets the passing threshold used to report passing rate in *gen_ctpm* and *validate_ctpm*.

Syntax

string *set_check_ctpm_tolerance*

```
[-delay float-list]
[-slew float-list]
[-constraint_setup float-list]
[-constraint_hold float-list]
[-constraint_min_pulse_width float-list]
[-delay_sigma float-list]
[-slew_sigma float-list]
[-constraint_setup_sigma float-list]
```

Feedback

```
[-constraint_hold_sigma float-list]
[-pin_cap float-list]
```

Data Types

```
float-list      list of floats
```

Arguments

`-delay float-list`

Specifies the list of delay tolerance values {rel_tol abs_tol}

`-slew float-list`

Specifies the list of slew tolerance values {rel_tol abs_tol}

`-constraint_setup float-list`

Specifies the list of setup constraint tolerance values {rel_tol abs_tol}

`-constraint_hold float-list`

Specifies the list of hold constraint tolerance values {rel_tol abs_tol}

`-constraint_min_pulse_wdith float-list`

Specifies the list of min_pulse_wdith constraint tolerance values {rel_tol abs_tol}

`-delay_sigma float-list`

Specifies the list of delay sigma tolerance values {rel_tol abs_tol}

`-slew_sigma float-list`

Specifies the list of slew sigma tolerance values {rel_tol abs_tol}

`-constraint_setup_sigma float-list`

Specifies the list of setup constraint sigma tolerance values {rel_tol abs_tol}

`-constraint_hold_sigma float-list`

Specifies the list of hold constraint sigma tolerance values {rel_tol abs_tol}

`-pin_cap float-list`

Specifies the list of pin capacitance tolerance values {rel_tol abs_tol}

Description

The *set_check_ctpm_tolerance* command sets the passing threshold used to report passing rate in *gen_ctpm* and *validate_ctpm*. If abs(error percentatage) <= rel_tol or abs(error_in_ns)<abs_tol, the data point is considered as passing. *report_check_ctpm_tolerance* command can be used to report tolerance used.

Feedback

Examples

The following script set delay and slew passing tolerance as 5%/5ps, and report the user-defined tolerance for CTPM checking.

```
set ps_enable_analysis true
set ps_enable_spice2design_analysis true

set_check_ctpm_tolerance -delay {0.05 0.005} -slew {0.05 0.005}
pt_shell> report_check_ctpm_tolerance
  type                          relative_error    absolute_error
  delay                           0.050000            0.005000

set_clock_eco_options

Specifies options for Clock ECO such as *fix_eco_timing* and *fix_eco_drc* command.

Syntax

```
status set_clock_eco_options
   [-from  from_pin]
   [-to to_pin]
   [-levels cell_count]
```

Data Types

```
from_pin          string
to_pin            string
cell_cout         int
```

Feedback

Arguments

`-from` *`from_pin`*

Specifies a clock driver pin or port.

`-to` *`to_pin`*

Specifies a clock load pin or port.

`-levels` *`cell_count`*

Specifies a maximum allowable levels between from_pin and to_pin.

Description

The *set_clock_eco_options* command specifies maximum allowable levels between given from pin and to pin. To run Clock ECO commands such as *fix_eco_timing* and *fix_eco_drc* targeting fixing in clock network. You must use this command before running Clock ECO.

Distributed Multi-Scenario Analysis

To execute the *set_clock_eco_options* command in all scenarios, use the *remote_execute* command. Note that you cannot execute the *set_clock_eco_options* command in the manager process.

Examples

The following example shows setting maximum allowable levels between *U1/Y* and *U2/A* to 3. Suppose there are already 2 cells in between, then *fix_eco_timing\P or fix_eco_drc commands can only insert one buffer between the from_pin and to_pin specified.*

```
pt_shell> set_clock_eco_options -from U1/Y -to U2/A -levels 3
```

The following example shows how to specify the same information in a distributed multi-scenario analysis environment.

```
remote_execute -verbose {
        pt_shell> set_clock_eco_options -from U1/Y -to U2/A -levels 3
}
```

See Also

- fix_eco_drc
- fix_eco_timing

---

set_clock_exclusivity

Specifies a cell for which all the clocks that traverse from the input pins to the output pin will be mutually exclusive.

Feedback

Syntax

```
status set_clock_exclusivity
   -output output_pin
   [-type mux | user_defined]
   [-inputs input_pin_list]
```

Data Types

```
output_pin              list
input_pin_list          list
```

Arguments

`-output output_pin`

This option specifies a single output pin as the exclusivity point. Depending on the *-type* option, all or some of the clocks going out of this pin are considered mutually exclusive.

`-type mux | user_defined`

Specifies the type of clock exclusivity setting, either *mux* or *user_defined*. Use the *mux* setting to set the clock exclusivity for a multiplexer (MUX) cell. Use the *user_defined* setting for a non-MUX cell.

Use the *mux* setting only with the *-output* option, not the *-inputs* option. The specified output pin must belong to a MUX. All clocks at different data signal inputs of the MUX (inputs that are not MUX select pins) are considered mutually exclusive clocks beyond the output. This behavior is similar to setting the *timing_enable_auto_mux_clock_exclusivity* variable to *true*.

You can use the *user_defined* setting for both MUX or non-MUX cells. Use this option with the *-inputs* and *-output* options; the specified input and output pins must belong to the same cell in the design. All clocks at the specified inputs are considered mutually exclusive clocks beyond the output.

`-inputs input_pin_list`

Use this option together with the *-type user_defined* option. The clocks coming through these input pins are exclusive at the output pin specified by the *-output* option.

Description

IC designs often contain MUXes in the clock network to select between multiple exclusive clocks. If the MUX select lines are known not to dynamically change, the clocks going through the input pins of the MUX are in fact exclusive.

In this case, to properly constrain a MUXed clock, we can specify the output pin of cell by using *set_clock_exclusivity* command. The timing paths that are launched from a clock that goes through one input pin and captured by a clock that goes through another input

pin are considered false timing paths. Furthermore, crosstalk interactions between the two clocks coming from different inputs of the exclusive cell are ignored. Please note that if there is a generated clock defined after the exclusivity point, the exclusivity states will be lost. This is similar to the existing behavior of the generated clocks. When a generated clock is created at a pin, all other clocks arriving at that pin are blocked unless they also have generated clock versions created at that pin.

Note that clock exclusivity is not supported by the *extract_model* and *write_eco_design* commands.

HyperScale analysis does consider clock exclusivity. The *characterize_context* command captures clock exclusivity, which is then written out by the *write_context* command. However, note that cross-boundary exclusivity is only written in the binary GBC format; it is not included in the ASCII PTSH constraint format.

To undo the *set_clock_exclusivity* command, use the *remove_clock_exclusivity* command.

To report the exclusivities defined in a design, use the *report_clock* command with the *-exclusivity* option.

Examples

The following example defines a MUX25 cell as a point of exclusivity:

```
pt_shell> set_clock_exclusivity -type mux -output MUX25/Z
```

The following example defines the AND37 gate as a point of exclusivity:

```
pt_shell> set_clock_exclusivity -type user_defined \\
  -output AND37/Z -inputs {AND37/A AND37/B}
```

See Also

- remove_clock_exclusivity
- report_clock
- set_disable_auto_mux_clock_exclusivity
- timing_enable_auto_mux_clock_exclusivity

---

set_clock_gating_check

Specifies the value of setup and hold time for clock gating checks.

Syntax

string *set_clock_gating_check*

```
[-setup setup_value]
[-hold hold_value]
```

```
[-rise | -fall]
[-high | -low]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

setup_value	float
hold_value	float
object_list	list
sms_scenarios_list	collection

Arguments

`-setup` *setup_value*

Specifies the clock gating setup time. The default is 0.0.

`-hold` *hold_value*

Specifies the clock gating hold time. The default is 0.0.

`-rise`

Specifies that only rising delays are constrained. By default, if neither the *-rise* or *-fall* options are specified, both rising and falling delays are constrained.

`-fall`

Specifies that only falling delays are constrained. By default, if neither the *-rise* or *-fall* options are specified, both rising and falling delays are constrained.

`-high`

Specifies that the check is performed on the high level of the clock. By default, PrimeTime determines whether to use the high or low level of the clock using information from the cell's logic. That is, for AND and NAND gates PrimeTime performs the check on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX and OR-AND) PrimeTime cannot determine which to use, and does not perform checks unless you specify either the *-high* or *-low* options. If the user-specified value differs from that derived by PrimeTime, the user-specified value takes precedence, and a warning message is issued.

This option sets the attribute only on the specified pin or cell. If you specify the *-high* or *-low* options, you must also specify the *object_list* variable; in that case, the *object_list* variable must not contain a clock.

`-low`

Indicates that the check is performed on the low level of the clock. By default, PrimeTime determines whether to use the high or low clock level using information from the cell's logic. That is, for AND and NAND gates, PrimeTime

performs the check on the high level; for OR and NOR gates, on the low edge. For some complex cells (for example, MUX and OR-AND) PrimeTime cannot determine which to use, and does not perform checks unless you specify either the *-high* or *-low* options. If the user-specified value differs from that derived by PrimeTime, the user-specified value takes precedence, and a warning message is issued.

This option sets the attribute only on the specified pin or cell. If you specify the *-high* or *-low* options, you must also specify the *object_list* variable; in that case, the *object_list* variable must not contain a clock.

object_list

Specifies a list of objects in the current design for which the clock gating check is applied. The objects can be clocks, pins, or cells. If a cell is specified, all input pins of that cell are affected. If a pin or cell is specified, any clock gating checks located at the specified objects are affected. If a clock is specified, the clock gating check is applied to all gating gates driven by that clock. If you specify the *-high* or *-low* options, you must also specify the *object_list* variable; in that case, the *object_list* variable must not contain a clock. By default, if the *object_list* variable is not specified, the clock gating check is applied to the current design.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this clock gating check is applied. When this option is not given the clock gating check applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

The *set_clock_gating_check* command specifies a setup or hold time clock gating check used for clocks, pins, or cells. The gating check is performed on pins that gate a clock signal.

The behavior of the *set_clock_gating_check* command is controlled by the *timing_clock_gating_check_fanout_compatibility* variable.

The clock gating setup check is used to ensure the controlling data signals are stable before the clock is active. This check is performed on combinational gates through which the clock signals are propagated. The arrival time of the leading edge of the clock pin is checked against both levels of any data signals gating the clock. A clock gating setup failure can cause either a glitch at the leading edge of the clock pulse, or a clipped clock pulse.

The clock gating hold check is used to ensure that the controlling data signals are stable while the clock is active. The arrival time of the trailing edge of the clock pin is checked against both levels of any data signal gating the clipped clock pulse.

The *-high* and *-low* options are intended to specify clock gating checks that PrimeTime cannot determine. These options apply only to the pins specified.

To remove information set by *set_clock_gating_check* command, use the *remove_clock_gating_check* command. The *reset_design* command removes all attributes from the design, including those set by the *set_clock_gating_check* command.

To report information for the clock gating check, use the *report_clock_gating_check* command.

Clock gating check constraints are applied in this order:

- Clock gating check set on specific pins or cells
- Clock gating constraint arcs from library or cells on which gating check is set
- Clock gating constraint set on clocks and design

Examples

The following example specifies a setup time of 0.2 and a hold time of 0.4 for all gates in the clock network of clock CK1.

```
pt_shell> set_clock_gating_check -setup 0.2 -hold 0.4 [get_clocks CK1]
```

The following example specifies a setup time of 0.5 on the and1 cell.

```
pt_shell> set_clock_gating_check -setup 0.5 [get_cells and1]
```

---

set_clock_gating_percentage

Sets percentage of clock gating cells to be enabled during vector free vector generation.

Syntax

status *set_clock_gating_percentage*

```
-value percentage_value
[-object_list objecto_list]
```

Data Types

```
percentage_value  float
object_list       list
```

Arguments

`-value percentage_value`

Specifies percentage value for clock gating cells to be enabled. Accepted value is between 0.0 and 1.0, which means 0% to 100% of clock gating cells will be turned on. When this option is specified, it is used to guide vector generation such that the percentage of clock gating cells to be turned on does not exceed this limit. Default is 0.5 which means 50% of clock gating cells will be enabled during vector generation, and the other 50% clock gating cells will be turned off.

`-object_list object_list`

Specifies a list of clock gating cell objects for which the percentage value is applied for. When a clock gating cell is specified with a percentage value, the number of its fanout clock gating cells that can be turned on will be limited by this percentage value. When this option is ommited, the percentage value is applied to the whole design, which means the number of clock gating cells that can be turned on is limited by this percentage value.

Description

This command is used to specify percentage of clock gating cells to be turned on during vector generation in command *write_vectors*.

Examples

The following example sets clock gating cell percentage 20% instead of default 50%, then invokes the command *write_vectors*.

```
pt_shell> set_clock_gating_percentage -value 0.2
pt_shell> write_vectors rtl.vcd
```

Assuming a cascaded clock gating cell structure, clock gating cells icg2, icg3 and icg4 are on the fanout cone of clock gating cell icg1. If icg1 is turned off, none of icg2, icg3 and icg4 can be turned on. If any of icg2, icg3 and icg4 is turned on, that requires icg1 to be turned on first. The following example sets the percentage value 35% on icg1, so at most one of icg2, icg3 and icg4 can be turned on during vector generation.

```
pt_shell> set_clock_gating_percentage -value 0.35 -object_list [get_cell
 icg1]
pt_shell> write_vectors rtl.vcd
```

Feedback

See Also

- write_vectors

---

set_clock_groups

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during the timing analysis.

Syntax

```
status set_clock_groups
   -group clock_list
   [-exclusive]
   [-physically_exclusive]
   [-logically_exclusive]
   [-asynchronous]
   [-allow_paths]
   [-name name]
   [-comment comment_string]
```

Data Types

clock_list	list
comment_string	string
name	string

Arguments

`-group clock_list`

Specifies a list of clocks.

You can use this option multiple times in a single *set_clock_groups* command. Each *-group* option specifies a group of clocks, which are exclusive or asynchronous with the clocks in all other groups. If only one group is specified, it means that the clocks in that group are exclusive or asynchronous with all other clocks in the design. Therefore, a default other group is created for this single group. Whenever a new clock is created, it is automatically included in the default exclusive or asynchronous group.

`-exclusive`

This is an alias for *-logically_exclusive* and is provided for backward compatibility.

`-physically_exclusive`

Specifies that the clock groups are physically exclusive with each other. Physically exclusive clocks cannot coexist in the design physically. An

example of this is multiple clocks that are defined on the same source pin. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive; you must choose only one.

`-logically_exclusive`

Logically exclusive clocks do not have any functional paths between them but might have coupling interactions with each other. An example of logically exclusive clocks is multiple clocks, which are selected by a MUX but can still interact through coupling upstream of the MUX cell. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive; you must choose only one.

`-asynchronous`

Specifies that the clock groups are asynchronous to each other. Two clocks are asynchronous with respect to each other if they have no phase relationship at all. Signal integrity analysis uses an infinite arrival window on the aggressor unless all the arrival windows on the victim net and the aggressor net are defined by synchronous clocks. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive; you must choose only one.

`-allow_paths`

Enable the timing analysis between specified asynchronous clock groups. The default behavior is to suppress timing paths between asynchronous clocks. The *-allow_paths* option must be used with *-asynchronous* option.

`-name` *`name`*

Specifies a name for the clock grouping to be created. Each command should specify a unique name, which identifies the exclusive or asynchronous relationship among specified clock groups, and this name is used later on to easily remove the clock grouping defined here. By default, the command creates a unique name. It takes the first clock name of the first list specified by -group option as the nucleus of the group name. if there is only one group list, then the unique string "_others" is appended. At last, the name is appended with a unique number, starting from 1.

`-comment` *`comment_string`*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

Description

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during the timing analysis. This is similar to using the set_false_path command. In addition, these

relationships also imply the type of crosstalk analysis which should be performed between the clocks. A clock cannot be present in multiple groups during one *set_clock_groups* command execution, but can be included in multiple groups by executing multiple *set_clock_groups* commands. Clock relationships are only implied across the specified clock groups; no relationship is implied across clocks within a group.

For all three relationships, timing paths between the clocks are suppressed. The relationships differ in how crosstalk is handled. If clocks are asynchronous, the clocks are assumed to have an infinite window relationship with each other. If clocks are physically exclusive, only one clock can act as an aggressor or victim during crosstalk analysis; interactions between the clocks are not explored. If clocks are logically exclusive, the crosstalk computation is computed normally (synchronously if the clocks are synchronous) even though the timing paths between the clocks are not reported.

Multiple relationship types can exist between two clocks. When this happens, the relationships obey the following precedence:

- Physically exclusive (highest)
- Asynchronous
- Logically exclusive (lowest)

These precedence rules reflect the real physical behavior of the resulting circuit. For example, if two clocks are asynchronous but they are never simultaneously present, then no crosstalk should be computed.

Note that the traditional *set_false_path* exception between clocks does not result in infinite window crosstalk computation between two clocks. If multiple clocks are asynchronous with each other, the asynchronous relationship should be specified with the *set_clock_groups* command. Failure to specify this relationship for asynchronous clocks could result in an optimistic analysis.

A special *-allow_paths* modifier can be used with the *-asynchronous* option. When used, the clocks are assumed to have an infinite window relationship for crosstalk purposes, but timing paths between the clocks are treated normally. When using this option, paths between the clock domains can be manually disabled using the *set_false_path* command.

When a clock pair is defined such that it has false paths (using either physically or logically exclusive or asynchronous) but subsequently modified to have *-asynchronous -allow_paths*, then this is an error and the first definition holds. In the reverse situation, also the redefinition to false paths from *-allow_paths* between the clock pairs would also be an error. See the UITE-457 and UITE-458 messages.

This command should be used to specify the relationships among clocks before using the *set_active_clocks* command. You should not also set a false path if you have already specified two clocks as exclusive or asynchronous. An error message is issued if you attempt to set a false path between two clocks which are already exclusive or

asynchronous. If a false path was previously set between two clocks when an exclusive or asynchronous relationship is applied, the false path is overwritten by the *set_clock_groups* command. Other exceptions are unaffected.

A clock relationship on a master clock does not automatically propagate to any generated clocks. If the relationship should also apply to generated clocks, they should be explicitly included in the *set_clock_groups* command.

To undo the *set_clock_groups* command, use the *remove_clock_groups* command. To report the clock groups defined in a design, use the *report_clock* command with the *-groups* option.

Examples

The following example defines two asynchronous clock domains:

```
pt_shell> set_clock_groups -asynchronous -name g1 -group CLK33 -group
 CLK50
```

The following example defines a clock named *TESTCLK* to be asynchronous with all other clocks in the design:

```
pt_shell> set_clock_groups -asynchronous -group TESTCLK
```

The following example shows how to simultaneously analyze multiple clocks per register without manually specifying false paths. Assume two pairs of mutually exclusive clocks that are multiplexed:

- CLK1 and CLK2
- CLK3 and CLK4

If each pair of clocks is selected by a different signal, you must execute two *set_clock_groups* commands to specify two independent exclusivity relationships, one for each MUX selection signal:

```
pt_shell> set_clock_groups -physically_exclusive -group CLK1 -group CLK2
pt_shell> set_clock_groups -physically_exclusive -group CLK3 -group CLK4
```

If each pair of clocks is selected by a single MUX selection signal, you would execute only one *set_clock_groups* command to simultaneously analyze all four clocks.

```
pt_shell> set_clock_groups -physically_exclusive -group {CLK1 CLK3}
 -group {CLK2 CLK4}
```

This example does not imply any type of relationship between CLK1-CLK3 or CLK2-CLK4. For example, f CLK1 and CLK3 were also asynchronous with each other, you would need to specify an additional relationship between them.

---

set_clock_jitter

Sets the duty-cycle jitter and/or the cycle clock jitter.

Syntax

```
status set_clock_jitter
   -clock clock_list
   [-cycle cycle_to_cycle_jitter]
   [-duty_cycle duty_cycle_jitter]
```

Data Types

```
clock_list              list
cycle_to_cycle_jitter   float
duty_cycle_jitter       float
```

Arguments

`-clock clock_list`

Specifies a list of clock on which to set the clock jitter.

`-cycle cycle_to_cycle_jitter`

Specifies the cycle-to-cycle jitter on the clock.

`-duty_cycle duty_cycle_jitter`

Specifies the duty-cycle jitter on the clock.

Description

This command specifies the cycle-to-cycle jitter and the duty-cycle jitter on a primary master clock(a clock that is not a generated clock itself), or a generated clock that is defined with the *-multiply_by* option.

Cycle-to-cycle jitter models the variation between the edges that are in-phase. In other words, it models the variation between the edges that are multiple clock cycles apart.

Duty-cycle jitter models the variation between the edges that are out-of-phase. In other words, they are 0.5, 1.5, 2.5, and so on, cycles apart.

Duty-cycle jitter and cycle-to-cycle jitter are realized between the launch clock and the capture clock that are both generated from the same master clock. To figure out the right clock jitter value between the launch clock and capture clock, we trace the launch edge and the capture edge to corresponding edges of the master clock. There are three cases to consider:

1. If the corresponding edges of the master clock are multiple cycles apart. cycle-to-cycle jitter is realized.
2. If they are not and integral number of cycles apart. duty-cycle jitter is realized.
3. If both cycle-to-cycle jitter and duty-cycle jitter are possible. worst jitter among the two is realized.
4. If they are traced back to the same edge of the master clock. no clock jitter is realized.

In crosstalk analysis, clock jitter does not change the arrival windows used in overlap analysis. However, in level-sensitive latch designs, latches can start borrowing in the presence of clock jitter, leading to changes in delta delays for logic nets in the fanout of affected latches.

Please note that the generated clocks defined with the *-multiply_by* option do not inherit the clock jitter from their master clocks.

To remove the clock jitters set by the *set_clock_jitter* command, use the *remove_clock_jitter* command.

To view clock jitter information, use the *report_clock_jitter* command.

Examples

The following example specifies a cycle-to-cycle jitter of 0.5 and duty-cycle jitter of 0.7 on the clock mclk

```
pt_shell> set_clock_jitter -clock [get_clocks mclk] -cycle 0.5
 -duty_cycle 0.7
```

Feedback

set_clock_latency

Specifies the latency of the clock network.

Syntax

```
status set_clock_latency
[-clock clock_list]
[-rise]
[-fall]
[-min]
[-max]
[-source]
[-dynamic dynamic_component_of_delay]
[-late]
[-early]
[-pll_shift]
[-generated]
[-primary]
[-clock_fall]
[-clock_rise]
[-sms_scenarios sms_scenarios_list]
delay
object_list
```

Data Types

clock_list	list
delay	float
dynamic_component_of_delay	float
object_list	list
sms_scenarios_list	collection

Arguments

`-clock` *clock_list*

Specifies a list of clock objects associated with the network latency placed on all pin/port objects in the *object_list*. Use this option only when the *object_list* contains port/pin objects, not clock objects. To apply a latency value to all objects clocked by a given clock, specify that clock in the *object_list*; do not use the *-clock* option.

`-rise`

Specifies clock rise latency.

`-fall`

Specifies clock fall latency.

`-min`

Specifies clock latency for the minimum operating condition.

`-max`

Specifies clock latency for the maximum operating condition.

`-source`

Specifies clock source latency.

`-dynamic` *`dynamic_component_of_delay`*

Specifies dynamic component of clock latency value.

`-late`

Specifies clock late source latency.

`-early`

Specifies clock early source latency.

`-pll_shift`

Specifies the phase error for output clocks coming out of phase-locked loops (PLLs). This option adds the specified delay to the phase adjustment of the PLL.

`-generated`

Specifies the generated clock signal type. Proper sense should be set on the clock definition point by *set_sense* before applying this option. This option is valid only for clock definition points.

`-primary`

Specifies primary clock signal type (default). Proper sense should be set on the clock definition point by *set_sense* before applying this option. This option is valid only for clock definition points.

`-clock_fall`

Specifies that the signal is coming from the falling edge of the clock. If not specified, it uses the falling edge for *-fall*. Proper sense should be set on the clock definition point by *set_sense* before applying this option. This option is valid only for clock definition points.

`-clock_rise`

Specifies that the signal is coming from the rising edge of the clock. If not specified, it uses the rising edge for *-rise*. Proper sense should be set on the clock definition point by *set_sense* before applying this option. This option is valid only for clock definition points.

delay

Specifies the clock latency value.

object_list

Specifies a list of clocks, pins, or ports for which the latency value applies. If multiple clocks reach these objects, you can restrict the scope of the command to specific clocks by using the *-clock* option.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this clock latency is applied. When this option is not given the clock latency applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

Two types of clock latency can be specified for a design:

- Clock network latency - This is the time it takes a clock signal to propagate from the clock definition point to a register clock pin. The rise and fall latencies are the latencies for rising and falling transitions at the register clock pin, respectively. Inversion of the clock waveform, if present in the clock network, is not taken into consideration when computing clock network latencies at register clock pins.
- Clock source latency - This is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. It can be used to model off-chip clock latency when the clock generation circuit is not part of the current design. You can use clock source latency for generated clocks to model the delay from master-clock to generated-clock definition point.

Dynamic clock latency is the component of the total clock latency which is considered dynamic in nature. A dynamic value might differ along successive clock cycles and therefore can only be used to calculate CRP if a zero-cycle path is being considered. A zero-cycle path is one in which the same clock edge both launches and captures.

To specify the dynamic component of any clock latency, use the *-dynamic* option. It can only be specified if the *-source* option and total clock latency is also specified with the command. You can specify dynamic latency on only clock objects, or pin or port objects that are clock sources. When a pin or port object is specified, the clock also has to be specified by *-clock* option.

By default, the tool assumes ideal clocking, which means clocks have a specified network latency, designated by the *set_clock_latency* command, or zero network latency if no latency value is specified. Propagated clock network latency, designated by the *set_propagated_clock* command, is normally used after layout after final clock tree generation. Ideal clock network latency provides an estimate of the clock tree for pre-layout.

You can specify clock source latency for ideal or propagated clocks. The total clock latency at a register clock pin is the sum of clock source latency and clock network latency. If the rise and fall latencies are different, the source latencies for a latch are chosen based on the sense at the clock port and network latencies are chosen based on the sense at the latch clock pin. Thus, source latency takes into account the clock inversions on the clock network, but network latency does not.

In the on_chip_variation_analysis mode, the min/max operating conditions are the variation bounds within the single corner analysis. Therefore, only the min-early and max-late latencies are used for the analysis; it is sufficient to specify either the *-early* or *-late* options or the *-min* or *-max* options for the *set_clock_latency* command.

For internally generated clocks, the tool automatically computes the clock source latency if the master clock of the generated clock has propagated latency and there is no user-specified value for the generated clock source. Zero latency is assumed if the master clock is ideal, the master clock has source latency, and there is no user-specified value for the generated clock's source latency.

If the *set_clock_latency* command is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports. Directly setting a network latency makes the affected registers ideal. A warning is issued if the *set_propagated_clock* command has previously set a propagated attribute on the same object (clock, pin, or port). Clock source latencies are allowed only on clocks and clock source pins.

The command does not check to see whether a clock specified with the *-clock* option passes through the pin or pins referenced in the object list. If the clock specified does not pass through the pin, the command has no effect and there is no warning about this condition.

To undo the *set_clock_latency* command, use the *remove_clock_latency* command.

To see clock network and source latency information (including dynamic component), use the *report_clock* command with the *-skew* option.

Examples

The following example specifies a rise latency of 1.2 and a fall latency of 0.9 for the CLK1 clock.

```
pt_shell> set_clock_latency 1.2 \\
          -rise [get_clocks CLK1]
pt_shell> set_clock_latency 0.9 \\
          -fall [get_clocks CLK1]
```

The following example specifies an early rise and a fall source latency of 0.8 and a late rise and fall source latency of 0.9 for the CLK1 clock.

```
pt_shell> set_clock_latency 0.8 -source \\
          -early [get_clocks CLK1]
```

```
pt_shell> set_clock_latency 0.9 -source \\
          -late  [get_clocks CLK1]
```

The following example specifies an early and late source latency of 3 and 5, respectively, with dynamic components of 0.5.

```
pt_shell> set_clock_latency 3 -source \\
          -early -dynamic 0.5 [get_clocks CLK1]
pt_shell> set_clock_latency 5 -source \\
          -late  -dynamic 0.5 [get_clocks CLK1]
```

The following example specifies the source latency as well as the dynamic portion of source latency on a clock source pin.

```
pt_shell> create_clock -name clk -period 10 [get_pins clk_source_pin]
pt_shell> set_clock_latency 100 -source [get_pins clk_source_pin] \\
          -dynamic 20 -clock [get_clocks CLK1]
```

The following example specifies generated clock source latencies of 0.5 to the rise-to-rise clock edge and 0.6 to the fall-to-fall clock edge on pin and2/Y.

```
pt_shell> set_clock_latency 0.5 -source \\
          -generated -rise -clock_rise and2/Y
pt_shell> set_clock_latency 0.6 -source \\
          -generated -fall -clock_fall and2/Y
```

The following example specifies primary clock source latencies of 0.1 to the rise-to-rise clock edge and 0.2 to the fall-to-fall clock edge on pin and2/Y.

```
pt_shell> set_clock_latency 0.1 -source \\
          -primary -rise -clock_rise and2/Y
pt_shell> set_clock_latency 0.2 -source \\
          -primary -fall -clock_fall and2/Y
```

The following example shows a timing report where dynamic clock latency has been specified with the *set_clock_latency* command:

```
pt_shell> report_timing -path_type full_clock_expanded
 ...

  Startpoint: ff1 (rising edge-triggered flip-flop clocked by clk)
  Endpoint: ff2 (rising edge-triggered flip-flop clocked by clk)
  Path Group: clk

set_clock_map

Defines the mapping of clocks across hierarchical design levels for HyperScale analysis, overriding the default inferred clock mapping.

Syntax

status *set_clock_map*

```
[-parent_clocks parent_clock_names]
[-block_clocks block_clock_names]
[-instances inst_cells]
[-add]
clock_list
```

Feedback

Data Types

parent_clock_names	list
block_clock_names	list
inst_cells	list
clock_list	list

Arguments

`-parent_clocks` *parent_clock_names*

Specifies the names of the clocks used at the parent hierarchy level that are the same as the clocks listed in the *clock_list*. This option is valid only for block-level analysis and cannot be used with the *-block_clocks* option.

`-block_clocks` *block_clock_names*

Specifies the names of the clocks used at the subblock level that are the same as the clocks identified in the *clock_list*. This option is valid only for analysis at a higher level of hierarchy and cannot be used with the *-parent_clocks* option.

`-instances` *inst_cells*

Specifies a list of hierarchical subblock instances in the current design for which the clock mapping applies. Clock mapping can be instance-specific even when different instances refer to same physical block. This option can be used only with the *-block_clocks* option.

`-add`

Adds this clock mapping to the default inferred clock associations. Without this option, you take full control of the clock mapping to the parent level or block level; the new clock mapping overwrites any existing clock mappings inferred by the tool. This option does not affect clock mappings defined by previous *set_clock_map* commands; such mappings remain in effect until you use the *remove_clock_map* command.

clock_list

Specifies a list of collections containing clocks or patterns matching the clock names in the current design. The command maps these clocks to the parent clock named by the *-parent_clocks* option or to the lower-level clocks named by the *-block_clocks* option.

Description

In a hierarchical design flow, top-level and block-level designs often need to be implemented and analyzed separately, with separate but highly associated block-level and top-level timing constraints. The same clocks might be assigned different names at different hierarchical levels.

The PrimeTime tool automatically detects and associates clocks with mismatching names across hierarchical levels by considering the clock characteristics. In the HyperScale flow, the tool usually establishes the clock mapping correctly, especially when you use HyperScale constraint extraction.

However, in complex or ambiguous clocking situations with multiple clocks, using the available design information, the tool cannot always associate these clocks as intended. To explicitly specify the mapping and override the default inferred mapping, use the *set_clock_map* command with the appropriate options:

- To define the mapping of clocks at the current level with clocks at the parent level, use the *-parent_clocks* option.
- To define the mapping of clocks at the current level with clocks at the subblock level, use the *-block_clocks* option, and optionally use the *-instances* option to apply the mapping to specific instances.

You cannot use the *-parent_clocks* and *-block_clocks* options at the same time. To define both parent and subblock mappings for an intermediate-level design, use two separate *set_clock_map* commands.

To remove clock mappings set with the *set_clock_map* command, use the *remove_clock_map* command.

Reporting the Clock Mapping

To show the clock mappings used by the tool for timing analysis, use the *report_clock -map* command. The report shows an asterisk next to each clock mapped explicitly by the *report_clock -map* command:

```
pt_shell> set_clock_map MCLK -block_clocks SCLK
Information: Abandoning fast timing updates. (PTE-018)
1
pt_shell> update_timing -full
Information: Loading block timing data for block instance low_1. (HS-001)
Information: applying user mapping between block clock 'SCLK' and clock
 'MCLK'.
Information: Loading block timing data for block instance low_1. (HS-001)
1
pt_shell> report_clock -map
 ...
Instance          Top level clock     Block level clock
-------------------------------------------------------------
low_1             (N/A)               MCLK
                  MCLK                SCLK*
```

Situations That Require Explicit Clock Mapping

The most common type of ambiguity is caused by clocks with same period and waveform propagating though overlapping networks across a block boundary. For example, multiple

top-level clocks with same basic period and waveform characteristics can all reach a single block port and enter into a block. In this case, block-level constraints have multiple clocks defined on the port to represent all the top clocks. Explicitly defining the mapping with the *set_clock_map* command is the most reliable way to ensure correct mapping.

Another common ambiguity is caused by virtual clocks, which are used to model a clock signal without a physical source (and network) present in the current level of design. For example, even when a top-level clock does not physically propagate into a specific hierarchical block itself, it can still launch data signals that enter the block or capture signals that leave the block. To model such a clock in block-level constraints, you can define a virtual clock with a period and waveform matching the top-level physical clock, but without attaching it to any source or source network objects in the block design. Ambiguity arises when multiple top-level clocks have the same characteristics. Use the *set_clock_map* command to resolve such ambiguities.

You can choose to overdesign at the block level by defining clocks with tighter margins or higher frequencies than the same clocks at the top level. When the clock characteristics do not match exactly between the block-level and top-level clocks, the tool does not establish mapping between the clocks by default because of the clock differences. To override this default behavior, use the *set_clock_map* command to explicitly map the slightly mismatching clocks. In this situation, the *report_constraint* command still reports the mismatching clocks as a boundary constraint violations.

You can modify the behavior of automatic clock mapping by setting the variables *hier_disable_auto_clock_mapping* and *hier_clock_mapping_period_percent_tolerance*.

Clock Mapping and HyperScale Technology

Use the *set_clock_map* command in a manner consistent with the HyperScale configuration command *set_hier_config*. For example, for block-level analysis, a clock is defined with the name BCLK, which represents a top-level counterpart with the name TCLK. (Note that TCLK is defined in a separate set of top-level constraints and is not included in the constraints for block-level analysis.) Use the following commands at the block level:

```
set_hier_config -parent -path $top_dir ...
 ...
create_clock -name BCLK ...
 ...
set_clock_map BCLK -parent_clocks TCLK
 ...
update_timing
 ...
```

For top-level analysis, the clock is defined with name TCLK:

```
set_hier_config -block A_BLK -path $blk_dir ...
 ...
create_clock -name TCLK ...
```

```
 ...
set_clock_map TCLK -block_clocks BCLK
 ...
update_timing
 ...
```

Mapping a Top-Level Clock to Multiple Block-Level Clocks

HyperScale technology supports one-to-one, one-to-N, and N-to-one clock mappings between the top-level clocks and block-level clocks.

Most often, with a top-level clock propagating into a block through a single port, a single block-level clock is defined on the port and uniquely maps to the top-level clock. However, there are cases a single block-level clock definition cannot fully represent the top-level clock intent. For example:

- Multiple waveforms from the same clock -- The top-level clock enters into a block through multiple ports with a positive waveform on some ports but inverted through others. This requires block-level constraints to define two clocks with opposite waveforms on the associated ports.
- Re-entrant generated clocks -- This happens when a generated clock defined inside a block propagates outside of the block and re-enters the same block through some port. A generated clock requires the source network path back to its master clock to have a valid source latency computation. The portion of the source network traveling outside of the block does not exist for block-level analysis, so block-level constraints need to define two separate clocks to fully represent the single generated clock in top-level constraints.

By default, the tool automatically establishes 1-to-N clock mapping for most of the these configurations. However, if the design is too complex or ambiguous for reliable automatic mapping, you should use the *set_clock_map* command to explicitly specify the mapping.

Examples

The following example defines the mapping of top-level clock SYSCLK to block-level clock BCLK in HyperScale top-level analysis.

```
# Map SYSCLK at current level to BCLK in HyperScale block
set_clock_map SYSCLK -block_clocks BCLK
```

The following example defines the mapping of top-level clock SYSCLK to block-level clock BCLK_1 for one instance and BCLK_2 for another instance.

```
set_clock_map SYSCLK -block_clocks BCLK_1 -instance blk_inst1
set_clock_map SYSCLK -block_clocks BCLK_2 -instance blk_inst2
```

In the following block-level analysis example, two block-level clocks map to the same top-level clock.

```
set_clock_map sysCLK_pos -parent_clocks SYSCLK
set_clock_map sysCLK_neg -parent_clocks SYSCLK
```

The following example shows the clock mapping reported with both automatically resolved and user-specified explicit clock mappings. User-specified mappings are annotated with an asterisk (*) in the report.

```
pt_shell> report_clock -map
 ...
Instance        Top level clock     Block level clock
-----------------------------------------------------
core3           CLK1                CLK1* CLK1_v*
                CLK2                CLK2  CLK2_v
                CLK3                CLK3  CLK3_v
                CLK4                CLK4* CLK4_v*
core4           CLK1                CLK1* CLK1_v*
                CLK2                CLK2  CLK2_v
                CLK3                CLK3  CLK3_v
                CLK4                CLK4  CLK4_v
core1           CLK1                CLK1* CLK1_v*
                CLK2                CLK2* CLK2_v*
                CLK3                CLK3  CLK3_v
                CLK4                CLK4  CLK4_v
core2           CLK1                CLK1* CLK1_v*
                CLK2                CLK2* CLK2_v*
                CLK3                CLK3  CLK3_v
                CLK4                CLK4  CLK4_v
```

set_clock_transition

Specifies transition time of register clock pins.

Syntax

string *set_clock_transition*

```
[-rise]
[-fall]
[-min]
[-max]
transition
clock_list
```

Data Types

transition	float
clock_list	list

Arguments

`-rise`

Specifies clock transition time for rising clock edge.

`-fall`

Specifies clock transition time for falling clock edge.

`-min`

Specifies clock transition time for minimum conditions.

`-max`

Specifies clock transition time for maximum conditions.

transition

Specifies transition time of clock pins.

clock_list

Provides a list of clocks in the design. The transition times on all register clock pins and clock gating constraint arcs in the transitive fanout of specified clock are affected. You only can specify clocks with ideal latency in the list. When

affected clock pins in the fanout of a clock are marked with propagated latency, the values are ignored in the *set_clock_transition* command.

Description

This command provides the ability to override the calculated transition times on clock pins of registers and clock gating constraint arcs.

This command is useful for pre-layout when clock trees are incomplete and using calculated transition times at register clock pins and for clock gating constraint arcs can be highly pessimistic. The transition value specified with this command overrides the transition times of all nets directly feeding a sequential element clocked by the specified clock.

Use the *set_clock_transition* command only with ideal clocks. For propagated clocks the calculated transition times are used. Propagated clocks are only set after the final clock tree is constructed.

If a clock transition is not specified for an ideal clock, and if the timing_ideal_clock_zero_default_transition variable is TRUE (by default it is TRUE), then zero transition is used. Otherwise, the transition time is calculated as it is for other pins in the design.

To undo the *set_clock_transition* command, use the *remove_clock_transition* command.

To list all clock transition values which have been set, use *report_clock -skew*.

Examples

This example specifies a rise transition time of 0.38 and fall transition time of 0.25 for register clock pins clocked by "CLK1".

```
pt_shell> set_clock_transition 0.38 -rise [get_clocks CLK1]
pt_shell> set_clock_transition 0.25 -fall [get_clocks CLK1]
```

- set_clock_uncertainty
- set_propagated_clock
- timing_ideal_clock_zero_default_transition

Feedback

set_clock_uncertainty

Specifies the uncertainty (skew) of specified clock networks.

Syntax

string *set_clock_uncertainty*

```
[-from from_clock]
[-rise_from rise_from_clock]
[-fall_from fall_from_clock]
[-to to_clock]
[-rise_to rise_to_clock]
[-fall_to fall_to_clock]
[object_list]
[-rise]
[-fall]
[-setup]
[-hold]
[-sms_scenarios sms_scenarios_list]
uncertainty
```

Data Types

```
fall_from_clock      list
fall_to_clock        list
from_clock           list
object_list          list
rise_from_clock      list
rise_to_clock        list
sms_scenarios_list   collection
to_clock             list
uncertainty          float
```

Arguments

`-from from_clock`

Specifies the source clock for interclock uncertainty.

You must specify either simple uncertainty using an object list or interclock uncertainty using a combination of *-from*, *-rise_from*, or *-fall_from* and *-to*, *-rise_to*, or *-fall_to*. You cannot specify both simple and interclock uncertainty in the same command.

`-rise_from rise_from_clock`

Specifies the source clock for interclock uncertainty for only rising edges of the clock.

`-fall_from` *`fall_from_clock`*

Specifies the source clock for interclock uncertainty for only falling edges of the clock.

`-to` *`to_clock`*

Specifies the destination clock for interclock uncertainty.

`-rise_to` *`rise_to_clock`*

Specifies the destination clock for interclock uncertainty for only rising edges of the clock.

`-fall_to` *`fall_to_clock`*

Specifies the destination clock for interclock uncertainty for only rising edges of the clock.

`object_list`

Specifies a list of clocks, ports, or pins for simple uncertainty. For a clock object, the uncertainty applies to capturing latches clocked by that clock. For a port or pin, the uncertainty applies to capturing latches whose clock pins are in the fanout of that port or pin, including transitive fanout through combinational logic. This option cannot be used with the "from" and "to" type options.

`-rise`

Applies interclock uncertainty only to the rising edge of the destination clock. This option is supported only for backward compatibility; use the *-rise_to* option instead.

`-fall`

Applies interclock uncertainty only to the falling edge of the destination clock. This option is supported only for backward compatibility; use the *-fall_to* option instead.

`-setup`

Applies the uncertainty only to setup checks. By default, the uncertainty applies to both setup and hold checks.

`-hold`

Applies the uncertainty only to hold checks. By default, the uncertainty applies to both setup and hold checks.

`uncertainty`

The clock uncertainty, a positive number representing the amount of variation in arrival times of successive clock edges, in library time units.

Negative uncertainty values are supported for constraining designs with complex clock relationships. However, setting a negative value could lead to optimistic analysis and should be done with extreme care.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this specification is applied. When this option is not given, the specification applies to all SMS scenarios. This collection is created by the *get_sms_scenarios* command.

Description

The *set_clock_uncertainty* command specifies the clock uncertainty (skew) of specified clock networks. This is the amount of variation in clock edge arrivals away from the exact times expected for a perfect clock.

Set the uncertainty to the worst skew expected to the endpoint or between the clock domains. You can increase this value get additional margin for setup and hold checking.

When calculating slack, the tool adjusts the required data arrival time to make the check more restrictive, thus considering the worst possible variation in arrival times for successive clock edges.

You can specify either interclock or simple uncertainty:

- For interclock uncertainty (between two different clocks), use a combination of the *-from*, *-rise_from*, or *-fall_to* option to specify the source (launch) clock and the *-to*, *-rise_to*, or *-fall_to* option to specify the destination (capture) clock, as well as the applicable edge types (rising, falling, or both). The interclock uncertainty value applies to all paths launched and captured by the respective specified clocks.
- For simple uncertainty (between successive edges of the same clock), specify an object list containing one or more clocks, ports, or pins to which the uncertainty applies. For a clock, the uncertainty applies to all capturing devices clocked by that clock. For a port or pin, the uncertainty applies to capturing devices whose clock pins are in the fanout of that port or pin.

Be sure to specify interclock uncertainty for all possible interactions of clock domains. For example, if you have paths from CLKA to CLKB and from CLKB to CLKA, you need to specify the uncertainty for both combinations, even if the values are the same.

In crosstalk analysis, clock uncertainty does not change the arrival windows used in overlap analysis. However, in level-sensitive latch designs, latches can start borrowing in the presence of clock uncertainty, leading to changes in delta delays for logic nets in the fanout of affected latches.

Feedback

Conflicting uncertainty settings have the following order of priority, from highest to lowest:

- Interclock uncertainty set with *-from* and *-to* type options
- Simple uncertainty set on ports or pins
- Simple uncertainty set on clocks

If you set simple uncertainty on a clock port or pin, the uncertainty applies to capturing latches whose clock pins are in the transitive fanout of the specified object. If different uncertainty values are propagated from multiple ports or pins to inputs of a clock MUX, the worst uncertainty setting applies to the entire fanout of the MUX, even when the associated clock is disabled at the MUX. To ensure usage of the proper uncertainty value in this situation, set the uncertainty on the clock object rather than on a clock port or clock pin.

To view clock uncertainty settings, use the *report_clock -skew* command.

To remove uncertainty settings, use the *remove_clock_uncertainty* command.

Examples

The following commands set the simple uncertainty to 0.65 for setup checking and 0.45 for hold checking for all paths leading to registers or ports clocked by clock CLK.

```
pt_shell> set_clock_uncertainty -setup 0.65 [get_clocks CLK]
pt_shell> set_clock_uncertainty -hold 0.45 [get_clocks CLK]
```

The following commands specify the interclock uncertainty values between the PHI1 and PHI2 clock domains.

```
pt_shell> set_clock_uncertainty 0.4 -from PHI1 -to PHI1
pt_shell> set_clock_uncertainty 0.4 -from PHI2 -to PHI2
pt_shell> set_clock_uncertainty 1.1 -from PHI1 -to PHI2
pt_shell> set_clock_uncertainty 1.1 -from PHI2 -to PHI1
```

Note that both PHI1 to PHI2 and PHI2 to PHI1 must be specified, even though it is the same uncertainty value. Each uncertainty setting applies only in the specified direction, from source to destination.

The following commands specify interclock uncertainty values between PHI1 and PHI2 clock domains for specific rise/fall edge types.

```
pt_shell> set_clock_uncertainty 0.4 -rise_from PHI1 -to PHI2
pt_shell> set_clock_uncertainty 0.4 -fall_from PHI2 -rise_to PHI2
pt_shell> set_clock_uncertainty 1.0 -from PHI1 -fall_to PHI2
```

The following commands set both simple and interclock uncertainty. Where the settings are in conflict, the interclock uncertainty setting (2.0) has higher priority.

```
pt_shell> set_clock_uncertainty 4.0 [get_clocks CLKA]
pt_shell> set_clock_uncertainty 2.0 -from CLKB -to CLKA
```

---

set_command_option_value

Set a command option default or current value.

Syntax

string *set_command_option_value*

-default | -current

-command *command_name*

-option *option_name* | -position *positional_option_position*

-value *value* | -undefined

Arguments

`-default`

Set the default option value.

`-current`

Set the current option value.

`-command` *`command_name`*

Set the option value for an option of this command.

`-option` *`option_name`*

Set the option value for this option of the command.

`-position` *`positional_option_position`*

Set the option value for this positional option of the command.

`-value value`

Set the option value to this value.

`-undefined`

Set the option value to the "undefined value".

Description

Sets the current or default value of a command option.

Either -default must be specified (to specify setting the default value of the option), or -current must be specified (to specify setting the current value of the option). Unlike for get_command_option_values, one of -current or -default must be specified for set_command_option_value.

An option of a command must be specified (for value setting) by passing a command name via -command and either an option name (for an option of the command) via -option, or the position of a positional option via -position. The *option_name* passed via -option (for a dash option) must not have its leading dash character omitted. An option name passed via -option may be either the name of a dash option or the name of a positional option. A positional option may be specified either via -option or via -position. Positional option positions of a command are numbered 0, 1, 2, ... (N-1), where N is the number of positional options of the command.

To set the (current or default) value of the option, a string value should be passed via -value. Alternatively, you can pass -undefined to reset the option to have the "undefined value". (CAVEAT: For some "set value implementations" for numeric options, -undefined does not really "undefine" the value - instead the value is set to 0.)

Processing of the -value value does not include any CCI option checking of the value (such as checking whether the option value has correct syntax for its type).

The command "throws" a Tcl error for various conditions:

* the command does not exist

* the command exists but no such option of the command exists

* the set operation failed (could be due to a failed conversion for one of the "set value" implementations which does a conversion from string to one of integer, double, etc.)

The -undefined option is a mutually exclusive alternative to the -value option. -undefined has the effect of resetting the option value to the "undefined value".

A possible power user application: power users could put set_command_option_value commands in their home directory Tcl startup files for their favorite dialogs/commands to "seed" initial current values for these dialogs. This may lower the need for automatically saving replay scripts (of set_command_option_value commands for each command/dialog option/field) on exit from the application.

Feedback

Examples

The following example sets the current value for the -bar option of the foo command to a value of abc.

```
prompt> set_command_option_value -current -command foo \\
   -option "-bar" -value abc
```

The following example sets the current value for the first positional argument of the foo command to a value of xyz.

```
prompt> set_command_option_value -current -command foo \\
   -position 1 -value xyz
```

---

set_concurrent_event_analysis_options

Sets the options for concurrent event analysis in PrimePower.

Syntax

integer *set_concurrent_event_analysis_options*

```
[-max_process number]
[-partition_by_design ]
[-merge_output_waveform]
[-merge_activity_waveform]
[-keep_overlapped]
```

Data Types

number	integer

Arguments

`-max_process`

Specifies the maximum number of processes to be used for concurrent event analysis.

`-partition_by_design`

When this option is specified , design partitioning is used instead of FSDB time partitions. The design is partitioned into multiple sub designs and each process runs a sub design. This method is suitable when the design size is huge and processing the entire design in a given machine may not be feasible due to memory constraints. This option is supported only for time-based mode.

`-merge_output_waveform`

Merge output fsdb waveform generated inside partitions into single fsdb waveform.

IP -merge_activity_waveform Merges the output activity waveforms generated inside partitions into single activity waveform.

`-keep_overlapped`

This can be used to smoothen the merged power waveform if it has holes at the borders of partition windows.

Description

This command specifies the options for concurrent event analysis. A maximum of 16 processes are allowed for concurrent event analysis . Depending on the FSDB data on the given time window, PrimePower may be choose less number of processes. If this command is not specified , PrimePower uses 4 processes for concurrent event analysis. Increasing the number of processes can speedup the runtime at the cost of more memory .

If you are setting the max_process value above 4 , it is recommended to increase the multi-core limit of the tool by using *'set_host_options -max_cores'* at the beginning of the script . This will ensure maximum runtime benefit for concurrent event analysis .

Examples

The following example will cause PrimePower to do concurrent event analysis with upto 16 processes.

```
pt_shell> set power_enable_concurrent_event_analysis true
pt_shell> set_concurrent_event_analysis_options -max_process 16
pt_shell> update_power
```

See Also

- power_enable_concurrent_event_analysis
- set_host_options

---

set_connection_class

Sets the connection class value on ports.

Syntax

int *set_connection_class*

```
connection_class_value
object_list
```

Feedback

Data Types

connection_class_value	string
object_list	list

Arguments

connection_class_value

Specifies the desired *connection_class* value of ports contained in the *object_list* option. The *connection_class_value* option is a single string value. This string can contain any number of space separated connection classes (see the example below).

object_list

Specifies ports whose connection classes are set.

Description

The *connection class* label is an attribute that is used to describe connection requirements for a given technology. Only those loads and drivers with the same connection class label can be legally connected. The labels "universal" and "default" are reserved labels. The "universal" label indicates that a pin or port can legally connect with any other load or driver. The "default" label is used for those library pins that do not otherwise have a connection class assigned to them through any library attributes. For designs being optimized analyzed, the "universal" label is assigned to those ports that do not otherwise have a connection class assigned to them. To change the default connection class label for those ports, use the *default_port_connection_class* variable.

Connection classes are placed on ports of designs in a technology library by using Library Compiler. The *set_connection_class* command places connection classes on ports of designs being analyzed (such as the current design). This is used to indicate a connection class requirement for the network that is connected to the specified port.

To view connection class values on ports, use the *get_attribute* command. To check your design for connection class violations, use the *report_constraint* command.

Examples

The following example sets a connection class "internal" to the port named "xyz" in the current design.

```
pt_shell> set_connection_class  internal xyz
```

The following example sets the connection classes "internal" and "external" on the port "out" in the design "test".

```
dc_shell> set_connection_class "internal
                          external" test/out
```

In the following example, the connection class on a port is removed.

```
pt_shell> remove_connection_class  test/out
```

See Also

- remove_connection_class
- report_constraint

---

set_context_margin

Adds delay margin to the block context data written by the *write_hier_data* and *write_context* commands, resulting in a more conservative hierarchical analysis.

Syntax

status *set_context_margin*

```
[-max]
[-min]
[-rise]
[-fall]
[-type clock | data]
[-allocation pin_slack | clock_period | user_override]
[-percent]
value
[objects]
```

Data Types

value	double
objects	list

Arguments

`-max`

Indicates that the specification applies only to max-delay delays at block boundaries.

`-min`

Indicates that the specification applies only to min-delay delays at block boundaries.

`-rise`

Indicates that the specification applies only to rising-edge delays at block boundaries.

`-fall`

Indicates that the specification applies only to falling-edge delays at block boundaries.

`-type clock | data`

Modifies the delay constraints only for the specified type of paths cross the block boundary, either *clock* (*set_clock_latency* commands) or *data* (*set_input_delay* and *set_output_delay* commands). By default, both types of delay constraints are affected.

`-allocation pin_slack | clock_period | user_override`

Modifies delay constraints using the specified method:

- *pin_slack* - Allocates a percentage (specified by the *-percent* option) of the delay slack to the block level and the remaining portion to the top level. The top-level portion of the slack is added to or subtracted from the actual delay at the top level to or from the pin, thereby budgeting that portion of the slack to the context surrounding the block. You can use this option only with the *-type data* option.
- *clock_period* - Sets the delay value to the percentage of the clock period specified by the *-percent* option. The actual delay at the top level is ignored.
- *user_override* - Sets the delay to exactly the value specified by the *value* argument of the command. The actual delay at the top level is ignored. Do this with caution, as relaxed delay values cause optimism.

If you do not use the *-allocation* option, the command adds the *value* argument to (or subtracts the *value* argument from) the delay values of the *set_input_delay*, *set_output_delay*, or *set_clock_latency* commands written out for the block context.

`-percent`

Specifies percentage by which the context delay value is modified, or specifies the percentage value for the *-allocation clock_period* or *-allocation user_override* option. Using the *-percent* option is mandatory for the *-allocation clock_period* or *-allocation pin_slack* option.

When using the *-max* and *-percent* options (without the *-allocation* option), specify a *value* of 10.0 for a 10 percent increase in the delays specified by the *set_input_delay* and *set_output_delay* commands written for the block context.

Without the *-percent* option, by default, the *value* argument is an absolute amount added to, or subtracted from, the actual delay value for the context.

objects

Specifies where to add the block context margin.

In a top-level analysis, you can specify a list of block instance cells or instance pins. If you omit the *objects* argument, the margin applies to all block instances. The margin is included in the block context data written out by the *write_hier_data* command.

In a block-level analysis, you can specify a list of ports. The margin is applied to the block context data read in by the *read_context_data* command. If the context data already contains margins from the top level, they are combined additively.

Port objects cannot be specified with the following options: *-allocation pin_slack*, *-allocation clock_period*, *-percent*.

value

Specifies the margin value to be added to (or subtracted from) delay values used in block context data.

If you specify a positive value, both min-delay and max-delay values are modified to tighten the constraint and increase conservatism. To relax rather than tighten the constraint check, specify a negative value. The units are the applicable time units of the logic library.

If the *-percent* option is used, the *value* specifies the applicable percentage, from 0.0 to 100.0 percent.

If the *-allocation user_override* option is used, the *value* specifies the time value of the delay constraint.

Description

The *set_context_margin* command tightens or relaxes clock/data delay values by a specified amount in the block context data written or read by the following commands:

- *write_context*
- *write_hier_data* (in a HyperScale top-level run)
- *read_context_data* (in a HyperScale block-level run)

If the top-level logic is still uncertain, this margin can help improve future convergence between block-level and top-level timing analysis runs.

The specified margin modifies the delay values of the following commands in the block context data:

```
set_input_delay
set_output_delay
set_clock_latency -source
```

A positive margin *value* tightens both min-delay and max-delay analysis. (In the *set_input_delay* and *set_output_delay* commands in the block context, the margin is added to *-max* delay values and subtracted from *-min* delay values.)

A negative *value* relaxes the constraints instead of tightening them. Do this with caution because it introduces optimism.

Using the *set_context_margin* command triggers a full timing update. To reduce runtime, use the command early in the analysis flow, before the *update_timing* or *report_timing* command.

The *set_context_margin* command offers the following options:

- The amount and direction of the delay constraint adjustment
- The adjustment method: absolute adjustment, delay percentage, slack percentage, total delay as a percentage of the clock period, or total delay in time units
- Whether to apply the delay change to maximum or minimum constraints only, to rise or fall transitions only, or to data or clock paths only (default is all)
- In a HyperScale top-level run, whether to apply the delay change only to specific blocks or block pins, or to all blocks for which the context is being generated (the default)
- In a HyperScale block-level run, which ports the delay change should apply to

To cancel a margin setting made previously by the *set_context_margin* command, use the *remove_context_margin* command.

These are the available adjustment methods:

- Absolute adjustment (added to or subtracted from the actual delay)
- Adjustment as a percentage of the actual delay
- Adjustment as a percentage of the pin slack
- Total delay as a percentage of the clock period
- Total delay in time units

Relative Adjustment in Time Units

The *write_context* command writes out the block context as *set_input_delay* commands that specify the delays from data launch to arrival at the block inputs, and *set_output_delay* commands that specify the delays from block outputs to data capture. These commands provide the constraints for block timing analysis in isolation from the top level.

To adjust these delays by a specified amount of time, use the *set_context_margin* command with the *value* option. Specify a positive value for a more restrictive constraint or a negative value for a more relaxed constraint. For example,

```
pt_shell> set_context_margin -type data -max 1.5
```

The *write_context* command adds 1.5 to the delays specified in *set_input_delay -max* and *set_output_delay -max* commands to make the maximum delay constraint more restrictive.

```
pt_shell> set_context_margin -type data -min 1.2
```

The *write_context* command subtracts 1.2 from the delays specified in *set_input_delay -min* and *set_output_delay -min* commands to make the minimum delay constraint more restrictive.

Adjustment as a Percentage of the Actual Delay

To adjust the delays by a specified percentage of the actual delays, use the *set_context_margin* command with the *-percent* option and specify the percentage using the *value* argument. For example,

```
pt_shell> set_context_margin -type data -max -percent 10
```

The *write_context* command adds 10 percent to the delays specified in *set_input_delay -max* and *set_output_delay -max* commands to make the maximum delay constraint more restrictive. For example, an actual maximum delay of 4.0 is changed to 4.4.

Adjustment as a Percentage of the Pin Slack

To adjust the delays by a specified percentage of the worst slack through each block input pin and output pin, use the *set_context_margin* command with the *-allocation pin_slack* and *-percent* options and specify the percentage using the *value* argument. For example,

```
pt_shell> set_context_margin -max -type data -allocation pin_slack
 -percent 40
```

The command allocates 40 percent of the maximum-delay slack to the block level and the remaining 60 percent to the top level. In each *set_input_delay -max* and *set_output_delay -max* command written by the *write_context* command, the delay value is determined as follows:

max_delay_constraint = actual_delay + (0.60 * slack_value)

For a positive slack, the constraint is tightened. For a negative slack, the constraint is relaxed.

The *-allocation pin_slack* option can be used only with the *-type data* option.

Here is a minimum delay constraint example:

```
pt_shell> set_context_margin -min -type data -allocation pin_slack
 -percent 45
```

min_delay_constraint = actual_delay - (0.55 * slack_value)

A pin slack allocation of 100 percent allocates all of the slack to the block and none to the top. This uses the actual top-level delay, the same as not setting any context margin.

A pin slack allocation of zero percent allocates none of the slack to the block and all to the top. This adds the full slack to the actual delay for a maximum delay constraint, or subtracts it from the actual delay for a minimum delay constraint.

Total Delay as a Percentage of the Clock Period

To specify the context delay as a percentage of the clock period, irrespective of the actual top-level delay, use the *set_context_margin* command with the *-allocation clock_period* and *-percent* options and specify the percentage using the *value* argument. For example,

```
pt_shell> set_context_margin -type data -max -allocation clock_period
 -percent 45
```

In each *set_input_delay -max* and *set_output_delay -max* command written by the *write_context* command, the delay value is 45 percent of the applicable clock period.

Absolute Specification (Override) in Time Units

To specify the context delay as an absolute number of time units, irrespective of the actual top-level delay, use the *set_context_margin* command with the *-allocation user_override* option and specify the time value using the *value* argument. For example,

```
pt_shell> set_context_margin -type data -max \\
  -allocation user_override 3.7 [get_pins blkB/in1]
```

In the *set_input_delay -max* command written by the *write_context* command for pin blkB/in1, the input delay value is 3.7 time units.

MIM Blocks

If you set the same type of margin on the same object more than once, the latest setting overrides the older setting. Blocks that belong to a multiply instantiated module (MIM) group are considered a single object in this respect. For example, suppose that blocks blkA and blkB belong to the same MIM group and you run the following commands:

```
set_context_margin -min -rise 0.5 [get_pins blkA/in1]
set_context_margin -min -fall 1.0 [get_pins blkB/in1]
```

Each command applies to all blocks in the MIM group, so the later margin setting replaces the older one for both blocks.

Examples

The following command adds a margin of 0.5 to all input and output maximum delay values, and subtracts that same value from all input and output minimum delay values, in the block context written out as *set_input_delay* and *set_output_delay* commands for data pins and *set_clock_latency -source* for clock pins. This applies to all blocks for which the tool is generating and writing out the block context.

```
pt_shell> set_context_margin 0.5
```

Use the *set_context_margin* command before *update_timing*. Otherwise, the *set_context_margin* command incurs the cost of another timing update.

The following command increases the calculated delays by 10 percent for the context generated and written out for block instance I2.

```
pt_shell> set_context_margin -max -delay -percent 10.0 -objects I2
```

The following script demonstrates usage of the *-allocation* option. Note that a more specific command has higher priority than a more general command.

```
# Set the delay constraint as a percentage of the launch clock period
create_clock -period 10 CLK
set_context_margin -type data -allocation clock_period -percent 50
# Input and output delays are set to 10*.50 = 5.0
#  irrespective of actual delays to input pins and from output pins

# Apply the context margin to a specific pin
set_context_margin -type data -allocation clock_period -percent 30
 [get_pins blkA/in1]
# Input delay for pin blkA/in1 is set to 10*.30 = 3.0

# Override the constraint setting for a specific pin
set_context_margin -type data -allocation user_override 1.23 [get_pins
 blkB/in1]
# Input delay for pin blkB/in1 is set to 1.23

# Allocate 60 percent of the slack to the block and the rest to the top
set_context_margin -type data -allocation pin_slack -percent 60 [get_pins
 blkB/in2]
# If worst setup slack is +2.0 and actual worst arrival at 3.5,
#  input delay for pin blkB/in2 is set to 3.5 + 2.0*(1.00-0.60) = 4.3

# Override the calculated source latency for a clock pin
set_context_margin -type clock -allocation user_override 4.5 [get_pins
 blkB/clk]
# Source latency of blkB/clk pin is set to 4.5
```

set_coupling_separation

Creates a separation constraint on nets.

Syntax

```
status set_coupling_separation
   [-pairwise pnets]
   nets
```

Data Types

```
pnets                list
nets                 list
```

Arguments

`-pairwise pnets`

Specifies that coupling capacitances between only *pnets* and *nets* are excluded. This is referred to as "pairwise exclusion.

`nets`

Specifies the nets for which the separation constraint is applied. If you do not use the *-pairwise* option, the separation constraint is applied for this net with respect to all its aggressors.

Description

By default, all nets with coupling capacitors (non-filtered) are included in crosstalk and noise analysis as both victim and aggressor. This command creates a separation constraint on nets which means that all coupling capacitors on each net in *nets* are excluded for noise and crosstalk analysis.

Feedback

From an analysis point of view, this command has the same effect of applying both the *set_si_delay_analysis* and *set_si_noise_analysis* commands with the *-exclude* option and specifying *nets* as both victims and aggressors. However, this constraint takes precedence over the constraints set by the *set_si_delay_analysis* and *set_si_noise_analysis* command.

Instances of this command are recorded for output by the *write_changes* command. This feature allows you to communicate the separation constraint to other implementation tools along with netlist changes.

To remove the result of this command, use the *remove_coupling_separation* command.

To view the result of this command, use the *report_si_delay_analysis* or *report_si_noise_analysis* command with the *-coupling_separated* option.

Examples

The following example sets a separation constraint on all nets referred to by *CLK_NET_**.

```
pt_shell> set_coupling_separation [get_nets CLK_NET*]
1
```

The following example sets a separation constraint between net n3 and n1 and n2. It does not affect analysis of cross-coupling between n1 and n2 nor n3 and any other net.

```
pt_shell> set_coupling_separation -pairwise [get_nets {n1 n2}] [get_nets
 n3]
1
```

---

set_create_lib_options

Specify options for create_lib command during synthesis

Syntax

int *set_create_lib_options*

Feedback

[-scale_factor *precision*]

Data Types

precision int

Arguments

-scale_factor *precision*

Specifies the length precision for the library. The length precision for the library and all of its reference libraries must be identical. The value is specified in terms of units per micron. By default, a length precision of 10000 is used, which implies one internal unit is equal to one Angstrom or 0.1 nm

Description

The *set_create_lib_options* command pass options for create_lib to synthesis module.

Examples

The following example shows how to specify create_lib options

```
prompt> set_create_lib_options -scale_factor 1
```

---

set_cross_voltage_domain_analysis_guardband

Sets incremental derating factors to be used during cross-voltage-domain analysis for specified UPF supply nets or library cells.

Syntax

status *set_cross_voltage_domain_analysis_guardband*

```
-early | -late
-cell_check
derate_value
object_list
```

Data Types

derate_value	float
object_list	list

Arguments

`-early`

Applies the *derate_value* to early delays (shortest paths) during cross-voltage-domain analysis.

`-late`

Applies the *derate_value* to late delays (longest paths) during cross-voltage-domain analysis. The *-early* and *-late* options are mutually exclusive.

`-cell_check`

Applies the *derate_value* to cell_check arcs as with set_timing_derate the value specified combined with -late is used for setup checks and the value specified combined with -early is used for hold checks. This option is intended to derate the lauch capture delay difference inside of extracted timing models. To achieve this in pessimistic fashion it apllies the guardband derate by simple multiplication even to negative check values.

derate_value

Specifies the timing derate value applied as a scalar multiplier to cell delays during cross-voltage-domain analysis. This factor is applied in addition to any derate value specified with the *set_timing_derate* command or any advanced on-chip variation analysis invoked with the *timing_aocvm_enable_analysis* variable.

object_list

Specifies a collection of either UPF supply nets or library cells. If one or more supply nets are specified, the derating adjustment applies to all cells connected to those supply nets. If one or more library cells are specified, the derating adjustment applies to all instances of those cells. If the *object_list* argument is not used, the guard band setting applies to all UPF supply nets in the design.

Description

Cross-voltage-domain analysis uses two separate means of modeling the timing behavior of cells due to different supply voltage values. The preferred approach is to use the PrimeTime multivoltage delay calculation capability by providing libraries

characterized at the relevant corner voltages using the *define_scaling_lib_group* command. If library characterization information at different voltage values is not available, the *set_cross_voltage_domain_analysis_guardband* command can be used to model the change in timing behavior of cells at different voltage values by derating the calculated delays.

If no object list is provided in the command, the specified *derate_value* applies to all UPF supply nets in the design. If an object list is provided, it can be heterogeneous collection of either UPF supply nets or library cells.

Derating adjustment values can be set for both a UPF supply net collection and a library cell collection. Both adjustments are applied where applicable, one in addition to the other. Any new guard band set for a supply net collection overwrites any previous settings for supply nets. Similarly, any new guard band set for a library cell collection overwrites any previous settings for library cells.

The *set_cross_voltage_domain_analysis_guardband* derate is an incremental derate applied in addition to any other derate specified through the *set_timing_derate* command or advanced on-chip variation (AOCV) analysis. It is not recommended to use *set_cross_voltage_domain_analysis_guardband* in addition to *define_scaling_lib_group*. However, if you use both commands, the timing value obtained from the scaling lib group analysis is also derated according to the *derate_value* specified by the *set_cross_voltage_domain_analysis_guardband* command.

Examples

The following example sets a 10% delay derating for the late arrivals of on the supply nets VDD and VDD1:

```
pt_shell> set_cross_voltage_domain_analysis_guardband -late 0.1 \\
           [get_supply_nets {VDD VDD1]
```

When the *timing_enable_cross_voltage_domain_analysis* variable is set to *true*, cross-voltage-domain analysis is performed; the late delays of all cells supplied by the supply nets VDD and VDD1 are multiplied by 1.1. If ordinary derating is also specified with the *set_timing_derate* command, then both derating factors are applied to the calculated delays.

- timing_enable_cross_voltage_domain_analysis

Feedback

set_current_command_mode

Syntax

string *set_current_command_mode*

-mode *command_mode* | -command *command*

```
string command_mode
string command
```

Arguments

`-mode command_mode`

Specifies the name of the new command mode to be made current. *-mode* and *-command* are mutually exclusive; you must specify one, but not both.

`-command command`

Specifies the name of the command whose associated command mode is to be made current. *-mode* and *-command* are mutually exclusive; you must specify one, but not both.

Description

The *set_current_command_mode* sets the current command mode. If there is a current mode in effect, the current mode is first canceled, causing the associated clean up to be executed. The initialization for the new command mode is then executed as it is made current.

If the name of the given command mode is empty, the current command mode is cancelled and no new command mode is made current.

A current command mode stays in effect until it is displaced by a new command mode or until it is cleared by an empty command mode.

If the command completes successfully, the new current command mode name is returned. On failure, the command returns the previous command mode name which will remain current and prints an error message unless error messages are suppressed.

Examples

The following example sets the current command mode to a mode called "mode_1"

```
shell> set_current_command_mode -mode mode_1
```

The following example clears the current command mode without setting a new mode.

```
shell> set_current_command_mode -mode ""
```

The following example sets the current command mode to the mode associated with the command "modal_command"

```
shell> set_current_command_mode -command modal_command
```

---

set_current_power_domain

Sets the specific power domains defined by the UPF *create_power_domain* command to be included in the power analysis.

Syntax

status *set_current_power_domain*

```
        list_of_power_domains
```

Data Types

list_of_power_domains	list

Arguments

list_of_power_domains

Specifies the power domains defined in the design to be included in the power analysis. If *list_of_power_domains* specifies an undefined power domain, the tool issues an error and does not change the current power domain setting.

Description

This command provides the control of calculating power consumption for the domains of interest. Domain-based power consumption data can be generated for a design with multiple power domains. Only the power dissipated in the blocks covered by the current power domain list is calculated and reported.

If you do not use this command, by default, all defined power domains are included in the power analysis.

This command has no effect on power results in non-UPF mode.

For both dynamic (internal and switching) and static (leakage) power, the domain-based power numbers are calculated based on which domain a cell belongs to. Before using this command, user has to define power domains by using the *create_power_domain* UPF command. The *get_current_power_domain* command returns the power domains being included in the power analysis.

The following power analysis results are affected by this command in UPF mode:

- Average power report • Time-based power report • Power-related attributes:
  - total_power
  - dynamic_power
  - internal_power
  - switching_power
  - leakage_power
  - intrinsic_leakage_power
  - gate_leakage_power
  - x_transition_power
  - glitch_power
  - peak_power
  - peak_time

To revert to the default behavior, which includes the whole design covered by all the defined power domains, use the *set_current_power_domain [get_power_domain *]* command.

Examples

The following example generates domain-based power analysis results. The design has two subblocks, InstA and InstB, which are covered by the PD1 and PD2 power domains, respectively. The first *report_power* generates the power analysis results for the whole design, which is the default behavior. The second *report_power* generates the power analysis results for the power consumed in the PD1 power domain. The third *report_power* generates the results for the power consumed in the PD2 power domain.

```
pt_shell> ...
  pt_shell> create_power_domain PD1 -elements {InstA}
  pt_shell> create_power_domain PD2 -elements {InstB}
  pt_shell> ...
  pt_shell> report_power
  pt_shell> set_current_power_domain PD1
  pt_shell> report_power
  pt_shell> get_current_power_domain
  pt_shell> set_current_power_domain PD2
  pt_shell> report_power
  pt_shell> get_current_power_domain
```

Feedback

---

set_current_power_net

When the variable power_enable_multi_rail_analysis is true, specifes the power nets defined by UPF create_supply_net for power reporting. When false, sets the specific power nets to be included in the power analysis. By default (if not specified), the whole design covered by all the defined supply nets are included in the power analysis and report.

This command has no effect on power results in non-UPF mode.

Syntax

status *set_current_power_net*

```
        list_of_power_nets
```

Data Types

list_of_power_nets list

Arguments

list_of_power_nets

Specifies the power nets defined in the design to be included in the power analysis. If the *list_of_power_nets* option specifies an undefined supply net, an error is issued, and the current power net setting remains unchanged. All supply nets are selected as current_power_nets if the "all" is provided as list of power nets.

Description

The command behavior depends on the power_enable_multi_rail_analysis variable. When false, (the default); concurrent multi-rail analysis is disabled; and power for all the power nets in the design are calculated. This command controls which supply nets are to be included in the power analysis. When specified, only the power dissipation on the listed

supply nets is calculated and reported. To report power consumption per supply net, the command must be applied for each supply net, and the power reanalyzed per supply net.

When the power_enable_multi_rail_analysis variable is true, power per supply net is calculated, and the command controls the power reporting and attribute values. When specified, the power dissipation on the listed supply nets is accessible via the get_attribute and report_attribute commands, as well as the report_power command. To access the power attribute values per supply net, the command must be applied for each supply net, before issueing the get_attribute or report_attribute commands.

For both dynamic (internal and switching) and static (leakage) power, the power net-based power numbers are calculated based on the PG connection of the cell.

If using the CCS power model in the logic library:

- Dynamic_currents are based on pg_pin association.
- Leakage_currents are based on pg_pin association.
- Gate leakages are based on the related_power_pin for the input related pins.
- Switching powers are based on the related_power_pin for the output pins.

If using the NLPM Power model in the technology library with PG pin definitions:

- Internal powers are based on related_pg_pin attribute.
- Leakage powers are based on related_pg_pin attribute.
- Switching powers are based on the related_power_pin for the output pins.

Before using this command, you must define power nets by using the *create_supply_net* UPF command. You can use the *report_supply_net* command to show the defined power nets. You can use the *report_pg_pin_info* and *report_power_network* commands to show the power connections. the *get_current_power_net* command returns the supply nets being included in the power analysis.

The following power analysis results are affected by this command in UPF mode:

- Average power report • Time-based power report • Power-related attributes:
  - total_power
  - dynamic_power
  - internal_power
  - switching_power
  - leakage_power
  - intrinsic_leakage_power

- gate_leakage_power
- x_transition_power
- glitch_power
- peak_power
- peak_time

To revert to the default behavior, which includes the whole design covered by all the defined supply nets, use the *set_current_power_domain [get_supply_net *]* command.

Peak_power and peak_time per rail are only accessible when power_enable_multi_rail_analysis is false. When concurrent multi-rail analysis is performed, only the peak power and peak time for the all the supply nets is accessible. Per rail the peak power attributes are available only when concurrent multi-rail analysis is disabled.

Examples

The following example generates power net-based power analysis results. The design has two subblocks, InstA and InstB, which are covered by tje PD1 and PD2 power domains, respectively. There are six supply nets defined. Among them, four are power nets, and two are ground nets. The primary power net for power domain PD1 is VDDIS, and the primary power net for power domain PD2 is VDDGS.

The first *report_power* command generates the power analysis results for the whole design, which is the default behavior.

The second *report_power* command generates the power consumption associated with power net "VDDI".

The third *report_power* command generates the power consumption associated with power net VDDIS, which is the output of power switch top_header.

The fourth and fifth reports are for VDDG and VDDGS, respectively.

```
pt_shell> ...
pt_shell> create_power_domain PD1 -elements {InstA}

Feedback

set_data_check

Defines a setup or hold timing check between two data signals arriving at specified points in the design.

Syntax

string *set_data_check*

```
-from from_object
   | -rise_from from_object
   | -fall_from from_object
-to to_object
   | -rise_to to_object
   | -fall_to to_object
[-setup]
[-hold]
[-clock clock_object]
[check_value]
```

Data Types

check_value	float
clock_object	collection
from_object	collection
to_object	collection

Arguments

`-from from_object`

Specifies the related pin or port of the data-to-data check. Both rising and falling transitions at this object are checked.

`-rise_from from_object`

Similar to the *-from* option, but only rising transitions at the pin are checked.

`-fall_from from_object`

Similar to the *-from* option, but only falling transitions at the pin are checked.

You must specify *-from*, *-rise_from*, or *-fall_from*.

`-to to_object`

Specifies the constrained pin or port of the data-to-data check. Both rising and falling transitions at this object are checked.

`-rise_to to_object`

Similar to the *-to* option, but only rising transitions at the pin are checked.

`-fall_to` *`to_object`*

Similar to the *-to* option, but only falling transitions at the pin are checked.

You must specify *-to*, *-rise_to*, or *-fall_to*.

For a setup check, the data must arrive at the constrained pin before the transition at the related pin by at least the *check_value* amount of time.

For a hold check, the data must remain valid at the constrained pin for at least the *check_value* amount of time after the transition at the related pin.

`-setup`

Performs only setup analysis in the data check.

`-hold`

Performs only hold analysis in the data check.

By default, the data check performs both setup and hold analysis using the same *check_value* for both. To specify different setup and hold times for the same data-to-data check, use two separate *set_data_check* commands.

`-clock` *`clock_object`*

Specifies the name of the single clock used for the data check. Use this option only if your design has multiple clocks per register and you want to select a single clock for the check.

`-sms_scenarios`

Limits the specification to only the provided SMS scenarios. When this option is not given, the specified value applies to all scenarios. The *get_sms_scenarios* command is used to specify the SMS scenario of interest.

`check_value`

Specifies the setup time or hold time requirement for the check.

Description

The *set_data_check* command specifies a data-to-data check performed between a "from" (related) object and a "to" (constrained) object. The "from" and "to" objects are ports or pins in the design where data signals arrive.

For a setup check, the data must arrive at the constrained pin before the transition at the related pin by at least the *check_value* amount of time.

For a hold check, the data must remain valid at the constrained pin for at least the *check_value* amount of time after the transition at the related pin.

The timing relationship between the contrained and related pins is based on zero cycles. This is different from usual sequential timing checks, which assume one cycle of delay from launch to capture by default.

The data check is treated as nonsequential; that is, the path goes through the related and constrained pins and is not broken at these pins.

To perform the data check, use the *report_timing* command. To report the specific data-to-data check, use the *report_timing* command with the *-to* option and specify the constrained pin as the "to" object.

The data signals arriving at the constrained pin could come from startpoints with multiple clocks in either of these situations:

- A single latch has multiple clocks propagating to the clock or gate pin.
- Different latches have different clocks propagating to their clock or gate pins. For such cases, these clock relations are checked separately. Similarly, data signals arriving at the related pin could also come from startpoints with multiple clocks. Use the *-clock* option to select a specific clock at the related pin for the analysis. Otherwise, the command analyzes multiple clocks and groups them into their respective clock groups.

A data-to-data check must have valid arrival times on both the constrained pin and the related pin. If an unclocked flip-flop does not launch any data, the related pin for the data-to-data check has no arrival time, which means that the path is still unconstrained.

Data-to-data checks are expected to operate on two data signals, and are not intended to perform clock skew checks. The tool does not prevent you from defining a data-to-data checks in the clock network, but the results of such checks might be incorrect.

To remove information set by the *set_data_check* command, use the *remove_data_check* command. *remove_data_check* can be used for per scenario timing check removal by adding the -sms_scenarios option.

Examples

The following command creates a data-to-data check from and1/B to and1/A with respect to the rising edge of signal at and1/B, using a setup and hold time of 0.4.

```
pt_shell> set_data_check -rise_from and1/B -to and1/A 0.4
```

The following command creates a data-to-data check from and1/B to and1/A with respect to the rising edge of signal at and1/B, coming from the clock domain of CK1, constraining only the falling edge of signal at and1/A, using a setup time of 0.5 and no hold check.

```
pt_shell> set_data_check -rise_from and1/B -fall_to and1/A -setup \\
            -clock [get_clock CK1] 0.5
```

The following commands specify different setup and hold values for the same data-to-data check.

Feedback

```
pt_shell> set_data_check -rise_from D2 -to D1 -setup 3.5
pt_shell> set_data_check -rise_from D2 -to D1 -hold 6.0
```

The following commands set a setup and hold timing check values between the same data signals, for different SMS scenarios using the -sms_scenarios option.

```
pt_shell> set_data_check -from D2 -to D1 -setup -sms_scenarios $low_low
 2.5
pt_shell> set_data_check -from D2 -to D1 -setup -sms_scenarios $high_low
 6.5
```

The following command removes the check value for a specific scenario.

```
pt_shell> remove_data_check -from D2 -to D1 -sms_scenarios $low_low
```

- remove_data_check
- report_timing
- update_timing

---

set_design_attributes

Sets the specified attributes and their value on specified cells.

Syntax

string *set_design_attributes*

```
[-elements list]
[-attribute name_value_pair]
[-models model_list]
[-is_soft_macro TRUE | FALSE]
[-is_hard_macro TRUE | FALSE]
[-switch_cell_type coarse_grain | fine_grain]
```

Data Types

list	list
name_value_pair	string
model_list	list
is_soft_macro	boolean
is_hard_macro	boolean
switch_cell_type	string

Feedback

Arguments

`-elements` *list*

Specifies the collection of cells on which the attributes must be set. Wildcards are accepted in cell names.

`-attribute` *name_value_pair*

Specifies the name and value of the attribute to be set on the cells specified by the *-elements* option.

`-models` *model_list*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-is_soft_macro` *TRUE* | *FALSE*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-is_hard_macro` *TRUE* | *FALSE*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-switch_cell_type` *coarse_grain* | *fine_grain*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignores this option.

`-lower_domain_boundary`

Defines the logical boundary of the root cells of the power domain in the hierarchical flow. PrimeTime reads and ignores this option.

Description

This command sets the attributes and their value on a list of cells specified by the *-elements* option.

Attributes can be set multiple times on the same cells. The latest value prevails.

PrimeTime supports a limited number of attributes. For attributes that are unsupported, PrimeTime ignores them and issues a warning message.

Examples

The following example sets the *merge_domain* attribute to *true* on the mid1 cell.

```
prompt> set_design_attributes -elements {mid1} -attribute merge_domain
 TRUE
1
```

Feedback

See Also

- report_attribute
- set_port_attributes

---

set_design_top

Sets or gets the current design in PrimeTime. It is a synonym for the *current_design* command.

Syntax

status *set_design_top*

`[design_name]`

Data Types

`design_name` `string`

Arguments

`design_name`

Specifies the working or focal design for many PrimeTime commands. If the *design_name* option is not specified, the *current_design* command returns a collection containing the current design. If the *design_name* option refers to a design that cannot be located, an error is issued and the working design remains unchanged.

Description

The UPF specification defines the *set_design_top* command that is in PrimeTime - implemented as a synonym to the *current_design* command.

Note: The *current_design* command removes all assertions (such as SDC, SPEF, and UPF). Therefore, the *set_design_top* command cannot be arbitrarily used in UPF scripts. It has to be used as the first command in UPF script, which is also used before any SDC or other assertions.

See Also

- current_design

---

set_device_parameter_margin

Set device physical parameter margin.

Feedback

Syntax

string *set_device_parameter_margin*

```
[-min min_value]
[-max max_value]
-parameter_name parameter_name
[-cell_check]
[-cell_delay]
[-increment]
[-override]
[object_list]
```

Data Types

min_value	float
max_value	float
i*parameter_name*	string
object_list	collection

Arguments

`-min` *min_value*

Specifies the value of device parameter margin for min analysis.

`-max` *max_value*

Specifies the value of device parameter margin for max analysis.

`-parameter_name` *parameter_name*

Specifies the physical parameter name to set margin.

`-cell_check`

Specify parameter value for cell timing checks only.

`-cell_delay`

Specify parameter value for cell delays only.

`-increment`

Specify an incremental value.

`-override`

Specify the margin is for override if parameter value is already defined in CTPM or PVT explorer condition. Without the option, default behavior is addition.

object_list

Specifies the cells or lib_cells to set device parameter margin. Without the option, the margin applies to whole design.

Feedback

Description

The *set_device_parameter_margin* command sets the device physical parameter margin on a group of cells or lib_cells, which allows you to add additional margin for physical parameter available in sensitivity augmented side-file defined by *define_sensitivity_lib_mapping*. Timing analysis with device parameter margin will refect the timing impact from phsyical parameter shift, and different margin can be applied for min and max analysis.

Examples

The following script enables Project Sicily Spice2Design flow, defines mapping between base library and sensitivity side-file, then set margin for SVT NMOS vth control parameter "delvtrandn_mos_svt" to 0.01 (min analysis of cell delays), 0.02 (max analysis of cell delays), 0.03 (min analysis of constraint arcs), and 0.04 (max analysis of constraint arcs).

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
set_device_parameter_margin -min 0.01 -parameter_name delvtrandn_mos_svt
 -cell_delay
set_device_parameter_margin -max 0.02 -parameter_name delvtrandn_mos_svt
 -cell_delay
set_device_parameter_margin -min 0.03 -parameter_name delvtrandn_mos_svt
 -cell_check
set_device_parameter_margin -max 0.04 -parameter_name delvtrandn_mos_svt
 -cell_check
```

See Also

- read_ctpm
- set_pvt_explorer_condition
- ps_enable_spice2design_analysis
- ps_enable_pvt_explorer_analysis

---

set_disable_auto_mux_clock_exclusivity

Disables automatic inference of MUXed clock exclusivity at specified cell output pins.

Syntax

```
status set_disable_auto_mux_clock_exclusivity
  [object_list]
```

Feedback

Data Types

object_list list

Arguments

object_list

Specifies a list of one or more MUX output pins for which automatic inference of MUXed clock exclusivity is disabled.

Description

Automatic inference of clock exclusivity at MUX output pins is enabled by setting the *timing_enable_auto_mux_clock_exclusivity* variable to *true*.

To prevent automatic inference of a specific MUX cell output as an exclusivity point, apply this command to the MUX output pin.

To undo the *set_disable_auto_mux_clock_exclusivity* command, use the *set_clock_exclusivity* command on the same output pin.

Examples

The following example prevents pins MUX32/Z and MUX33/Z from being automatically inferred as clock exclusivity points.

```
pt_shell> set_disable_auto_mux_clock_exclusivity {MUX32/Z MUX33/Z}
```

See Also

- remove_clock_exclusivity
- report_clock
- set_disable_auto_mux_clock_exclusivity

---

set_disable_check_timing

Sets certain objects to be excluded from check_timing signal_level and operating condition .

Syntax

boolean *set_disable_check_timinge*

```
[-check_type]
[-object_list]
```

Arguments

`-check_type`

Type of check_timing for which the timing checks needs to be disabled. Only two permissible values for this is operating_condition and signal_level.

`-object_list`

List of objects for which the timing check needs to be excluded.

Description

set_disable_check_timing command allows the users to set some objects to exclude them from timing checks in check_timing command. Currently exclude objects can be specified for operating_condition and signal_level checks using -check_type option.

For operating_conditions exclusion, only list of cells is allowed for the object_list. For signal_level exclusion, pins, lib_pins and ports are allowed as values to object_list.

See Also

- check_timing

---

set_disable_clock_gating_check

Disables the clock gating check for specified cell, pin, lib_cell, or lib_pin objects.

Syntax

string *set_disable_clock_gating_check*

object_list

Data Types

object_list list

Arguments

object_list

Specifies a list of cell, pin, lib_cell, or lib_pin objects for which the clock gating check is disabled.

Description

The *set_disable_clock_gating_check* command disables clock gating checks inferred automatically and possibly modified by the *set_clock_gating_check* command. It does not affect clock gating checks defined in the library for integrated clock-gating cells.

Feedback

You can disable clock gating checks on cells or pins in the current design or its subdesigns. Specify cells at lower levels in the design hierarchy as *instance1*/*instance2*/*cell_name*. Specify pins at lower levels in the design hierarchy as *instance1*/*instance2*/*cell_name*/*pin_name*. For subdesigns in the hierarchy, specify instance names, not design names.

Specifying a cell disables all gating checks in the cell. Specifying a pin disables any gating check in which the pin is the gating clock pin or gating enable pin. Specifying a lib_cell or lib_pin object affects all instances of that object used in the design.

To restore gating checks previously disabled by the *set_disable_clock_gating_check* command, use the *remove_disable_clock_gating_check* command. To globally disable all clock gating checks, including those defined in the library, set the *timing_disable_clock_gating_checks* variable to *true*.

Examples

The following command disables all clock gating checks on cell U123.

```
pt_shell> set_disable_clock_gating_check [get_cells U123]
```

The following command disables clock gating checks that use pin U123/I as a gating enable pin or gating clock pin.

```
pt_shell> set_disable_clock_gating_check [get_pins U123/I]
```

The following command disables clock gating checks for all instances of the mylib/AND1 library cell.

```
pt_shell> set_disable_clock_gating_check [get_lib_cells mylib/AND1]
```

The following command disables clock gating checks that use pin A1 as a gating enable pin or gating clock pin in instances of the mylib/AND1 library cell.

```
pt_shell> set_disable_clock_gating_check [get_lib_pins {mylib/AND1/A1}]
```

See Also

- remove_disable_clock_gating_check
- timing_disable_clock_gating_checks

---

set_disable_pg_pins

Disables PG pins of specific library cells, so they are not considered by timing analysis.

Syntax

status *set_disable_pg_pins*

Feedback

```
lib_cells
-pg_pins pg_pin_name_list
```

Data Types

```
lib_cells      collection
pg_pins        list
```

Arguments

lib_cells

Specifies the set of library cells on which PG pins will be disabled.

-pg_pins pg_pin_name_list

Specifies the names of the PG pins to be disabled.

Description

The *set_disable_pg_pins* command specifies the list of PG pins, belonging to specific library cells, to be disabled for timing analysis.

When a PG pin is disabled for a library cell, its connectivity and voltage value no longer affect the analysis.

This command can be used in both regular and scaling-group flows.

When this command is used in voltage-scaling flows, it must be specified before the scaling groups are defined by the *define_scaling_lib_group* command; it cannot be applied to a library after it is in a scaling group.

Note that the *define_scaling_lib_group* command has an *-excluded_rail_names* option that can be used to exclude a rail from an entire scaling group (all cells, not just specific cells).

Examples

The following script disables PG pin VDD on a libcell A in libray XYZ.

```
set_disable_pg_pin [get_lib_cell XYZ/A] -pg_pins {VDD}
```

See Also

- define_scaling_lib_group
- report_disable_pg_pins

---

set_disable_timing

Disables timing arcs in a circuit.

Feedback

Syntax

status *set_disable_timing*

```
[-from from_pin_name]
[-to to_pin_name]
object_list
comment
```

Data Types

```
from_pin_name     string
to_pin_name       string
object_list       list
comment           string
```

Arguments

`-from from_pin_name`

Specifies that arcs only from this pin on the specified cell are disabled. The *from_pin_name* value must be a valid library pin name corresponding to the cell in the *object_list* value. When used, the *-from* and *-to* options must be specified together. The *object_list* value must contain only cells, and the command specifies that arcs only between these two pins on the specified cells are disabled.

`-to to_pin_name`

Specifies that arcs only to this pin on the specified cell are disabled. The *to_pin_name* value must be a valid library pin name corresponding to the cell in the *object_list* value. When used, the *-from* and *-to* options must be specified together. The *object_list* value must contain only cells, and the command specifies that arcs only between these two pins on the specified cells are disabled.

object_list

Specifies a list of cells, pins, lib-cells, lib-pins, ports, or timing-arcs that are disabled. This list can include library objects.

comment

Associates a string description with the command for tracking purposes. You must begin and end the comment string with double quotation marks ("). Currently, this option is disabled as a default. To enable it set pt_enabled_comment_option gvar to true.

Description

Disables timing through the specified cells, pins, ports, or timing arcs in the *current_design* command.

Feedback

Any cell, pin, port, or timing arc in the *current_design* command or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*. Pins at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*/*pin_name*. Ports at lower levels in the design hierarchy are specified as *instance1*/*instance2*/*cell_name*/*port_name*. Timing arcs have to be collected using the *get_timing_arcs* command.

Note: For subdesigns in the hierarchy, you must specify instance names instead of design names.

When the timing through a cell is disabled, only those cell arcs are disabled that lead to the output pins of the cell. When the timing through a pin or port is disabled, only those cell arcs that lead from a load pin and to a driver pin are disabled. For bidirectional pins or ports the cell arcs from the load side and to the driver side are disabled.

When the *-from* and *-to* option pins are specified, all arcs between these two pins on the cell are disabled.

To view disabled timing arcs in the current design, use the *report_disable_timing* command. To restore timing arcs disabled by the *set_disable_timing* command, use the *remove_disable_timing* command. The *reset_design* command removes all user-specified attributes from the current design, including those set by the *set_disable_timing* command.

Examples

Consider the following reported path:

```
pt_shell> report_timing -input_pins

****************************************
Report : timing
         -path full
         -delay max
         -input_pins
         -max_paths 1
Design : counter
 ...
****************************************

  Startpoint: ffb (rising edge-triggered flip-flop)
  Endpoint: CO (output port)
  Path Group: (none)
  Path Type: max

  Point                                          Incr       Path
  -----------------------------------------------------------------
  ffb/CP (FD3)                                   0.00       0.00 r
  ffb/QN (FD3)                                   2.42       2.42 r
  m/C (AN4)                                      0.00       2.42 r
  m/Z (AN4)                                      1.12       3.54 r
```

```
  CO/A (AN2)                                0.00       3.54 r
  CO/Z (AN2)                                0.48       4.02 r
  CO (out)                                  0.00       4.02 r
  data arrival time                                    4.02
  ---------------------------------------------------------------
  (Path is unconstrained)
```

Assuming you want to disable timing arcs through the CO cell, you can view all timing arcs of the CO cell by examining its library cell, AN2.

```
pt_shell> report_lib -timing lsi_10k { AN2 }

****************************************
Report : library
        -timing_arcs
Library: ...
 ...
****************************************

Library Cells:

   Attributes:
    b - black box (function unknown)
    d - dont_touch
    s - state table
    u - dont_use
    A - abstracted timing model
    E - extracted timing model
    I - Interface timing spec model (ITS)
    S - Stamp timing model
    Q - Quick timing model (QTM)

                              Arc                    Arc Pins
   Lib Cell  Attributes     #  Type/Sense       From         To          When

 ------------------------------------------------------------------------------
   AN2                      0  positive_unate   A            Z
                            1  positive_unate   B            Z
```

To disable the timing arc used in the preceding reported path, use the *set_disable_timing* command:

```
pt_shell> set_disable_timing -from A -to Z [ get_cells { CO } ]

pt_shell> report_timing

****************************************
Report : timing
        -path full
        -delay max
        -max_paths 1
 ...
****************************************
```

```
  Startpoint: ffa (rising edge-triggered flip-flop)
  Endpoint: QA (output port)
  Path Group: (none)
  Path Type: max

  Point                                    Incr       Path
  -----------------------------------------------------------
  ffa/CP (FD2)                             0.00       0.00 r
  ffa/Q (FD2)                              1.42       1.42 f
  QA/Z (IV)                                0.38       1.80 r
  QA (out)                                 0.00       1.80 r
  data arrival time                                   1.80
  -----------------------------------------------------------
  (Path is unconstrained)
```

Alternatively, the same arc is disabled as follows:

```
pt_shell> set_disable_timing [get_timing_arcs -from { CO/A } -to
 { CO/Z } ]
```

- report_timing
- reset_design
- timing_disable_cond_default_arcs

---

set_distributed_parameters

Configures the distributed environment.

Syntax

status *set_distributed_parameters*

```
[-collection_levels collection_level]
 [-script script]
 [-worker_common_user_data worker_script]
```

Feedback

Data Types

```
collection_level    string
script              string
worker_script       string
```

Arguments

`-script` *script*

The user-defined/custom wrapper script to be used when launching remote processes. If this option is not specified, the wrapper is taken by default to be $synopsys_root/bin/pt_shell.

`-collection_levels` *collection_level*

Specifies the number of collection levels to traverse when retrieving collection attributes from the workers. The higher this collection level is set, the more memory is potentially consumed at the manager.

`-worker_common_user_data` *worker_script*

Specifies the filename of the Primetime script to be sourced at the startup of each worker process. The script may contain definitions of common Tcl procedures, setting of common variables and so on. The script is run after sourcing .synopsys_pt.setup files and is not intented to replace .synopsys_pt.setup.

Description

The *set_distributed_parameters* command allows you to configure the distributed environment. The command should be issued before the *start_hosts* command for your configurations to take effect.

Examples

In the following example one worker process is allocated on a host called platinum1. The process is launched using the *start_hosts* command.

```
pt_shell> set_host_options -num_processes 1 platinum1
1
pt_shell> set_distributed_parameters -script /usr/pt_shell
1
pt_shell> start_hosts
1] Launched: rsh -n -l user platinum1 /usr/pt_shell
             -env_start ...
             ...
               Status: Forking successful
               Stdout: Process group is (4492)
               Stderr: **<<EMPTY>>**
```

Feedback

```
 ------------------------------------------------------------------------
---------------
  Distributed farm creation timeout : 21600 seconds
  Waiting for   1 (of   1) distributed hosts (Mon Dec  9 05:04:36 2013)
  Waiting for   0 (of   1) distributed hosts (Mon Dec  9 05:04:46 2013)

 ------------------------------------------------------------------------
---------------
```

In the following example, the *-collection_levels* option is used to restrict the amount of information returned by the *get_distributed_variable* command. By setting the collection level to *4* only four levels of collections can be traversed.

```
pt_shell> set_distributed_parameters -collection_level 4
pt_shell> remote_execute { set m_pins [get_pins A]}
pt_shell> get_distributed_variables m_pins -attr {clocks sources}
pt_shell> echo [set clock1 [get_attribute $m_pins(scen1) clocks]]
_sel12
pt_shell> echo [set clock_source1 [get_attribute $clock1 sources]]
_sel13
pt_shell> echo [set clock2 [get_attribute $clock_source1 clocks]]
_sel14
pt_shell> echo [set clock_source2 [get_attribute $clock2 sources]]
_sel15
pt_shell> echo [set clock3 [get_attribute $clock_source2 clocks]]
Warning: Attribute 'clocks' does not exist on port 'CLK' (ATTR-3)
```

In the example below, the *-worker_common_user_data* option specifies the script file to be sourced at the start of each worker process:

```
pt_shell> set_distributed_parameters
 -worker_common_user_data /home/user/set_worker_env.tcl
```

See Also

- set_host_options
- start_hosts

---

set_distributed_power_analysis_options

Sets the options for distributed power analysis in PrimePower. Currently supported only in time based analysis.

Syntax

integer *set_distributed_power_analysis_options*

```
[-partition_style string]
[-common_scripts string]
```

```
[-merge_output_waveform]
[-merge_activity_waveform]
[-keep_overlapped]
```

Data Types

string string

Arguments

-partition_style

This option specifies the scheme used for partitioning the task execution among different workers.

The schemes currently available are : partition_by_time (Default, if no scheme is specified) partition_by_design partition_by_design_and_time

If scheme specified is 'partition_by_time', the partitioning of task is done by dividing FSDB time interval.

If the scheme specified is 'partition_by_design', the design is partitioned into multiple sub designs and each worker runs a sub design.

If the scheme specified is 'partition_by_design_and_time', the design is partitioned into sub designs and if required, FSDB time based partitioning is also done. This is suitable for huge design sizes with virtual FSDB where processing entire design in a given machine may not be feasible.

-common_scripts

This option is required when it is required to do a common setting in all the workers. Eg - If 'set_switching_activity' is done in master, it should be put in a file, say 'common_script', and this file name should be passed as argument to '-common_scripts'

-merge_output_waveform

Merge output fsdb waveform generated inside partitions into single fsdb waveform.

-merge_activity_waveform

Merges the output activity waveforms generated inside partitions into single activity waveform.

-keep_overlapped

This can be used to smoothen the merged power waveform if it has holes at the borders of partition windows.

Feedback

Description

This command specifies the options for distributed power analysis. With distributed analysis, it is expeceted to see runtime improvement.

Examples

The following example will cause PrimePower to do distributed power analysis.

```
pt_shell> set power_enable_distributed_analysis true
pt_shell> set_distributed_power_analysis_options -partition_style
 partition_by_design_and_time -common_scripts common_script
pt_shell> update_power
```

set_distributed_variables

Passes Tcl variables from the manager process to the worker processes.

Syntax

status *set_distributed_variables*

```
[-pre_commands pre_command_string]
[-post_commands post_command_string]
object_list
```

Data Types

pre_command_string	string
post_command_string	string
object_list	list

Arguments

`-pre_commands` *pre_command_string*

Specifies a string of commands to be executed in the worker context before the setting of variables. To group commands, use the semicolon (;) character. The maximum size of a command is 1000 chars.

`-post_commands` *post_command_string*

Specifies a string of commands to be executed in the worker context after the setting of variables. To group commands, use the semicolon (;) character. The maximum size of a command is 1000 chars.

object_list

Specifies a list of objects.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

This command sets variables at the worker processes running PrimeTime scenarios given a set of variables at the manager. If the variable to be sent is a simple Tcl list, the Tcl list is recreated at workers for all scenarios in focus. If the variable is an array indexed by the scenario name, the variable is set for each scenario in focus that has an entry in the array.

Examples

The following example sets a scenario_id variable for each scenario and a max_fanout variable in both scenarios. In the scen1 scenario, the scenario_id variable is created and set to 1. In the scen2 scenario, the scenario_id variable is created and set to 2. In both scenarios, the max_fanout variable is created and set to 10.

```
pt_shell> set max_fanout 10
pt_shell> array set scenario_id {scen1 1 scen2 2}
pt_shell> set_distributed_variables {scenario_id max_fanout}
```

---

set_domain_supply_net

Sets the primary power net and primary ground net of an existing power domain.

Syntax

int *set_domain_supply_net*

```
domain_name
-primary_power_net supply_net_name
-primary_ground_net supply_net_name
```

Data Types

```
domain_name           string
supply_net_name       string
```

Arguments

domain_name

Specifies the name of the power domain to set.

If there is no such power domain with the specified name in the current scope, the command fails.

`-primary_power_net` *`supply_net_name`*

Specifies the power net of the power domain.

If there is no such supply net with the specified name in the current scope, the command fails. If the supply net is not associated with the specified power domain, the command also fails.

`-primary_ground_net` *`supply_net_name`*

Specifies the ground net of the power domain.

If there is no such supply net with the specified name in the current scope, the command fails. If the supply net is not associated with the specified power domain, but is associated with other power domains, the command also fails.

Description

The *set_domain_supply_net* command enables you to set the primary power net and the primary ground net of a power domain. All extent of the power domains shares the same power/ground supply until explicitly excluded. Here "explicitly excluded" means it is explicitly connected with another supply net (non primary power/ground supply net) by the following commands: *connect_supply_net*, *set_isolation*, *set_retention*. This command fails if the domain already has a primary power and ground net.

The supply net must be created in the same power domain first before it is set as the primary power/ground supply net. Use the *create_supply_net* command to create a supply net at a specified power domain.

The command returns 1 if is is successful, and returns 0 otherwise.

Examples

The following example creates two supply_net on power_domain PD1, then sets them as primary power/ground net.

```
prompt> create_power_domain PD1 -elements INST_1
PD1
prompt> create_supply_net A_VDD -domain PD1
A_VDD
prompt> create_supply_net A_VSS -domain PD1
A_VSS
prompt> set_domain_supply_net PD1 -primary_power_net A_VDD \
-primary_ground_net A_VSS
1
```

---

set_dont_override

Specifies the objects for which user-defined budgeted constraints should not be automatically overridden during the HyperScale analysis flow. This command is only effective during block-level analyses.

Syntax

string *set_dont_override*

```
[-include arc_delay | case_value | pin_transition]
object_list
```

Data Types

```
object_list     list
```

Arguments

`-include arc_delay | case_value | pin_transition`

Specifies the name of the include list during the block-level analysis which can ignore the data from the top level and the block level can use the data from itself. Currently you can use -include arc_delay, case_value or pin_transition during block-level analysis to ignore the arc_delay, case_value or pin_transition respectively from the top level and use the arc_delay, case_value or pin_transition from block itself.

object_list

Specifies the design or ports for which boundary budgeted constraints should be maintained without automatic override.

Description

This command is used to select the ports or the entire block for which the boundary timing context pushed down from parent level analysis should not be used to override user-defined budgets.

In the HyperScale analysis flow, a top-level run pushes accurate and up-to-date boundary timing and noise context for the subblocks represented by abstraction; the subsequent block-level run automatically loads the latest timing context for the block boundary and override user-defined I/O context to perform the block level analysis. These boundary

timing context for the input and output ports override user-defined I/O timing constraints, such as *set_input_delay*, *set_output_delay*, *set_input_transition*, *set_clock_latency*, *set_timing_derate* and *set_input_noise*.

In a design flow, sometimes you might want the block-level design to meet a fixed timing budget prescribed for the block, instead of allowing PrimeTime to automatically override with actual timing context, which can represent some intermediate state of the parent level or other surrounding blocks. Particularly in the early design flow, or for certain portion of the design with known and clear timing specification.

You can use this command only when you also use the *set_hier_config -parent* command, meaning that the current run is for a block, and *hier_enabled_analysis* is set to *true*.

Examples

Assuming a design with two levels of hierarchy, where TOP instantiates a subblock BOT, and the named scenario of interest is fast_func. To perform hierarchical timing analysis for BOT and automatically generate a reduced and accurate timing representation for its parent level analysis, use the following commands:

```
pt_shell> set hier_enable_analysis true
pt_shell> set_hier_config -parent -name "fast_func" -path /design/TOP
pt_shell> set_hier_config -name "fast_func" -path /design/blocks/BOT
```

In addition, for the block BOT, it is necessary to freeze the timing budget defined for the bused port DATAIN so that PrimeTime does not automatically use the actual context pushed from TOP to override your settings, use the following command:

```
pt_shell> set_dont_override [get_port DATAIN*]
```

Feedback

set_dont_touch

Sets the *dont_touch* attribute on cells, nets, designs, or library cells to prevent those objects from being modified or replaced during ECO fixing.

Syntax

status *set_dont_touch*

```
object_list
[value]
```

Data Types

```
object_list    list
value          Boolean
```

Arguments

object_list

Specifies a list of cells, nets, designs, or library cells, preventing those objects from being modified or replaced during ECO fixing.

value

Sets the value, either *true* or *false*, for the *dont_touch* attribute of the specified objects. The default is *true*. Use the value *false* to cancel the effects a previous *set_dont_touch* command.

Description

This command sets the *dont_touch* attribute on cells or nets in the current design, or on designs or library cells, to prevent those objects from being modified or replaced during ECO fixing by the *fix_eco_drc*, *fix_eco_power*, and *fix_eco_timing* commands. The specified objects must be in one of the target libraries or in a library already loaded into memory.

When set on a cell instance, that cell cannot be sized, removed, or replaced. For a hierarchical cell, the *dont_touch* setting applies to all its lower-level cells, except where their *dont_touch* attribute is set to *false*.

When set on a net, buffer insertion is not allowed on that net. Driver and load cells connected to the net can still be modified or removed. For a net that crosses hierarchical boundaries, the *dont_touch* setting applies only to the named net segment and does not propagate across the hierarchical boundaries.

When set on a design, the *dont_touch* attribute applies to all instances of that design. When set on the *[current_design]*, the *dont_touch* attribute applies from the top level down. Lower-level hierarchical values take precedence over higher-level values, and leaf-level attributes take precedence over design-level attributes.

Feedback

When set on a library cell, the *dont_touch* setting applies to all instances of that cell. It affects only the library cells loaded into memory, not the library stored on disk.

You can query the *dont_touch* attribute by using the *get_attribute* command. To cancel the effects of a *set_dont_touch* command, run the command again and specify the *value* as *false*. A *false* setting on an object overrides a *true* setting on the parent object.

In distributed multi-scenario analysis (DMSA), you should apply the *set_dont_touch* command in all the scenarios.

The *dont_touch* attribute is characterized by the *characterize_context* command and exported to other tools by the *write_context* command.

When the *dont_touch* attribute on a design or library cell is written to scripts, the target objects vary based on the script format. A *dont_touch* design is applied to a design for PrimeTime and to a reference for Design Compiler. Similarly, a *dont_touch* library cell is applied to a lib_cell for PrimeTime, and to a reference for Design Compiler.

If your database contains a *dont_touch* attribute on an object, and you explicitly use the *set_dont_touch* command to set the value to *false* for that object, the *write_script* command does not write this information.

The *dont_touch* attribute is inherited by cells if the cell is an instance of a design or library cell that has the *dont_touch* attribute. In these cases, the *get_attribute* command returns *true* for the *dont_touch* attribute for that cell. This affects the result of the *get_attribute* command but does not actually transfer the *dont_touch* attribute to the cell. So the output of the *write_script* command does not contain extra *set_dont_touch* commands applied to cells.

Examples

The following commands specify not to modify the "block1" and "analog1" cells during ECO fixing, but allow the net "N1" to be modified.

```
pt_shell> set_dont_touch [get_cells {block1 analog1}]
1
pt_shell> set_dont_touch  [get_nets N1] false
1
```

In the following example, applying a *dont_touch* attribute to design d1 affects its instances. The *get_attribute* command returns *true* for the *dont_touch* attribute. The example also shows the difference in the *write_script* command output for the PrimeTime and Design Compiler tools; the applicable line of output for each tool is shown below.

```
pt_shell> get_attribute [get_cells u1] ref_name
d1

pt_shell> get_attribute [get_cells u1] dont_touch
false
```

```
pt_shell> set_dont_touch [get_designs d1]
1

pt_shell> get_attribute [get_cells u1] dont_touch
true

pt_shell> write_script -format ptsh

 Script contains this command:
 set_dont_touch [get_designs "design1.db:d1"]

pt_shell> write_script -format dcsh

 Script contains this command:
 set_dont_touch find(reference, "d1")
```

The following example shows that the *dont_touch* setting applied to a net at the top level, sdramA, is not propagated across a hierarchical boundary to a lower-level connected net, I_ORCA_TOP/sdA.

```
pt_shell> get_nets sdramA
{"sdramA"}
pt_shell> get_nets -segments sdramA
{"sdramA", "I_ORCA_TOP/sdA"}
pt_shell> get_attribute [get_nets -segments sdramA] dont_touch
Warning: Attribute 'dont_touch' does not exist on net 'sdramA' (ATTR-3)
Warning: Attribute 'dont_touch' does not exist on net
 'I_ORCA_TOP/sdA' (ATTR-3)

pt_shell> set_dont_touch [get_nets sdramA] true
1
pt_shell> get_attribute [get_nets -segments sdramA] dont_touch
Warning: Attribute 'dont_touch' does not exist on net
 'I_ORCA_TOP/sdA' (ATTR-3)
true
```

Feedback

set_dont_touch_network

Sets the dont_touch_network attribute on clocks, pins, or ports in the current design to prevent cells and nets in the transitive fanout of the set_dont_touch_network objects to prevent synthesis from replacing or modifying them during optimization.

Syntax

```
status set_dont_touch_network
  object_list
```

Data Types

```
object_list      list
```

Arguments

object_list

Specifies a list of clocks, pins, or ports.

Description

Sets the *dont_touch_network* attribute on clocks, pins, or ports in the current design. It also assigns *dont_touch* attributes to all cells and nets in the transitive fanout of the *dont_touch_network* objects so that they are not modified or replaced during optimization.

The *set_dont_touch_network* command is intended primarily for clock circuitry. Placing a *dont_touch_network* attribute on a clock object prevents synthesis from modifying the clock buffer network.

This attribute is characterized by the *characterize_context* command and exported to synthesis using the *write_context* command.

If you specify a pin or a port, all nets and cells in its transitive fanout are recursively marked *dont_touch*. This recursion propagates through combinational cells but stops at registers (without marking the registers as *dont_touch*). An element is recognized as a register only if it has setup or hold constraints. If you specify an input pin, its own cell is marked *dont_touch* but its connected net is not marked *dont_touch*. If you specify an output pin, its own cell is not marked *dont_touch* but its connected net is marked *dont_touch*.

Refer to the *set_dont_touch* command man page in Design Compiler for a complete description of the *dont_touch* attribute and its effect.

Use the *reset_design* command to remove the *dont_touch_network* and *dont_touch* attribute.

Examples

The following command adds a *dont_touch_network* attribute to the port named "clock_in".

```
pt_shell> set_dont_touch_network [get_ports clock_in]
```

The following command adds the *dont_touch* attribute to a net named net1 and a cell named cell2 but not to the cell named cell1:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y cell2/A}
prompt> set_dont_touch_network [get_pins cell1/Y]
1
```

The following command adds the *dont_touch* attribute to a net named net1 and cell named cell1 but not on the net named net0 and register reg1:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y reg1/D}
prompt> get_pins -of_objects [get_cells cell1]
{cell1/A cell1/Y}
prompt> get_nets -of_objects [get_pins cell1/A]
{net0}
prompt> set_dont_touch_network [get_pins cell1/A]
1
```

---

set_dont_use

Sets the *dont_use* attribute on library cells to exclude them from the target library during optimization.

Syntax

```
status set_dont_use
   object_list
   [true | false]
```

Data Types

```
object_list    list
```

Feedback

Arguments

object_list

Specifies a list of objects (library cells, modules, or implementations) on which the *dont_use* attribute is to be set.

`true | false`

Specifies whether the *dont_use* attribute is set to *true* (the default) or *false*.

Description

This command sets the *dont_use* attribute on specified library objects, so that they are not used for ECO. The specified objects must be in one of the target libraries or in a library already loaded into memory.

use this command with care, especially when changing the value of the *dont_use* attribute from *true* to *false*. Follow the design requirements that establish which library cells can be used for ECO. Disabling library cells can have an impact on PrimeTime ECO results depending on the choices of library cells available for ECO.

This command affects only the copy of the library that is currently loaded into memory and has no effect on the version that exists on disk.

In the distributed multi-scenario analysis flow, you should apply the *set_dont_use* command in all the scenarios so that the specified library cells are not used during optimization, such as when using the *fix_eco_timing* command.

Examples

Setting the *dont_use* attribute to *true* on a library cell disables it from ECO usage while setting it to *false* enables it for ECO usage.

The following command sets the *dont_use* attribute on the G1 and G2 lib_cells in the mylib library:

```
pt_shell> set_dont_use {mylib/G1 mylib/G2}
1
```

The following command unsets the *dont_use* attribute on the G1 lib_cell in the mylib library:

```
pt_shell> set_dont_use {mylib/G1} false
1
```

---

set_drive

Sets the resistance to a specified value on specified input or inout ports in the current design.

Syntax

status *set_drive*

```
[-rise]
[-fall]
[-min]
[-max]
resistance_value
port_list
```

Data Types

resistance_value	float
port_list	list

Arguments

`-rise`

Specifies that the *resistance_value* argument is used to drive the ports only for the rising case.

`-fall`

Specifies that the *resistance_value* argument is used to drive the ports only for the falling case.

`-min`

Applies only to designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* argument is the minimum resistance.

`-max`

Applies only to designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* argument is the maximum resistance.

resistance_value

Specifies a nonnegative port drive resistance value for the ports in the *port_list*. The value must be >= 0; units must be the same as those in the logic library.

port_list

Specifies a list of input or inout ports in the current design, in which the *resistance_value* argument is set.

Description

This command sets the resistance to a specified value on specified input or inout ports in the current design. PrimeTime models the driver as a resistance and uses that value to calculate the wire delay of the port. To view the drive that is set, use the *report_port -drive* attribute.

Depending on the options used, the *set_drive* command sets these attributes on the specified ports:

```
drive_resistance_fall_max
drive_resistance_fall_min
drive_resistance_rise_max
drive_resistance_rise_min
```

If the *set_drive* command is issued without any options, the *drive_resistance_fall_max* and *drive_resistance_rise_max* attributes are set; in min-max mode, the other two attributes are also set.

If the *set_drive* command is issued with only the *-rise* option, only the *drive_resistance_rise_max* attribute is set; in min-max mode, the *drive_resistance_rise_min* attribute is also set.

If the *set_drive* command is issued with only the *-fall* option, only the *drive_resistance_fall_max* attribute is set; in min-max mode, the *drive_resistance_fall_min* attribute is also set.

Drive resistance is the output resistance of the cell that drives the port, so that a higher drive resistance means less drive capability and longer delays. Thus, a drive *resistance_value* of 0 is infinite drive, or no delay between the ports and all ports connected to them. Setting *resistance_value* to 0 is the same as removing the drive resistance with the *remove_drive_resistance* command.

There are two other methods of describing port drive capability. *set_driving_cell* command or the *set_input_transition* command. The most recent drive command has precedence.

Examples

The following example sets the drive resistance to 5 on all input ports in the current design, and displays the ports on which the drive resistance has been set.

```
pt_shell> set_drive 5 [all_inputs]
1
pt_shell> report_port -drive
****************************************
Report : port
```

Feedback

```
        -drive
Design : counter
*************************************

                 Resistance          Transition

```

See Also

- remove_drive_resistance
- report_port
- set_load

---

set_drive_resistance

Sets drive resistance for input or inout ports.

Note: This command is obsolete, and has been replaced by the *set_drive* command. Use the *set_drive* command instead.

Syntax

string *set_drive_resistance*

```
[-rise]
[-fall]
[-min]
[-max]
resistance
port_list
```

Data Types

```
resistance            float
port_list             list
```

Feedback

Arguments

`-rise`

Specifies to use the resistance to drive the ports for the rising case.

`-fall`

Specifies to use the resistance to drive the ports for the falling case.

`-min`

Specifies to use the resistance to drive the ports for the minimum case.

`-max`

Specifies to use the resistance to drive the ports for the maximum case.

`resistance`

Specifies a nonnegative resistance value for the ports. Port drive resistance (value >= 0).

`port_list`

Specifies a list of input or inout port names of the current design on which the drive attributes are to be set.

Description

Model the driver as a resistance and use that value to calculate the wire delay of the port. The *report_port -drive* command can be used to view the drive that is set.

Drive resistance is the output resistance of the cell that drives the port; such that a higher drive resistance means less drive capability and longer delays. Thus, a drive *resistance* of 0 is infinite drive, or no delay between the ports and all connected to them. This is the same as removing the drive resistance with the *remove_drive_resistance* command.

Drive resistance must be in units with the technology library.

Examples

Here is an example of the *set_drive_resistance* command in use.

```
pt_shell> set_drive_resistance 5 [all_inputs]
1
pt_shell> report_port -drive
****************************************
Report : port
         -drive
Design : counter
****************************************

                 Resistance          Transition
Input Port     Rise      Fall      Rise      Fall
```

Feedback

```

---

set_driving_cell

Sets the port driving cell.

Syntax

string *set_driving_cell*

```
-lib_cell lib_cell_name
[-rise]
[-fall]
[-min]
[-max]
[-library lib_name]
[-pin pin_name]
[-from_pin from_pin_name]
[-no_design_rule]
[-input_transition_rise rtran]
[-input_transition_fall ftran]
[-clock clock_name]
[-clock_fall]
[-sms_scenarios sms_scenarios_list]
port_list
```

Data Types

```
clock_name          string
from_pin_name       string
ftran               float
```

```
lib_cell_name          string
lib_name               string
pin_name               string
port_list              list
rtran                  float
sms_scenarios_list     collection
```

Arguments

`-lib_cell` *lib_cell_name*

Specifies the name of the library cell used to drive the ports. You must use the *-pin* option if the cell has more than one output pin. If different cells are needed for the rising and the falling cases, use separate commands with the *-rise* or *-fall* option.

Use the *-from_pin* option to choose between multiple input pins with arcs to this output pin. This option is required.

`-rise`

Sets driving cell information for only the rising port transition.

`-fall`

Sets driving cell information for only the falling port transition.

`-min`

Sets driving cell information for only the minimum analysis. This option is valid only in min-max mode.

`-max`

Sets driving cell information for only the maximum analysis. This option is valid even when not in min-max mode. When not in min-max mode, the option is not required because it is the default.

`-library` *lib_name*

Specifies the name of the library containing the *library_cell_name* value. This is the library of the driving cell. By default, the libraries specified with the *link_path* variable are searched for the cell.

`-pin` *pin_name*

Specifies the output pin whose drive is used. This is the driving pin name. If you do not include the *-from_pin* option, the command uses an arbitrary pin arc ending at the specified pin.

`-from_pin` *from_pin_name*

Specifies an input pin on the specified cell so the command uses the drive of the timing arc from this pin to the specified pin.

`-no_design_rule`

Prevents the transfer of design rules from the driving cell to the port. If you do not include this option, the design rules (such as *max_capacitance*) of the library pin are applied to the port.

`-input_transition_rise` *`rtran`*

Specifies the input rising transition time associated with the *-from_pin* option; if you do not include this option, the default is 0. Use the *-input_transition_rise* and *-input_transition_fall* options to capture the accurate transition time associated with the *from_pin_name* value. This can obtain more accurate information on the transition time and delay time at the output pin.

`-input_transition_fall` *`ftran`*

Specifies the input falling transition time associated with the *from_pin_name* value; if you do not include this option, the default is 0.

`-clock` *`clock_name`*

Specifies the clock related to the driving cell. This option is deprecated and ignored by the tool.

`-clock_fall`

Specifies that driving cell is relative to the falling edge of the clock. The default is the rising edge. This option is deprecated and ignored by the tool.

`-sms_scenarios`

Limits the specification to only the provided SMS scenarios. When this option is not given, the specification applies to all SMS scenarios. Use the *get_sms_scenarios* command to obtain SMS scenarios.

Only input transition times (*-input_transition_rise* and *-input_transition_fall* support this option. For other options, such as *-lib_cell*, the last value applies to all SMS scenarios.

`port_list`

Provides a list of input ports. The list contains input or inout port names in the current design on which the driving cell information is set.

Description

The *set_driving_cell* command sets the port driving cell. It sets attributes on the specified input or inout ports in the current design to associate an external driving cell with the ports. The drive capability of the port is the same as if the specified driving cell were connected in the same context to allow accurate modeling of port drive capability for nonlinear delay models. Use the *report_port* command with the *-drive* option to view drive information on ports.

To automatically set driving cell information on subdesign ports based on their context in the entire design, use the *characterize_context* command. To remove driving cell information from ports, use the *remove_driving_cell* command.

Note: There are two other methods of describing port drive capability, using the *set_drive* or *set_input_transition* command. The most recent drive command has precedence. If possible, always use the *set_driving_cell* command instead of the *set_drive* command because the *set_driving_cell* command allows accurate calculation of port delay and transition time for library cells with nonlinear dependence on capacitance.

Examples

The following example shows how to use the *set_driving_cell* command, and shows how to view drive information on ports using the *report_port* command.

```
pt_shell> set_driving_cell -lib_cell AND [get_ports A]

pt_shell> report_port -drive A
  ...

                 Resistance          Transition
Input Port    Rise      Fall      Rise      Fall
-----------------------------------------------------------
A             --        --        --        --

                     Driving Cell
Input Port    Rise                Fall          Mult    Attrs
-------------------------------------------------------------
A             AND                 AND           --
```

Feedback

set_eco_options

Specifies options for the *fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power* commands.

Syntax

```
status set_eco_options
   [-physical_tech_lib_path file_name_list]
   [-physical_lib_path file_name_list]
   [-physical_design_path file_name_list]
   [-physical_icc2_lib icc2_lib_directory_path]
   [-physical_icc2_blocks icc2_block_name_list]
   [-physical_constraint_file file_name]
   [-physical_lib_constraint_file file_name_list]
   [-log_file file_name]
   [-mim_group cell_list]
   [-filler_cell_names list]
   [-programmable_spare_cell_names list]
   [-drc_setup_margin margin]
   [-drc_hold_margin margin]
   [-timing_setup_margin margin]
   [-timing_hold_margin margin]
   [-power_setup_margin margin]
   [-power_hold_margin margin]
   [-physical_enable_clock_data]
   [-physical_enable_all_vias]
   [-keep_site_names site_name_list]
   [-convert_sites site_name_list]
   [-power_ground_net_layer pg_layer_name]
   [-allow_missing_lef macro_name_list]
   [-cell_em_profile profile_name]
   [-enable_pin_color_alignment_check]
   [-enable_via0_alignment_check]
```

Feedback

Arguments

`-physical_tech_lib_path` *`file_name_list`*

Specifies a list of technology files in Library Exchange Format (LEF). The tool uses the technology LEF files to understand the physical constraints that apply to the cell LEF files, including the layer definitions, via definitions, via rules, and overlapped layer constructs used to specify polygon shapes for LEF macros.

If multiple LEF files are being used, be sure to specify the technology LEF files before the cell LEF files in the file name list. Otherwise, physically aware ECO commands will not have the correct physical constraint definitions, leading to incorrect physical ECO results.

`-physical_lib_path` *`file_name_list`*

Specifies a list of physical library files in Library Exchange Format (LEF). The tool uses the physical library data to understand the physical constraints such as the physical shapes of pins, cells, and blocks.

For more information, see "Specifying LEF/DEF Files" in the EXAMPLES section.

`-physical_design_path` *`file_name_list`*

Specifies a list of physical data files in Design Exchange Format (DEF). The tool uses the physical design data to understand the design layout details such as available free sites and area utilization density.

The specified DEF files must exist, and the *DESIGN_NAME* fields in them must match block names in the current design. If a block already has DEF associated with it, this new specification overwrites the previous specification.

If this option is used together with the *-physical_constraint_file* option, only a single DEF file can be specified.

`-physical_icc2_lib` *`icc2_lib_directory_path`*

Specifies an IC Compiler II reference library directory path. The tool obtains all technology and cell LEF information from reference libraries in this directory. If you need additional LEF information not available in these reference libraries, you can also use the *-physical_lib_path* option.

Each *set_eco_options* command accepts no more than one physical IC Compiler II reference library directory path. However, you can use multiple *set_eco_options* commands to specify multiple reference library directory paths for the session.

`-physical_icc2_blocks` *`icc2_block_name_list`*

Specifies a list of IC Compiler II block names. The PrimeTime tool reads in the physical block data from the library directory path specified by the *-physical_icc2_lib* option. The tool reads in only the physical data for the listed blocks.

`-physical_constraint_file` *`file_name`*

Specifies a file that contains *create_voltage_area* or *create_placement_blockage* commands. These commands specify the following physical constraints:

- Voltage areas - In a design with multiple voltage areas, the tool needs to know their locations so it can place each buffer in the correct area. To specify voltage areas, include *create_voltage_area* commands in the physical constraint file.
- Placement blockages - To prevent buffer insertion and cell resizing in specific areas, specify the placement blockage areas by including *create_placement_blockage* commands in the physical constraint file.

Failing to include necessary *create_voltage_area* and *create_placement_blockage* commands in the physical constraint file might result in poor QoR or incorrect results.

The physical constraint file is applied to the physical block specified by the *-physical_design_path* DEF file. As a result, only a single DEF file can be specified at a time when a physical constraint file is also specified.

Physical constraint file specifications remain on a block until replaced or explicitly removed with an empty string (*-physical_constraint_file {}*) specification.

`-physical_lib_constraint_file` *`file_name_list`*

Specifies a list of physical library constraint files. A file can contain user-specified *set_lib_cell_spacing_label* and *set_spacing_label_rule* commands to specify intercell spacing labels and rules. It can also contain advanced-node spacing constraints for objects on the Vth implant, diffusion, and poly layers. It can be a user-written ASCII text file or a binary file written by the *export_advanced_technology_rules* command of the IC Compiler or IC Compiler II tool.

`-log_file` *`file_name`*

Specifies the name of a log file. The tool writes warning and error messages to this file when it loads the physical library and physical design files. Review the log file if the tool encounters any issues during physical ECO fixing.

`-mim_group` *`cell_list`*

Specifies a list of cells to be treated as a set of multiply instantiated module (MIM) instances that share a similar context. This option has an effect only if the *eco_enable_mim* variable is set to *true*.

When the *eco_enable_mim* variable is set to *true*, the tool automatically detects multiple instances of the same cell and puts those cells into a MIM group. The *write_changes* command assumes that the members of a MIM group have similar context, and therefore creates a single change list that applies to all members of the MIM group. You can use the *-mim_group* option to separate a large MIM group into smaller MIM groups, each having a different context and a separate change list.

No actual changes are made to the design until you run an ECO command: *fix_eco_timing*, *fix_eco_drc*, or *fix_eco_power*. As a result, the tool reports any MIM specification errors at that time.

You can view the current MIM configuration by using the *report_eco_options* command. You can use the *reset_eco_options* command to remove it if no ECO changes have been made to the design.

For more information, see "Specifying Multiply Instantiated Module (MIM) Groups" in the DESCRIPTION section.

`-filler_cell_names` *`list`*

Specifies the names of LEF library cells that are to be treated as filler cells by physically aware ECO commands, even when the cells do not meet the filler cell LEF requirements. For details, see "Filler Cells" in the EXAMPLES section.

`-programmable_spare_cell_names` *`list`*

Specifies a list of programmable spare cell leaf names for the freeze silicon physical ECO flow. Each programmable spare cell in the list must be:

- Defined in the .lib library files
- Defined as a MACRO in the LEF files specified by the *-physical_lib_path* option
- Instantiated as + *SOURCE DIST* + *PLACED* components in the DEF files specified by the *-physical_design_path* option

  Do not use wildcard characters to specify the leaf names.

  For more information, see "Programmable Spare Cells" in the EXAMPLES section.

`-drc_setup_margin` *`margin`*

Specifies the amount of setup slack to maintain during DRC fixing by the *fix_eco_drc* command. The default is negative infinity; that is, the *fix_eco_drc* command fixes violations no matter how much setup slack is degraded. Specify the margin in library time units.

`-drc_hold_margin` *`margin`*

Specifies the amount of hold slack to maintain during DRC fixing by the *fix_eco_drc* command. The default is negative infinity; that is, the *fix_eco_drc* command fixes violations no matter how much hold slack is degraded.

`-timing_setup_margin` *`margin`*

Specifies the amount of setup slack to maintain during timing fixing by the *fix_eco_timing* command. The default is zero. Specify the margin in library time units.

`-timing_hold_margin` *`margin`*

Specifies the amount of hold slack to maintain during timing fixing by the *fix_eco_timing* command. The default is zero.

`-power_setup_margin` *`margin`*

Specifies the amount of setup slack to maintain during power recovery by the *fix_eco_power* command. The default is zero. Specify the margin in library time units.

`-power_hold_margin` *`margin`*

Specifies the amount of hold slack to maintain during buffer removal by the *fix_eco_power* command. The default is zero. This option applies only to buffer removal, not cell swapping or downsizing.

`-physical_enable_clock_data`

Enables usage of clock network physical data for ECO purposes. Without this option, ECO operations ignore physical data for the clock network.

`-physical_enable_all_vias`

Enables reading of physical data for all vias. Without this option, the tool ignores physical data for all vias.

`-keep_site_names` *`site_name_list`*

Specifies a list of DEF cell row site names. When reading physical data, the tool saves the corresponding rows defined in DEF. By default, the tool saves all cell rows that have legal site definitions in LEF.

`-convert_sites` *site_name_list*

Specifies the conversion of the DEF and LEF site names in physically aware ECO flows. Use the following syntax to specify the site name conversion:

`-convert_sites {{`*old_site1 new_site_1*`} {`*old_site2 new_site2*`} ...}`

Use this option when the LEF site names do not match the DEF site names or identical sites are defined with different site names in multiple DEF or LEF files. When the tool reads in the physical data for the design, any site names that match the old site names of site_name_list are converted to the new site names in DEF and LEF files.

`-power_ground_net_layer` *pg_layer_name*

Specifies the power/ground (PG) net layer name for power/ground (PG) straps. These straps are typically vertical on bottom metal layers.

With this option, the tool keeps information for PG straps on the specified layer when the physical data is read. ECO commands (*fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power*) use this saved data during physically aware ECO to avoid DRC violations between PG straps and signal pins.

Without this option, PG straps will not be known to ECO fixing. This can lead to physical DRC violations caused by ECO cell signal pin proximity to PG straps in the design, resulting in cell displacements or routing challenges.

Note: This option requires a PrimeTime-ADV-PLUS license.

`-allow_missing_lef`

Specifies a list of model names that are allowed to have missing LEF macros. Components associated with these model names are ignored by physical ECO commands, instead of causing them to fail.

`-cell_em_profile`

Specifies the name of cell electromigration (EM) lifetime profile to be considered during cell EM fixing (*fix_eco_drc -type cell_em*). Only those EM violations will be considered whose profile name matches with that provided with this option. By default, all EM violations will be considered for fixing. To reset a previously specified value back to default behavior, behavior, specify a value of *default* with this option.

`-enable_pin_color_alignment_check`

Enables checking for proper color alignment of cell internal pins and metal shapes with routing tracks during ECO optimization. Without this option, ECO optimization does not perform the pin color alignment check.

Note: This option requires a PrimeTime-ADV-PLUS license.

`-enable_via0_alignment_check`

Enables checking for proper alignment of cell PG pin internal via0 shapes with the via0 grid during ECO optimization. Without this option, ECO optimization does not perform the via0 alignment check.

Description

The *set_eco_options* command specifies the files that contain physical data for physical ECO commands: *fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power*. You must set the ECO options before you run the physical ECO commands.

Like the *link_path* variable that specifies the files to be linked, the files specified by *set_eco_options* command are not loaded into memory when you run the command. Instead, a physical ECO command (such as *fix_eco_timing*) identifies the files specified by the *set_eco_options* command and loads them into memory before fixing begins.

Distributed Multi-Scenario Analysis

To run the *set_eco_options* command in the DMSA flow, use the *remote_execute* command to run it in the worker processes. You cannot run the *set_eco_options* command in the manager process.

Specifying Multiply Instantiated Module (MIM) Groups

When the *eco_enable_mim* variable is set to *true*, the tool automatically detects multiple instances of the same cell and puts those cells into a MIM group. The *write_changes* command assumes that the members of a MIM group have similar context, and therefore creates a single change list that applies to all members of the MIM group.

You can break an existing MIM group into multiple groups or specify a MIM group for a flat parasitics file by using the *-mim_group* option of the *set_eco_options* command. Note that if there is an existing MIM group, you cannot specify a new MIM group or add new instances to the MIM group; you can only break a MIM group into smaller MIM groups.

Suppose a module called CPU is instantiated five times in the TOP design as CPU1 through CPU5, and there are CPU.def and CPU.SPEF files associated with the CPU module. Also you have the following command in your script:

```
read_parasitics -path {CPU1 CPU2 CPU3 CPU4 CPU5} CPU.SPEF
```

If the *eco_enable_mim* variable is set to *true*, when you use the *fix_eco_timing*, *fix_eco_drc*, or *fix_eco_power* command, the tool detects the CPU module as a MIM. However, you might want to break the 5-instance MIM three groups, {CPU1 CPU2}, {CPU3 CPU4}, and {CPU5}, because of large timing differences between the three groups. In this case, use the following script:

```
set_eco_options -mim_group {CPU1 CPU2}
set_eco_options -mim_group {CPU3 CPU4}
```

The instance CPU5 implicitly belongs to its own MIM group, so it is effectively treated as an independent, non-MIM instance.

Suppose the CPU instances are now grouped into three MIM groups: {CPU1 CPU2}, {CPU3 CPU4} and {CPU5}. Suppose each CPU module also includes two instances of the ALU module, ALU1 and ALU2. The ALU instances are not treated as MIMs because regrouping instances in different MIM groups is not allowed, and creating new MIM groups is not allowed.

Suppose that you have a hierarchical netlist but a single flat parasitic data file. In this case, the tool cannot infer MIM groups from identical parasitic data, even when the *eco_enable_mim* variable is set to *true*. However, you can explicitly specify the MIM groups as follows:

```
set_eco_options -mim_group {CPU1 CPU2 CPU3 CPU4 CPU5}
```

Suppose the CPU module includes an ALU module, which is also a MIM. This is an example of a nested MIM hierarchy. The following commands specify this configuration to recognize both the CPU and ALU modules as MIMs.

```
set_eco_options -mim_group [all_instances -hierarchy CPU]
set_eco_options -mim_group [all_instances -hierarchy ALU]
```

The *set_eco_options* commands must define the MIM groups in order, from higher to lower in the hierarchy. Reversing the order of the two commands would not work correctly.

Examples

Specifying LEF/DEF files

Specify LEF files with the *-physical_lib_path* option and DEF files with the *-physical_design_path* option:

```
pt_shell> set lef_files      [glob $my_physical_data/lef/cell_lef_*.lef]
pt_shell> set tech_lef_files [$my_physical_data/lef/technology.lef]
pt_shell> set_eco_options -physical_tech_lib_path $tech_lef_files \\
                          -physical_lib_path $lef_files \\
                          -physical_design_path design.def.gz \\
                          -log_file ./error.log
```

The following script specifies the same information in a distributed multi-scenario analysis environment.

```
remote_execute -verbose {
  set lef_files      [glob $my_physical_data/lef/cell_lef_*.lef]
  set tech_lef_files [$my_physical_data/lef/technology.lef]
  set_eco_options -physical_tech_lib_path $tech_lef_files
                  -physical_lib_path $lef_files
                  -physical_design_path design.def.gz
                  -log_file ./error.log
}
```

Overwriting DEF and physical constraint file specifications

Specify a DEF file and its associated physical constraint file:

```
pt_shell> set_eco_options -physical_design_path     design.def.gz \\
                          -physical_constraint_file phy_constr.tcl
```

Replace the previous DEF specification by a new DEF file for the same design, while preserving the physical constraint file specification:

```
pt_shell> set_eco_options -physical_design_path
  same_design.new_def.gz
Warning: Overwriting previously defined physical data specification for
 block 'design'.
```

Replace both specifications by new files:

```
pt_shell> set_eco_options -physical_design_path
  same_design.new_def.gz \\
                          -physical_constraint_file new_phy_constr.tcl
Warning: Overwriting previously defined physical data specification for
 block 'design'.
```

Specifying Physical Data From the IC Compiler II Database

To specify technology and cell LEF information from the IC Compiler II tool, use the *-physical_icc2_lib* option; and to specify the physical block design information, use the *-physical_icc2_blocks* option:

```
pt_shell> set icc2_lib_directory_path $my_icc2_ndm_lib_directory
pt_shell> set icc2_blocks $my_block
pt_shell> set_eco_options -physical_icc2_lib $icc2_lib_directory_path \\
                             -physical_icc2_blocks $my_block \\
                             -log_file ./error.log
```

Labels may be used to distinguish between alternate versions of a block. To do so, specify the label name after the block name, separated by a slash:

```
pt_shell> set_eco_options -physical_icc2_lib $icc2_lib_directory_path \\
                             -physical_icc2_blocks $my_block/$my_label \\
                             -log_file ./error.log
```

Filler Cells

PrimeTime physically aware ECO commands follow LEF and DEF rules to identify filler cells. Both the LEF and DEF requirements must be met for components to be treated as filler cells.

To identify a filler cell macro, the LEF macro must have its CLASS CORE type specified as SPACER or FEEDTHRU, as shown in the following example.

```
MACRO FILL1TLL
 CLASS CORE SPACER ;
 ORIGIN 0 0 ;
 SIZE 6.4 BY 1.6 ;
```

To identify a filler cell component, the DEF component must be a physical-only cell as specified by the + SOURCE DIST construct in the component definition. In addition, the filler cell component must be marked as + PLACED, must have valid physical coordinates and orientation specified, and must not be present in the Verilog netlist. For example,

```
xofiller!FILL4TLL!11037 FILL43TLL + SOURCE DIST + PLACED ( 264300
 624100 ) N ;
```

Filler cell components marked as + FIXED or + COVER cannot be used for ECO and are treated as permanent occupied sites.

You can relax the LEF requirements for filler cells by using the *-filler_cell_names* option of the *set_eco_options* command. With this option, you can specify any LEF macro to be a filler cell. For example,

```
set user_filler_cells "FILL4TLL"
set_eco_options -physical_lib_path $lef_files
                -physical_design_path design.def.gz
                -filler_cell_names $user_filler_cells
                -log_file ./error.log
```

All automatically detected and user-specified LEF filler cell macros are reported in the LEF/DEF log file as shown in the following examples.

```
Information: Identified auto filler cell FILL8TLL at lineNumber 10.
Information: Identified user filler cell FILL4TLL at lineNumber 11.
```

The DEF filler cell requirements must be met, even if you relax the LEF filler cell requirements. The physically aware ECO commands treat all components that meet the LEF and DEF requirements as filler cells. If the *eco_allow_filler_cells_as_open_sites* variable is set to *true*, physically aware ECO commands treat all filler cell components as open sites.

Programmable Spare Cells

The following example specifies programmable spare cells in the LEF/DEF files.

To identify a programmable spare cell macro, the LEF macro must be defined in one of the LEF files specified by the *-physical_lib_path* option; there are no other LEF requirements. For example,

```
MACRO FILL4TLL
 CLASS CORE ;
 ORIGIN 0 0 ;
 SIZE 6.4 BY 1.6 ;
```

To identify a programmable spare cell component, the DEF component must be a physical-only cell as specified by the + SOURCE DIST construct in the component definition. In addition, the programmable spare cell component must be marked as + PLACED and must have valid physical coordinates and orientation specified. For example,

```
xofiller!FILL4TLL!lvt!11037 FILL4TLL + SOURCE DIST + PLACED ( 264300
 624100 ) N ;
```

Spare cell components marked as + FIXED or + COVER are not treated as programmable spare cells in the freeze silicon physical ECO flow.

To report all user-specified programmable spare cells names, use the *report_eco_options* command. All LEF programmable spare cell macros detected by the tool are reported in the LEF/DEF log as shown in the following example:

```
Information: Identified programmable spare cell FILL4TLL at lineNumber
 10.
```

Specifying Physical Library Spacing Rule Constraints

The following example specifies a physical library constraint file containing spacing rules.

```
set rule_file spacing_rules.tcl
set_eco_options -physical_lib_path $lef_files
                -physical_design_path design.def.gz
                -physical_lib_constraint_file $rule_file
                -log_file ./error.log
```

Enabling Physically Aware Clock Network ECOs

The following example enables reading physical data for the clock network.

```
pt_shell> set_eco_options -physical_enable_clock_data
```

Enabling Physical Loading of All Vias

The following example enables reading physical data for all vias.

```
pt_shell> set_eco_options -physical_enable_all_vias
```

Specifying Site Names

The following example enables saving DEF rows defined with the site name "unit1" when reading physical data.

```
pt_shell> set_eco_options -keep_site_names {unit1}
```

Converting DEF Sites

The following example converts DEF rows of site "unit" into rows of site "CORE2T".

```
pt_shell> set_eco_options -convert_sites {{unit CORE2T}}
```

This specifies the mapping of site names from the DEF to the LEF file:

```
In DEF file:

ROW STD_ROW_324 unit 560 85680 FS ...;
ROW STD_ROW_325 unit 560 88200 N ...;

In LEF file:

SITE CORE2T
  CLASS CORE ;
  SYMMETRY X Y ;
  SIZE 0.14 BY 1.2 ;
END CORE2T
```

Specifying Power Ground Net Layer

The following example enables PG aware ECO and saves physical data for PG on layer M1.

```
pt_shell> set_eco_options -power_ground_net_layer M1
```

Allowing Missing LEF Macros

The following example allows components to be associated with two model names that are not present as LEF macros.

```
pt_shell> set_eco_options -allow_missing_lef { MODEL1 MODEL2 }
```

Specifying Cell EM Lifetime Profile name

The following example sets profile_a as profile to be considered during cell EM fixing

```
pt_shell> set_eco_options -cell_em_profile profile_a
```

Enabling Cell Pin Color Alignment Checking

The following example enables color alignment checking during ECO optimization for cell-internal pins and metal shapes.

```
pt_shell> set_eco_options -enable_pin_color_alignment_check
```

Enabling via0 Alignment Checking

The following example enables via0 alignment checking during ECO optimization.

```
pt_shell> set_eco_options -enable_via0_alignment_check
```

set_eco_scenarios

Controls how violation types are considered across scenarios during live and static scenario analysis.

Syntax

```
status set_eco_scenarios
[-only]
[-ignore]
-type fix_type_list
scenario_name_list
```

Data Types

```
scenario_name_list   list
fix_type_list        list
```

Arguments

`-only`

Specifies that in the *scenario_name_list* scenarios, only the *fix_type_list* violation types will be considered by live/static scenario selection. Other violation types will be ignored.

Feedback

`-ignore`

Specifies that in the *scenario_name_list* scenarios, the specified *fix_type_list* violation types will be ignored by live/static scenario selection. Other violation types will be considered.

`-type` *`fix_type_list`*

Specifies a list of one or more timing violation types: *setup*, *hold*, *max_transition*, *max_capacitance*, or *noise*.

`scenario_name_list`

Specifies one or more scenarios to which the specification applies.

Description

The *set_eco_scenarios* command allows you to control what data is considered for live and static scenario analysis and selection in the hybrid ECO flow. For example, you could ignore setup slacks in certain hold-only scenarios.

The *-only* and *-ignore* options are mutually exclusive; one of them must be specified.

Note that this command affects only the live and static scenario analysis performed during the *start_eco_scenarios* or *report_eco_scenarios* command; it does not affect what data is used by the *fix_eco_** commands themselves.

Examples

The following example considers only setup timing violations in ss1, ss2, ss3 and ss4 scenarios:

```
pt_shell> set_eco_scenarios -only -type {setup} {ss1 ss2 ss3 ss4}
```

The following example ignores setup timing violations in ff1, ff2, ff3 and ff4 scenarios:

```
pt_shell> set_eco_scenarios -ignore -type {setup} {ff1 ff2 ff3 ff4}
```

---

set_em_analysis_options

Sets the options for cell EM analysis.

Feedback

Syntax

status *set_em_analysis_options*

```
[-in_slew slew_type]
[-cload_type load_type]
[-cload_val load_val]
[-current_type current_type]
```

Data Types

```
slew_type          max | min | avg
load_type          tot | eff
load_val           max | min | avg
current_type       rms | peak | ave
```

Arguments

`-slew_val max | min | avg`

Specifies slew value to be used in cell EM analysis. Default slew value is avg.

`-cload_type tot | eff`

Specifies load type to be used in cell EM analysis. Default cload type is effective.

`-cload_val max | min | avg`

Specifies load value to be used in cell EM analysis. Default load value is avg.

`-current_type rms | peak | ave`

Specifies that EM analysis options will be applied to spesific current type.

Description

Command to specify various analysis options for cell EM analysis in PrimePower. The options from this command will control how cell EM analysis behaves for specific analysis type.

Examples

The following example will use effective max capacitance, min slew for rms type cell EM analysis.

```
pt_shell> > set_em_analysis_options -in_slew min -cload_val max
 -cload_type eff -current_type rms
```

See Also

- get_em_max_toggle_rate
- report_cell_em_violation

Feedback

set_em_scaling_factor

Sets EM scaling factors for specified current type on a library cell EM arc.

Syntax

status *set_em_scaling_factor*

```
[-input_pin input_pin]
[-output_pin output_pin]
[-factor factor]
[-current_type current_type]
object
```

Data Types

```
input_pin         list
output_pin        list
factor            float
current_type      rms | peak | ave
object               list
```

Arguments

`-input_pin list`

Specifies input library pin name for EM arc.

`-output_pin list`

Specifies output library pin name for EM arc.

`-factor float`

Specifies cell EM scaling factor that is to be applied on the specified arc.

`-current_type rms | peak | ave`

Specifies scaling factor to be set for specific current type on an arc. The current type are ave, rms, peak. Default it will applied to all current type.

`object list`

Specifies library cells for which the EM scaling factor is applied.

Description

The command allows user to set a scaling factor for max toggle rate looked up from library cell EM arc. Scaling factor can be EM arc specific and current type specific. The scaling factor is applied on original max toggle rate from library.

Feedback

Examples

```
pt_shell> > set_em_scaling_factor -input_pin  a -output_pin  a
 -current_type ave -factor 0.5 tech_3.3v_25t_1p/buf1
```

See Also

- get_em_max_toggle_rate
- report_cell_em_violation

---

set_emmp_configuration

Specifies the configuration options to run estimate_memory_max_power command for a hierarchical cell and groups of leaf cell.

Syntax

status *set_emmp_configuration*

```
hier_instance_name
-list leaf_instance_group_list
```

Data Types

```
hier_instance_name           string
leaf_instance_group_list     list
```

Arguments

hier_instance_name

To specify the hierarchical cell for which the maximum power estimation is to be done.

leaf_instance_group_list

To specify the list of groups, the groups specify list of leaf cell.

Description

The *set_emmp_configuration* command specifies the logical memory configuration for a hierarchical memory cell which has leaf level memory cells. The user can specify groups of leaf memory cells. The activity on hierarchy memory cell will be shared between groups. The user must set this configuration before estimate_memory_max_power analysis with state_derate_pairs options.

Examples

The following examples shows set memory configuration. Here mem is the hierarchical cell and p1, p2, p3 and p4 are leaf level memory cells inside "mem".

Feedback

```
pt_shell> set_emmp_configuration mem -list "{p1 p2} {p3 p4}"
```

See Also

- reset_emmp_configuration
- estimate_memory_max_power

---

set_equal

Sets two ports to be logically equivalent.

Syntax

```
status set_equal
  port1
  port2
```

Data Types

```
port1        string
port2        string
```

Arguments

port1

Specifies the first input port.

port2

Specifies the second input port.

Description

Defines two input ports in the current design as logically equivalent. This information is used during synthesis to eliminate redundant ports, improving optimization quality.

Logical inconsistencies are checked for in relationships between ports. Specifying an inconsistent logical relationship between ports is not allowed.

To remove this property from a port, run the *reset_design* command.

This attribute is characterized by the *characterize_context* command and exported to synthesis using the *write_context* command.

Examples

The following example sets two input ports "A" and "B" logically equal.

```
pt_shell> set_equal A [get_ports B]
1
```

The following example sets up a contradictory relationship between two ports and creates an error.

```
pt_shell> set_equal A B
1
pt_shell> set_opposite A B
Error: Can't set equal ports opposite in design 'top': 'A' 'B'. (DDB-22)
0
```

See Also

- characterize_context
- set_opposite
- write_context

---

set_equivalent

Declares a set of supply nets to be treated as equivalent.

Syntax

string *set_equivalent*

```
-nets list_of_supply_nets
-reset
```

Data Types

list_of_supply_nets	list
reset	boolean

Arguments

`-nets list_of_supply_nets`

Specifies the list of supply nets declared equivalent by this command.

`-reset`

Reset the equivalence of the supply nets specified with optional -nets argument. If -nets is not specified, all equivalences set before are removed. All other arguments are invalid if this option is specified.

`-primary_net supply_net name`

Specifies the supply net that is to refer all other nets declared equivalent by this command.

Feedback

Description

The *set_equivalent* command declares a list of supply nets to be equivalent. As a result, the supply nets are considered to be always at the same voltage. The *set_voltage* and *set_voltage_levels* commands apply to all the supply net segments of the equivalent supply nets. For simultaneous multivoltage analysis (SMVA), no domain crossing is inferred between the equivalent supply nets.

The behavior of *set_equivalent* is analogous to the connections inferred through UPF power switches when the *upf_power_switches_always_on* variable is set to *true*.

Examples

The following command declares the supply nets VDD, VDDS, VDD2 and VDD2S to be equivalent:

```
pt_shell> set_equivalent -nets {VDD VDDS VDD2 VDD2S}
1
```

The following command declares the supply nets VDDI, VDDIS and VDDW to be equivalent, and it also sets VDDW to be the supply group that refers to them:

```
pt_shell> set_equivalent -nets {VDDI VDDIS VDDW} -primary_net VDDW
1
```

Note that the *set_equivalent* command does not create a supply group for each equivalent net. The *-primary_net* option must be used to identify a single net to be used as the supply group reference net, which can then be referenced by other commands such as *set_voltage_levels*.

- set_voltage_levels
- upf_power_switches_always_on

---

set_essential_map

Sets the dumping of essential mapping files.

Syntax

int *set_essential_map*

option

Feedback

Data Types

option bool

Arguments

option

Specifies whether to write out the essential or non-essential mapping files.

Description

The *set_essential_map* writes out the essential and non-essential mapping files in the PrimePower RTL tool. Essential mapping file: Contains mapping for all essential design nodes such as primary inputs, sequential outputs, memory, instantiated clock gate cell outputs and black-box pins. Non-essential mapping file: Contains map info only for design nodes that underwent a name change. The default is true, the RTL Architect tool writes out an essential mapping file. When set to false, the RTL Architect writes out the non-essential map file.

Examples

This example writes out the essential mapping file

```
pwr_shell> set_essential_map true
```

---

set_extract_model_indexes

Sets indexes on specified ports for extracted timing model (ETM) generation.

Syntax

```
status set_extract_model_indexes
  [-ports port_list]
```

```
  -type transition | capacitance
  [-min]
  [-max]
  [-rise]
  [-fall]
  index_list
```

Data Types

```
port_list      list
index_list     list
```

Arguments

`-ports port_list`

Specifies a list of ports on which to set the index values. If you do not specify this option, the command sets index values on all ports by default.

`-type transition | capacitance`

Applies the *index_list* to transition (slew) or capacitance (load) tables in the ETM library.

`-min`

Applies the *index_list* to minimum arcs only. If you specify neither *-min* nor *-max*, the command applies the index values to both minimum and maximum arcs.

`-max`

Applies the *index_list* to maximum arcs only. If you specify neither *-min* nor *-max*, the command applies the index values to both minimum and maximum arcs.

`-rise`

Applies the *index_list* to rise timing tables only. If you specify neither *-rise* nor *-fall*, the command applies the index values to both rise and fall tables.

`-fall`

Applies the *index_list* to fall timing tables only. If you specify neither *-rise* nor *-fall*, the command applies the index values to both rise and fall tables.

index_list

Specifies a list of index values (floating) to be applied on specified ports. The index values should be positive and monotonically increasing.

Description

This command replaces automatically generated indexes with the user-specified indexes on specific ports.

If the *extract_model* command detects index values that violate maximum and minimum bounds set in the library for max_transition and max_capacitance, automatic indexing is used for those ports.

See Also

- extract_model
- reset_extract_model_indexes

---

set_extract_model_margin

Sets margins to be applied to specified ports in extracted timing model (ETMs).

Syntax

```
status set_extract_model_margin
 [-ports port_list]
 [-min]
 [-max]
 margin_value
```

Data Types

```
port_list    list
margin_value   float
```

Arguments

`-ports port_list`

Specifies a list of ports on which to apply the specified margin. If you do not specify this option, the command sets the margin on all ports by default.

`-min`

Applies the *margin_value* to minimum arcs only. If you specify neither *-min* nor *-max*, the command applies the margin to both minimum and maximum arcs.

`-max`

Applies the *margin_value* to maximum arcs only. If you specify neither *-min* nor *-max*, the command applies the margin to both minimum and maximum arcs.

margin_value

Specifies the absolute margin as a positive floating point number in units of main library. The margin is applied after ETM generation.

Feedback

Description

This command applies a margin value to offset the values in the table. For maximum arcs, the margin is added to already computed delay values. For minimum arcs, the margin is subtracted from the delay values.

To reset the margin values, specify a margin value of 0.

See Also

- extract_model

---

set_false_path

Identifies paths in a design that are to be marked as false, so that they are not considered during timing analysis.

Syntax

status *set_false_path*

```
[-setup]
[-hold]
[-rise]
[-fall]
[-reset_path]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-comment comment_string]
[-sms_scenarios sms_scenarios_list]
```

Data Types

comment_string	string
fall_from_list	list
fall_through_list	list
fall_to_list	list
from_list	list
rise_from_list	list
rise_through_list	list
rise_to_list	list
sms_scenarios_list	collection
through_list	list
to_list	list

Feedback

Arguments

`-setup`

Indicates that setup (maximum) paths are to be marked as false. This option disables setup checking for specified paths. If you do not specify either the *-setup* or *-hold* option, both setup and hold timing are marked false.

`-hold`

Indicates that hold (minimum) paths are to be marked as false. This option disables hold checking for specified paths. If you do not specify either the *-setup* or *-hold* option, both setup and hold timing are marked false.

`-rise`

Indicates that rising delays are to be marked as false, as measured on the path endpoint. If you do not specify either the *-rise* or *-fall* option, both rise and fall timing are marked false.

`-fall`

Indicates that falling delays are to be marked as false, as measured on the path endpoint. If you do not specify either the *-rise* or *-fall* option, both rise and fall timing are marked false.

`-reset_path`

Indicates that existing point-to-point exception information is to be removed from the specified paths. If used with only the *-to* option, all paths leading to the specified endpoints are reset. If used with only the *-from* option, all paths leading from the specified startpoints are reset. If used with the *-from* and *-to* options, only paths between those points are reset. Only information of the same rise/fall setup/hold type is reset. This is equivalent to using the *reset_path* command with similar arguments before the *set_false_path* command is issued.

`-from` *`from_list`*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected.

You can use only one of the *-from*, *-rise_from*, or *-fall_from* options.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the

clock source, taking into account any logical inversions along the clock path. You can use only one of the *-from*, *-rise_from*, or *-fall_from* options.

`-fall_from` *`fall_from_list`*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the *-from*, *-rise_from*, or *-fall_from* options.

`-through` *`through_list`*

Specifies a list of pins, ports, cells or nets through which the disabled paths must pass. By default, a net is interpreted to imply its driver pins. In case the previous *through_list* includes the driver, the net is interpreted to imply its load pins. If you do not specify any type of *through* option, all timing paths specified using the *-from* and *-to* options are affected.

You can use multiple *-through*, *-rise_through*, and *-fall_through* options in a single command to specify paths that traverse through multiple points in the design. The tool respects the order in which you specify these options.

The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If you specify more than one object with one *-through*, *-rise_through*, or *-fall_through* option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

`-rise_through` *`rise_through_list`*

The same as the *-through* option, but the paths must have a rising transition at the through points.

`-fall_through` *`fall_through_list`*

The same as the *-through* option, but the paths must have a falling transition at the through points.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and

primary outputs related to that clock are used as path endpoints. If you specify a cell, one path endpoint on that cell is affected.

You can use only one of the *-to*, *-rise_to*, or *-fall_to* options.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options.

`-fall_to` *`fall_to_list`*

Same as the *-to* option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options.

`-comment` *`comment_string`*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this false path is applied. When this option is not given the false applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

The *set_false_path* command marks startpoint/endpoint pairs as false timing paths; that is, paths that cannot propagate a signal. The command removes timing constraints on these false paths, so that they are not considered during timing analysis. Path startpoints are input ports or register clock pins; path endpoints are register data pins or output ports. The command disables maximum delay (setup) checking and minimum delay (hold) checking for the specified paths.

The *set_false_path* command is a point-to-point timing exception command, and overrides the default single-cycle timing relationship for one or more timing paths. False path information always takes precedence over multicycle path information. Also, the *set_false_path* command overrides the *set_max_delay* and *set_min_delay* commands.

In general, for timing exceptions with different path specifications, the more specific command has priority over the more general one. False paths represent an exception to

this rule. If a timing path is satisfied by two or more false path specifications, the more general one wins. This can be seen with the *report_exceptions -ignored* command.

To disable the timing at a particular cell along a path, use the *set_disable_timing* command.

To remove the false path designations set by the *set_false_path* command, use the *reset_path* command.

For crosstalk analysis the false paths are treated as sensitizable. Therefore, the aggressors on the false paths could still effect its victims. However, the presence of false path could change the borrow behavior in level-sensitive latch designs, potentially borrow latches may no longer borrow leading to change in delta delays for logic nets that are in the fanout of affected latches. When the clocks are asynchronous to each other, the *set_clock_groups -asynchronous* command should be used instead of the *set_false_path* command between the asynchronous clocks. Without the *set_clock_groups -asynchronous* command, the clocks are treated to be synchronous to each other.

When a path has transparent latches in the interior of the path, and there are more than one path specifier (*-from*, *-through*, or \B-to*), set_false_path is only applied when all the path specifiers can be satisfied within one combinational segment between sequential elements. Commands using -from pin, and -to pin, with a transparent latch in between, will be ignored, because both specifiers could not be satisfied in a single combinational segment between sequential elements.*

Examples

The following example disables timing paths from ff12 to ff34.

```
pt_shell> set_false_path -from ff12 -to ff34
```

The following example disables rising timing paths from U14/Z to ff29/Reset.

```
pt_shell> set_false_path -rise_from U14/Z -to ff29/Reset
```

The following examples disables hold checking for endpoints clocked by CLK1.

```
pt_shell> set_false_path -hold -to [get_clocks CLK1]
```

The following example disables all timing paths from ff1/CP to ff2/D that pass through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C}.

```
pt_shell> set_false_path -from ff1/CP -through {U1/Z U2/Z}
            -through {U3/Z U4/C} -to ff2/D
```

The following example disables all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall to one or more of {U3/Z U4/C}.

Feedback

```
pt_shell> set_false_path -from ff1/CP
            -rise_through {U1/Z U2/Z}
            -fall_through {U3/Z U4/C} -to ff2/D
```

---

set_fanout_load

Sets fanout_load for output ports in the current design.

Syntax

string *set_fanout_load*

```
[-sms_scenarios sms_scenarios_list]
value
port_list
```

Data Types

```
port_list           list
sms_scenarios_list  collection
value               float
```

Arguments

value

Shows the *fanout_load* value, in units consistent with the *fanout_load* and *max_fanout* values in the technology library.

port_list

Provides a list of output ports.

Feedback

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this fanout load is applied. When this option is not given the fanout load applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

Specifies a *fanout_load* for output ports in the current design. By default, ports are considered to have fanout_load of 0.0. Fanout load for a net is the sum of *fanout_load* attributes for all input pins and output ports connected to the net. Output pins may have maximum fanout limits, specified in the library or with the *set_max_fanout* command.

The *report_constraint -max_fanout* command shows maximum fanout constraint evaluations. The *report_port -design_rule* command shows port *fanout_load* values.

To remove *fanout_load* information from ports, use the *remove_fanout_load* command.

Examples

This example sets the fanout_load on ports matching "OUT*" to 3.0.

```
pt_shell> set_fanout_load 3.0 "OUT*"
```

See Also

- remove_fanout_load
- report_constraint
- report_port

---

set_glitch_power_analysis_options

Sets the options for glitch power analysis.

Syntax

Boolean *set_glitch_power_analysis_options*

```
[-exclude_nets exclude_nets]
[-max_fanout max_fanout ]
[-max_slew max_slew]
```

Data Types

```
exclude_nets          list
max_fanout            integer
max_slew              float
cycle_based_glitch    booean
```

Feedback

Arguments

`-exclude_nets` *exclude_nets*

Specifies the net which are selectively disabled for glitch analysis.

`-max_fanout` *max_fanout*

Specifies max_fanout limit for net to be considered as HFN net for glitch analysis.

`-max_slew` *max_slew*

Specifies max_slew limit for net to be considered as HFN net for glitch analysis.

`-cycle_based_glitch`

Enables PrimePower to do clock cycle based glitch detection in time based analysis. This is allowed for regular time_based flow (VCD/FSDB with delays) or delay shifted flow. The power associated with glitch transitions will be categotized as glitch power. The fastest clock period in the design is considered as reference clock period. Depending on the pulse width , a glitch transition will be categorized as inertial glitch (IG) or transport glitch (TG) and this information will be available in the detailed and summary report of 'report_power_calculation'.

Description

Use this command to selectively disable the net during the glitch power analysis.It will impact both the default glith power analysis flow as well as the clock cycle based glitch analysis.

pt_shell> *set_glitch_power_analysis_options -exclude_nets I1 \\ -max_fanout 5 -max_slew 2.0*

See Also

- report_power

---

set_gpd_config

Specifies the parameters for reading parasitic data in GPD format: capacitor filtering thresholds, net subset, and netlist type.

Syntax

string *set_gpd_config*

```
[-absolute_coupling_threshold threshold]
[-relative_coupling_threshold threshold]
[-coupling_threshold_operation and | or]
```

```
[-netlist_select_nets net_names]
[-netlist_type netlist_type_specification]
-gpd gpd_directory
```

Data Types

threshold	float
net_names	list
netlist_type_specification	list
gpd_directory	string

Arguments

`-absolute_coupling_threshold` *threshold*

Specifies the absolute coupling threshold for filtering coupling capacitors. A capacitor having less that this capacitance value is split into two capacitors to ground. The threshold value must be greater than or equal to the corresponding parameter in the original GPD configuration file, COUPLING_ABS_THRESHOLD.

`-relative_coupling_threshold` *threshold*

Specifies the relative coupling threshold for filtering coupling capacitors. A capacitor is split to ground if its capacitance value divided by the total net capacitance is less than this threshold. The threshold value must be greater than or equal to the corresponding parameter in the original GPD configuration file, COUPLING_REL_THRESHOLD.

`-coupling_threshold_operation and | or`

Specifies whether coupling capacitors are filtered when the capacitance value is less than both the absolute AND relative thresholds (the default), or filtered when the value is less than either the absolute OR relative threshold (resulting in more filtering of coupling capacitors). If the original GPD database parameter COUPLING_THRESHOLD_OPERATION is set to OR, you cannot change it.

`-netlist_select_nets` *net_names*

Specifies a subset of nets to be read from the GPD database. The default is to read all nets.

`-netlist_type` *netlist_type_specification*

Specifies the parasitics network form to consider when reading the GPD database, as described the StarRC User Guide under NETLIST_TYPE. The allowed settings are *no_couple*, *R*, *CG*, *CC*, *RCG*, and *RCC* (the default).

`-gpd` *gpd_directory*

Specifies the absolute or relative path to the GPD directory.

Feedback

Description

This command allows you to override certain parameters for reading parasitic data from a Galaxy Parasitic Database (GPD) directory using the *read_parasitics -format gpd* command. The default parameters are defined in a file called the GPD configuration file. This file is generated by the *StarXtract -set_gpd_config* command in the StarRC tool.

The options you specify with the *set_gpd_config* command are appended to the existing GPD configuration file in the GPD directory. Note that this requires write access to the GPD directory.

If there is not already a user-defined GPD configuration file in the GPD directory, the command obtains the configuration values original GPD configuration and writes out a new configuration file.

To report the GPD properties that have been set, use the *report_gpd_config* command.

To cancel the effects of the *set_gpd_config* command and revert to the original GPD database, use the *reset_gpd_config* command.

Examples

The following example sets the absolute and relative thresholds for filtering coupling capacitors in the GPD database called my_design1.gpd.

```
pt_shell> set_gpd_config -gpd my_design1.gpd \\
 -absolute_coupling_threshold 0.005 \\
 -relative_coupling_threshold 0.05
 1
 pt_shell> report_gpd_config -gpd my_design1.gpd
  ...
```

After you run these commands, when you read in this parasitic data with the *read_parasitics* command, a coupling capacitor is split to ground when the capacitance is less than 0.005 and less than 5 percent of the total net capacitance.

---

set_gui_stroke_binding

Set the command binding for a stroke.

Feedback

Syntax

set_gui_stroke_binding

```
dictionary_name
stroke_sequence
[-builtin builtin_cmd_name]
[-clear]
[-tcl_cmd tcl_command]
[-label tcl_command_label]
```

Arguments

dictionary_name

Specify the dictionary to set the binding into. Windows that support stroke commands have one or more dictionaries to use when evaluating stroke commands.

stroke_sequence

Specifies the sequence of grids that defines the path of the stroke. See the *Stroke Sequences* section, below, for more information.

-builtin *builtin_cmd_name*

Specifies the name of a built-in command option to be executed.

-clear

Clears the existing command for the specified stroke sequence.

-tcl_cmd *tcl_command*

Specifies the Tcl command to be executed when the stroke is entered.

-label *tcl_command_label*

Specifies the menu label for the tcl command. This menu is displayed for line and snap_line strokes after a delay to provide information on the current bindings.

Description

Select a stroke by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

You can use the *report_gui_stroke_builtins* command to determine the available built-in (non-Tcl) commands. You can use the *report_gui_stroke_bindings* command to determine the existing bindings.

Stroke Types

The stroke command facility supports the following modes for entering strokes: line-based, rectangle-based, and path-based. All stroke entry types generate stroke bindings that are the same.

If you are an occasional user, the line-based and rectangle-based entry modes are easier to specify, but they limit the number of strokes that can be generated. If you are an advanced user, the path-based entry mode, which is more difficult to specify, allows many more strokes to be generated.

See the man page for the *set_gui_stroke_preferences* command for complete information on stroke entry types,

Stroke Sequences

The path of a stroke is mapped onto a 3x3 grid. The size of the grid squares are determined to ensure that the stroke covers the width or height of the grid. The stroke is centered in the grid of horizontal or vertical strokes.

The grid is numbered as shown below:

```
1 2 3
4 5 6
7 8 9
```

The stroke is mapped onto the grid and converted to a sequence of these grid numbers, which is called a *stroke sequence*. For example, a diagonal stroke from the top-left corner of the grid to the bottom-right corner has a stroke sequence of *159*; a left-to-right horizontal stroke has a stroke sequence of *456*.

Since the strokes are path-based, a single grid might occur more than once in a sequence. For example, a stroke that moves horizontally left-to-right and right-to-left has a stroke sequence of *12321*.

Strokes also support the Shift, Control, and Alt modifier keys. If one or more of these modifiers are depressed when the stroke is started, they are applied to the stroke. The modifiers are prepended to the stroke sequence, with *s* delimiting Shift, *c* delimiting control, and *a* specifying Alt. The modifiers are separated from the sequence by using a colon (*:*). For example, a left-to-right horizontal stroke sequence is *123*, if unmodified; *s:123* with Shift; *c:123* with Control; and *sc:123* with Shift-Control modifiers.

A click is supported as a special (degenerate) case of a stroke. If the mouse down-click and mouse up-click event happen close enough together (in both time and location), the stroke is recognized as a click and a stroke sequence of *5* is generated.

The stroke facility also supports the definition of a default command binding that is to be used for any bindings not explicitly set. This default binding is specified by using a simple stroke sequence of *0*. If no binding is registered for a given set of modifiers and sequence,

the tool searches for a stroke binding with the same modifiers and a sequence of *0* and uses that if it is found.

Built-In Commands

The application supporting stroke commands might support operations that are not available from the Tcl command language to be invoked via the stroke command. These commands are given a name, and you can use the *-builtin* option to specify a stroke binding to invoke these commands

The stroke facility always supports the built-in commands for zooming and panning listed below.

Zoom_In

Zoom in by a fixed percentage.

Zoom_Out

Zoom out by a fixed percentage

Zoom_In_Rect

Zoom in to fix the rectangle specified by the bounding box for the stroke.

Zoom_Out_Rect

Zoom out centering on the rectangle specified by the bounding box for the stroke.

Zoom_Full

Zoom and pan to fit the entire drawing centered in the window.

Pan_Center_Rect

Pan to center the rectangle specified by the bounding box for the stroke.

Tcl Command Bindings

The bindings support invoking Tcl-based commands to allow the functionality of the mechanism to be expanded. Tcl-based commands are allowed to contain key values that are substituted with data from the command before they are executed by the interpreter, thus allowing these commands to have access to the context information for the stroke. A leading percent (%) character specifies a key value..

The keys listed below are supported by tcl commands.

%rect

Substitutes the coordinates for the bounding box of the stroke. The value is a list of points {{*x1 y1*} {*x1 y2*}}, where you substitute bounding box coordinates for *x1*, *y1*,*x1*, and *y2*.

%startPoint

Specifies the starting point of the stroke. The value is in the form {*x y*}, where you substitute starting point coordinates for *x* and *y*.

%endPoint

Specifies the ending point of the stroke. The value is in the form {*x y*}, where you substitute starting point coordinates for *x* and *y*.

%sequence

Specifies the stroke sequence that invoked this command.

%modifiers

Specifies the modifiers of the stroke sequence that invoked this command.

Examples

The following example defines a left-to-right horizontal binding to execute the built-in operation that centers the location of the stroke in the viewport.

```
psyn_gui-t> set_gui_stroke_binding Graphics 123 \\
-builtin Pan_Center_Rect
```

The following example calls a tcl command for the Shift-modified, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics  \\
-tcl s:753 my_tcl_command
```

The following example calls a tcl command taking a rectangle as an argument for the Shift-control, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics \\
ss:753 -tcl {my_tcl_command %rect}
```

---

set_gui_stroke_preferences

Set preferences controlling stroke command entry.

Feedback

Syntax

set_gui_stroke_preferences

```
[-type stroke_entry_type]
[-shift]
[-ctrl]
[-alt]
[-extended_help_delay ms_delay]
```

Arguments

`-type stroke_entry_type`

Specifies the are *snap_line*, *line*, *rect*, *snap_path*, and *path*.

`-shift`

Sets the type for the shift modifier. This option is valid only when using the *-type* option.

`-alt`

Sets the type for the alt modifier. This option is valid only when using the *-type* option.

`-ctrl`

Sets the type for the ctrl modifier. This option is valid only when using the *-type* option.

`-extended_help_delay ms_delay`

Specifies the number of milliseconds to wait before showing the extended help (menu) for a stroke. A value of less than *500* makes the extended feedback immediate. Extremely large values suppress the extended feedback almost completely.

Description

Select a stroke command by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

Use this command to control the user interface behavior when you are specifying a stroke. The preferences allow the strokes to be used by both application experts and occasional users of the application.

The two primary types of stroke entry mechanisms are the line-based type and the stroke type. The primary preference supported is the stroke type. A line-based type determines

the stroke based on the values of the stroke's start and end points. The path between the points is ignored. A line-based stroke turns the stroke facility into a form of "pie-menu" that supports nine different menu items. A path-based type determines the stroke based on the path between the stroke's start and end points. This allows an extremely large number of unique strokes to be defined, and it also requires a significantly-higher amount of precision when specifying the stroke than when using the line-based type.

The snap_line, line, and rect stroke types are all line-based strokes: the snap_path and path are path-based strokes.

Stroke Types

snap_line

The line between the start and end points is snapped onto the nearest 45 degree angle. It allows the generation of eight different stroke sequences and the click stroke sequence.

line

The line between the start and end points specifies the stroke. It allows the generation of eight different stroke sequences and the click stroke sequence.

rect

The rectangle between the start and end points specifies the stroke. It allows the generation of four different stroke sequences and the click stroke sequence.

snap_path

This path-based stroke snaps the segments of the path onto the nearest 45 degree angle to make it easier to generate stroke sequences with diagonals and straight lines. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

path

This path-based stroke is a free-formed path from the start point to the end point. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

The unmodified stroke type is the default type for all modifiers when a type has not been specified for the modifier. Different stroke types can be used for each combination of modifiers by setting the stroke type for the modifier with this command.

Examples

The following example sets the stroke type to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -type \\
snap_line
```

Feedback

The following example sets the stroke type for Shift-Control modified strokes to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -shift  \\
-ctrl -type snap_line
```

---

set_hier_config

Specifies the HyperScale hierarchical analysis configuration options.

Syntax

status *set_hier_config*

```
[-path directory_for_data_storage]
[-block name_of_subblock]
[-instances names_of_instances]
[-name mim_group_name]
[-mim_reference mim_reference_instance_name]
[-enable_mim]
[-enable_top_only_flow]
[-session]
[-top]
[-partitions names_of_instances]
[-split names_of_instances]
[-exclude names_of_instances]
[-affinity host_option_names]
```

Data Types

```
directory_for_data_storage   string
name_of_subblock             string
names_of_instances           list
mim_group_name               string
mim_reference_instance_name  string
host_option_names            list
```

Arguments

`-path directory_for_data_storage`

Specifies the name of the directory in which the HyperScale block data was previously stored by the *write_hier_data* command during block-level timing analysis. Use this option together with the *-block* option to specify a HyperScale block and the location of its timing data.

`-block` *`name_of_subblock`*

Specifies the library name of a HyperScale block that was previously analyzed for timing. Use this option together with the *-path* option to specify a HyperScale block and the directory containing its timing data.

To analyze the timing of the current design, for each instance of the named block, the tool uses the block timing model previously created and stored in the specified directory. When you use the *write_hier_data* command, the tool writes out the context for each HyperScale block existing in the current design.

By default, all instances of the specified block are treated as HyperScale blocks. To specify only a subset of these instances as HyperScale blocks, use the *-instances* option. To specify multiple library blocks as HyperScale blocks, use a separate *set_hier_config* command for each library block.

The *-path* and *-block* options are used in a higher-level discrete analysis session to identify lower-level HyperScale blocks; they are not used in the full-chip automatic distributed analysis flow.

`-instances` *`names_of_instances`*

Specifies a list of one or more instances of the library block specified by the *-block* option. Only the listed instances are treated as HyperScale blocks; they are analyzed by using the HyperScale model previously stored during block-level analysis. Other instances of the same block undergo full-netlist timing analysis without using the HyperScale model. By default, all instances of the block are treated as HyperScale blocks.

For HyperScale context generation, by default, the tool performs context merging for all instances of the block specified by the *-block* option. When you use the *-instances* option, the tool performs context merging only for the listed instances and does not merge the context for instances not in the list. It uses the first instance in the list as the reference and merges the contexts of the other listed instances to match the first instance.

`-name` *`mim_group_name`*

Specifies a name for the multiply instantiated module (MIM) set, consisting of all instances that share the same merged context, whether all instances of the block by default or a subset of those instances by usage of the *-instances* option. Specifying a MIM group name is optional.

Assigning a specific name can be useful if you create multiple MIM groups for instances of the same library block. Later in the HyperScale analysis flow, when you perform block-level analysis, you can load the context of the specific MIM group by using the *-name* option of the *read_context* command.

Multiple subsets of merged instances can share the same MIM group name, and these merged instance groups can be stored in different directories by different *set_hier_config* commands. For block-level analysis, when you use the *read_context* command with the *-name* option, the command reads in the context for all merged instance groups that share the same MIM group name.

`-mim_reference` *`mim_reference_instance_name`*

Specifies the instance name of the multiply instantiated module (MIM) reference used for context merging. By default, MIM context merging automatically chooses a reference instance from the largest mergeable instance cluster. With this option, the specified instance is used for context merging, overriding the default.

`-enable_mim`

Specifies merging of the generated context for multiple HyperScale instances of the same library block in the full-chip distributed analysis flow. By default, the contexts for multiple instances of the same block are not merged in this flow; the context for each individual block is generated separately.

Use this option for more efficient HyperScale block context generation when multiple instances of the same HyperScale block have the same (or very similar) timing environment and therefore share the same timing context.

When the *-enable_mim* option is set, all reports in distributed analysis refer to only the primary MIM partition, except for reports generated by the *report_attribute* command.

`-enable_top_only_flow`

Performs timing analysis of only the top design in the distributed analysis flow, instead of the whole design. In this flow, valid timing reports are available only for active objects (a subset of the top design). To identify active objects, query their is_active attribute.

Use this option for more efficient distributed analysis when you are interested in timing results only for the top design. By default, the compute resources for block partitions are released after a timing update. To change this default behavior, set the *hier_enable_release_resources_in_top_only_flow* variable.

`-session`

Specifies the reading of session data saved by the *save_session* command in the full-chip distributed analysis flow. By default, without the *-session* option, the command reads HyperScale modeling data saved by the *write_hier_data* command.

With the *-session* option, you can read either the top-level session data by using the *-top* option or block session data by using the *-block* option; use the *-path*

option to specify the session data location, whether top or block. Use multiple *set_hier_config* commands with the *-session* option to read in the session data for the top level and for each HyperScale block.

`-top`

Specifies the reading of top-level session data with the *-session* option in the full-chip distributed analysis flow. Use either the *-top* or *-block* option, together with the *-path* option, to specify the top-level or block-level session data to read in.

`-partitions` *`names_of_instances`*

Specifies the block instances to be analyzed separately in the full-chip distributed analysis flow. By default, all hierarchical blocks at the top level are analyzed separately. Using the *-partitions* option overrides the default behavior, causing only the listed blocks at the top level to analyzed separately.

Use this option to specify only the larger blocks for separate analysis, leaving the remaining smaller blocks to be analyzed together with the rest of the top level. This option cannot be used with the *-exclude* or *-split* option.

To assign partitions for analysis on specific host resources, use the *-affinity* option.

`-split` *`names_of_instances`*

Specifies the blocks contained at the top level whose next-lower-level subblocks are to be analyzed separately in the full-chip distributed analysis flow. By default, all hierarchical blocks at the top level are analyzed separately and all blocks at levels below the first level are not analyzed separately.

Using *-split* option extends the splitting of the design into smaller units to two levels down instead of only one level down, for the specified instances. Use this option to break down the analysis of very large blocks into smaller units.

For each named instance, HyperScale distributed analysis performs a separate analysis of each highest-level subblock in that instance. The rest of the logic in that instance is pulled up to the top level and analyzed as part of the top level.

`-exclude` *`names_of_instances`*

Specifies the block instances at the top level to be excluded from separate analysis in the full-chip distributed analysis flow, overriding the default behavior. The listed instances are analyzed together with the top level instead of separately. Use this option to keep small blocks with the top level.

`-affinity` *`host_option_names`*

Defines the resource affinity for the partitions listed in the *-partitions* option. The *-affinity* option specifies a list of host options previously defined by

the *-name* option of the *set_host_options* command. The tool assigns the partitions for analysis on the worker processes defined by the corresponding *set_host_options* commands.

You can use the *-affinity* option only with the *-partitions* option, and only after the design has been linked.

If you specify multiple host option names, the tool assigns the partitions with the largest number of cells to the resources that have the largest reserved memory. To assign each partition to a specific host resource, use a separate *set_hier_config* command for each partition-to-resource assignment.

Description

The *set_hier_config* command specifies the HyperScale hierarchical analysis configuration options. You must set this configuration before you link the design, and HyperScale analysis must be enabled by setting the *hier_enable_analysis* variable to *true*.

For top-level discrete HyperScale analysis, use the following *set_hier_config* options to specify each HyperScale block and the block's associated data storage directory:

```
set_hier_config
  -path directory_for_data_storage
  -block name_of_subblock
  [-instances names_of_instances]
  [-name mim_group_name]
```

For full-chip distributed analysis, use the following *set_hier_config* options to enable merging of multiply instantiated blocks, to load existing session data, or to override the default block partitioning:

```
set_hier_config
  [-enable_mim]
  [-session  -top | -block name_of_subblock -path session_dir]
  [-partitions names_of_instances | -exclude names_of_instances]
  [-split names_of_instances]
```

HyperScale Technology

HyperScale technology greatly increases timing analysis performance and capacity by controlling the visibility into the design hierarchy. With accurate data reduction and automated design visibility control, and with the block-level timing data saved in the database, a combined block-level and top-level timing analysis requires significantly less memory and takes significantly less runtime.

In the HyperScale flow, the visibility at the top level is the portion of design that consists of the interblock glue logic and the block interfaces connected at the top level. This is the only portion of the design that the top-level timing integration actually needs for accurate analysis.

HyperScale analysis flow makes no sacrifices in the quality of results. It is designed to provide a level of accuracy that is identical or equivalent to that achieved by classic flat analysis where full visibility of the entire design is available from the top level.

The tool offers both discrete and full-chip distributed HyperScale analysis flows. In the discrete flow, you analyze each HyperScale block and the top level in a separate tool session. In that case, you use *set_hier_config* commands to specify which blocks at the top level are HyperScale blocks and the name of each block's storage directory containing modeling and context data. When you use multiple *set_hier_config* commands, a more specific setting overrides a more general one, and a new setting overrides any earlier conflicting setting.

In the full-chip distributed analysis flow, the tool automatically distributes the analysis of HyperScale blocks to a specified set of hosts. In that case, to override the default distribution of blocks to analysis processes, use the *set_hier_config* command to specify which blocks to analyze separately. You can optionally specify the usage of existing top-level or block-level analysis session data previously saved with the *save_session* command instead of data saved by the *write_hier_data* command. You can also specify whether to merge the context data for multiply instantiated modules (MIMs).

Discrete HyperScale Analysis

In the discrete HyperScale analysis flow, you use a separate PrimeTime session for each HyperScale block and for the top level.

For block-level analysis, use the *read_context* command to read the block context generated by top-level analysis, or use budgeted constraints if the block context information is not available; and upon completion of timing analysis, use the *write_hier_data* command to write out the block-level modeling data for future top-level analysis.

For top-level analysis, use the *set_hier_config* command to specify the blocks to be handled as HyperScale blocks. Upon completion of timing analysis, use the *write_hier_data* command to write out the block-level context for future block-level analysis. You can iterate between block-level and top-level analysis to handle any design or constraint changes.

In the top-level analysis session, use the following *set_hier_config* command options to specify each HyperScale block and the block's associated data storage directory:

```
set_hier_config
  -path directory_for_data_storage
  -block name_of_subblock
  [-instances names_of_instances]
  [-name mim_group_name]
```

Using the *-block* option, specify the library block name, and using the *-path* option, specify the path to the directory used for block model and context data storage. If multiple instances of that block exist in the design, by default they are all treated as HyperScale

blocks and share the same merged context. To specify only a subset of these instances as HyperScale blocks, list those instances with the *-instances* option. Use a separate *set_hier_config* command for each HyperScale library block.

You can optionally specify a name for the multiply instantiated module (MIM) set, consisting of all instances that share the same merged context. This can be useful if you create multiple MIM groups for instances of the same library block. Later in the HyperScale analysis flow, when you perform block-level analysis in a discrete tool session, you can load the context of the specific MIM group by using the *-name* option of the *read_context* command.

Full-Chip Distributed Analysis

In the full-chip distributed analysis flow, you specify a full-chip analysis in a single PrimeTime session, and the tool automatically distributes analysis of blocks to separate processes on different hosts. For example:

```
# Enable hierarchical analysis
set_app_var hier_enable_analysis true

# Set working directory for analysis data
set_app_var hier_distributed_working_directory $nfs_dir

# Specify hosts for automated distributed analysis
set_host_options -num_processes $nProc1 -max_cores $mCore1
 -submit_command ...
set_host_options -num_processes $nProc2 -max_cores $mCore2
 -submit_command ...
 ...
start_hosts

# Run full-chip flat analysis script
read_verilog blk_A.v
read_verilog blk_B.v
read_verilog top.v
link_design TOP
 ...
update_timing
 ...
```

Use the following *set_hier_config* command options to enable context merging for multiply instantiated modules (MIMs), to load existing top-level or block-level analysis session data for the current full-chip analysis, or to override the default block partitioning:

```
set_hier_config
  [-enable_mim]
  [-session  -top | -block name_of_subblock -path session_dir]
  [-partitions names_of_instances | -exclude names_of_instances]
  [-split names_of_instances]
```

In the full-chip distributed analysis flow, by default the context is *not* merged for MIMs. To enable context merging for MIMs, use the *-enable_mim* option.

To load existing top-level or block-level analysis session data (saved by the *save_session* command) for the current full-chip analysis, use the *-session* and *-top* options or the *-session*, *-block*, and *-path* options, respectively. Use a separate *set_hier_config* command for the top level and for each HyperScale library block. By default, without the *-session* option, the command reads HyperScale modeling data saved by the *write_hier_data* command.

By default, the distributed analysis flow treats all hierarchical blocks at the top level as HyperScale blocks and analyzes each such block using a single separate process. To override the default block distribution, use the *-partitions*, *-split*, and *-exclude* options:

- The *-partitions* option causes only the listed blocks to analyzed separately, leaving the unlisted blocks to be analyzed with the top level.
- The *-exclude* option does the opposite; it causes the listed blocks to be analyzed with the top level, allowing the unlisted blocks to be analyzed separately.
- The *-split* option breaks down the listed blocks even further, allowing their highest-level subblocks to be analyzed separately.

Top-Down and Bottom-Up Views

From a bottom-up point of view, HyperScale timing analysis typically starts with the block-level designers implementing each block with prescribed budgeting constraints, and performing timing analysis and optimization to ensure the block-internal paths meet the timing requirements. Then they use the *write_hier_data* command to store all block timing data into the HyperScale database.

After that, at the top level of hierarchy (or at the next-higher, intermediate level of hierarchy), the tool reads the block-level timing model data from the HyperScale database for timing analysis. For the case of an intermediate hierarchy level, it can generate its own timing analysis data and pass the timing model further up to its parent-level hierarchy, again using the *write_hier_data* command.

From a top-down point of view, HyperScale timing analysis uses the already-saved block models to perform the timing analysis for the visible portion of the design, including paths at the top level and paths that cross the boundaries of the HyperScale blocks, but excluding register-to-register paths inside the HyperScale blocks. This top-level analysis also checks the actual timing and environmental context at the subblock boundaries for all instances of HyperScale blocks to ensure that the block contexts match the conditions used during block-level analysis. To report the details boundary checking, use the *report_constraint* command.

At the top level, if further refinement of the subblocks is necessary, you can save the block context by using the *write_hier_data* command. Then, for subsequent block-level analysis,

the tool uses the stored context information for accurate refinement and optimization of the block in the context of the higher level.

In a top-down analysis flow in which the lower-level block netlists are not yet available, you can generate the block-level constraints from the top level by using the *characterize_context* and *write_context* commands.

Examples

To convert a full-chip flat analysis script to a HyperScale hierarchical analysis script, add lines at the beginning of the script similar to the following:

```
set_app_var hier_enable_analysis true
set_app_var hier_distributed_working_directory $nfs_dir
set_host_options -num_processes $nProc1 -max_cores $mCore1
 -submit_command ...
set_host_options -num_processes $nProc2 -max_cores $mCore2
 -submit_command ...
start_hosts
```

These lines invoke HyperScale automated distributed analysis, which treats all hierarchical blocks at the top level as HyperScale blocks. It analyzes each of these blocks using a separate process. To override the default behavior, use the *set_hier_config* command. For example,

```
set_hier_config \\
 -enable_mim \\       # Merge context for MIM blocks
 -exclude {U1} \\     # Keep block instance U1 with top level
 -split {U6}         # Split block instance U6 further
```

To perform a discrete analysis for each HyperScale block and for the top level, use commands similar to the following.

```
# Top-Level Analysis Session
set hier_enable_analysis true
 ...
set_hier_config -block BLKA -path $model_A
set_hier_config -block BLKB -path $model_B
 ...
read_verilog TOP.v
link_design TOP
 ...
update_timing
 ...
write_hier_data $topContextDir

# Block BLKA Analysis Session
set hier_enable_analysis true
 ...
read_verilog BLKA.v
link_design BLKA
 ...
```

```
read_context $topContextDir
 ...
update_timing
 ...
write_hier_data $model_A

# Block BLKB Analysis Session
set hier_enable_analysis true
 ...
read_verilog BLKB.v
link_design BLKB
 ...
read_context $topContextDir
 ...
update_timing
 ...
write_hier_data $model_B
```

You can iterate between the top-level and block-level analysis sessions to close timing or to handle design changes.

For each initial block-level analysis, you can use budgeted constraints, or you can generate block-level constraints from the top level by the *characterize_context* and *write_context* commands:

```
# Perform full-chip extraction of block constraints
# from top level (minimal update, no parasitics)
set_app_var hier_characterize_context_mode constraints_only
 ... read, link ...
characterize_context -block blkA
update_timing
write_context -format ptsh blkA -output $cnsDir

# Perform initial block-level analysis using extracted constraints
source $cnsDir/CONSTRAINT/blkA/.../variables.pt
source $cnsDir/CONSTRAINT/blkA/.../constraints.pt
 ... read, link, update timing ...
write_hier_data $blkDir1
```

In the following example, the design has three levels of hierarchy: TOP, MID, and BOT. Starting from lowest level, the following commands configure the analysis.

```
# BOT Analysis Script
set hier_enable_analysis true
read_context /design/blocks/MID
 ...
write_hier_data /design/blocks/BOT
```

For MID, the tool loads the timing data saved for its subblock BOT and the timing context pushed down from the parent-level design TOP:

```
# MID Analysis Script
set hier_enable_analysis true
read_context /design/TOP
set_hier_config -path /design/blocks/BOT -block BOT
 ...
write_hier_data /design/blocks/MID
```

For TOP, the tool loads the timing data saved for its subblock MID:

```
# TOP Analysis Script
set hier_enable_analysis true
set_hier_config -block MID -path /design/blocks/MID
 ...
write_hier_data /design/TOP
```

This HyperScale setup can significantly improve the runtime and memory for analysis of TOP.

The following commands define the host resources and analyze block instances P1, P2, and P3 as HyperScale blocks using the specified resources. All other hierarchical blocks at the top level are analyzed together with the top level.

```
set_host_options -name RA -num_processes 1 -max_cores 2 ... host1
set_host_options -name RB -num_processes 1 -max_cores 1 ... host2
set_host_options -name RC -num_processes 1 -max_cores 1 ... host3
start_hosts
report_host_usage -verbose
 ...
set_hier_config -partitions {P1 P2} -affinity {RA RB} ...
set_hier_config -partitions {P3} -affinity {RC} ...
 ...
```

The tool assigns partitions P1 and P2 for analysis on resources RA and RB, and partition P3 for analysis on resource RC. The larger of partition P1 or P2 (based on number of cells) is analyzed on the larger of resources RA and RB (based on allocated memory).

---

set_hier_resource_limits

Specifies the constraints on resources to assist in faster runtime of Distributed Hyperscale analysis.

Syntax

status *set_hier_resource_limits*

```
[-max_mem_per_block max_mem_per_block]
[-max_cores_per_block max_cores_per_block]
[-total_cores total_cores]
```

Data Types

```
max_mem_per_block           string
max_cores_per_block         string
total_cores                 string
```

Arguments

`-max_mem_per_block max_mem_per_block`

Specifies max memory in megabytes that can be allocated per hyperscale block. Value should be greater than 0.

`-max_cores_per_block max_cores_per_block`

Specifies max cores that can be allocated per hyperscale block. Value should be greater than 0.

`-total_cores total_cores`

Specifies total core budget that we have for assigning to Distributed hyperscale. Value should be greater than 0.

This commands setups constraints for optimal partitioning and resource allocation that is reported by *report_hier_analysis command with suboption -explore_partitions*

Feedback

Examples

Given a design with multiple hyperscale blocks. To allocate 14 processors where we can maximum of 4 processors that can be allocated for each hyperscale block and with 16G per block max memory that can be allocated we specify constraints :

set_hier_resource_limits -max_memory_per_block 16000 -total_cores 14 -max_cores_per_block 4

We then invoke partitioner to list out suggestions that should be done to distribute load evenly:

report_hier_analysis -explore_partitions

set_host_options

Specifies the host options for computation resources used in threaded, parallel, multi-scenario, and HyperScale analysis.

Syntax

status *set_host_options*

```
[-max_cores number]
[-local_process]
[-num_processes number]
[-load_factor number]
[-name name]
[-submit_command command]
[-terminate_command command]
[-protocol auto | custom | lsf | netbatch | pbs | rsh | rtda | sge | sh |
 slurm | ssh]
[-reserved_memory number]
[host_names]
```

Data Types

```
number      integer
name        string
command     string
host_names  list
```

Feedback

Arguments

`-max_cores` *number*

Specifies the maximum number of CPU cores that can be used for the current local process, or for each subsequently launched remote process if the *-num_processses* option is used. The number can be an integer between 1 and the number of cores available on the host, up to a maximum of 260. Setting a number larger than 16 requires additional licenses to be checked out; see the *PrimeTime User Guide* for details. The default maximum is 4 cores per host.

`-local_process`

Sets the resource usage limits for the current local process, overriding the default limits. The *-local_process* and *-num_processes* options are mutually exclusive. If neither of these options is used, the command applies to the local process by default.

`-num_processes` *number*

Specifies the number of processes to launch per host for future PrimeTime jobs and creates a set of host options for those processes. You can use multiple *set_host_options -num_processes* commands to create multiple sets of processes to launch, each with its own host options, and optionally assign a name to each set by using the *-name* option. When the *-num_processes* option is used, the command does not affect the current local process.

`-load_factor` *number*

Specifies the effective load per host, either 1 (the default) or 2. When the number of scenarios exceeds the number of available hosts, setting a larger load factor reduces or eliminates session save and restore operations, saving time at the cost of more memory.

Each real worker process (specified by *-num_processes*) can in turn launch virtual workers on the same host, such that the total number of workers (real and virtual) equals the specified load factor. The real and virtual workers take turns using cores (specified by *-max_cores*) of the host. Because virtual workers are processes forked by the real workers, they do not consume slots on the farm.

In the context of DMSA, the virtual workers are identical PrimeTime sessions that run scenarios. This option is useful when the number of hosts available on the farm is less than the number of scenarios. By launching additional virtual workers, multiple scenarios are held in memory, thereby reducing the number of automatic save restore operations that would otherwise consume a lot of runtime. Note that storing multiple scenarios in memory increases the total memory usage by approximately a factor of *-load_factor*. Account for this additional usage when you reserve memory on the farm.

`-name` *`name`*

Specifies a name for the set of host options being defined with the *-num_processes* option, allowing you to reference that set of options in future commands. If the name already exists, the new host option settings overwrite the existing settings, and any remote processes already started under that name are shut down.

If you do not use the *-name* option, the set of host options created by the *-num_processes* option is automatically assigned a new name: AUTO_0, AUTO_1, and so on. Only explicitly (not automatically) named option sets can be used with the *-affinity* option of the *create_scenario* command.

`-submit_command` *`command`*

Specifies the command that the tool uses to submit and launch PrimeTime processes associated with the *-num_processes* option. The specified submit command should be non-interactive in nature. When the command is executed, the tool captures the job/process ID, which you can report by using the *report_host_usage* command.

By default, if the *-submit_command* option is not used, and if the *host_name* option is not used (or it specifies the same host as the local host or the host of the manager process), the processes are launched on the local host or by the operating system of the manager; or if the specified host is a different host, the tool uses the *rsh* command by default to make remote connections to the host for setting up the processes.

`-terminate_command` *`command`*

Specifies the command that the tool uses to terminate jobs submitted by the *-submit_command* option (for example, upon exit).

`-protocol auto | custom | lsf | netbatch | pbs | rsh | rtda | sge | sh | slurm | ssh`

Specifies the type of the communication protocol used for submitting jobs. The default is *auto*, which automatically infers the protocol from the command specified in the *-submit_command* option. For automatic selection, the base name of the submission command must match a known protocol submission command: sh, rsh, ssh, bsub (LSF), qsub (SGE), nc (RTDA), qsub (PBS), or sbatch (SLURM). If no match is found, the tool infers a custom protocol. For more information, see "Establishing the Protocol" in the DESCRIPTION section.

`host_names`

Specifies a list of names of hosts on which to launch worker processes, for the set of processes created by the *-num_processes* option. By default, if you do not specify a list of host names, the command applies to the local host on which

the current process is running, and the *report_host_usage* command reports the host name as "localhost".

If any host names are specified other than localhost or the name of the host on which the manager process is running, you can use the *-submit_command* option to specify the command that the tool uses to set up a remote connection to the hosts to launch PrimeTime worker processes.

Note: If a custom protocol is used to directly target a specific host, the host must be part of the *-submit_command* string; it cannot be specified as the *host_names* option, because the PrimeTime tool cannot understand the relationship between the submit command and how that command targets a host.

`-reserved_memory` *number*

Specifies the amount of memory reserved for each process associated with the *-num_processes* option. Ensure that the value matches the memory reserved by the *-submit_command* option. The number can be an integer between 1 and 2147483646, representing the number of Gigabytes of memory reserved for each process. The *report_host_usage* command generates a reserved memory section in its report only if the *-reserved_memory* option is used.

Description

This command specifies the host options for the current process or for launching future PrimeTime processes. The PrimeTime tool uses multiple processes for threaded, parallel, multi-scenario, and HyperScale analysis.

To specify the maximum number of cores to use on the current local host, use the *-max_cores* option. For example,

```
pt_shell> set_host_options -max_cores 6
Information: The max_cores limit for the local (current) process
 has been modified by 2 to 6. (CMCR-103)
```

The default maximum is 4, or the number of physically available cores if that number is less than 4.

To specify the host options for launching future processes, use the *-num_processes* option together with the desired options:

```
set_host_options
  -num_processes number                  ; processes to launch per host
  [host_names]                           ; default is localhost
  [-max_cores number]                    ; default is 4
  [-submit_command command]              ; example: "/usr/bin/rsh"
  [-terminate_command command]           ; example: "[sh which bkill]"
  [-protocol auto | custom | protocol_name]    ; example: lsf
  [-name name_of_host_option_set]        ; default AUTO_0, AUTO_1, ...
```

```
  [-reserved_memory number]                ; reserved memory (GB)
preprocess
```

To report the host option settings, use the *report_host_usage* command.

Specifying these host options does not actually launch the processes. For details, see the man page for the *start_hosts* command.

You can use multiple *set_host_options -num_processes* commands to create multiple sets of processes to launch, each with its own host options, and optionally assign a name to each set by using the *-name* option. Then you can reference each set of options by name.

By default, the tool launches remote processes by using the pt_shell executable "$synopsys_root/bin/pt_shell". To specify a different executable or a custom wrapper script for launching remote processes, use the *set_distributed_parameters* command.

Establishing the Protocol

The *-protocol* option specifies the type of the communication protocol used for submitting jobs:

```
-protocol auto | custom | lsf | netbatch | pbs | rsh | rtda | sge | sh |
 slurm | ssh
```

The following rules apply to usage of the *-protocol* option and related usage of the *-submit_command* option:

- The PBS and SGE protocols use the same submission command (qsub). By default, automatic selection assumes that the protocol is SGE. To use PBS instead, explicitly specify *-protocol pbs*.
- A wrapper script using sh, rsh, or ssh should explicitly specify the protocol, for example, using *-protocol sh*.
- To target a protocol that is not one of the of known protocols, or if you must wrap a known protocol with a script that alters the protocol submit command interface, then use the *-protocol custom* option with the *-submit_command* option. In that case, the *-submit_command* option should specify the custom submit script to execute (along with appropriate options) to submit a worker job.
- If you wrap a known protocol with a script that does NOT alter the protocol submit command interface, you can select the underlying protocol by using the *-protocol* option. In that case, the *-submit_command* should specify a custom submit script that passes all options accepted by the protocol through to the underlying protocol submit command, as the PrimeTime tool passes additional arguments through to the protocol submit command. If the base name of the script does not match the normal protocol submit command name, a warning message tells you to ensure compatibility between the submit command and the selected protocol.

- If the custom protocol is used to directly target a specific host, the host must be part of the *-submit_command* string; it cannot be specified in the *host_names* option.
- The command argument of the *-submit_comamnd* option cannot contain the semicolon character (;). Using that character triggers an immediate error when you attempt to run the *set_host_options* command.
- If you use *-protocol sge*, you cannot pass "-b y" in the *-submit_command* argument. Doing so triggers an immediate error (or a launch failure if "-b y" is inside a qsub call enclosed in a wrapper).
- If you use *-protocol rtda*, you cannot pass not pass "-wl" or "-w" in the *-submit_command* argument. Doing so triggers an immediate error (or a launch failure if "-wl" or "-w" is inside an nc call enclosed in a wrapper).
- If you use *-protocol lsf*, you cannot pass not pass "-K" in the *-submit_command* argument. Doing so triggers an immediate error (or a launch failure if "-K" is inside a bsub call enclosed in a wrapper).
- If you use PrimeTime inside the container environment initiated by launching pt_shell with the *-container* option or by setting the *SNPS_CONTAINER* environmental variable, you cannot use protocols *rsh* or *custom*.

Examples

In the following examples, the manager process is running on the host named roger15. Multiple *set_host_options* commands specify several different sets of host options.

The following command specifies the execution of one process on the same host as the manager, and names this set of host options "my_opts1". It does not specify a limit on the maximum number of cores to use, so the default value of 4 applies (or the number of available cores, if less than 4).

```
pt_shell> set_host_options -name my_opts1 -num_processes 1
```

The following command does the same as the first example, but explicitly states the name of the host and limits the maximum number of cores to 2, and names this set of host options "my_opts2".

```
pt_shell> set_host_options -name my_opts2 -num_processes 1 \
          roger15 -max_cores 2
```

The following command specifies the usage of one process on the host named roger11, sets the maximum number of cores to 3, and names this set of host options "my_opts3". Because the command does not specify a submit command, "rsh" will be used to connect to roger11, as indicated in a warning message.

```
pt_shell> set_host_options -name my_opts3 -num_processes 1 \
          roger11 -max_cores 3
```

```
Warning: no submit command specified to access remote host
 'roger11'. The 'rsh' command will be used. (CMCR-004)
```

The following command specifies the usage of one process on the host named roger12 using the submit command "/usr/bin/rsh", and names this set of host options "my_opts4". The default maximum number of cores applies.

```
pt_shell> set_host_options -name my_opts4 -num_processes 1 \
          -submit_command "/usr/bin/rsh" roger12
```

The following command explicitly specifies the type of the communication protocol to be used (lsf), using the "bsub" command found from the environment path (sh which bsub) to submit the job, requiring 1 GB of memory and 2 slots per compute server, using a maximum of 2 cores. The farm job must be specified with the number of slots needed to support the number of cores to use with the -n 2 -R span[ptile=2] options; the square brace characters must be escaped. To terminate jobs that do not come online, the tool uses the "bkill" command found from the environment path. The name of this set of options is "my_opts5".

```
pt_shell> set_host_options -name my_opts5 -num_processes 1 \
          -protocol lsf \
          -submit_command "[sh which bsub] -n 2 -R rusage\[mem=1000\] \
          -R span\[ptile=2\]" -terminate_command "[sh which bkill]" \
          -max_cores 2
```

The following command specifies the usage of 2 processes on a Grid farm, using the "qsub" command found from the environment path to submit the job, using the project named "bnormal", requiring 1 GB of memory and 4 slots per compute server, using a maximum of 4 cores. The farm job must be specified with the number of slots needed to support the number of cores to use by targeting the parallel environment "mt", requesting 4 slots with the "-pe mt 4" options. To terminate jobs that do not come online, the tool uses the "qdel" command found from the environment path. The name of this set of options is "my_opts6".

```
pt_shell> set_host_options -name my_opts6 -num_processes 2 \
          -submit_command "[sh which qsub] -P bnormal -pe mt 4 \
          -l mem_free=1G" -terminate_command "[sh which qdel]" \
          -max_cores 4
1
```

To report the host options created by the *set_host_options* command, run the *report_host_usage* command with the *-verbose* option before starting the hosts.

Note: The submit command for my_opts1 and my_opts2 are empty because the processes are directly launched on the manager's host.

```
pt_shell> report_host_usage -verbose
 ...

  Options Name    Host Name    Num Processes          Protocol
```

set_ideal_aggressor

Marks the specified aggressor nets as ideal aggressors. Sets the *si_ideal_aggressor* attribute on these nets.

Syntax

status *set_ideal_aggressor*

```
        net_list
```

Data Types

net_list list

Arguments

net_list

Specifies a list of aggressor nets.

Description

This command marks the specified aggressor nets as ideal aggressor nets and sets the *si_ideal_aggressor* attribute these nets. Ideal aggressor nets are handled specially when they are agressing other nets for the purpose of crosstalk delay and noise calculations. The secondary coupling of these nets is ignored for SI computations.

For regular aggressor nets, secondary coupling to other nets is treated as ground capacitance for SI computations. For special aggressor nets coupled with a large number of other nets, the secondary coupling can be very large and the effective crosstalk impact of these nets may be mitigated due to this. These nets can be marked as ideal aggressors for their secondary coupling to be ignored.

You can query the *si_ideal_aggressor* attribute by using the *get_attribute* command. To remove the ideal aggressor marking on a net, use the *remove_ideal_aggressor* command.

Examples

The following command marks aggressor nets "n_ideal_aggr1" and "n_ideal_aggr2" as ideal aggressor nets.

```
pt_shell> set_ideal_aggressor [get_nets {n_ideal_aggr1 n_ideal_aggr2}]
1
```

In the following example, the *si_ideal_aggressor* attribute is set using *set_ideal_aggressor* command and then queried using *get_attribute* command. The *get_attribute* command returns *true* for the *si_ideal_aggressor* attribute. The *wire_script* command writes *set_ideal_aggressor* command for net "n_ideal_aggr".

```
pt_shell> get_attribute [get_net n_ideal_aggr] ref_name
n_ideal_aggr

pt_shell> get_attribute [get_net n_ideal_aggr] si_ideal_aggressor
false

pt_shell> set_ideal_aggressor [get_net n_ideal_aggr]
1

pt_shell> get_attribute [get_net n_ideal_aggr] si_ideal_aggressor
true

pt_shell> write_script -format ptsh

 Script contains this command:
 set_ideal_aggressor [get_nets {n_ideal_aggr}]
```

Feedback

---

set_ideal_latency

Specifies ideal latency values for the pins in an ideal network.

Syntax

int *set_ideal_latency*

```
[-rise] [-fall]
[-min] [-max]
value
object_list
```

Data Types

value	float
object_list	list

Arguments

`-rise`

Indicates that the *value* option represents the rise latency time. If you do not specify the *-rise* or *-fall* options, both values are set.

`-fall`

Indicates that the *value* option represents the fall latency time. If you do not specify the *-rise* or *-fall* option, both values are set.

`-min`

Indicates that the *value* option represents the minimum latency time. If you do not specify the *-min* or *-max* option, both values are set.

`-max`

Indicates that the *value* option represents the maximum latency time. If you do not specify the *-min* or *-max* option, both values are set.

value

Specifies an ideal latency value on leaf cell pins or top-level ports in an ideal network.

object_list

Specifies a list of leaf cell pins and top-level ports on which ideal latency is set.

Description

Sets an ideal latency value on leaf cell pins and top-level ports of an ideal network.

PrimeTime uses ideal timing for ideal networks, which means that pins and ports have a specified ideal latency (from the *set_ideal_latency* command) or zero ideal latency by default. Ideal networks are normally used during pre-layout to avoid unnecessary DRCs. The specified ideal latency value provides an estimate of the latency time in the ideal network for pre-layout.

The specified latency value overrides the internally-estimated cell and net delay value and any other delay annotations. If the specified pins do not belong to an ideal network, a warning message is generated by the *report_ideal_network* command and the ideal latency *value* option is ignored for those pins. Ideal latency values do not have any effect in ideal clock networks (for example, non-propagated clock networks).

The *set_ideal_latency* command affects all pins in the transitive fanout of the pins or ports on which ideal latency is specified. The total ideal latency at an ideal boundary pin is the sum of latency on the ideal network source and all ideal latencies on the path.

You can use the *set_ideal_latency* command for pins at lower levels of the design hierarchy.

To list ideal latency values, use the *report_ideal_network* command.

To remove the ideal latency values from a design, use the *remove_ideal_latency* or *reset_design* command.

Examples

The following example specifies a rise latency of *1.2* and a fall latency of *0.9* for ports named *A*, *B*, and *C*.

```
pt_shell> set_ideal_latency 1.2 -rise {A B C}
pt_shell> set_ideal_latency 0.9 -fall {A B C}
```

See Also

- report_ideal_network
- report_timing

- set_ideal_transition
- set_ideal_network

set_ideal_network

Marks a set of ports or pins in the design as sources of an ideal network. This disables timing update of cells and nets in the transitive fanout of the specified objects.

Syntax

integer *set_ideal_network*

```
[-no_propagate]
object_list
```

Data Types

object_list	list

Arguments

`-no_propagate`

Indicates that the ideal network is not propagated through leaf cells. Ideal properties are enabled on all nets that are electrically connected to the ideal network sources.

object_list

Specifies a list of objects to mark as the sources of an ideal network. Ideal network source objects may be ports or pins of leaf cells at any hierarchical level of the design. If nets are specified in the *object_list*, all of the nets' global driver pins are marked as ideal network sources. The *set_ideal_network* command accepts nets only when you specify the *-no_propagate* option.

Description

This command marks a set of ports or pins in the design as sources of an ideal network. You specify only the source of the network. PrimeTime marks all nets, cells, and pins in the transitive fanout of ideal sources as ideal. The ideal property is automatically spread by the tool and spread again, as necessary, after netlist changes. The criteria for propagating the ideal property, starting at the source pins and ports, are as follows:

- A pin is marked as ideal if you specify it by using the *set_ideal_network* command, if it is either a driver pin and its cell is ideal or if it is a load pin attached to a net that is ideal.
- A net is marked as ideal if all its driving pins are ideal.

- A combinational cell is marked as ideal if at least one of its input pins is ideal and all the other input pins are either ideal, unconnected or attached to a logic constant nets. Objects with the case analysis attribute set are not treated as constant.
- Propagation traverses through combinational cells but stops at sequential cells.
- Design rule checks (DRCs) are disabled on ideal network objects.
- Ideal networks can be specified in the clock or data network.

The latency and transition times of an ideal network are zero by default, but you can override them by using the *set_ideal_latency* and *set_ideal_transition* commands. Ideal timing values do not have any effect in ideal clock networks (for example, non-propagated clock networks).

To reverse the effect of the *set_ideal_network* command, use the *remove_ideal_network* command and specify the source pins or ports for the network. All ideal networks are removed using the *reset_design* command.

Ideal sources, non-source ideal pins with ideal timing values, boundary pins of ideal networks and ideal nets and cells are displayed using the *report_ideal_network* command.

Examples

The following example creates an ideal network on ports in a design called 'TOP'.

```
pt_shell> current_design {TOP}
pt_shell> set_ideal_network {IN1 IN2}
```

The following example creates an ideal network on the multi-driven net named 'netA'.

```
pt_shell> set_ideal_network -no_propagate {netA}
Warning: Transferring ideal net attribute onto driver pin 'U1/Z' of net
 'netA'. (UITE-450)
Warning: Transferring ideal net attribute onto driver pin 'FFD/Q' of net
 'netA'. (UITE-450)
```

See Also

- report_ideal_network
- reset_design
- set_ideal_latency
- set_ideal_transition

Feedback

set_ideal_transition

Specifies ideal transition values for the pins in an ideal network.

Syntax

int *set_ideal_transition*

```
[-rise] [-fall]
[-min] [-max]
value
object_list
```

Data Types

value	float
object_list	list

Arguments

`-rise`

Indicates that the *value* option represents the rise transition time. If you do not specify the *-rise* or *-fall* option, both values are set.

`-fall`

Indicates that the *value* option represents the fall transition time. If you do not specify the *-rise* or *-fall*option, both values are set.

`-min`

Indicates that the *value* option represents the minimum transition time. If you do not specify the *-min* or *-max*, both values are set.

`-max`

Indicates that the *value* option represents the maximum transition time. If you do not specify the *-min* or *-max* option, both values are set.

value

Specifies an ideal transition value on leaf cell pins or top-level ports in an ideal network.

object_list

Specifies a list of leaf cell pins and top-level ports on which ideal transition is set.

Description

Sets an ideal transition value on leaf cell pins and top-level ports of an ideal network.

Feedback

PrimeTime uses ideal timing for ideal networks, which means that pins and ports have a specified ideal transition (from the *set_ideal_transition* command) or zero ideal transition by default. Ideal networks are normally used during pre-layout to avoid unnecessary DRCs. The specified ideal transition value provides an estimate of the transition time in the ideal network for pre-layout.

The specified transition value overrides the internally-estimated cell and net transition value and any other transition annotations. If the specified pins do not belong to an ideal network, a warning message is generated by the *report_ideal_network* command and the ideal transition *value* option is ignored for those pins. Ideal transition values do not have any effect in ideal clock networks (i.e. non-propagated clock networks).

You can use the *set_ideal_transition* command for pins at lower levels of the design hierarchy.

To list ideal transition values, use the *report_ideal_network* command.

To remove the ideal transition values from a design, use the *remove_ideal_transition* or *reset_design* command.

Examples

The following example specifies a rise transition of *1.2* and a fall transition of *0.9* for ports named *A*, *B*, and *C*.

```
pt_shell> set_ideal_transition 1.2 -rise {A B C}
pt_shell> set_ideal_transition 0.9 -fall {A B C}
```

---

set_implement_options

Specifies the PrimeECO configuration options for the *check_eco* and *implement_eco* commands.

Feedback

Syntax

```
status set_implement_options
   [-icc2_exec path_name]
   [-icc2_max_cores core_count]
   [-icc2_initialize_script file_name]
   [-icc2_post_link_script file_name]
   [-icc2_pre_legalize_script file_name]
   [-icc2_eco_legalize_script file_name]
   [-icc2_pre_route_script file_name]
   [-icc2_eco_route_script file_name]
   [-icc2_pre_extract_script file_name]
   [-starrc_exec path_name]
   [-starrc_cmd_files file_name_list]
   [-starrc_mode full | incremental]
   [-parasitic_corners pair_list]
   [-parasitic_extractor starrc | icc2]
   [-work_dir directory_name]
   [-insert_fillers]
   [-load_advanced_technology_rules]
```

Data Types

path_name	string
core_count	int
file_name	string
file_name_list	string
pair_list	list
directory_name	string

Arguments

`-icc2_exec` *path_name*

Specifies the path to the icc2_shell executable for IC Compiler II tool.

`-icc2_max_cores` *core_count*

Controls the maximum number of cores that can be used by multicore commands in IC Compiler II.

`-icc2_initialize_script` *file_name*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* before opening library.

`-icc2_post_link_script` *file_name*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* after the current working block is loaded.

`-icc2_pre_legalize_script` *`file_name`*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* before placement legalization.

`-icc2_eco_legalize_script` *`file_name`*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* instead of the built-in default placement legalization strategy.

`-icc2_pre_route_script` *`file_name`*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* after placement legalization, before ECO routing.

`-icc2_eco_route_script` *`file_name`*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* instead of the built-in default ECO routing strategy.

`-icc2_pre_extract_script` *`file_name`*

Specifies the file that contains a custom IC Compiler II script, which is executed during *implement_eco* after ECO routing, before parasitic extraction.

`-starrc_exec` *`path_name`*

Specifies the path to the StarXtract executable for the StarRC tool.

`-starrc_cmd_files` *`file_name_list`*

Specifies the names of one or more StarRC configuration files used to perform parasitic extraction in a signoff environment.

`-starrc_mode full | incremental`

Specifies StarRC parasitic extraction mode. The default is *full*.

`-parasitic_corners` *`pair_list`*

Specifies the parasitic corner name for each active scenario using the following format:

`{{`*`scenario_1 para_corner_1`*`} {`*`scenario_2 para_corner_2`*`} ...}`

`-parasitic_extractor starrc | icc2`

Specifies the Synopsys tool to perform parasitic extraction. The default is *starrc*.

`-work_dir` *`directory_name`*

Specifies the directory where PrimeTime, IC Compiler II, and StarRC exchange data and generate log files. The default is a directory called work_dir created in your current working directory.

Feedback

`-insert_fillers`

Enables stdcell filler insertion during *implement_eco* after ECO routing, before parasitic extraction.

`-load_advanced_technology_rules`

Enables loading advanced technology rules such as spacing rules from the IC Compiler II reference library.

Description

The *set_implement_options* command specifies information to configure PrimeECO operation for physical signoff ECO closure, involving IC Compiler II and StarRC.

You must set these options before you run the *check_eco* command.

For further details, see the *implement_eco* man page.

Examples

The following command sets the path to the IC Compiler II executable and the StarRC executable.

```
prompt> set_implement_options \\
  -icc2_exec /path/to/icc2_shell \\
  -starrc_exec /path/to/StarXtract
```

- set_implement_options
- write_implement_changes

---

set_imsa_attributes

Adds, removes, or reports attributes to be saved by the *save_session -only_timing_paths* command and restored by the *restore_session* command into an IMSA session.

Feedback

Syntax

string *set_imsa_attributes*

```
[-add]
[-remove]
[-report]
[-class class_name]
[attribute_list]
```

Data Types

class_name	string
attribute_list	list

Arguments

`-add`

Adds to the list of attributes to be saved and restored into IMSA sessions.

`-remove`

Removes from the list of attributes to be saved and restored into IMSA sessions.

`-report`

Reports the list of additional attributes to be saved and restored into IMSA sessions, as specified previously by the *-add* and *-remove* options, and by usage of the *imsa_save_reporting_attributes* and *imsa_save_eco_data* variables. This is the default action if no options are used in the *set_imsa_attributes* command.

`-class` *class_name*

Specifies the object class of attributes to be added to (or removed from) the list: *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, or *lib_pin*. Specifying the object class is mandatory when you use the *-add* or *-remove* option.

attribute_list

Specifies a list of attributes for the given object class to add to (or remove from) the list of of attributes to be saved and restored into an IMSA sessions.

Description

This command specifes or reports additional attributes to be saved by the *save_session -only_timing_paths* command and restored by the *restore_session* command into an interactive multi-scenario analysis (IMSA) session.

In an IMSA session, timing path collections from multiple scenarios sharing an identical netlist are restored into a single PrimeTime shell session. You can report the timing paths

and query the path attributes in the session, using a limited set of PrimeTime commands. You cannot change constraints or perform timing updates in the session.

By default, the *save_session -only_timing_paths* command saves only the paths in the specified timing path collection, the attributes of those timing paths and their timing points, and the attributes of the associated clocks. No other attributes are saved or restored.

To enable saving and restoring of additional specific object attributes, use the *set_imsa_attributes* with the *-add* option. Specify the object class and the attribute names using the *-class* and *attribute_list* arguments. Use the *-remove* option in a similar manner to remove attributes from the list previously added. You can specify both application attributes and user-defined attributes.

Use the *-report* option to report the current list of attributes to be saved and restored into IMSA sessions. The list is affected by previous usage of the *set_imsa_attributes* command and by the *imsa_save_reporting_attributes* and *imsa_save_eco_data* variable settings.

In the IMSA session, you can use the *get_attribute* command to query the object attributes that were saved and restored into the session.

Examples

The following example shows how to add to the list of saved IMSA attributes and how to report the current list of attributes to be saved:

```
pt_shell> set_imsa_attributes -add -class design max_capacitance
Information: Added attribute max_capacitance of object class design ...
pt_shell> set_imsa_attributes -add -class pin \\
  {max_rise_slack max_fall_slack min_rise_slack min_fall_slack}
Information: Added attribute max_rise_slack of object class pin ...
 ...
pt_shell> set_imsa_attributes -report
 ...
Properties:
    A - Application-defined
    U - User-defined
    I - Importable

Class      Attribute Name           Type          Properties
-----------------------------------------------------------
design     max_capacitance          float         A
pin        max_rise_slack           float         A
pin        max_fall_slack           float         A
pin        min_rise_slack           float         A
pin        min_fall_slack           float         A
```

set_input_delay

Defines the arrival time relative to a clock.

Syntax

string *set_input_delay*

```
[-clock clock_name]
[-reference_pin pin_port_name]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-sms_scenarios sms_scenarios_list]
delay_value
port_pin_list
```

Data Types

clock_name	list
delay_value	float
pin_port_name	list
port_pin_list	list
sms_scenarios_list	collection

Arguments

`-clock clock_name`

Specifies the clock to which the specified delay is related. If you use the *-clock_fall* option, you must specify the *-clock clock_name* option. If you do not specify the *-clock* option, the delay is relative to time zero for combinational designs. Without using *-clock*, the input delay is not relative to any clock and will not create constrained paths from the port with repspect to any clock. See the variable *timing_input_port_default_clock* to change this behavior.

`-reference_pin pin_port_name`

Specifies the clock pin or port to which the specified delay is related. If you use this option and the propagated clocking is being used, the delay value is

related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The *-network_latency_included* and *-source_latency_included* options cannot be used at the same time as the *-reference_pin* option. For ideal clock network, only source latency is applied.

The pin specified with the *-reference_pin* option should be a leaf pin or port in a clock network, in the direct or transitive fanout of a clock source specified with the *-clock* option. If multiple clocks reach the port or pin where you are setting the input delay and if the *-clock* option is not used, the command considers all of the clocks.

`-clock_fall`

Specifies that the delay is relative to the falling edge of the clock. When it is used with *-reference_pin* option, the delay is relative to the falling transition of the reference pin. The default is the rising edge or rising transition of a reference pin.

`-level_sensitive`

Specifies that the source of the delay is a level-sensitive latch. This allows the tool to derive setup and hold relationship for paths from this port as if it were a level-sensitive latch. If you do not use the *-level_sensitive* option, the input delay is treated as if it were a path from a flip-flop.

`-rise`

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If you do not specify the *-rise* or *-fall* option, rising and falling delays are assumed to be equal.

`-fall`

Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If you do not specify the *-rise* or *-fall* option, rising and falling delays are assumed to be equal.

`-max`

Specifies that *delay_value* refers to the longest path. If you do not specify the *-max* or *-min* option, maximum and minimum input delays are assumed to be equal.

`-min`

Specifies that *delay_value* refers to the shortest path. If you do not specify the *-max* or *-min* option, maximum and minimum input delays are assumed to be equal.

`-add_delay`

Specifies whether to add delay information to the existing input delay or to overwrite. Use the *-add_delay* option to capture information about multiple paths leading to an input port that are relative to different clocks or clock edges.

For example, *set_input_delay 5.0 -max -rise -clock phi1 {A}* removes all other maximum rise input delay from "A", because the *-add_delay* option is not specified. Other input delays with different clocks or with clock_fall are removed.

In another example, the *-add_delay* option is specified as *set_input_delay 5.0 -max -rise -clock phi1 -add_delay {A}*. If there is an input maximum rise delay for "A" relative to clock "phi1" rising edge, the larger value is used. The smaller value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise input delay relative to a different clock or different edge of the same clock, it remains with the new delay.

`-network_latency_included`

Specifies whether the clock network latency should not be added to the input delay value. If this option is not specified , the clock network latency of the related clock will be added to the input delay value. It has no effect if the clock is propagated or the input delay is not specified with respect to any clock.

`-source_latency_included`

Specifies whether the clock source latency should not be added to the input delay value. If this option is not specified , the clock source latency of the related clock will be added to the input delay value. It has no effect if the input delay is not specified with respect to any clock.

`delay_value`

Specifies the path delay. The *delay_value* option must be in units consistent with the technology library used during analysis. The *delay_value* option represents the amount of time that the signal is available after a clock edge. This usually represents a combinational path delay from the clock pin of a register.

`port_pin_list`

Provides a list of input port or internal pin names in the current design to which *delay_value* is assigned. If you specify more than one object, the objects are enclosed in braces ({}).

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this input delay is applied. When this option is not given the input delay applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Feedback

Description

Sets input path delay values for the current design. Used with the *set_load* and *set_driving_cell* commands, the input and output delays characterize the operating environment of the current design.

The *set_input_delay* command sets input path delays on input ports relative to a clock edge. Unless specified, input ports are assumed to have zero input delay. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay from a level-sensitive latch, use the *-level_sensitive* option. If the latch is positive-enabled, set the input delay relative to the rising clock edge. If the latch is negative enabled, set the input delay relative to the falling clock edge. If time is borrowed at that latch, add that time borrowed to the path delay from the latch when determining input delay.

The *characterize_context* command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

If for a specific clock the maximum delay is less than minimum delay, PrimeTime makes the maximum delay equal to that of the minimum delay.

PrimeTime adds input delay to path delay for paths starting at primary inputs, and to output delay for paths ending at primary outputs.

PrimeTime allows an input port to behave simultaneously as a clock and data port. You can use the *timing_simultaneous_clock_data_port_compatibility* variable to enable or disable the simultaneous behavior of the input port as a clock and data port. When this variable is set to its default of *false*, simultaneous behavior is enabled and you can use the *set_input_delay* command to define the timing requirements for input ports relative to a clock. In this situation, the following applies:

- If you specify the *set_input_delay* command relative to a clock defined at the same port and the port has data sinks, the command is ignored and an error message is issued. There is only one signal coming to port, and it cannot be at the same time data relative to a clock and the clock signal itself.
- If you specify the *set_input_delay* command relative to a clock defined at a different port and the port has data sinks, the input delay is set and controls data edges launched from the port relative to the clock.
- Regardless of the location of the data port, if the clock port does not fanout to data sinks, the input delay on the clock port is ignored and you receive an error message.

When you set the *timing_simultaneous_clock_data_port_compatibility* variable to *true*, the simultaneous behavior is disabled and the *set_input_delays* command defines the arrival time relative to a clock. In this situation, when an input port has a clock defined on it, PrimeTime considers the port exclusively as a clock port and imposes restriction on the

data edges that are launched. PrimeTime also prevents setting input delays relative to another clock.

To control the clock source latency for any clocks defined on an input port, you must use the *set_clock_latency* command.

If a reference pin is not reachable by any given clock, zero arrival time is assumed. If no clock is specified with a reference pin and this reference pin is not reachable by any clock, an unconstrained path is reported. This behavior is changed after version X-2005.06. The new behavior is these invalid constraints are ignored and the path is constrained by whatever it should be as if no such constraints are defined at all. The *check_timing* command generates a warning if the reference pin is not reachable by any active clock, or if multiple clocks reach the reference pin and no clock is specified in the command.

To get a report on the latency calculation using a reference pin, use one of the following commands:

```
report_timing -path_type full_clock
report_timing -path_type full_clock_expanded
```

To list input delays associated with ports, use the *report_port* command. To list input delays of internal pins, use the *report_design* command. To remove input delay values, use the *remove_input_delay* or *reset_design* command.

Examples

The following example sets an input delay of 2.3 for ports "IN1" and "IN2" on a combinational design. Because the design is combinational, no clock is needed.

```
pt_shell> set_input_delay 2.3 {IN1 IN2}
```

The following example sets input delay of 1.2 relative to the rising edge of "CLK1" for all input ports in the design.

```
pt_shell> set_input_delay 1.2 -clock CLK1 [all_inputs]
```

The following example sets the input and output delays for the bidirectional port "INOUT1". The input signal arrives at "INOUT1" 2.5 units after the falling edge of "CLK1". The output signal is required at "INOUT1" at 1.4 units before the rising edge of "CLK2".

```
pt_shell> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}

pt_shell> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

The following example models the situation where there are three paths to input port "IN1". The first path is relative to the rising edge of "CLK1". The second path is relative to the falling edge of "CLK1". The third path is relative to the falling edge of "CLK2". The *-add_delay* option is used to indicate that new input delay information does not cause old information to be removed.

```
pt_shell> set_input_delay 2.2 -max clock CLK1 -add_delay {IN1}

pt_shell> set_input_delay 1.7 -max clock CLK1 -clock_fall -add_delay
 {IN1}

pt_shell> set_input_delay 4.3 -max clock CLK2 -clock_fall -add_delay
 {IN1}
```

In the following example, two different maximum delays and two minimum delays for port "A" are specified using the *-add_delay* option. Since the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained (in this case, 5.0 and 1.1). If the *-add_delay* option is not used, the new information overwrites the old information.

```
pt_shell> set_input_delay 3.4 -max -clock CLK1 -add_delay {A}

pt_shell> set_input_delay 5.0 -max -clock CLK1 -add_delay {A}

pt_shell> set_input_delay 1.1 -min -clock CLK1 -add_delay {A}

pt_shell> set_input_delay 1.3 -min -clock CLK1 -add_delay {A}
```

Feedback

set_input_noise

Sets a noise bump for a pin or port.

Syntax

int *set_input_noise*

```
[-add_noise]
[-above]
[-below]
[-low]
[-high]
[-height width_value]
[-width  height_value]
object_list
```

Data Types

width_value	float
height_value	float
object_list	list

Arguments

`-add_noise`

Specifies whether to add noise information to the existing input noise or to overwrite it. For example, if the *set_input_noise* is used previously, another *set_input_noise* with the *-add_noise* option will sum the noise information with value previously set by the *set_input_noise* command.

`-above`

Specifies a noise bump for above ground or power rail noise analysis region.

`-below`

Specifies a noise bump for below ground or power rail noise analysis region.

`-low`

Specifies a noise bump for ground rail noise.

`-high`

Specifies a noise bump for power rail noise.

`-height height_value`

Specifies the height of the noise bump. The height is in the voltage units of the library.

`-width` *`width_value`*

Specifies the width of the noise bump. The width is in the time units of the library. 1.0.

`object_list`

Specifies a list of pins or ports.

Description

Rather than allow PrimeTime SI to calculate propagated noise bumps, you can explicitly specify a noise bump at any port or pin. In this command, you specify the port or pin in the design on which to apply the noise and the characteristics of the noise bump: the type (above/below high/low), the width in library time units, the height in library voltage units (always entered as a positive number).

PrimeTime SI treats this injected noise as propagated noise from the driver of the net connected to the pin. This noise bump overrides any propagated noise that would otherwise be calculated from the driver of the net.

You can specify propagated noise on an output pin rather than a load pin. In that case, the specified noise bump overrides any propagated noise that would otherwise be calculated from the driver. The specified noise bump is propagated through the subnets and attenuated by the parasitic capacitance and resistance specified for the net, until the propagated noise reaches each of load pin on the net.

The *report_noise_calculation* command shows whether input noise information was calculated or annotated by this command.

Examples

This example specifies a noise bump height of 0.58, width of 1.70 for pin B of cell U1 in the current design.

```
pt_shell> set_input_noise -above -low -width 1.70 -height 0.58\\
 [get_pins U1/B]
```

---

set_input_transition

Sets a fixed transition time on input or inout ports.

Feedback

Syntax

string *set_input_transition*

```
[-rise]
[-fall]
[-min]
[-max]
[-clock clock_name]
[-clock_fall]
[-sms_scenarios sms_scenarios_list]
transition
port_list
```

Data Types

clock_name	string
transition	float
port_list	list

Arguments

`-rise`

Sets only the rise transition.

`-fall`

Sets only the fall transition.

`-min`

Sets transition for minimum conditions.

`-max`

Sets transition for maximum conditions.

`-clock` *clock_name*

The input transition is set relative the specified clock. This option is deprecated, and will be ignored.

`-clock_fall`

Specifies that the transition is relative to the falling edge of the clock. The default is the rising edge. This option is deprecated, and will be ignored.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios for which the specification applies. When this option is not given, the specification applies to all SMS scenarios. This collection is created by the *get_sms_scenarios* command.

Only scenarios relating to the corner domain and voltage domain at the port are honored. Scenario specifications for other corner or voltage domains are accepted by the command but ignored when propagating transitions.

transition

Port transition value. This is a floating point number greater than or equal to zero.

port_list

A list of input or inout ports.

Description

The *set_input_transition* command specifies a fixed transition time for a list of input or inout ports. This transition time is not affected by the capacitance of the net connected to the port. The transition time calculates delays for nets and cells in the transitive fanout of the port. The port itself has no cell delay.

To display port transition or drive capability information, use the *report_port -drive* command.

There are two other methods of describing port drive capability. The *set_driving_cell* command causes the port to have transition time calculated as if a given library cell was driving the net. The *set_driving_cell* command also has a cell delay equal to the load-dependent portion of the delay driving the net of the library cell. The driving cell approach is accurate for nonlinear delay models even if the capacitance is changed. Another method is to use the *set_drive* command, which models the driver as a linear resistance. The most recent drive command has precedence.

Examples

This example specifies that ports matching the pattern "DATA_IN*" has a transition time of 0.75 units.

```
pt_shell> set_input_transition 0.75 [get_ports DATA_IN*]
```

Feedback

set_isolation

Defines the UPF isolation strategy for the power domains in the design.

Syntax

int *set_isolation*

```
-domain power_domain
[-isolation_power_net supply_net_name]
[-isolation_ground_net supply_net_name]
[-isolation_supply_set supply_set_name]
[-no_isolation]
[-elements objects]
[-clamp_value 0 | 1 | latch | Z]
[-applies_to input | output | both]
[-applies_to_boundary upper | lower | both]
[-source source_supply_set_name]
[-sink sink_supply_set_name]
[-diff_supply_only TRUE | FALSE]
[-isolation_signal signal]
[-location self | parent | fanout]
[-isolation_sense sense]
[-force_isolation]
[-name_prefix prefix_string]
[-name_suffix suffix_string]
isolation_strategy
```

Data Types

```
power_domain                string
supply_net_name             string
supply_set_name             string
objects                     list
source_supply_set_name      string
sink_supply_set_name        string
prefix_string               string
suffix_string               string
isolation_strategy          string
signal                   string
sense                    string
location                    string
```

Arguments

`-domain power_domain`

Specifies the power domain name that this UPF isolation strategy is applied to.

`-isolation_power_net supply_net_name`

Specifies the isolation power net for the isolation cells that are created based on this UPF isolation strategy.

`-isolation_ground_net` *`supply_net_name`*

Specifies the isolation ground net for the isolation cells that are created based on this UPF isolation strategy. At least one of the *-isolation_power_net* or *-isolation_ground_net* options should be specified if the *-no_isolation* option is not specified.

`-isolation_supply_set` *`supply_set_name`*

Specifies the supply set whose power and ground functions are to be used as the isolation power and ground nets respectively. This option is mutually exclusive with the *-isolation_power_net* and *-isolation_ground_net* options.

`-no_isolation`

Specifies that elements under the influence of this *set_isolation* command should not be isolated.

`-elements` *`objects`*

Specifies the objects that this UPF isolation strategy are applied to. The objects can be pins of the root cells of the power domain, ports of the top-level design for top-level power domains.

`-clamp_value 0 | 1 | latch | Z`

Specifies the clamp value of the isolation cells that should be created based on this strategy. The default of this option is 0.

`-applies_to input | output | both`

Specifies whether the given *set_isolation* command applies to all inputs or outputs or both kind of ports of the power domain. The default of this option is *output*.

`-applies_to_boundary upper | lower | both`

Specifies explicitly whether to apply the strategy to upper boundaries(lowConns) only, to lower boundaries(highConns) only, or to both upper and lower boundaries of the power domain. PT/PrimePower does not use this option for any analysis. PrimeTime ignores this option.

`-source` *`source_supply_set_name`*

Specifies the source supply set that applies on the elements of the strategy. It filters the ports/pins receiving a net that is driven by logic powered by the supply set. This option is mutually exclusive with the *-applies_to* option.

`-sink` *`sink_supply_set_name`*

Specifies the sink supply set that applies on the elements of the strategy. It filters the ports/pins driving a net that fans out to logic powered by the supply set. This option is mutually exclusive with the *-applies_to* option.

`-diff_supply_only TRUE | FALSE`

Determines the isolation behavior between driver and receiver supply sets. If the driver is powered by the same supply set as a receiver of the port, no isolation cell is introduced into the path. The default for this option is *FALSE*. The *-source*, *-sink*, and *-diff_supply_only* options are mutually exclusive.

`-isolation_signal` *`signal`*

Specifies the isolation signal to use as the control signal of the isolation cells that should be created as a result of this isolation strategy. The *signal* value can be a pin, port, or net.

`-location self | parent | fanout`

Specifies the hierarchical location of the isolation cells that should be created as a result of this isolation strategy. The default value is *self*.

A value of *self* specifies that the isolation cell is placed in the hierarchy of the port being isolated.

A value of *parent* specifies that isolation cells is added in the parent hierarchy of the isolating port's hierarchy.

A value of *fanout* specifies that isolation cells is added in the fanout of the isolating port.

`-isolation_sense` *`sense`*

Specifies the isolation sense of the isolation cells that should be created as a result of this isolation strategy. Excepted values are either *low* or *high*. The default value is *high*.

`-force_isolation`

Forces isolation.

`-name_prefix` *`prefix_string`*

Prepends the specified prefix to the names of generated isolation instances or nets related to implementation of the isolation strategy. This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-name_suffix` *`suffix_string`*

Appends the specified suffix to the names of generated isolation instances or nets related to implementation of the isolation strategy. This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

isolation_strategy

Specifies the name of the UPF isolation strategy. The name must be unique within the specified power domain.

update

Specifies the elements to be updated for existing isolation.

Description

This command defines the UPF isolation strategy for the ports of the specified power domain.

If *-elements* and *-applies_to* options are not specified, the isolation strategy is applied to all the outputs ports of the power domain.

If neither the *-isolation_supply_set*, *-isolation_power_net*, nor *-isolation_ground_net* option is specified, the isolation power and ground nets are automatically set to the power and ground functions of the *default_isolation* handle of the power domain, for which the strategy is being defined.

PrimeTime uses the *set_isolation* command to build virtual power ground connectivity. The command creates explicit connection for isolation power and ground nets to power and ground pins of isolation cells. If a cell matches multiple isolation rules (*set_isolation* and *set_isolation_control* commands), the last entered *set_isolation* command rule is used to derive the PG connectivity of the cell. Use the *upf_isolation_strategy* cell attribute to check which isolation rule was applied to the cell.

Examples

The following example shows how to define a UPF isolation strategy for all the output ports of the specified power domain PD1. Power domain PD1 is defined on the shutdown_inst instance.

```
pt_shell> set_isolation isolation_1 -domain PD1 \\
            -isolation_power_net PN1 \\
            -isolation_ground_net GN1
```

The following example shows how to define a UPF isolation strategy for specific ports of the specified power domain.

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -isolation_power_net PN1 \\
            -isolation_ground_net GN1 \\
            -elements shutdowm_inst/special_port
```

The following example shows how to find all isolation cells in the design and the strategy applied to each cell:

```
pt_shell> foreach_in_collection c [sort_collection [get_cells
 -hierarchical *
            -filter "upf_isolation_strategy != {}"] full_name] {
               echo [format {  Cell  %-8s  isolation %s}
                  [get_attribute $c full_name] [get_attribute $c
 upf_isolation_strategy]]
            }
```

The following example shows how to define a UPF isolation strategy using a supply set:

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -isolation_supply_set iso_supply_set \\
            -elements shutdown_inst/special_port
```

The following example shows how to define a UPF isolation strategy without using a supply set or supply nets.

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -elements shutdown_inst/special_port
```

The following example shows how to define a UPF isolation strategy using the *-source* and *-sink* options.

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -isolation_supply_set iso_supply_set \\
            -source PD_primary_set \\
            -sink sset
```

The following example shows how to define a UPF isolation strategy using the *-diff_supply_only* option.

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -isolation_supply_set iso_supply_set \\
            -source PD_primary_set \\
            -diff_supply_only TRUE
```

The following example shows how to update elements using the *-update* option.

```
pt_shell> set_isolation isolation_2 -domain PD1 \\
            -element PD1_INST/INPUT \\
            -isolation_supply_set  SS1 \\
            -update PD2_INST/INPUT
```

Feedback

set_isolation_control

Provides additional options needed for creating isolation cells. This command is needed with most *set_isolation* commands.

Syntax

status *set_isolation_control*

```
-domain domain
-isolation_signal signal
[-location self | parent | fanout]
[-isolation_sense sense]
isolation_name
```

Data Types

```
domain                  string
signal                  string
sense                   string
isolation_name          string
```

Arguments

`-domain domain`

Specifies the power domain name to which this UPF isolation strategy is applied.

This option is required.

`-isolation_signal signal`

Specifies the isolation signal to use as the control signal of the isolation cells that should be created as a result of this isolation strategy. The *signal* value can be a pin, port, or net.

This option is required.

`-location self | parent | fanout`

Specifies the hierarchical location of the isolation cells that should be created as a result of this isolation strategy. The default value is *self*.

A value of *self* specifies that the isolation cell is placed in the hierarchy of the port being isolated.

A value of *parent* specifies that isolation cells is added in the parent hierarchy of the isolating port's hierarchy.

A value of *fanout* specifies that isolation cells is added in the fanout of the isolating port.

`-isolation_sense` *sense*

Specifies the isolation sense of the isolation cells that should be created as a result of this isolation strategy. Excepted values are either *low* or *high*. The default value is *high*.

isolation_name

Specifies the UPF isolation strategy name. The isolation strategy should already be defined in the specified power domain.

This argument is required.

Description

This command applies to an existing isolation strategy specified by the *set_isolation* command. It provides extra parameters needed for creating isolation cells.

PrimeTime uses additional information about the isolation strategy provided by this command to properly match isolation strategies to individual leaf cells (PrimeTime does not create isolation cells). Isolation strategy is used for deriving PG connectivity from UPF description.

Examples

The following example shows how to define a UPF isolation strategy for all output ports of the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst, and isolation strategy isolation_1 is already defined

```
pt_shell> set_isolation_control isolation_1 -domain PD1 \\
            -location parent \\
            -isolation_signal en \\
            -isolation_sense high \\
```

See Also

- set_isolation

---

set_latch_loop_breaker

Specifies transparent latch data pins to be used as loop breaker latch data pins when the *timing_enable_through_paths* variable is set to *true*.

Feedback

Syntax

status *set_latch_loop_breaker*

```
-pin pin_list
[-remove]
[-avoid]
```

Data Types

pin_list	list

Arguments

`-pin` *pin_list*

Specifies data pins of transparent latches to be loop breakers.

`-remove`

Removes the user-specified setting on pins.

`-avoid`

Avoids using the specified pins as loop breakers. Requests to avoid using specified pins as loop breaker pins cannot always be honored, especially if there is a loop from the pin through combinational logic to itself.

Description

When sequential loops of transparent latches exist in a design, the tool selects certain latch data pins for special analysis as loop breaker data pins. Reporting paths through these latch data pins is not permitted except by using the *-trace_latch_borrow* option of the *report_timing* command.

Use the *set_latch_loop_breaker* command to guide the tool in selecting data pins as loop breaker data pins. By guiding the tool to select some latch data pins as loop breakers and not others, you can report the paths of interest.

Before using the *set_latch_loop_breaker* command, set the *timing_enable_through_paths* variable to *true*.

Examples

The following example specifies that the L1/D pin is a loop breaker pin.

```
pt_shell> set_latch_loop_breaker -pin [get_pin L1/D]
```

Feedback

---

set_level_shifter_strategy

Sets the type of strategy to use for reporting the signal level mismatches in the design.

Syntax

status *set_level_shifter_strategy*

`[-rule strategy]`

Data Types

`strategy` `string`

Arguments

`-rule strategy`

Specifies types of source-sink pairs of mismatching signal levels that the *check_timing -include signal_level* command reports. The following values are allowed:

- *all* (the default) - Reports all voltage level mismatches.
- *low_to_high* - Reports the voltage level mismatches when a source at a lower voltage drives a sink at a higher voltage.
- *high_to_low* - Reports the voltage level mismatches when a source at a higher voltage drives a sink at a lower voltage.

Description

This command specifies the strategy for reporting nets that need insertion of level-shifters.

Examples

The following example sets the level-shifter strategy to the *high_to_low* option:

```
prompt> set_level_shifter_strategy -rule high_to_low
```

Feedback

See Also

- check_timing
- set_level_shifter_threshold

---

set_level_shifter_threshold

Sets the minimum threshold beyond which the voltage adjustment is required.

Syntax

integer *set_level_shifter_threshold*

```
-voltage volt
-percent diff
```

Data Types

```
volt      float
diff      float
```

Arguments

`-voltage volt`

The absolute difference between the source and sink voltages.

`-percent diff`

The percentage by which the source and sink voltages must differ. The percentage is determined as follows:

```
abs(driver(v)-load(v))/driver(v)*100
```

Description

This command specifies the minimum threshold value for the voltage difference between a source and a sink. Voltage differences above the minimum threshold are reported by *check_timing -include signal_level*. The threshold can be specified as the absolute difference in voltages or a percentage difference or both.

When both *-voltage* and the *-percent* options are both specified: Since physical tools insert level shifters when either absolute or relative threshold is exceeded the *check_timing -include signal_level* only skips signal level mismatches that are smaller than both the absolute and the relative thresholds.

The default threshold voltage and percentage is zero. Therfore you typically must specify both absolute and relative thresholds to suppress reporting of below-threshold level mismatches.

Feedback

Examples

The following example sets the level shifter threshold value to the absolute difference of 0.1 (and sets large relative threshold):

```
psyn_shell-t> set_level_shifter_threshold -voltage 0.1 -percent 100
```

The following example sets the threshold value 5 percent (and sets large absolute threshold):

```
prompt> set_level_shifter_threshold -percent 5 -voltage 10
```

The following example sets the threshold value to 0.1 difference and 5 percent, so if either value is reached, the signal level mismatch is reported:

```
prompt> set_level_shifter_threshold -voltage 0.1 -percent 5
```

See Also

- check_timing
- set_level_shifter_strategy

---

set_lib_cell_spacing_label

Sets an inter cell spacing constraint label on a reference cell in preparation for defining minimum spacing rules between library cells.

Syntax

status *set_lib_cell_spacing_label*

```
-name label_name
[-left_lib_cells list_of_lib_cells]
[-right_lib_cells list_of_lib_cells]
```

Data Types

```
label_name           string
list_of_lib_cells    list
```

Arguments

`-name label_name`

Inter cell constraint label to assign to one or more reference cells.

`-left_lib_cells list_of_lib_cells`

Specifies a list of reference cells that have the given label assigned to the left side of the cell in the "North" orientation. The argument must be a string list of library cells.

`-right_lib_cells` *`list_of_lib_cells`*

Specifies a list of reference cells that have the given label assigned to the right side of the cell in the "North" orientation. The argument must be a string list of library cells.

Description

This command assigns a label to a list of reference (library) cells to set inter cell spacing constraints to be enforced by the legalization tool. A label is a string that you assign to the left or right side of a standard cell.

This command works together with the *set_spacing_label_rule* command, which defines the illegal range of spacing between two adjacent labels. All spacing rules specified by *set_spacing_label_rule* command must be satisfied to produce a legal placement.

With inter cell spacing rules specified, standard cells can be placed next to each other only when they do not violate the spacing rules.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and are applied to all designs using the library.

Examples

The following command assigns the label "X" to reference cells AND* on the left side of the cell, and to reference cells NAND* on the right side of the cell (for cells in the "North" orientation).

```
prompt> set_lib_cell_spacing_label -name {X} \ -left_lib_cells {AND*} \ -right_lib_cells {NAND*}
```

The following command assigns the labels "Y" and "Z" to the right side of reference cell OR2X4.

```
prompt> set_lib_cell_spacing_label -name {Y Z} -right_lib_cells {OR2X4}
```

See Also

- set_spacing_label_rule

---

set_lib_rail_connection

Sets a physical power pin on a library cell.

Syntax

status *set_lib_rail_connection*

Feedback

```
-lib_cell_names lib_cells
-lib_pin_names library_pin_names
-lib_rail_names power_rail_names
```

Data Types

```
lib_cells              list
library_pin_names      list
power_rail_names       list
```

Arguments

`-lib_cell_names lib_cells`

Recognizes the specified list of library cells on power rails.

`-lib_pin_names library_pin_names`

Annotates the specified library pin names.

`-lib_rail_names power_rail_names`

This argument is accepted but not currently supported in PrimeTime.

Description

The *set_lib_rail_connection* command associates the name of a power pin with a library cell. When linking physical Verilog to a logic library, pins specified by this command can be present in the Verilog but not in the logic library.

Examples

The following example shows how to set a physical power pin on a library cell to link with to logic library.

```
pt_shell> set_lib_rail_connection -lib_cell_names typ/INVX1
 -lib_pin_names VDD1
```

When subsequently linking physical Verilog, pins named VDD1 on the INVX1 library cell are ignored when linking to the typ logic library. This allows successful linking of physical Verilog to logic libraries in which power pins not specified.

See Also

- read_verilog

---

set_library_driver_waveform

Sets the driver waveform used to characterize the timing library.

Feedback

Syntax

status *set_library_driver_waveform*

```
-type ramp | standard
  [lib_objs]
```

Data Types

```
lib_objs          list
```

Arguments

```
-type ramp | standard
```

Specifies the type of the waveforms:

- *ramp* - Linear waveforms.
- *standard* - Waveforms commonly known as Synopsys predriver.

lib_objs

List of libraries or library cells on which the driver waveform applies.

Description

The data tables in the timing libraries are indexed by slew. The library characterization process could use the standard Synopsys predriver waveform or a simple ramp waveform to characterize the library. The library data reflects the type of waveform used for characterization. The shape of the waveform generally has only a small effect on the timing results. However, for some forms of advanced analysis, the waveform shape can become significant:

- For advanced crosstalk delay analysis using a CCS noise library, using the exact waveform shape in PrimeTime SI is necessary to get the best possible accuracy.
- When the *write_spice_deck* command writes out a SPICE deck for a given path or arc, and advanced waveform propagation is not enabled, each input to the cell should use the same waveform that was used to characterize the library, to get the best possible correlation between PrimeTime SI and SPICE simulation results.

This command specifies the waveform shape for the library objects. This command allows two type of waveforms: *ramp* and *standard* (Synopsys predriver waveform). If the library object is not provided the waveform is applied to the whole design. When waveform specified on a library cell it gets higher priority than the waveform set on library and the waveform set on library gets higher priority than the design. This command triggers the *update_timing* command.

Feedback

Examples

This example specifies how to set ramp for the whole design. When the *write_spice_deck* command generates the SPICE deck, it uses ramp for voltage sources if no other waveform is specified on the library or library cell.

```
pt_shell> set_library_driver_waveform  -type ramp
```

In the following example the *libOld* is characterized with ramp and the *libNew* library is characterized with standard waveforms. It shows how to set these waveforms after the libraries read to PrimeTime. The *lib_pin* attribute of the *driver_waveform_fall/ driver_waveform_rise* could be used to get the name of the characterization waveforms.

```
pt_shell> set_library_driver_waveform -type ramp [get_lib libOld]
pt_shell> set_library_driver_waveform -type standard [get_lib libNew]
pt_shell> get_attr [get_lib_pin libOld/INV/A] driver_waveform_fall
pt_shell> get_attr [get_lib_pin libOld/INV/A] driver_waveform_rise
```

---

set_license_limit

Specifies the upper limit on the number of licenses of given features that can be checked out.

Syntax

```
status set_license_limit
  feature_list
  -quantity num_licenses
```

Data Types

feature_list	list
num_licenses	integer

Arguments

feature_list

Specifies a list of features to which the limit applies.

-quantity *num_licenses*

Specifies the maximum number of licenses that can be checked out.

Feedback

Description

The *set_license_limit* command specifies the upper limit on the number of licenses of given features that can be checked out.

Licenses can be checked out explicitly using the *get_license* command or implicitly by the tool itself.

If the given license limit is lower than the number of licenses already checked out, the command will try to reduce the number of checked out licenses to the limit.

To remove the license limit, use the *remove_license_limit* command. Currently defined license limits can be reported using the *report_license_limit* command.

Examples

In the following example, the upper limit on the number of PrimeTime licenses is set to seven and the number of PrimeTime SI licenses set to four. No licenses are checked out at the point at which the commands are called, the licenses are checked out as and when they are needed during the subsequent analysis.

```
pt_shell> set_license_limit PrimeTime -quantity 7
Information: Setting license limit for feature 'PrimeTime' to 7. (PT-021)
1
pt_shell> set_license_limit PrimeTime-SI -quantity 4
Information: Setting license limit for feature 'PrimeTime-SI' to 4.
 (PT-021)
1
```

See Also

---

set_link_lib_map

Set the library map for a design or for an instance or for a referece using a file.

Syntax

string *set_link_lib_map*

```
link_lib_map_file
[-reference module_name]
[-instance instance_name]
```

Data Types

```
link_lib_map_file     string
module_name           string
instance_name         string
```

Arguments

`link_lib_map_file`

Specifis the mapping file which contains the library mapping for modules or instances.

`-reference`

Name of the verilog module to which the mapping file is to be applied.

`-instance`

Name of the cell instance to which the mapping file is to be applied.

Description

The set_link_lib_map command is used to specify the library mapping to the instances or verilog modules. This is used as an alternative to the link_path_per_instance setting. Hence the setting and the set_link_lib_map commands are mutually exclusive. An LNK-068 is thrown if link_path_per_instance is already set.

The link_lib_map_file should contain the library mapping in the format: [instace_name : [list_of_libraries]. An entry, '*' is allowed in list of libraries, which means to pick up from the memory.

By default link_lib_map_file is used for the mappping to the top_design, if none of -reference or -instance options are specifed. The options "-reference" and "-instance" are mutually exclusive. When one of them is specified link_lib_map_file is considered for the specified module or instance.

Examples

The following scripts illustrates the set_link_lib_map command.

```
set link_path "* my_linked_lib.db"
set_link_lib_map -ref test $map_path/test_map
read_verilog ./test.v
current_design test
link

set link_path "* my_linked_lib.db"
set_link_lib_map -instance V2 $map_path/test_map
```

```
read_verilog ./test.v
current_design test
link
```

See Also

- current_design
- read_verilog
- link_path

---

set_load

Sets the capacitance on the specified ports and nets in the current design.

Syntax

```
status set_load
  [-min]
  [-max]
  [-rise]
  [-fall]
  [-pin_load]
  [-wire_load]
  [-subtract_pin_load]
  [-allow_negative_cap]
  capacitance
  objects
```

Data Types

```
capacitance   float
objects       list
```

Arguments

`-min`

Indicates that the *capacitance* is the minimum capacitance. Applies only to designs in min-max mode (minimum and maximum operating conditions).

`-max`

Indicates that the *capacitance* is the maximum capacitance. Applies only to designs in min-max mode (minimum and maximum operating conditions).

`-rise`

Indicates that the *capacitance* is the rise capacitance. This option can be used in combination with the *-min* or *-max* option. Use this option only with ports. An error message is generated if the *objects* list contains nets.

`-fall`

Indicates that the *capacitance* is the fall capacitance. This option can be used in combination with the *-min* or *-max* option. Use this option only with ports. An error message is generated if the *objects* list contains nets.

`-pin_load`

Indicates that the specified *capacitance* is a pin capacitance. Pin capacitance is not subject to "scaling" using tree_type. Use this option only with ports. An error message is generated if the *objects* list contains nets.

If you do not specify either the *-pin_load* or *-wire_load* option or specify both options, the *-pin_load* option is the default.

`-wire_load`

Indicates that the specified *capacitance* is a wire capacitance. Pin capacitance is subject to "scaling" using tree_type. Use this option only with ports. An error message is generated if the *objects* list contains nets.

If you do not specify either the *-pin_load* or *-wire_load* option or specify both options, the *-pin_load* option is the default.

`-subtract_pin_load`

Indicates that the current pin capacitances of the specified net are to be subtracted from *capacitance* before the net capacitance value is set. Any resulting negative net capacitance values are set to zero. Use this option only if *capacitance* includes pin capacitances.

`-allow_negative_cap`

Allows the command allowed to set a negative capacitance. Use this option only with the *-subtract_pin_load* option. After subtracting the pin capacitance, the resulting capacitance can become negative.

`capacitance`

Specifies the capacitance value to be set on the ports and nets in *objects*. It is in the units of the logic library. The capacitance value must be greater than or equal to zero. Any negative value is set to zero.

`objects`

Specifies a list of ports and nets in the current design, on which the *capacitance* is to be set. If you specify a name (for example, *net_name*) instead of a real object_list (for example, by using the *get_port* command with the *port_name* option or the *get_net* command with the *net_name* option), the tool first searches the list of all ports and then searches the list of all nets for a match.

`-sms_scenarios`

Limits the specification to only the provided SMS scenarios. When this option is not given, the specification applies to all SMS scenarios. Use the *get_sms_scenarios* command to obtain SMS scenarios.

Only *-pin_load* values support this option. For *-wire_load* values, the last specified value applies to all SMS scenarios.

Description

This command sets the capacitance to a specified value on specified ports and nets in the current design. If the current design is hierarchical, you must link it using the *link_design* command.

Depending on the options used, the *set_load* command sets these attributes on the specified objects:

```
wire_capacitance_max
wire_capacitance_min
pin_capacitance_max
pin_capacitance_min
```

If this command is run without any options, the *pin_capacitance_max* attribute is set; in min-max mode, the *pin_capacitance_min* attribute is also set.

For ports, if the *set_load* command is issued with only the *-wire_load* option, the *wire_capacitance_max* attribute is set on the specified ports; in min-max mode, the *wire_capacitance_min* attribute is also set. However, the value is actually counted as part of the total wire capacitance and not as part of the pin/port capacitance.

In min-max mode, using either the *-min* or *-max* option sets only the **_min* or **_max* attributes, respectively.

If the *-rise* option is specified, the *pin_capacitance_max_rise* and *pin_capacitance_min_rise* attributes are set. You can use this option in conjunction with either the *-min* or *-max* option to set only one of the two attributes. The same conditions apply for the *-fall* option and the *pin_capacitance_*_fall* attributes.

The total capacitance on a net is the sum of all pin capacitances, port capacitances, and wire capacitances associated with that net. The specified *capacitance* overrides both the internally-estimated net capacitance value and any net capacitance set by the *read_parasitics* command.

You can also use the *set_load* command for nets at lower levels of the design hierarchy. These nets are specified in the "BLOCK1/BLOCK2/NET_NAME" format. The tool treats capacitances in such a way that timing on a subblock should be the same as timing on the higher-level design, since pin/wire caps on ports represent a part of the higher-level design.

To view capacitance values on ports and nets, use the *report_port* and *report_net* commands, respectively. To remove a capacitance value, use the *remove_capacitance* command; you can remove annotated capacitances from the full design by using the *reset_design* command.

Examples

The following example sets a capacitance of 2 units on the xyz port.

```
pt_shell> set_load 2 xyz
```

The following example sets a capacitance of 2.5 units (the estimated wire capacitance) plus the capacitance of three inverter input pins from the tech_lib library named on all output ports. It uses the user-defined *port_capacitance* variable to store this capacitance value.

```
pt_shell> set pin_cap \\
            [get_attribute [get_lib_pins tech_lib/IV/A] pin_capacitance]
2.0
pt_shell> set port_capacitance [expr 2.5 + (3 * $pin_cap)]
8.5
pt_shell> set_load $port_capacitance [all_outputs]
1
```

The following example uses the *get_attribute* command to get the value of the *pin_capacitance* attribute on the Z pin of IV from the tech_lib library and sets that value on the input_1 and input_2 ports.

```
pt_shell> set_load \\
            [get_attribute [get_lib_pins tech_lib/IV/Z] pin_capacitance]
 \\
            [get_ports {input_1 input_2}]
```

The following example sets a capacitance of 3 on the U1/U2/NET3 net. The wire capacitance is set to 3. (Total net capacitance is 3 + the sum of the pin and port capacitances.)

```
pt_shell> set_load 3 U1/U2/NET3
```

The following example sets a total net capacitance (wire capacitance + pin capacitances) of 3 on the U1/U2/NET3 net. If the pin and port capacitances equal 2, the wire capacitance is annotated with 1; if the pin and port capacitances are 3 or greater, the wire capacitance is annotated with 0.

```
pt_shell> set_load -subtract_pin_load 3 U1/U2/NET3
```

The following example sets a wire capacitance of 5 units on the xyz port.

```
pt_shell> set_load -wire_load 5 xyz
```

The following example sets different capacitances values for different scenarios.

Feedback

```
pt_shell> set_load -sms_scenario $low_low 2 [get_port OUT]
pt_shell> set_load -sms_scenario $high_high 3 [get_port OUT]

pt-shell> get_attribute [get_port OUT] pin_capacitance_max($low_low)
2.0
pt-shell> get_attribute [get_port OUT] pin_capacitance_max($high_high)
3.0
```

The following example removes the back-annotated capacitance on a port and on a net.

```
pt_shell> remove_capacitance [get_ports the_answer]
pt_shell> remove_capacitance [get_nets net12]
```

---

set_max_area

Sets the *max_area* attribute on the current design to a specified value.

Syntax

int *set_max_area*

area_value

Data Types

area_value float

Feedback

Arguments

area_value

Specifies the value to which the *max_area* attribute is to be set. The value must be greater than or equal to 0 (>= 0). The units of the *area_value* option must be consistent with the units in the technology library used during optimization.

Description

The *set_max_area* command sets the *max_area* attribute on the current design to the specified *area_value*. This attribute represents the target area of the design.

Use the *remove_max_area* or *reset_design* command to remove the *max_area* attribute on the current design.

Use the *report_constraint* command to show area cost of the design.

Examples

The following example sets the target area for the current design to 250.

```
pt_shell> set_max_area 250.0
1
pt_shell> get_attribute [current_design] max_area
250.000000
```

See Also

- current_design
- get_attribute
- remove_max_area
- report_constraint
- reset_design

---

set_max_capacitance

Sets maximum capacitance limit for pins, library pins, ports, clocks, or designs.

Syntax

string *set_max_capacitance*

```
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-force]
```

Feedback

```
[-sms_scenarios sms_scenarios_list]
capacitance_value
object_list
```

Data Types

```
capacitance_value          float
object_list                list
sms_scenarios_list         collection
```

Arguments

`-clock_path`

Applies the limit only to pins in the clock network of the clocks specified in the *object_list*.

`-data_path`

Applies the limit only to pins in the data paths launched by the clocks specified in the *object_list*.

`-rise`

Applies the limit only to rising capacitance values. This option requires that the *object_list* contains only clock objects.

`-fall`

Applies the limit only to falling capacitance values. This option requires that the *object_list* contains only clock objects.

`-force`

Force the limit to be set to the specified value, overriding other more restrictive constraints if they exist.

`-sms_scenarios` *sms_scenarios_list*

Limits the specification to only the given SMS scenarios. Without this option, the specification applies to all SMS scenarios. This collection is created by the *get_sms_scenarios* command.

capacitance_value

Specifies the capacitance limit (value >= 0). This is the maximum total capacitance (pin plus wire capacitance) in library capacitance units.

object_list

Provides a list of pins, library pins, ports, clocks, or designs on which to set maximum capacitance.

Feedback

Description

Specifies a maximum capacitance limit on pins, library pins, ports, clocks, or designs. If maximum capacitance is set on a pin or port, the net connected to that pin or port is expected to have a total capacitance less than the specified *capacitance_value*. If specified on a design, the default maximum capacitance for that design is set. If specified on a library pin, the requirement is inherited by all leaf pin instances.

If maximum capacitance is set on a clock, the maximum capacitance is applied to all pins in this specified clock domain (clock and data). Within a clock domain, you can optionally restrict the constraint further to only clock paths or data paths, and to only rising or falling capacitances. (Note that the *-clock_path*, *-data_path*, *-rise*, and *-fall* options can only be used for limits applied to clock objects.)

During analysis, the most restrictive of the design, pin, clock, library, and port limits is used.

The *report_constraint -max_capacitance* command shows maximum capacitance constraint evaluations. The minimum slack of rise and fall capacitance is reported. When there are violations across multiple clock-specific limit values, the worst slack is reported.

The *report_port -design_rule* command shows port maximum capacitance limits. The *report_design* command shows the default maximum capacitance limit for the current design.

To remove maximum capacitance limits applied by this command, use the *remove_max_capacitance* command.

Examples

The following example sets a maximum capacitance limit of 2.0 units on ports "OUT*".

```
pt_shell> set_max_capacitance 2.0 [get_ports "OUT*"]
```

The following example sets the default maximum capacitance limit of 5.0 units on the current design.

```
pt_shell> set_max_capacitance 5.0 [current_design]
```

The following example sets a maximum capacitance limit of 0.8 units on all pins in the clock network of CLK.

```
pt_shell> set_max_capacitance 0.8 [get_clocks CLK] -clock_path
```

The following example sets a maximum capacitance limit of 0.7 units on all pins of the data path of CLK.

```
pt_shell> set_max_capacitance 0.7 [get_clocks CLK] -data_path
```

Feedback

set_max_delay

Specifies the maximum delay constraint for timing paths that start from, pass through, or end at specified objects.

Syntax

status *set_max_delay*

```
[-rise]
[-fall]
[-reset_path]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-to to_list]
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-through through_list
   | -rise_through rise_through_list
   | -fall_through fall_through_list]
[-ignore_clock_latency]
[-probe]
[-comment comment_string]
[-sms_scenarios sms_scenarios_list]
delay_value
```

Data Types

comment_string	string
delay_value	float
fall_from_list	list
fall_through_list	list
fall_to_list	list
from_list	list
rise_from_list	list

```
rise_through_list          list
rise_to_list               list
sms_scenarios_list         collection
through_list               list
to_list                    list
```

Arguments

`-rise`

Applies the delay constraint only to paths with a rising transition at the path endpoint.

`-fall`

Applies the delay constraint only to paths with a falling transition at the path endpoint.

By default, the constraint applies to both rising and falling transitions.

`-reset_path`

Removes existing point-to-point timing exceptions from the specified paths before applying the maximum delay constraint. Using this option is equivalent to using the *reset_path* command with similar arguments before the *set_max_delay* command. Only exceptions defined with the same path settings are affected: *-from*, *-to*, *-rise*, *-fall*, *-setup*, *-hold*, and so on.

`-from` *`from_list`*

Specifies a list of timing path startpoint objects: a clock, primary input port, sequential cell, clock pin of a sequential cell, data pin of a level-sensitive latch, or pin that has an input delay specified.

If you specify a clock, all registers and primary inputs related to that clock are considered path startpoints. If you specify a sequential cell, the command is automatically expanded to apply to each individual clock input pin of the cell. If public variable *timing_enable_from_clock_to_dangling_load_endpoints* is set to true, then all registers and primary inputs related to the clock are used as startpoints to constrain any dangling load endpoints in their fanout.

You can specify any pin in a data path as a startpoint so that the *report_timing* command checks the path delay starting from that pin. This effectively breaks the data path into two segments and prevents path tracing through the pin. To prevent breaking of other timing paths through the pin, use the *-probe* option.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the delay constraint applies only to rising transitions at the specified objects.

If you specify a clock, the delay constraint applies to paths with a startpoint clocked by the named clock and launched by a rising edge at the clock source. The actual edge at the launch register can be either rising or falling, depending on logical inversions in the clock network.

`-fall_from` *`fall_from_list`*

Same as the *-rise_from* option, except that the constraint applies only to falling transitions at the specified objects.

You can use no more than one of the *-from*, *-rise_from*, and *-fall_from* options.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects: a clock, primary output port, sequential cell, data pin of a sequential cell, or pin that has an output delay specified.

If you specify a clock, all registers and primary outputs related to that clock are considered path endpoints. If you specify a sequential cell, the command is automatically expanded to apply to each individual data input pin of the cell.

You can specify any pin in a data path as an endpoint so that the *report_timing* command checks the path delay ending at that pin. This effectively breaks the data path into two segments and prevents path tracing through the pin. To prevent breaking of other timing paths through the pin, use the *-probe* option.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, except that the delay constraint applies only to rising transitions at the specified objects.

If you specify a clock, the delay constraint applies to paths with an endpoint clocked by the named clock and captured by a rising edge at the clock source. The actual edge at the capture register can be either rising or falling, depending on logical inversions in the clock network.

`-fall_to` *`fall_to_list`*

Same as the *-rise_to* option, except that the constraint applies only to falling transitions at the specified objects.

You can use no more than one of the *-to*, *-rise_to*, and *-fall_to* options.

`-through` *`through_list`*

Specifies a list of pins, ports, cells, and nets through which the paths must pass for the delay constraint to apply.

`-rise_through` *`rise_through_list`*

Same as the *-through* option, but applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

Same as the *-through* option, but applies only to paths with a falling transition at the specified objects.

`-ignore_clock_latency`

Causes the launch and capture clock latencies to be ignored when the *report_timing* command computes slack for the specified paths; and if SI analysis is enabled, causes path-based reporting to conservatively use graph-based crosstalk delta delays. By default, launch and capture clock latencies are considered in the delay slack calculation, and path-based reporting uses path-based crosstalk delta delays.

`-probe`

Prevents the breaking of timing paths at a specified *-from* pin that is not the clock pin of a sequential device, or at a specified *-to* pin that is not the data input pin of a sequential device. Instead, the timing exception applies to the specified startpoints and endpoints without affecting other paths through the specified pins.

If you do not use the *-probe* option, specifying an intermediate pin of a path as a startpoint or endpoint forces that pin to be a startpoint or endpoint for all timing paths, effectively breaking all paths into two separate segments at that pin.

`-comment` *`comment_string`*

Associates a comment string with the command, which is included in the command text written out by the *write_sdc* command. This can be useful for tracking information about the source of the command.

`delay_value`

Specifies the maximum allowed delay for the path, in time units of the logic library used for timing analysis. For this maximum delay constraint, the clock period and clock edge times are ignored.

If a path startpoint has an input delay specified, that delay value is added to the path delay. If a path startpoint is on a sequential device, launch clock latency is included in the computed delay.

If the path endpoint has an output delay specified, that delay is used in the data required-time calculation. If a path endpoint is on a sequential device, the library setup time and capture clock latency are used in the data required-time calculation.

To prevent consideration of launch and capture clock latencies, use the *-ignore_clock_latency* option.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this maximum delay constraint is applied. When this option is not given the maximum delay constraint applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

This command specifies a maximum delay constraint for timing paths that start from, pass through, or end at specified objects in the design. This constraint overrides the default setup time constraint established by the arrival times of launch and capture clock edges.

The *report_timing* command reports violations of the maximum delay constraint, taking into account the input delay, output delay, library setup time at the endpoint register, and clock latencies. To prevent consideration of clock latencies, use the *-ignore_clock_latency* option of the *set_max_delay* command.

The *set_max_delay* command is a point-to-point timing exception command like the *set_multicycle_path*, *set_min_delay*, and *set_false_path* commands. A *set_max_delay* or *set_min_delay* command has higher priority than a *set_multicycle_path* command.

If you specify a sequential cell as the argument of the *-from*, *-rise_from*, or *-fall_from* option, the command is automatically expanded to apply to each clock input pin of the cell. If the cell has multiple clock input pins, the exceptions are maintained separately for each pin. You can see these exceptions by using the *report_exceptions* or *write_sdc* command.

Similarly, if you specify a sequential cell as the argument of the *-to*, *-rise_to*, or *-fall_to* option, the command is automatically expanded to apply to each data input pin of the cell.

The expansion of an exception set on a sequential cell to the individual pins of the cell does not occur in some other tools such as IC Compiler II. In those tools, the exception is maintained at the cell level.

Using the *-from* and *-to* (and similar) options of the *set_max_delay* command, you can specify any pin in a data path as a startpoint or endpoint so that the *report_timing* command checks the path delay between those points. The *set_max_delay* command responds with a UITE-217 warning message because path tracing stops at the specified point, effectively breaking the path into multiple segments. If you set a startpoint or endpoint in a clock network, clock propagation stops at that point. To remove a maximum delay constraint that has been set, use the *reset_path* command.

For a nonsequential timing check defined by the *set_data_check* command, the maximum delay constraint is valid only if clocked signals arrive at both the related ("from") pin and the constrained ("to") pin of the data check. If a clock cannot reach the related pin or constrained pin, the path is considered unconstrained and the timing check is not performed.

When multiple exceptions commands of different types apply to the same path, they apply with the following precedence (highest to lowest):

1. set_false_path
2. set_max_delay and set_min_delay
3. set_multicycle_path

When multiple exception commands of the same type apply to a path, the more specific command overrides the more general. They apply with the following precedence (more specific to more general):

1. set_max_delay -from *pin* -to *pin*
2. set_max_delay -from *pin* -to *clock*
3. set_max_delay -from *pin*
4. set_max_delay -from *clock* -to *pin*
5. set_max_delay -to *pin*
6. set_max_delay -from *clock* -to *clock*
7. set_max_delay -from *clock*
8. set_max_delay -to *clock*

When multiple exception commands of the same specificity apply that differ only by the presence or absence of the *-ignore_clock_latency* option, the command *without* the option takes precedence:

1. set_max_delay
2. set_max_delay -ignore_clock_latency

If multiple exceptions have the same path options and differ only in the specified rise/fall sense, the most constraining time value has priority. For example, the following commands are arranged in order, from the highest to lowest priority, due to their increasing maximum delay values.

1. set_max_delay -fall_from *pin* -to *pin* 5.0
2. set_max_delay -from *pin* -to *pin* 5.5
3. set_max_delay -rise_from *pin* -to *pin* 6.0

To report the current *set_max_delay* settings and other timing exception settings, use the *report_exceptions* command.

To remove timing exceptions set by the *set_max_delay* command, use the *reset_path* command with the same path settings; or the *reset_design* command to remove all timing constraints, including clocks.

Examples

The following example specifies that the delay can be no more than 3.0 time units for a path from a specific register clock pin to a specific output port. This new constraint overrides the default setup constraint for the path.

```
pt_shell> set_max_delay 3.0 -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to
 sd_DQ[8]
```

```
Information: Invalidating logical update. (PTE-139)
1
pt_shell> report_timing -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to sd_DQ[8]
 ...

  Point                                                   Incr       Path

  data required time                                                6.187
  ------------------------------------------------------------------------
  data required time                                                6.187
  data arrival time                                                -5.461
  ------------------------------------------------------------------------
  slack (MET)                                                       0.726
```

The timing check considers clock network delays (latencies) of the launch and capture clocks, but not the clock edge times.

To ignore the clock network delays as well as clock edge times, use the *set_max_delay* command with the *-ignore_clock_latency* option:

```
pt_shell> set_max_delay 3.0 -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to
 sd_DQ[8] \\
           -ignore_clock_latency
Information: Invalidating logical update. (PTE-139)
1
pt_shell> report_timing -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to sd_DQ[8]
 ...

  Point                                                   Incr       Path
  ------------------------------------------------------------------------
  I_ORCA_TOP/I_SDRAM/reg[8]/CPN (sepfq1)                 0.000      0.000 f
  I_ORCA_TOP/I_SDRAM/reg[8]/Q (sepfq1)                   0.347      0.347 f
  I_ORCA_TOP/I_SDRAM/sd_mux_dq_out_8/Z (mx02d4)          0.715      1.062 f
  sdram_DQ_iopad_8/PAD (pc3b05)                          2.071      3.132 f
  sd_DQ[8] (inout)                                       0.048      3.180 f
  data arrival time                                                 3.180

  max_delay                                              3.000      3.000
  clock reconvergence pessimism                          0.000      3.000
  output external delay                                 -0.750      2.250
```

```
  data required time                                                 2.250
  ------------------------------------------------------------------------
  data required time                                                 2.250
  data arrival time                                                 -3.180
  ------------------------------------------------------------------------
  slack (VIOLATED)                                                  -0.930
```

The following *reset_path* command removes the constraint set by the *set_max_delay* command, restoring the default setup timing check for the path.

```
pt_shell> reset_path -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to sd_DQ[8]
1
pt_shell> report_timing -from I_ORCA_TOP/I_SDRAM/reg[8]/CPN -to sd_DQ[8]
 ...

  Point                                                 Incr       Path

  data arrival time                                              -9.211
  ------------------------------------------------------------------------
  slack (MET)                                                     1.476
```

The following command specifies that all paths from flip-flop ff1a or ff1b to flip-flop ff2e must have a delay of no more than 6.0 time units.

```
pt_shell> set_max_delay -from {ff1a ff1b} -to {ff2e} 6.0
```

The following command specifies that all paths to endpoints clocked by PHI2 must have a delay of no more than 8.5 time units.

```
pt_shell> set_max_delay -to [get_clocks PHI2] 8.5
```

The following command specifies that all paths leading to ports named "busA[*]" must have a delay of no than 5.0 time units.

```
pt_shell> set_max_delay 5.0 -to "busA[*]"
```

The following command specifies that all timing paths from ff1/CP to ff2/D that pass through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C}, in that order, must have a delay of no more than 8.0 time units.

```
pt_shell> set_max_delay 8.0 -from ff1/CP \\
            -through {U1/Z U2/Z} -through {U3/Z U4/C} -to ff2/D
```

The following command specifies that all timing paths from ff1/CP to ff2/D that rise through one or more of {U1/Z U2/Z} and fall through one or more of {U3/Z U4/C}, in that order, must have a delay of no more than 8.0 time units.

```
pt_shell> set_max_delay 8.0 -from ff1/CP -rise_through {U1/Z U2/Z} \\
            -fall_through {U3/Z U4/C} -to ff2/D
```

set_max_fanout

Sets maximum fanout for input ports or designs.

Syntax

string *set_max_fanout*

Feedback

```
[-sms_scenarios sms_scenarios_list
fanout_value
object_list
```

Data Types

```
fanout_value          float
object_list           list
sms_scenarios_list    collection
```

Arguments

fanout_value

Fanout limit (Value >= 0). This is the maximum fanout load in library fanout units.

object_list

Provides a list of input ports or designs on which to set maximum fanout.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this maximum fanout is applied. When this option is not given the maximum fanout applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

Specifies a maximum fanout on input ports or designs. If maximum fanout is set on a port, the net connected to that port is expected to have the *fanout_load* attribute less than the specified *fanout_value* attribute. Fanout load for a net is the sum of the *fanout_load* attributes for all input pins on the net. If specified on a design, the default maximum fanout for that design is set. Library cell pins may also have the *max_fanout* value specified. The most restrictive of the design limit and the pin or port limit will be used.

The *report_constraint -max_fanout* command shows maximum fanout constraint evaluations. The *report_port -design_rule* command shows port maximum fanout limits. The *report_design* command shows the default maximum fanout setting for the current design.

To remove maximum fanout limits from designs or ports, use the *remove_max_fanout* command.

Examples

The following example sets a maximum fanout limit of 2.0 units on ports "IN*".

```
pt_shell> set_max_fanout 2.0 [ge_ports "IN*"]
```

The following example sets the default maximum fanout limit of 5.0 units on the current design.

```
pt_shell> set_max_fanout 5.0 [current_design]
```

---

set_max_time_borrow

Limits time borrowing for latches.

Syntax

status *set_max_time_borrow*

```
value
object_list
```

Data Types

```
value          float
object_list    list
```

Arguments

value

Specifies the value to which the *max_time_borrow* attribute is set. Specifies the limit of time borrowing on the latches specified in the *object_list* option. The *delay_value* option must be between zero and the default maximum derived from the waveform. By default, the maximum is derived from the ideal clock waveform driving each latch, and is equal to (closing_edge - open_edge). Library setup and data-to-Q propagation times are automatically taken into account. The *delay_value* option is in the same units as those in the logic library used during analysis.

object_list

Specifies a list of objects in the *current_design* command for which time borrowing is to be limited to the *value* option. The objects can be clocks, latch cells, data pins, or clock (enable) pins. If a cell is specified, all enabled pins on that cell are affected.

Feedback

Description

Sets the *max_time_borrow* attribute to the *value* option to constrain the amount of time borrowing possible for level-sensitive latches. To meet delay targets, the *set_max_time_borrow* command prevents automatic use of all or part of the enabling clock pulse on a latch.

If the *max_time_borrow* attribute is set on both data and clock (enable) pins of a level-sensitive latch, the value set on the data pin takes higher priority.

To get the *max_time_borrow* attributes on the design, use the *get_attribute* or *report_exceptions* command.

To undo the *set_max_time_borrow* command, use the *remove_max_time_borrow* command.

Examples

The following example restricts time borrowing on latches *latch1a* and *latch2f* to 4.0 units.

```
pt_shell> set_max_time_borrow 4.0 { latch1a latch2f }
```

The following example specifies that no time borrowing will take place on *latch1c*.

```
pt_shell> set_max_time_borrow 0.0 { latch1c }
```

---

set_max_transition

Sets maximum transition limit for pins, ports, clocks, or designs with respect to the main library trip-points.

Syntax

string *set_max_transition*

```
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-force]
[-sms_scenarios sms_scenarios_list]
```

transition_value
object_list

Data Types

object_list	list
sms_scenarios_list	collection
transition_value	float

Arguments

`-clock_path`

Applies the limit only to pins in the clock network of the clocks specified in the *object_list*.

`-data_path`

Applies the limit only to pins in the data paths launched by the clocks specified in the *object_list*.

`-rise`

Applies the limit only to rising transition values. This option requires that the *object_list* contains only clock objects.

`-fall`

Applies the limit only to falling transition values. This option requires that the *object_list* contains only clock objects.

`-force`

Force the limit to be set to the specified value, overriding other more restrictive constraints if they exist.

This option is supported only for pin and port objects.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this maximum transition is applied. When this option is not given the maximum transition applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

transition_value

Specifies the transition limit (value >= 0). This is the maximum transition time in library time units.

object_list

Provides a list of pins, library pins, ports, clocks, or designs on which to set maximum transition.

Feedback

Description

Specifies a maximum transition limit on pins, library pins, ports, clocks, or designs. If maximum transition is set on a pin, library pin, or port, the pin, library pin, or port is expected to have transition time less than the specified *transition_value* option. If specified on a design, the default maximum transition for that design is set.

If maximum transition is set on a clock, the maximum transition is applied to all pins in this specified clock domain (clock and data). Within a clock domain, you can optionally restrict the constraint further to only clock paths or data paths, and to only rising or falling transitions. (Note that the *-clock_path*, *-data_path*, *-rise*, and *-fall* options can only be used for limits applied to clock objects.)

During analysis, the most restrictive of the design, pin, clock, library, and port limits is used. The limit value is scaled to the appropriate library pin trip-points as needed during delay calculation.

The *report_constraint -max_transition* command shows maximum transition constraint evaluations. The actual limit used for slack computation is reported. If a user-defined value is used, the reported limit is different for pins with different trip-points. The minimum slack of rise and fall transition is reported. When there are violations across multiple clock-specific limit values, the worst slack is reported.

The *report_port -design_rule* command shows port maximum transition limits. The *report_design* command shows the default maximum transition setting for the current design.

To remove maximum transition limits applied by this command, use the *remove_max_transition* command.

Examples

The following example sets a maximum transition limit of 2.0 units on ports "OUT*".

```
pt_shell> set_max_transition 2.0 [get_ports "OUT*"]
```

The following example sets the default maximum transition limit of 5.0 units on the current design.

```
pt_shell> set_max_transition 5.0 [current_design]
```

The following example sets a maximum transition limit of 2.0 units on all pins in the clock network of CLK.

```
pt_shell> set_max_transition 2.0 [get_clocks CLK] -clock_path
```

The following example sets a maximum transition limit of 1.8 units on all pins of the data path of CLK.

```
pt_shell> set_max_transition 1.8 [get_clocks CLK] -data_path
```

set_memory_cell_info

Specify memory library cells for RTL power analysis.

Syntax

int *set_memory_cell_info*

```
[-raddr pin_list]
[-waddr pin_list]
[-dpins pin_list]
[-qpins pin_list]
[-clock pin_name]
[-rclk pin_name]
[-wclk pin_name]
[-read  condition]
[-write condition]
[-disable condition]
libcell_list
```

Data Types

pin_list	list
pin_name	string
condition	string
libcell_list	list

Arguments

`-raddr`

Specifies the list of Read Address pins.

`-waddr`

Specifies the list of Write Address pins.

`-dpins`

Specifies the list of Input Data pins.

Feedback

`-qpins`

Specifies the list of Output pins.

`-clock`

Specifies the Clock pin.

`-rclk`

Specifies the Read Clock pin.

`-wclk`

Specifies the Write Clock pin.

`-read`

Specifies a boolean condition to indicate when the memory performs read operation.

`-write`

Specifies a boolean condition to indicate when the memory performs write operation.

`-disable`

Specifies a boolean condition to indicate when the memory is disabled.

`libcell_list`

Specifies a list of memory library cells or a single reference name.

Description

The *set_memory_cell_info* command is used to identify memory library cells and their read/write/input/output/clock pins. This is useful for various applications such as reporting the power and attributes of memory instances in the design.

Examples

The following example shows how to use this command.

```
pwr_shell> set_memory_cell_info -raddr RA[*] -waddr WA[*] -qpins
 DO[*] -dpins DI[*] -read "!CS & WE" -write "!CS & !WE" -clock CLK
 [get_lib_cells */sram32x64_hscm4]

pwr_shell> set_memory_cell_info -raddr AB[*] -waddr AA[*] -dpins D[*]
 -qpins Q[*] -read !REB -write !WEB -disable "REB & WEB" -rclk CLKR -wclk
 CLKW [get_lib_cells */FFCLLSVTA80X18M2SSHO]
```

- report_rtl_metrics

Feedback

set_memory_percentage

Sets percentage of memory cells to be switched during vector free vector generation.

Syntax

status *set_memory_percentage*

```
-value percentage_value
[-type type]
```

Data Types

```
percentage_value  float
type              type
```

Arguments

`-value percentage_value`

Specifies percentage of memory cells which will be switched during vector generation. Accepted value is between 0.0 and 1.0, which means 0% to 100% of memory cells have switching events triggered. When this option is specified, it is used to guide vector generation such that the percentage of memory cells to be switched does not exceed this limit. Default value is 0.5, which means 50% memory cells will have switching events, and the other 50% memory cells are in steady state.

`-type type`

Specifies the type of memory cells for which the percentage value is applied. Accepted values are icg_controlled and non_icg_controlled. The type *icg_controlled* means the percentage value is applied to memory cells where clocks are controlled by clock gating cells. The type *non_icg_controlled* means the percentage value is applied to memory cells where clocks are controlled by non clock gating cells, for example, MUX cells. When this option is omitted, the percentage value is applied to all memory cells in the whole design.

Description

This command is used to specify percentage of memory cells to be switched during vector generation in command *write_vectors*.

Examples

The following example sets memory cell percentage 20% instead of default 50%, then invokes the command *write_vectors*.

```
pt_shell> set_memory_percentage -value 0.2
pt_shell> write_vectors rtl.vcd
```

Feedback

Assuming the whole design consists of two types of memory cells. The following example sets 30% for memory cells controlled by clock gating cells, and 10% for memory cells controlled by non clock gating cells. Then the command *write_vectors* is invoked:

```
pt_shell> set_memory_percentage -value 0.3 -type icg_controlled
pt_shell> set_memory_percentage -value 0.1 -type non_icg_controlled
pt_shell> write_vectors rtl.vcd
```

See Also

- write_vectors

---

set_message_info

Sets limits on the numbers of tool messages issued, stores messages for retrieval, or forces a Tcl error on specified system conditions.

Syntax

string *set_message_info*

```
-id message_id ]
[-limit max_limit]
[-save_limit max_limit]
[-stop_on]
[-stop_off]
```

Data Types

```
message_id   string
max_limit    integer
```

Arguments

`-id message_id`

Specifies the tool message ID affected by the command, for example, RC-011 or UITE-214.

`-limit max_limit`

Sets the maximum number of times that the message is reported in the remainder of the current session. When the limit is reached, the tool issues a warning that future messages of that type will be suppressed. After that, occurrences of the related condition no longer generate messages.

Setting this option to 0 means no limit on the number of messages generated.

`-save_limit` *`max_limit`*

Sets the maximum number of times that the message is saved for later retrieval by the *get_attribute* command or query by the *get_message_info* command.

Setting this option to 0 means no limit on the number of messages saved for later retrieval. Setting this option to -1 means no messages are saved, which is the default.

`-stop_on`

Causes any occurrence of the specified message ID to trigger a Tcl error, which stops execution of a Tcl script being run.

`-stop_off`

Cancels the effects of the *-stop_on* option, so that occurrences of the specified message ID no longer stop execution of a Tcl script.

Description

The *set_message_info* command lets you do any one of the following:

- Set a limit on the number of tool messages (error, warning, or information) of a specified message ID type generated in the remainder of the session; messages beyond this limit are suppressed.
- Save system messages of a specified type for later retrieval by the *get_message_info* and *get_attribute* commands.
- Cause the condition associated with a specific message to generate a Tcl error, which stops execution of the Tcl script that triggered the message.

To find out about the message settings and the number of messages that have been suppressed or saved, use the *get_message_info* command.

Examples

The following example sets a limit of 100 on the number of RC-011 messages reported in the remainder of the session. When the 100th RC-011 message is generated, the tool issues a warning that further messages will be suppressed, and then RC-011 conditions are no longer reported.

```
pt_shell> set_message_info -id RC-011 -limit 100
1
pt_shell> update_timing
 ...
Warning: An extrapolation far outside the library characterization range
 has
occurred for the cell timing arc, (my_lib/BUFD3) U564/I-->Z ...
 ...
 ...
```

```
Note - message 'RC-011' limit (100) exceeded.  Remainder will be
 suppressed.
 ...
```

The following example saves up to 100 PTE-064 messages for later retrieval.

```
pt_shell> set_message_info -id PTE-064 -save_limit 100
1
pt_shell> get_message_info -id PTE-064
id PTE-064 severity Information limit 10000 save_limit 100 occurrences
22 suppressed 0 message {Related clock set %d includes clock '%s' with
 period %.3f.}
 ...
pt_shell> set my_msgs [get_message_instances PTE-064]
_sel122
pt_shell> get_attribute -class message_instance $my_msgs arguments
0,SDRAM_CLK,7.500 0,SD_DDR_CLK,7.500 1,SYS_CLK,8.000 ...
 ...
pt_shell> get_attribute -class message_instance $my_msgs message_body
{Related clock set 0 includes clock 'SDRAM_CLK' with period 7.500.}
{Related clock set 0 includes clock 'SD_DDR_CLK' with period 7.500.}
pt_shell> get_attribute -class message_instance $my_msgs message_id
PTE-064 PTE-064 PTE-064 PTE-064 PTE-064 PTE-064 ...
```

The following example causes any occurrence of the PTE-023 warning condtion to trigger a Tcl error, which stops execution of the currenly running Tcl script.

```
pt_shell> set_message_info -id PTE-023 -stop_on
1
pt_shell> source my_script.tcl
 ...
Error: Severe error encountered
        Use error_info for more info. (CMD-013)
Information: script 'my_script.tcl'
        stopped at line 49 due to error. (CMD-081)
 ...
```

Feedback

set_min_capacitance

Sets minimum capacitance limit for ports or designs.

Syntax

string *set_min_capacitance*

```
[-sms_scenarios sms_scenarios_list]
capacitance_value
object_list
```

Data Types

capacitance_value	float
object_list	list
sms_scenarios_list	collection

Arguments

`-sms_scenarios sms_scenarios_list`

Specifies a collection of SMS scenarios for which this minimum capacitance is applied. When this option is not given the minimum capacitance applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

capacitance_value

Specifies the capacitance limit (value >= 0). This is the minimum total capacitance (pin plus wire capacitance) in library capacitance units.

object_list

Specifies a list of input or inout ports or designs on which to set minimum capacitance.

Description

Specifies a minimum capacitance on input/inout ports or designs. If minimum capacitance is set on a port, the net connected to that port is expected to have a total capacitance greater than the specified *capacitance_value*. If specified on a design, the default minimum capacitance for that design is set. During analysis, the most restrictive of the design and port limits is used. The *report_constraint -min_capacitance* command shows minimum capacitance constraint evaluations.

The *report_port -design_rule* command shows port minimum capacitance limits. The *report_design* command shows the default minimum capacitance limit for the current design.

To remove minimum capacitance limits applied by this command, use the *remove_min_capacitance* command.

Feedback

Examples

The following example sets a minimum capacitance limit of 0.2 units on ports "IN*".

```
pt_shell> set_min_capacitance 0.2 [get_ports "IN*"]
```

The following example sets the default minimum capacitance limit of 0.1 units on the current design.

```
pt_shell> set_min_capacitance 0.1 [current_design]
```

---

set_min_delay

Specifies the minimum delay constraint for timing paths that start from, pass through, or end at specified objects.

Syntax

status *set_min_delay*

```
[-rise]
[-fall]
[-reset_path]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-through through_list
   | -rise_through rise_through_list
   | -fall_through fall_through_list]
[-ignore_clock_latency]
[-probe]
[-comment comment_string]
[-sms_scenarios sms_scenarios_list]
delay_value
```

Feedback

Data Types

comment_string	string
delay_value	float
fall_from_list	list
fall_through_list	list
fall_to_list	list
from_list	list
rise_from_list	list
rise_through_list	list
rise_to_list	list
sms_scenarios_list	collection
through_list	list
to_list	list

Arguments

`-rise`

Applies the delay constraint only to paths with a rising transition at the path endpoint.

`-fall`

Applies the delay constraint only to paths with a falling transition at the path endpoint.

By default, the constraint applies to both rising and falling transitions.

`-reset_path`

Removes existing point-to-point timing exceptions from the specified paths before applying the minimum delay constraint. Using this option is equivalent to using the *reset_path* command with similar arguments before the *set_min_delay* command. Only exceptions defined with the same path settings are affected: *-from*, *-to*, *-rise*, *-fall*, *-setup*, *-hold*, and so on.

`-from` *from_list*

Specifies a list of timing path startpoint objects: a clock, primary input port, sequential cell, clock pin of a sequential cell, data pin of a level-sensitive latch, or pin that has an input delay specified.

If you specify a clock, all registers and primary inputs related to that clock are considered path startpoints. If you specify a sequential cell, the command is automatically expanded to apply to each individual clock input pin of the cell. If public variable *timing_enable_from_clock_to_dangling_load_endpoints* is set to true, then all registers and primary inputs related to the clock are used as startpoints to constrain any dangling load endpoints in their fanout.

You can specify any pin in a data path as a startpoint so that the *report_timing* command checks the path delay starting from that pin. This effectively breaks

the data path into two segments and prevents path tracing through the pin. To prevent breaking of other timing paths through the pin, use the *-probe* option.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the delay constraint applies only to rising transitions at the specified objects.

If you specify a clock, the delay constraint applies to paths with a startpoint clocked by the named clock and launched by a rising edge at the clock source. The actual edge at the launch register can be either rising or falling, depending on logical inversions in the clock network.

`-fall_from` *`fall_from_list`*

Same as the *-rise_from* option, except that the constraint applies only to falling transitions at the specified objects.

You can use no more than one of the *-from*, *-rise_from*, and *-fall_from* options.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects: a clock, primary output port, sequential cell, data pin of a sequential cell, or pin that has an output delay specified.

If you specify a clock, all registers and primary outputs related to that clock are considered path endpoints. If you specify a sequential cell, the command is automatically expanded to apply to each individual data input pin of the cell.

You can specify any pin in a data path as an endpoint so that the *report_timing* command checks the path delay ending at that pin. This effectively breaks the data path into two segments and prevents path tracing through the pin. To prevent breaking of other timing paths through the pin, use the *-probe* option.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, except that the delay constraint applies only to rising transitions at the specified objects.

If you specify a clock, the delay constraint applies to paths with an endpoint clocked by the named clock and captured by a rising edge at the clock source. The actual edge at the capture register can be either rising or falling, depending on logical inversions in the clock network.

`-fall_to` *`fall_to_list`*

Same as the *-rise_to* option, except that the constraint applies only to falling transitions at the specified objects.

You can use no more than one of the *-to*, *-rise_to*, and *-fall_to* options.

`-through` *`through_list`*

Specifies a list of pins, ports, cells, and nets through which the paths must pass for the delay constraint to apply.

`-rise_through` *`rise_through_list`*

Same as the *-through* option, but applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

Same as the *-through* option, but applies only to paths with a falling transition at the specified objects.

`-ignore_clock_latency`

Causes the launch and capture clock latencies to be ignored when the *report_timing* command computes slack for the specified paths; and if SI analysis is enabled, causes path-based reporting to conservatively use graph-based crosstalk delta delays. By default, launch and capture clock latencies are considered in the delay slack calculation, and path-based reporting uses path-based crosstalk delta delays.

`-probe`

Prevents the breaking of timing paths at a specified *-from* pin that is not the clock pin of a sequential device, or at a specified *-to* pin that is not the data input pin of a sequential device. Instead, the timing exception applies to the specified startpoints and endpoints without affecting other paths through the specified pins.

If you do not use the *-probe* option, specifying an intermediate pin of a path as a startpoint or endpoint forces that pin to be a startpoint or endpoint for all timing paths, effectively breaking all paths into two separate segments at that pin.

`-comment` *`comment_string`*

Associates a comment string with the command, which is included in the command text written out by the *write_sdc* command. This can be useful for tracking information about the source of the command.

`delay_value`

Specifies the minimum allowed delay for the path, in time units of the logic library used for timing analysis. For this minimum delay constraint, the clock period and clock edge times are ignored.

If a path startpoint has an input delay specified, that delay value is added to the path delay. If a path startpoint is on a sequential device, launch clock latency is included in the computed delay.

If the path endpoint has an output delay specified, that delay is used in the data required-time calculation. If a path endpoint is on a sequential device, the library hold time and capture clock latency are used in the data required-time calculation.

To prevent consideration of launch and capture clock latencies, use the *-ignore_clock_latency* option.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this minimum delay constraint is applied. When this option is not given the minimum delay constraint applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

This command specifies a minimum delay constraint for timing paths that start from, pass through, or end at specified objects in the design. This constraint overrides the default hold time constraint established by the arrival times of launch and capture clock edges.

The *report_timing* command reports violations of the minimum delay constraint, taking into account the input delay, output delay, library hold time at the endpoint register, and clock latencies. To prevent consideration of clock latencies, use the *-ignore_clock_latency* option of the *set_min_delay* command.

The *set_min_delay* command is a point-to-point timing exception command like the *set_multicycle_path*, *set_max_delay*, and *set_false_path* commands. A *set_max_delay* or *set_min_delay* command has higher priority than a *set_multicycle_path* command.

If you specify a sequential cell as the argument of the *-from*, *-rise_from*, or *-fall_from* option, the command is automatically expanded to apply to each clock input pin of the cell. If the cell has multiple clock input pins, the exceptions are maintained separately for each pin. You can see these exceptions by using the *report_exceptions* or *write_sdc* command.

Similarly, if you specify a sequential cell as the argument of the *-to*, *-rise_to*, or *-fall_to* option, the command is automatically expanded to apply to each data input pin of the cell.

The expansion of an exception set on a sequential cell to the individual pins of the cell does not occur in some other tools such as IC Compiler II. In those tools, the exception is maintained at the cell level.

Using the *-from* and *-to* (and similar) options of the *set_min_delay* command, you can specify any pin in a data path as a startpoint or endpoint so that the *report_timing* command checks the path delay between those points. The *set_min_delay* command responds with a UITE-217 warning message because path tracing stops at the specified point, effectively breaking the path into multiple segments. If you set a startpoint or endpoint in a clock network, clock propagation stops at that point. To remove a minimum delay constraint that has been set, use the *reset_path* command.

For a nonsequential timing check defined by the *set_data_check* command, the minimum delay constraint is valid only if clocked signals arrive at both the related ("from") pin and the constrained ("to") pin of the data check. If a clock cannot reach the related pin or constrained pin, the path is considered unconstrained and the timing check is not performed.

When multiple exceptions commands of different types apply to the same path, they apply with the following precedence (highest to lowest):

```
1. set_false_path
2. set_max_delay and set_min_delay
3. set_multicycle_path
```

When multiple exception commands of the same type apply to a path, the more specific command overrides the more general. They apply with the following precedence (more specific to more general):

```
1. set_min_delay -from pin -to pin
2. set_min_delay -from pin -to clock
3. set_min_delay -from pin
4. set_min_delay -from clock -to pin
5. set_min_delay -to pin
6. set_min_delay -from clock -to clock
7. set_min_delay -from clock
8. set_min_delay -to clock
```

When multiple exception commands of the same specificity apply that differ only by the presence or absence of the *-ignore_clock_latency* option, the command *without* the option takes precedence:

```
1. set_min_delay
2. set_min_delay -ignore_clock_latency
```

If multiple exceptions have the same path options and differ only in the specified rise/fall sense, the most constraining time value has priority. For example, the following commands are arranged in order, from the highest to lowest priority, due to their decreasing minimum delay values.

```
1. set_min_delay -fall_from pin -to pin 2.5
2. set_min_delay      -from pin -to pin 2.0
3. set_min_delay -rise_from pin -to pin 1.5
```

To report the current *set_min_delay* settings and other timing exception settings, use the *report_exceptions* command.

To remove timing exceptions set by the *set_min_delay* command, use the *reset_path* command with the same path settings; or the *reset_design* command to remove all timing constraints, including clocks.

Feedback

Examples

The following example specifies that the delay must be at least 0.5 time units for a path from a specific input port to a specific register data pin. This new constraint overrides the default hold constraint for the path.

```
pt_shell> set_min_delay 0.5 -from sd_DQ[15] -to
 I_ORCA_TOP/I_SDRAM/reg[15]/D
Information: Invalidating logical update. (PTE-139)
1
pt_shell> report_timing -delay_type min \\
            -from sd_DQ[15] -to I_ORCA_TOP/I_SDRAM/reg[15]/D
 ...

  ---------------------------------------------------------------------
  data required time                                              2.540
  data arrival time                                              -0.894
  ---------------------------------------------------------------------
  slack (VIOLATED)                                               -1.646
```

The timing check considers clock network delays (latencies) of the launch and capture clocks, but not the clock edge times.

To ignore the clock network delays as well as clock edge times, use the *set_min_delay* command with the *-ignore_clock_latency* option:

```
pt_shell> set_min_delay 0.5 -from sd_DQ[15] -to
 I_ORCA_TOP/I_SDRAM/reg[15]/D \\
            -ignore_clock_latency
Information: Invalidating logical update. (PTE-139)
1
pt_shell> report_timing -delay_type min \\
            -from sd_DQ[15] -to I_ORCA_TOP/I_SDRAM/reg[15]/D
 ...

  Point                                                 Incr       Path
```

```
  ------------------------------------------------------------------
  input external delay                          0.200      0.200 f
  sd_DQ[15] (inout)                             0.000      0.200 f
  sdram_DQ_iopad_15/PAD (pc3b05)                0.043      0.243 f
  sdram_DQ_iopad_15/CIN (pc3b05)                0.467      0.710 f
  I_ORCA_TOP/I_SDRAM/Inst938/Z (buffd1)         0.092      0.802 f
  I_ORCA_TOP/I_SDRAM/Inst1079/Z (bufbd1)        0.092      0.894 f
  I_ORCA_TOP/I_SDRAM/reg[15]/D (sdnrb1)         0.000      0.894 f
  data arrival time                                        0.894

  min_delay                                     0.500      0.500
  clock reconvergence pessimism                 0.000      0.500

set_min_library

Sets the library to be used for minimum delay analysis

The *set_min_library* command is used to relate a minimum conditions library to a maximum conditions library.

Syntax

string *set_min_library*

```
[-min_version min_library]
[-none]
max_library
```

Data Types

```
min_library     string
max_library     string
```

Arguments

`-min_version` *min_library*

The library for min analysis. This library is not to be used in the *link_path* command.

`-none`

Dissociates the *max_library* option from its min library.

max_library

The library for max analysis. This library should be used in the *link_path* command.

Description

The *set_min_library* command creates a max/min relationship between two libraries. After you establish the relationship, the tool uses the *max_library* for maximum delay analysis and the *min_library* for minimum delay analysis.

For each library cell in the *max_library*, the *set_min_library* command searches for a library cell of the same name in the *min_library*. If it is not found, a warning is issued, and there is no max/min relationship for that library cell. If the *min_library* does have the named library cell, the command compares the two library cells to verify that they have the same pins (in the same order, with the same directions), and the same timing arcs. If any

of these conditions fails, a warning is issued, and there is no max/min relationship for that library cell.

At least one library cell must match for the command to succeed.

When PrimeTime needs to compute a minimum delay value, if there is a max/min relationship for the library cell, the timing information from the min library is used. Otherwise, the information is taken from the max library.

Both libraries and objects in them can be referenced in commands such as the *set_operating_conditions* and *set_wire_load_model* commands.

Libraries used as the *min_library* in a *set_min_library* command should never be placed in the link path. Only the *max_library*, which is the root of the relationship, is used in the link path. A warning is issued if you use a min library in the link path.

A library in use as a min library can be removed with the *remove_lib* command as long as no environment information (operating conditions, wire load models, and so on) is being used from that library. When you remove a library in this way, any designs using the max/min library is scheduled for a full timing update.

The *list_libs* command shows max/min relationships. In addition, the *report_lib* command indicates when a max library has a relationship to a min library. See the examples or the man pages for these commands.

Examples

The following example shows a typical usage of *set_min_library*:

```
pt_shell> set_min_library LIB_WC_COM.db -min_version LIB_BC_COM.db
Loading db file '/u/libraries/LIB_WC_COM.db'
Loading db file '/u/libraries/LIB_BC_COM.db'
Created max/min library relationship:
  Max: /u/libraries/LIB_WC_COM.db:LIB_WC_COM
  Max: /u/libraries/LIB_BC_COM.db:LIB_BC_COM
1
pt_shell> list_libs
Library Registry:
   m LIB_BC_COM    /u/libraries/LIB_BC_COM.db:LIB_BC_COM
  *M LIB_WC_COM    /u/libraries/LIB_WC_COM.db:LIB_WC_COM

1
pt_shell> set_operating_conditions -max WC_COM -max_library LIB_WC_COM \\
          -min BC_COM -min_library LIB_BC_COM
1
pt_shell> report_timing -delay min
 ...
```

---

set_min_pulse_width

Sets a minimum pulse width constraint for specified design objects.

Syntax

string *set_min_pulse_width*

```
[-low]
[-high]
value
[object_list]
```

Data Types

value	float
object_list	list

Arguments

`-low`

Indicates that the minimum pulse width constraint specified by *value* is to apply only to low clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

`-high`

Indicates that the minimum pulse width constraint specified by *value* is to apply only to high clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

value

A positive floating point value that specifies the minimum pulse width check to be applied to clock signals.

object_list

Specifies a list of clocks, cells, pins, or ports in the current design, to which the minimum pulse width check is to be applied. If you specify a cell or clock, all pins on the cell or clock are affected. If you do not specify any objects, the minimum pulse width check is applied to the current design; this value is applied to clock tree pulse width checks only (i.e. not sequential checks) if no pin-specific check (whether library- or user-specified) applies to a given pin.

Description

The *set_min_pulse_width* command specifies a minimum pulse width check to be applied to clock signals in the clock tree or at sequential devices. Use this command to add a more restrictive value than the one specified in library.

A clock pulse width problem occurs if the negation of the clock signal happens too soon after the assertion of the clock signal. Clock pulse width violations can cause the following problems:

- Sequential devices (flip-flops and latches) might not capture data properly.
- In some logic circuits, the entire pulse could disappear.

Two types of minimum pulse width checks are performed:

- Clock Pulse Width Check at Sequential Devices: This check is performed on clock pins of sequential elements. This check verifies that a minimum separation exists between the trailing edge and leading edge of the clock that is clocking the sequential elements. The library defines the constraints, which are environmentally scalable. The most restrictive value of pulse width (library-specified or user-asserted) is used. No default value is assumed.
- Clock Tree Pulse Width Check at Logic Circuits: The clock tree pulse width check ensures that the clock pulse is propagated reliably through the logic. This check is performed on the combinational logic circuits through which the clock signals are propagated. No default is assumed for the clock tree pulse width check. The most restrictive value of pulse width (library-specified or user-asserted) is used.

Note: If the *timing_enable_pulse_clock_constraints* variable is set to its default of *true*, the constraint set by this command does not apply to pulse clock networks. To apply the constraints to pulse clock networks use the *set_pulse_clock_min_width* command. To constrain pulse clock network using the *set_min_pulse_width* command from UI, set the *timing_enable_pulse_clock_constraints* variable to *false*.

To generate a report of pulse width constraints, use the *report_constraint -min_pulse_width* or *report_min_pulse_width* command. To remove minimum pulse width constraints set by *set_min_pulse_width*, use the *remove_min_pulse_width* command.

The *reset_design* command removes all user-specified attributes from a design, including those set by the *set_min_pulse_width* command.

Examples

The following example sets a minimum pulse width requirement of 2.0 for both low and high pulses of clock signals.

```
pt_shell> set_min_pulse_width 2.0 [get_clocks CK1]
```

The following example sets a minimum pulse width requirement of 2.5 for the low pulse of the clock signal on the pin U1/Z.

```
pt_shell> set_min_pulse_width -low 2.5 U1/Z
```

---

set_mode

Selects the active mode of cell mode groups or design mode groups

Syntax

status *set_mode*

```
[-type cell | design]
[mode_list]
[instance_list]
```

Data Types

mode_list	list
instance_list	list

Feedback

Arguments

`-type cell | design`

Indicates the type of mode to be made active. This option has the following mutually-exclusive valid values: *design* and *cell*. The *cell* value specifies that cell modes are to be made active. Cell modes are defined on library cells in the library. The *design* value specifies that design modes are to be made active. Design modes are user-specified using the *define_design_mode_group* and *map_design_mode* commands. If the *-type* value is omitted from the command, then this is equivalent to specifying the *-type cell* value.

`mode_list`

Specifies a list of modes, each of which is to be made the active mode for its mode group. If the *-type* has a cell value, then the *mode_list* option must contain only cell modes. If the *-type* has a design value, then the mode list must contain only design modes.

`instance_list`

Specifies a list of instances for which the specified cell modes are made active. This list must only be included with the *-type cell* value.

Description

Selects the active mode for a mode group or for several mode groups and disables modes in the same group as the selected active mode. Mode groups must either have all modes enabled (default setting) or have one of their modes enabled and all others disabled. This command sets either cell modes or design modes depending on the value of the type option.

Cell mode groups are defined in the library. Each library cell can have a set of cell mode groups. Each of these cell mode groups can have two or more cell modes. Each of these cell modes can be mapped to a set of timing arcs of the library cell. When a cell mode is made active for a given instance of the library cell, the cell mode is enabled and all of its timing arcs are enabled for that cell. All other cell modes are automatically disabled. The timing arcs of the disabled cell modes are then automatically disabled. To view what modes have been enabled or disabled use the *report_mode -type* cell. To view what arcs have been disabled, use the *report_disable_timing* command.

In the special case of an arc having multiple cell modes mapped to it, the arc is enabled if any of the modes are enabled.

Cell modes can be made active in three different ways, using the *set_mode -type cell* command, using the *set_mode -type design* command or through evaluation of mode conditions. When conflict arises the following precedence rule is employed: *set_mode* -type cell > *set_mode* -type_design > evaluation of mode conditions

Feedback

Design modes and design mode groups are defined by you with the *define_design_mode_group* and *map_design_mode* commands. Design modes can be mapped to a set of cell modes or a set of paths. When a design mode of a particular design mode group is made active, all cell modes mapped to the design mode are made active and all paths mapped to the design mode are reset. All other design modes in the design mode group are disabled. All paths associated with these disabled design modes will be set to false path. No action is taken to any cell modes mapped to the disabled design modes.

Examples

In the following example, the first command defines two design modes, DM1 and DM2. (Since no mode group name was specified, the mode group is named "default".) The second command specifies that for design mode DM1, the READ cell mode is active for the RAM instance Uram1. The third command specifies that for design mode DM2, the WRITE component mode is active for the RAM instance Uram1. The fourth command maps all paths ending at Uram1/D0 to the design mode DM2.

```
pt_shell> define_design_mode_group {DM1 DM2}
pt_shell> map_design_mode DM1 READ Uram1
pt_shell> map_design_mode DM2 WRITE Uram1
pt_shell> map_design_mode DM2 -to Uram1/D0
```

The following example selects the design mode DM1 as the active mode for the current design, which in turn causes the cell mode READ to be selected as the active mode for the instance Uram1. Since design mode DM2 is automatically disabled all paths ending at Uram1/D0 become false paths.

```
pt_shell> set_mode -type design DM1
```

The following command directly selects the READ cell mode as the active mode for the RAM instance Uram1.

```
pt_shell> set_mode READ Uram1
```

The following command is equivalent to the previous command.

```
pt_shell> set_mode -type cell READ Uram1
```

Feedback

set_multi_input_switching_analysis

Sets inclusion or exclusion of multi-input switching (MIS) analysis for specified library cells or cell instances.

Syntax

int *set_multi_input_switching_analysis*

```
-exclude_only
   | -include_only
[-reset]
[-analysis_mode lib_cell | lib_arc | advanced]
object_list
```

Data Types

analysis_mode	one-of-string
object_list	list

Arguments

`-exclude_only`

Excludes the specified cells or library cells for MIS analysis.

`-include_only`

Includes only the specified cells or library cells for MIS analysis.

`-reset`

Resets a previously applied *set_multi_input_switching_analysis* specification.

`-analysis_mode lib_cell | lib_arc | advanced`

When used, indicates that the inclusion or exclusion list applies only to the specified type of MIS analysis. By default, the inclusion or exclusion list applies to all types of MIS analysis.

The *user_coefficient* value is deprecated; it is supported for compatibility as equivalent to *lib_cell*, but it will be obsoleted in a future release.

object_list

Specifies a list of cell instances or library cells for inclusion or exclusion of multi-input switching analysis.

Description

This command defines a list of cells or library cells to include or exclude in multi-input switching (MIS) analysis. It allows you to override the default behavior of which cells to analyze for MIS analysis.

Either the *-exclude_only* or *-include_only* option must be specified; they cannot both be specified.

Note the following:

- Specifying *-exclude_only* invalidates any previous *-include_only* for the same type of object specification (cell instances or library cells).
- Specifying *-include_only* invalidates any previous *-exclude_only* for the same type of object specification (cell instances or library cells).
- Specifying an *-include_only* list of library cells and an *-exclude_only* list of cell instances is allowed.
- Specifying an *-include_only* list of cell instances and an *-exclude_only* list of library cells is allowed.

Examples

The following example excludes MIS analysis for cell instance nand2_1:

```
pt_shell> set_multi_input_switching_analysis -exclude_only [get_cell
 nand2_1]
```

The following example excludes MIS analysis for library cell NAND2:

```
pt_shell> set_multi_input_switching_analysis -exclude_only [get_lib_cell
 NAND2]
```

The following example excludes all cells from MIS analysis, except for library cell NAND2:

```
pt_shell> set_multi_input_switching_analysis -include_only [get_lib_cell
 NAND2]
```

The following example excludes all cells from advanced MIS analysis except for library cell NAND2 (but still uses user-defined coefficients, if defined with the *set_multi_input_switching_coefficient* command):

```
pt_shell> set_multi_input_switching_analysis -analysis_mode advanced
 -include_only [get_lib_cell NAND2]
```

See Also

- si_enable_multi_input_switching_analysis
- si_multi_input_switching_analysis_mode

Feedback

set_multi_input_switching_coefficient

Sets delay coefficients for multi-input switching (MIS) analysis for a specified list of library cells.

Syntax

int *set_multi_input_switching_coefficient*

```
[-rise]
[-fall]
-delay coeff_value
object_list
```

Data Types

coeff_value	float
object_list	list

Arguments

`-rise`

Applies the coefficients to rise transitions only.

`-fall`

Applies the coefficients to fall transitions only.

`-delay` *coeff_value*

Indicates the base coefficient of the cell delay for multi-input switching analysis when the specified library cell is used.

object_list

Specifies a list of library cells for multi-input switching analysis.

Description

This command sets the base coefficients for the cell delay and delta delay of a victim net driven by this cell during multi-input switching (MIS) analysis. To enable multi-input switching analysis, set the *si_enable_multi_input_switching_analysis* variable to true; the default of this variable is false.

If the si_enable_multi_input_switching_timing_window_filter variable is set to true, the tool uses the base coefficient value to derive the actual MIS factor by considering the arrival windows of the input pins and their overlap analysis.

If the si_enable_multi_input_switching_timing_window_filter variable is set to false, the base coefficient value is directly applied to the MIS factor.

If you use the *set_multi_input_switching_coefficient* command multiple times on the same library cell, the last specified coefficient overwrites the previously specified coefficients.

Examples

The following example sets the delay coefficient value of 0.7 for all instances of library cell AND2 in the library MY_LIB:

```
pt_shell> set_multi_input_switching_coefficient -delay 0.7 [get_lib_cells
 MY_LIB/AND2]
```

- si_enable_multi_input_switching_analysis
- si_enable_multi_input_switching_timing_window_filter

---

set_multicycle_path

Defines a multicycle path exception.

Syntax

status *set_multicycle_path*

```
[-setup]
[-hold]
[-rise]
[-fall]
[-start]
[-end]
[-reset_path]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-comment comment_string]
[-sms_scenarios sms_scenarios_list]
path_multiplier
```

Feedback

Data Types

comment_string	string
fall_from_list	list
fall_through_list	list
fall_to_list	list
from_list	list
path_multiplier	integer
rise_from_list	list
rise_through_list	list
rise_to_list	list
sms_scenarios_list	collection
through_list	list
to_list	list

Arguments

`-setup`

Indicates that setup (maximum delay) calculations are to use the specified *path_multiplier*. Note that changing the *path_multiplier* for setup affects the default hold check as well. If neither *-setup* nor *-hold* is specified, *path_multiplier* is used for setup calculations and 0 is used for hold calculations.

`-hold`

Indicates that hold (minimum delay) calculations are to use the specified *path_multiplier*. Note that changing the *path_multiplier for setup affects the default hold check as well. If neither -setup nor -hold is specified, path_multiplier is used for setup calculations and 0 is used for hold calculations.*

`-rise`

Indicates that only rising path delays are to use *path_multiplier*. If neither *-rise* nor *-fall* is specified, both rising and falling delays are affected. "Rise" refers to a rising edge at the path endpoint.

`-fall`

Indicates that only falling path delays are to use *path_multiplier*. If neither *-rise* nor *-fall* is specified, both rising and falling delays are affected. "Fall" refers to a falling edge at the path endpoint.

`-start`

Indicates that the multicycle specification is relative to the period of the startpoint clock. The *-start* and *-end* options are needed only for multifrequency designs; otherwise, "start" and "end" specifications are equivalent.

The "start" clock is the clock source related to the register or primary input at the path startpoint. The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with *-start*

moves the relation backward one cycle of the start clock. A hold multiplier of 1 with *-start* moves the relation forward one cycle of the start clock.

`-end`

Indicates that the multicycle specification is relative to the period of the endpoint clock. The *-start* and *-end* options are needed only for multifrequency designs; otherwise, "start" and "end" specifications are equivalent.

The "end" clock is the clock source related to the register or primary output at the path endpoint. The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with *-end* moves the relation forward one cycle of the end clock. A hold multiplier of 1 with *-end* moves the relation backward one cycle of the end clock.

`-reset_path`

Indicates that existing point-to-point exception are to be removed from the specified paths. If used with *-to* only, all paths leading to the specified endpoints are reset. If used with *-from* only, all paths leading from the specified startpoints are reset. If used with *-from* and *-to*, only paths between those points are reset. Only exceptions of the same rise/fall setup/hold type are reset. Using this option is equivalent to using the *reset_path* command with similar arguments before issuing the *set_multicycle_path* command.

`-from` *`from_list`*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified, one path startpoint on that cell is affected. You can use only one of the *-from*, *-rise_from*, and *-fall_from* options.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the *-from*, *-rise_from*, and *-fall_from* options.

`-fall_from` *`fall_from_list`*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the *-from*, *-rise_from*, and *-fall_from* options.

`-through` *`through_list`*

Specifies a list of pins, ports, cells and nets through which the multicycle paths must pass. By default, a net is interpreted to imply its driver pins. In case the previous *through_list* includes the driver, the net is interpreted to imply its load pins. If you omit *-through*, all timing paths specified using the *-from* and *-to* options are affected.

`-rise_through` *`rise_through_list`*

This option is similar to the *-through* option, but applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

This option is similar to the *-through* option, but applies only to paths with a fall transition at the specified objects.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected. You can use only one of the *-to*, *-rise_to*, and *-fall_to* options.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of the *-to*, *-rise_to*, and *-fall_to* options.

`-fall_to` *`fall_to_list`*

Same as the *-to* option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of the *-to*, *-rise_to*, and *-fall_to* options.

`-comment` *`comment_string`*

Associates a string description with the command for tracking purposes. When writing out SDC, this option is useful for tagging the methodology or tool that originally synthesized the command. You must begin and end the *comment_string* with double quotation marks (").

path_multiplier

An integer that specifies the number of cycles the data path must have for setup or hold, relative to the startpoint or endpoint clock, before data is required at the endpoint.

For example, specifying a *path_multiplier* of 2 for setup implies a 2-cycle data path. If you use *-setup*, *path_multiplier* is applied to setup path calculations. If you use *-hold*, *path_multiplier* is applied to hold path calculations. If you do not specify either *-setup* or *-hold*, *path_multiplier* is used for setup and 0 is used for hold. Note that changing the multiplier for setup affects the hold check as well.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this multi cycle constraint is applied. When this option is not given the multi cycle constraint applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

This command specifies the number of clock cycles to adjust the setup or hold check of timing paths.

PrimeTime applies certain rules to determine single-cycle timing relationships for paths between clocked elements; the rules are based on active edges. For flip-flops, a single active edge both launches and captures data. For latches, the open edge launches data and the close edge latches data.

The setup check ensures that the correct data signal is available at destination registers in time to be correctly latched. The default setup behavior, called single-cycle setup, is as follows:

For multifrequency designs, there can be multiple setup relations between two clocks. For every latch edge of the destination clock, the setup check determines the nearest launch edge that precedes each latch edge. The smallest value of (setup_latch_edge - setup_launch_edge) determines the maximum delay requirement for this path.

You can override this default relationship by applying the *set_multicycle_path* or *set_max_delay* command to clocks, pins, ports, or cells. For example, setting the setup path multiplier to 2 with the *set_multicycle_path* command delays the latch edge one clock pulse. Note that changing the setup multiplier also affects the default hold check.

Most often, the setup check moves relative to the end clock. This move changes the data latch time at the path endpoint. In multifrequency designs, use the *set_multicycle_path -setup -start* command to move the data launch time backward. The hold check ensures that data from the source clock edge that follows the setup launch edge is not latched by the setup latch edge, and also ensures that data from the setup launch edge is not latched by the destination clock edge that precedes the setup latch edge.

The hold check is determined relative to each valid setup relationship, after applying multicycle path multipliers. The most restrictive (largest) difference of (hold_latch_edge - hold_launch_edge) is used as a minimum delay requirement for the path.

Important Note: The hold relationship is conservative. In some cases, you must override the default hold relationship. For multifrequency designs, it might might be more straightforward to use the *set_min_delay* command instead of the *set_multicycle_path -hold* command.

There are separate setup and hold multipliers for rise and fall. In most cases, these are set to the same value. You can use the *-rise* or *-fall* option to apply different values.

The *set_multicycle_path* command is a point-to-point timing exception command. The command can override the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include *set_max_delay*, *set_min_delay*, and *set_false_path*. False path exceptions always takes precedence over multicycle path exceptions. A more specific *set_max_delay* or *set_min_delay* command overrides a more general *set_multicycle_path* command.

When multiple exceptions commands of different types apply to the same path, they apply with the following precedence (highest to lowest):

```
1. set_false_path
2. set_max_delay and set_min_delay
3. set_multicycle_path
```

When multiple exception commands of the same type apply to a path, the more specific command overrides the more general. They apply with the following precedence (more specific to more general):

```
1. set_multicycle_path -from pin -to pin
2. set_multicycle_path -from pin -to clock
3. set_multicycle_path -from pin
4. set_multicycle_path -from clock -to pin
5. set_multicycle_path -to pin
6. set_multicycle_path -from clock -to clock
7. set_multicycle_path -from clock
8. set_multicycle_path -to clock
```

When multiple *set_multicycle_path* commands are applied that differ only by their cycle count, the last specification applies, even if it is less constraining than earlier specifications.

To undo a *set_multicycle_path* command, use the *reset_path* command. The *reset_design* command removes all attributes from the design, including specifications set by the *set_multicycle_path* command.

To disable setup and hold calculations for paths, use the *set_false_path* command. To list the point-to-point exceptions on a design, use the *report_exceptions* command.

When a path has transparent latches in the interior of the path, the *set_multicycle_path* command will only be applied if all the speficiers can be satisfied within one combinational segment between sequential elements. Commands using *-from* pin, and *-to* pin, with a transparent latch in between, will be ignored, because both specifiers could not be satisfied in a single combinational segment between sequential elements. When a command affects the Nth combinational segment, between the (N-1)th and Nth interior latches, the clock edge used by the Nth latch is adjusted according to the *path_multiplier*. All subsequent latches, and the final capture, are also adjusted. On such paths with interior transparent latches, it is possible for *set_multicycle_path* commands to affect each segement between sequential elements. The *path_multiplier* values for the various commands will affect corresponding segments. All the applied commands will affect the clock edge of the final capture on the path.

Examples

The following example sets all paths between latch1b and latch2d to 2-cycle paths for setup. Hold is measured at the previous edge of the clock at latch2d.

```
pt_shell> set_multicycle_path 2 -from { latch1b } -to { latch2d }
```

The following example moves the hold check to the preceding edge of the start clock.

```
pt_shell> set_multicycle_path -1 -from { latch1b } -to { latch2d }
```

The following example is a two-phase level-sensitive design, where the designer expects paths from phi1 to phi1 to be zero cycles.

```
pt_shell> set_multicycle_path 0 -from phi1 -to phi1
```

The following example uses *-start* to specify a 3-cycle path relative to the clock at the path startpoint. Clock sources are specified, affecting all sequential elements clocked by that clock, or ports with input or output delay relative to that clock.

```
pt_shell> set_multicycle_path 3 -start -from { clk50mhz } -to
 { clk10mhz }
```

The following example sets all rising paths to ff12/D to 2 cycles, and falling paths to 1 cycle.

```
pt_shell> set_multicycle_path 2 -rise -to { ff12/D }
pt_shell> set_multicycle_path 1 -fall -to { ff12/D }
```

The following multifrequency example shows a 20ns clock to 10ns clock with multicycle path of 2. Assume a path from ff1 (clocked by CLK2) to ff2 (clocked by CLK1).

```
pt_shell> create_clock -period 20 -waveform {0 10} CLK2
pt_shell> create_clock -period 10 -waveform {0 5} CLK1
pt_shell> set_multicycle_path 2 -setup -from ff1/CP -to ff2/D
```

The single-cycle setup relation is from the CLK1 edge at 0ns to the CLK2 edge at 10ns. With the multicycle path, the setup relation is now 20ns (from CLK1 edge at 0ns to CLK2 edge at 20ns). The hold relations are determined according to that setup relation.

1. Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge. This implies a hold relation of 0ns (from CLK1 edge at 20ns to CLK2 edge at 20ns).
2. Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge. This implies a hold relation of 10ns (from CLK1 edge at 0ns to CLK2 edge at 10ns).

The most restrictive (largest) hold relation is used, so the minimum delay requirement for this path is 10ns. This is a conservative check which might not apply to certain designs. Often you know that the destination register is disabled for the clock edge at 10ns. You can modify this default hold relation with the following to get an 0ns requirement.

```
pt_shell> set_multicycle_path 1 -hold -end -from ff1/CP -to ff2/D
```

However, a simpler approach is to use the following:

```
pt_shell> set_min_delay 0 -from ff1/CP -to ff2/D
```

The following example sets all timing paths from ff1/CP to ff2/D which passes through one or more of {U1/Z U2/Z} and one or more of {U3/Z U4/C} to 2 cycle paths for setup.

```
pt_shell> set_multicycle_path 2 -from ff1/CP -through {U1/Z U2/Z}
 -through {U3/Z U4/C} -to ff2/D
```

The following example applies both setup and hold multicycle path multipliers of 2 to two registers clocked by the same clock:

```
pt_shell> # don't do this - read explanation below
pt_shell> set_multicycle_path -setup -hold 2 -from ff1/CP -to ff2/D
```

This example results in incorrect (and optimistic) hold analysis. The meaning of the *-setup* and *-hold* multipliers are different - the *-setup* multiplier moves both the setup and hold checks forward, then the *-hold* multiplier moves the hold check backward from its setup-adjusted position. To ensure correct same-clock hold analysis, a setup multiplier of *N* should be accompanied by a hold multiplier of *N*-1:

```
pt_shell> set_multicycle_path -setup 2 -from ff1/CP -to ff2/D
pt_shell> set_multicycle_path -hold 1 -from ff1/CP -to ff2/D
```

For multifrequency designs, different multipliers or additional options (such as *-start* or *-end*) might be required.

---

set_net_pattern

Set specific pattern for nets which will be used during multi-cycle vector generation or special mode vector generation.

Syntax

status *set_net_pattern*

```
[-object_list object_list]
[-file file_name]
[-strip_path strip_path]
[-format file_format]
[-start_time start_time]
[-mode one_hot | one_cold | constraint]
[-pattern pattern]
```

Data Types

```
object_list       list
file_name         string
strip_path        string
file_format       string
start_time        float
pattern           string
```

Arguments

`-object_list`

Specifies a list of net objects to be used with the option *-file*, *-pattern*, or *-mode*.

`-file`

Specifies a VCD file from which patterns will be read and applied on the list of nets in the option *-object_list*. The number of bits in the pattern is determined by number of cycles specifed in the option *set_vector_generation_options*

-number_of_cycles. Once the number of cycles is reached, the rest of the bits in the VCD file will be ignored. This option is only used with the options *-strip_path*, *-format*, or *-start_time*. This option is honored in multi-cycle generation only.

`-strip_path`

Specifies a path prefix that is to be stripped from all the object names read from the VCD file. This option is applied to strip the testbench and instance path from the VCD file.

`-format`

Specifies the format for the file in the options *-file*. VCD is the only format supported.

`-start_time`

Specifies start time from which patterns will be read from the VCD file. Patterns before this start time will be ignored.

`-mode`

Specifies mode used to generate a bit pattern for nets specified in the option *-object_list*. Accepted values are one_hot, one_cold, or constraint. Mode one_hot (or one_cold) is used to specify for a list of nets, where at any cycle, there should be one net stays at hot (or cold), and others stay at cold (or hot). When constraint mode is specified, a random bit pattern is generated based on the toggle rate and state probability from power analysis. This option is honored in multi-cycle vector generation only.

`-pattern`

Specifies a bit pattern where state value 0 or 1 is used to construct a bit string. The bit pattern is then applied cycle by cycle. This option is honored in either multi-cycle vector generation or special mode vector generation. Since special mode vector generation is for one clock cycle, only the first bit will be used in special mode.

Description

The *set_net_pattern* command specifies a bit pattern for a list of nets, which will be used during multi-cycle vector generation or special mode vector generation.

Examples

The following example reads patterns from a VCD file for all control nets, and sets one hot mode for a list of bus nets. For all primary input, constraint mode is applied. Then the command *write_vectors* is invoked to generate 100 cycle VCD.

```
pt_shell> set_vector_generation_options -number_of_cycles 100
pt_shell> set_net_pattern -file control.vcd -format VCD -strip_path tb
 -object_list [get_nets control*]
```

Feedback

```
pt_shell> set_net_pattern -mode one_hot -object_list [get_nets mbus[*]]
pt_shell> set_net_pattern -object_list [get_nets -of [get_ports]] -mode
 constraint
pt_shell> write_vectors 100_cycle.vcd
```

The following example shows how to generate a special mode VCD file, where all nets are considered as special nets, and 75% of those nets are toggling. At the same time, state 0 is set on all clock gating cell enable nets through the command *set_net_pattern*.

```
pt_shell> set_vector_generation_options -special_nets [get_nets -hier]
pt_shell> set_vector_generation_options -toggle_percentage 0.75
pt_shell> set_net_pattern -pattern 0 -object_list [get_nets -of [get_pins
 icg_*/enble]
pt_shell> write_vectors special_mode_75.vcd
```

---

set_noise_derate

Sets noise derating information for the current design. This does not affect aggressor screening and filtering result.

Syntax

int *set_noise_derate*

```
[-above]
[-below]
[-low]
[-high]
[-height_offset hoffset]
[-absolute_height_offset_in_volts abshoffset]
[-height_factor hfactor]
[-width_factor wfactor]
[object_list]
```

Data Types

hoffset	float
abshoffset	float
hfactor	float
wfactor	float
object_list	list

Feedback

Arguments

`-above`

Specifies a derating for above ground or power rails noise analysis region.

`-below`

Specifies a derating for below ground or power rails noise analysis region.

`-low`

Specifies a derating for ground rail noise.

`-high`

Specifies a derating for power rail noise.

`-height_offset` *`hoffset`*

Specifies an offset voltage in ratio of Vdd, that is directly added to each aggressor and total noise height of a pin in the design. The value of this offset must be between -1.0 to 1.0. The default for this offset is 0.0.

`-absolute_height_offset_in_volts` *`abshoffset`*

Specifies an offset voltage in absolute voltage units that is directly added to each aggressor and total noise height of a pin in the design. The default for this offset is 0.0.

`-height_factor` *`hfactor`*

Specifies a scale factor that could increase or decrease the calculated height of the noise waveform of each aggressor and the total noise height of a pin in the design. The value for this scale factor must be larger than 0.0. The default for this scale factor is 1.0.

`-width_factor` *`wfactor`*

Specifies a scale factor that could increase or decrease the calculated width of the noise waveform of each aggressor and the total noise width of a pin in the design. The value for this scale factor must be larger than 0.0. The default for this scale factor is 1.0.

`object_list`

Specifies a list of input pins, output ports or library pins

Description

This command sets the noise derate offset and scale factors

- On the current design if you do not use the *object_list* option
- On the specified pins and ports if you use the *object_list* option

Feedback

Noise derating offset and scale factors

- Affect the noise height and width values shown in noise reports
- Affect the noise propagated through stages
- Do not affect aggressor filtering or screening

If the offset is not specified for a noise analysis region, 0.0 offset is assumed. The absolute and relative height offsets can be specified together. If scale factors are not specified for a noise analysis region, 1.0 scale factors are assumed.

To show derating offsets and scale factors settings, use the *report_noise_calculation* command.

Examples

This example specifies a voltage offset of 0.10 and noise height and width scale factors of 0.90 for above the ground rail noise:

```
pt_shell> set_noise_derate -above -low -height_offset 0.10 \\
          -height_factor 0.90 -width_factor 0.90
```

To restore the settings to their original values:

```
pt_shell> set_noise_derate -above -low -height_offset 0.0 \\
          -height_factor 1.0 -width_factor 1.0
```

See Also

- report_noise
- report_noise_calculation
- set_noise_parameters

---

set_noise_immunity_curve

Specifies the noise immunity curve at an input of a library cell or at an output port of the design.

Syntax

status *set_noise_immunity_curve*

```
[-above]
[-below]
[-low]
[-high]
[-height height_value]
[-width  width_value]
```

```
[-area   area_value]
object_list
```

Data Types

```
height_value     float
width_value      float
area_value       float
object_list      list
```

Arguments

`-above`

Specifies an immunity curve for above ground or power rail noise analysis region.

`-below`

Specifies an immunity curve for below ground or power rail noise analysis region.

`-low`

Specifies an immunity curve for ground rail noise. When used with the *-above* or *-below* option, the *-low* option specifies the immunity curve for above-low or below-low rail noise, respectively.

`-high`

Specifies an immunity curve for power rail noise. When used with the *-above* or *-below* option, the *-high* option specifies the immunity curve for above-high or below-high rail noise, respectively.

`-height` *`height_value`*

Specifies the height offset of the noise immunity curve above the horizontal axis, in the voltage units of the library. A smaller value increases the likelihood that violations are reported.

`-width` *`width_value`*

Specifies the width offset of the noise immunity curve from the vertical axis, in time units of the library. A smaller value increases the likelihood that violations are reported.

`-area` *`area_value`*

Specifies a relative area under the hyperbolic curve, in units equal to the product of the voltage units and time units of the library.

`object_list`

Specifies a list of library pins or ports.

Feedback

Description

Each cell input can tolerate a certain amount of noise without causing a failure at the cell output. This characteristic is called noise immunity. This command specifies noise immunity at library input pins or design output ports to determine whether noise failures occur as well as the amount of noise slack.

Noise immunity in the library can be specified as noise immunity curves, polynomials, tables, or in terms of noise margins that consider only the bump heights at the cell inputs.

This command specifies a noise immunity curve at an input of a library cell or at an output port of the design. Use this command in the absence of library-specified noise immunity characteristics, or to override the library-specified characteristics by replacing them with a noise immunity curve. This command also overrides noise margins that have been annotated using the *set_noise_margin* command,

The noise immunity curve is a hyperbola described by the following equation:

y = C1 + C2 / (x - C3)

where

- y = noise immunity height in library voltage units
- x = bump width in library time units
- C1 = height offset set with the *-height* option
- C2 = area parameter set with the *-area* option
- C3 = width offset set with the *-width* option

A noise violation is reported when bump height is above the hyperbola, or in other words,

bump_height > C1 + C2 / (bump_width - C3)

Specify the three constants C1, C2, and C3 (the *-height*, *-area*, and *-width* options) so that the hyperbolic curve matches the noise immunity points obtained by circuit simulation of the cell containing the pin.

Noise immunity characteristics can vary for different noise bump types, so you can specify four different noise immunity curves associated with each input: below low, above low, below high, and above high. Specify the C1, C2, and C3 constants as positive numbers for all four types of noise bumps.

The *report_noise_calculation* command shows whether noise immunity information was taken from the library or annotated by this command.

Feedback

Examples

This example specifies a noise height offset of 0.59 voltage units, a noise width offset of 0.04 time units, and a hyperbolic area constant of 0.0064 voltage-time units for above-the-ground rail noise at the A pin of the IV library cell in the lsi_10k library:

```
pt_shell> set_noise_immunity_curve -above -low -height 0.59 -width 0.04
 \\
            -area 0.0064 lsi_10k/IV/A
```

A violation is reported when bump_height > 0.59 + 0.0064 / (bump_width - 0.04).

---

set_noise_lib_pin

Sets an equivalent noise library pin for a driver or load.

Syntax

int *set_noise_lib_pin*

```
pins
lib_pin
```

Data Types

```
pins        list
lib_pin     list
```

Arguments

pins

Specifies a collection of pins for which the noise library pin is set.

lib_pin

Specifies the equivalent library pin from which the noise information is used.

Description

This command allows to redefine the noise information for a certain library pin. For output pins, setting an equivalent noise library pin means that the I/V curves of the equivalent noise library pin is used. For input pins, noise immunity information of the equivalent noise library pin is used.

Feedback

Examples

This example specifies an equivalence for noise information on two inputs pins of the design to be the same as an input library pin:

```
pt_shell> set_noise_lib_pin [get_pins {cell/pin1 cell/pin2}]
 lsi_10k/IV/A\\
```

See Also

- update_noise
- report_noise
- report_noise_calculation

---

set_noise_margin

Specifies the noise margin for a library pin, port, or pin.

Syntax

status *set_noise_margin*

```
[-above]
[-below]
[-low]
[-high]
margin_value
object_list
```

Data Types

margin_value	float
object_list	list

Arguments

`-above`

Specifies the noise margin for above ground or power rail noise analysis region.

`-below`

Specifies the noise margin for below ground or power rail noise analysis region.

`-low`

Specifies the noise margin for ground rail noise.

`-high`

Specifies the noise margin for power rail noise.

margin_value

Specifies a margin value. The value is the input height in voltage units.

object_list

Specifies a list of library pins, ports, or pins.

Description

Each library cell input can tolerate a certain amount of noise without causing a failure at the cell output. This characteristic is called noise immunity. This command specifies noise immunity at library pins to determine whether noise failures occur as well as the amount of noise slack.

Noise immunity in the library can be specified as noise immunity curves, polynomials, or tables or in terms of noise margins.

This command specifies a noise margin for a library pin, design port, or pin. It can be used in the absence of library-specified noise immunity characteristics, or to override the library-specified characteristics by replacing them with noise margins. Noise immunity curves that have been annotated using the *set_noise_immunity_curve* command overrides noise margins set by this command.

Noise margins consider only the bump heights at the cell inputs. Using height-only noise margins are faster and more conservative than the other methods.

For high, narrow noise bumps, using height-only noise margins is pessimistic because it treats some bumps as noise failures that would otherwise pass with the immunity curve model. However, for wide noise bumps, using noise margins gives the same results as using noise immunity curves.

Noise immunity characteristics can vary for different noise bump types, so there can be four different noise margins associated with each input: below low, above low, below high, and above high. Specify all values as positive numbers for all four types of noise bumps.

In the absence of command-specified or library-specified noise immunity data, the tool calculates the maximum allowable noise bump heights based on DC noise margins of the driver and receiver, as defined in the .lib logic library by the input/output logic-level parameters.

The *report_noise_calculation* command shows whether noise margin information was taken from the library or annotated by this command.

Examples

This example specifies a noise margin of 4 for above-the-ground rail noise for the A pin of the IV library cell in the lsi_10k library:

```
pt_shell> set_noise_margin -above -low 4 lsi_10k/IV/A
```

Feedback

- set_noise_immunity_curve

---

set_noise_parameters

Defines the noise analysis parameters for the current design.

Syntax

status *set_noise_parameters*

```
[-ignore_arrival]
[-include_beyond_rails]
[-enable_propagation]
[-analysis_mode report_at_source | report_at_endpoint]
[-analysis_type violators | all]
```

Arguments

`-ignore_arrival`

Ignores the arrival window information of the aggressors during noise analysis. Therefore, the aggressors are assumed to be always overlapping to maximize the effect of a coupled noise bump.

`-include_beyond_rails`

Enables the analysis of noise beyond the high and low regions. If you do not use this option, the analysis of noise above the high rail and below the low rail is disabled.

`-enable_propagation`

Enables noise propagation. Propagated noise on a victim net is caused by noise at an input of the cell that is driving the victim net. PrimeTime SI can calculate propagated noise at a cell output, given the propagation characteristics of the cell, the noise bump at the cell input, and the load on the cell output.

`-analysis_mode report_at_source | report_at_endpoint`

Specifies one of the following analysis modes:

- *report_at_source* (the default) - Reports violations at the source of violations.
- *report_at_endpoint mode* - Propagates violations through fanout and reports violations at endpoints.

Feedback

`-analysis_type violators | all`

Focuses the noise analysis with one of the following analysis types; both analysis types catch all noise violations:

- *violators* (the default) - Evaluates each net in the design for potential noise violations. The tool performs detailed noise analysis on only nets with potential violations. This analysis type is particularly useful if the main purpose of noise analysis is to detect noise violations. This mode can be considerably faster than the *all* analysis type.
- *all* - Performs detailed noise analysis on all nets, regardless of whether they have potential violations.

Description

This command specifies the parameters that are considered during the noise analysis. If you do not use this command, or you use the *reset_noise_parameters* command, the tool follows the default noise analysis behavior -- the tool ignores beyond-the-rail analysis, considers the arrival times of aggressors, and ignores propagated noise.

If you do not specify any options with this command, the command has no effect, and the tool follows the default noise analysis behavior.

To report the status of the noise analysis parameters for the current design, use the *report_noise_parameters* command.

To reset the noise analysis parameters to the default settings, use the *reset_noise_parameters* command.

Examples

In the following example, the noise propagation is enabled while other parameters are not affected.

```
pt_shell> set_noise_parameters -enable_propagation
```

Feedback

set_ocvm_table_group

Associates an AOCV or POCV named table group or Liberty-based AOCV or POCV derating group with the list of specified design objects.

Syntax

status *set_ocvm_table_group*

```
ocvm_table_group_name
-type aocvm | pocvm
[-table_type coefficient | distance]
[object_list]
```

Data Types

```
ocvm_table_group_name     string
object_list               list
```

Arguments

ocvm_table_group_name

Specifies the name of the AOCV or POCV table group.

`-type aocvm | pocvm`

Specifies AOCV or POCV tables.

`-table_type coefficient | distance`

Specifies coefficient or distance-based POCV tables. The default is *coefficient*. Do not use this option for AOCV.

object_list

Specifies the list of design objects.

Description

The *set_ocvm_table_group* command can operate on either hierarchical cells / top level design or on lib_cells.

When operating on hierarchical cells or a top-level design, the command sets the association between a named AOCV or POCV table group and a hierarchical instance. An AOCV or POCV table group is a collection of AOCV or POCV tables with the same name. Names are specified using the group_name field in the AOCV or POCV table syntax. When associations are specified between hierarchical cells in the design and named AOCV or POCV table groups, a cell (or net) derives its AOCV or POCV derating from the table group associated with the hierarchical cell (or design) that (a) fully contains the cell (or net), and (b) is the lowest-level (closest ancestor) hierarchical cell (or design) with an associated AOCV or POCV table group. If no such hierarchical cell (or design) containing

the cell (or net) is found, the unnamed AOCV or POCV table group is used. Note that a net inherits the AOCV or POCV derating set of a hierarchical cell (design) that fully contains the net. For example, for nets that cross the boundary between the top level and a block (with an associated AOCV or POCV table group), the lowest-level hierarchical cell that fully contains the net is not the block. Therefore, the net derating used comes from an AOCV or POCV table group that contains the block and fully encloses the net. Note that for POCV, table groups for coefficients and distance-based tables are independent.

When operating on lib_cells the *set_ocvm_table_group* command can be used to assign a Liberty based AOCVM table from a Liberty library to the given lib cell. The Liberty AOCVM format allows for tables, which are not assigned to any library cell by default, to still be referenced by name. This command provides the ability to setup this reference. The syntax for the P/AOCVM derate group to be referenced follows this pattern:

lib_name/[*lib_cell_name*]/*derate_group_name*

The *lib_cell_name* is optional and applicable only for lib_cell based table. A lib_cell based can only be assigned to a library cell of the same name.

Examples

In the following example, the *set_ocvm_table_group* command performs an association between the hierarchical cell H1 and the named POCV coefficient table group A1. A POCV coefficient table belonging to the A1 table group is also shown.

```
pt_shell> set_ocvm_table_group -type pocvm -table_type coefficient A1
 [get_cells H1]

pt_shell> sh cat test.pocvm

version:        4.0
ocvm_type:      pocvm
group_name:     A1
object_type:    lib_cell
rf_type:        rise
delay_type:     cell
derate_type:    late
object_spec:    my_lib/*
coefficient:    0.05
```

Feedback

set_operating_conditions

Defines the operating conditions or environmental characteristics for the current design.

Syntax

status *set_operating_conditions*

```
[-analysis_type single | on_chip_variation]
[-library lib]
[condition]
[-min min_condition]
[-max max_condition]
[-min_library min_lib]
[-max_library max_lib]
[-object_list objects]
```

Data Types

```
lib                 string
condition           string
min_condition       string
max_condition       string
min_lib             string
max_lib             string
objects             list
```

Arguments

`-analysis_type single | on_chip_variation`

Specifies how the specified operating conditions are used:

- *single* - Specifies that only one operating condition is to be used.
- *on_chip_variation* - Switches the design to min_max mode; specifies that the minimum and maximum operating conditions represent, respectively, the lower and upper bounds of the maximum variation of operating conditions on the chip. All maximum path delays use the maximum operating condition, and all minimum path delays use the minimum operating condition.

`-library lib`

Specifies the library that contains definitions of the environmental characteristics to be used. This is either a library name or a collection object.

`condition`

Specifies the name of the single operating condition.

`-min` *`min_condition`*

Specifies the minimum operating condition used for checking minimum delays and hold violations (see the *report_timing* command with the *-delay min* option). If you use this option, you must also use the *-max* option.

`-max` *`max_condition`*

Specifies the maximum operating condition used for checking maximum delays and setup violations (see the *report_timing* command with the *-delay max* option). If you use this option, you must also use the *-min* option.

`-min_library` *`min_lib`*

Specifies the library that contains the *min_condition*. This is either a library name or a collection object. If you use this option, you must also use the *-min* option.

`-max_library` *`max_lib`*

Specifies the library that contains the *max_condition*. This is either a library name or a collection object. If you use this option, you must also use the *-max* option.

`-object_list` *`objects`*

Applies the operating conditions on the specified the cells or ports. If you do not use this option, the operating conditions are applied to the entire design. This option accepts both leaf cells and hierarchical blocks. You cannot use this option with the *-analysis_type* option. This option is only supported in legacy flows; use the *set_voltage* command instead.

Description

This command defines the operating conditions (or environmental characteristics) for performing timing analysis on the current design. You are in min_max mode if you use the *-min* and *-max* options.

The specified operating conditions must be defined in one of the following ways:

- Use the *min_lib* value for only the *min_condition*
- Use the *max_lib* value for only the *max_condition*
- Use one of the libraries in the *link_path*

The order for a library search is as follows:

•

1. *lib* • 2. *min_lib* or *max_lib* • 3. *link_path*

If no operating conditions are specified for a design, the tool uses the default operating condition of the library to which the cell is linked. If the library does not have a default operating conditions, no operating conditions are used.

Operating conditions set by using the *-object_list* option override the operating conditions set on design or higher levels of hierarchy.

To view the operating conditions defined for the current design and to determine the libraries to which the current design are linked, use the *report_design* command.

To view the operating conditions defined in the specified library, use the *report_lib* command.

To view the nondefault operating conditions set on cells, use the *report_cell* command.

To remove operating conditions from the current design, use the *remove_operating_conditions* or *reset_design* command.

When process factor, operating temperature, and operating voltage deviate from their nominal values, the tool uses delay scaling among multiple libraries.

PrimeTime derives cell instance voltages as follows:

- Default supply voltage in library cell definition (voltage_map in Liberty syntax)
- *set_operating_conditions* applied at the design level
- *set_voltage* on a supply net
- *set_voltage* on a PG pin

Since operating condition defines only single voltage value caution should be exercised when setting operating conditions on designs containing multirail cells such as level shifters and power management cells. PrimeTime applies the operating condition voltage value to all the library power rail.

The correct way to completely avoid this issue on multirail cells is to use the proper multivoltage flow, such as the UPF flow, to define all design rails using the *set_voltage* command. To verify voltage values of all rails of a multirail cell use the *report_power_pin_info* command.

An alternative is not to use any *set_operating_conditions* command and thus all power rails default to the library nominal voltage defined by voltage_map. Otherwise, use the design-wide *set_operating_conditions*; however, add the *set_voltage* command on specific PG pins of all multirail cells. Also, Liberty libraries should be created with the first voltage_map to match the nominal voltage nom_voltage.

Note that if the analysis type is set to *single*, only maximum delays from a SDF file are used to annotate timing arcs. Changing from a different analysis type into the single

operating condition analysis causes all minimum delays to be overwritten by maximum delay values.

Examples

The following example shows an operating condition definition, as it appears in the source text of a library.

```
operating_conditions("BCCOM") {
  process : 0.6 ;
  temperature : 20 ;
  voltage : 5.25 ;
  tree_type : "best_case_tree" ;
}
```

The name of this set of operating conditions is BCCOM. The parameters are defined as follows:

- *process* - A floating-point number that represents the characteristics of a semiconductor manufacturing process.
- *temperature* - A floating-point number that represents the temperature of the defined environment.
- *voltage* - A floating-point number that defines the upper boundary of the voltage range in which the defined environment operates. The lower boundary is always 0.0.
- *tree-type* - The interconnect model for the environment. The tool uses the interconnect model to select a formula for calculating interconnect delays. Three models are available:
  - *best_case_tree* - Uses a lumped RC model.
  - *worst_case_tree* - All loads assume full wire resistance.
  - *balanced_tree* - All loads share the wire resistance evenly.

The following example uses operating condition WCIND found in the my_lib.db library to set the operating conditions to WCIND if the *link_path* is my_lib.db.

```
pt_shell> set_operating_conditions WCIND
```

The following example uses the WCIND operating conditions in the other_lib.db library:

```
pt_shell> set_operating_conditions WCIND -library other_lib.db
```

In the following example, the tool uses

Feedback

- BCCOM values for the minimum operating conditions when calculating minimum delays
- WCCOM values for the maximum operating conditions when calculating maximum delays

```
pt_shell> set_operating_conditions -min BCCOM -max WCCOM \\
          -analysis_type on_chip_variation
```

set_opposite

Sets two ports to be logically opposite.

Syntax

```
status set_opposite
  port1
  port2
```

Data Types

```
port1      string
port2      string
```

Feedback

Arguments

port1

Specifies the first input port.

port2

Specifies the second input port.

Description

This command defines two input ports in the current design as logically opposite. This information is used during synthesis to eliminate redundant ports to improve optimization quality.

Logical inconsistencies are checked in relationships between ports. Specifying an inconsistent logical relationship between ports is not allowed.

Use the *reset_design* command to remove this property from a port.

The logical relationship is characterized by the *characterize_context* command and exported to synthesis using the *write_context* command.

Examples

The following example sets two input ports "A" and "B" to be logically opposite.

```
pt_shell> set_opposite A [get_ports B]
1
```

The following example sets up a contradictory relationship between two ports and generates an error message.

```
pt_shell> set_opposite A B
1

pt_shell> set_equal A B
Error: Can't set opposite ports equal in design 'top': 'A' 'B'. (DDB-23)
0
```

See Also

- set_equal

---

set_output_delay

Sets output path delay values for the current design.

Feedback

Syntax

string *set_output_delay*

```
[-clock clock_name]
[-reference_pin pin_port_name]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-group_path group_name]
[-sms_scenarios sms_scenarios_list]
delay_value
port_pin_list
```

Data Types

clock_name	list
delay_value	float
group_name	string
pin_port_name	list
port_pin_list	list
sms_scenarios_list	collection

Arguments

`-clock` *clock_name*

Specifies the name of a clock to which the specified delay is to be related. If you specify the *-clock_fall* option, you must also specify the *-clock* option.

`-reference_pin` *pin_port_name*

Specifies the clock pin or port to which the specified delay is related. If you use this option, and if propagated clocking is used, the delay value is related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The *-network_latency_included* and *-source_latency_included* options cannot be used at the same time as the *-reference_pin* option. For ideal clock network, only source latency is applied.

The pin specified with the *-reference_pin* option should be a leaf pin or port in a clock network, and in the direct or transitive fanout of a clock source specified with the *-clock* option. If multiple clocks reach the port or pin where you are setting the input delay, and if the *-clock* option is not used, the command considers all of the clocks.

`-clock_fall`

Indicates that the delay is relative to the falling edge of the clock. If you specify the *-clock_fall* with the *-reference_pin* option, the delay is relative to the falling transition of the reference pin. If you specify the *-clock* option, the default is the rising edge or the rising transition of the reference pin. If you specify the *-clock_fall* option, you must also specify the *-clock* option.

`-level_sensitive`

Indicates that the destination of the delay is a level-sensitive latch. This allows the tool to derive a setup and hold a relationship for paths to this port as if it were a level-sensitive latch. If you do not use the *-level_sensitive* option, the output delay is treated as if it were a path to a flip-flop.

`-rise`

Indicates that the *delay_value* option refers to a rising transition on specified ports of the current design. If you do not specify the *-rise* or *-fall* options, rising and falling delays are assumed to be equal.

`-fall`

Indicates that the *delay_value* option refers to a falling transition on specified ports of the current design. If you do not specify the *-rise* or *-fall* options, rising and falling delays are assumed to be equal.

`-max`

Indicates that the *delay_value* option refers to the longest path. If you do not specify the *-max* or *-min* options, maximum and minimum output delays are assumed to be equal.

`-min`

Indicates that the *delay_value* option refers to the shortest path. If you do not specify the *-max* or *-min* options, maximum and minimum output delays are assumed to be equal.

`-add_delay`

Indicates that delay information is added to the existing output delay, instead of overwriting the output delay. By using the *-add_delay* option, you can capture information about multiple paths leading from an output port that are relative to different clocks or clock edges. For example, the *set_output_delay 5.0 -max -rise -clock phi1 {OUT1}* command removes all other maximum rise output delays from *OUT1*, because the *-add_delay* option is not specified. Other output delays with a different clock or with the *-clock_fall* option are removed.

In another example, the *-add_delay* option is specified: *set_output_delay 5.0 -max -rise -clock phi1 -add_delay {Z}*. If there is an output maximum rise delay for Z relative to the clock phi1 rising edge, the larger value is used. The smaller

value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is a maximum rise output delay relative to a different clock or different edge of the same clock, it remains with the new delay.

`-network_latency_included`

Specifies whether the clock network latency should not be added to the output delay value. If this option is not specified, the clock network latency of the related clock is added to the output delay value. It has no effect if the clock is propagated or the output delay is not specified with respect to any clock.

`-source_latency_included`

Specifies whether the clock source latency should not be added to the output delay value. If this option is not specified, the clock source latency of the related clock is added to the output delay value. It has no effect if the output delay is not specified with respect to any clock.

`-group_path` *`group_name`*

Specifies the name of a group into which paths ending at the specified ports or pins are added. If the group does not already exist, one is created. The *-group_path* option of the *set_output_delay* command is equivalent to specifying the *group_path -name group_name -to port_pin_list* command. If you do not specify the *-group_path* option of the *set_output_delay* command, the existing path grouping does not change.

`delay_value`

Specifies the path delay in units consistent with the technology library used during analysis. The *delay_value* option represents the amount of time before a clock edge that the signal is required. For maximum output delay, this represents a combinational path delay to a register plus the library setup time of that register. For minimum output delay, this value is usually the shortest path delay to a register minus the library hold time.

`port_pin_list`

Specifies a list of output port or internal pin names in the current design to which the *delay_value* option is assigned. If more than one object is specified, the objects are enclosed in braces ({}).

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this output delay is applied. When this option is not given the output delay applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Feedback

Description

This command sets output path delay values for the current design. The input and output delays characterize the operating environment of the current design when used with the *set_load* and *set_driving_cell* commands.

The *set_output_delay* command sets output path delays on output ports relative to a clock edge. Output ports have no output delay unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay to a level-sensitive latch, use the *-level_sensitive* option. If the latch is positive-enabled, set the output delay relative to the rising clock edge; if it is negative-enabled, set the output delay relative to the falling clock edge. If time is borrowed at that latch, subtract that time from the path delay to the latch when determining output delay.

The *characterize_context* command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

PrimeTime adds input delay to path delay for paths starting at primary inputs and to output delay for paths ending at primary outputs.

The *-group_path* option modifies the path grouping. Path grouping affects the maximum delay cost. The worst violator within each group adds to the cost.

If a reference pin is not reachable by any given clock, zero arrival time is assumed. If no clock is specified with a reference pin and this reference pin is not reachable by any clock, an unconstrained path is reported. This behavior is changed after X0506. The new behavior of these invalid constraints are ignored and path is constrained by whatever it should be, as if no such constraints were defined. The *check_timing* command generates a warning if the reference pin is not reachable by any active clock, or if multiple clocks reach the reference pin and no clock is specified in the command.

To get a report on the latency calculation using a reference pin, use the *report_timing -path_type full_clock* or *report_timing -path_type full_clock_expanded* commands.

To list output delays associated with ports, use the *report_port* command. To list output delays of internal pins, use the *report_timing* command. To list the path groups that are defined, use the *report_path_group* command.

To remove output delay values, use the *remove_output_delay* or *reset_design* commands. To modify paths grouped with the *-group_path* option, use the *group_path* command to place the paths in another group or the default group.

Examples

The following example sets an output delay of 1.7 relative to the rising edge of CLK1 for all output ports in the design.

```
pt_shell> set_output_delay 1.7 -clock CLK1 [all_outputs]
```

The following example sets the input and output delays for the bidirectional port INOUT1. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
pt_shell> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}

pt_shell> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

The following example models the situation where there are three paths from output port OUT1. One of the paths is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The *-add_delay* option indicates that new output delay information does not cause the removal of old information.

```
pt_shell> set_output_delay 2.2 -max clock CLK1 -add_delay {OUT1}

pt_shell> set_output_delay 1.7 -max clock CLK1 -clock_fall -add_delay
 {OUT1}

pt_shell> set_output_delay 4.3 -max clock CLK2 -clock_fall -add_delay
 {OUT1}
```

In the following example, two different maximum delays and two minimum delays for port Z are specified using the *-add_delay* option. Because the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained (in this case, 5.0 and 1.1). If the *-add_delay* option is not used, the new information overwrites the old information.

```
pt_shell> set_output_delay 3.4 -max -clock CLK1 -add_delay {Z}

pt_shell> set_output_delay 5.0 -max -clock CLK1 -add_delay {Z}

pt_shell> set_output_delay 1.1 -min -clock CLK1 -add_delay {Z}

pt_shell> set_output_delay 1.3 -min -clock CLK1 -add_delay {Z}
```

The following example shows how to use the *-group_path* option to add ports into a named group. Note that without this option, paths to these ports are included in the CLK group.

```
pt_shell> set_output_delay 4.5 -max -clock CLK -group_path busA {busA[*]}
```

---

set_parasitic_corner

Sets a parasitic corner for the timing analysis in the presence of variation-aware parasitics.

Syntax

status *set_parasitic_corner*

```
-name corner_name
file_name
```

DATA TYPES

file_name string *corner_name* string

Arguments

`-name corner_name`

Specifies the name of the parasitic corner to be used from the corner file. A given corner file can contain definitions of a number of parasitic corners and this option specifies which corner definition is to be used to be set as the corner for analysis.

file_name

Specifies the name of the parasitic corner or corner file. The file is supposed to contain the percentage variation values for all the parasitic parameters in the variation-aware parasitics.

Description

The *set_parasitic_corner* command reads parasitic corner information from a disk file and sets it as the corner for analysis in the presence of variation-aware parasitics. The command succeeds only if variation-aware parasitics were previously annotated.

The syntax of the corner parasitic file is very simple. It simply defines various parasitic corners by specifying the VARIATION_RATIOs for all the parameters.

A VARIATION_RATIO signifies the actual amount of variation from the mean (or nominal) for a given parameter. A VARIATION_RATIO is expressed in terms of the percentage variation of a given parameter with respect to its variation coefficient. For example, a given parameter has a variation coefficient of 0.09. The actual amount of variation allowed for this parameter is between -0.27 and 0.27. The VARIATION_RATIO is the multiplier to the variation coefficient that gets us to the actual amount of variation for the parameter. So, by definition, the value of VARIATION_RATIO has to be between -3.0 and +3.0.

Technically, the syntax of a corner file can be expressed as:

```
(CORNER_NAME: <name of the corner>  (PARAM_NAME PARAM_VARIATION_RATIO)*)+
```

The corner file should contain definition for at least one corner. A corner can contain VARIATION_RATIO values for ZERO or more number of parameters. If a parameter is not specified in the corner definition, the VARIATION_RATIO is assumed to be ZERO.

Comments can be written in the file following Tcl style - so, anything after the characters " #" (space and pound) on a line is assumed to be a comment until the end of the line. Only line comments are supported.

An example of the corner file is as follows:

```
CORNER_NAME: CMAX
     M1_W         3.0
     M2_T         3.0
     ILD_c_T     -0.04
CORNER_NAME: RCMAX
 ## my definition of RCMAX
     M1_W         3.0
     M2_T         2.0
     ILD_c_T     -0.22
CORNER_NAME: RCMIN
     M1_W         -3.0
     M2_T         -3.0
     ILD_c_T       0.4
```

Feedback

This indicates that the CMAX corner parasitics must be inferred where the M1_W parameter is changed by positive (3.0 * variation_coeff of M1_W) from the nominal and so on.

You can issue this command multiple times to change the corner for analysis. Only the last command takes effect. You can remove the parasitic corner setting by using the *remove_parasitic_corner* command.

Note that this command has no effect on the *write_parasitics* command. This command sets the corner only for analysis and does not change the variation-aware parasitics.

The parasitic attributes, such as the *rc_network* and *total_coupling_capacitance* attributes, are all modified to reflect the corner values.

Examples

The following example reads the parasitics corner file "./corner_file" from disk and uses the settings of the RCMAX corner to set the default parasitic corner on the design with variation-aware parasitics.

```
pt_shell> set_parasitic_corner -name RCMAX ./corner_file
```

- read_parasitics
- report_annotated_parasitics

---

set_parasitics_range

Specifies the range of parasitic resistance and capacitance values to model interconnect skew effects.

Syntax

status *set_parasitics_range*

```
[-resistance_factor {r_factor1 r_factor2}]
[-ground_capacitance_factor {c_factor1 c_facator2}]
[-coupling_capacitance_factor {cc_factor1 cc_factor2}]
[-capacitance_factor {cap_factor1 cap_factor2}]
[-layers  {layer_name1, layer_name2, …}]
[-correlation_factor corr_factor]
```

Data Types

```
r_factor1, r_factor2       float
c_factor1, c_factor2       float
cc_factor1, cc_factor2     float
```

```
layer_name1                 string
corr_factor          float
```

Arguments

`-resistance_factor {r_factor1, r_factor2}`

Two scaling factors to represent the min and max corners of parasitic resistance values. The factors are positive floating-point numbers. For example, {1.0 1.2} represents the resistance values can be increased from typical (1.0) to max corner (1.2). {0.8 1.2} represents the resistance values can be increased from min corner (0.8) to max corner (1.2).

`-ground_capacitance_factor {c_factor1, f_factor2}`

Two scaling factors for the min and max corner of net-to-ground capacitance values.

`-coupling_capacitance_factor {cc_factor1, cc_factor2}`

Two scaling factors for the min and max corner of cross-coupling capacitance values. If -ground_capacitance_factor is also set, coupling capacitances and ground capacitaces should use the same factors.

`-layers {layer_name1, layer_name2, …}`

Applies the parasitic scaling to the specified layers. Multiple input layers specified in the same set_parasitics_range command is designed for double patterning and they should be fully correlated.

`-correlation_factor corr_factor`

Set correlation coefficient for resistance and capacitance factors. Default is -1. If this option is applied, user must provide both resistance and capacitance factors.

Description

The *set_parasitics_range* command is perquisite for both interconnect skew bounding analysis and interconnect skew path analysis. This is a more accurate analysis to model the parasitic variations for min and max parasitic corners compared to scaled_parasitcs.

This command accepts three kinds of parasitic ranges:

o One-sided parasitic range: Parasitic range has 1.0 on one side and other positive values on the other side. This will model the parasitic effect between typical and min/max corners.

o Two-sided parasitic range: Parasitic range two different values that is greater than 1.0 on one side and lesser than 1.0 on the other side. This will model the parasitic effect between min and max corners.

o Single-valued parasitic range: Parasitic range has the same positive value that is not 1.0 on both side. In this setting, interconnect skew analysis will simply scale the parasitics.

To report or cancel scaling factors, use the *report_parasitics_range* or *reset_parasitics_range* command.

Examples

The following example model the interconnect skew impact from typical to CMAX corner with the resistance scaling factor 1.1, the ground capacitance and coupling capacitances scaling factor 0.92. This scaling applies to layer M1 and M1_mask1, M1_mask2.

```
pt_shell> set_parasitics_range -resistance_factor {1.0 1.1}

                  -capacitance_factor {1.0 0.92} -layers {M1 M1_mask1
 M1_mask2}
```

See Also

---

set_path_margin

Specifies a margin to adjust required times for specified paths in the current design.

Syntax

status *set_path_margin*

```
[-rise]
[-fall]
[-setup]
[-hold]
[-reset_path]
[-increment]
[-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
[-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
[-through through_list
   | -rise_through rise_through_list
   | -fall_through fall_through_list]
[-sms_scenarios sms_scenarios_list]
[-domain_crossing domain_crossing_mode]
[-comment comment_string]
margin_value
```

Feedback

Data Types

comment_string	string
fall_from_list	list
fall_through_list	list
fall_to_list	list
from_list	list
margin_value	float
rise_from_list	list
rise_through_list	list
rise_to_list	list
sms_scenarios_list	collection
domain_crossing_mode	string
through_list	list
to_list	list

Arguments

`margin_value`

Specifies the value of the margin by which the required time is adjusted for the specified paths. A positive value results in a more restrictive or tighter check. A negative value results in a less restrictive or looser check. The value must be specified in the same units as those of the technology library used during optimization.

`-rise`

Applies the timing adjustment only to paths having a rising signal at the path endpoint.

`-fall`

Applies the timing adjustment only to paths having a falling signal at the path endpoint.

By default, paths having either a rising or falling at the endpoint are adjusted.

`-setup`

Applies the timing adjustment to only setup timing constraints for the specified paths.

`-hold`

Applies the timing adjustment to only hold timing constraints for the specified paths.

By default, both setup and hold constraints are adjusted.

`-reset_path`

Indicates that existing point-to-point exception information is to be removed from the specified paths. If used with the *-to* option only, all paths leading to

the specified endpoints are reset. If used with *-from* only, all paths leading from the specified startpoints are reset. If used with the *-from* and *-to* options, only the paths between those points are reset. Only information of the same rise or fall setup or hold type is reset. Using this option is equivalent to using the *reset_path* command with similar arguments before issuing the *set_path_margin* command.

`-increment`

When multiple set_path_margin commands are applied at different stages of the design without using the *-increment* option, only one path margin is applied to the path. With the*-increment* option it is possible to have multiple path margins applied to the path. There is a variable, *timing_enable_cumulative_incremental_path_margin*, to control the accumulation of all the incremental path margins. If there are multiple set_path_margin for the same path with the different precedence, the path margin with highest precedence gets applied. But, with this new *-increment* command option all the satisfied exceptions path margins are applied. If *set_path_margin* is set for all the nets in the path, this option helps to add all the path margins of the nets and applied to the same end point. The *report_timing -exceptions all* shows all the path_margins that were applied to the path.

`-from` *`from_list`*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified, one path startpoint on that cell is affected.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *`fall_from_list`*

Similar to the *-rise_from* option, except that the path must fall from the objects specified.

When the timing path has interior transparent latches, the *-from*, *-rise_from*, and *-fall_from* options refer to the clock, clock pin, or data pin of the last interior latch on the path, not to the initial startpoint of the timing path.

You can use only one of the *-from*, *-rise_from*, and *-fall_from* options.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Similar to the *-rise_to* option, but applies only to paths falling at the endpoint.

You can use only one of the *-to*, *-rise_to*, and *-fall_to* options.

`-through` *`through_list`*

Specifies a list of pins, ports, cells, and nets through which the paths must pass for maximum delay definition. By default, a net is interpreted to imply its driver pins. In case the previous *through_list* includes the driver, the net is interpreted to imply its load pins. If you omit the *-through* option, all timing paths specified using the *-from* and *-to* options are affected.

`-rise_through` *`rise_through_list`*

Similar to the *-through* option, but applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

Similar to the *-through* option, but applies only to paths with a falling transition at the specified objects.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this path margin is applied. When this option is not given the path margin applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

`-domain_crossing` *`domain_crossing_mode`*

Specifies one of the domain crosing modes for which this path margin is applied. The domain crossing modes are "only_crossing" and "exclude_crossing". If only_crossing option is used, then the path margin is applied only for cross domain paths. If exclude_crossing option is used, then the path margin is applied only for non-cross domain paths. When -domain_crossing option is not given, path margin applies for all the paths.

`-comment` *`comment_string`*

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

Description

This command adjusts the data required time for specified paths by a specified amount, *margin_value*. The required time for any startpoint in *from_list* to any endpoint in *to_list* is adjusted by *margin_value*. A positive margin value results in a more restrictive or tighter check, whereas a negative margin value results in a less restrictive or looser check. Based on the type of timing constraint, either setup or hold, the margin value is either subtracted from or added to the default data required time.

The *set_path_margin* command is a point-to-point timing exception command; that is, it adjusts the required time of the path and therefore the endpoint slack for the timing paths.

Other point-to-point exception commands include the *set_multicycle_path*, *set_min_delay*, *set_max_delay*, and *set_false_path* commands.

When a path has transparent latches in the interior of the path, *set_path_margin* is only applied when all the path specifiers are satisfied at or after the last interior latch on the path. The *-from* parameter refers to the clock, clock pin, or D pin of the last interior latch. The *-through* pins must be after the last interior latch.

If a path satisfies multiple timing exceptions, the following rules are applied to determine which exceptions take effect. Rules referring to *-from* apply equally to *-rise_from* and *-fall_from*, and similarly for the rise and fall options of *-through* and *-to*.

1. `set_path_margin -from` *`pin`* `-to` *`pin`*
2. `set_path_margin -from` *`pin`* `-to` *`clock`*
3. `set_path_margin -from` *`pin`*
4. `set_path_margin -from` *`clock`* `-to` *`pin`*
5. `set_path_margin -to` *`pin`*
6. `set_path_margin -from` *`clock`* `-to` *`clock`*
7. `set_path_margin -from` *`clock`*
8. `set_path_margin -to` *`clock`*

Note that if two or more exceptions have the same path options but differ only on the sense specified, then the most constraining value is used. An example is shown below:

1. `set_path_margin -from` *`pin`* `-to` *`pin`* `55`

```
2. set_path_margin -rise_from pin -to pin 60

3. set_path_margin -fall_from pin -to pin 50
```

In this example, all three exceptions will have the same precedence, however, the more constraining value will be used. Exception (1) -from is more constraining than exception (3) -fall_from path; and exception (2) -rise_from is more constraining than (1) -from path.

To report the path margin that applies to a given timing path, use the *report_timing -exceptions dominant* command.

Examples

The following example adjusts the required time to a port named OUT by 12 units. The adjustment results in a more restrictive, tighter timing constraint because the margin value is positive.

```
pt_shell> set_path_margin 12 -to {OUT}
```

The following example specifies that the required time of all paths from cell FF1 that pass through cell I1 and end at cell FF2 must be adjusted by 15.0 units.

```
pt_shell> set_path_margin 15 -from {FF1} -through {I1} -to {FF2}
```

The following example specifies that all paths to endpoints clocked by CLK must be adjusted by 10 units.

```
pt_shell> set_path_margin 10 -to [get_clocks CLK]
```

The following example specifies that required time of all the cross domain paths from cell FF1 and end at cell FF2 must be adjusted by 11.0 units.

```
pt_shell> set_path_margin 11 -from {FF1} -to {FF2} -domain_crossing
 only_crossing
```

The following example specifies that required time of all the paths from INFF2 and to OUTFF2 must be adjusted by 0.3. The incremental path margin 0.2 is added to the regular path margin 0.1.

```
pt_shell> set_path_margin 0.10 -from INFF2/CP -to OUTFF2/D
pt_shell> set_path_margin 0.20 -from INFF2/CP -to OUTFF2/D -increment
```

The following example specifies that the required time of all the paths from INFF2 and to OUTFF2 must be adjusted by 0.4. The incremental path margin 0.3 is added to the regular path margin 0.1. The last incremental path margin 0.3 overrides all the preceding ones.

```
pt_shell> set_path_margin 0.10 -from INFF2/CP -to OUTFF2/D
pt_shell> set_path_margin 0.20 -from INFF2/CP -to OUTFF2/D -increment
pt_shell> set_path_margin 0.30 -from INFF2/CP -to OUTFF2/D -increment
```

Feedback

The following example specifies that the required time of all the paths to the end point OUTFF2 must be adjusted by 0.6. If the -increment path margin values applied at through pins that satisfies the end point, it accumulates all those increment values and value of 0.6 is applied to the end point.

```
pt_shell> set_path_margin 0.10 -from INFF2/CP -to OUTFF2/D
pt_shell> set_path_margin 0.20 -through DPB1/YB -increment
pt_shell> set_path_margin 0.30 -through DPB2/YB -increment
```

set_pin_abstraction

Specifies the pins to include in a block abstraction.

Syntax

```
status set_pin_abstraction
  [-keep]
  [-clear]
  [-list]
  [pin_list]
```

Feedback

Data Types

pin_list list

Arguments

-keep

Includes the specified pins in the block abstraction generated at HyperScale block-level analysis and visible at top-level analysis.

-clear

Clears all pins with user-specified abstraction settings.

-list

Reports pins with user-specified abstraction control.

pin_list

Specifies a list of pins. Either a collection of pins or a list of patterns that match pins in the current design.

Description

This command customizes the HyperScale block abstraction behavior for specific pins.

This command is only effective in block-level HyperScale runs. The pins specified are considered by subsequent *update_timing*.

By default, HyperScale block-level analysis makes decisions based on the block interface topology and timing characteristics to retain interface portion of the circuit and make them visible for top-level analysis to achieve the best runtime and memory.

This command allows you to retain and keep specific pins from HyperScale block abstraction, such that these pins become visible at top-level analysis.

For each pin specified in the list, PrimeTime keeps the exact pin and the net connected with it, plus all the leaf pins on the same net to make the net complete. The actual objects retained is strictly based on local physical wire connectivity. There are no forward or backward path or logic tracing from these pins to span the visibility to additional objects.

Examples

This example keeps all the pins in the fanout of myReg in the block abstraction:

```
pt_shell> set_pin_abstraction -keep [all_fanout -from myReg/Q]
```

Feedback

See Also

---

set_placement_spacing_label

Sets an inter-cell spacing constraint label on one or more reference cells in preparation for defining minimum spacing rules between library cells.

Syntax

status *set_placement_spacing_label*

```
-name label_name
-side (left|right|both)
-lib_cells fIlist_of_lib_cells
[-row cell_row]
```

Data Types

```
label_name          string
list_of_lib_cells   list
cell_row            integer
```

Arguments

`-name label_name`

Inter-cell constraint label to assign to one or more reference cells.

`-side (left|right|both)`

Specifies that the given list of reference cells have the given label assigned to the left side, the right side, or both sides of the cell, when viewed in the "north" orientation.

`-lib_cells list_of_lib_cells`

Specifies a list of reference cells that have the given label assigned to them on one or both sides. The argument must be a list of library cell names.

`-row cell_row`

Specifies a row (starting at 1) upon which the given reference cells are assigned the given label. By default, the label is assigned to all rows of a multi-height cell.

Feedback

Description

This command assigns a label to a list of reference (library) cells to set inter-cell spacing constraints to be enforced by the legalization tool. A label is a string that you assign to one or both sides of a standard cell.

This command works together with the *set_placement_spacing_rule* command, which defines the illegal range of spacing between two adjacent labels. All spacing rules specified by *set_placement_spacing_rule* command must be satisfied to produce a legal placement.

With inter-cell spacing rules specified, standard cells can be placed next to each other only when they do not violate the spacing rules.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and are applied to all designs using the library.

Examples

The following commands assign the label "X" to reference cells AND* on the left side of the cell, and to reference cells NAND* on the right side of the cell (for cells in the "North" orientation).

prompt> set_placement_spacing_label -name X -side left -lib_cells AND* prompt> set_placement_spacing_label -name X -side right -lib_cells NAND*

See Also

- set_placement_spacing_rule

---

set_placement_spacing_rule

Sets an intercell spacing constraint between reference cells that have been assigned labels with the set_placement_spacing_label command.

Syntax

status *set_placement_spacing_rule*

```
-labels list_of_label_names
min_max_spec
```

Data Types

```
list_of_label_names          list of two strings
min_max_spec                 list of two integers
```

Feedback

Arguments

`-labels list_of_label_names`

Specifies a list of exactly two intercell constraint labels previously defined by the set_placement_spacing_label command.

min_max_spec

Specifies the range of illegal x-spacing values in units of sites. *min_max_spec* follows the format *{minx maxx}* where minx <= maxx. The spacing between the labeled edges cannot be in the range from minx to maxx placement sites.

Description

This command assigns intercell spacing constraints between reference cells that have been assigned labels with the set_placement_spacing_label command. Cells with the given labels are prohibited from being placed adjacent to one another with a spacing between minx and maxx. The values are specified in units of placement sites.

Given two adjacent standard cells with an empty space in between, each label from the right side of the left cell is checked against each label from the left side of the right cell to see if any spacing rules are violated. Such pairwise checking of labels is applied to all adjacent cells to ensure placement legality.

A label typically represents some layout features inside a standard cell. A label is associated with the left or right boundary of a standard cell in the "North" orientation. When a cell is flipped, its associated labels are also flipped.

With intercell spacing rules specified, standard cells can be placed next to each other only when they do not violate the spacing rules.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and are applied to all designs using the library.

Examples

In the following example, cells with labels "X" and "Y" are prohibited to abut (a spacing of 0 is prohibited).

```
prompt> set_placement_spacing_rule -labels {X Y} {0 0}
```

In the following example, cells with labels "X" are prohibited to be spaced within range of 3 to 5 placement sites.

```
prompt> set_placement_spacing_rule -labels {X X} {3 5}
```

See Also

- set_placement_spacing_label

Feedback

set_port_abstraction

Specifies the port fanin and fanout abstraction.

Syntax

```
status set_port_abstraction
  [-ignore]
  [-keep]
  [-clear]
  [-list]
  [port_list]
```

Data Types

port_list list

Arguments

`-ignore`

Indicates that the specified ports in the *port_list* whose fanout and/or fanin logic are pruned from the block abstraction generated at HyperScale block level analysis and not visible at top level analysis.

`-keep`

Indicates that the specified ports in the *port_list* whose fanout and/or fanin logic are included in the block abstraction generated at HyperScale block level analysis and visible at top level analysis.

`-clear`

Clears all the ports with user-specified abstraction settings. It clears both *-keep* and *-ignore* ports.

`-list`

Reports the ports with user-specified abstraction control.

port_list

Specifies a list of ports. Either a collection of ports or a list of patterns that match ports in the current design.

Description

This command specifies the HyperScale block abstraction behavior for specific ports and their fanout or fanin logic.

This command is only effective in block level HyperScale runs. The specified ports are considered by subsequent *update_timing* commands.

Feedback

By default, HyperScale block level analysis makes decisions of whether and how much a given port's fanin/fanout logic is retained based on the block interface topology and timing characteristics. If the port's fanin or fanout logic is retained, that interface portion of the circuit becomes completely visible for top level analysis, otherwise, only reduced visibility is expected for these ports at top level. These internal decisions are made to achieve the best runtime and memory.

This command allows you to customize HyperScale block abstraction behavior. Either force retain (with -keep) or remove (with -ignore) specific ports and their fanin/fanout logic in the HyperScale block abstraction, such that these ports become visible (with -keep) or reduced (with -ignore) at top level analysis.

For each port specified to keep, PrimeTime traces the fanin and fanout logic of the port and keep all the pins, cells and nets up to the first register (if input port) or from the last register (if output port) connected.

Examples

This example specifies that the fanout logic for ports SCAN* to be retained:

```
pt_shell> set_port_abstraction -keep [get_ports SCAN*]
```

This example specifies that the fanout logic for ports RST* be reduced or pruned:

```
pt_shell> set_port_abstraction -ignore [get_ports RST*]
```

This example removes all the user ignored or kept ports for custom abstraction:

```
pt_shell> set_port_abstraction -clear
```

---

set_port_attributes

Sets the specified attributes and their values on port objects.

Syntax

string *set_port_attributes*

```
[-ports port_list]
[-elements element_list]
[-applies_to inputs | outputs | both]
[-driver_supply supply_set_ref]
```

```
[-receiver_supply receiver_supply_set_name]
[-repeater_supply repeater_supply_set_name]
[-attribute name_value_pair]
[-is_analog]
[-literal_supply]
[-model model_name]
```

Data Types

port_list	list
element_list	list
supply_set_ref	string
receiver_supply_set_name	string
repeater_supply_set_name	string
name_value_pair	string
is_analog	boolean
literal_supply	string
model_name	string

Arguments

`-ports` *port_list*

Specifies the collection of ports on which the attributes must be set. Wildcards are accepted in port names.

`-elements` *element_list*

Specifies a set of ports on the interface to the specified elements, excluding any supply ports. A design element reference '.' is accepted to designate the current scope.

`-applies_to` *inputs* | *outputs* | *both*

Specifies whether the given *set_port_attributes* command applies to input ports, output ports, or both for the specified elements. This option must be used in conjunction with the *-elements* option. The default is *both*.

`-attribute` *name_value_pair*

Specifies the name and value of the attribute to be set on the ports specified by the *-ports* option.

This option can be repeated multiple times to specify multiple attributes for the same set of ports in a single command.

`-driver_supply` *supply_set_ref*

Specifies the supply of the logic driving the port.

`-receiver_supply` *receiver_supply_set_name*

Specifies the supply of the logic reading the port.

`-repeater_supply` *repeater_supply_set_name*

Specifies the supply set used by a repeater driving the port.

`-is_analog`

Applies the *is_analog* attribute to mark the port as an analog port.

`-literal_supply`

Specifies the supply set used to implement a literal constant value associated with an input port instance. This option is read and ignore in PrimeTime.

`-model`

Specifies a module or library cell on whose ports the attribute is to be applied.

Description

This command sets the attributes and their value on a list of ports specified by the *-ports* option or on a list of instances specified by the *-elements* option.

Attributes can be set multiple times on the same ports. The last-applied value is used.

PrimeTime suite tools only support limited number of attributes. Unsupported attributes are ignored and a warning message is issued.

The *-receiver_supply* and *-driver_supply* port attributes can only be specified on the top-level ports and design. A warning is issued if non top-level design element is specified for the *-elements* option for the *-driver_supply* or *-receiver_supply* option. Specifications on invalid design elements are ignored.

The *-model* option can be used with *-is_analog* attribute.The *-is_analog* option is allowed to be used with or without *-model*.

The tool interprets a port attribute specified on a design element as less specific than one specified on a particular port of the design element.

Examples

The following example sets SS1 as the *driver_supply* on top-level input port IN1 and sets SS2 as the *receiver_supply* on top-level output port OUT1.

```
prompt> set_port_attributes -ports {IN1} \\
                -driver_supply SS1
prompt> set_port_attributes -ports {OUT1} \\
                -receiver_supply SS2
```

The following example sets SS1 as the *driver_supply* on top-level input ports and sets SS2 as the receiver_supply *on top-level output ports using -elements {.} -applies_to. '.' refers to the current scope, which is set to the top-level design in this case.*

Feedback

```
prompt> set_port_attributes -elements {.} \\
              -applies_to inputs \\
       -driver_supply SS1
prompt> set_port_attributes -elements {.} \\
              -applies_to outputs \\
              -receiver_supply SS2
```

The following example sets the *snsp_derived* attribute to *true* on ports power_port and ground_port in block Mult.

```
prompt> set_port_attributes -ports {Mult/power_port Mult/ground_port}
 -attribute iso_sink SS1
1
```

---

set_port_fanout_number

Sets the number of external fanout points on ports.

Syntax

string *set_port_fanout_number*

```
[-min]
[-max]
fanout_number
port_list
```

Data Types

fanout_number	int
port_list	list

Arguments

`-min`

Specifies the value for minimum condition.

`-max`

Specifies the value for maximum condition.

fanout_number

Specifies the number of external fanout points (Range: 0 to 100000).

port_list

Specifies a list of ports. Each element in the list is either a collection of ports or a pattern that matches ports on the current design.

Description

Sets the number of external fanout pins for ports in the current design. The number of pins is used (along with wire load models) to calculate capacitance and resistance of nets.

To remove port fanout number values, use the *remove_port_fanout_number* command. To show port fanout number information, use the *report_port -wire_load* command.

Examples

This example sets the external wire load model for ports OUT1* to 70x70 and specifies an external fanout number of 2.

```
pt_shell> set_wire_load_model 70x70 [get_ports OUT1*]
pt_shell> set_port_fanout_number 2 [get_ports OUT1*]
```

---

set_postsynth_options

Specify RTL Architect commands to be executed after compilation is done.

Syntax

int *set_presynth_options*

```
[-file file_name]
[-cmds cmd_list]
```

Data Types

```
file_name       string
cmd_list        list
```

Arguments

-file *file_name*

Specifies tcl file which contains tcl commands to be executed after compile.

Feedback

`-cmds` *`cmd_list`*

if number of tcl commands is small, specify commands directly instead of creating separate file.

Description

The *set_postsynth_options* command pass RTL Architect tcl commands to be executed after compile. Use this command for reporting purpose.

Examples

The following example shows how to pass arbitrary command

```
pwr_shell> set_postsynth_options -cmds {
              puts "*** after compile ***"
              report_qor
           }
```

set_power_analysis_options

Sets the options for power analysis.

Syntax

integer *set_power_analysis_options*

```
[-static_leakage_only]
[-through_mode]
[-waveform_interval sampling_interval]
[-cycle_accurate_cycle_count cycles]
[-cycle_accurate_clock clock]
[-waveform_format fsdb | out | none]
[-waveform_output file_prefix]
```

```
[-multi_rail_waveform supply_net_list]
[-include top | all_without_leaf | all_with_leaf]
[-include_groups group_list]
[-cells cell_list]
[-cycle_power_hierarchy cell_list]
[-sdpd_tracking enabled | disabled]
[-sdpd_tracking_cells cell_list]
[-separate_power_waveform leakage | glitch | all]
[-conflict_activity_cells cell_list]
[-exclude_arc_scaling_libcells libcell_list]
[-npeak npeak_size]
[-npeak_out file_prefix]
[-peak_power_instances]
[-propagate_through_feedbackloop]
```

Data Types

```
quantile              float
sampling_interval     float
cycles                integer
clock                 string
file_prefix           string
supply_net_list       list
group_list            list
cell_list             list
libcell_list          list
npeak_size                integer
```

Arguments

`-static_leakage_only`

Specifies that averaged power analysis will only calculate static leakage power and skip dynamic power calculation. This option applies only to averaged power analysis.

`-through_mode`

Enables through_mode propagation of clock activity throughout the clock network. When not specified, regular probabilistic propagation takes place in the clock networks as well. This option applies only to averaged power analysis.

`-waveform_interval`

Specifies the sampling interval that is used for power waveform. The default value is the timescale from the VCD file. This option applies only to time_based power analysis. The option will be ignored if VCD comes from RTL or zero-delay simulation.

`-cycle_accurate_cycle_count`

Specifies the number of clock cycles over which the power consumed by the design is considered constant when VCD is RTL or zero-delay. The default is 1.

This option applies only to time_based power analysis, specifically for RTL or zero-delay VCD or its equivalents (such as, VPD, etc.).

`-cycle_accurate_clock`

Specifies the reference clock for time_based power analysis, when VCD is RTL or zero-delay. The power consumed by the design is considered constant over one or more cycles of the specified clock. The default is the fastest clock in the design. This option applies only to time_based power analysis, specifically for RTL or zero-delay VCD or its equivalents (such as, VPD etc.).

`-waveform_format`

Specifies the format of the file in which the waveform data is to be written. The value for this option can be: *fsdb*, *out* or *none*. The default is *fsdb*. If the format is set to none, waveform data is not to be dumped, but peak power is still calculated. This option applies only to time_based power analysis.

`-waveform_output`

Specifies the prefix of the file in which the waveform data is to be written. The default is *primetime_px*. This option applies only to time_based power analysis.

`-multi_rail_waveform`

Specifies the list of supply nets for which the waveform data is to be written. Separate waveforms will be generated for each of these rails. You need to enable multirail analysis to use this feature. This option applies only to time_based power analysis. By default, multirail wave generation is disabled.

`-include`

Specifies the objects in the design hierarchy to be monitored for waveform generation. The tool will only be able to show the power waveforms limited by this option. There are three allowed values for the option. If the value is *top*, only the top-level design is monitored for power waveform generation. If the value is *all_without_leaf*, all design hierarchies except leaf cells are monitored. If the value is *all_with_leaf*, all design hierarchies including leaf cells are monitored. The default value is *all_without_leaf*. This option applies only to time_based power analysis.

`-include_groups`

Specifies the power groups to be monitored for power waveform generation. When specified, the tool shows the power waveforms only for the specified power groups. By default, no power group is monitored. This option applies only to time_based power analysis.

`-cells`

Specifies the cell names or collections of cells for which power needs to be calculated. By default, PrimePower calculates power for the whole design.

`-propagate_through_feedbackloops`

Enables activity propagation outside of power analysis cells through feedback loops.This option can only be used with -cells option.

`-cycle_power_hierarchy`

Specifies the names or collections of hierarchical cells for which cycle based power reports will be created from Cycle Power. By default, Cycle Power only outputs cycle based power reports for the whole design.

`-sdpd_tracking`

Enables or disables SDPD activity tracking for cells specified in the -sdpd_tracking_cells list. The default is *disabled*.

`-sdpd_tracking_cells`

Specifies the list of cells for which SDPD activity is to be tracked. The default list contains all black box and memory cells.

`-separate_power_waveform`

Enables generation of separate leakage, glitch and all power waveforms. This option can be used with -multi_rail_waveform option. In this case, separate waveforms will be generated for each supply net from the given list of supply nets. This option applies only to time_based mode.

`-conflict_activity_cells`

Specifies the list of cells for which activity in the VCD/FSDB file has conflicts with the activity of the parent cells. A conflict activity for a given net is defined as activity with different transitions in the same time stamp. A net can have several net segments which are across hierarchical levels. For these nets, the user can generate separate VCD/FSDB files which can be later merged together into a single FSDB file. The activities for different net segments of such a net can be different across hierarchical levels. This option helps to define the list of conflict cells with such conflicting activity and tries to resolve them.

In order to enable this feature, set the *power_enable_merged_fsdb* variable to true. This feature works in both averaged and time-based analysis modes. For time-based mode, this feature only works with gate-level VCD/FSDB files which do not need any activity propagation.

`-exclude_arc_scaling_libcells`

Specifies the list of library cells for which internal power arc would not be scaled.

`-npeak`

Reports N worst power values of the design in time_based mode. The allowed values are from 2 to 100. When specified, the tool generates a separate report

which contains the N worst power values of the design and their corresponding time.

`-npeak_out`

Specifies the prefix of the npeak report to be generated. If this option is not specified, by default the report file is named *primepower_npeak.out*.

`-peak_power_instances`

Reports instances which contribut to N worst power values of the design waveform in time_based mode. This option works only with the -npeak option; the allowed values are from 2 to 10. When used together with the -npeak option, the tool generates a separate report which contains the N worst power values of the design, corresponding time and design instances contributing to N worst power values. Use the -npeak_out option to specify the name of the generated instance report. If the -npeak_out option is not specified, by default the report file is named *primepower_npeak_instances.out*.

Description

There are several power analysis modes in PrimePower, such as *averaged, time_based, or leakage_variation. The mode is specified by the power_analysis_mode variable before the key power analysis commands. The working command for all power analysis mode is update_power. The update_power command itself does not take any option. The set_power_analysis_options command is used between the power_analysis_mode variable and the update_power command to specify various options for different power modes in PrimePower. The options from this command will control how power analysis of the specified mode behaves.*

Each option may be used for one or more modes of power analysis. If an option is not supposed to be used in a power mode, the command stops and issues an error message. The *set_power_analysis_options* command without any option resets all the power analysis options to the default values. Rerunning the *set_power_analysis_options* command overwrites the previous configuration and resets the rest of power analysis options to the default values. The -cycle_accurate_clock and -cycle_accurate_cycle_count options are exclusive with the -waveform_interval option in this command.

The following table lists the options supported in each of the power modes.

```
------------------------------+----------+------------+-----------------
-------+-------------------+
 |                              |          |            |       time_based
       |                     |
 |                              | averaged | time_based | (RTL or zero

        |          No        |
 ------------------------------+----------+------------+-----------------
--------+--------------------+
```

When SDPD tracking is enabled, SDPD (state-dependent and path-dependent) switching activity for the sepcified cells will be tracked during power analysis. So later when the *write_saif* command is performed, the resulting SAIF file has the SDPD switching activity data.

Examples

The following example runs time_based power analysis. The time interval is 10 ns. The waveform output file is named my_design.fsdb.

```
pt_shell> set power_analysis_mode time_based
pt_shell> read_vcd -strip_path this_strip_path my_design.vcd
pt_shell> set_power_analysis_options -waveform_interval 10
 -waveform_output my_design
pt_shell> update_power
```

The following example runs averaged power analysis. Only leakage power is calculated for fast turn-around time.

```
pt_shell> set power_analysis_mode averaged
pt_shell> set_power_analysis_options -static_leakage_only
pt_shell> update_power
```

The following example runs averaged power analysis. This will enable the pass-through propagation of toggle rates in the clock network.

```
pt_shell> set power_analysis_mode averaged
pt_shell> set_power_analysis_options -through_mode
pt_shell> update_power
```

The following example runs time_based power analysis for an RTL-based design. The reference clock is *clk*.

```
pt_shell> set power_analysis_mode time_based
pt_shell> source name_mapping_info.tcl
pt_shell> read_vcd -rtl -strip_path this_strip_path my_rtl_design.vcd
pt_shell> set_power_analysis_options -cycle_accurate_clock clk
pt_shell> update_power
```

The following example will cause PrimePower to do leakage power variation analysis. The variation quantile is *0.9*.

```
pt_shell> set power_analysis_mode leakage_variation
pt_shell> set_power_analysis_options -variation_quantile quantile
pt_shell> update_power
```

The following example resolves conflict activity on a list of cells. This option needs to be set before reading the merged VCD or FSDB file. This feature works in average and time_based power modes (with a gate-level VCD or FSDB file).

```
pt_shell> set power_enable_merged_fsdb true
pt_shell> set_power_analysis_options -conflict_activity_cells { u0 }
pt_shell> read_vcd -strip_path this_strip_path my_design.vcd
pt_shell> update_power
pt_shell> report_power -cell -leaf
```

---

set_power_base_clock

Specify power_base_clock for a given set of objects.

Syntax

integer *set_power_base_clock*

```
[-clock_name name_string]
[object_list]
```

Data Types

name_string	string
object_list	list

Feedback

Arguments

`-clock_name` *name_string*

Specify the clock name.

object_list

Specify a list of objects in the design. Only nets, pins and ports are supported.

Description

For a given net/pin activities are applied by specifying toggle rates relative to it's related clock (power_base_clock) . Currently for every pin, power_base_clock is identified by PrimePower based on design constraints and timing paths through the pin. This command allows PrimePower to use the specified clock as the power_base_clock of a given pin/net instead of the implied one.

This needs to be specified before any set_switching_activity command and prior to 'update_power' . The actual association is done during 'set_switching_activity / 'update_power'.

See Also

- power_enable_clock_scaling

---

set_power_budget

Sets target power budget on hierarchical instances in the design.

Syntax

```
int set_power_budget
budget_value
[-cell cell_list]
[-rails rail_list]
[-propagate]
[-exclude exclude_list]
[-exclude_group exclude_group_list]
[-exclude_rail exclude_rail_list]
[-cell_group cell_group_list]
[-power_type power_type_list]
```

Data Types

```
cell_list           list
rail_list           list
exclude_list        list
exclude_group_list  list
cell_group_list     list
exclude_rail_list   list
```

```
power_type_list     list
budget_value        float
```

Arguments

budget_value

Specifies the power budget that is applied on the specified hierarchical instances.

-cell *cell_list*

Specifies a list of hierarchical instances on which the specified power budget is applied.

-rails *rail_list*

Specifies a list of supply nets for applying supply-net-specific power budget on the specified hierarchical instances.

-propagate

Specifies derived scale factor upon setting the power budget on a supply net, to propagate to all the child supply net segment of this supply net.

-exclude *exclude_list*

Specifies a list of cells to exclude from power budget getting applied on them.

-exclude_group *exclude_group_list*

Specifies a list of power groups to exclude from power budget getting applied on them.

-exclude_rail *exclude_rail_list*

Specifies a list of supply_nets to exclude from power budget getting applied on them.

-cell_group *cell_group_list*

Specifies a list of power groups under hierarchies specified by -cell option on which power budget is applied. Must be used with -cell option.

-power_type *power_type_list*

Specifies a list of power types on which power budget is applied. Valid values are internal, switching and leakage.

Description

The command sets power budget on a list of hierarchical instances in the design. If the list is not specified, power budget is applied on the design. The specified power budget and actual computed power for the hierarchical instance would be used to calculate a scaling factor to scale power for all the instance in the hierarchical block, so that the

scaled power matches the specified power budget for the instance. With power budget set on the design, the *report_power* command would report the scaled power for the design.

Total power budget applied on the hierarchical instance must not be smaller than the calculated actual total leakage power for the hierarchical instance.

Supply-net-specific power budget can also be applied on the hierarchical blocks in which case power associated with the supply net would only be scaled.

Budget can be applied across multiple hierarchy levels; precedence increases with moving down the hierarchy levels in the design. Setting power budget on a hierarchical instance overrides the previously set budget, if any.

Use the *reset_power_budget* command to clear the applied budgets on the design.

Examples

The following example sets a power budget of value 1.135e-04 on the hierarchical instance four_mini_inst/two_mini_1/a.

```
pt_shell> set_power_budget 1.135e-04 -cell four_mini_inst/two_mini_1/a
```

The following example sets a power budget of value 9.354e-05 on the rail four_mini_inst/VDD_MINI_1 for the hierarchical instance four_mini_inst/two_mini_1/a.

```
pt_shell> set_power_budget 9.354e-05 -cell four_mini_inst/two_mini_1/a
 -rails four_mini_inst/VDD_MINI_1
```

---

set_power_check_attributes

Allows user to specify whether attribute pin_propagation_check, pin_qm_propagation_check, internal_power_check, leakage_power_check will be computed or not. User must set variable power_enable_check_attributes to true for this command to work.

Feedback

Syntax

```
string set_power_check_attributes
[-pin_propagation_check]
[-pin_qm_propagation_check]
[-internal_power_check]
[-leakage_power_check]
[-all]
```

Arguments

`-pin_propagation_check`

This option must be provided for attribute pin_propagation_check to get computed.

`-pin_qm_propagation_check`

This option must be provided for attribute pin_qm_propagation_check to get computed.

`-internal_power_check`

This option must be provided for attribute internal_power_check to get computed.

`-leakage_power_check`

This option must be provided for attribute leakage_power_check to get computed.

`-all`

This option must be provided for attribute pin_propagation_check , pin_qm_propagation_check , internal_power_check and leakage_power_check to get computed.

Description

This command enables user to select which attribute to be computed from pin_propagation_check, pin_qm_propagation_check , internal_power_check , leakage_power_check or all attributes.

Examples

The following *set_power_check_attributes command only enable pin_propagation_check.*

```
pt_shell> set_power_check_attributes -pin_propagation_check
```

The following *set_power_check_attributes command enable pin_propagation_check and pin_qm_propagation_check.*

```
pt_shell> set_power_check_attributes -pin_propagation_check
 -pin_qm_propagation_check
```

The following *set_power_check_attributes command enable pin_propagation_check , pin_qm_propagation_check, internal_power_check and leakage_power_check.*

```
pt_shell> set_power_check_attributes -all
```

See Also

- report_power_check_attributes

---

set_power_clock_scaling

Specify clock clock scaling for power analysis.

Syntax

integer *set_power_clock_scaling*

```
[-period period_value]
[-ratio ratio_value]
[clock_objects]
```

Data Types

period_value	float
ratio_value	float
clock_objects	list

Arguments

`-period period_value`

Specify the period of clock which is used in simulation.

`-ratio ratio_value`

Specify the clock ratio (period_used_in_VCD_or_SAIF / period_used_in_SDC).

clock_objects

Specify a list of clocks in the design.

Description

Clock frequency used in value change dump (VCD) and Switching Activity Interchange Format (SAIF) files, from logic simulation, for functional verification can differ from the clock frequency used in Synopsys Design Constraints (SDC) file for timing and power analysis. This command tells PrimePower what frequency is used in logic simulation so that PrimePower can scale averaged power numbers properly.

To enable this feature, set the *power_enable_clock_scaling* variable to *true*.

The clock_objects option in this command is a list of clocks in the design that have the specified period or ratio values used in simulation for VCD or SAIF generation. Here the ratio is defined as period-in-simulation / period-in-analysis. The command can be used multiple times, once for each clock. If the same clock is used more than once, a warning message is issued and the clock specified last takes effect. The *-period* and *-ratio* options cannot be used simultaneously. If no clock object is specified, only the ratio option is allowed and the ratio value is applied to all the nets that do not have an associated simulation clock.

The tool only scales the switching activities from the VCD file or the SAIF file and activities that are propagated or implied. The actual scaling for switching activity and averaged power analysis is performed by the tool during the execution of the update_power command. You can also check the power_base_clock attribute on the nets to identify the clock that controls the activity scaling of the net. The command returns 1 on success and 0 on failure.

To perform repeated scaling, you need to re-specify the scaling factor. The scaling factor is applied w.r.t the original toggle rate . The tool keeps track of the factor by which the toggle rates are already scaled. For example, if a net has an original toggle rate 1.0 and the *-ratio* option of the *set_power_clock_scaling* command is set to 2, the 1st scaling results in the net's toggle rate to 2 (the original toggle rate 1.0 is replaced). To further scale the toggle rates by twice , you need to specify a scaling factor of 4. To come back to the original toggle rates, you can use *set_power_clock_scaling 1* .

The clock scaling is done only for averaged power. This feature cannot be applied to a time-based peak power analysis.

Examples

A sample script is listed below. In this case, duration logic simulation the SAIF file mac.saif is generated with clock period 24, so you use set_power_clock_scaling period 24 [get_clock clk], and you specify SDC clock in mac.sdc (it could be period 12, for example). Report_power will report the power consumption when the design is operated at SDC clock period 12, rather than logic simulation clock period 24.

```
set power_enable_analysis true
set power_analysis_mode averaged
set search_path         "../src/hdl/gate ../src/lib/snps . "
set link_library        " * core_typ.db"

read_verilog            mac.vg
current_design          mac
link
read_sdc ../src/hdl/gate/mac.sdc
read_parasitics ../src/annotate/mac.spef.gz
read_saif "../sim/mac.saif" -strip_path "tb/macinst"

set_power_clock_scaling -period 24 [get_clock clk]
set power_enable_clock_scaling true
```

```
update_power
report_power

quit
```

See Also

---

set_power_delay_shifted_event_analysis_options

Sets the options for delay shifted event analysis.

Syntax

integer *set_power_delay_shifted_event_analysis_options*

```
[-effort_level effort_string]
[-write_activity_file output_file_name]
[-include_external_delay ]
[-glitch_pulse_r pulse_ratio]
[-zero_delay_power ]
[-zero_delay_report_type report_type_string]
[-rtl]
[-nets report_type_string]
[-exclude_nets report_type_string]
[-max_fanout report_type_int]
[-max_slew  pulse_ratio]
[-disable_shifting_through_power_switch ]
```

Data Types

```
effort_string          string
output_file_name       string
pulse_ratio            float
report_type_string     string
report_type_int        int
```

Arguments

`-effort_level`

Specifies the effort that is used in shifting the events using the delays obtained from timer (PrimeTime). Valid values are *low* and *high*. The default is *high*.

`-exclude_nets`

Specifies the nets that is excluded from delay shifting. Wire delay is taken to be zero for delay shifting purpose. For the driver and load cell of the net ,input and output arc is capped at max cell delay.

`-max_fanout`

Specifies max_fanout limit for net to be considered as high fanout net for delay shifting purpose.

`-max_slew`

Specifies max_slew limit for net to be considered as high fanout net for delay shifting purpose.

`-write_activity_file`

Generates a Gate-level delay annotated activity file (in the FSDB format) during power analysis.

`-include_external_delay`

Includes external delays for primary input ports in event shifting. By default, external delays are not used in event shifting.

`-rtl`

When option '-rtl' is specified then activity files contains rtl objects only. This option is applicable only when option 'write_activity_file' is provided by user.

`-nets`

When option '-nets' is specified then activity files contains nets objects provided by user. This option is applicable only when option 'write_activity_file' is provided by user.

`-glitch_pulse_r`

Filters out glitch pulses on a cell whose width is less than the specified percentage of the cell delay. By default, this value is 100, meaning all glitch pulses whose width is greater than the cell delay is propagated.

`-zero_delay_power`

Runs zero-delay power analysis simultaneously in the background, along with "delay-shifted event analysis". At the end of the analysis, a power report, named report_power_zd.txt, is generated for zero-delay analysis.

Redirection of log from update_power command is not supported with option *-zero_delay_power*.

`-zero_delay_report_type`

Specifies the power report type for background zero-delay power analysis. Three file types are supported: summary, cell_power, and net_power. The default is summary.

`-disable_shifting_through_power_switch`

Disables delay shifting through power switch cells.

Feedback

Description

This command is used when the *power_enable_delay_shifted_event_analysis* variable is set to true. The command is used between *power_enable_delay_shifted_event_analysis* and *update_power*. The options from this command control how delay aware peak power analysis uses RTL or zero-delay VCD/FSDB.

The delay as obtained from timer is added to each event time in the zero-delay input FSDB/VCD. Starting from each register output, the tools adds the delays and accumulated along the combinational path and continues till another register is found in the path where the delay is reset. Latches and clock gating cells (ICGs) are also included in this path between two registers.

For "low" effort level, the tool uses the worst path delay through a cell output to shift the event of the given cell output. For "high" effort level, the tool chooses the path that is sensitized by the input FSDB/VCD at each timestamp and uses the delay along this path to shift the events. This option has a high runtime overhead but is expected to give better accuracy.

When the -include_external_delay option is specified, the tool uses the delay specified by *set_input_delay* to shift events for primary input ports.

Examples

The following example runs peak power analysis with delay shifted events.

```
pwr_shell> set power_analysis_mode time_based
pwr_shell> set power_enable_delay_shifted_event_analysis true
pwr_shell> read_vcd -rtl -strip_path this_strip_path my_design.vcd
pwr_shell> update_power
```

The following example runs peak power analysis with delay shifted events and generates a delay-annotated gate-level activity file named shifted_activity.fsdb.

```
pwr_shell> set power_analysis_mode time_based
pwr_shell> set power_enable_delay_shifted_event_analysis true
pwr_shell> read_vcd -rtl -strip_path this_strip_path my_design.vcd
pwr_shell> set_power_delay_shifted_event_analysis_options
                -write_activity_file "shifted_activity.fsdb"
pwr_shell> update_power
```

The following example rejects glitch pulses whose width is less than 75% of the cell delay.

```
pwr_shell> set_power_delay_shifted_event_analysis_options -glitch_pulse_r
 75
```

---

set_power_derate

Sets power derating factors for either the current design or a specified list of instances (cells, library cells, power groups, pins or nets).

Syntax

```
int set_power_derate
[-switching]
[-internal]
[-leakage]
[-x_transition]
[-rails rail_list]
[-pg_pin pg_pin_list]
[-groups group_name_list]
[-pin_switching pin_list]
derate_value
object_list
```

Data Types

group_name_list	list
rail_list	list
pg_pin_list	list
derate_value	float
object_list	list

Arguments

`-switching`

Indicates that the *derate_value* specified should be applied to switching power.

`-internal`

Indicates that the *derate_value* specified should be applied to internal power.

`-leakage`

Indicates that the *derate_value* specified should be applied to leakage power only. For CCS power library, it should be applied to both gate leakage and subthreshold leakage power.

`-x_transition`

Indicates that the *derate_value* specified should be applied to x-transition power. This feature is only valid for pins and nets objects.

`-groups` *`group_name_list`*

Specifies the power groups to which the *derate_value* is applied. The *derate_value* applies directly to each cell object in the power group.

`-rails` *`rail_list`*

Specifies a list of power supply nets on which power derate factor applied. This option is not supported for non-UPF mode. This feature is only valid on the following objects hierarchycal_cell, leaf_cell, Design and, power- groups. Derated values can be reported by *report_power_derate* command.

`-pg_pins` *`pg_pin_list`*

Specifies a list of pg_pins on which power derate factor applied. This feature is only valid on the following objects leaf_cell,and lib_cell. Derated values can be reported by *report_power_derate* command.

`-pin_switching`

Indicates that the *derate_value* specified should be applied to pin switching power. This feature is only valid for pins objects when variable *power_enable_pin_power_to_receiver_mode set to true.*

`derate_value`

Specifies the power derating factor that is applied to the specified power components as a scalar multiplicative factor.

`object_list`

Specifies current design or a list of cells or library cells to which the specified power derating factor is applied.

Description

Sets power derating factors on different power components for either the current design, a list of cells, library cells , pins or nets in the current design. If no object or power group is specified, the power derating factor (except for x-transition power derating factor) is set on the current design The power derating factors are used as a scalar multiplicative factor in power calculation.

Power derating factors affect power analysis results in power reports and power attributes. Power analysis results are multiplied by the derating factors. If power derating factors are not specified, the value of 1.0 is assumed (and value of 0.5 for x-transition power derating factor is assumed).

If you use the *set_power_derate* command with the *-internal*, *-switching*, or *-leakage* option, the specified power derating factor is only be applied to internal, switching, or leakage power accordingly. If you do not specify the *-internal*, *-switching*, or *-leakage* option, the power derating factor applies to all power components, which includes internal, switching, and leakage power. You can first set a generic power derating factor that applies to all power components, and then refine it by setting specific power derating factors for particular power components on particular design objects.

The *object_list* option can be used to set power specific derating factors on instances (cells, library cells, pins or nets) in the design. On each instance the *-switching*, *-internal*, and *-leakage* options can be used in the same way as previously described to specify exactly how the derating factors should be applied to each instance in the object list.

When applying power derating factors the following priority is used (in decreasing order of precedence):

1) Leaf Cell or Power Group

2) Hierarchical Cell

3) Library Cell

4) Design

Therefore, when power derating factors are being applied for a cell, PrimePower first checks if they have been set for the cell itself (leaf cell). It then checks if it has been set for any of the cells hierarchical parents. If no derate factors are found, it checks for the library cell and after that it uses the factors set globally on the design.

If power derating factors are set multiple times on the same design object for the same power component, the later value overrides the previous value.

Use the *-groups* option to set specific derating factors on all the cell objects in particular power groups. Power group can be user generated or default, such as clock_network, memory, register. They are considered as a collection of leaf and hierarchical cells. When applying power derating factors, the factors are set directly on the cell objects in the collection. There is one exception. Currently in PrimePower, clock network power includes the clock pin power of registers by default. The clock network power derating factors are not applied to registers, but only applied to the clock pin power of the registers when it was included in the clock network power. The power derating factors set on clock network power group are reset with the *reset_power_derate* command on current design or without any option.

In addition, if the *-switching* option is specified and the *object_list* contains any hierarchical cells, all cells within that hierarchical cell and also all lower hierarchical cells have that derating factor set on them.

The *-groups* option can be used to set specific derating factors on all the cell objects in particular power groups. Power group can be user generated or default, such as

clock_network, memory, register, etc.. If a derate factor is set on a power group, the specified derating factors are applied to all cell objects in the power group.

Power derating factors affect power values shown in power reports. The intended usage mode of this command is that you first set global or default derates on the design. Then you can use the *object_list* option to set specific derate values for cells or library cells in the design. To set derates globally on a design simply issue the command with no object list specified.

To set derating values back to the default (derating factor of 1.0 and x-transition derating factor of 0.5 for every instance in the design), use the *reset_power_derate* command.

Examples

The following example sets a power derating factor of value 0.95 on all cells in the design.

```
pt_shell> set_power_derate 0.95
```

The following example sets switching power derate and internal power derate to 0.9.

```
pt_shell> set_power_derate 0.9 -switching -internal
```

The following example sets x-transition power derate to 0.75 on pin U0/CP.

```
pt_shell> set_power_derate 0.75 -x_transition [get_pin U0/CP]
```

The following example sets the power derate to 0.5 for all power components on the default clock network power group.

```
pt_shell> set_power_derate 0.5 -groups clock_network
```

The following example sets a leakage power derating factor of 1.1 on all instances of library cell IV in the library MY_LIB:

```
pt_shell> set_power_derate -leakage 1.1 [get_lib_cells MY_LIB/IV]
```

Assuming that cell, "inv" is a particular instantiation of MY_LIB/IV in the design the following command overwrites the power derating factor for the instance "inv" only:

```
pt_shell> set_power_derate -leakage 1.05 [get_cells inv]
```

The following example illustrates how to set a power derating factor except leakage power on all cells (including sub-hierarchies) within the hierarchy top/H1:

```
pt_shell> set_power_derate -switching -internal 1.05 [get_cells top/H1]
```

```
pt_shell> set_power_derate -pin_switching 1.05 [get_pins
 add_1_root_add_27_2/U1_0/A]
```

---

set_power_profile_options

Sets the options for power profile generation.

Syntax

status *set_power_profile_options*

```
[-enable_time_based true | false]
[-interval nterval]
[-start_time event_start_time]
[-end_time end_time]
[-row row]
[-column column]
[-grid_size_x grid_size_x]
[-grid_size_y grid_size_y]
[-physical_hierarchy object_list]
[-count_toggle_by_total_power true | false]
```

Data Types

interval	float
start_time	float
end_time	float
row	integer
column	integer
grid_size_x	float
grid_size_y	float
physical_hierarchy	list

Arguments

`-enable_time_based`

Enables generating time based power profile. Default is false, which means a static power profile is generated. When this option is set to true, an Excel spreadsheet of format XLSX is used to generate time based power profile, where each sheet represents power profile from each time interval.

`-interval`

Specifies time interval for generation of time based power profile. Default interval is the dominant clock period of the current design.

`-start_time`

Specifies start time for time based power profile. Default is the start time of the FSDB file from which power profile is generated.

`-end_time`

Specifies end time for time based power profile. Default is the end time of the FSDB file from which power profile is generated.

`-row`

Specifies number of rows in the power profile. When the option *-physical_hierarchy* is not specified, the row specification is applied to the whole design. When the option *-physical_hierarchy* is specified, the row specification is applied to that physical hierarchy. This option cannot be use with the option *-grid_size_y*.

`-column`

Specifies number of columns in the power profile. When the option *-physical_hierarchy* is not specified, the column specification is applied to the whole design. When the option *-physical_hierarchy* is specified, the column specification is applied to that physical hierarchy. This option cannot be use with the option *-grid_size_x*.

`-grid_size_x`

Specifies grid size in X direction for power profile. When the option *-physical_hierarchy* is not specified, the grid size specification is applied to the whole design. When the option *-physical_hierarchy* is specified, the grid size specification is applied to that physical hierarchy. This option cannot be use with the option *-column*.

`-grid_size_y`

Specifies grid size in Y direction for power profile. When the option *-physical_hierarchy* is not specified, the grid size specification is applied to the whole design. When the option *-physical_hierarchy* is specified, the grid size specification is applied to that physical hierarchy. This option cannot be use with the option *-row*.

`-physical_hierarchy`

Specified a list of physical hierarchial cell objects such that the profile specification such as number of rows, columns, and grid size in X/Y direction is

applied to. When this option is omitted, the profile specification is applied to the whole design.

`-count_toggle_by_total_power`

Specifies whether to use total power with a predefined threshold to determine if a toggle occurs in the FSDB file. Default is true. When this option is set to false, toggle will be counted by value changes on internal power and switching power in the FSDB file.

Description

This command is used to specify options for the command *generate_power_profile*.

For power profile generation, user need to provide LEF/DEF files through the command *set_eco_options* with options *-physical_tech_lib_path -physical_lib_path -physical_design_path*.

For static power profile generation, static power analysis has be run first before invoking the command *generate_power_profile*.

Examples

The following example sets number of rows as 20, and number of columns as 10 for power profile generation.

```
pt_shell> update_power
pt_shell> set_eco_options -physical_tech_lib_path tech.lef
pt_shell> set_eco_options -physical_lib_path design.lef
pt_shell> set_eco_options -physical_design_path design.def
pt_shell> set_power_profile_options -row 20 -column 10
pt_shell> generate_power_profile power.csv
```

The following example enables time based power profile generation.

```
pt_shell> set_power_profile_options -enable_time_based true
pt_shell> generate_power_profile power.xlsx
```

The following example specifies different number of rows and columns between top level design and a physical block A.

```
pt_shell> set_power_profile_options -row 10 -column 10
 -physical_hierarchy A
pt_shell> set_power_profile_options -row 20 -column 20
pt_shell> generate_power_profile physical.csv
```

Feedback

set_power_scenario

Specify scenario name for power analysis.

Syntax

int *set_power_scenario*

```
        scenario_name
```

Data Types

scenario_name	string

Arguments

scenario_name

Specifies scenario for power analysis. PrimePower RTL will use operating condition of given scenario to choose proper reference libraries.

Description

The *set_power_scenario* command specifies scenario for power analysis purpose. For scenario for synthesis, it follows defined scenario in synth option setting.

Examples

The following example shows how to specify different scenario for power. In synth options, two scenarios are defined 'func.fast' and 'func.slow'. Current scenario in synth option is 'func.fast' but user want to use 'func.slow' for power analysis.

```
pwr_shell> set_power_scenario func.slow
```

Feedback

set_pprtl_flow_options

Specify PrimePower RTL flow options

Syntax

int *set_pprtl_flow_options*

```
[-ignore_version_checks]
[-enable_variable_restore]
[-disable_hard_errors]
[-reset]
```

Arguments

-ignore_version_checks

Specify this option to skip tool version compatibility checks when an existing workspace is reused.

-enable_variable_restore

Specify this option to restore the previous state variables when reusing a workspace. This option creates and saves the state of all app vars and user variables into the workspace in a separate file. When the workspace is reused, the tool restores the state variables files automatically.

-disable_hard_errors

This option is used to prevent the tool RTL from exiting on errors.

-reset

This option is used to clear all previous settings of the set_pprtl_flow_options command.

Description

The *set_pprtl_flow_options* command sets the options to configure the PrimePower RTL flow.

Examples

The following example automatically saves and restores a PrimePower RTL session.

```
pwr_shell> set_pprtl_flow_options -enable_variable_restore
```

```
The following example restores the session and ignore version checks.
```

```
pwr_shell> set_pprtl_flow_options -enable_variable_restore
 -ignore_version_checks
```

Feedback

```
The following example restores the session, ignore version checks and
 disables hard errors.

pwr_shell> set_pprtl_flow_options -enable_variable_restore
 -ignore_version_checks -disable_hard_errors

The following example clears all previous settings.

pwr_shell> set_pprtl_flow_options -reset
```

See Also

- compute_metrics

---

set_prepower_options

Specify PrimePower RTL commands to be executed before update_power

Syntax

int *set_prepower_options*

```
[-file file_name]
[-cmds cmd_list]
```

Data Types

```
file_name       string
cmd_list        list
```

Arguments

`-file file_name`

Specifies tcl file which contains tcl commands to be executed before update_power.

`-cmds cmd_list`

if number of tcl commands is small, specify commands directly instead of creating separate file.

Description

The *set_prepower_options* command pass PrimePower RTL tcl commands to be executed before update_timing/update_power. To set options for timing/power use this command.

Examples

The following example shows how to pass arbitrary command

Feedback

```
pwr_shell> set_prepower_options -cmds {
              set_propagated_net [get_net CLK]
           }
```

See Also

- compute_metrics
- set_rtl_activity_file

---

set_presynth_options

Specify RTL Architect commands to be executed before analyze/elaborate.

Syntax

int *set_presynth_options*

```
[-file file_name]
[-cmds cmd_list]
```

Data Types

```
file_name       string
cmd_list        list
```

Arguments

`-file file_name`

Specifies tcl file which contains tcl commands to be executed before analyze/elaborate.

`-cmds cmd_list`

if number of tcl commands is small, specify commands directly instead of creating separate file.

Description

The *set_presynth_options* command pass RTL Architect tcl commands to be executed before analyze/elaborate. To set options for analyze/elaborate, use this command.

Examples

The following example shows how to pass arbitrary command

```
pwr_shell> set_presynth_options -cmds {
              puts "*** before analyze ***"
           }
```

---

set_program_options

Sets options that affect the performance and capacity.

Syntax

status *set_program_options*

```
[-enable_high_capacity]
[-disable_high_capacity]
```

Arguments

`-enable_high_capacity`

Runs the tool in high capacity mode, which reduces the peak memory footprint.

`-disable_high_capacity`

Disables the high capacity mode of the program and returns to the default normal analysis mode, which usually increases the peak memory footprint.

Description

This command provides options that trade off performance and capacity without affecting the quality of the timing analysis results.

High Capacity Mode

In high capacity mode, the tool temporarily stores data to a local disk partition specified by the *pt_tmp_dir* variable; the default is the /tmp directory. When you exit the session, the consumed disk space is automatically released. For effective use of this mode, it is recommended that the capacity of the local disk on the host machine should be as large

Feedback

as the physical RAM. The potential capacity improvement might not be fully realizable in case of insufficient disk space.

Using high capacity mode does not change the timing analysis results. You can enable or disable high capacity mode only when there are no designs and libraries loaded in the program memory.

By default, high capacity mode is enabled. To see whether high capacity mode is enabled, check the setting of the *sh_high_capacity_enabled* read-only variable.

To specify the actual capacity improvement in high capacity mode, set the *sh_high_capacity_effort* variable.

Examples

The following command enables high capacity mode with the default settings:

```
pt_shell> set sh_high_capacity_effort high
Information: The setting will be effective after next
 'set_program_options' command. (PTHC-001)
high

pt_shell> set_program_options -enable_high_capacity
Information: enabling high capacity analysis in 'high' effort........
 (PTHC-001)
pt_shell> printvar sh_high_capacity_enabled
sh_high_capacity_enabled = "true"
```

See Also

- pt_tmp_dir
- sh_high_capacity_effort
- sh_high_capacity_enabled

---

set_propagated_clock

Specifies propagated clock latency.

Syntax

string *set_propagated_clock*

object_list

Data Types

object_list list

Feedback

Arguments

object_list

Specifies a list of clocks, ports, or pins.

Description

Specifies that delays be propagated through the clock network to determine latency at register clock pins. If it is not specified, ideal clocking is assumed. Ideal clocking means clock networks have a specified latency (designated by the *set_clock_latency* command), or zero latency, by default. Propagated clock latency is used for post-layout, after final clock tree generation. Ideal clock latency provides an estimate of the clock tree for pre-layout.

If the *set_propagated_clock* command is applied to pins or ports, it affects all register clock pins in the transitive fanout of the pins or ports. If it is applied to an object (clock, port, or pin) on which network latency is already defined, then a warning is issued.

Virtual clocks do not have any source, and they cannot affect any register in the design. Thus, virtual clocks cannot be made propagated, and an error is issued if the *set_propagated_clock* command is applied on a virtual clock.

To undo the *set_propagated_clock* command, use either the *remove_propagated_clock* or *set_clock_latency* command to provide an ideal latency.

To see propagated clock attributes on clocks, use the *report_clock* command.

Limitations: CRPR does not support propagated clocks set on pins or ports unless they are source pins or ports of common clock for a path. If the *timing_remove_clock_reconvergence_pessimism* variable is set to TRUE, then propagated clocks should be defined on clock objects, not pins or ports.

Examples

The following example specifies using propagated clock latency for all clocks in the design.

```
pt_shell> set_propagated_clock [all_clocks]
```

See Also

- timing_remove_clock_reconvergence_pessimism
- remove_propagated_clock
- report_clock
- set_clock_latency

Feedback

set_pulse_clock_max_transition

Sets the maximum transition for pulse generator input and pulse clock network with respect to the main library trip-points.

Syntax

string *set_pulse_clock_max_transition*

```
transition_value
[-rise]
[-fall]
[-transitive_fanout]
object_list
```

Data Types

transition_value	float
object_list	list

Arguments

`-rise`

Specifies rising transition for all selected pins.

`-fall`

Specifies falling transition for all selected pins.

`-transitive_fanout`

Specifies the constraint is set at the transitive fanout of pulse generator. If this option is not set, only the input of the pulse generators are constrained.

transition_value

Sets the transition limit (Value >= 0). This is the maximum transition time in main library time units.

object_list

Provides a list of pulse generator cell, pulse generator lib cell, clock and design.

Description

Specifies the maximum transition in the pulse clock network at the forward of pulse generator cell, pulse generator lib cell, clock and design if *-transitive_fanout* option is set. By default, the maximum transition constraint is set at the input of the pulse generator of the specified object list. If the cell or lib cell is not a pulse generator, or if the clock or design does not have any pulse generators, then this maximum transition limit has no effect. The pulse clock network or the input of pulse generator is expected to have transition time less than the specified the *transition_value* option.

The maximum transition constraint set on design by the *set_max_transition* command applies to the pulse clock network and input of pulse generator as also maximum transition constraint set on the pins in the library. Transition constraints are interpreted in main library trip-points and derate. During slack computation, the constraints are scaled to the pin trip-points and derate. In the case of conflicting constraints on a pin, the tightest constraint applies.

The maximum transition constraint can be optionally restricted to rising transitions only or falling transitions only by using the *-rise* or *-fall* options respectively. If the *-rise* or *-fall* options are not specified, both rise and falling transitions are constrained.

The *report_constraint -pulse_clock_max_transition* and *report_pulse_clock_max_transition* commands show the maximum transition constraint evaluations. The limit with appropriate scaling used for slack computation is reported.

To remove maximum pulse clock transition limits, use the *remove_pulse_clock_max_transition* command.

Examples

The following example sets a maximum transition limit of 0.4 units on input of all the cells corresponding to lib cell pulse_rise_high in library celllib.

```
pt_shell> set_pulse_clock_max_transition 0.4 {"celllib/pulse_rise_high"}
```

The following example sets a maximum transition limit of 0.4 units on all the pulse clock networks in the clock network clk.

```
pt_shell> set_pulse_clock_max_transition -transitive_fanout 0.4
 [get_clocks clk]
```

See Also

- current_design
- remove_pulse_clock_max_transition
- report_pulse_clock_max_transition
- report_constraint

---

set_pulse_clock_max_width

Sets the maximum pulse width constraint for pulse generator network.

Syntax

string *set_pulse_clock_max_width*

```
[-transitive_fanout]
pulse_width_value
object_list
```

Data Types

```
pulse_width_value       float
object_list             list
```

Arguments

`-transitive_fanout`

The constraints are applied to the transitive fanout of pulse generators. In this release, specifying or not specifying this option has the same behavior.

`pulse_width_value`

Sets the pulse width limit (Value >= 0).

`object_list`

Provides a list of pulse generator cell, pulse generator lib cell, clock and design.

Description

Specifies the maximum pulse width limit for the pulse clock network at the forward of pulse generator cell by pulse generator instance name or pulse generator library cell. Setting the pulse width constraint by clock applies the constraint to the forward of all pulse generators driven by the clock. Setting by pulse width constraint by design applies the constraint to all the pulse clock networks in the design. In the presence of a conflicting constraint, the most restrictive constraint is used. If the cell or lib cell is not a pulse generator, or clock or design does not have any pulse generators, then this maximum width limit has no effect. The pulse clock network is expected to have pulse width time less than the specified *pulse_width_value* option.

The high or low pulse width constraint is inferred based on sense propagation. For example, after an inverter, a high pulse width constraint is converted to a low pulse width constraint.

The *report_constraint -pulse_clock_max_width* and *report_pulse_clock_max_width* commands show maximum pulse width constraint evaluations.

To remove maximum pulse width limits, use the *remove_pulse_clock_max_width* command.

Examples

The following example sets a maximum pulse width limit of 0.4 units on all the pulse clock networks in the design.

```
pt_shell> set_pulse_clock_max_width 0.4 [current_design]
```

Feedback

---

set_pulse_clock_min_transition

Sets the minimum transition at the input of pulse generator with respect to the main library trip-points.

Syntax

string *set_pulse_clock_min_transition*

```
transition_value
[-rise]
[-fall]
object_list
```

Data Types

transition_value	float
object_list	list

Arguments

`-rise`

Specifies rising transition for all selected pins.

`-fall`

Specifies falling transition for all selected pins.

transition_value

Sets the transition limit (Value >= 0). This is the minimum transition time in main library time units.

object_list

Provides a list of pulse generator cell, pulse generator lib cell, clock and design.

Description

Specifies the minimum transition at the input of pulse generator cell and pulse generator lib cell. If the constraint is specified on the clock and design, all the inputs of pulse generators in the clock network and design respectively are constrained. If the cell or lib

cell is not a pulse generator or clock or design does not have any pulse generators, then minimum pulse clock transition limit has no effect. The input of pulse generator is expected to have transition time greater than the specified *transition_value* option.

Transition constraints are interpreted in main library trip-points and derate. During slack computation, the constraints are scaled to the pin trip-points and derate. In the case of conflicting constraints on a pin, the tightest constraint applies.

The minimum transition constraint can be optionally restricted to rising transitions only or falling transitions only by using the *-rise* or *-fall* options, respectively. If the *-rise* or *-fall* options are not specified, both rise and falling transitions are constrained.

The *report_constraint -pulse_clock_min_transition* and *report_pulse_clock_min_transition* commands show minimum transition constraint evaluations. The constraint with appropriate scaling used for slack computation is reported.

To remove minimum pulse clock transition limits, use the *remove_pulse_clock_min_transition* command.

Examples

The following example sets a minimum transition limit of 0.4 units on input of all the cells corresponding to lib cell pulse_rise_high in library celllib.

```
pt_shell> set_pulse_clock_min_transition 0.4 {"celllib/pulse_rise_high"}
```

See Also

- current_design
- remove_pulse_clock_min_transition
- report_pulse_clock_min_transition
- report_constraint

---

set_pulse_clock_min_width

Sets minimum pulse width constraint for pulse generator network.

Syntax

string *set_pulse_clock_min_width*

```
pulse_width_value
[-transitive_fanout]
object_list
```

Feedback

Data Types

pulse_width_value	float
object_list	list

Arguments

`-transitive_fanout`

The constraints are applied to the transitive fanout of pulse generators. In this release, specifying or not specifying this option has the same behavior.

pulse_width_value

Sets the pulse width limit (Value >= 0).

object_list

Provides a list of pulse generator cell, pulse generator lib cell, clock and design.

Description

Specifies the minimum pulse width limit for the pulse clock network at the forward of pulse generator cell by pulse generator instance name or pulse generator library cell. Setting the pulse width constraint by clock applies the constraint to the forward of all pulse generators driven by the clock. Setting by pulse width constraint by design applies the constraint to all the pulse clock networks in the design. Minimum pulse width constraint from the library also applies to the pulse clock network. In the presence of a conflicting constraint, the most restrictive constraint is used. If the cell or lib cell is not a pulse generator or clock or design does not have any pulse generators, then this minimum width limit has no effect. The pulse clock network at the forward of pulse generator is expected to have width more than the specified *pulse_width_value* option.

The high or low pulse width constraint is inferred based on sense propagation. For example, after an inverter, a high pulse width constraint is a low pulse width constraint.

The *report_constraint -pulse_clock_min_width* and *report_pulse_clock_min_width* commands show minimum pulse width constraint evaluations.

To remove minimum pulse width limits, use the *remove_pulse_clock_min_width* command.

Examples

The following example sets a minimum pulse width limit of 0.4 units on all the pulse clock networks in the clock network clk:

```
pt_shell> set_pulse_clock_min_width 0.4 [get_clocks clk]
```

Feedback

---

set_pvt_explorer_condition

Sets PVT explorer condition for PrimeShield PVT Variation Exploration what-if analysis.

Syntax

string *set_pvt_explorer_condition*

```
        input_file
```

Data Types

input_file string

Arguments

input_file

Specifies the PVT Explorer condition input file.

Description

The *set_pvt_explorer_condition* command set PVT explorer condition, which is used in PrimeShield Power, voltage, and temperature (PVT) parameter variation and exploration.

define_sensitivity_lib_mapping is required in the feature. And *set ps_enable_pvt_explorer_analysis true* is required to use *set_pvt_explorer_condition* command.

Examples

The following script enables Power, performance, area (PPA) what-if analysis, which enables you to change the design PVT parameters and quickly assess their PPA impact. It allows process sweet-spot exploration and technology option assessment.

"one_cond.txt" file content as follows:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15

The timing and power analysis results after *set_pvt_explorer_condition* will reflect the physical parameter shift defined in "one_cond.txt".

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode false
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]

set_pvt_explorer_condition one_cond.txt
update_timing -full
update_power
```

You must change the "one_cond.txt" file content to include the device model names and values, based on your PDK or side file. The "one_cond.txt" file includes the delta shift values. In the preceding example, the vt shift provided is +20mV and the idsat shift provided is +15%, from their respective nominal values. For SPICE correlation, the actual value, that is, the nominal value plus the delta value, must be specified with the *-sim_option* option. In the above example, it will be like following: *sim_setup_simulator -sim_option ".param pmos_lvt_vt=0.020 nmos_lvt_vt=0.020 pmos_lvt_ids0=1.15 nmos_lvt_ids0=1.15"*

Timing robustness what-if analysis enables you to perform path-based timing analysis with multiple what-if specifications. It allows you to identify paths susceptible to PVT changes, o provide ECO guidance to improve the design robustness.
The following script enables what-if analysis for timing path robustness, where "multiple_DoEs.txt" file content as follows to cover multiple what-if specifications:
#index,pmos_lvt_vt,nmos_lvt_vt,pmos_lvt_ids0,nmos_lvt_ids0 1,0.020,0.020,0.15,0.15 2,0.011,0.011,0.10,0.10

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_pvt_explorer_analysis true
set ps_pvt_explorer_pba_only_mode true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
update_timing -full  # baseline QoR
set paths [get_timing_paths ...]

set_pvt_explorer_condition multiple_DoEs.txt
#update original path collection with slack shift per DoE
set paths_new [get_timing_paths -pba_mode path $paths]
#generate slack shift per DoE for all paths
puts [get_attr $paths_mew pvt_explorer_slack_shift]
```

The slack of paths in paths_new collection will be the worst among all what-if specifications, and attribute *pvt_explorer_slack_shift* is a list of float for per specification slack shift.

---

set_qtm_attribute

Sets an attribute to the specified value on QTM object(s).

Syntax

string *set_qtm_attribute*

```
-class class_name
attr_name
value
[object_names]
```

Data Types

class_name	string
attr_name	string
value	string
object_names	list

Arguments

-class class_name

Specifies the class of the QTM objects to set attribute on. Allowed values are *lib*, *lib_cell*, or *lib_pin*.

attr_name

Specifies the name of the attribute.

value

Specifies the value of the attribute.

object_names

Specifies the names of the objects on which to set the attribute. Each element in the list is a name to identify an object in the specified class. The object names

should not be specified when the object class is either a *lib* or *lib_cell* value. It must be specified when the class is a *lib_pin* value, in which case the object names should be the names of ports already defined for the QTM.

Description

The *set_qtm_attribute* command sets attributes on objects. These attributes are either application attributes that are reserved by PrimeTime or defined with the *define_qtm_attribute* command as the user attributes. Please note the order of the command arguments. Also note that PrimeTime the *list_attribute*, *report_attribute*, and *get_attribute* commands do not work on attributes defined or set on the QTM objects.

Examples

The following example defines a Boolean attribute 'is_XYZ' for QTM cell, then sets the value on the QTM cell under construction.

```
pt_shell> define_qtm_attribute -type boolean -class lib_cell "is_XYZ"
pt_shell> set_qtm_attribute -class lib_cell "is_XYZ" "true"
```

The following example sets the attribute 'max_transition' for 2 QTM ports. Because 'max_transition' is an application reserved attribute for the object class 'lib_pin', it should be set directly.

```
pt_shell> set_qtm_attribute -class lib_pin "max_transition" 1.0 {IN, CLK}
```

See Also

- define_qtm_attribute

---

set_qtm_global_parameter

Sets a global parameter for a quick timing model.

Syntax

string *set_qtm_global_parameter*

```
[-param setup | hold | recovery |removal | clk_to_output]
[-lib_cell lib_cell]
[-pin pin_name]
[-clock pin_name]
[-value parameter_value]
```

Data Types

```
lib_cell              string
pin_name              string
parameter_value       float
```

Arguments

`-param setup | hold | recovery |removal | clk_to_output`

Sets one of the following global parameters: *setup*, *hold*, *recovery*, *removal* or *clk_to_output*.

`-lib_cell` *lib_cell*

Specifies the library cell that you want to use to mimic the global parameter.

`-pin` *pin_name*

Specifies the related pin for the global parameter if you are using the *-lib_cell* option to mimic the behavior. If the parameter is *setup* or *hold*, this pin must be an input pin. If the parameter is *clk_to_output*, this pin must be an output pin. If you do not use this option, the quick timing model uses the first encountered input pin that is constrained, in the case of the *setup* or *hold* parameter; and the first output pin that has an edge delay arc coming into it, in the case of the *clk_to_output* parameter.

`-clock` *pin_name*

Specifies the constraining pin in the case of *setup* or *hold*; and the launch pin in the case of *clk_to_output* parameter.

`-value` *parameter_value*

The value of the global parameter in time units.

Description

This command sets the value of a quick timing model (QTM) global parameter. The global parameter can be either *setup*, *hold*, , *recovery*, *removal* or *clk_to_output*. These parameters specify the global parameter which is added to the arcs. To the QTM setup/hold/recovery/removal arc, the time is added to arrive at the final delay. To the QTM edge triggered delay arc the global clk_to_output time is added to arrive at the final delay.

You can specify the global parameters of the sequential element by specifying a cell in the library (the *-lib_cell* option), or by giving the actual value, by using the *-value* option. If the *-lib_cell* option is specified, you can specify the clock pin and the input pin name. If you do not specify one, the first setup, hold, or clk_to_output arc encountered is chosen (based on which parameter is being set). If only the *-clock* option is specified, the first setup, hold, or clk_to_output arc (depending on the global parameter) from that clock pin is chosen. If only the *-pin* option is specified, the first setup, hold, or clk_to_output arc (depending on the type of global parameter) coming into the pin is chosen.

Feedback

To report information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

In the following examples, before using the *-lib_cell* option, you must load the technology library and set the QTM technology. To do this, use the following sequence of commands:

```
read_db my_technology_library.db
set_qtm_technology -library my_technology_library
```

The following example sets the global setup time equivalent to the setup time of library cell DFF1:

```
pt_shell> set_qtm_global_parameter -param setup -lib_cell DFF1
```

The following example sets the global hold time equivalent to the setup time of pin D of library cell DFF1:

```
pt_shell> set_qtm_global_parameter -param setup -lib_cell DFF1 -pin D
```

The following example sets the global clk_to_out time to be 1.5 time units:

```
pt_shell> set_qtm_global_parameter -param clk_to_output -value 1.5
```

---

set_qtm_port_drive

Sets the drive on the quick timing model port.

Syntax

string *set_qtm_port_drive*

```
[-type drive_type]
[-value drive_value]
[-input_transition_rise rtrans]
[-input_transition_fall ftrans]
[-subtract_max_delay_from_total]
port_list
```

Data Types

drive_type	string
drive_value	float
rtrans	float
ftrans	float
port_list	list

Arguments

`-type` *drive_type*

Specifies the global *drive_type* parameter.

`-value` *drive_value*

Specifies the drive value in terms of drive resistance units.

port_list

Specifies a list of input or inout ports on which to set the attribute. Each element in the list is either a collection of quick timing model ports or a pattern that matches quick timing model ports.

`-input_transition_rise` *rtrans*

Specifies the input rising transition time associated with the *-input_pin* option of the specified drive type to compute the delay for the drive arc for this port. If you do not use this option, the delay table for rising input of the drive arc is loaded from library as is.

Use the *-input_transition_rise* and *-input_transition_fall* options to capture the transition time associated with the *-input_pin* option defined for the drive type referred. This can obtain more accurate information on the transition time and delay time for the drive arc defined for this port.

`-input_transition_fall` *ftrans*

Specifies the input falling transition time associated with the *-input_pin* option of the specified drive type to compute the delay for the drive arc for this port. If you do not use this option, the delay table for falling input of the drive arc is loaded from library as is.

Feedback

`-subtract_max_delay_from_total`

Indicates that the drive arc delay computed with max load is subtracted from the total delay budgeted to this output port. This affects all types of delay arcs that reach this output port. By default, the drive arc delay is added on top of the quick timing model delay arcs created to the output port and therefore increase the actual delay.

Description

This command sets the drive of the output port of the quick timing model. There are two methods for setting the drive:

- Use one of the global *drive_type* parameters, if you have drive types defined.
- Define the drive in terms of the drive resistance units.

When drive is defined for an output port, by default, the actual delay to the output port is the delay arc defined by the *create_qtm_delay_arc* command for the port plus the delay computed for this drive arc. If in your QTM creation, the delay defined by the *create_qtm_delay_arc* command for the port is actually the maximum delay budgeted for the output and you do not want the drive arc to add extra delay on top of that budget, you can optionally use the *-subtract_max_delay_from_total* option to keep the delay with maximum load at port unchanged. But with smaller load at the output port, the delay might actually be smaller than the budgeted maximum delay.

To define drive types, use the *create_qtm_drive_type* command.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following command sets the drive of the OUT1 output port to be the drive1 drive type.

```
pt_shell> set_qtm_port_drive -type drive 1 OUT1
```

The following command sets the drive of the OUT2 output port to be 5 drive units.

```
pt_shell> set_qtm_port_drive -value 5.0 OUT2
```

See Also

- create_qtm_load_type
- create_qtm_model
- report_qtm_model
- save_qtm_model

set_qtm_port_load

Sets the load on quick timing model (QTM) ports.

Syntax

string *set_qtm_port_load*

```
[-type load_type]
[-factor multiplication_factor]
[-value load_value]
port_list
```

Data Types

load_type	string
multiplication_factor	float
load_value	float
port_list	list

Arguments

`-type load_type`

Specifies the global *load_type* parameter.

`-factor multiplication_factor`

Specifies the multiplication factor for the load type to set the load on the quick timing model port.

`-value load_value`

Specifies the load value in the capacitance units.

port_list

Specifies a list of input or inout ports on which to set the attribute. Each element in the list is either a collection of quick timing model ports or a pattern that matches quick timing model ports.

Feedback

Description

This command sets the load of the input port of the quick timing model. There are two methods for setting the load:

- Use the global *load_type* parameter along with a multiplication factor if you have load types defined.
- Define the load in terms of the capacitance units.

To define load types, use the *create_qtm_load_type* command.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following command sets the load on IN1 to be 2 times the global *load_type* load1.

```
pt_shell> set_qtm_port_load -type load1 -factor 2 IN1
```

The following command sets the load on IN2 to be 4.5 capacitance units.

```
pt_shell> set_qtm_port_load -value 4.5 IN2
```

See Also

- create_qtm_load_type
- create_qtm_model
- get_qtm_ports
- report_qtm_model
- save_qtm_model
- set_qtm_port_drive

---

set_qtm_technology

Sets the quick timing model (QTM) technology variables.

Syntax

string *set_qtm_technology*

```
[-library name]
[-max_transition trans_value]
[-min_transition trans_value]
```

```
[-max_capacitance cap_value]
[-min_capacitance cap_value]
[-wire_load_model wlm_name]
[-operating_condition opcond_name]
[-process process_value]
[-voltage voltage_value]
[-temperature temperature_value]
```

Data Types

```
name              string
trans_value       float
cap_value         float
wlm_name          string
opcond_name       string
process_value     float
voltage_value     float
temperature_value   float
```

Arguments

`-library name`

Specifies the library name for using library elements to define global parameters.

`-max_transition trans_value`

Specifies the maximum transition value.

`-min_transition trans_value`

Specifies the minimum transition value.

`-max_capacitance cap_value`

Specifies the maximum capacitance value.

`-min_capacitance cap_value`

Specifies the minimum capacitance value.

`-wire_load_model wlm_name`

Specifies the wire load model used while calculating delays.

`-operating_condition opcond_name`

Specifies the default operating condition name for the quick timing model in a multicorner, multimode (MCMM) design. Must be specified together with *-process*, *-voltage*, and *-temperature*.

`-process process_value`

Specifies the process scaling factor for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the

following options, you must use all of them: *-operating_condition*, *-process*, *-voltage*, and *-temperature*. Allowed values are 0.0 through 100.0.

`-voltage` *`voltage_value`*

Specifies the voltage value, in Volts, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: *-operating_condition*, *-process*, *-voltage*, and *-temperature*.

`-temperature` *`temperature_value`*

Specifies the temperature value, in degrees Celsius, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: *-operating_condition*, *-process*, *-voltage*, and *-temperature*.

Description

This command sets the various quick timing model technology parameters. Use the *-library* option if you use library cells to define path_types, drive_types, load_types, or if you set the other global parameters in terms of library cells. Before setting the library, you must ensure that the library is loaded.

If you use the *-wire_load_model* option, the path_type delays are calculated using the information. You can use the *-operating_condition* option to specify the default operating condition name for the quick timing model in a multicorner, multimode (MCMM) design. It must be specified together with *-process*, *-voltage*, and *-temperature* options.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following example sets the library to my_lib, which is in the my_lib.db file.

```
pt_shell> read_db my_lib.db
pt_shell> set_qtm_technology -library my_lib
```

The following command sets the *-wire_load_model* option to wlm1.

```
pt_shell> set_qtm_technology -wire_load_model wlm1
```

See Also

- create_qtm_model
- report_qtm_model

Feedback

set_query_rules

Defines rules for rule-based query in golden UPF mode. In non-golden UPF mode, this command is ignored.

Syntax

status *set_query_rules*

```
[-hierarchical_separators separator_list]
[-bus_name_notations bus_name_list]
[-class class_list]
[-regsub regsub_list]
[-regsub_cumulative]
[-wildcard]
[-suffix suffix_list]
[-verbose]
[-nocase]
[-reset]
```

Data Types

separator_list	list
bus_name_list	list
class_list	list
regsub_list	list
suffix_list	list

Arguments

`-hierarchical_separators` *separator_list*

Specifies a list of equivalent hierarchy separators in object names. There must be at least two elements in the list. The default list is {/ _ .}. The elements are preferably all single character, although at most one multicharacter element is allowed. No more than one alphabetical character, a-z or A-Z, is allowed as a hierarchical separator. The single alphabetical character element is also mutually exclusive with the multicharacter element. The following special characters are not supported as hierarchy separators nor they are allowed as one of the characters for the multicharacter hierarchy separator: 0-9, *, ?, \, +, ^, [,], (,), <, >, and {, }.

`-bus_name_notations` *bus_name_list*

Specifies a list of equivalent bus name notations in object names. There must be at least two elements in the list, and the list element must be of two characters exactly. The first character of the element is the opening bus name character, and the second character is the closing bus name character. The default list is {[] __ ()}. No more than one matching pair of alphabetical characters a-z or A-Z is allowed as bus name notations. The following characters are not supported as opening or closing bus name characters: 0-9, *, ?, \\, +, ^, and /. Bracketed

bus notations must be paired. For example, "[)" are not properly paired brackets, therefore it is not supported. For non-bracket bus name notations, the opening and closing bus name character must be the same. For example, "-_" is not a supported bus name notation.

`-class` *`class_list`*

Specifies a list of object class names for which the query rules are applied. Object classes cell, port, pin, net, power_domain, supply_net, supply_set, supply_port and power_switch are supported. The default is to enable all of them, however you could specify a subset of them.

`-regsub` *`regsub_list`*

Specifies a list of options for the *regsub* Tcl command. Each list should include three string elements: {{*options*} {*match_regexp*} {*substitution_exp*}}. Query uses the *-regsub* option to evaluate the object name and pattern strings during the matching process.

The *-regsub* option can be specified multiple times in one *set_query_rules* command. When multiple *-regsub* options are used, the *-regsub* options are applied to the leaf object name and pattern in the order you specify.

The *-regsub* options applies only to pin, port, net, and leaf cells. If *-regsub* is used without other query rules, the default values for the other options are still used. To save runtime, use this option only if the existing rule-based matching scheme fails to match an object.

In addition to the Tcl built-in options for the command *regsub*, the following options are supported:

- *-class* specifies a single object class name such as cell, port pin or net. The *-class* option makes the *-regsub* query rule object specific. Object class specific *-regsub* rule is the preferred to legacy global *-regsub* rule. The latter has been deprecated. For backward compatibility purposes, the global *-regsub* query rule is automatically converted to the class specific rules for port, pin and net, but not for cell class.
- *-cumulative* specifies that the multiple *-regsub* rules for the same object class are executed with cumulative effect in the sense that the subsequent *-regsub* rule is applied to the outputs of the object name and pattern string from the previous *-regsub* rules. After this option is used for an object class in one *-regsub*, all *-regsub* rules for that object class have the cumulative option.

`-regsub_cumulative`

Although this legacy option is supported, you should use *-regsub -cumulative* instead. If you use the *-regsub_cumulative* option, the tool automatically

converts to the class-specific *-cumulative* option for port, pin, and net, but not for cell class.

`-wildcard`

Enables wildcard support in rule-based match. Be cautious with this option because this option can end up matching more objects after ungroup and change_names.

`-suffix` *`suffix_list`*

Enables suffix name rule. Only the predefined suffix *_reg* and *_tri* are supported. Suffix *_reg* is only applicable to register cells. When enabled, a cell name pattern such as U4 would match the U4_reg register cell. Suffix *_tri* is only applicable to tristate cells. When enabled, a cell name pattern such as U8 would match the U8_tri tristate cell object.

`-verbose`

Prints messages indicating the object is matched using query rules.

`-nocase`

Enables case-insensitive rule-based match. This is the preferred way of enabling case-insensitive rule-based match.

`-reset`

Resets query rules to the program default.

Description

The *set_query_rules* defines query rules to guide the object queries in golden UPF mode. The purpose of the rule-based matching is to resolve the naming differences caused by altering names in Design Compiler and IC Compiler. The hierarchy separators and bus names are typical sources of the naming differences.

When a list of characters is defined as equivalent in terms of hierarchy separator, the object query uses the equivalence when matching the objects in the in-memory netlist. For example, if the list {/ _ .} is defined as equivalent hierarchy separators, the cell named "a.b_c/d_e" is matched with name string "a/b_c.d/e" provided in the golden UPF files.

When a list of bus notations is defined as equivalent in terms of bus names, the object query uses the equivalence when matching the objects in the in-memory netlist. For example, if the list {[] __} is defined as equivalent bus notations, the cell named "a[4][5]" is matched with the name string "a_4__5_" provided in the golden UPF files.

When the *-regsub* rules are specified, Tcl *regsub* command applies the rules to both the object name and the pattern string for rule-based matching if the other rule-based matching scheme fails to match an object.

Feedback

Be very cautious about enabling wildcard support in rule-based match, because the greedy nature of the wildcard match could often give you more matches than you want.

Use the *-reset* option to reset the query rules to the program default. Use *-show* to report the current query rules. When *-show* is used with other options, the new rules are set first and then reported.

The *-nocase* option of command *set_query_rules* is the preferred way of enabling case-insensitive rule-based matching, although global variable *find_ignore_case* variable is honored. For runtime reasons, avoid using the *-nocase* option in query commands such as *get_cells* or *get_pins*.

The *set_query_rules* command can be issued multiple times. Unless the *-show* option is used alone, the new rules always overwrite the previous rule settings.

Be cautious when defining query rules. To save runtime, do not use unnecessary query rules.

The *set_query_rules* command is effective only in golden UPF mode. Runtime for rule-based matching could be much slower.

Examples

```
# Show program default
prompt> set_query_rules -show

---

set_rail_voltage

Sets power rail voltage on cells.

Syntax

int *set_rail_voltage*

```
[-rail_value rvalue]
[-rail_list rname_value_list]
[-min]
[-max]
[-dynamic_rail_value dynamic_component]
[-dynamic_rail_list name_value_list]
cell_list
```

Data Types

rvalue	float
rname_value_list	list
dynamic_component	float
name_value_list	list
cell_list	list

Arguments

`-rail_value` *rvalue*

Sets voltage on single-rail cells. If you use this option, you cannot use the *-rail_list* option because these options are mutually exclusive. Replace *rvalue* with a decimal or an integer value.

`-rail_list` *rname_value_list*

Sets voltages on individual rails of multirail cells. Replace *rname_value_list* with a list, which must have even number of elements. Odd elements are names of rails; even elements are voltage values.

The rail names must match the definitions of rails in the library power_supply section and in the library operating conditions. If you use this option, you cannot use the *-rail_value* option because these options are mutually exclusive.

`-min`

Sets rail voltages for the minimum operating condition. If you do not specify either the *-min* or *-max* option, the tool assumes you are using both the *-min* and *-max* options.

`-max`

Sets rail voltages for the maximum operating condition. If you do not specify either the *-min* or *-max* option, the tool assumes you are using both the *-min* and *-max* options.

`-dynamic_rail_value` *dynamic_component*

Specifies what portion of *rvalue* is dynamic. You can only specify this option if the *-rail_value* option is specified. If you attempt to specify this option with the *-rail_list* option, an error message is issued.

`-dynamic_rail_list` *`name_value_list`*

Specifies the dynamic portion of each rail voltage listed with the *-rail_list* option. The list of dynamic component values must match the entries in the *rname_value_list*.

`cell_list`

Specifies a list of cells on which to set rail voltages. Replace *cell_list* with the collection of cells you want.

Description

Sets power rail voltage on cells. This command overrides voltages specified in operating conditions. It can be applied to both leaf cells and hierarchical blocks. If used on hierarchical cells, all cells in the block must come from the same library, unless another *set_rail_voltage* or *set_operating_conditions* command has been set on them.

It should be noted that since *-min* and *-max* refer to operating conditions, the *-max* voltage is typically lower than the *-min* voltage.

The voltages are passed to delay equations in the library. Ground rail voltages cannot be changed; the tool assumes zero voltage.

In a typical multi-voltage flow you can set operating conditions on hierarchical blocks corresponding to voltage islands. You can then use a power network analysis tool to calculate the IR drop in power networks; subtract power and ground voltages on cells; and, by using the *set_rail_voltage* command, annotate them on important leaf cells or blocks.

The *-dynamic_rail_value* or *-dynamic_rail_list* option can be used to specify the dynamic component of IR drop. In this case, the *-rail_value* or *-rail_list* option can be used to specify the total voltage on a cell and the dynamic options can specify what portion of that voltage is dynamic.

Care should be taken when specifying the dynamic component of the rail voltage for the max operating condition. In this case, the dynamic component should be negative. This ensures that the static component of rail voltage is not less than the total minimum rail voltage (corresponding to max operating condition).

If Clock Reconvergence Pessimism Removal (CRPR) is enabled and dynamic rail voltages are specified, the Dynamic CRPR mode is turned on. In this mode only CRPR is computed using clock totals considering the dynamic component of rail voltage if the path is zero-cycle. A zero-cycle path is one in which the same clock edge both launches and captures.

Note that the operating condition (or rail voltage) that is set on the lower levels of the hierarchy (or leaf cell) overrides the operating condition (or rail voltage) on the higher levels of hierarchy.

Feedback

Examples

The following example sets the operating conditions named *OC1* and *OC2* on the block named *h1* and then overrides the voltage on the cell named *u3* in *h1*.

```
pt_shell> set_operating_conditions -min OC1 -max OC2 \\
     -object_list [get_cells {h1}]
1

pt_shell> set_rail_voltage -min -rail_value 1.4 [get_cells {h1/u3}]
1

pt_shell> set_rail_voltage -max -rail_value 1.1 [get_cells {h1/u3}]
1
```

To specify a dynamic component of 0.2 for the example above, you should use the following commands (Note the negative value for the max operating condition):

```
pt_shell> set_rail_voltage -min -rail_value 1.4 -dynamic_rail_value 0.2
 [get_cells {h1/u3}]
1

pt_shell> set_rail_voltage -max -rail_value 1.1 -dynamic_rail_value -0.2
 [get_cells {h1/u3}]
1
```

See Also

- remove_rail_voltage
- set_operating_conditions

---

set_related_supply_net

Associates an external supply net to the port of the design.

Syntax

status *set_related_supply_net*

```
[-object_list ports]
[-ground ground_net]
[-power power_net]
[-reset]
[power_net]
```

Data Types

ports	list
ground_net	string
power_net	string

Feedback

Arguments

`-object_list` *`ports`*

Specifies the list of ports (pins) to be associated with power/ground nets or that must be reset. If this option is not specified, all the ports are considered.

`-ground` *`ground_net`*

Specifies the ground net.

`-power` *`power_net`*

Specifies the power net.

`-reset`

Resets the related power and ground nets of the ports specified with the *-object_list* option. This cannot be used in conjunction with either the *-power* or *-ground* option.

`power_net`

Specifies the power net. This is deprecated and supported for backward compatibility only. New scripts should specify the power net using the *-power* option.

Description

This command is used to associate supply nets with design ports. The tool uses this information for constraining and checking design. The level shifter insertion tool also uses supply nets to determine if level shifter is required between a port and the logic connected to the port.

Setting related supply nets on pins is used for level shifter insertion in synthesis and design optimization tools. PrimeTime accepts pins in *-object_list* but does not use such information for its analysis.

If this command is not specified, the tool assumes that ports are externally connected to the primary supply net of the domain of the top design.

Examples

The following example sets the *VDD_EXT* power net and *VSS_EXT* ground net with *INPUT* port.

```
pt_shell> set_related_supply_net -object_list \\
[get_ports INPUT] -power VDD_EXT -ground VSS_EXT
```

This example resets the power net and ground net on all ports.

```
pt_shell> set_related_supply_net -reset
```

Feedback

See Also

- create_supply_net
- get_supply_nets
- get_ports

---

set_resistance

Sets the *ba_net_resistance* attribute with a resistance value on specified nets.

Syntax

int *set_resistance*

```
[-min]
[-max]
resistance_value
object_list
```

Data Types

```
resistance_value     float
object_list          list
```

Arguments

`-min`

Applies only for designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* option is the minimum resistance.

`-max`

Applies only for designs in min-max mode (min and max operating conditions). Indicates that the *resistance_value* option is the maximum resistance.

`resistance_value`

Specifies the resistance value for nets in the *object_list* option in units consistent with those used by the technology library.

`object_list`

A list of nets on which the *resistance_value* option is set.

Description

Sets the *ba_net_resistance* attribute, which specifies the back-annotation of resistance values on nets in the current design. If the current design is hierarchical, you must link it using the *link* command. The specified *resistance_value* option overrides the

Feedback

internally estimated net resistance value and also overrides any net resistance set by the *read_parasitics* command.

You can also use the *set_resistance* command for nets at lower levels of the design hierarchy. You can specify these nets as "BLOCK1/BLOCK2/NET_NAME".

To view resistance values, use the *report_net* command.

To remove a resistance value, use the *remove_resistance* command. To reset all back-annotated resistance values in a design, use the *reset_design* command.

Examples

The following example sets a resistance of 200 units to nets "a" and "b."

```
pt_shell> set_resistance 200 {a,b}
```

In the following example, a resistance of 300 units is set on net "U1/U2/NET3."

```
pt_shell> set_resistance 300 U1/U2/NET3
```

In the following example, the back-annotated resistance on net "U1/U2/NET3" is removed.

```
pt_shell> remove_resistance {get_nets U1/U2/NET3}
```

---

set_retention

Defines the UPF retention strategy for the power domains in the design.

Syntax

```
status set_retention
   -domain domain_name
   [-no_retention]
   [-retention_power_net supply_net_name]
   [-retention_ground_net supply_net_name]
```

Feedback

```
[-retention_supply_set supply_set_name]
[-save_signal save_signal_and_save_sense]
[-restore_signal restore_signal_and_restore_sense]
[-elements object_list]
retention_name
```

Data Types

```
domain_name                 string
supply_net_name             string
supply_set_name             string
save_signal_and_save_sense    string
restore_signal_and_restore_sense     string
object_list                 list
retention_name              string
```

Arguments

`-domain` *domain_name*

Specifies the power domain name that this UPF retention strategy is applied to.

`-no_retention`

Specifies that the specified objects in the power domain does not have retention.

`-retention_power_net` *supply_net_name*

Specifies the retention power net for the retention cells that are under this UPF retention strategy.

`-retention_ground_net` *supply_net_name*

Specifies the retention ground net for the retention cells that are under this UPF retention strategy.

`-retention_supply_set` *supply_set_name*

Specifies the supply set whose power and ground function associations need to be used as the retention power and retention ground nets respectively. This argument is mutually exclusive with *-retention_power_net* and *-retention_ground_net*.

`-save_signal` *save_signal_and_save_sense*

Specifies the save signal net and the save signal sense for the retention cells under this retention strategy. Use the following syntax: {*save_signal* high|low}.

`-restore_signal` *restore_signal_and_restore_sense*

Specifies the restore signal net and the restore sense for the retention cells under this retention strategy. Use the following syntax: {*restore_signal* high|low}.

`-elements object_list`

Specifies the objects to which this UPF retention strategy is applied. The objects can be hierarchical cells, leaf cells, hdl blocks, nets.

retention_name

Specifies the UPF retention strategy name. The retention strategy name should be unique within the specified power domain.

Description

This command defines the UPF retention strategy on the specified power domain under which to map the unmapped sequential cells to retention cells.

PrimeTime uses the *set_retention* command to build virtual power ground connectivity. The command creates explicit connection for retention(backup) power and ground nets to power and ground pins of retention cells. The *-no_retention* option on specific elements takes precedence over domain-wide strategy.

If the *-elements* option is not specified, the retention strategy is applied to all of the unmapped sequential cells under the power domain. If the *-elements* option is specified, the UPF retention strategy is applied to all the unmapped sequential cells that are under the objects from *-elements*.

If neither the *-retention_supply_set* argument nor *-retention_power_net/-retention_ground_net* is specified, the retention power and ground nets are automatically set to the power and ground functions of the *default_retention* supply set handle of the power domain, for which the strategy is being defined.

For a list of UPF commands, use this command:

```
prompt>  help upf
```

Examples

The following example shows how to define a UPF retention strategy in the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_retention retention_1 -domain PD1 \\
          -retention_power_net PN1 \\
          -retention_ground_net GN1 \\
```

In the following example, it shows how to define a UPF retention strategy in the objects under the specified power domain.

```
prompt> set_retention retention_2 -domain PD1 \\
        -retention_power_net PN1 \\
        -retention_ground_net GN1 \\
        -elements shutdowm_inst/mid_inst \\
```

The following example shows how to define a UPF retention strategy using a supply set.

```
prompt> set_retention retention_2 -domain PD1 \\
        -retention_supply_set ret_supply_set \\
        -elements shutdown_inst/mid_inst/R_reg
```

The following example shows how a UPF retention strategy can be defined without using a supply set or supply nets.

```
prompt> set_retention retention_2 -domain PD1 \\
        -elements shutdown_inst/mid_inst/R_reg
```

See Also

- create_power_domain
- create_supply_net
- create_supply_set
- report_power_pin_info
- set_retention_control

---

set_retention_control

Defines the UPF retention control signals for the defined UPF retention strategy.

Syntax

status *set_retention_control*

```
-domain power_domain
-save_signal save_signal_and_save_sense
-restore_signal restore_signal_and_restore_sense
retention_strategy_name
```

Data Types

power_domain	string
save_signal_and_save_sense	string
restore_signal_and_restore_sense	string
retention_strategy_name	string

Arguments

`-domain` *power_domain*

Specifies the power domain name that this UPF retention strategy that is applied to.

`-save_signal` *`save_signal_and_save_sense`*

Specifies the save signal net and the save signal sense for the retention cells under this retention strategy. Use the following syntax: {*save_signal* high|low}.

`-restore_signal` *`restore_signal_and_restore_sense`*

Specifies the restore signal net and the restore sense for the retention cells under this retention strategy. Use the following syntax: {*restore_signal* high|low}.

`retention_strategy_name`

Specifies the UPF retention strategy name. The retention strategy should have already been defined using *set_retention* command

Description

This command defines the UPF retention control signals and control signal sense for this retention strategy of this power domain. The specified control signals are applied to the retention cells under the associated retention strategy.

PrimeTime uses additional information about the retention strategy provided by this command to properly match retention strategies to individual leaf cells. Retention strategy is used for deriving PG connectivity from UPF description. When multiple retention strategies match a retention cell, the last one entered is used.

Examples

The following example shows how to define the retention control signals on the defined UPF retention strategy *retention_1* of the power domain *PD1*.

```
prompt> set_retention_control retention_1 \\
         -domain PD1 \\
         -save_signal {save_net high} \\
         -restore_signal {restore_net low}
```

The following example shows how to find which retention strategy was used on which retention register to derive backup PG connectivity:

```
foreach_in_collection c [sort_collection
  [get_cells -hier * -filter "upf_retention_strategy != {}"] full_name] {
    echo [format
      {  Cell  %-8s  retention %s} [get_attribute $c full_name]
        [get_attribute $c upf_retention_strategy]]
}
```

See Also

- set_retention

Feedback

set_retention_elements

Defines a set of elements for a UPF retention strategy in the design.

Syntax

```
status set_retention_elements
   [-elements object_list]
   retention_element_name
```

Data Types

```
object_list              list
retention_element_name   string
```

Arguments

`-elements object_list`

Specifies the objects to which this UPF retention strategy is applied. The objects can be hierarchical cells, leaf cells, hdl blocks, nets.

`retention_element_name`

Specifies the UPF retention element name. This name is used for defining set of elements to be used in a retention strategy.

Description

This command works with *set_retention* command. It is used for defining a set of elements to be used in a retention strategy. Implementation tools use this command for error checking when applying a retention strategy. The PrimeTime tool does not perform any of this error checking; it only uses this element name when it directly refers to the element set in the *set_retetion* command.

For a list of UPF commands, use this command:

```
prompt>  help upf
```

Examples

The following example shows how to define a set of UPF retention elements.

```
prompt> set_retention_elements RET_ELEM -domain PD1 \\
        -elements {h2/r3}

prompt> set_retention my_retention -domain PD1 \\
        -retention_power_net PN1 \\
        -retention_ground_net GN1 \\
        -elements {RET_ELEM}
```

---

set_routing_rule

Assigns a non-default or default routing rule to specific nets.

Syntax

integer *set_routing_rule*

```
[-rule rule | -default_rule | -no_rule]
[-min_routing_layer layer]
[-max_routing_layer layer]
[-min_layer_mode mode]
[-max_layer_mode mode]
[-min_layer_mode_soft_cost cost]
[-max_layer_mode_soft_cost cost]
[-min_layer_is_user true|false]
[-max_layer_is_user true|false]
[-clear]
[net_list]
```

Data Types

rule	string
layer	list
mode	string
cost	string
net_list	list

Arguments

`-rule rule`

Specifies the name of the non-default routing rule to be assigned to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

Feedback

`-default_rule`

Specifies that the default routing rule should be assigned to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

`-no_rule`

Removes the current routing rule, if any, from the nets. This allows the tool to automatically assign a non-default rule or the default rule to the nets.

The -rule, -default_rule, and -no_rule options are mutually exclusive; you can specify only one.

`-min_routing_layer` *`layer`*

Specifies the minimum routing layer for the nets. Only one layer can be specified.

`-max_routing_layer` *`layer`*

Specifies the maximum routing layer for the nets. Only one layer can be specified.

`-min_layer_mode` *`mode`*

Specifies the minimum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

`-max_layer_mode` *`mode`*

Specifies the maximum routing layer mode for the nets. Valid values are unknown, extract_only, soft, allow_pin_connection, and hard. The default value is unknown.

`-min_layer_mode_soft_cost` *`cost`*

Specifies the minimum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

`-max_layer_mode_soft_cost` *`cost`*

Specifies the maximum routing layer mode soft cost for the nets. Valid values are unknown, low, medium, and high. The default value is unknown.

`-min_layer_is_user true|false`

Indicates whether or not the minimum routing layer is user-generated. True indicates it is user-generated. False indicates it is tool-generated. Default value is true.

Feedback

`-max_layer_is_user true|false`

Indicates whether or not the maximum routing layer is user-generated. True indicates it is user-generated. False indicates it is tool-generated. Default value is true.

`-clear`

Clears the nets' values. This resets the nets' routing rule, min/max routing layers, min/max layer modes, and min/max soft costs back to their default values. If this option is specified along with other options, the nets' values are cleared first and then set to the new values specified by the other options.

net_list

Lists of nets to which a routing rule is assigned.

Description

This command assigns a non-default rule, default routing rule, or no rule to specific nets. This command also assigns minimum and maximum routing layer, mode, and cost constraints to the nets.

Examples

The following example, assigns a non-default rule named *WideMetal* to a net named *B_CLK*.

```
prompt> set_routing_rule {B_CLK} -rule WideMetal
```

See Also

- reset_routing_rule
- report_routing_rules

---

set_rtl_activity_file

Specify RTL activity file for power analysis

Syntax

int *set_rtl_activity_file*

```
-file_type format_name
-strip_path strip_path
-path path
[-systemverilog]
[-time window_list]
file_name
```

Feedback

Data Types

format_name	string
strip_path	string
path	*string*
window_list	*list*
file_name	*string*

Arguments

`-file_type` *format_name*

Specifies file type of the given activity file. Supported format is fsdb/vcd/saif

`-strip_path` *strip_path*

Prefix to strip out from signal names of activity file.

`-path` *path*

Specifies a relative path from the current design to the hierarchical low-level design for which the SAIF file has been created. By default, absolute path names are used.

-systemverilog

Specifies the language format of names in the fsdb as systemverilog. Without this option, default language format is verilog.

`-time` *window_list*

Specifies time windows in which the activities are counted for power calculation. The option accepts an even number list of float values in increasing order. For example, *-time {10 20 50 70}* specifies the time window [10ns, 20ns] and [50ns, 70ns]. The default time window is the whole simulation time in FSDB/VCD.

file_name

Specifies the switching activity file name to be read.

Description

The *set_rtl_activity_file* command specify the switching activity file generated by RTL simulation. This command attempts to find the name mapping between the objects in activity file and in the gate level netlist automatically.

Examples

The following example shows how to specify systemverilog RTL FSDB for power analysis.

```
pwr_shell> set_rtl_activity_file -file_type fsdb -strip_path tb/top
 -systemverilog -time {10 20} rtl.fsdb
```

The following example shows how to specify RTL SAIF file

```
for power analysis.

pwr_shell> set_rtl_activity_file -file_type saif -strip_path top rtl.saif
```

set_rtl_architect_shell

Specify LEF technology file for NDM design database

Syntax

int *set_rtl_architect_shell*

```
        file_name
```

Data Types

```
file_name       string
```

Arguments

file_name

Specifies the location of the RTL Architect shell.

Description

The *set_rtl_architect_shell* command specifies location of the RTL Architect shell.

Examples

The following example shows how to specify RTL Architect shell.

```
pwr_shell> set_rtl_architect_shell full_path_to/rtl_shell
```

See Also

---

set_rtl_export_data_options

Specify RTL export data options

Syntax

int *set_rtl_export_data_options*

```
[-include_libraries lib_type]
[-remove_existing_workspace]
```

Data Types

```
lib_type        string
```

Arguments

`-include_libraries lib_type`

Indicates what libraries to copy to the workspace. Currently only ‘design’ and ‘none’ is supported. Setting this to ‘design’ will copy the design library to the workspace. The default is ‘none’, which will not copy any libraries to the workspace.

-remove_existing_workspace

Removes any existing workspace and creates a new one. The default is not to remove any existing workspace. It reuses the workspace directory, thus overwrites on any existing content.

Description

The *set_rtl_export_data_options* command sets the options for the export_power_data or compute_metrics command that creates the workspace.

Examples

The following example copies the design library to the workspace.

```
pwr_shell> set_rtl_export_data_options -include_libraries {design}
```

```
The following example removes any existing workspace directory and
 creates a new one.

pwr_shell> set_rtl_export_data_options -remove_existing_workspace
```

See Also

- compute_metrics

---

set_rtl_to_gate_name

Sets the name mapping between the RTL and gate-level objects. Use this mapping to read the RTL backward SAIF file or VCD file for power estimation.

Syntax

integer *set_rtl_to_gate_name*

```
-rtl rtl_name
-gate gate_name
-substitute substitute
-inverted
```

Data Types

rtl_name	string
gate_name	string
substitute	string

Arguments

`-rtl` *rtl_name*

This option provides the name of a RTL object, whose name has changed after synthesis. The RTL object appears in the RTL backward SAIF or VCD file.

`-gate` *gate_name*

This option provides the name of gate-level object, for the corresponding RTL object. The name of the RTL object in the RTL backward SAIF or VCD file might change after synthesis. The *gate_name* is the new gate-level name of the RTL object after synthesis. This RTL object can be mapped to multiple gate-level objects due to replication.

`-substitute` *substitute*

This option directs the tool to substitute all the *from_string* occurrences in the RTL VCD or SAIF file with the *to_string*. Specify as *-substitute {from_string to_string}*.

Feedback

`-inverted`

This option specifies that the signal in the RTL activity file gets inverted when mapped to the gate-level design. You can use this option only when the object specified with the *-gate* option is a net or a pin.

Description

After synthesis, the names of the RTL objects might change due to which the *read_saif* or *read_vcd* command is not able to map the names present in the RTL SAIF or VCD file to the gate-level objects. Due to this, many of the nets, ports, and pins might not have the user-defined switching activity values, resulting in inaccurate power numbers.

To avoid this situation, the *set_rtl_to_gate_command* command allows you to set the mapping between the RTL and gate-level names after you have completed the RTL simulation only. You can set the RTL and gate-level names by using the *-rtl* and *-gate* options, respectively.

During the *read_saif* and *read_vcd* command, if the tool is unable to find the gate-level object matching the RTL object name, it looks for the corresponding gate-level name; however, if the gate-level name is provided using the *set_rtl_to_gate_command* command, the tool tries to find the corresponding gate-level object.

Note: Specify the full name of the object with respect to the current instance to the *gate_name* argument. Similarly, specify the the full name as it appears in the backward RTL SAIF or VCD file to the *rtl_name* argument.

When you use the *-substitute* option, any signal name in the RTL VCD or SAIF is scanned only one time. The substitutions are not applied recursively.

Examples

The following example provides the mapping between RTL and gate-level objects.

```
pt_shell> set_rtl_to_gate_name -rtl reg_i[1] -gate reg_i_1
```

The following example provides the mapping for an RTL level signal to a gate-level pin, and instructs the tool to invert the signal found in the RTL activity file.

```
pt_shell> set_rtl_to_gate_name -rtl test_signal \\
             -gate test_signal_reg/Q  -inverted
```

See Also

- unset_rtl_to_gate_name
- reset_rtl_to_gate_name
- report_switching_activity
- read_saif

set_rule_severity

Sets the severity of a rule.

Syntax

Boolean *set_rule_severity*

```
severity_value
rule_list
```

Data Types

```
severity_value    string
patterns          list
```

Arguments

severity_value

Specifies the new severity value. Valid values are *info*, *warning*, *error*, or *fatal*.

rule_list

Lists the rule names or patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type rule.

Description

Modifies the severity of specified rules. You can change the severity of built-in or user-defined rules. Severity is shown in the output of the *check_constraints* command. You can get the severity of a rule using *get_attribute $rule severity*.

Examples

The following example sets the severity for rule *EXD_0009* to "error".

```
pt_shell> set_rule_severity error EXD_0009
```

Feedback

See Also

- check_constraints
- get_attribute

---

set_scenario_case_analysis

Specifies a constant logic value for a list of ports or pins for specific SMS scenarios.

Syntax

```
status set_scenario_case_analysis
  value
  port_or_pin_list
  [-sms_scenarios sms_scenarios_list]
```

Data Types

value	string
port_or_pin_list	list
sms_scenarios_list	collection

Arguments

value

Specifies a constant logic value or a transition type assigned to the given ports or pins. These are the valid values:

- *0* or *zero* - Constant logic 0
- *1* or *one* - Constant logic 1

port_or_pin_list

Specifies the ports or pins affected by the case analysis setting.

Description

Scenario case analysis is a limited form of case analysis settings for SMS scenarios. Scenario case analysis settings can affect clock latencies and datapaths by preventing arrivals from some scenarios from propagating through certain arcs.

Case analysis specifies a list of ports or pins that have a constant logic value (*0*, *1*).

When case analysis is specified, this value is propagated through the network where the constant value controls the traversed logic. For example, if you specify a constant value of 0 at an input of a NAND gate, the output of the NAND gate has a constant value of 1. This value is then propagated further to all cells driven by this output.

Feedback

Scenario case analysis can be used to affect signal propagation especially when cell arcs have "when" conditions. Arcs may become blocked for arrival signal propagation in the given SMS scenario.

Arcs disabled by scenario can be reported with *report_disable_timing*.

The current *set_scenario_case_analysis* settings can be reported using the *report_case_analysis* command.

Scenario case settings can be removed using the \Bremove_scenario_case_analysis command.

Scenario case analysis has limitations compared to the regular *set_case_analysis* command:

1. Scenario case analysis does not affect design topology, including combinational loop breaking or determination of which registers are clocked by which clock. 2. Scenario case analysis does not affect slew propagation or delay calculation on the design. Slews are propagated through arcs in a given scenario even if the arc is blocked for arrival propagation in the same scenario. 3. Scenario case analysis does not affect mode settings of cells in the design. 4. *report_case_analysis* can show the user specified settings, but does not show propagated scenario case analysis.

Examples

The following command sets the IN1 port to constant logic 0 for a specific scenario:

```
pt_shell> set_case_analysis 0 IN1 -sms_scenarios [get_sms_scenarios
 -corner {A}]
```

If there are cells downstream of IN1, some arcs on those cells may become blocked for clock latency and data arrival propagation in the specified scenario. If the cells are part of the clock network, clock paths reported by *report_timing -path_type full_clock_expanded* may take different paths because of the setting.

See Also

- remove_scenario_case_analysis
- report_case_analysis
- report_disable_timing

---

set_scope

Specify the current UPF scope. Return the current UPF scope prior to the execution of this command as a full path string relative to the current design top if successful and null string if it fails.

Feedback

Syntax

string *set_scope*

`[instance]`

Data Types

`instance` `string`

Arguments

`instance`

Specifies the working instance in pt_shell. If the *instance* option is not specified, the focus returns to the top level of the current design. If *instance* is ".", pt_shell returns to the working instance. If *instance* is "..", the context is moved up one level in the instance hierarchy. If *instance* begins with "/", pt_shell returns to the working instance of the design whose name is after the "/". More complex examples of *instance* arguments are described below in EXAMPLES.

Description

This command sets the UPF scope in pt_shell. Functionally, this command is the subset of the *current_instance* command, but with different return value.

- If no *instance* argument is specified, the UPF scope of pt_shell is returned to the top level of the hierarchy.
- If *instance* is ".", the UPF scope is returned and no change is made.
- If *instance* is "..", the UPF scope is moved up one level in the design hierarchy.
- If *instance* is a valid cell at the current level of hierarchy, the UPF scope is moved down to that level of the design hierarchy.
- Multiple levels of hierarchy can be traversed in a single call to *set_scope* by separating multiple cell names with slashes.
- If *instance* begins with "/", the tool returns to the working instance under current design top instance whose name is after the "/". Basically, the "/" in the beginning of instance name is interpreted as design top instance. If *instance* is "/", the tool returns the current design top instance. load_upf -scope implicitly changes the design top instance (and design top model)to the -scope value.

  For example, the *set_scope U1/U2* command sets the UPF scope down two levels of hierarchy if both cells exist at the current levels in the design hierarchy.
- The ".." directive can also be nested in complex *instance* arguments.

  For example, the *set_scope "../../MY_INST"* command attempts to move the context up two levels of hierarchy, then down one level to the "MY_INST" cell.

NOTE: The *set_scope* command does not work on leaf cells. If you attempt to run this command on a leaf cell, an error occurs.

- current_instance
- current_design

---

set_sense

Specifies unateness propagating forward for pins with respect to clock source.

Syntax

status *set_sense*

```
[-type clock | data]
[-non_unate]
[-rise]
[-fall]
[-clock_fall]
[-clock_rise]
[-primary]
[-generated]
[-positive]
[-negative]
[-stop_propagation]
[-clock_leaf]
[-pulse pulse_type]
[-clocks clock_list]
object_list
```

Data Types

```
pulse_type      string
clock_list      list
object_list      list
```

Arguments

`-type clock | data`

Specifies whether the sense is applied to clock or data networks. If you do not specify this option, the default is *clock*. If you specify *data*, you must also use the *-stop_propagation* and *-clocks* options.

`-non_unate`

Launches both the positive-unate sense and the negative-unate sense of the clock from the clock source. If you use the *-non_unate* option, you must also use

the *-clocks* option. Please note that this option is only valid for clock source pins/ports.

`-rise`

Specifies rising clock sense. Please note that this option is only valid for clock source pins/ports.

`-fall`

Specifies falling clock sense. Please note that this option is only valid for clock source pins/ports.

`-clock_fall`

Specifies that the signal is coming from the falling edge of the clock. If not specified, the command uses the falling edge for *-fall*. Please note that this option is only valid for clock definition points.

`-clock_rise`

Specifies that the signal is coming from the rising edge of the clock. If not specified, the command uses the rising edge for *-rise*. Please note that this option is only valid for clock definition points.

`-primary`

Specifies primary clock signal type, primary is the default. Please note that this option is only valid for clock definition points.

`-generated`

Specifies generated clock signal type. Please note that this option is only valid for clock definition points.

`-positive`

Applies positive unateness to all pins in the *object_list* with respect to clock source. If you use the *-positive* option, you cannot use the *-negative* or *-pulse* options.

`-negative`

Applies negative unateness to all pins in the *object_list* with respect to clock source. If you use the *-negative* option, you cannot use the *-positive* or *-pulse* options.

`-stop_propagation`

Stops the propagation of specified clocks in the *clock_list* from the specified pins or cell timing arcs in the *object_list*. Only a clock used as a clock is stopped if you specify the *-type clock* option. To stop propagation for both clock-as-clock and clock-as-data, you need to use a *set_sense -type clock* command with a

set_sense -type data command. You cannot use the *-stop_propagation* option with the *-positive*, *-negative*, or *-pulse* options.

`-clock_leaf`

Stops the propagation of specified clocks in the *clock_list* from the specified pins in the *object_list*. Also, it specifies the pin as a clock consumer, so that the clock branches reaching this pin will be considered as clock consumer as well. In other words, the attribute *"is_clock_used_as_clock"* will be true for all the pins of the clock branches that reach the clock leaf pin. You cannot use the *-clock_leaf* option with the *-positive*, *-negative*, *-stop_propagation* or *-pulse* options.

`-pulse` *`pulse_type`*

Specifies the type of pulse clock applied to all pins in the *object_list* with respect to clock source. The possible values for the *pulse_type* argument are

- *rise_triggered_high_pulse*
- *fall_triggered_high_pulse*
- *rise_triggered_low_pulse*
- *fall_triggered_low_pulse*

If you use the *-pulse* option, you cannot use the *-positive* or *-negative* options.

`-clocks` *`clock_list`*

Specifies a list of clock objects to be applied with the given unateness that is placed on all pin objects in the *object_list*. If you do not specify the *-clocks* option, all clocks passing through the given pin objects are considered.

`object_list`

List of pins, ports, or cell timing arcs with specified unateness to propagate. The timing arcs object can be used with the *-stop_propagation* option only.

Description

This command modifies the waveform of the clock in two distinct ways: 1. You can use this command to restrict unateness at pin (to positive or negative unate) with respect to clock source. However, the specified unateness only applies within the non-unate clock network. In this case, user-defined sense propagates forward from the given pins.

1. You can specify the waveform of the clock at its definition point. This option is only valid for the clock sources of the clock. You can specify the waveform to be launched from the clock source as positive, negative or non-unate. You can also specify whether the clock is only used for source latency computation of the generated clocks. This can be specified by the *-generated* option.

Feedback

If you use the *-clocks* option, only the specified clock domains are applied. Otherwise, all clocks passing through the given pin objects are considered.

PrimeTime issues warning messages if the specified sense on given pins cannot be respected in case there is predefined unateness for given pins. A hierarchical pin is not supported.

In addition, you can completely stop propagation of certain clocks in clock networks or data networks by using the *-stop_propagation* option along with the *-type* option.

To undo the *set_sense* command, use the *remove_sense* command.

Examples

The following example specifies a positive unateness for the XOR/Z pin with respect to the CLK1 clock.

```
pt_shell> set_sense -positive -clocks [get_clocks CLK1] XOR/Z
```

The following example specifies negative unateness for the MUX/Z pin for all clocks.

```
pt_shell> set_sense -negative MUX/Z
```

The following example specifies a positive unate clock sense on primary clock CLK1 using a combination of -fall, -rise, -clock_fall, -clock_rise.

```
pt_shell> set_sense -primary -rise -clock_rise -clocks CLK1 inv2/Y
pt_shell> set_sense -primary -fall -clock_fall -clocks CLK1 inv2/Y
```

The following example specifies a positive unate waveform for the clock and a negative unate waveform for the clock when it is used for source latency computation.

```
pt_shell> set_sense -primary -fall -clock_fall -clocks CLK1 inv2/Y
pt_shell> set_sense -primary -rise -clock_rise -clocks CLK1 inv2/Y
pt_shell> set_sense -generated -fall -clock_rise -clocks CLK1 inv2/Y
pt_shell> set_sense -generated -rise -clock_fall -clocks CLK1 inv2/Y
```

See Also

- remove_sense

---

set_si_aggressor_exclusion

Sets the given nets to be exclusive while switching in the given direction, when they are aggressors to the same victim net.

Syntax

integer *set_si_aggressor_exclusion*

```
[-number_of_active_aggressors n]
[-rise]
[-fall]
anets
```

Data Types

```
anets        list
n            integer
```

Arguments

`-number_of_active_aggressors n`

Specifies the maximum number of aggressors among the given list of exclusive aggressors that can be active at a given instant. This option is used to set n-hot or n-cold behavior, where only the *n* nets are active(hot) or quiet(cold) at a given instant. If this option is not specified, the default value of *n=1* is used; i.e only one of the given exclusive aggressors is considered active at a given time.

`-rise`

Specifies the aggressor nets to be exclusive while switching in the rise direction. If neither the *-rise* nor the *-fall* options are specified, the aggressor *anets* nets are considered exclusive in the directions of both the *-rise* and *-fall* options.

`-fall`

Specifies the aggressor nets to be exclusive while switching in the fall direction. If neither the *-rise* nor *-fall* options are specified, the aggressor *anets* net are considered exclusive in in the directions of both the *-rise* and *-fall*.

`anets`

Specifies the list of nets which are exclusive when they are aggressors to the same victim net.

Description

The *set_si_aggressor_exclusion* command sets the aggressor nets to exclusive while switching in the given direction at the same time. Among all combinations of active aggressors allowed by the *-number_of_active_aggressors option, only the combination which produces the worst alignment are considered for crosstalk analysis.*

Only the aggressor nets specified in the *anets* list are considered exclusive. If a victim net is specified in the *anets* list, it is not considered exclusive with any of its aggressor nets.

To view which aggressor nets were considered active and which aggressor nets were set to quiet, use the *report_delay_calculation* or *report_noise_calculation* commands on the victim net. The quiet aggressor nets are reported to be screened due to aggressor exclusion.

Feedback

These exclusive commands are independent of parasitics, so they are applied even before reading in parasitics.

Note that application of exclusive aggressors cannot be done incrementally; next update_timing and update_noise would be a full update.

The command *report_si_aggressor_exclusion* is used to check which groups are set by the *set_si_aggressor_exclusion* command.

Examples

The following example shows how the nets *SCAN_LOGIC** are set to be exclusive while switching in the rise direction.

```
pt_shell> set_si_aggressor_exclusion [get_nets SCAN_LOGIC*] -rise
1
```

The following example shows how the nets *LCO_LOGIC** are set to be exclusive while switching in the fall direction.

```
pt_shell> set_si_aggressor_exclusion [get_nets LCO_LOGIC*] -fall
1
```

The following example shows how only 3 of the nets *LOGIC_BUS** considered to be active while switching in the rise direction.

```
pt_shell> set_si_aggressor_exclusion [get_nets LOGIC_BUS*] -rise
-number_of_active_aggressors 3
1
```

See Also

- remove_si_aggressor_exclusion
- report_si_aggressor_exclusion
- report_delay_calculation
- report_noise_calculation
- si_analysis_logical_correlation_mode
- set_si_delay_analysis
- set_si_noise_analysis

---

set_si_delay_analysis

Sets coupling information on nets for crosstalk analysis.

Feedback

Syntax

integer *set_si_delay_analysis*

```
[-ignore_arrival inets]
[-exclude]
[-victims vnets]
[-aggressors anets]
[-rise]
[-fall]
[-min]
[-max]
```

Data Types

inets	list
vnets	list
anets	list

Arguments

`-ignore_arrival inets`

Specifies a list of nets to be analyzed as infinite window. You cannot use this option with the *-exclude*, *-victims*, or *-aggressors* options. The physical exclusivity analysis for SI is considered for these nets when si_xtalk_use_physical_exclusivity_on_ignore_arrival_nets variable is set to true.

`-exclude`

Indicates that nets specified as a *vnets* or *anets* variable are to be excluded from the crosstalk analysis as victim nets or aggressor nets, respectively. You cannot use this option with the *-ignore_arrival* option. When both the *-victims vnets* and *-aggressors anets* options are applied, all cross capacitances between the *vnets* and *anets* variables are excluded, when *vnets* are victims and *anets* are aggressors.

`-victims vnets`

Specifies the list of nets on which the *-exclude* option information is applied as a victim. You cannot use this option with the *-ignore_arrival* option. If you use the *-victims* option, you must use the *-exclude* option. When used with the *-aggressors* option, the *-victims* option excludes the cross capacitances between the victim nets (*vnets*) and the aggressor nets (*anets*).

`-aggressors anets`

The list of nets on which the *-exclude* option information is applied as an aggressor. You cannot use this option with the *-ignore_arrival* option. If you use the *-aggressors* option, you must use the *-exclude* option. When used with the *-victims* option, the *-aggressors* option excludes the cross capacitances between the victim nets (*vnets*) and the aggressor nets (*anets*).

`-rise`

Excludes a list of nets for victim rising. If you use the *-rise* option, you must use the *-exclude* option.

`-fall`

Excludes a list of nets for victim falling. If you use the *-fall* option, you must use the *-exclude* option.

`-min`

Excludes a list of nets for min path analysis. If you use the *-min* option, you must use the *-exclude* option.

`-max`

Excludes a list of nets for max path analysis. If you use the *-max* option, you must use the *-exclude* option.

Description

Sets coupling information on nets for crosstalk analysis.

The *set_si_delay_analysis* command allows you to set some net as infinite window as both aggressor and victim. This command has no default. To remove the result of this command, use the *remove_si_delay_analysis* command.

The *set_si_delay_analysis* command and the *-exclude* option allows you to select nets to be excluded from crosstalk analysis. By default, all nets with coupling capacitances (non-filtered) are included in crosstalk analysis as both victim and aggressor. This command allows the nets to be excluded as victim (by using the *-victim* option) or aggressor (by using the *-aggressors* option). When you use both the *-victims* and *-aggressors* options, the command excludes the relationship between the specified victim nets (*vnets*) and aggressor nets (*anets*); this is referred to as "pair-wise exclusion."

By using the *set_si_delay_analysis* command with the *-ignore_arrival* option, you can set the *inets* as infinite window. When *inets* is analyzed as victim, the timing relationship between all the nets in this coupling cluster is ignored, and all aggressors become active (even those driven by clock domains which are physically exclusive). When *inets* is analyzed as aggressor the arrival time of *inets* is ignored. The infinite window analysis could make the crosstalk calculation more pessimistic.

The *set_si_delay_analysis* command returns a *1* if successful and a *0* if unsuccessful.

To view the results of this command, use the *report_si_delay_analysis* command.

Examples

The following example shows that all nets described by *CLK_NET_** are excluded from crosstalk analysis as victim nets.

Feedback

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets CLK_NET*]
1
```

The following example shows how all nets in a design to be analyzed as infinite window.

```
pt_shell> set_si_delay_analysis -ignore_arrival [get_nets -hier *]
1
```

The following example shows how to ensure that the scan clock described by *SCN_CLK_** is not effecting the main clock network described by *CLK_NET_**, and vice versa.

```
pt_shell> set_si_delay_analysis -exclude -victims \\
[get_nets SCN_CLK_*] \\
-aggressors [get_nets CLK_NET*]
pt_shell> set_si_delay_analysis -exclude -aggressors \\
[get_nets SCN_CLK_*] -victims [get_nets CLK_NET*]
1
```

---

set_si_delay_disable_statistical

Disables composite aggressor statistical analysis on nets for crosstalk analysis.

Syntax

int *set_si_delay_disable_statistical*

```
        dnets
```

Data Types

dnets list

Arguments

dnets

A list of nets in the current design for which the composite aggressor statistical analysis is disabled.

Feedback

Description

If selected in composite aggressor group for crosstalk analysis, *dnets* specified by this command are not treated statistically. If they are not selected into composite aggressor group, this command has no effect.

To remove the result of this command, use the *remove_si_delay_disable_statistical* command.

Examples

The following example shows how to disable net from statistical analysis when considered as a composite aggressor.

```
pt_shell> set_si_delay_disable_statistical [get_nets LOGIC1]
1
```

See Also

- remove_si_delay_disable_statistical
- report_si_delay_analysis

---

set_si_noise_analysis

Sets coupling information on nets for noise analysis.

Syntax

int *set_si_noise_analysis*

```
[-ignore_arrival inets]
[-exclude]
[-victims vnets]
[-aggressors anets]
[-above]
[-below]
[-low]
[-high]
```

Data Types

inets list *vnets* list *anets* list

Arguments

`-ignore_arrival inets`

Specifies a list of nets to be set as infinite window. When *inets* are analyzed as victims, all of their aggressors are set with infinite window. When *inets* are analyzed as aggressors, they are set as aggressors with arrival time ignored.

You cannot use this option with the *-exclude*, *-victims*, *-aggressors*, *-high*, *-low*, *-above*, or *-below* option.

`-exclude`

Indicates that nets specified as *vnets* or *anets*) are to be excluded from the noise analysis as victim nets or aggressor nets, respectively. You cannot use this option with the *-ignore_arrival* option. When both the *-victims vnets* and *-aggressors anets* options are applied, the noise between *vnets* and *anets* is not analyzed, when *vnets* are victims and *anets* are aggressors.

`-victims` *`vnets`*

Specifies the list of nets on which *-exclude* information is applied as a victim. You cannot use this option with the *-ignore_arrival* option. If you use the *-victims* option, you must use the *-exclude* option. When used with the *-aggressors* option, the *-victims* option excludes the noise analysis between the victim nets (*vnets*) and the aggressor nets (*anets*).

`-aggressors` *`anets`*

Indicates the list of nets on which the *-exclude* option information is applied as an aggressor. You cannot use this option with the *-ignore_arrival* option. If you use the *-aggressors* option, you must use the *-exclude* option. When used with the *-victims* option, *-aggressors* excludes the noise analysis between the victim nets (*vnets*) and the aggressor nets (*anets*).

`-above`

Excludes a list of nets for victim above rail. If you use the *-above* option, you must use the *-exclude* option.

`-below`

Excludes a list of nets for victim below rail. If you use the *-below* option, you must use the *-exclude* option.

`-low`

Excludes a list of nets for low rail noise analysis. If you use the *-low* option, you must use the *-exclude* option.

`-high`

Excludes a list of nets for high rail noise analysis. If you use the *-high* option, you must use the *-exclude* option.

Description

Sets coupling information on nets for noise analysis.

The *set_si_noise_analysis* command allows you to exclude some net from noise analysis or set some net as infinite window as aggressor. This command has no default. To remove the result of this command, use the *remove_si_noise_analysis* command.

The *-exclude* option of the *set_si_noise_analysis* command allows you to select nets to be excluded from noise analysis. By default, all nets with coupling capacitances (non-filtered) are included in noise analysis as both victim and aggressor. This command allows the nets to be excluded as victim (by using the *-victim* option) and/or aggressor (by using the *-aggressors* option). When you use both the *-victims* and *-aggressors* options, the command excludes the noise analysis between the specified victim nets (*vnets*) and aggressor nets (*anets*); this is referred to as "pair-wise exclusion."

By using the *set_si_noise_analysis* command with the *-ignore_arrival* option, you can set the *inets* as infinite window as aggressor if they are analyzed as aggressors. When *inets* are analyzed as noise victims, all of their aggressors are infinite window.

The *set_si_noise_analysis* command returns a *1* if successful and a *0* if unsuccessful.

To view the results of this command, use the *report_si_noise_analysis* command.

Examples

The following example shows that all nets described by *CLK_NET_** are excluded from noise analysis as victim nets.

```
pt_shell> set_si_noise_analysis -exclude -victims [get_nets CLK_NET*]
1
```

The following example shows that when all nets described by *SOME_LOGIC** are analyzed as aggressors, they are set as infinite window as aggressors in noise analysis.

```
pt_shell> set_si_noise_analysis -ignore_arrival [get_nets SOME_LOGIC*]
1
```

The following example shows how to ensure that the scan clock described by *SCN_CLK_** is not effecting the main clock network described by *CLK_NET_**, and vice versa.

```
pt_shell> set_si_noise_analysis -exclude -victims \\
           [get_nets SCN_CLK_*] \\
           -aggressors [get_nets CLK_NET*]
pt_shell> set_si_noise_analysis -exclude -aggressors \\
           [get_nets SCN_CLK_*] -victims [get_nets CLK_NET*]
1
```

---

set_si_noise_disable_statistical

Disables composite aggressor statistical analysis on nets for noise analysis.

Syntax

int *set_si_noise_disable_statistical*

```
        dnets
```

Data Types

dnets	list

Arguments

dnets

A list of nets in the current design for which the composite aggressor statistical analysis is disabled.

Description

If selected in composite aggressor group for noise analysis, *dnets* specified by this command are not treated statistically. If they are not selected into composite aggressor group, this command has no effect.

To remove the result of this command, use the *remove_si_noise_disable_statistical* command.

Examples

The following example shows how to disable net from statistical analysis when considered as a composite aggressor.

```
pt_shell> set_si_noise_disable_statistical [get_nets LOGIC1]
1
```

See Also

- remove_si_noise_disable_statistical

Feedback

set_signal_em_analysis_options

Sets the options for signal electromigration analysis.

Syntax

status *set_signal_em_analysis_options*

```
[-em_temperature temperature]
[-em_delta_temperature temperature]
```

Data Types

```
temperature        float
```

Arguments

`-em_temperature temperature`

Specifies temperature for AVG current limit lookup. Default temperature is parasitics temperature.

`-em_delta_temperature temperature`

Specifies delta temperature used in RMS current limit lookup. Default value is 5.0.

Description

Command to specify various analysis options for signal electromigration analysis in PrimePower. The options from this command controls how signal electromigration analysis behaves for specific analysis type.

Examples

The following example sets temperatures for signal electromigration analysis.

```
pt_shell> > set_signal_em_analysis_options -em_temperature 95 \
                        -em_delta_temperature 10
```

set_size_only

Sets the *size_only* attribute on leaf cells to prevent those objects from being removed during ECO fixing.

Syntax

status *set_size_only*

```
object_list
[value]
```

Feedback

Data Types

```
object_list     list
value           Boolean
```

Arguments

object_list

Specifies a collection of leaf cells, preventing those objects from being removed during ECO fixing.

Lists are not supported.

value

Sets the value, either *true* or *false*, for the *size_only* attribute of the specified objects. If no value is provided, the default is *true*. Use the value *false* to cancel the effects a previous *set_size_only* command.

Description

This command sets the *size_only* attribute on leaf cells to prevent those objects from being removed during ECO fixing by the *fix_eco_drc*, *fix_eco_power*, and *fix_eco_timing* commands. The specified objects must be in one of the target libraries or in a library already loaded into memory.

You can query the *size_only* attribute by using the *get_attribute* command. To cancel the effects of a *set_size_only* command, run the command again and specify the *value* as *false*. A *false* setting on an object overrides a *true* setting on the object.

In distributed multi-scenario analysis (DMSA), you should apply the *set_size_only* command in all scenarios using *remote_execute*.

Examples

The following commands specify that the cell "u1" is *size_only* and should not be removed during ECO.

```
pt_shell> set_size_only [get_cells {u1}]
1
pt_shell> get_attribute [get_cells {u1}] size_only
true
```

Feedback

- get_attribute
- set_dont_touch

---

set_spacing_label_rule

Sets an intercell spacing constraint between reference cells that have been assigned labels with set_lib_cell_spacing_label command.

Syntax

status *set_spacing_label_rule*

```
-labels list_of_label_names
min_max_spec
```

Data Types

list_of_label_names	list
min_max_spec	integer

Arguments

`-labels` *list_of_label_names*

Specifies a list of exactly two intercell constraint labels previously defined by the set_lib_cell_spacing_label command.

min_max_spec

Specifies the range of illegal x-spacing values in units of sites. *min_max_spec* follows the format *{minx maxx}* where minx <= maxx. The spacing between the labeled edges cannot be in the range from minx to maxx placement sites.

Description

This command assigns intercell spacing constraints between reference cells that have been assigned labels with the set_lib_cell_spacing_label command. Cells with the given labels are prohibited from being placed adjacent to one another with a spacing between minx and maxx. The range is specified in units of placement sites.

Given two adjacent standard cells with an empty space in between, each label from the right side of the left cell is checked against each label from the left side of the right cell to see if any spacing rules are violated. Such pairwise checking of labels is applied to all adjacent cells to ensure placement legality.

A label typically represents some layout features inside a standard cell. A label is associated with the left or right boundary of a standard cell in the "North" orientation. When a cell is flipped, its associated labels are also flipped.

With intercell spacing rules specified, standard cells can be placed next to each other only when they do not violate the spacing rules.

The labels and spacing rules can be used to express spacing requirements that originate from mask rules and the layout of standard cells. The labels and spacing rules are stored in the library and are applied to all designs using the library.

Examples

In the following example, cells with labels "X" and "Y" are prohibited to abut (a spacing of 0 is prohibited).

```
prompt> set_spacing_label_rule -labels {X Y} {0 0}
```

In the following example, cells with labels "X" are prohibited to be spaced within range of 3 to 5 placement sites.

```
prompt> set_spacing_label_rule -labels {X X} {3 5}
```

See Also

- set_lib_cell_spacing_label

---

set_steady_state_resistance

Specifies the steady-state resistance for a library pin or port.

Syntax

status *set_steady_state_resistance*

```
[-above]
[-below]
[-low]
[-high]
res_value
object_list
```

Data Types

res_value	float
object_list	list

Arguments

`-above`

Specifies steady state resistance for above ground or power rail noise analysis region.

`-below`

Specifies steady state resistance for below ground or power rail noise analysis region.

`-low`

Specifies steady state resistance for ground rail noise.

`-high`

Specifies steady state resistance for power rail noise.

`res_value`

Specifies the steady state resistance value in units of resistance.

`object_list`

Specifies a list of library pins or ports.

Description

A steady-state driver of a net affects the size of crosstalk bumps on the net due to its loading effects on the net. To accurately calculate the characteristics of crosstalk noise bumps, the tool needs the steady-state I-V characteristics of the driver output.

Noise bumps can occur in the following regions: below low, above low, below high, and above high. You can specify a steady-state resistance for each region.

This command can be used in the absence of library-specified I-V characteristics, or to override the library-specified characteristics by replacing them with a steady-state resistance value.

The *report_noise_calculation* command shows whether noise immunity information was taken from the library or annotated by this command.

Examples

This example specifies a steady state resistance of 2.0 for above-the-ground rail noise for the Z pin of the AN4 library cell in the lsi_10k library:

```
pt_shell> set_steady_state_resistance -above -low  2.0 lsi_10k/AN4/Z
```

See Also

- remove_steady_state_resistance
- report_noise_calculation

Feedback

set_supply_net_probability

Sets the static probability annotation on selected supply nets. This probability affects average and time-based power analysis.

Syntax

```
int set_supply_net_probability
[-remove]
supply_nets
[static_prob]
```

Data Types

```
supply_nets          list
static_pro          float
```

Arguments

`-remove`

Removes the annotation on given supply nets.

supply_nets

Specifies the supply net or supply nets to apply the probability to. This argument can be a supply net name, a list of supply net names, a supply net obtained using the get_supply_nets com- mand, or a collection of supply nets obtained using the get_sup- ply_nets command.

static_prob

Specifies the probability that the supply net is powered. Use a value between 0 and 1.

This argument is optional. If not supplied, no annotation is performed and a description of the static probability on the supply nets is returned.

Description

Averaged power analysis uses the supply net probability to determine what fraction of the time the cells connected to this supply net are powered. Time-based power analysis uses the supply net probability to determine the cells connected to this supply net are powered on/off. This command can be used for any supply net irrespective of whether they are connected to a on chip switch cell or not.

Examples

The following examples show how to use the command:

```
pt_shell> get_supply_nets *
{"VDDI", "VDDM", "VDDIS", "VDD", "VDDMS", "VDDGS", "VDDG", "VSS"}
```

Feedback

```
pt_shell> set_supply_net_probability VDDI 0.25
{"VDDI" 0.25 annotated}

pt_shell> set_supply_net_probability [list VDDI VDD] 0.4
{"VDDI" 0.4 annotated} {"VDD" 0.4 annotated}

pt_shell> set_supply_net_probability [get_supply_nets *] 0.4
{"VDDI" 0.4 annotated} {"VDD" 0.4 annotated} ...

pt_shell> set_supply_net_probability [get_supply_nets VDDI] 0.4
{"VDDI" 0.4 annotated}
```

See Also

---

set_switching_activity

Sets switching activity annotation on the selected nets, pins, ports, and cells of the current design.

Syntax

integer *set_switching_activity*

```
[-state_condition state_condition]
[-path_sources path_sources]
[-toggle_rate toggle_rate]
[-clock_derate derate_value]
[-glitch_rate glitch_rate]
[-static_probability static_probability]
[-rise_ratio rise_ratio]
[-period period_value]
[-base_clock clock]
[-type object_type_list]
[-hierarchy]
[-verbose]
[-force]
[-clock_domains clock_list]
[object_list]
```

Data Types

state_condition	string
path_sources	list
toggle_rate	float
derate_value	float
glitch_rate	float

```
static_probability          float
rise_ratio                  float
period_value                float
clock                       string
object_type_list            list
clock_list                  list
object_list                 list
```

Arguments

`-state_condition` *state_condition*

Specifies the state condition when annotating state-dependent toggle rate and glitch rate on pins or state-dependent static probabilities on cells. State-dependent toggle rates and glitch rates can be annotated when the internal power of the library cell pin is characterized with state-dependent power tables. State-dependent static probabilities can be annotated when the cell leakage power is characterized with state-dependent power tables. The state condition specified with this argument must be logically equivalent to a state condition in the internal or leakage power characterization. The state condition should be enclosed between " ". To set switching activity for the default state condition, specify the argument of *-state_condition* option as *default*.

`-path_sources` *path_sources*

Specifies the path sources when annotating path-dependent toggle rate and glitch rate on pins. This is used when the library cell pin has path-dependent internal power. The path sources specified with this argument must be the same as the path sources in the internal power characterization. When listing more than one pin in path sources, the pin names must be separated by a space and enclosed between " ". For example, if the pins in path sources are A and B, the argument for the *-path_sources* option must be "A B". Note: If you use the *-path_sources* option to specify the *path_sources value, then you must use the -state_condition option to specify the value of the path_sources.*

`-static_probability` *static_probability*

Specifies the value of the static_probability switching activity. The *static_probability* value represents the percentage of time the signal is at the logic state 1. For example, a *static_probability* of 0.25 indicates that the signal is in the logic state 1 for 25% of the time.

`-toggle_rate` *toggle_rate*

Specifies the value of the toggle rate switching activity. The rate is a floating point number that represents the number of 0->1 and 1->0 glitch free transitions, that the signal makes during a period of time. You can specify the period with the *-period* option. Alternatively, you can annotate a related clock with the *-base_clock* option, and the specified toggle rate is relative to the related clock period. If you specify the *-clock_domains* option, the related clock is chosen

based on which clock domain the object belongs. If it belongs to multiple clock domains, the faster clock is the related clock. If no clock domain is found for the object, the fastest clock in the design is the related clock.

`-clock_derate` *`derate_value`*

The *-clock_derate* option is an alternative to the *-toggle_rate* option if the *-base_clock* option is specified. The annotated toggle rate for an object is a factor of the toggle rate of the related clock of the object. The related clock is chosen based on the clock domain to which the object belongs. If it belongs to multiple clock domains, the fastest one is selected. If the object does not belong to any clock domain, the related clock is set to the fastest clock in the design.

`-glitch_rate` *`glitch_rate`*

Specifies the value of the glitch rate switching activity. The value is a floating point number that represents the number of 0->1 and 1->0 glitch transitions, that the signal makes during a period of time. You can specify the period with the *-period* option. Alternatively, you can annotate a related clock using the *-base_clock* option, and the specified glitch rate is relative to the related clock period. Note: If either of the *-toggle_rate* or the *-glitch_rate* option is specified, the other is assumed to be zero.

For PrimePower version D-2010.06 and earlier releases, the *toggle_rate* and *glitch_rate* options are known as *-toggle_count* and *-glitch_count* respectively. If you specify the older names, the tool generates a warning message.

`-rise_ratio` *`rise_ratio`*

Specifies the ratio of rise transitions to total transitions for the specified toggle rate and glitch rate when annotating pins that are characterized with both rise and fall internal power. The *rise_ratio* argument is a floating point number between 0.0 (all transitions are falling) and 1.0 (all transitions are rising). You need to specify a toggle rate and glitch rate to use this option. The default is 0.5.

`-period` *`period_value`*

Specifies the time period for which the number of transitions given in the *toggle_rate* and *glitch_rate* occur. The time units for this value are those specified by the main technology library. When you specify this option, the values of the specified toggle and glitch rates are divided by the given *period_value*. The resulting toggle rate and glitch rate are then annotated to the objects provided in the *set_switching_activity* command. If the *-period* option is not specified, a default *period_value* of 1.0 is assumed.

`-base_clock` *`clock`*

Specifies a clock by which the toggle and glitch rate values are referenced. When applied, the toggle and glitch rates are divided by the period of the

specified clock. When the *-base_clock* value is set to "*", the toggle and glitch rates are divided by the period of the related clock.

`-type` *`object_type_list`*

Specifies a list of object types used for implicitly selecting the objects that are annotated with the specified switching activity. The *object_type_list* argument can be a list of one or more of the following object types:

- *registers* (sequential cell outputs)
- *three_states* (tristate cell outputs)
- *inputs* (input design ports / hierarchical instance pins)
- *outputs* (output design ports / hierarchical instance pins)
- *inout* (inout design ports / hierarchical instance pins)
- *ports* (design port / hierarchical instance pins)
- *nets* (nets)
- *clock_gating_cells* (clock-gating cell output)
- *black_boxes* (black box outputs)
- *non_clock_network* (nonclock network objects)
- *memory* (memory cell outputs)

When you specify the *-type* option, the tool annotates all the objects in the current instance (current design, if no current instance is set) that satisfy the selection criteria with the specified switching activity. If you specify the *registers* type, the tool annotates both the noninverting (Q) and inverting (QN) sequential cell outputs. The annotated toggle rate and glitch rate on the inverting outputs is the same as that on the noninverting outputs. The static probability on the inverting outputs is 1.0 - *value* where *value* is the specified static probability.

If you specify the *black_boxes* type, the tool annotates the black-box cell outputs. Generated clock nets are excluded from this group.

If you specify the *non_clock_network* type, the tool annotates the activity on the nonclock network cells of the design.

If you specify the *-clock_domains* option, the tool constrains the selected objects further to fall into the specified clock domains. However, the source pins of the clock are not included.

`-hierarchy`

Use with the *-type* option to specify that the objects in all the hierarchies in the current instance that satisfy the selection criteria. If not specified, the tool annotates only the top-level objects in the current instance that satisfy the selection criteria.

For PrimePower version D-2010.06 and earlier releases, by default, the objects in all the hierarchies in the current instance are considered unless you specify the *-no_hierarchy* option; For PrimePower version E-2010.12 and later, the *-no_hierarchy* option replaces the *-hierarchy* option. For the tool to consider all the hierarchies in the current instance, specify the *-hierarchy* option.

`-verbose`

Prints the detailed information, such as the design objects that are not annotated. By default, the tool suppresses detailed information.

For PrimePower version D-2010.06 and earlier releases, verbose information was provided by default. A *-quiet* option was used to suppress the detailed information. In the E-2010.12 release, detailed information is suppressed by default; the *-quiet* option replaces the *-verbose* option. If you use the invalid *-quiet* option instead of the valid *-verbose* option, a warning message is generated.

`-force`

If "-force" option is specified, then PrimePower will force the SP and TR values over any other activity which is annotated from either file (VCD, FSDB, etc.), normal "set_switching_activity", "set_case_analysis", logic constants, propagated and default activities. The "force_annotated" pin will have the highest precedence among all other activities. This command works in average as well as time based analysis mode.

`-clock_domains` *`clock_list`*

Filters the selection to include only the objects that belong to the specified clock domains and divides the toggle and glitch rate by the period of the related clock. If an object belongs to multiple clock domains, the fastest of the clocks, is selected as the related clock. Objects which belong to no clock domain, are automatically placed in the domain of the fastest design clock.

For PrimePower version D-2010.06 and earlier releases, this option is called *-clocks*. For PrimePower version E-2010.12 and later, the *-clocks* option is *-glitch_rate*. If you use the *-clocks* option, a warning message is issued.

`object_list`

Specifies a list of nets, pins, ports, or instances in the current design on which the *static_probability*, *toggle_rate*, and *glitch_rate* switching activity values are

to be set. Use this option with the *-type* argument to specify that all the objects in the given list of instances that satisfy the selection criteria are annotated. This option can also be used with or without the *-no_hierarchy* option.

Description

Use this command to annotate design nets, ports, pins, and cells with the different kinds of switching activity. These include simple toggle rate, glitch rate, and static probability on nets, ports and pins; state and path dependent toggle rate and glitch rate on cell pins, and state dependent static probabilities on cells.

Toggle rates, glitch rates, and static probabilities are annotated by using the *-toggle_rate*, *-glitch_rate* and *-static_probability* options respectively. The toggle rate, glitch rate, and static probability can be made state-dependent by specifying the state condition with the *-state_condition* option. The toggle rate and glitch rate can be made path-dependent by specifying the path sources with the *-path_sources* option. You can specify a related clock using the *-base_clock* option. The annotated toggle rate and glitch rate are divided by 1 time unit defined in the main library unless the -period, *-base_clock* or *-clock_domains* options are applied. When you specify the *-period* option, the toggle and glitch rates are divided by the period value. When you specify *-base_clock* option, the toggle and glitch rates are divided by the clock period of the specified base clock. When you specify the *-clock_domains* option, the glitch and toggle rates are divided by the period of the related clock for each domain.

The design objects that are annotated with switching activity can be specified explicitly as a list of objects. The objects can also be specified implicitly by using the *-type*, and *object_list* options together.

For statistics on the switching activity annotation on the current design, use the *report_switching_activity* command.

Examples

In the following example, tool annotates a simple toggle rate value of 33 / 1320 = 0.025, glitch rate value of 10 / 1320 = 0.0075 and a static probability value of 0.015 to all design input ports.

```
pt_shell> set_switching_activity -toggle_rate 33 -glitch_rate 10 \\
           -period 1320 -static_probability 0.015 [all_inputs]
```

The following example annotates the same activity to all input ports, relative to a clock with a period of 10.

pt_shell> *create_clock CLK -period 10* pt_shell> *set_switching_activity -toggle_rate .25 -glitch_rate .05* \\ *-base_clock CLK -static_probability .015 -type inputs*

The toggle rate value of 0.25 and glitch rate value of 0.05 are divided by clock period (10). The resulting toggle rate value of 0.025 and glitch rate value of 0.005 are annotated on the design objects.

In the following example, the tool annotates the state_condition dependent static probabilities on the cell or1:

```
pt_shell> set_switching_activity -static_probability 0.10 \\
           -state_condition "A & B" [get_cell or1]

pt_shell> set_switching_activity -static_probability 0.25 \\
           -state_condition "A & ! B" [get_cell or1]

pt_shell> set_switching_activity -static_probability 0.25 \\
           -state_condition "! A & B" [get_cell or1]

pt_shell> set_switching_activity -static_probability 0.30 \\
           -state_condition "! A & ! B" [get_cell or1]

pt_shell> set_switching_activity -static_probability 0.10 \\
           -state_condition "default" [get_cell or1]
```

In the following example, the tool annotates simple and path dependent toggle rates and glitch rates on the output pin Y of the cell xor1:

```
pt_shell> set_switching_activity -toggle_rate 0.022 -glitch_rate 0.001 \\
           [get_pin xor1/Y]

pt_shell> set_switching_activity -toggle_rate 0.020 -glitch_rate 0.001 \\
           -path_sources "A" -state_condition "B" [get_pin xor1/Y]

pt_shell> set_switching_activity -toggle_rate 0.002 -glitch_rate 0.0001
 \\
           -path_sources "B" -state_condition "A" [get_pin xor1/Y]

pt_shell> set_switching_activity -toggle_rate 0.002 -glitch_rate 0.0001
 \\
           -path_sources "A B" -state_condition "default" [get_pin
 xor1/Y]
```

In the following example, the command annotates a toggle rate which is a fraction of the related clock on all the clock-gating cells.

```
pt_shell> set_switching_activity -clock_derate 0.1 \\
           -clock_domains [all_clocks] \\
           -type clock_gating_cells
```

The clock-gating cell outputs are annotated with a toggle rate which is 0.1 of the input clock toggle rate. If the input clock period is 10ns, its toggle rate is 2 toggle/10ns = 0.2 and the toggle rate on the clock gating output is 0.1 * 0.2 = 0.02.

In the following example, the "force" option is used. The command annotates a static probability of 1.0 and toggle rate of 0 on the A2 pin of cell "and_gate". The force value of 1 should match the value of static probability in the command.

Feedback

```
pt_shell> set_switching_activity -force 1 \\
            -toggle_rate 0 -static_probability 1.0  [get_pin and_gate/A2]
```

set_synth_options

Specify RTL Architect commands to be executed before compile.

Syntax

int *set_synth_options*

```
[-file file_name]
[-cmds cmd_list]
[-synth_mode mode_name]
```

Data Types

```
file_name       string
cmd_list        list
mode_name       string
```

Arguments

`-file file_name`

Specifies tcl file which contains tcl commands to be executed before compile.

`-cmds cmd_list`

if number of tcl commands is small, specify commands directly instead of creating separate file.

`-synth_mode mode_name`

Use the -synth_mode option for logical and physical mode of synthesis. Logical mode: Used for quick clock gating analysis and lint checks. Physical mode: Used for full timing and physical aware synthesis along with the clock gating analysis and lint checks. The default is physical mode.

Feedback

Description

The *set_synth_options* command pass RTL Architect tcl commands to be executed before compile. Use this command for most of RTL Architect options which are related with SDC, Timing, Clock Gating, MultiBit, Scenario and DFT.

Examples

The following example shows how to pass RTL Architect setting.

```
pwr_shell> set_synth_options -file tz_setup.tcl
```

See Also

- set_rtl_architect_shell
- set_presynth_options
- set_postsynth_options

---

set_synth_output_dir

Specify output directory.

Syntax

int *set_synth_output_dir*

```
        dir_name
```

Data Types

```
dir_name        string
```

Arguments

dir_name

Specifies output directory for all temporary files and result files. Usually it is relative path to current working directory.

Feedback

Description

The *set_synth_output_dir* command specifies output directory for all temporary files and result files.

Examples

The following example shows how to specify output directory

```
pwr_shell> set_synth_output_dir PP_WORKSPACE
```

---

set_synth_phy_tech_file

Specify LEF technology file for NDM design database

Syntax

int *set_synth_phy_tech_file*

```
[-ndm]
file_name
```

Data Types

```
file_name       string
```

Arguments

file_name

Specifies the name of the LEF technology file. if *-ndm* is specified, user can specify NDM library for technology setting.

Feedback

`-ndm`

Given file format is NDM library.

Description

The *set_synth_phy_tech_file* command pass LEF technology file to synthesis module. if *-ndm* is specified, PrimePower RTL will use technology settings from given NDM library.

Examples

The following example shows how to setup LEF techlogy file

```
pwr_shell> set_synth_phy_tech_file full_path_to/techfile.tech
```

set_synth_ref_libs

Specify NDM reference libraries for synthesis

Syntax

int *set_synth_ref_libs*

```
[-power_libs file_list]
file_name ...
```

Data Types

```
file_list       list
file_name       string
```

Feedback

Arguments

file_name

Specifies the name of the NDM reference library for synthesis. PrimePower RTL honor *search_path* to find actual location of file.

-power_libs *file_list*

Specifies list of db files for power analysis in PrimePower RTL PrimePower RTL honor *search_path* to find actual location of file.

Description

The *set_synth_ref_libs* command collect NDM reference libraries to synthesis module. Use *-power_libs* option if user want to use different libraries for power analysis purpose. These libraries have higher priority than NDM reference libraries during design linking.

You can automatically generate fusion libraries for RTL synthesis. To build a Fusion Library, use the set_synth_ref_libs command with the following options:

Option Description

-lc_shell Path to the Library Compiler shell (mandatory)

-lc_tech_file To specify tech file used for Library Compiler (optional)

-lc_lef_files To specify LEF files used for Library Compiler (optional)

Examples

The following example shows how to setup NDM reference libraries

```
pwr_shell> set_synth_ref_libs A_ff.ndm B_ff.ndm

The following example shows how to specify db files for power analysis.

pwr_shell> set_synth_ref_libs -power_libs { a.db b.db } a_full.ndm
 b_full.ndm

The following example generates a complete fusion library using tech file
 and LEF files.

pwr_shell> set_synth_ref_libs -lc_shell"abc/lc_shell" -lc_tech_file
 "ts16nc.tf" -lc_lef "LEF/*.lef" ts16ncfslogl16hdl090f_ffg0p88v125c.db
 ts16ncfslogl16hdl090f_ffgnp0p88v0c.db

The following example generates a physical-less Fusion Library without
 LEF files:

pwr_shell> set_synth_ref_libs -lc_shell"abc/lc_shell"
 ts16ncfslogl16hdl090f_ffg0p88v125c.db
 ts16ncfslogl16hdl090f_ffgnp0p88v0c.db
```

```
The following example shows how to specify pre-built fusion libraries as
reference libraries using the set_synth_ref_libs command

pwr_shell> set_synth_ref_libs flibs/ts16ncfslogl16hdl090f_c
```

---

set_synth_rtl_files

Specify RTL files for synthesis

Syntax

int *set_synth_rtl_files*

```
-top_module module_name
[-list_file file_name]
[-format lformat]
[-top_rtl file_name]
file_name ...
```

Data Types

```
module_name     string
file_name       string
lformat         string
```

Arguments

file_name

Specifies the name of the Verilog/SystemVerilog RTL files for synthesis.

-top_module *module_name*

Specifies top module name.

`-list_file` *`file_name`*

Specifies optional text file contains RTL file names. PrimePower RTL supports two type of list file. For *plain* format file, it contains single file name per each line. For *vcs* format file, it supports VCS list file format. Refer VCS Users manual for detail.

`-format` *`lformat`*

Format of list file. *plain* or *vcs*. Default is *plain*. For VHDL RTL file, use vcs format file list to specify these files.

`-top_rtl` *`file_name`*

Specifies top level RTL file. It is required option for vcs format of list file.

Description

The *set_synth_rtl_files* command collect RTL file related information to synthesis module especially analyze stage. Use vcs format of list file which provides most flexible and powerful features.

Examples

The following example shows how to setup two verilog files.

```
pwr_shell> set_synth_rtl_files -top_module top top.v alu.v
```

```
The following example shows how to specify vcs file list file.
```

```
pwr_shell> set_synth_rtl_files -top_module top -format vcs -list_file
 manifest.f -top_rtl full_path_to/top.v
```

Feedback

set_target_library_subset

Sets target library subset specifications on the top-level design or hierarchical cells.

Syntax

status *set_target_library_subset*

```
[-objects objects]
[-top]
-dont_use lib_cells
```

Data Types

objects	list or collection
lib_cells	list or collection

Arguments

`-objects objects`

Specifies the hierarchical cells on which to apply the *dont_use* restrictions.

The restrictions also implicitly apply to the cell's children, if they are not explicitly assigned their own restrictions.

If you do not specify this option or the -top option, the tool uses the -top option by default.

`-top`

Sets the target library subset on the top block. The subset also applies to all cells in the hierarchy, if they are not explicitly assigned their own target library subsets.

If you do not specify this option or the -objects option, the tool uses the -top option by default.

`-dont_use lib_cells`

Specifies the library cells that cannot be used for optimization within the specified objects. This is a required option.

The library cells must exist in the reference library list. You can specify library cells by name, such as "mylib/AN2", or by collections, such as "get_lib_cells */AN2". You can also use wildcards. Wildcards are expanded according to the library cells in memory at the time the command is issued.

Description

This command sets the target library subset on the top block and hierarchical cells. Target library subsets restrict optimization on the specified objects to a subset of library cells.

Feedback

Optimization is constrained by the target library subsets on the top block and hierarchical cells. During optimization, a library cell is selected from the reference libraries. The *set_target_library_subset* command allows you to specify or filter the library cells considered within the specified objects. The subset restriction applies only to cells that are created or modified during optimization. The subset does not affect existing, unoptimized portions of the block.

A subset applied at a lower level completely overrides a subset applied at a higher level.

Use the *remove_target_library_subset* command to remove the target library subset from a top block or hierarchical cell.

Use the *report_target_library_subset* command to report the target library subset of a top block or hierarchical cell.

Examples

The following example sets a target library subset on the top-level design.

```
prompt> set_target_library_subset -top \\
   -dont_use  [get_lib_cells lib2/AND*]
```

The following example sets a target library subset on a hierarchical cell.

```
prompt> set_target_library_subset -objects [get_cells top/mid] \\
   -dont_use  [get_lib_cells lib2/INV*]
```

See Also

- report_target_library_subset
- remove_target_library_subset

---

set_temperature

Applies an operating temperature on a list of cell objects.

Syntax

int *set_temperature*

```
max_case_temperature
[-min min_case_temperature]
-object_list list_of_cells
```

Data Types

```
max_case_temperature      float
min_case_temperature      float
list_of_cells             list
```

Feedback

Arguments

max_case_temperature

Specifies the operating temperature for the maximum (worst) case.

-min *min_case_temperature*

Specifies the operating temperature for the minimum (best) case.

-object_list *list_of_cells*

Specifies the list of cells that have the operating temperatures as specified in this command.

Description

Defines the operating temperature on the cells so that these cells of the design are timed and optimized at the specified temperature. If you do not specify any operating temperature for the cells, they continue to be timed and optimized based on the available operating condition settings.

If *temperature_ranges* are specified for a cell, the operating temperatures of the cell must fall within one of the ranges specified in the *temperature_ranges*. Furthermore, *min_case_temperature* must fall within the same range as the *max_case_temperature*.

The operating temperature of a cell, once defined, can only be overridden with the *set_temperature* command used on a cell. It can also be cleared using the *reset_design* command.

Examples

The following example shows a typical context for using the *set_temperature* command, and has the max_case_temperature set at 125 on cell I1:

```
pt_shell> set_temperature 125 \\
           -object_list [get_cells I1]
1
```

The following example sets a max_case_temperature of 125 and min_case_temperature of 25 on cell I2.

```
pt_shell> set_temperature 125 \\
         -min 25 \\
         -object_list [get_cells I2]
1
```

See Also

- set_voltage

Feedback

set_timing_budget

Specifies the budget allocation mode, and provides detailed controls

Syntax

status *set_timing_budget*

```
[-mode pin_slack | clock_period]
[-slack_margin margin_value]
[-positive_slack_margin margin_value_for_positive_slack]
[-target_slack target_slack_value]
[-delay_value segment_delay_value]
[-percent_value percent_value]
[-max]
[-min]
[-rise]
[-fall]
[object_list]
```

Data Types

margin_value	float
margin_value_for_positive_slack	float
target_slack_value	float
segment_delay_value	float
percent_value	float
object_list	list

Arguments

`-mode pin_slack | clock_period`

Specifies whether the budget computation is based on the slack or the clock cycle time of the critical path through each hierarchical pin that has context captured. Please note that this option is a global setting and cannot be used with any other options that require objects, including *-delay_value*, *-percent_value*, *-max*, *-min*, *-rise*, *-fall*, *object_list*.

`-slack_margin`

Specifies a margin for negative slack paths under pin_slack mode. Please note that this option is only valid for pin_slack mode, and it can't be used together with *object_list* options.

`-positive_slack_margin`

Specifies a margin for postive slack paths under pin_slack mode. This option can be used only with the *-slack_margin* options.

`-target_slack`

Specifies a target slack value for a path segment. Please note that this option will only work for feed-through segments.

`-delay_value`

Specifies a pre-defined value as the budget of given blocks or pins. This option can be used only with the *object_list* options.

`-percent_value`

Specifies a pre-defined percentage of the clock time as the budget of given blocks or pins. Please note that this option is only valid for clock_period mode. And this option can be used only with the *object_list* options.

`-max`

Applies the configurations only when calculating budget on timing paths with max delay constraint. This option can be used only with the *object_list* options.

`-min`

Same as the *-max* option, except that the paths must be with min delay constraint. This option can be used only with the *object_list* options.

`-rise`

Applies the configurations only when calculating budget on rising timing paths. This option can be used only with the *object_list* options.

`-fall`

Applies the configurations only when calculating budget on rising timing paths. This option can be used only with the *object_list* options.

`object_list`

Specifies a list of block instances or hierarchical pins affected by the command. By default, the command modifies the context of all blocks and pins for which the context is being generated. This option can't be used with the *-mode* option.

Description

This command is used to either specify the global mode of budget allocation or to provides detailed controls for budget computation of certain segments. 1. *-mode* is to globally control the way of budget computation - pin_slack or clock_period based, while *-slack_margin* and *-positivere_slack_margin* are used to tighten or relax the slack specifically when pin_slack mode is specified.

1. Fine control for block segments are achieved through options *-delay_value*, *-percent_value* and *-target_slack*. When *-delay_value* or *-percent_value* is specified, the budget of related segments will be fixed to the value provided. When *-target_slack*

Feedback

is specified, the target slack of related segments will be fixed to the provided value, and their corresponding budgets will also be shifted accordingly. Segments with either option specified won't be considered for automatic allocation anymore. When multiple options are specified on the same segment, their priority order is *-delay_value* > *-percent_value* > *-target_slack*

2. Please note that for min delay type timing paths, only pin_slack mode can be used.

Examples

The following example specifies pin_slack mode for all blocks.

```
pt_shell> set_timing_budget -mode pin_slack
```

The following example specifies the pin_slack mode, and specifies a margin value for paths with negative slacks in the meantime.

```
pt_shell> set_timing_budget -mode pin_slack -slack_margin 1
```

The following example is same with above example, except that it also specifies a target slack value for all feed-through segments.

```
pt_shell> set_timing_budget -mode pin_slack -slack_margin 1 -target_slack
 -2
```

The following example specifies a target slack for a given block.

```
pt_shell> set_timing_budget -mode pin_slack
pt_shell> set_timing_budget -target_salck 1 blk1
```

The following example specifies a fixed budget value for path segments begin with blk1/i1.

```
pt_shell> set_timing_budget -mode pin_slack
pt_shell> set_timing_budget -delay_value 10 blk1/i1
```

---

set_timing_derate

Adjusts the calculated cell and net delays by a specified factor to add margin for on-chip variation effects.

Syntax

integer *set_timing_derate*

```
-early | -late
[-rise] [-fall]
[-data] [-clock]
[-cell_delay] [-net_delay] [-cell_check]
[-static] [-dynamic]
[-aocvm_guardband]
[-pocvm_guardband]
[-pocvm_subtract_sigma_factor_from_nominal]
[-pocvm_coefficient_scale_factor]
[-increment]
[-min_period]
[-min_pulse_width]
[-sms_scenarios sms_scenarios_list]
derate_value
[object_list]
```

Data Types

derate_value	float
object_list	list
sms_scenarios_list	collection

Arguments

`-early`

Applies the derating to the early delays (shortest paths), such as cell and net delays in the data path of a hold check.

The command must specify either *-early* or *-late*. To set both early and late derating, use two separate *set_timing_derate* commands.

`-late`

Applies the derating to the late delays (longest paths), such as cell and net delays in the data path of a setup check.

`-rise`

Applies the derating only to cell and net delays that end with a rising transition.

By default, both rising and falling delays are derated. To specify different derating values for rising and falling delays, use two separate *set_timing_derate* commands.

`-fall`

Applies the derating only to cell and net delays that end with a falling transition.

`-data`

Applies the derating only to delays in data paths. By default, delays are derated in both data paths and clock paths. To specify different derating values for data paths and clock paths, use two separate *set_timing_derate* commands.

`-clock`

Applies the derating only to delays in clock paths.

`-cell_delay`

Applies the derating only to cell delays. By default, derating applies to both cell and net delays, but not to cell timing check constraints.

`-net_delay`

Applies the derating only to net delays.

`-cell_check`

Applies the derating to cell timing check constraints instead of delays. Derating set with the *-early* option applies to hold and removal timing checks. Derating set with the *-late* option applies to setup and recovery timing checks. The *-cell_check* option cannot be used with the *-clock*, *-data*, *-cell_delay*, *-net_delay*, or *-aocvm_guardband* options.

`-static`

Applies the derating to only the static component of net delay, which is the net delay without considering crosstalk. This option works only with the *-net_delay* option. By default, both the static and dynamic delay components are derated.

`-dynamic`

Applies the derating to only the dynamic component of net delay, which is the change in delay (delta delay) caused by crosstalk. This option works only with the *-net_delay* option and cannot be used with the *-aocvm_guardband* or *-pocvm_guardband* option.

`-aocvm_guardband`

Applies the derating on top of advanced on-chip variation (AOCV) derating. The total derating applied to a timing arc is the product of the AOCV derating factor and the AOCV guardband factor.

This option has an effect only when the *timing_aocvm_enable_analysis* variable is set to *true*, and only affects the timing arcs derated by AOCV analysis. The *-aocvm_guardband* option cannot be used with the *-dynamic* or *-cell_check* option.

`-pocvm_guardband`

Applies the derating on top of parametric on-chip variation (POCV) analysis. The specified derating factor applies to both the mean and standard deviation of the statistical delay distribution.

This option has an effect only when the *timing_pocvm_enable_analysis* variable is set to *true*, and only affects the timing arcs analyzed by POCV analysis. The *-pocvm_guardband* option cannot be used with the *-dynamic* option.

`-pocvm_subtract_sigma_factor_from_nominal`

In POCV analysis, modifies the nominal value of constraint arcs of the cell instances or library cells specified by the *object_list* argument. This option can be used only with the *-cell_check* option, which modifies cell timing check constraints.

This option be applied prior to other "cell check" derating factors, such as *-pocvm_coefficient_scale_factor* and *-pocvm_guardband*.

When you use the *-pocvm_subtract_sigma_factor_from_nominal* option, the command multiplies the *derate_value* argument by the intrinsic (i.e. LVF) standard deviation of the constraint arc distribution, then subtracts the result from the existing nominal value to obtain a new nominal value.

When the library vendor has already added the standard deviation (or some fraction or multiple of it) to the nominal value, you can use this option to restore the original nominal value.

This option modifies the nominal value of the constraint arc distribution by using the standard deviation but does not affect the standard deviation itself. To modify the standard deviation, use the *-pocvm_coefficient_scale_factor* option.

`-pocvm_coefficient_scale_factor`

Applies the derating to the variation coefficient C of the statistical delay distribution in POCV analysis. This effectively scales the sigma without affecting the mean. This option has an effect only when the *timing_pocvm_enable_analysis* variable is set to *true*, and only affects the sigma of timing arcs analyzed by POCV analysis. The *-pocvm_coefficieint_scale_factor* option cannot be used with the *-dynamic* option.

To report the settings for AOCV guardband, POCV guardband, or POCV coefficient scaling, use the *report_timing_derate* command with the *-aocvm_guardband*, *-pocvm_guardband*, or *-pocvm_coefficient_scale_factor* option.

`-increment`

Applies an incremental derate setting that is added to the baseline derate settings.

Incremental derates allow you to adjust derate settings without completely replacing them. For details, see "Incremental Derate Values" below.

The *-increment* option cannot be used with AOCV/POCV options (*-aocvm_guardband*, *-pocvm_guardband*, and *-pocvm_coefficient_scale_factor*) in the same *set_timing_derate* command.

The incremental derate can be used to derate the mean delay in POCV and other derate flows.

`-min_period`

Applies the derating to cell's minimum period constraint timing check. The *-min_period* option can be used only with *-rise* or *-fall* options. *-rise* derate is used for derating rising-edge to rising-edge period, and *-fall* derate is used for derating falling-edge to falling-edge period.

To report the minimum period derating settings, use the *report_timing_derate* command with the *-min_period* option. To see the impact of derating use *report_min_period* command with *-derate* option for derate numbers.

`-min_pulse_width`

Applies the derating to cell's minimum pulse width constraint timing check. The *-min_pulse_width* option can be used only with *-rise* or *-fall* options. Derate specified with *-rise* is for derating high pulse width and *-fall* derate is used for derating low pulse width.

To report the minimum pulse width derating settings, use the *report_timing_derate* command with the *-min_pulse_width* option. To see the impact of derating use *report_min_period* command with *-derate* option for derate numbers.

`derate_value`

Specifies the derating value. This value is multiplied by the calculated cell and net delays (or timing constraint values if the *-cell_check* option is used), or added to the existing derating factor if the *-increment* option is used.

`object_list`

Specifies a list or collection of cells, library cells, or nets. The derating factor applies only to the specified objects. By default, the derating factor applies to all cell and net delays in the current design.

If settings applied to different object types overlap in scope, the setting with the narrowest object scope takes precedence. For details, see "Conflicting Derate Settings" below.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this timing derate is applied. When this option is not given the timing derate applies for all SMS scenarios.

This option is used for SMVA or SMC analysis and is currently only supported for cells and nets. This collection is created by *get_sms_scenarios*.

Description

The *set_timing_derate* command modifies calculated delays, allowing you to model on-chip variation effects. The effect is to multiply the calculated early and late delays by factors that you specify, which changes the delay and slack values reported by the *report_timing* command and other reporting commands.

The *set_timing_derate* command specifies the early or late delay adjustment factor and optionally the scope of the design affected by derating. For example,

```
pt_shell> set_timing_derate -early 0.9
pt_shell> set_timing_derate -late 1.2
```

The first command decreases all early (shortest-path) cell and net delays by 10 percent, such as those in the data path of a hold check. The second command increases late (longest-path) cell and net delays by 20 percent, such as those in the data path of a setup check. These two adjustments result in a more conservative analysis.

Using the *set_timing_derate* command implicitly changes the tool to on-chip variation mode, if not already in that mode, like using the following command:

pt_shell> *set_operating_conditions -analysis_type on_chip_variation*

In on-chip variation mode, the tool applies worst-case delay adjustments (both early and late) at the same time. For example, for a setup check, it applies late derating on the launch clock path and data path, and early derating on the capture clock path. For a hold check, it does the opposite.

In the *set_timing_derate* command, you must use either *-early* or *-late* to specify either shortest-path or longest-path delays for applying the derating. To set both early and late derating, use two separate *set_timing_derate* commands.

You must also specify the derating factor, which is a floating-point number. For a more conservative analysis that adds margin for on-chip variation effects, use a derating factor less than 1.0 for early derating or greater than 1.0 for late derating.

To report derating that has been set, use the *report_timing_derate* command.

To report the derating factor used for each incremental delay in a timing report, use the *-derate* option in the *report_timing* command:

```
pt_shell> report_timing -derate
 ...

 Path Type: max

 Point                                          Derate    Incr       Path
 ---------------------------------------------------------------------------
```

```
clock PCI_CLK (rise edge)                                  0.000     0.000
clock network delay (propagated)                           1.802     1.802

I_ORCA_TOP/I_PCI_CORE/pad_en_reg/Q (sdcrq1)      1.200     0.485 &   2.287 r
U7/I (inv0d1)                                    1.200     0.010 &   2.297 r
U7/ZN (inv0d1)                                   1.100     0.063 &   2.360 f
U62/I (inv0d1)                                   1.100     0.005 &   2.365 f
U62/ZN (inv0d1)                                  1.200     0.046 &   2.410 r
U63/A2 (or02d7)                                  1.200     0.005 &   2.415 r
U63/Z (or02d7)                                   1.200     0.318 &   2.733 r
...
```

To remove all derating, use the *reset_timing_derate* command.

Derating Options

By default, the *set_timing_derate* command applies the specified early (or late) derating factor to all cell and net delays in early (or late) timing path segments in the design. You can optionally modify the scope of the command in several ways:

- To derate only clock paths or only data paths, use the *-clock* or *-data* option.
- To derate only net delays or only cell delays, use the *-net_delay* or *-cell_delay* option.
- To derate only rising-edge delays, use the *-rise* option. Then the derating applies only to cell and net delays that end with a rising transition. Similarly, to derate only falling-edge delays, use the *-fall* option.
- To derate only certain nets, cell instances, or library cells, enter an object list in the command. You can use an embedded *get_nets*, *get_cells*, or *get_lib_cells* command to generate the list.
- To derate only the static or dynamic component of net delay, use the *-net_delay* option together with the *-static* or *-dynamic* option. By default, both the static and dynamic components are derated. The static component is the net delay without considering crosstalk. The dynamic component is the change in net delay (delta delay) caused by crosstalk.
- To derate cell timing check constraints instead of delays, use the *-cell_check* option. Derating set with the *-early* option applies to hold and removal timing checks. Derating set with the *-late* option applies to setup and recovery timing checks. A *derate_value* greater than 1.0 increases the value of the timing constraint, resulting in a more conservative check. By default, cell timing checks are not derated.
- To apply derating to advanced on-chip variation (AOCV) analysis or parametric on-chip variation (POCV) analysis, use the *-aocvm_guardband*, *-pocvm_guardband*, or *-pocvm_coefficient_scale_factor* option. By default, the *set_timing_derate* command affects ordinary cell and net delays, not AOCV or POCV analysis.

To report the derating options that have been set, use the *report_timing_derate* command. For example,

```
pt_shell> report_timing_derate -significant_digits 2
 ...
                          ----- Clock -----             ----- Data -----
                        Rise          Fall           Rise
 Fall
                     Early  Late    Early  Late    Early  Late    Early
 Late
-------------------------------------------------------------------------

```

If you set derating on a net or leaf-level cell, the command implicitly matches the derating type to the object type: net derating for a net, or cell derating for a leaf-level cell. Derating set on a net applies to the whole net, even as it crosses into a lower level of hierarchy.

To set derating on a hierarchical cell, you must explicitly specify the type of derating by using the *-net_delay* or *-cell_delay* option (or both), or the *-cell_check* option.

If the *timing_use_constraint_derates_for_pulse_checks* variable is set to *true*, then a legacy derating method is used for *min_period* and *min_pulse_width* checks. For details, see the variable man page.

Conflicting Derating Settings

A new *set_timing_derate* command overrides any derating setting previously applied to that object.

If settings applied to different object types overlap in scope, the setting with the narrowest object scope (not the worst value) takes precedence:

- Leaf cell or net derate
- Library cell derate

- Derate applied to lowest-level enclosing hierarchical cell
- Global derate

In the following script example, the earlier commands are more specific in scope than the later ones, so the earlier ones have priority.

```
# Derate a collection of cell instances
set_timing_derate -late -cell_delay 1.4 [get_cells U2*]
#
# Derate a collection of library cells
set_timing_derate -late -cell_delay 1.3 [get_lib_cells libAZ/ND*]
#
# Derate all cell delays
set_timing_derate -late -cell_delay 1.2
#
# Derate the design (all cell and net delays)
set_timing_derate -late -1.1
```

When scaling libraries are used, and you set derating on a library cell object, the tool uses the derating value set on the library cell in the link library. To avoid ambiguity or conflict, it is recommended that you set the same derating values on the same library cell in all libraries that belong to the scaling library group.

Incremental Derate Values

To adjust derate settings without completely replacing them, two independent components of derate can be applied:

- Baseline derate
  - Specified by *set_timing_derate* or computed by the tool (such as in POCV analysis)
  - Defaults to *1.0*
- Incremental derate
  - Specified by *set_timing_derate -increment*
  - Defaults to *0.0*

When the tool computes the final derate for analysis, the incremental value is added to (not multiplied by) the baseline derate value.

Baseline and incremental derate settings can be independently applied to multiple object scopes (cells, library cells, or nets) and conditions (*-cell_delay*, *-net_delay*, *-rise*, *-fall*, and so on).

Object scope precedence is applied independently to baseline and incremental derate settings. The winning baseline derate is determined, then the winning incremental derate is determined, then both winning values are summed to compute the final derate.

To report incremental derating settings, use the *report_timing_derate* command with the *-increment* option. To see the composite (combined) derating values applied to individual cell and net delays, use the *report_timing* command with the *-derate* option.

Derating Negative Delays

Delays can be negative in some unusual situations. For example, if a cell's input transition is slow and its output transition is fast, and if the input-to-output delay is very short, the output signal can reach the 50 percent trip point before the input signal, resulting in a negative delay for the cell. A similar situation can occur for a change in net delay caused by crosstalk.

In general, delays are adjusted according to the following formula:

```
delay_new = old_delay + ( (derating_factor - 1.0) * abs(old_delay) )
```

When the delay is a positive value (the usual case), this equation is reduced to:

```
delay_new = old_delay * derating_factor
```

For negative delay, the delay adjustment equation is reduced to:

```
delay_new = old_delay * ( 2.0 - derating_factor )
```

When both the static and dynamic components of a net delay are derated, the two components are derated separately first, and then combined, so that a negative delta delay is properly derated before it is combined with a positive static delay.

Clock to data paths

If a signal is launched from a clock source, it gets a clock derate. I.e. clock to data paths are derated with clock derates.

Examples

The following commands set an early (shortest path) derating factor of 0.70 and a late (longest path) derating factor of 1.05 globally on all cell and net delays the design:

```
pt_shell> set_timing_derate -early 0.70
pt_shell> set_timing_derate -late 1.05
```

The following command sets an early derating factor of 0.75 on a specific net, n123, overriding the global derating factor for net delays:

```
pt_shell> set_timing_derate -net_delay -early 0.75 [get_nets n123]
```

The following command sets an early derating factor of 0.80 for the cell delay of cell instance U1, overriding the global derating factor for cell delays:

```
pt_shell> set_timing_derate -early 0.80 -cell_delay [get_cells U1]
```

The first command below sets a late derating factor of 1.10 on all instances of library cell IV in the library MY_LIB. The next command overrides that setting for one particular instance of that cell, inv82:

```
pt_shell> set_timing_derate -late 1.10 [get_lib_cells MY_LIB/IV]
pt_shell> set_timing_derate -late 1.05 [get_cells inv82]
```

The following command sets a late derating factor on all cells and nets in the hierarchical cell top/H1, including its lower-level hierarchical cells:

```
pt_shell> set_timing_derate -cell_delay -net_delay -late 1.05 [get_cells
 top/H1]
```

The following commands set global late and early derating factors, and then incrementally adjust those settings at particular cell instances:

```
set_timing_derate -late 1.09
set_timing_derate -early 0.91
set_timing_derate -late 1.11 [get_cells u1/u252]
set_timing_derate -increment -late 0.04 [get_cells u1/u252]
set_timing_derate -increment -early -0.03 [get_cells u1/u252]
```

These commands set a late derating factor of 1.15 (1.11 + 0.04) and an early derating factor of 0.88 (0.91 + (-0.03)) for the cell delay of cell u1/u252.

---

set_trace_option

Set an option value controlling behavior of command tracing and output annotation..

Feedback

Syntax

set_trace_option [-command name |-profile profile_metric_types |-memory_threshold threshold |-cpu_threshold threshold |-time_treshold threshold] [-annotate annnotate_type]

string *name* string *annotate_type* list rofile_metric_types *integer threshold*

Arguments

`-command` *`name`*

This option is mutually exclusive with -profile, -memory_threshold, -cpu_threshold, and -time_threshold. The option identifies the command for which annotation option is being set.

`-annotate` *`annotate_type`*

This option is meaningful only when given with the -command option. Set the annotation type of the given command with this option. The allowed values are {annotate, omit}.

The *annotate* option value causes the traced command execution to be annotated to the shell output. If the application supports an output log, the annotation is also output to the output log.

The *omit* option value causes the command execution string to be omitted from output annotation.

`-profile` *`profile_metric_types`*

This option is mutually exclusive with all others. The option sets the currently enabled profile metrics, or "all" if all metrics are enabled. Allowed values are a list of: memory, cpu, time, or the value all to indicate enabling of all metrics, or the value none to indicate disabling of all metrics. If none is given in a list with any other value, it is ignored. The enabled profile metrics are reported with command annotations in the tool output to shell, and to the output log if supported by the tool.

`-memory_threshold` *`threshold`*

This option is mutually exclusive with all others. The option sets the threshold for gathering memory metrics. The profile data annotation will be output at the end of a command inovcation only when the delta memory use for a command invocation matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in kilobyges. The special value -1 unsets the threshold.

Feedback

`-cpu_threshold` *`threshold`*

This option is mutually exclusive with all others. The option sets the threshold for gathering CPU usage metrics. The profile data annotation will be output at the end of a command inovcation only when the delta CPU usage for a command invocation matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in seconds. The special value -1 unsets the threshold. If cpu threshold isunset, then the default threshold of 1 second is used. To effect no threshold, set the threshold to 0 (zero).

`-time_threshold` *`threshold`*

This option is mutually exclusive with all others. The option sets the threshold for gathering elapsed time metrics. The profile data annotation will be output at the end of a command inovcation only when the elapsed time for a command invocation matches or exceeds the threshold. The threshold has no effect on profile data output at the beginning of command invocation when this is enabled. The threshold is expressed in seconds. The special value -1 unsets the threshold. If time threshold is unset, then the threshold for cpu is used.

Description

If a command is given with -annotate option, then the *set_trace_option* command informs the tool on how to behave during command annotation output, which is started with the *annotate_trace* command.

If profile, memory_threshold, cpu_threshold, or time_threshold is given, the the *set_trace_option* configures the behavior of performance profile gathering and the data reported in command annotations to the output.

Examples

The following example sets profile configurations, turns annotation off for the command *get_attribute*, then starts command annotations to the output.

```
prompt> set_trace_topion -profile all
prompt> set_trace_topion -memory_threshold 10
prompt> set_trace_topion -cpu_threshold 30
prompt> set_trace_topion -command get_attribute -annotate omit
prompt> annotate_trace -start -profile on
```

Feedback

set_units

Checks the specified units with the main library units.

Syntax

status *set_units*

```
[-time time_in_sec]
[-capacitance capacitance_in_farad]
[-current current_in_ampere]
[-voltage voltage_in_volt]
[-resistance resistance_in_ohm]
[-power power_in_watt]
```

Data Types

time_in_sec	float
capacitance_in_farad	float
current_in_ampere	float
voltage_in_volt	float
resistance_in_ohm	float
power_in_watt	float

Arguments

`-time` *time_in_sec*

Checks the time unit with the time unit of the main library.

`-capacitance` *capacitance_in_farad*

Checks the capacitance unit with the capacitance unit of the main library.

`-current` *current_in_ampere*

Checks the current unit with the current unit of the main library.

`-voltage` *voltage_in_volt*

Checks the voltage with the voltage unit of the main library.

`-resistance` *resistance_in_ohm*

Checks the resistance unit with the resistance unit of the main library.

`-power` *power_in_watt*

Checks the power unit with the leakage power unit of the main library. The power units can only be checked if power analysis mode is enabled.

Feedback

Description

The *set_units* command checks the specified units with the main library units. The command issues a warning if the specified units do not match the main library units. You can use this command only after linking the design.

The main library units are the design units. The *set_units* command does not set the design units, but it prevents the inadvertent use of the wrong units from different SDC files.

The power units can only be checked if power analysis mode is enabled. This can be done by setting the *power_enable_analysis* variable to *true* and running power related commands, such as *update_power*, *read_vcd*, *read_saif*, and *set_switching_activity*.

To report all units, run the *report_units* command. The *read_sdc* command supports the *set_units* command. The *write_sdc* and *write_script* commands write the *set_units* command as the first command at their output.

The *set_units* command does not affect the output of reporting commands. Reports continue to use the units defined in the main library.

Examples

The following example checks the if the main library time unit is 1ns, capacitance unit is 1pF, current unit is 1mA and voltage unit is 1V.

```
pt_shell> set_units -time ns -capacitance pF -current mA -voltage V
```

The following example checks if the main library capacitance unit is 0.5pF.

```
pt_shell> set_units -capacitance 0.5pF
```

---

set_user_attribute

Sets a user attribute to a specified value on an object.

Syntax

string *set_user_attribute*

```
[-class class_name]
[-quiet]
object_spec
attr_name
value
```

Data Types

```
class_name          string
object_spec         list
attr_name           string
value               string
```

Arguments

`-class class_name`

If the *object_spec* option is a name, this is its class. Allowable values are *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, *lib_pin*, *timing_path*, *clock*, or *lib_timing_arc*.

`-quiet`

Suppresses all report messages.

object_spec

Objects on which to set the attribute. Each element in the list is a collection or a pattern which is combined with the *class_name* option to find the objects.

attr_name

Shows the name of the attribute.

value

Shows the value of the attribute.

Description

The *set_user_attribute* command sets attributes on objects. These attributes are defined with the *define_user_attribute* command.

You cannot set application attributes with this command. Each settable application attribute has a command dedicated to it. For example, the *fanout_load* attribute is set with the *set_fanout_load* command. However, you can still retrieve the values of any application or user-defined attribute using the *get_attribute* command.

Examples

This example defines an attribute 'X' for cells, then sets the value on all cells in this level of the hierarchy.

```
pt_shell> define_user_attribute -type int -class cell X
pt_shell> set_user_attribute [get_cells *] X 30
Set attribute 'X' on 'i1'
Set attribute 'X' on 'i2'
```

To be queried, the attribute must be set on a timing path collection that has been set to a variable, for example,

```
pt_shell> define_user_attribute -classes timing_path -type boolean
 is_special
pt_shell> set mypath [get_timing_paths ...]
pt_shell> set_user_attribute -class timing_path $mypath is_special true
pt_shell> get_attribute $mypath is_special
true
```

This behavior differs from user attributes set on other objects, such as pins, which allow user attributes to be set and queried directly in the design (not stored in a collection variable).

The *get_timing_paths* command constructs a new timing path at every invocation so two timing paths derived from identical get_timing_paths commands and stored in two different collection variables do not share the same user attributes. For example,

```
pt_shell> define_user_attribute comment -type string -class timing_path
pt_shell> set p1 [get_timing_paths]
pt_shell> set p2 [get_timing_paths]
pt_shell> set_user_attribute $p1 comment "Hello world"
pt_shell> get_attribute $p1 comment
Hello world
pt_shell> get_attribute $p2 comment
Warning: Attribute 'comment' does not exist on timing_path
 'path' (ATTR-3)
```

---

set_user_units

This command sets the units that are used for user input.

Syntax

string *set_user_units*

```
[-input]
-type unit_type
-value unit_value

string unit_type
string unit_value
```

Arguments

`-input`

Set the units for data input such as source and read_sdc.

`-type unit_type`

Specifies the type of unit to set. This is one of "capacitance", "current", "length", "power", "resistance", "time" or "voltage".

`-value unit_value`

Specifies the unit value. For time, equivalent examples would include "1ps", "1.0ps", "1e-12".

Description

This command sets the units that are used for data input. The tool maintains separate units for input and input. There are unit values for time, resistance, capacitance, power, voltage and current.

Examples

The following example sets input units to 10ps, 1kOhm, 1pF, 1V and 1mA.

```
prompt> set_user_units -type time -value 10ps
prompt> set_user_units -type resistance -value 1kOhm
prompt> set_user_units -type capacitance -value 1pF
prompt> set_user_units -type voltage -value 1V
prompt> set_user_units -type current -value 1mA
```

The following example sets input time units to 1ps.

```
prompt> set_user_units -input -type time -value 1ps
```

---

set_vector_generation_options

Sets the options for vector free vector generation.

Syntax

integer *set_vector_generation_options*

```
[-enable_activity true | false]
[-propagate_zero_activity_nets true | false]
[-event_start_time event_start_time]
[-time_unit ps | ns]
[-retention_mode save | restore]
[-seed_objects object_list]
[-number_of_cycles number_of_cycles]
[-clock object_list]
[-include_ports true | false]
[-events_on_pins true | false]
[-events_on_user_specified_nets_only true | false]
[-special_nets object_list]
[-toggle_percentage toggle_percentage]
[-reset]
```

Data Types

event_start_time	integer
object_list	list
number_of_cycles	integer
toggle_percentage	float

Arguments

`-enable_activity`

Enables using switching activity and state probability to guide single cycle vector generation. Default is true. This option is not honored in multi-cycle vector generation.

`-propagate_zero_activity_nets`

Treats zero switching activity nets as logic constant nets, and propagate the logic forward and backward during vector generation. Default is true.

`-event_start_time`

Specifies start time for the first event in the VCD file. By default the first event starts at 1 time unit, where the time unit is the time unit in *report_unit* command.

`-time_unit`

Specifies time unit in the VCD file. Default is the time unit in *report_unit*. Accepted option is *ps* or *ns*.

`-retention_mode`

Specifies mode for retention cells during single cycle vector generation. Accepted option value is save or restore. Default is save mode. This option is not honored in multi-cycle vector generation.

`-seed_objects`

Specified a list of cell objects as seeds such that vectors will be generated from those seed objects first.

`-number_of_cycles`

Specifies number of clock cycles during multi-cycle vector generation. This number is based on dominant clock, which is defined as the clock which has most power associated with. Default value is 1, which means default is single cycle vector generation.

`-clock`

Specifies clock object list for multi-cycle vector generation. By default, vectors are generated for cells on all clocks. When clock object list is specified, vectors will only be generated on cells associated with those clocks in the list.

`-include_port`

Enables ports to be included in VCD or FSDB file. Default value is false, which means only RTL nets are included.

`-events_on_pins`

Enables pins to be includes in VCD or FSDB file. Default value is false, which means only RTL nets are included.

`-events_on_user_specified_nets_only`

Enables writing out events for user specified nets only to VCD or FSDB file. Default value is false, which means all RTL nets will be written out. User specified nets are net objects specified in the command *set_net_pattern*. This option is only honored in multi-cycle vector generation.

`-special_nets`

Specifies net objects to be considered in special mode vector generation. When this option is specified, special mode vector generation will be turned on. Vectors will be generated for single clock cycle only. Default is empty list, which means special mode vector generation is off.

`-toggle_percentage`

Specifies percentage of nets to be toggled during special mode vector generation. It is to be used with the option *-special_nets*. Default value is 0, which means none of the nets will be toggling. This is the only option honored in special mode vector generation, and all other options are not honored.

`-reset`

Resets all options in the command to default values.

Description

This command is used to specify options for the command *write_vectors*, while the command *write_vectors* does not take any option. Those options are specified such that different VCD files can be generated where different events are generated.

There are three different types of vectors can be generated, and each one can be specified by corresponding option in this command. Default is single clock cycle vector generation. The second one is multi-cycle vector generation, which is enabled by the option *-number_of_cycles*. The third one is special mode vector generation for single cycle, which is enabled by the option *-special_nets*.

Examples

The following example sets clock gating percentage to 20% instead of default 50%, memory percentage to 25% instead of default 50%, and then invokes the command *write_vectors*.

```
pt_shell> set_clock_gating_percentage -value 0.2
pt_shell> set_memory_percentage -value 0.25
pt_shell> write_vectors rtl.vcd
```

The following example disables using switching activity and state probability for the command *write_vectors*. At the same time it disables propagting zero activity nets. In the second invocation of the command *write_vectors*, it resets all options to default values, and generates a new VCD file.

```
pt_shell> set_vector_generation_options -enable_activity false
pt_shell> set_vector_generation_options -propagate_zero_activity_nets
 false
pt_shell> write_vectors rtl_no_activity.vcd
pt_shell> set_vector_generation_options -reset
pt_shell> write_vectors rtl_default.vcd
```

The following example specifies a list of buffers as seeds for vector generation.

```
pt_shell> set_vector_generation_options -seed_objects [get_cells
 inst_buf*]
pt_shell> write_vectors rtl_default.vcd
```

The following example shows how to generate a 100 cycle VCD file.

```
pt_shell> set_vector_generation_options -number_of_cycles 100
pt_shell> write_vectors 100_cycle.vcd
```

The following example shows how to generate a special mode VCD file, where all nets are considered as special nets, and 75% of those nets are toggling. At the same time, state 0 is set on all clock gating cell enable nets through the command *set_net_pattern*.

```
pt_shell> set_vector_generation_options -special_nets [get_nets -hier]
pt_shell> set_vector_generation_options -toggle_percentage 0.75
pt_shell> set_net_pattern -pattern 0 -object_list [get_nets -of [get_pins
 icg_*/enble]
pt_shell> write_vectors special_mode_75.vcd
```

The following example shows how to utilize the option *-events_on_user_specified_nets_only* to achieve the goal: only random events are generated on primmary ports, and all internal nets will get events propagated including RTL points during power analysis.

```
pt_shell> set_net_pattern -object_list [get_nets -of [get_ports]] -mode
 constraint
pt_shell> set_vector_generation_options -number_of_cycles 100
pt_shell> set_vector_generation_options
 -events_on_user_specified_nets_only true
pt_shell> write_vectors pi.vcd
```

- set_clock_gating_percentage
- set_net_pattern

---

set_voltage

Specifies the operating voltage for a list of power nets or PG pins.

Syntax

int *set_voltage*

```
[-min min_case_voltage]
[-min_dynamic dynamic_min_case_value]
[-dynamic dynamic_max_case_value]
[-object_list list_of_supply_nets]
[-cell cell]
[-pg_pin_name pg_pin]
```

```
[-reference_name voltage_level_name]
[-reset]
max_case_voltage
[-nominal nominal_voltage]
```

Data Types

min_case_voltage	float
dynamic_min_case_value	float
dynamic_max_case_value	float
list_of_supply_nets	list
cell	list
pg_pin	string
max_case_voltage	float
voltage_level_name	string
reset	boolean
nominal_voltage	float

Arguments

`-min` *min_case_voltage*

Specifies the operating voltage for the minimum delay (fastest) case. This is typically larger than the *max_case_voltage* value.

`-min_dynamic` *dynamic_min_case_value*

Specifies the dynamic portion of the full (static+dynamic) min-delay rail voltage value. This is the largest dynamic voltage change, specified as a small positive delta, that can occur in min-delay (high voltage) analysis. For details, see EXAMPLES.

`-dynamic` *dynamic_max_case_value*

Specifies the dynamic portion of the full (static+dynamic) max-delay rail voltage value. This is the largest dynamic voltage change, specified as a small negative delta, that can occur in max-delay (low voltage) analysis. For details, see EXAMPLES.

`-object_list` *list_of_supply_nets*

Specifies a list of supply nets or supply groups on which to set the operating voltage.

`-cell` *cell*

Specifies a cell instance on which to apply the operating voltage for IR drop annotation.

`-pg_pin_name` *pg_pin*

Specifies the name of the PG pin of the cell on which to apply the operating voltage for IR drop annotation purposes.

The *-cell* and *-pg_pin_name* options together specify the power or ground pin of a cell instance on which to apply the operating voltage. These two options are always used together and cannot be used with the *-object_list* option.

max_case_voltage

Specifies the operating voltage for the maximum delay (slowest) case. This is typically less than the *-min min_case_voltage* value.

-reference_name *voltage_level_name*

Specifies the name of the voltage level associated with the supply group object specified with the -object_list option. The reference name is defined using a *set_voltage_levels* command. The specified voltage information is associated with this reference name and is used in SMVA analysis.

-reset

Resets the voltage of the nets specified with optional -object_list option. If object list is not specified, then the voltage of all supplied nets is reset. All other options except object_list are invalid with -reset. After reset, report_supply_net will not show any voltage for the supply nets whose voltage is reset. Please note that if voltage on supply net is reset calculation will fallback to voltage on corresponding PG pins.

-nominal *nominal_voltage*

Specifies an operating voltage for the rail. This should be a nominal value between the *max_case_voltage* value and the *min_case_voltage* value. This option cannot be used with *-cell* option.

Description

This command defines the operating voltage on power nets or PG pins so that the parts of the design powered by these nets are analyzed at the specified voltage. The specified voltage must be consistent with the voltage ranges defined by the UPF commands.

If you do not specify any operating voltage for a power net, the part of the design connected by the power net is analyzed according to the voltage defined under the *voltage_map* attribute in Liberty syntax for the library cell, or by the operating conditions set by the *set_operating_conditions* command.

After you set the operating voltage of a power net with the *set_voltage* command, you can override that setting by using the *set_voltage* command again. The *reset_design* clears all *set_voltage* settings.

When you set the voltage on UPF supply nets, the voltage is set only on the net segments existing at that time that are connected to the supplies specified by the *-object_list* option. Therefore, it is important to load the complete UPF description of the power network before you use the *set_voltage* command.

To check whether any supply net segment is missing a voltage assignment, use the *check_timing -override_defaults supply_net_voltage* command.

Examples

The following command sets the voltages for the supply net named VDD1 for maximum-delay analysis (0.89 volts) and minimum-delay analysis (0.91 volts):

```
pt_shell> set_voltage -object_list VDD1 0.89 -min 0.91
```

The following script defines the supply nets of a power domain and sets specific power and ground voltages for cell instance U18, overriding the supply voltages set by the *create_operating_conditions* and *set_operating_conditions* commands at the design level, or the default supply voltages defined in the library.

```
create_power_domain TOP
create_supply_net VDD -domain TOP
create_supply_net VSS -domain TOP
set_domain_supply_net TOP -primary_power_net VDD \\
                          -primary_ground_net VSS
set_voltage 0.88 -min 1.188 -cell U18 -pg_pin_name PWR
set_voltage 0.04 -min -0.05 -cell U18 -pg_pin_name GND
```

The first *set_voltage* command sets a supply voltage of 0.88 for maximum delay analysis and 1.188 for minimum delay analysis. The second one sets a ground voltage of 0.04 for maximum delay analysis and -0.05 for minimum delay analysis.

The following command specifies the dynamic part of the supply voltage for the supply net named VDD1:

```
pt_shell> set_voltage -object_list VDD1 \\
       0.80   -dynamic     -0.05 \\
  -min 0.90   -min_dynamic  0.02
```

In this example, the operating voltage can vary between 0.80 and 0.90. These are the total (static+dynamic) values. The specified dynamic values are the dynamic components of these total values:

```
total = static + dynamic
```

This maps to the preceding example as follows:

```
Maximum delay analysis:   0.80    =  0.85    +  (-0.05)
Minimum delay analysis    0.90    =  0.88    +  (+0.02)
                          (total) = (static) + (dynamic)
```

During clock reconvergence pessimism removal (CRPR), the tool removes the early/late delay differences leading up to the common point.

For a typical setup path (launch and capture come from different edges in time), CRPR removes the static early/late difference at the common point, but leaves the dynamic early/

late difference in place. Accordingly, CRPR computes the adjustment using static min/max supply voltages along the common path cells so that only the static early/late difference is removed. (This static-only voltage computation occurs entirely within CRPR; arrivals propagation and reporting use static+dynamic values as usual.)

For a typical hold path (launch and capture come from the same edge in time), CRPR removes the static+dynamic early/late difference because the same physical edge cannot be both early and late at the same time. In this case, CRPR computes the adjustment using the full (static+dynamic) min/max supply voltages along the common path cells, so that all of the static+dynamic early/late delay difference at the common point is removed.

set_voltage_levels

Assings a supply group to have multiple voltage levels for SMVA analysis.

Syntax

int *set_voltage_levels*

```
supply_group_list
[-reference_names reference_names_list]
[-reset]
```

Data Types

supply_group_list	string
reference_names_list	list

Arguments

supply_group_list

Specifies the supply groups for which the voltage levels will be set.

`-reset`

Reset the voltage levels to undefined state.

`-reference_names` *`reference_names_list`*

Specifies the reference voltage names associated with the supply groups.

Description

The *set_voltage_levels* command is used to assign multiple voltage levels to a given supply_group. These voltage levels are used in SMVA analysis. The voltage levels get created with labels 'low' and 'high'. In SMVA analysis all combinations of high and low voltage levels of the supply_groups on the path are explored. The supply_groups that don't have voltage levels assigned are treated as fixed voltage in SMVA analysis.

The voltage level assignment can be reported using the report_supply_group command.

Examples

The following example shows a typical usage of the *set_voltage_levels* command:

```
prompt> set_voltage_levels T.primary.power -reference_names { low high }
1
```

See Also

- report_supply_group
- set_voltage

---

set_vsa_margin_table

Defines the margin table consisting of derating factors against different voltages, for a library macro cell that does not have voltage scaling libraries.

Syntax

status *set_vsa_margin_table*

`-cell` *`lib_cell`*
`margin_table`

DATA TYPES

lib_cell string *margin_table* list

Arguments

`-cell` *`lib_cell`*

Specifies a marco cell instance that does not have voltage scaling libraries.

margin_table

The syntax of *margin_table* can be expressed as:

```
{ {VDD1 derating_factor1} {VDD2 derating_factor2} {VDD3
 derating_factor3} ... }
```

Description

When VSA calculates the delay of a marco cell with a set margin table, VSA looks up the table and applies the corresponding derating factor to its delay at the nominal voltage, to get the delay at a specified voltage.

When VSA computes delay at a voltage that is not specified in the margin table, VSA uses interpolation or extrapolation to obtain the derating factor.

An example of margin_table is as follows:

```
{ {0.5 1.10} {0.55 1.05} {0.6 1.0} {0.65 1.03} {0.7 1.8} }
```

When VSA computes slack at *0.55 V*, VSA uses *1.05* as the derating factor.

When VSA computes slack at *0.57 V*, VSA uses *1.02* as the derating factor which is interpolated from *{0.55 1.05}* and *{0.6 1.0}*.

Examples

The following command sets a margin table to a library cell *MACRO*, for voltage slack analysis.

```
pt_shell> set_vsa_margin_table -cell MACRO { {0.5 1.10} {0.55 1.05} {0.6
 1.0} {0.65 1.03} {0.7 1.8} }
```

See Also

- reset_vsa_margin_table

---

set_vt_mistracking_derate

Specifies the derating factors used to model Vt mistracking effects.

Syntax

integer *set_vt_mistracking_derate*

```
-min value
-max value
object_list
[-vt_type name]
```

Data Types

value	float
name	string
object_list	collection

Arguments

`-min` *value*

Specifies the min-delay Vt mistracking derating factor.

`-max` *value*

Specifies the max-delay Vt mistracking derating factor.

object_list

Specifies the collection of *lib_cell* objects to apply the specification to.

`-vt_type` *name*

Specifies a Vt type name. This is a user-defined label that allows the tool to differentiate the specifications.

Description

Vt mistracking effects are modeled by a set of min/max corner derate factors, applied to library cells with this command.

Issue this command once for each Vt class. For each command,

- Specify a user-defined Vt class name with the *-vt_type* option, such as *hvt*, *svt*, or *lvt*.
- Specify the collection of library cells belonging to this Vt class.
- Specify min-delay and max-delay derate factors that model the extent of the Vt mistracking effect.

These Vt mistracking derate specifications are a prerequisite for both bounding Vt mistracking analysis and advanced path-based Vt mistracking analysis.

In bounding Vt mistracking analysis, opposing Vt derate values are applied to the launch and capture sides of timing analysis. This is a pessimistic analysis (same-Vt cells get opposing derates across launch and capture), but it is a bounding analysis that ensures no paths are missed. See the *vt_mistracking_enable_bounding_analysis* man page for details.

In advanced Vt mistracking analysis, the min/max derating values are used to build less pessimistic mistracking models in path-based analysis (PBA):

- In enumeration mode, all min/max Vt-family configurations are explored.
- In Monte Carlo mode, statistical models are used (optionally with user-specified partial correlations).

See the *vt_mistracking_enable_path_analysis* man page for details.

Examples

The following example shows a typical usage of the *set_vt_mistracking_derate* command.

```
prompt> set_vt_mistracking_derate -min 0.95 -max 1.05 -vt_type svt
 [get_lib_cell */*svt*]
prompt> set_vt_mistracking_derate -min 0.96 -max 1.04 -vt_type lvt
 [get_lib_cell */*lvt*]
prompt> set_vt_mistracking_derate -min 0.97 -max 1.03 -vt_type ulvt
 [get_lib_cell */*ulvt*]

prompt> set vt_mistracking_enable_bounding_analysis true
prompt> update_timing -full

prompt> set vt_mistracking_enable_path_analysis true

prompt> set vt_paths \\
          [get_timing_paths \\
            -pba_mode path \\
            -path_type full_clock -nworst 10 \\
            -max_paths 2000000 -slack_lesser_than 0.0]
```

See Also

- vt_mistracking_enable_path_analysis
- vt_mistracking_enable_bounding_analysis

---

set_vt_skew_derate

Specifies the derating factors used to model Vt skew effects.

Syntax

integer *set_vt_skew_derate*

```
-min value
-max value
object_list
[-vt_type name]
```

Feedback

Data Types

value	float
name	string
object_list	collection

Arguments

`-min` *value*

Specifies the minimum-delay Vt skew derating factor.

`-max` *value*

Specifies the maximum-delay Vt skew derating factor.

object_list

Specifies the collection of *lib_cell* objects to apply the specification to.

`-vt_type` *name*

Specifies a Vt type name. This is a user-defined label that allows the tool to differentiate the specifications.

Description

Vt skew effects are modeled by a set of minimum/maximum corner derate factors, applied to library cells with this command.

Issue this command once for each Vt class. For each command,

- Specify a user-defined Vt class name with the *-vt_type* option, such as *hvt*, *svt*, or *lvt*.
- Specify the collection of library cells belonging to this Vt class.
- Specify minimum-delay and maximum-delay derate factors that model the extent of the Vt skew effect.

These Vt skew derate specifications are a prerequisite for both bounding Vt skew analysis and advanced path-based Vt skew analysis.

In bounding Vt skew analysis, opposing Vt derate values are applied to the launch and capture sides of timing analysis. This is a pessimistic analysis (same-Vt cells get opposing derates across launch and capture), but it is a bounding analysis that ensures no paths are missed. See the *vt_skew_enable_bounding_analysis* man page for details.

In advanced Vt skew analysis, the minimum/maximum derating values are used to build less pessimistic skew models in path-based analysis (PBA):

- In enumeration mode, all minimum/maximum Vt-family configurations are explored.
- In Monte Carlo mode, statistical models are used (optionally with user-specified partial correlations).

See the *vt_skew_enable_path_analysis* man page for details.

Examples

The following example shows a typical usage of the *set_vt_skew_derate* command.

```
prompt> set_vt_skew_derate -min 0.95 -max 1.05 -vt_type svt [get_lib_cell
 */*svt*]
prompt> set_vt_skew_derate -min 0.96 -max 1.04 -vt_type lvt [get_lib_cell
 */*lvt*]
prompt> set_vt_skew_derate -min 0.97 -max 1.03 -vt_type ulvt
 [get_lib_cell */*ulvt*]

prompt> set vt_skew_enable_bounding_analysis true
prompt> update_timing -full

prompt> set vt_skew_enable_path_analysis true

prompt> set vt_paths \\
          [get_timing_paths \\
            -pba_mode path \\
            -path_type full_clock -nworst 10 \\
            -max_paths 2000000 -slack_lesser_than 0.0]
```

See Also

- vt_skew_enable_path_analysis

---

set_waveform_integrity_analysis

Sets static or dynamic constraints for waveform integrity analysis.

Syntax

status *set_waveform_integrity_analysis*

```
[-static]
[-dynamic]
[-sms_scenarios sms_scenarios_list]
constraint_value
[object_list]
```

Data Types

constraint_value	float
object_list	list
sms_scenarios_list	collection

Feedback

Arguments

`-static`

Applies the constraint to static waveform integrity analysis.

`-dynamic`

Applies the constraint to dynamic waveform integrity analysis.

`constraint_value`

Specifies the constraint limit (Value >= 0). For static analysis, this should be in library time unit. For dynamic analysis, this should be percentage of the supply voltage.

`object_list`

Specifies a list of cell input pins.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this waveform integrity information is applied. When this option is not given the waveform integrity information applies for all SMS scenarios. This collection is created by *get_sms_scenarios*.

Description

Specifies a constraint limit for waveform integrity analysis. For static analysis, the constraint value is the constraint limit for waveform distortion. If the distorted waveform from the advanced waveform propagation has larger distortion metric than the constraint value, it is reported by the *report_constraint -waveform_analysis static* command.

The distortion metric is calculated in the max time difference between the distorted waveform and its concave bounding waveform at the same voltage level. Thus, the constraint value for static analysis should be in library time units. Note that the static constraint can be set only to the input pins of synchronous elements of the design. Since it requires the waveform, advanced waveform propagation should be enabled for static waveform integrity analysis.

For dynamic analysis, the constraint value is the constraint limit for the aggressor bumps. If the sum of all active aggressors to this input pin is larger than the constraint limit, it is reported by the *report_constraint -waveform_analysis dynamic* command. Thus, the constraint value for dynamic analysis should be a percentage of the supply voltage. Note that the dynamic constraint can be set to any input pins of the design, and it is available only when signal integrity analysis is enabled.

The constraint value is applied to the specified cell input pins. If no pins are specified, the constraint value is applied as a design-level constraint. When both design-level and pin-level constraints are specified, the most restrictive constraint is used.

Feedback

Examples

The following example sets a static constraint of 0.3 library time unit on synchronous input pin DFF/CLK.

```
pt_shell> set_waveform_integrity_analysis -static 0.3 [get_pins DFF/CLK]
```

The following example sets a dynamic constraint of 0.5 on input pin mycell/A.

```
pt_shell> set_waveform_integrity_analysis -dynamic 0.5 [get_pins
 mycell/A]
```

See Also

- remove_waveform_integrity_analysis
- report_waveform_integrity_analysis
- report_constraint

---

set_wire_load_min_block_size

Sets the minimum block area for automatic wire load selection. Any blocks with an area below the minimum are promoted to the minimum.

Syntax

int *set_wire_load_min_block_size*

block_size

Data Types

block_size	float

Arguments

block_size

Minimum block size for auto wire load selection. This float value must be greater than or equal to 0.0.

Description

Specifies the minimum block area for automatic wire load selection in the current design. When automatic wire load selection is enabled, hierarchical cells are assigned wire load models based on their area. Any cells with an area below the minimum block size are assigned the minimum *block_size* value before a wire load model is selected. If the minimum block size is not explicitly set, the default value of 0.0 used.

Feedback

Examples

This example specifies a minimum block size of 1000 area units.

```
pt_shell> set_wire_load_min_block_size 1000
```

See Also

- report_wire_load
- set_wire_load_selection_group
- auto_wire_load_selection

---

set_wire_load_mode

Sets wire load mode for the current design.

Syntax

string *set_wire_load_mode*

mode_name

Data Types

mode_name	string

Arguments

mode_name

Name of mode: *top*, *enclosed*, or *segmented*.

Description

Specifies a wire load mode with the *set_wire_load_mode* command. If the mode for the top level design is *top*, the wire load model on hierarchical cells has no effect, and the top-level wire load model is used to compute wire capacitance for all nets within the design.

If the mode for the top-level design is either *enclosed* or *segmented*, wire load models on hierarchical cells are used to calculate wire capacitance, resistance, and area in nets inside these blocks. If the *enclosed* mode is set, net values are determined using the wire load model of the hierarchical cell which fully encloses the net. If the *segmented* mode is set, segments of the net in each level of hierarchy are calculated separately, and the net value is the total of all segments. Hierarchical boundary pins are included in the pin count for the segment.

If no *wire_load_model_mode* is specified for a design, a default wire load mode is searched for in the first library in the link path. If the library checked does not have a default set, *top* is assumed.

Examples

This example sets the wire load mode to *enclosed* on the current design.

```
pt_shell> set_wire_load_mode enclosed
```

See Also

- report_wire_load
- set_wire_load_model

---

set_wire_load_model

Sets wire load model on designs, ports, or hierarchical cells.

Syntax

int *set_wire_load_model*

```
-name model_name
[-library lib_spec]
[-min]
[-max]
[object_list]
```

Data Types

```
model_name        string
lib_spec          string
object_list       list
```

Arguments

`-name model_name`

Specifies the name of the wire load model; must be a valid wire load model in a library specified in the *link_path* command.

`-library lib_spec`

Specifies the library in which to search for the *model_name* variable. If not specified, libraries in the *link_path* command are searched.

`-min`

Indicates that the model is for minimum conditions.

`-max`

Indicates that the model is for maximum conditions.

`object_list`

Specifies a list of designs, ports, or hierarchical cells. The default is to set the wire model on the current instance, if set; or on the current design otherwise.

Description

Sets the wire load model on designs, ports, or hierarchical cells. The wire load model calculates net capacitance, resistance, and area for designs that have not been placed and routed.

Use automatic wire load selection for the design as another way to specify wire load models. If this is enabled, hierarchical blocks have wire load models assigned automatically based on their cell area.

To remove the wire load model setting, use the *remove_wire_load_model* command.

Examples

The following example specifies a wire load model of "BIG" on the top level design, a model of "MEDIUM" on hierarchical cell "u1", and a model of "SMALL" on hierarchical cell u1/u2.

```
pt_shell> current_design TOP
{"TOP"}
pt_shell> set_wire_load_model -name BIG
1
pt_shell> current_instance u1
u1
pt_shell> set_wire_load_model -name MEDIUM
1
pt_shell> current_instance u2
u1/u2
pt_shell> set_wire_load_model -name SMALL
1
pt_shell> current_instance
Current instance is the top-level of design 'TOP'.
pt_shell>
```

The following example specifies a wire load model of "BIG" on the top-level design, and a model of "SMALL" on all instances of design "adder."

```
pt_shell> current_design TOP
{"TOP"}
pt_shell> set_wire_load_model -name BIG
1
```

Feedback

```
pt_shell> set_wire_load_model -name SMALL [all_instances -hierarchy
 adder]
1
```

The following example sets the external wire load model for ports OUT1* to 70x70, and specifies an external fanout number of 2.

```
pt_shell> set_wire_load_model 70x70 [get_ports OUT1*]
pt_shell> set_port_fanout_number 2 [get_ports OUT1*]
```

See Also

- remove_wire_load_model
- report_lib
- report_wire_load
- set_port_fanout_number
- set_wire_load_mode
- set_wire_load_selection_group
- auto_wire_load_selection
- link_path

---

set_wire_load_selection_group

Sets the wire load selection group for current design.

Syntax

int *set_wire_load_selection_group*

```
[-min]
[-max]
[-library lib_spec]
selection_group_name
[object_list]
```

Data Types

lib_spec	string
selection_group_name	string
object_list	list

Feedback

Arguments

`-min`

Specifies the selection group for minimum conditions.

`-max`

Specifies the selection group for maximum conditions.

`-library` *`lib_spec`*

Specifies the library in which to search for the *selection_group_name* variable. If it is not specified, libraries in the *link_path* command are searched.

`selection_group_name`

Name of the selection group. This must be a valid selection group in a library specified in the *link_path* command.

`object_list`

Provides a list of hierarchical cells or designs. If you do not specify the *object_list* variable, the wire load selection group is set on the current instance, or on the current design if current instance is not set.

Description

Specifies the name of the selection group used when determining the wire load model based on cell area of blocks, when the *auto_wire_load_selection* command is true. This option is required only when the main library has more than one selection group defined, and the default group defined in the library is not the desired group. Automatic wire load selection is supported only for the *enclosed* wire load mode, specified using the *set_wire_load_mode* command.

To remove the wire load selection group setting, use the *remove_wire_load_selection_group* command.

Examples

This example specifies that the selection group named "selgrp1" from library "tech_lib" be applied to the current design.

```
pt_shell> set_wire_load_selection_group selgrp1 -library tech_lib
```

See Also

---

setenv

Sets the value of a system environment variable.

Syntax

string *setenv variable_name new_value*

string *variable_name*

string *new_value*

Arguments

variable_name

Names of the system environment variable to set.

new_value

Specifies the new value for the system environment variable.

Description

The *setenv* command sets the specified system environment *variable_name* to the *new_value* within the application. If the variable is not defined in the environment, the environment variable is created. The *setenv* command returns the new value of *variable_name*. To develop scripts that interact with the invoking shell, use *getenv* and *setenv*.

Environment variables are stored in the Tcl array variable *env*. The environment commands *getenv*, *setenv*, and *printenv* are convenience functions to interact with this array.

The *setenv* command sets the value of a variable only within the process of your current application. Child processes initiated from the application using the *exec* command after a usage of *setenv* inherit the new variable value. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the *exec* command, that value is not reflected in the current application.

Feedback

Examples

The following example changes the default printer.

```
shell> getenv PRINTER
laser1
shell> setenv PRINTER "laser3"
laser3
shell> getenv PRINTER
laser3
```

See Also

- getenv
- printenv
- printvar
- sh

---

sh

Executes a command in a child process.

Syntax

string *sh* [*args*]

```
string args
```

Arguments

args

Command and arguments that you want to execute in the child process.

Description

This is very similar to the *exec* command. However, file name expansion is performed on the arguments. Remember that quoting and grouping is in terms of Tcl. Arguments which contain spaces will need to be grouped with double quotes or curly braces. Tcl special characters which are being passed to system commands will need to be quoted and/or escaped for Tcl. See the examples below.

Examples

This example shows how you can remove files with a wildcard.

```
prompt> ls aaa*
aaa1      aaa2      aaa3
prompt> sh rm aaa*
```

```
prompt> ls aaa*
Error: aaa*: No such file or directory
       Use error_info for more info. (CMD-013)
```

This example shows how to grep some files for a regular expression which contains spaces and Tcl special characters:

```
prompt> exec cat test3.out
blah blah blah
blah blah blah c blah
input [1:0] A;
output [2:0] B;
prompt>
prompt> sh egrep -v {[ ]+c[ ]+} test3.out
blah blah blah
prompt>
prompt> sh egrep {t[ ]+\\[} test3.out
input [1:0] A;
output [2:0] B;
```

---

sh_list_key_bindings

Displays all the key bindings and edit mode of current shell session.

Syntax

string *sh_list_key_bindings*

```
[-nosplit]
```

Arguments

`-nosplit`

Prevents line splitting when column fields overflow.

Description

The *sh_list_key_bindings* command displays current key bindings and the edit mode. To change the edit mode, set the *sh_line_editing_mode* variable in either the .synopsys_pt.setup file or directly in the shell.

The text Ctrl+K is read as 'Control+K' and describes the character produced when you hold the Ctrl key while pressing the K key.

The text META+K is read as 'Meta+K' and describes the character produced when you hold down the Meta key while pressing the K key. The Meta key is labeled Alt on many keyboards. On keyboards with two keys labeled Alt (usually to either side of the space bar), the Alt on the left side is generally set to work as a Meta key. The Alt key on the right can also be configured to work as a Meta key or can be configured as some other modifier, such as a Compose key for typing accented characters.

If you do not have a Meta or Alt key, or another key working as a Meta key, the identical keystroke can be generated by pressing Esc first, and then typing K. Either process is known as metafying the K key.

Alternative key bindings work only in vi alternate(command) mode.

---

show_rule_violation

Displays the violation details for the given rule on the terminal.

Syntax

string *show_rule_violation*

```
        rule
```

Data Types

```
rule              string
```

Arguments

`-rule` *rule*

Specifies the name of an existing rule.

Description

Displays the violation details for each violation of a particular rule along with debugging help. To be used after executing the check_constraints command.

Examples

The following example displays all the violations for rule *EXD_0009*.

```
pt_shell> show_rule_violation -rule EXD_0009
```

See Also

- check_constraints

Feedback

sim_analyze_clock_network

Analyzes a clock network with a SPICE simulator.

Syntax

int *sim_analyze_clock_network*

```
-from from_pins
[-from_rise_slew rise_slew]
[-from_fall_slew fall_slew]
[-output model_file_name]
[-to to_pins]
[-use_probe]
[-min]
[-max]
```

Data Types

from_pins	collection
rise_slew	float
fall_slew	float
model_file_name	string
to_pins	collection

Arguments

`-from` *from_pins*

Specifies a collection of one root pin or port of the clock network. clock network is extracted by tracing from the root until sequential loads are reached. Clock gating cells are included in the clock network. It is essential for you to choose the appropriate root for clock network to satisfy their needs.

`-from_rise_slew` *rise_slew*

Specifies the rise slew at the clock root node in main library units. If specified, it is used for creating input stimulus. Otherwise, slew from PrimeTime is used.

`-from_fall_slew` *fall_slew*

Specifies the fall slew at the clock root node in main library units. If specified, it is used for creating input stimulus. Otherwise, slew from PrimeTime is used.

`-output` *model_file_name*

Specifies the file name in which the results of the simulations are written. It is written in Synopsys Design Constraint format using the *set_annotated_delay*, *set_annotated_transition* and *set_disable_timing* commands. This file is the clock mesh model that can be used for multiple runs on the same design of PrimeTime if clock network has not changed between runs.

`-to` *`to_pins`*

Specifies the collection of pins, when reached, stops the clock network tracing. If one of the load pins of the net is included, other load pins of the net are also automatically included to stop clock network tracing. This option helps control the simulation and back annotation of the clock network logic that is being analyzed.

`-use_probe`

Adds probe points to the SPICE simulation for all pins in the clock network.

`-min`

Runs and annotates only the min analysis.

`-max`

Runs and annotates only the max analysis.

Description

This command extracts the clock network from the specified clock root and invokes the simulator specified by the *sim_setup_simulator* command. The purpose of the command is to create a SPICE deck, link to simulation environment, and back-annotate the results into PrimeTime. The SPICE deck generated is sensitized using the same rules as the *write_spice_deck* command. The input stimulus at the clock root is created based on the clock slew reaching at the root node. If you specify the rise and fall slews, they are used to create the input stimulus. Otherwise, the default rise and fall slews from PrimeTime are used. Only a single clock network can be traced with the specified *from_pins* and *to_pins*.

This command triggers an implicit *update_timing* command to extract timing and sensitization information needed for generating SPICE deck of the clock network.

This command errors out when any of these features are enabled: crosstalk analysis, power analysis, variation analysis, multicore distributed analysis, HyperScale analysis.

The command also errors out when variable timing_reduce_multi_drive_net_arcs is enabled.

Unless the -min/-max options are used, sim_analyze_clock_network will, be default, run only the max analysis and annotate for both min and max.

To use the *sim_analyze_clock_network* command, you must have a PrimeTime SI license.

Examples

The following example analyzes the clock network starting from CLK port and creates a corresponding clock model in clock_model.tcl file.

```
pt_shell> sim_analyze_clock_network -from [get_ports CLK] \\
          -output clock_model.tcl
```

---

sim_analyze_path

Analyzes timing paths by performing SPICE simulation.

Syntax

status *sim_analyze_path*

```
[-sim_mode sim_mode]
[-num_sigma sigma_value]
[-sample_size value]
[-transition_time]
[-variation]
[-crosstalk_delta]
[-derate]
[-significant_digits digits]
[-verbose]
path_objects
```

Data Types

sim_mode	string
sigma_value	float
value	integer
digits	integer
path_objects	collection

Arguments

`-sim_mode` *sim_mode*

Specifies the parts of the timing path to be simulated and analyzed. It can be set to one of the following strings: *launch* (launch segment only), *capture* (capture segment only), or *both*. The default is *both*.

`-num_sigma` *sigma_value*

Specifies the sigma value that is the focus of analysis, from 2.0 to 6.0. If you do not use this option, the *timing_pocvm_report_sigma* variable setting is used, which is 3.0 by default. The *-num_sigma* option works only with the *-variation* option.

`-sample_size` *value*

Specifies the number of Monte Carlo samples used for POCV simulation. If you do not specify the sample size, the command automatically chooses a suitable number based on the *-num_sigma* option setting, if any, or the default sigma value otherwise.

`-transition_time`

Reports the simulated transition times as well as delays. By default, only delays are reported.

`-variation`

Reports POCV simulated corner values as well as nominal values. POCV analysis must be enabled to use this option. By default, only nominal values are reported.

`-crosstalk_delta`

Reports the PrimeTime annotated delta delay values at cell input pins in a column labeled "Delta". By default, delta delays are not reported.

`-derate`

Reports derating factors in a column labeled "Derate". By default, derating values are not reported.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point displayed for time values in the generated report. The default value is 4.

`-verbose`

Reports more details, such as the location of temporary files.

path_objects

Specifies a collection of timing path objects to simulate; -pba_mode path is required. *-path_type full_clock_expanded* is recommended.

Description

The *sim_analyze_path* command performs HSPICE simulation on selected paths. This command is a PrimeShield feature, which requires a PrimeShield license. You must enable PrimeShield analysis (set *ps_enable_analysis* true) before you run simlink commands.

The *sim_analyze_path* command supports two variation simulation modes: full Monte Carlo and fast Monte Carlo. The default is full MC mode, which can require a very long

runtime. To enable the fast MC mode, set the *simlink_enable_fast_monte_carlo* variable to true:

```
pt_shell> set_app_var ps_enable_analysis true
Information: Checked out license 'PrimeShield' (PT-019)
true
pt_shell> set_app_var simlink_enable_fast_monte_carlo true
true
```

For cells that have a higher threshold voltage, the delay variation is larger and more MC samples are needed to make the simulation results converge to a real distribution at a high sigma corner. Fast MC speeds up simulation significantly, while getting accuracy similar to full MC.

By default, *sim_analyze_path* runs HSPICE simulation from the clock reconvergence pessimism (CRP) common point when the *-path_type full_clock_expanded* option is used in the *get_timing_paths* command. It is recommended to get timing paths with these options to make sure simulation is from the CRP point and the clock path is recalculated:

```
pt_shell> set_app_var pba_recalculate_full_path true
 ...
pt_shell> set mypaths \\
 [get_timing_paths -pba_mode path -path_type full_clock_expanded]
 ...
```

The *sim_analyze_path* command reports launch, capture, constraint, and slack using measured results from SPICE simulations whenever possible. When SPICE simulations are not applicable or not available, for example, zero-stage path without driving cell, crosstalk delta, constraint delay, derating factors, PrimeTime computed values are being used.

Before using this command, run the *sim_validate_setup* command to validate the SPICE simulation setup and environment. Incorrect setup often causes correlation problems.

Examples

The following example shows report with *sim_analyze_path* for nominal reporting.

```
pt_shell> sim_analyze_path -transition_time -crosstalk_delta -derate
 $mypaths

sim_corruption_control

Provides the ability to disable the corruptions of a specific set of design elements or types of design elements.

Syntax

string *sim_corruption_control*

```
[-type real | integer | seq | comb | port | process]
[-elements list]
[-exclude_elements list]
[-models model_list]
[-domain domain_name]
[-transitive TRUE | FALSE]
```

Data Types

list	list
model_list	list
domain_name	string
transitive	boolean

Arguments

`-type real | integer | seq | comb | port | process`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-elements list`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-exclude_elements list`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-models model_list`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-domain string`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-transitive TRUE | FALSE`

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

Description

This command exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

Feedback

Examples

The following command selects all real nets that start with L but excludes those that start with L1.

```
prompt> sim_corruption_control -type real
-elements [find_objects . -pattern "L*" -object_type net]
-exclude_elements [find_objects . -pattern "L1*" -object_type net]
1
```

---

sim_enable_si_correlation

Enables signal integrity correlation mode for specific nets.

Syntax

status *sim_enable_si_correlation*

net_list

Data Types

net_list list

Arguments

net_list

Specifies a list of nets for signal integrity SPICE correlation of coupled stage delay or noise. The *net_list* accepts a maximum of 1000 nets.

Description

This command specifies nets for signal integrity SPICE correlation.

To use this command, you must

- Enable crosstalk analysis by setting *si_enable_analysis* to *true*.
- Have PrimeTime SI license
- Follow the recommended settings for SPICE correlation

Feedback

Examples

The following example enables signal integrity correlation on a net and validates coupled stage accuracy on the corresponding net arc.

```
pt_shell> sim_enable_si_correlation [get_nets -of_objects I1/Z]
pt_shell> update_timing -full
pt_shell> sim_validate_stage [get_timing_arc -from I1/Z -to I2/A]
```

The following example enables signal integrity correlation on a net and validates noise bump height and area accuracy on the corresponding net arc.

```
pt_shell> sim_enable_si_correlation [get_nets -of_objects I1/Z]
pt_shell> update_timing -full
pt_shell> update_noise -full
pt_shell> sim_validate_noise -area [get_timing_arc -from I1/Z -to I2/A]
```

sim_replay_control

Specify initial blocks to be replayed when a domain powers up.

Syntax

string *sim_replay_control*

```
[-elements list]
[-exclude_elements list]
[-models model_list]
[-domain domain_name]
[-controlling_domain domain_name]
[-transitive TRUE | FALSE]
```

Feedback

Data Types

list	list
model_list	list
domain_name	string
controlling_domain	string
transitive	boolean

Arguments

`-elements` *list*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-exclude_elements` *list*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-models` *model_list*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-domain` *string*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-controlling_domain` *string*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

`-transitive` *TRUE* | *FALSE*

This option exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

Description

This command exists for compatibility with the Design Compiler and IC Compiler tools. PrimeTime reads and ignore this option.

Examples

The following command selects all initial blocks whose label starts with L but excludes those blocks whose label starts with L1.

```
prompt> sim_replay_control
-elements [find_objects . -pattern "L*" -object_type process]
-exclude_elements [find_objects . -pattern "L1*" -object_type process]
1
```

sim_setup_distributed

Specifies the host options to use for launching HSPICE simulations of multiple paths in parallel.

Syntax

status *sim_setup_distributed*

```
[-mode lsf | csh | grd | nc]
[-sim_per_job number]
[-farm_max_num_pending number]
[-max_job_requeue number]
[-farm_timeout number]
[-submit_command command]
[-pre_run_command command]
[-host_option_name host_option_name]
[-reset]
```

Data Types

number	integer
command	string
host_option_name	string

Arguments

`-mode lsf | csh | grd | nc`

Specifies the protocol used to launch the jobs.

`-sim_per_job number`

Specifies the number of simulations per submitted farm job.

`-farm_max_num_pending number`

Specifies the maximum number of pending jobs to allow in the farm queue.

`-max_job_requeue number`

Specifies the maximum number of times a failed job is requeued.

`-farm_timeout number`

Specifies the timeout limit for the farm run, in seconds.

`-submit_command command`

Specifies the submit command and arguments used to submit jobs to the farm.

`[-pre_run_command command]`

Specifies a pre-run command to run before simulation.

`[-host_option_name host_option_name]`

References a host configuration definited using the *set_host_options -name* command instead.

`[-reset]`

Resets all settings in the command to default values.

See the "Using CDPL Jobs" section for details.

Description

This command is used to configure how simulation jobs are launched when performing parallel HSPICE simulation of multiple paths in a timing path collection.

The *sim_setup_distributed* command must be specified before any SimLink commands that run the simulation and generate reports (such as the *sim_validate_path*, *sim_validate_stage*, and *sim_validate_noise* commands). Note that the *sim_setup_distributed* command does not support the *-from* or *-to* options of the *sim_validate_path* command.

Additional options of the *sim_setup_distributed* command allow the tool to monitor farm job status, such as the number of jobs still in the queue (not running), the time such jobs are allowed to remain in the queue, and how many times a failed job is resubmitted. The *-pre_run_command* option allows you to specify commands to be run prior to submitting the jobs.

After a SimLink command completes, it reports a status summary of the submitted jobs.

Using CDPL Jobs

The *sim_setup_distributed* command also allows you to use processing resources that are configured by CDPL (Common Distributed Processing Library), which is a standardized way of configuring job resources using the *set_host_options* command.

To do this, define compute resources using the *set_host_options -name* command then reference those named resources with the *-host_option_name -host_option_name* command. The *set_host_options* command must also use the *-target Hspice* option to indicate that the jobs will be used for simulation.

Here is an example of how to set up CDPL on compute farm machines:

```
set simlink_enable_fast_monte_carlo true
set simulator "/path/to/hspice/bin/hspice"

# start CDPL processes
set_host_options -target Hspice -name my_compute_farm_jobs \\
```

```
  -num_processes 10 -max_cores 8 \\
  -submit_command "qsub -P typ -V -cwd -l mem_free=10G"
start_hosts -min_hosts 1

# use CDPL processes for simulation
sim_setup_distributed -host_option_name my_compute_farm_jobs

sim_setup_simulator -simulator $simulator -simulator_type hspice \\
  -work_dir sim_dir -preserve all
sim_setup_library -lib [get_libs *] -sub spice_netlist -header
 spice_header
sim_analyze_path -variation -sample_size 10000 $paths
stop_hosts
```

Here is an example of how to set up CDPL on specific machines:

```
set simlink_enable_fast_monte_carlo true
set simulator "/path/to/hspice/bin/hspice"

# start CDPL processes
set_host_options -target Hspice -name my_direct_jobs \\
  -num_processes 10 -max_cores 8 {host1 host2 host3}
start_hosts -min_hosts 1

# use CDPL processes for simulation
sim_setup_distributed -host_option_name my_direct_jobs

sim_setup_simulator -simulator $simulator -simulator_type hspice \\
  -work_dir sim_dir -preserve all
sim_setup_library -lib [get_lib *] -sub spice_netlist -header
 spice_header
sim_analyze_path -variation -sample_size 10000 $paths
stop_hosts
```

Examples

The following example configures 10 simulations to be run in each farm job.

```
pt_shell> sim_setup_distributed -mode grd -sim_per_job 10 \\
            -submit_command {qsub -V -cwd -P typ -l mem_free=10G}
```

Consider a case where you want to run *sim_validate_path -variation* for a path collection of 100 paths. Because Monte Carlo simulation is slow, you want each job to run only one Monte Carlo simulation. In this case, use the *-sim_per_job 1* option, so that the tool launches individual Vsimulations for all paths in parallel:

```
pt_shell> sim_setup_distributed -mode grd -sim_per_job 1 \\
            -submit_command {qsub -V -cwd -P typ -l mem_free=10G}
```

To run *sim_validate_path -variation* simulations at high sigma values, you can use the HSPICE distributed processing *-dp* option to speed up fast Monte Carlo simulation for each path. It is recommended to use *-dp 8* to run fast Monte Carlo at high sigma values.

Feedback

```
pt_shell> set simulator "/2018.09-SP2-2/bin/hspice -dp 8 \\
            -dpconfig /abc/dpconfig -i"
pt_shell> sim_setup_distributed -mode grd -sim_per_job 1 \\
            -submit_command {qsub -V -cwd -P typ -l mem_free=10G}
```

Here is an example dpconfig file:

```
#flag|hostname|slots|tmpdir|protocal|command
    1|        | -1  | /tmp | SGE    |qsub -P typ -cwd -V -l mem_free=10G
#   1|        | -1   /tmp  | LSF    |bsub -q typ -R "rusage[mem=1000]"
```

---

sim_setup_library

Sets up files for a gate-level library used in SPICE circuit simulation.

Syntax

status *sim_setup_library*

```
-library library
-sub_circuit dir
-header file
[-file_name_pattern pattern]
```

Data Types

```
library     collection
dir         string
file        string
pattern     string
```

Arguments

`-library library`

Specifies the PrimeTime gate-level library to be used in SPICE simulation.

`-sub_circuit` *dir*

Specifies the directory that contains the subcircuit files (one file per cell) that are included in the simulation SPICE decks. Specifying a single file instead of a directory is allowed but might result in poor simulation performance.

`-header` *file*

Specifies a file to be included at the beginning of the SPICE file. This file must contain a model file, corner instantiation, and simulator options. The file must not contain any measure statement or other circuit-specific statements. Generally, the SPICE options must be the same in all header files for each library.

Temperature information must not be present in the header files; this is automatically added to the SPICE deck by PrimeTime.

By default, the power rail name is VDD (which uses the main library voltage) and the ground rail name is VSS (which uses 0 volts). To define rails other than VDD and VSS, specify the rail voltage definitions in the header files.

`-file_name_pattern` *pattern*

Restricts the files used for this library to those that follow the specified file name pattern. This option is helpful if the directory specified by the *-sub_circuit dir* option contains subcircuits for multiple libraries.

Description

This command performs setup for the gate-level library in preparation for SPICE simulation, such as mapping transistor models to gate-level models.

When the *simlink_enable_fast_monte_carlo* variable is set to *true*, the *sim_setup_library* command performs library-level learning for fast Monte Carlo analysis. This requires the *sim_setup_simulator* command to be run before the *sim_setup_library* command.

Examples

The following example associates a specified library with a SPICE subcircuit directory and header file.

```
pt_shell> sim_setup_library -library my_lib \\
          -sub_circuit /path/gem/hspice \\
          -header /path/gem/model_hspice \\
          -file_name_pattern {my_%s.spc}
```

In this example, the IV170BQ library cell uses the my_IV170BQ.spc file in the subcircuit directory to get its subcircuit.

The *-file_name_pattern* option helps in associating the library cell names to my_{lib_cell_name}.spc files in the subcircuit directory.

---

sim_setup_simulator

Sets up the simulation environment.

Syntax

status *sim_setup_simulator*

```
[-simulator sim_exec_path]
[-simulator_type hspice | nanosim | hsim]
[-sim_options option_string]
[-work_dir directory]
[-preserve failed | all | none]
```

Data Types

```
sim_exec_path      string
option_string      string
directory          string
```

Arguments

`-simulator sim_exec_path`

Specifies the path to the simulation executable.

`-simulator_type hspice | nanosim | hsim | customsim`

Specifies one of the following simulators

- *hspice* (default) - HSPICE
- *nanosim* - NanoSim
- *hsim* - HSIM
- *customsim* - CustomSim

If you do not use this option, PrimeTime tries to derive the simulator type by using the *-simulator* option. If PrimeTime cannot derive the simulator type, the default simulator is HSPICE. CustomSim is not recommanded for simlink commands for correlation purpose.

Feedback

`-sim_options` *option_string*

Specifies the default simulator options that are appended to the SPICE decks.

`-work_dir` *directory*

Specifies the directory that stores temporary SPICE files. This option overrides any previous *-work_dir* options -- that is, there is only one for all libraries. The default directory is $pt_tmp_dir.

`-preserve failed | all | none`

Specifies whether temporary files, such as SPICE decks, are kept on the disk.

- *all* - Preserves all files.
- *none* - Deletes all files.
- *failed* (default) - Keeps the files only if simulation failed.

Description

This command sets up the simulation environment. It specifies the simulator location, the type of simulator, and the working directory.

Examples

The following example sets the simulator exec, simulator type, and the default options for the simulator.

```
pt_shell> sim_setup_simulator -simulator /global/apps/hspice/bin/hspice
 \\
          -simulator_type hspice \\
          -sim_options ".option ingold=2 statfl=1 acct=0 autostop brief
 runlvl=5"
```

The following example sets the work directory and marks all the temporary files to be preserved after simulation has finished.

```
pt_shell> sim_setup_simulator -work_dir [pwd] \\
          -preserve all
```

- sim_validate_stage

---

sim_setup_spice_deck

Specifies setup options for SPICE deck generation.

Syntax

status *sim_setup_spice_deck*

```
[-enable_clock_mesh]
[-use_pin_load]
```

Arguments

`-enable_clock_mesh`

Enables the mesh model generation flow for performing clock network analysis using the *sim_analyze_clock_network* command. Set this option to enable the clock model generation flow before reading the parasitics of the design. Otherwise, there is a possibility of a few large multidriven nets (mesh nets) being treated as ideal nets.

`-use_pin_load`

Replaces all the side-load cell instances by its input pin capacitance. The input pin capacitance used is nonlinear delay model (NLDM) pin capacitance of the lib cell specified in the library. CCS pin capacitances (c1, c2) are ignored and an equivalent pin cap is used in the SPICE deck.

This option is beneficial in some cases because it improves the SPICE simulation runtime and also enables the SPICE simulations for load cells that do not have corresponding SPICE models. However, using this option results in loss of accuracy of SPICE simulation because the physical load cells are replaced by its equivalent pin cap model. This feature is also honored by the SPICE deck that is generated by the *write_spice_deck* command.

Description

This command specifies setup options for writing out the SPICE deck.

Examples

The following example enables clock mesh model generation flow.

```
pt_shell> sim_setup_spice_deck -enable_clock_mesh
```

The following example replaces all the side-loads in the SPICE deck with the input pin capacitance.

Feedback

```
pt_shell> sim_setup_spice_deck -use_pin_load
```

See Also

- sim_analyze_clock_network
- write_spice_deck

---

sim_validate_noise

Validates PrimeTime noise analysis accuracy compared with SPICE simulation.

Syntax

int *sim_validate_noise*

```
[-analysis_type above_low | below_high]
[-area]
[-verbose]
[-significant_digits digits]
net_arc_objects
```

Data Types

```
net_arc_objects    collection
```

Arguments

`-analysis_type above_low | below_high`

Reports the specified type of correlation. By default, both types of correlation are reported.

`-area`

Shows the noise bump area comparison results. By default, only noise bump heights are compared.

`-verbose`

Reports additional information, such as the location of temporary files.

`-significant_digits digits`

Specifies the number of digits after the decimal point displayed for timing values in the generated report. Allowed values are 0-13; the default is determined by the *simlink_report_default_significant_digits* variable, which is 4 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

net_arc_objects

Specifies a collection of net *timing_arc* objects to validate.

Description

The *sim_validate_noise* command simulates the specified net noise effects, comparing the bump height (and area) between PrimeTime and simulation. The error percentage in the report are reported as a percentage of VDD.

Before using this command, run the *sim_validate_setup* command to validate the SPICE simulation setup and environment. Incorrect setup of the simulation environment often causes correlation problems.

Then, run the *sim_enable_si_correlation* command before the *update_timing* and *update_noise* commands on the nets of interest, and follow the recommended settings for SPICE correlation.

This command is for noise correlation only. For uncoupled delay correlation, use the *sim_validate_path* command. For coupled delay correlation, use the *sim_validate_stage* command.

To use the *sim_validate_noise* command, you must have a PrimeTime SI license.

Examples

The following example simulates noise at U2/A, based on the U1/Z to U2/A net arc. It compares both bump height and area results with SPICE for *above_low*.

```
pt_shell> sim_enable_si_correlation [get_nets -of_objects U1/Z]
pt_shell> update_timing -full
pt_shell> update_noise -full
pt_shell> set net_arc [get_timing_arc -from U1/Z -to U2/A]
pt_shell> sim_validate_noise $net_arc -area -analysis_type above_low
```

See Also

- sim_enable_si_correlation
- sim_setup_library
- sim_setup_simulator
- sim_validate_path
- sim_validate_setup
- sim_validate_stage
- simlink_report_default_significant_digits

Feedback

sim_validate_path

Validates uncoupled PrimeTime delay and transition accuracy for a timing path using SPICE simulation.

Syntax

status *sim_validate_path*

```
[-from start_pin_object]
[-to end_pin_object]
[-transition_time]
[-verbose]
[-variation]
[-sample_size number_of_mc_samples]
[-significant_digits digits]
[-sep_init]
path_objects
```

Data Types

start_pin_object	collection
end_pin_object	collection
number_of_mc_samples	integer
path_objects	collection

Arguments

`-from` *start_pin_object*

Specifies the start pin object for simulation.

`-to` *end_pin_object*

Specifies the end pin object for simulation.

`-transition_time`

Shows the transition time comparison results. By default, only delays are compared.

`-verbose`

Reports additional information, such as the location of temporary files.

`-variation`

Reports POCV correlation for nominal and corner values of path arrival. POCV analysis must be enabled to use this feature. If the *-from* and *-to* options are specified, the variation correlation is reported for the path segment between *start_pin_object* and *end_pin_object* on *path_objects*.

`-sample_size` *`number_of_mc_samples`*

Specifies the number of Monte Carlo samples for POCV correlation. The default is 5000 samples. This option has an effect only when used with the *-variation* option.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point displayed for timing values in the generated report. Allowed values are 0-13; the default is determined by the *simlink_report_default_significant_digits* variable, which is 4 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-sep_init`

Separates the initialization SPICE simulation from the measurement simulation. This can reduce the chance of measurement failure when complicated sequential cells are involved.

`path_objects`

Specifies a collection of timing path objects to validate.

Description

The *sim_validate_path* command simulates the specified path or path segment and compares the delays (and optionally transition times) between PrimeTime analysis and SPICE simulation.

Before using this command, run the *sim_validate_setup* command to validate the SPICE simulation setup and environment. Incorrect setup often causes correlation problems. Use path-based PrimeTime analysis for correlation and follow the recommended settings for SPICE correlation.

This command works for uncoupled correlation only. In designs with cross-coupling, a *SIM-004* error is issued. For paths with cross-coupling, use the *sim_validate_stage* command.

For POCV validation with *sim_validate_path -variation*, it is highly recommended to enable fast Monte Carlo SPICE simulation by setting the *simlink_enable_fast_monte_carlo* variable to *true*, which significantly reduces POCV validation runtime.

Examples

The following example performs path-based analysis, sets a variable to a collection containing the worst path, and compares the delay and transition analysis results with SPICE simulation of the path.

Feedback

```
pt_shell> set pba_path [get_timing_paths -pba_mode path]
pt_shell> sim_validate_path $pba_path -transition
```

The following example analyzes a path segment of interest (from U1/A to U2/Z) and compares the PrimeTime delay results with SPICE simulation results.

```
pt_shell> set pba_path [get_timing_path -through U1/A \\
            -through U2/Z -pba_mode path]
pt_shell> sim_validate_path $pba_path -from U1/A -to U2/Z
```

The following example performs path-based analysis, sets a variable to a collection containing the worst path, and compares path arrival nominal and corner value with fast Monte Carlo simulated results.

```
pt_shell> set_app_var simlink_enable_fast_monte_carlo true
pt_shell> sim_setup_simulator -simulator /global/apps/hspice/bin/hspice
pt_shell> sim_setup_library -lib [get_libs *] -sub_circuit sub_path
 -header header_path
pt_shell> set pba_path [get_timing_paths -pba_mode path -path_type
 full_clock_expanded]
pt_shell> sim_validate_path $pba_path -variation
```

---

sim_validate_setup

Validates SPICE simulation setup and environment.

Syntax

status *sim_validate_setup*

```
-lib_cell library_cell
[-from from_pin]
[-to to_pin]
[-capacitance cap_value]
[-transition_time tran_value]
[-significant_digits digits]
[-verbose]
```

Data Types

library_cell	collection
from_pin	string
to_pin	string
cap_value	float
tran_value	float

Arguments

`-lib_cell` *library_cell*

Specifies the library cell object to verify

`-from` *from_pin*

Specifies the from pin of the library arc. The tool uses the library arc specified by the *-from* and *-to* options for setup verification.

`-to` *to_pin*

Specifies the to pin of the library arc. The tool uses the library arc specified by the *-from* and *-to* options for setup verification.

`-capacitance` *cap_value*

Specifies the output load to be driven by the library cell. The units are in PrimeTime main library units.

`-transition_time` *tran_value*

Specifies the input transition time (slew) for the arc. A ramp or CCS standard pre-driver waveform (as per the library driver waveform) with this slew is generated at the corresponding input pin of this library cell. Both rise and fall will be simulated. The units are in PrimeTime main library units.

`-significant_digits` *digits*

Specifies the number of digits after the decimal point displayed for timing values in the generated report. Allowed values are 0-13; the default is determined by the *simlink_report_default_significant_digits* variable, which is 4 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-verbose`

Shows more details such as location of temporary files.

Description

Incorrect user setup of the simulation environment often causes problems. The goal of this command is to help you ensure that the PrimeTime libraries and SPICE environment are matching. This command invokes the simulator specified by the

Feedback

sim_setup_simulator command on the given library cell arcs. The purpose is to verify that the basic characterization of a library matches the SPICE setup specified by the *sim_setup_** commands. To make the interface as simple as possible, only combinational cells are supported. If any error is detected in the SPICE run, FALSE is returned to the Tcl interpreter. Otherwise, the command displays the SPICE and PrimeTime computed delay and slew values, and returns TRUE.

This command checks for the presence of SPICE executable, SPICE netlist, SPICE model files, SPICE options, I/O rail settings, and correct units. It also checks the model license and compatibility of the SPICE version with the model.

This command does not replace Library checker or validation. The usage model is the other way around: Library has to be fully validated for accuracy first. This command assumes that the Liberty library is 100% correct and accurate, and therefore any PrimeTime and SPICE mismatch is due to incorrect simulation setup.

You can use this command only when there are no designs loaded in PrimeTime. Run this command after reading the libraries. The SPICE validation check is required one time for each library generally, for the first time the SPICE environment is setup in the design flow with the specific library.

To use the *sim_validate_setup* command, you must have a PrimeTime SI license.

Examples

The example validates the simulation setup using a library arc from A to Y pins of IV170BQ lib cell with an output load of 48 library units and transition time of 0.2 units of library units.

```
pt_shell> sim_validate_setup -from A -to Y \\
          -lib_cell [get_lib_cells $lib_name/IV170BQ] \\
          -capacitance 48 -transition_time 0.2
```

- sim_setup_simulator
- simlink_report_default_significant_digits

---

sim_validate_stage

Validates coupled PrimeTime accuracy compared with SPICE simulation.

Syntax

```
status sim_validate_stage
   [-verbose]
```

```
[-analysis_type min_rise | max_rise | min_fall | max_fall]
[-measure_type stage | lookahead]
[-significant_digits digits]
net_arc_objects
```

Data Types

net_arc_objects collection

Arguments

-verbose

Reports more details, such as the location of temporary files.

-analysis_type min_rise | max_rise | min_fall | max_fall

Specifies the analysis type of correlation, where "rise" or "fall" indicates a rising or falling transition on net arc load pin. If you do not specify this option, all four types of correlation are reported.

-measure_type lookahead | stage

Specifies the measure type of correlation:

- *lookahead* (the default) - Specifies one-and-half stage correlation.
- *stage* - Specifies stage correlation. Use this option for investigating outliers. When using this option, set the *si_ccs_aggressor_alignment_mode* variable to *stage* for correlation results.

-significant_digits *digits*

Specifies the number of digits after the decimal point displayed for timing values in the generated report. Allowed values are 0-13; the default is determined by the *simlink_report_default_significant_digits* variable, which is 4 by default. Use this option if you want to override the default for the current report. This option controls only the number of digits displayed, not the precision used internally for analysis.

net_arc_objects

Specifies a collection of net timing_arc objects to validate.

Description

The *sim_validate_stage* command simulates the specified stage and half and compares the delay between PrimeTime and simulation. For a net arc without receiver timing arc, stage correlation is reported.

Before using this command, run the *sim_validate_setup* command to validate the SPICE simulation setup and environment. Incorrect setup of the simulation environment often causes correlation problems. Run the *sim_enable_si_correlation* command before the

update_timing command on nets of interest, and follow recommended settings for SPICE correlation.

This command works for coupled correlation purpose only. For uncoupled correlation, use the *sim_validate_path* command.

To use the *sim_validate_stage* command, you must have a PrimeTime SI license.

Examples

The following example simulates one and half stage including U1/A to U1/Z cell arc, U1/Z to U2/A net arc, and U2/A to U2/Z cell arc. It compares delay results with SPICE for max_rise.

```
pt_shell> sim_enable_si_correlation [get_nets -of_objects U1/Z]
pt_shell> update_timing -full
pt_shell> set net_arc [get_timing_arc -from U1/Z -to U2/A]
pt_shell> sim_validate_stage $net_arc -analysis_type max_rise
```

See Also

- si_ccs_aggressor_alignment_mode
- simlink_report_default_significant_digits

---

size_cell

Relinks one or more leaf cell instances to a new library cell that has the same logical function but different properties such as size and drive strength.

Syntax

status *size_cell*

```
[-current_library]
[-libraries lib_spec]
[-all_mim_instances]
cell_list
lib_cell
```

Data Types

lib_spec	list
cell_list	list
lib_cell	string

Arguments

`-current_library`

Restricts selection of the new library cell to the same library as that of the cell being replaced. You can use the this option only if the *lib_cell* argument specifies a base cell name, without a library name.

`-libraries` *lib_spec*

Restricts selection of the new library cell to the specified list of libraries. The libraries are searched in the order in which they are listed. You can specify either a list of library names or a collection created by the *get_libs* command. You can use the this option only if the *lib_cell* argument specifies a base cell name, without a library name.

If you specify a base cell name and do not use the *-current_library* or *-libraries* option, the command looks for the new library cell in the current library first, then in the libraries specified by the *link_path_per_instance* variable, and finally in the libraries specified by the *link_path* variable. It uses the first matching library cell found.

`-all_mim_instances`

Relinking of one or more leaf cell instances to a new library cell in one MIM instance is replicated in all instances of a MIM set.

cell_list

Specifies one or more leaf cell instances to be relinked: a cell instance name, a list of cell instance names, or a cell collection gathered with the *get_cells* command. Each cell must be in the scope at or below the current instance.

lib_cell

Specifies the single library cell to which the specified cell instances are linked. It can be a simple base cell name such as "AND2a04", a full library/cell name such as "CBmax120/AND2a04", or a single library cell object collected by the *get_lib_cells* command. If you specify a simple base name, you can restrict the choice of libraries with the *-current_library* or *-libraries* option.

If you invoke *pt_shell* with the *-multi_scenario* option, you must specify only the base name of the library cell.

Feedback

Description

This command changes the drive strength or other properties of a leaf cell by relinking it to a new library cell that has the required properties and the same logical functionality.

You can get a list of library cells that are compatible with a given cell instance by using the *get_alternative_lib_cells* command. To report the timing effects of these compatible library cells, use the *report_alternative_lib_cells* command.

The *size_cell* command is only for leaf cells. To swap a hierarchical block for a different design, use the *swap_cell* command.

The *size_cell* command typically triggers an incremental timing update. However, a full timing update is required if the resized cell is in the clock tree or connected to the clock tree.

The *size_cell* command with *-all_mim_instances"* option applies changes to all the instances of the MIM set.

Suppose a CPU module is instantiated four times in the TOP module as CPU1, CPU2, CPU3 and CPU4.

The following example shows *size_cell* command being used in one instance of a MIM set i.e CPU1 with *-all_mim_instances"* option. The changes are replicated to all the other MIM instances of the set i.e CPU2, CPU3, CPU4.

```
pt_shell> size_cell CPU1/n1 mylib/NR4P -all_mim_instances"
Sized 'CPU1/n1' with 'mylib/NR4P'
Sized 'CPU2/n1' with 'mylib/NR4P'
Sized 'CPU3/n1' with 'mylib/NR4P'
Sized 'CPU4/n1' with 'mylib/NR4P'
1
```

Equivalent Library Cells

The *size_cell* command works only with library cells that are functionally equivalent to the cell being sized, in the following ways:

- Number of input pins
- Number of output pins
- Logical functionality
- Number, type, and sense of enabled cell timing arcs

By default, the I/O pins do *not* need to have the same names or ordering. Furthermore, the *size_cell* command recognizes a 2-input NAND gate and a 2-input OR gate, each cell with one negated input, as functionally equivalent (by DeMorgan's theorem), even if the replacement cell requires swapping the two input connections by name.

To enforce identical pin naming, set the *eco_strict_pin_name_equivalence* variable to true. In that case, the *size_cell* command considers matching pin names and their respective functions as an additional requirement for equivalence.

To disable the requirement that timing arcs must match between the target library cell and the original library cell, set the *eco_strict_lib_arc_equivalence* variable to *false*.

To determine functional equivalence, the *size_cell* command considers three lib_cell attributes created by the Library Compiler tool: *function_id*, *mog_func_id*, and *user_function_class*. If the attributes are present, they must match between the cell being resized and the replacement cell. The *mog_func_id* attribute is present only for a cell with multiple output gates. The *user_function_class* attribute is present only for functionally complex cells.

The *get_alternative_lib_cells* and *report_alternative_lib_cells* commands use the same criteria to determine functional equivalence.

Writing the Changes

The changes caused by netlist editing commands such as *size_cell* are recorded in a change list, which is annotated on the design. To view or export the change list, use the *write_changes* command.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design.

Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary, for example, when the design is relinked.

The tool automatically uniquifies the blocks as needed, including the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 mylib/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
```

```
Sized 'i1/low/n1' with 'mylib/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows how to query the *is_edited* attribute on i1/low.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following example, an attempt to size a cell fails because the target is not functionally equivalent. After finding a compatible library cell, the second attempt succeeds.

```
pt_shell> size_cell o_reg1 mylib/NR4P
Error: Could not size 'o_reg1' ('mylib/FD2') with 'mylib/NR4P':
       Cells not functionally equivalent. (NED-005)
Error: No changes made. (NED-040)
0

pt_shell> get_alternative_lib_cells o_reg1
{"mylib/FD2P"}

pt_shell> size_cell o_reg1 mylib/FD2P
Information: Sized 'o_reg1' with 'mylib/FD2P'. (NED-045)
1
```

The following example sizes two cell instances to alternative library cells using only the cell's current library and the library cell base name.

```
pt_shell> get_lib_cells -of_objects n1
{"mylib/ND2"}

pt_shell> get_alternative_lib_cells -current_library n1
{"mylib/ND2P"}

pt_shell> get_lib_cells -of_objects n2
{"libA/ND2"}

pt_shell> get_alternative_lib_cells -current_library n2
{"libA/ND2P"}

pt_shell> size_cell -current_library {U1 U2} ND2P
Information: Sized 'U1' with 'mylib/ND2P'. (NED-045)
Information: Sized 'U2' with 'libA/ND2P'. (NED-045)
1
```

The following example sizes to cell instances to alternative library cells using only specified libraries and the library cell base name. The first library, lib1, is searched first but

it does not contain the target library cell, so the command uses the library cell from the second library.

```
pt_shell> size_cell -libraries {lib1 lib2} {U1 U2} ND2P
Information: Sized 'U1' with 'lib2/ND2P'. (NED-045)
Information: Sized 'U2' with 'lib2/ND2P'. (NED-045)
1
```

---

sizeof_collection

Returns the number of objects in a collection.

Syntax

int *sizeof_collection* [-categorize]

collection1

Data Types

collection1 collection

Arguments

collection1

Specifies the collection for which to get the number of objects. If the empty collection (empty string) is used for the *collection1* argument, the command returns 0.

-categorize

Return 0, 1, 2 indicating if the collection has 1, or or more than 1 item.

Feedback

Description

The *sizeof_collection* command is an efficient mechanism for determining the number of objects in a collection.

Examples

The following example from PrimeTime shows a simple way to find out how many objects matched a particular pattern and filter in the *get_cells* command.

```
pt_shell> echo "Number of hierarchical cells: \\
?                 [sizeof_collection \\
?                   [filter_collection [get_cells * -hier \\
?                     "is_hierarchical == true"]]]"
Number of hierarchical cells is: 10
```

The following example from PrimeTime shows what happens when the argument for the *sizeof_collection* command results in an empty collection.

```
pt_shell> set s1 [get_cells *]
{"u1", "u2", "u3"}
pt_shell> set ssize [filter_collection $s1 "area < 0"]
pt_shell> echo "Cells with area < 0: [sizeof_collection $ssize]"
Cells with area < 0: 0
pt_shell> unset s1
```

---

snap_objects

Snaps specified objects to the default snap type. An object is snapped onto the nearest position that satisfies the snapping constraint.

Syntax

status *snap_objects*

```
[object_list]
```

Data Types

object_list collection or selection

Feedback

Arguments

object_list

Specifies the collection or selection set containing objects to snap. If this option is not specified, the global selection set is used.

Description

This command snaps the specified objects to the default snap types according to the object types of individual arguments.

The default snap type can be retrieved with the *get_snap_setting* command. Set the snap settings with the *set_snap_setting* command.

Examples

The following example snaps the cell "abc" to the nearest site row slot.

```
prompt> get_snap_setting -class std_cell
row_site
prompt> change_selection [get_cells "abc"]
prompt> snap_objects
```

The alternative syntax uses collection to specify objects.

```
prompt> snap_objects [get_cells "abc"]
```

---

snps.cmd

Python object that provides access to application commands.

Description

Synopsys applications are built around a series of commands. These commands are exposed into the Tcl interpreter and are also available (accessible) from within the Python interpreter as well. In Python these application commands are accessed as methods on the snps.cmd object).

Most application commands accept one or more arguments. The arguments can be either positional or keyword arguments. For example the following command calls the "get_cells"

command to find all soft macros with names matching the glob pattern '*mem*' using Tcl syntax:

```
get_cells *mem* -hierarchical -filter is_soft_macro
```

Using Python syntax, this becomes:

```
cmd.get_cells('*mem*', hierarchical=True, filter='is_soft_macro')
```

The arguments to the various commands are described in the man page for each command. Those may be accessed via the man command. For example:

```
cmd.man('get_attribute')
```

Additionally, Python specific help for a command can be displayed via the Python builtin help facility. This help displays the Python calling syntax. The man pages use Tcl syntax. For example:

```
prompt-py> help(cmd.get_attribute)
get_attribute(...)    Get the value of an attribute
Usage:
    get_attribute(object_spec, attr_name, _class=class_name, quiet=False,
                  value_list=False, objects=object_spec, name=attr_name)

    Positional arguments (brackets indicate optional arguments):
      object_spec:         Object(s) from which to get the attribute
      attr_name:           Name of the attribute

    Keyword arguments (brackets indicate optional arguments):
      [_class]:            If object_spec is a name, this is its class
      [quiet]:             Do not report any messages
      [value_list]:        Force single object return as list
      objects:             Object(s) from which to get the attribute
      name:                Name of the attribute
```

Understanding Manpages

The application man pages for commands describe the Tcl syntax for a command. The Tcl "dash" options map directly to Python keyword arguments. If the dash argument name refers to a Python keyword, then the keyword in Python uses a leading "_" as the above example shows for the "-class" option.

In Tcl, boolean arguments usually accept no value, but in Python all keyword arguments require a value. For boolean argument types you may pass the values: True, 1, False, 0.

Repeating Keyword Arguments

Some of our applications command allow for dash (keyword) arguments to be repeated. This is most common in the timing path related commands. Python does not allow repeating the name of a keyword option. In this case you need to use the "cmd.arg" class

along with the Python keyword expansion syntax (**) to pass the repeated argument names into the command. For example:

```
cmd.get_timing_path(**cmd.arg('through', a, 'through', b))
```

Is equivalent to calling the Tcl command:

```
get_timing_path -through a -through b
```

The "**cmd.arg" syntax can be interspersed with regular keyword argument syntax. Both of these styles are allowed and are equivalent to the first example:

```
cmd.get_timing_path(through=a, **cmd.arg('through', b))
cmd.get_timing_path(**cmd.arg('through', a), through=b)
```

Command Return Values

All commands return a value. The type of the value is one of the following.

Int or Float

Commands returning numeric values return types in one of these Python builtin types.

snps.collection

Commands that return database objects (Tcl collections).

snps.value

All other return types.

Communicating with Tcl

The snps.cmd object can be used to call any command that is registered with the Tcl environment, including Tcl defined procedures (proc). For example:

cmd.set('varName', value)

Sets the Tcl variable 'varName' to the specified value.

cmd.set('varName')

Retrieves the value of the Tcl variable 'varName'.

cmd.source(fileName)

Sources the fileName into the Tcl interpreter.

cmd.eval(commandScript)

Evaluates the supplied Tcl script.

---

snps.collection

Python class for Synopsys collection objects.

Description

Synopsys applications build an internal database of objects and attributes available on those objects. Some examples for class of database objects are designs, libraries, ports, cells, nets, pins, clocks, and so on. Most commands operate on these objects.

Accessing Elements

Collections represent an ordered sequence of database objects. Collection values support the Python sequence interface. The contents of a collection may be accessed like the standard Python list type. For example (x is a collection value):

x[0]

Retrieve the fist item. Returns a single item collection.

x[-1]

Retrieve the last item. All slice based indexing is supported.

len(x)]

Return the number of objects in the collection

for y in x:

Loop over the items. In the loop body "y" is a single item collection.

Building Collections

Collections can be created combining one or more collections. Both operator and function based methods are supported. For example:

x += y # x.append(y)

Add the items in the collection y into the collection referenced by x.

x + y # x.add(y)

Return a new collection by combining the objects in x and y.

x - y # x.remove(y)

Return a new collection containing the objects in x that are not also in y. (x -= y is also supported).

x ^ y # x.remove(y, intersect=True)

Return a new collection that contains the objects that exists in both x and y. (x ^= y is also supported).

Sorting and Filtering

Collections can be sorted and filtered. For example:

x.remove_duplicates()

Returns a new collection with duplicate objects removed.

x.sort(criteria)

Returns a new collection sorted by the sort criteria. This is shorthand for "cmd.sort_collection(x, criteria)"

x.filter(expr)

Returns a new collection by evaluating the filter expression. This is shorthand for "cmd.filter_collection(x, criteria)"

Attribute Values

Collections also provide methods to query and set attribute values on objects. Usually these are used with single item collections (see attribute iterators below for optimized access to attributes on larger collections):

x.set(attr, value)

Calls cmd.set_attribute(x, attr, value)

x.get(attr)

Calls cmd.get_attribute(x, attr)

x.unset(attr)

Calls cmd.remove_attribute(x, attr)

Attribute Iterators

As mentioned above collections may be indexed via an integer or slice value. This gives access to the individual items of a collection. Additionally collections may be indexed by a string or a tuple of strings. Indexing in this way provides access to the attributes of the collection via an iterator. For example:

for name,cost in x['full_name', 'cost']:

Iterate over the values of the full_name and cost attributes in the collection. In the body of the loop 'name' refers to the value of the full_name attribute for the current item.

for obj,(name,cost) in zip(x, x['full_name', 'cost']):

Similar to the above loop, but loop over the collection contents in addition to the attribute values.

x['full_name', 'cost'].to_pandas()

Build a Pandas DataFrame object. The DataFrame contains a column for each attribute specified, with a row for each item in the source collection. See the Pandas documentation for details about the DataFrame type. If the collection is empty, then None is returned.

x['cost'].to_array()

If a single attribute name is used, then the a NumPy array can be requested. If the collection is empty, then None is returned.

DataFrame Contents

A Pandas DataFrame is a grouping of multiple NumPy (np) arrays (each column is an array). When attribute values are converted into these arrays, the type of underlying array differs depending on the values in the attribute. Each attribute type converts like this:

Boolean

The array is of type np.dtype('bool'). If an attribute is unset on an object the value is 'False'.

Int

The array is of type np.dtype('int32') unless an attribute is unset on an object. In that case the type is np.dtype('float64'). Items with the unset attribute have value 'NaN'.

Double

The array is of type np.dtype('float64'). If an attribute is unset on an object, the value is 'NaN'.

Float

The array is of type np.dtype('float32'). If an attribute is unset on an object, the value is 'NaN'.

String

If the attribute values are less than 32 characters and no spaces exist in the in any attribute value (i.e. cannot be interpreted as a Tcl list), then the type is nd.dtype('<UN') where N is the length of the longest attribute result. Otherwise the type is nd.dtype('O') (i.e Object storage) and each entry has the type snps.value. Any unset attribute values are the empty string.

Collection

The array is of type nd.dtype('O') and each entry is of type snps.collection. Unset attributes use the empty collection.

---

snps.redirect

Python class used to redirect application output.

CONSTRUCTOR SYNTAX

```
snps.redirect(file=fileName, compress=False, tee=False)
snps.redirect(stream=ioStream, tee=False)
```

CONSTRUCTOR ARGUMENTS

file

Specifies an output file. This file is created on disk.

stream

Specifies an already open output stream. This can be an already open Python file handle, or any object that supports a write method such as an io.StringIO object.

tee

When True, send output to the specified destination but also send the output to the current output stream.

compress

If the output is to a file, the file is created using zgip compression.

Description

The redirect type is used to redirect tool output to another location. The type is a standard Python execution context object. Output can be redirected into either a file or an in memory buffer stream. This type is used in the Python "with" statement.

Feedback

Examples

```
# Redirect to a compressed file
with snps.redirect('myFile', compresss=True):
  cmd.report_timing()

# Redirect to a variable
out = io.StringIO()
with snps.redirect(out):
  cmd.report_timing()
```

See Also

- py_eval

---

snps.value

Python class for application command return values.

Description

Command return values that are not numeric or collections are returned as values of this type. The snps.value can be treated as either a Python string, sequenced container, or a dictionary as needed.

The documentation for a command will describe the return type.

List Values

For commands that retrieve a list of values, you can treat the returned value as if it is a Python list type. In the following examples, "x" is:

```
x = cmd.get_defined_commands()
```

x[0]

Retrieve the first item (command name). The return value is a snps.value object

x[-1]

Retrieve the last item. All slice based indexing is supported.

len(x)

Return the number of items in the value (number of commands)

for y in x:

Loop over the items. In the loop body "y" is also a snps.value object

Feedback

Dictionary Values

For commands that return key-value pair values, you can treat the returned values as if it is a Python dict type. In the following examples, "x" is

```
x = cmd.get_defined_commands('get_attribute', details=True)
```

x['name']

Access the dictionary key 'name'.

x.keys()

Return an iterator that returns the keys.

x.value()

Return an iterator that returns the values.

for k,v in x.items()

Iterate over the keys and values.

String Values

In many cases the snps.value can also be treated as just a plain string value. However you can explicitly cast a value to a Python str object: str(val)

See Also

- py_eval

---

sort_collection

Sorts a collection based on one or more attributes, resulting in a new, sorted collection. The sort is ascending by default.

Syntax

collection *sort_collection*

```
[-descending]
[-dictionary]
[-limit value_count]
collection
criteria

int value_count
string collection
list criteria
```

Feedback

Arguments

`-descending`

Indicates that the collection is to be sorted in reverse order. By default, the sort proceeds in ascending order.

`-dictionary`

Sort strings dictionary order. For example "a30" would come after "a4".

`-limit` *`value_count`*

Only return the first unique values from the primary sort key.

`collection`

Specifies the collection to be sorted.

`criteria`

Specifies a list of one or more application or user-defined attributes to use as sort keys.

Description

You can use the *sort_collection* command to order the objects in a collection based on one or more attributes. For example, to get a collection of leaf cells increasing alphabetically, followed by hierarchical cells increasing alphabetically, sort the collection of cells using the *is_hierarchical* and *full_name* attributes as *criteria*.

The *criteria* can specify an attribute on another object. The other object must be available as an attribute on this object. For example, if you had a collection of net shapes, you can sort the objects by net using *owner_net.name* for instance.

In an ascending sort, Boolean attributes are sorted with those objects first that have the attribute set to *false*, followed by the objects that have the attribute set to *true*. In the case of a sparse attribute, objects that have the attribute come first, followed by the objects that do not have the attribute.

Sorts are ascending by default. You can specify ascending or descending order on a per attribute basis. You do this by adding a suffix to the attribute name in the sort criteria. The '-' means sort descending and '+' means sort ascending. If no suffix is specified than the default order ascending unless the *-descending* option is used.

The *-limit* option limits the size of the returned collection by choosing the first unique values from the primary sort criteria. For example using a limit of 1 will return all the objects with the smallest (or biggest if descending) value according to the primary sort key.

Examples

The following example from PrimeTime sorts a collection of cells based on hierarchy, and adds a second key to list them alphabetically. In this example, cells i1, i2 and i10

Feedback

are hierarchical, and o1 and o2 are leaf cells. Because the *is_hierarchical* attribute is a Boolean attribute, those objects with the attribute set to *false* are listed first in the sorted collection.

```
pt_shell> set zc [get_cells {o2 i2 o1 i1 i10}]
{"o1" "i2" "o1" "i1" "i10"}
pt_shell> set zsort [sort_collection $zc {is_hierarchical full_name}]
{"o1" "o2","i1" "i10" "i2"}
pt_shell> set zsort [sort_collection -dictionary $zc {is_hierarchical
 full_name}]
{"o1" "o2" "i1" "i2", "i10"}
pt_shell> set zsort [sort_collection -dictionary $zc {area- full_name}]
{"i10" "o1" "o2" "i1" "i2" "i10"}
pt_shell> set zsort [sort_collection -dictionary $zc {area- full_name}
 -limit 1]
{"i10" "o1"}
```

- collections

---

source

Read a file and evaluate it as a Tcl script.

Syntax

string *source*

```
[-echo]
[-verbose]
[-continue_on_error]
[-sms_scenarios sms_scenarios_list]
file

string file
```

Arguments

`-echo`

Echoes each command as it is executed. Note that this option is a non-standard extension to Tcl.

`-verbose`

Displays the result of each command executed. Note that error messages are displayed regardless. Also note that this option is a non-standard extension to Tcl.

`-continue_on_error`

Don't stop script on errors. Similar to setting the shell variable sh_continue_on_error to true, but only applies to this particular script.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios in which context the script will be read. Using this option is equivalent to using push_sms_scenario before sourcing the script, and pop_sms_scenario after the script.

`file`

Script file to read.

Description

The *source* command takes the contents of the specified *file* and passes it to the command interpreter as a text script. The result of the source command is the result of the last command executed from the file. If an error occurs in evaluating the contents of the script, then the *source* command returns that error. If a return command is invoked from within the file, the remainder of the file is skipped and the source command returns normally with the result from the return command.

By default, source works quietly, like UNIX. It is possible to get various other intermediate information from the source command using the *-echo* and *-verbose* options. The *-echo* option echoes each command as it appears in the script. The *-verbose* option echoes the result of each command after execution.

NOTE: To emulate the behavior of the dc_shell *include* command, use both of these options.

The file name can be a fully expanded file name and can begin with a tilde. Under normal circumstances, the file is searched for based only on what you typed. However, if the system variable sh_source_uses_search_path is set to "true", the file is searched for based on the path established with the search_path variable.

The *source* command supports several file formats. The *file* can be a simple ascii script file, an ascii script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler. Some applications also supported encrupted files. The *-echo* and *-verbose* options are ignored for encrypted formatted files.

Examples

This example reads in a script of aliases:

```
prompt> source -echo aliases.tcl
alias q quit
alias hv {help -verbose}
alias include {source -echo -verbose}
prompt>
```

Feedback

See Also

- search_path
- sh_source_uses_search_path
- sh_continue_on_error

---

starrc_gpd_read_opens_shorts

Creates an error file that contains information in the vicinity of opens and shorts for specified nets or regions.

Syntax

status *starrc_gpd_read_opens_shorts*

```
[-gpd gpd_dir]
[-error_file err_file]
[-windowbbox]
[-type err_type]
[-limit limit]
[-add_gui_selection]
[-add_net_attributes option]
[-nets net_name]
[-summary_view]
[-shorts_types err_type]
```

Data Types

gpd_dir	string
err_file	string
bbox	list
err_type	string
limit	integer
option	string
net_name	string
err_type	string

Arguments

`-gpd gpd_dir`

The GPD generated from the StarRC extraction. The argument is the GPD directory.

`-error_file err_file`

An optional file name for the opens and shorts information; the default is starrc_openshort.err.

`-window`*`bbox`*

The design region to load. If this option is not used, the entire database is loaded. The argument is a list {x1,y1,x2,y2}, where x1 and y1 define the lower-left corner of the region and x2 and y2 define the upper-right corner.

`-type` *`err_type`*

Specifies which errors to analyze. Valid values are *open*, *short*, and *all* (default).

`-limit` *`limit`*

The maximum number of errors to display.

`-add_gui_selection`

If used, nets with opens and shorts are highlighted when the GUI is started. On by default.

`-add_net_attributes` *`option`*

Valid values are *replace* (default) and *append*. If *replace*, creates user attributes starrc_drc_violation and starrc_drc_coordinates. If *append*, previous attributes are not removed.

`-nets` *`net_name`*

A list of one or more nets for which to save extra information around opens and shorts. Glob-style wildcards (*) are supported.

`-summary_view`

Each type of shorts and opens errors gets distinctive color of X marker to categorize the errors.

`-shorts_types` *`err_type`*

Specifies which short error types to analyza. Valid values are net unselectable, nonselected, skip_cell, fill, and blockage.

Then, in the Parasitic Explorer error browser GUI, you can:

- Load types of shorts errors selectively
- Apply types of shorts errors to view the shorts errors
- Load and sort the selected types of shorts errors for debugging

Description

This command creates an error file that contains detailed information in the vicinity of opens and shorts for specified nets or regions.

The sources of information are the GPD and the star directory created after a StarRC extraction run. The Parasitic Explorer error browser then uses the generated error file to display layout information for the selected nets or regions.

Examples

The following example lists only those number of opens errors that fit within the specified design region (bounding box) in the Error Browser GUI:

```
pt_shell> starrc_gpd_read_opens_shorts -gpd top.gpd -window
 0,0,10000,5000 -type open
```

The following example lists only those number of shorts errors that fit within the specified design region (bounding box) in the Error Browser GUI, where the shorts errors types are net *unselectable*, *nonselected*, *blockage*, and *power*:

```
pt_shell> starrc_gpd_read_opens_shorts -gpd top.gpd -window
 0,0,10000,5000 -type short \\
            -short_types (net unselectable nonselected blockage power)
```

The following example lists all shorts errors of the blockage type in the summary view:

```
pt_shell> starrc_gpd_read_opens_shorts -gpd top.gpd -summary_view -type
 short  -short_types blockage
```

The following example lists only that number of shorts errors that fit within the specified design region (bounding box) in the summary view:

```
pt_shell> starrc_gpd_read_opens_shorts -gpd top.gpd -summary_view -type
 short  -window 0,0,10000,5000
```

To view all shorts and opens errors from the actual extracted database, instead of limiting only to the list of specified nets, use the commands as shown in the following example:

```
% StarXtract star_cmd
% StarXtract -write_short_regions -nets_file nets_file star_cmd
 ...
pt_shell> starrc_gpd_read_opens_shorts -gpd <gpd_directory> -error_file
 error_file.txt
```

Before invoking the PrimeTime shell, use the *StarXtract* command to access the original GPD directory and add more nets to see additional errors. Then, use the *starrc_gpd_read_opens_shorts* command to view open and short errors in the Error Browser GUI.

---

start_dsta

This command will begin the HyperGrid distributed analysis.

Feedback

Syntax

status *start_dsta*

```
-script analysis_script
[-num_partitions number_of_partitions]
[-min_partition minimum_number_of_partitions]
```

Data Types

```
analysis_script          string
number_of_partitions     integer
minimum_number_of_partitions     integer
```

Arguments

`-script analysis_script`

Specifies the analysis script to be sourced at manager and worker processes.

`-num_partitions number_of_partitions`

Specifies the desired number of partitions to be started. It is an optional field. If not specified, the tool will automatically infer the number of processes from set_host_options command.

Description

The *start_dsta* begins the HyperGrid distributed analysis for the design. Specifically, it will partition the design at manager and loads partitioned design data at workers. Runs the specified analysis script at manager and worker. The command is supported in *HyperGrid Analysis* mode.

Examples

The following example shows the usage of start_dsta command in *HyperGrid Analysis* mode.

```
pt_shell> start_dsta -script run_basic.pt -num_partitions 2

Information: Starting Hypergrid analysis with 2 partitions.
Start of Manager/Worker Task Processing
----------------------------------------
Started    : Task execution on 'partition0' (Hid=1)
Started    : Task execution on 'partition1' (Hid=2)
Successful : Task execution on 'partition0' (Hid=1)
Successful : Task execution on 'partition1' (Hid=2)
----------------------------------------
End of Manager/Worker Task Processing
```

The number of partitions here is 2 as specified by the user.

```
pt_shell> set_host_options -num_processes 2
pt_shell> start_hosts
pt_shell> start_dsta -script run_basic.pt

Information: Starting Hypergrid analysis with 2 partitions.
Start of Manager/Worker Task Processing
----------------------------------------
Started    : Task execution on 'partition0' (Hid=1)
Started    : Task execution on 'partition1' (Hid=2)
Successful : Task execution on 'partition0' (Hid=1)
Successful : Task execution on 'partition1' (Hid=2)
----------------------------------------
End of Manager/Worker Task Processing
```

The number of partitions here is 2 even though user has not provided -num_partitions option. In such cases, it internally picks the number of processes started by start_host command.

```
pt_shell> start_dsta -script run_basic.pt -num_partitions 4
 -min_partition 2

Information: Starting Hypergrid analysis with 2 partitions.
Start of Manager/Worker Task Processing
----------------------------------------
Started    : Task execution on 'partition0' (Hid=1)
Started    : Task execution on 'partition1' (Hid=2)
Successful : Task execution on 'partition0' (Hid=1)
Successful : Task execution on 'partition1' (Hid=2)
----------------------------------------
End of Manager/Worker Task Processing
```

The number of partitions here is 4 as specified by the user. The minimum number of partitions here is 2 as specified by the user. Here the final number of partitions will be decided based on number of workers available. If number of workers more than or equal to -num_partition then final number of partitions will be num_partition, otherwise final number of partitions will be max(min_partition, number of workers available). Note: -min_partition value can not be less than 1 or more than -num_partition.

Feedback

start_eco_scenarios

Starts running PrimeECO engineering change orders using the hybrid timing view ECO flow.

Syntax

```
status start_eco_scenarios
[-coverage_live_views coverage_limit]
[-include_scenarios scenario_name_list]
[-timeout seconds]
[-type fix_type_list]
```

Data Types

```
coverage_limit       float
scenario_name_list   list
seconds              integer
fix_type_list        list
```

Arguments

`-coverage_live_views coverage_limit`

Specifies the minimum coverage limit to determine live views. For example, if you specify 0.9 for this option, the tool selects live views to achieve 90% live view coverage. Once the number of live views is determined, the tool adjusts host options to launch the same number of worker processes as the live views.

`-include_scenarios scenario_name_list`

Specifies a list of scenarios to include as live views.

Even though PrimeECO selects the best configuration of live and static views, you might want include specific scenarios in live views for various reasons. Use this option to ensure that the specified scenarios are part of the live views selected by the tool. The scenarios specified with this option are always part of the live views, but the tool selects additional scenarios to meet the coverage target.

`-type fix_type_list`

Specifies a list of one or more types of timing violations to fix: *setup*, *hold*, *max_transition*, *max_capacitance*, or *noise*. By default, the tool fixes the *setup*, *hold*, *max_transition*, and *max_capacitance* types.

`-timeout seconds`

Specifies, in seconds, how long the *start_eco_scenarios* command waits for the remote hosts to come online. While the command is waiting, no other commands can be executed at the manager. If all the remote hosts come online before the timeout has expired, the command returns immediately upon

connection of the final host. If all the remote hosts do not come online before the timeout has expired, the command returns and accepts the remainder of the hosts online in the background. The value specified must be greater than or equal to *10s*. If the option is not specified, the default is *21600s* (6 hours).

Description

The *start_eco_scenarios* command runs hybrid timing view ECO operations. In the hybrid timing view ECO flow, the PrimeECO tool uses a combination of live views for accuracy-critical ECO scenarios and static views for less critical scenarios. The static-view timing and violation information is merged into the live-view scenarios at intervals determined by the tool.

The *start_eco_scenarios* command determines live views based on the number of processes specified by the *set_host_options -num_processes* command and launches live views as distributed multi-scenario analysis (DMSA) worker processes. Be sure to specify the number of processes with *set_host_options* before you use the *start_eco_scenarios* command, because this determines the number of live views.

Suppose you have 100 scenarios for your setup and hold timing fixing. If you run ordinary DMSA, you need to have 100 worker processes simultaneously running in one or multiple machines.

In the hybrid timing view ECO flow, if you have 25 live-view scenarios that cover 90 percent of the violations, the tool can merge the remaining 75 scenarios with the 25 live-view scenarios as static views. With this configuration, the tool runs setup and hold fixing with only 25 DMSA worker processes instead of 100.

For another example, because of machine resource limitations, you might be able to run only 10 DMSA worker processes simultaneously. In that case, you can have 10 live views and 90 static views with the live-view timing coverage of 80 percent of the violations. In this configuration, the resource reduction is even greater, but because the live views have less timing coverage, you might not be able to achieve the desired fixing coverage.

Examples

Suppose there are 100 scenarios, S1, S2, ... S100, and each scenario takes 10GB of memory. Running full DMSA requires 1,000 GB of memory to run 100 scenarios. In this example, you want to reduce the memory requirements so that you can run timing fixing on a single machine that has 256 GB of memory.

The following commands explore various configurations of live versus static views to evaluate the memory and coverage tradeoffs.

```
eco_shell> report_eco_scenarios -num_live_views 10
 ...
eco_shell> report_eco_scenarios -num_live_views 20
 ...
```

```
eco_shell> report_eco_scenarios -num_live_views 30
 ...
```

Each report shows the total number of scenarios, the selected number of live ECO scenarios, the number of remaining scenarios to be statically considered, and the resulting live-scenario coverage for the proposed scenario set for each violation type.

The report shows that using 20 live views achieves 95 percent scenario coverage. Because 20 live views requires 200 GB of memory, it satisfies your memory limit of 256 GB.

The following commands start 20 live views.

```
eco_shell> set_host_options -num_processes 20 ...
 ...
eco_shell> start_eco_scenarios
 ...
```

You might want to include specific scenarios in live views to make sure some scenarios are fully covered. The following example shows how to include scenarios S56 and S74.

```
eco_shell> set_host_options -num_processes 20 ...
 ...
eco_shell> start_eco_scenarios -include_scenarios {S56 S74}
 ...
```

The following session explores the usage of different numbers of live views, reporting the timing and other data coverage versus the machine resource usage. Then it performs ECOs using 20 live views running on 20 host processes.

```
create_scenario -name S1 \\
  -specific_data {specific_S2.tcl} -eco_data S1/eco_data
create_scenario -name S2 \\
  -specific_data {specific_S2.tcl} -eco_data S2/eco_data
create_scenario -name S3 \\
  -specific_data {specific_S3.tcl} -eco_data S3/eco_data

report_eco_scenarios -num_live_views 15
report_eco_scenarios -num_live_views 20
report_eco_scenarios -num_live_views 30

set_host_options -num_processes 20
start_eco_scenarios
fix_eco_timing -type setup ...
```

---

start_gui

Starts the application GUI.

Syntax

```
string start_gui
[-file script]
[-no_windows]
[-offscreen 1|0]
[-- x_args ...]

string script
```

Arguments

`-file script`

The given script file is sourced before the GUI starts.

`-no_windows`

The GUI starts without showing the default window.

`-offscreen`

If the specified value is 1 then the GUI starts in offscreen mode.

If the specified value is 0 then the GUI starts in normal (X Display) mode.

`-- x_args`

X11-specific arguments to pass to the X connection.

Description

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. This is an alias for the gui_start command.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful start_gui command has no effect.

Examples

The following example starts the application GUI.

shell> *start_gui*

See Also

- stop_gui
- gui_start
- gui_stop

---

start_hosts

Starts the hosts specified by the *set_host_options* command.

Syntax

status *start_hosts*

```
[-timeout   seconds]
[-min_hosts num_hosts]
```

Data Types

```
seconds         integer
num_hosts       integer
host_option_names       list
```

Arguments

`-timeout seconds`

Specifies, in seconds, how long the *start_hosts* command waits for the remote hosts to come online. While the command is waiting, no other commands can be executed at the manager. If all the remote hosts come online before the timeout has expired, the command returns immediately on connection of the final host. If all the remote hosts do not come online before the timeout has expired, the command returns and accept the remainder of the hosts online in the background. The value specified must be greater than or equal to zero. If the option is not specified, the default is 21600s (6 hours).

`-min_hosts num_hosts`

Specifies the minimum number of hosts that the *start_hosts* command waits to come online. While the command is waiting, no other commands can be executed at the manager. As soon as the minimum number of hosts have come online, the command returns immediately and allow commands to execute at the manager. The *-timeout* option to the command overrides the *-min_hosts* option. Therefore, if the minimum number of hosts does not come online before the timeout has expired, the command is governed by the behavior of the *-timeout* option as described previously. The value specified must be greater

than or equal to zero. If the option is not specified, by default the command waits for all hosts launched to come online. In the presence of virtual workers, the *-min_hosts* option refers to the number of real workers. Therefore, *start_hosts* will wait until these many real workers come online along with their respective virtual workers.

host_option_names

Start hosts belonging to the list of host options specified, which were previously defined by the *set_host_options* command. If you do not specify a list of host options, the command starts hosts for all host options by default.

Description

This command explicitly starts the hosts to be used as compute resources. Host options must first be setup using the *set_host_options* command. If the hosts are not explicitly started using this command, they are started during execution of the *update_timing* command.

If the host_options defined by the *set_host_options* command contains virtual workers, then the *start_hosts* command will wait for all workers (including real and virtual) to come online. In this situation however, if the *-min_hosts* option is specified, *start_hosts* will wait until that many real workers come online along with their respective virtual workers.

When hosts are started they end up in one of the following states

```
LAUNCHED      : The process is launched but not ready for use yet.
ONLINE        : The process is online and ready for use.
SHUTDOWN      : The process was shutdown.
FATAL         : The process abnormally terminated.
MISALIGNED    : The manager and worker processes are different versions
                of PrimeTime and the worker process is not usable.
SHUTTING_DOWN : The process is shutting down.
```

Remote Connection Considerations

1. For the manager process to interact with remote processes, there is a connection between the manager and the remote host. Each connection consumes two file descriptors from the operating system. Generally, there is a limit on the number of file descriptors that a user-specified process can open simultaneously. Typically, a user-specified process is allowed to open 1024 simultaneous file descriptors. Because the manager PrimeTime process uses several descriptors for normal operations, a maximum of 500 remote processes can be launched. The *start_hosts* command rejects any hosts beyond 500. To see the system user limit on the number of file descriptors allowed, run the *limit descriptors* command in the UNIX terminal.
2. When using the *rsh* command to launch remote processes, depending on the host configuration, there can be imposted limits in relation to the number of allowed connections.

- The host that you want to connect to can define a limit on the number of simultaneous connections that a process can make to the host in the /etc/xinetd.conf file. The *instances* keyword defines the maximum number of connections allowed. After the number of connections exceeds the limit, the circuit will fail to setup, and a protocol failure will be returned as an error. If this occurs, the manager log file shows the following message:

  poll: protocol failure in circuit setup

  Action: The system limit on the number of incoming connections can be changed only by a superuser. However, you can specify fewer remote processes to be launched on the specific remote host than the instance limit specified by that remote host.

- The host launching the remote processes can define a limit on the range of privileged ports accessible to you. The range is typically 512-1024. After all privileged ports are exhausted, subsequent *rsh* connections will fail to set up, and an out of sockets error will be returned as an error. If this occurs, the manager log file shows the following message:

  rcmd: socket: All ports in use

  Action: The system limit on the number of privileged ports available can be changed only by a superuser. However, you can use a different protocol to launch the subsequent processes beyond the number of privileged ports. For example, *ssh* does not use privileged ports, or you can submit the remote process to a managed resource such as LSF or Grid.

Examples

To start and verify the hosts, use the following flow:

```
# Specify the options of each host
set_host_options -name options1 ...
set_host_options -name options2 ...

# Start the hosts
start_hosts ...

# Verify that the hosts started correctly and report the usage
report_host_usage -verbose
```

Feedback

start_learning

Enables PrimeTime to learn users' custom ECO optimization.

Syntax

```
status start_learning
```

Arguments

None

Description

The *start_learning* command enables PrimeTime to learn users' custom ECO optimization. PrimeTime currently supports only the ECO optimization performed by one or more than one *size_cell* commands. After the *start_learning* command is executed, PrimeTime is ready to learn optimization that consists of one or multiple size_cell commands.

After PrimeTime learns custom optimization moves, the *save_training_data* command saves the training data for future usage. Later PrimeTime uses the training data to train itself with the custom optimization moves and apply them to new designs.

Examples

The example scripls below illustrate how to generate custom optimization training data. First perform the *start_learning* command to get PrimeTime ready for custom sizing operations. Then, apply *size_cell* commands manually or source a file that contains multiple *size_cell* commands. This is useful when a customized ECO script generates a sequence of *size_cell* commands. Once sizing operation is completed, use the *save_training_data* command to save the training data for future usage.

```
pt_shell> start_learning
pt_shell> size_cell U100
pt_shell> source my_eco_changes.tcl
pt_shell> size_cell U200
pt_shell> save_training_data -out my_custom_training.td
```

The following example illustrates the *fix_eco_power* command reads the training data in the example above, trains itself with the training data, and reduces power in the current design using the training data.

```
pt_shell> set training_data_directory ./my_training_data_dir
pt_shell> fix_eco_power -training_data my_custom_training.td
```

start_multi_user_server

Switches the PrimeTime session into multi-user server mode.

Syntax

status *start_multi_user_server*

```
[-access_group    group_name]
[-max_clients     num_clients]
[-file            script_file]
[-log             log_file]
```

Data Types

```
group_name        string
log_file          string
num_clients       integer
script_file       string
```

Arguments

`-access_group` *group_name*

Specifies the name of the UNIX group used to create the output files written by the multi-user server session. The files written will have read/write permissions enabled for all group members, ensuring that the client users can access and delete their files as needed. A default access_group can be specified by the *multi_user_required_access_group* variable. If both are specified, the option takes precedence.

`-max_clients` *num_clients*

Specifies the maximum number of clients that can connect simultaneously to the current multi-user session. Value must range between 1 <= value <= 16. If this option is not specified, the client limit is either 16 or [current number of cores], whichever is lesser.

`-file` *script_file*

Executes the commands in the specified script file before displaying the multi-user server's pt_shell prompt. If the last statement in the script file is the *quit*,

exit, or *stop_multi_user_server* command, no prompt is displayed and the command shell exits.

`-log` *`log_file`*

Path to file where the logs corresponding to the multi-user session will be written. The verbosity of the logs can be controlled using the *multi_user_logging_level* variable. If the option is not specified, the logs are written in the server's working directory as file named ${server_name}_multi_user.log.

Description

This command configures the PrimeTime session to run in multi-user server mode. The multi-user feature allows different users to connect to a common host and access the same PrimeTime design analysis to run read-only commands in parallel with each other.

The design state cannot be changed after the multi-user session is started. This command performs an implicit timing update if needed.

Upon successful execution, this command starts a new multi-user server shell. The server shell is limited to a subset of PrimeTime commands, including multi-user commands and built-in commands. The set of allowed commands can be queried by running *help ** at the server shell prompt. In the server shell, only PrimeTime variables that do not affect the timing state of the design can be set and modified. If a variable is modified that would change the design timing, a severe error occurs and the multi-user session is terminated.

When this command starts the server session, it reports information about the session, such as: session ID, maximum clients allowed, path to the session logs, verbosity level of session logs, and number of cores available for client use.

If the *start_multi_user_server* command was run in a batch analysis script, analysis script execution pauses while the server session runs.

When the server session is started,

- If a server shell script was specified with the *-file* option of this command, that script is run in the server shell. This script can be used to automate configuration, logging, and maintenance, or to monitor the session or exit the session after a period of time.
- If no server shell script is specified (or the specified script completes), the tool issues an interactive server shell prompt for the duration of the server session.

The server session terminates when the *quit*, *exit*, or *stop_multi_user_server* command is run. Depending on the command,

- If the *stop_multi_user_server* command was used, the original analysis session resumes execution at the point where the *start_multi_user_server* command was run.
- If the *quit* or *exit* command was used, the PrimeTime analysis session exits.

Client Connections

When the *start_multi_user_server* command starts a server session, it prints a report that includes a session ID string. This session ID should be given to any client users who want to connect to the server for analysis.

The server then begins listening on a socket port on the server machine for connection attempts from potential clients. This port number is part of the unique session ID string.

To start a client session, the client user provides the session ID to the *start_multi_user_client* script. When the server receives this request, it forks a subprocess to serve the client analysis requests efficiently.

Data Security

The multi-user analysis feature relies on UNIX groups to control security permissions and protect access to compute hosts and data. It requires a UNIX group to start the session, and it grants access only to client users that belong to that group. It also requires the client user to be logged in (using ssh, rsh, and so on) to the host where the server is running to request access to the session. By leveraging standard and trusted system security protocols (e.g. SSH), the server user can control access to the multi-user analysis by controlling access to the host machine upon which the server is running.

The access group also ensures that all client users have read-write permissions on files written by the client subprocess. Files written by client sessions are stored in the client's working directory, but they are created under the server user's ownership. Read-write permissions are appropriately set for group members, which ensures that client users can access the files and delete them as needed.

Processor Core Management

The maximum number of cores available to client sessions is equal to the number of cores available in the server's PrimeTime process. The server-side analysi script can change the number of cores by running the *set_host_options -max_cores* command before starting the multi-user server session.

The multi-user feature leverages the benefits from Dynamic Core Management (DCM) to optimally distribute cores among active clients. It will allow the client subprocesses to dynamically transfer cores amongst each other depending on the level of multi-threaded algorithm being run on them. Each client sub process will start with one core and DCM will transfer additional cores to clients running MT algorithms if cores are available.

Examples

The following information is printed after running the *start_multi_user_server* command in a PrimeTime session using 6 cores:

```
pt_shell> start_multi_user_server -access_group synopsys -max_client 2
Information: Checked out license 'PrimeTime-ADV-PLUS' (PT-019)
```

```
Information: Switching into multi-user mode. (MC-150)
  Server Name:     user.123
  Session ID:      31:35787
  Server Log:      user.123_multi_user.log
  Logging Level:   low
  Access Group:    synopsys
  Client Cores:    6 (Total)
  Client Limit:    2

pt_shell>
```

You can modify the number of cores allocated to the multi-user session before starting it by using the *set_host_options* command:

```
pt_shell> set_host_options -max_cores 16
  Information: The max_cores limit for the local (current) process has
 been modified by +10 to 16. (CMCR-103)

pt_shell> start_multi_user_server -access_group synopsys -max_client 2
  ...
  Client Cores:    16 (Total)
  Client Limit:    2
  ...
```

---

start_profile

Starts profiling PrimeTime commands.

Syntax

```
status start_profile
  [-output directory_name]
  [-verbose]
  [-include report_list]
```

Data Types

```
directory_name     string
report_list        list
```

Feedback

Arguments

`-output` *`directory_name`*

Specifies the name of a directory to save the profiling reports to. By default, the output directory name is *profile* in the current working directory.

`-verbose`

Specifies the tracking of all commands in profiling reports. Without this option, only commands which take more than 0.1 second to run or use more than 100 Kb of memory are reported.

`-include` *`report_list`*

Limits the profiling actions to selected items. Allowable list entries are: *stopwatch*, *tcl_profile* and *perf_cpu*.

Description

The *start_profile* command initiates command-level profiling in PrimeTime.

For every PrimeTime command or procedure invocation, the cpu time, elapsed time, delta memory, and number of calls are registered. Several commands or procedure invocations at the same scope level are collapsed into one and their CPU times, elapsed times, and delta memory are added; the number of calls is increased by one.

The PrimeTime profile handles the source command in a special manner. Since source can be used to arbitrarily call deep levels of scripts, source commands also show file names. Therefore, for source commands, even if two source commands are executed at the same scope level, they usually have two different entries, unless they source the exact same file.

In addition to the PrimeTime profile output, a stopwatch report is also created. For each PrimeTime command, a start and an end *events* are recorded. At each stopwatch event, metrics such as current CPU time, elapsed time, and peak memory usage are saved. For each metric, a difference between the current and the previous value is also reported.

PrimeTime profiling reports are written to an output directory at the exit of a PrimeTime session or when the command *stop_profile* is executed. Stopping of profiling also creates a summary HTML page with links to profiling reports or data files with short descriptions.

Use *-include* options to select only the report you want to see. For example, if you require only the code-level performance profiling data, use "*-include {perf_cpu}*".

The *stop_profile* command is used to stop the command level profiling in PrimeTime that was previously started by the *start_profile* command.

In the distributed multi-scenario flow, use *remote_execute* command to activate profiling of remote processes. Profiling is performed on a PrimeTime process, not on a scenario. So if

there are fewer hosts than scenarios, the profiling output appears only in scenario output directories for scenarios that were first to execute on worker hosts.

Examples

In the following script example of profiling, the reports are written to the reports/run_profile directory .

```
start_profile -output reports/run_profile
 ...   # Usual PT script
stop_profile
```

The following script example shows how to enable Tcl profiling in distributed multi-scenario analysis (DMSA). The profiling is first enabled on the DMSA manager and then on DMSA workers.

```
set multi_scenario_working_directory ./ms_data
set manager_profile_dir $multi_scenario_working_directory/manager_profile
start_profile -output $manager_profile_dir
 ...    # Setting up DMSA

current_session -all
remote_execute {
  set outdir
 $multi_scenario_working_directory/[current_scenario]/worker_profile
  start_profile -output $outdir
}
```

---

stop_gui

Stops the application GUI.

Syntax

string *stop_gui*

Arguments

None.

Feedback

Description

This command stops the application GUI and returns to the shell prompt. It is ignored if the application GUI has not been started or has been stopped. This is an alias for the gui_stop command.

Examples

The following example stops the application GUI and returns to the shell prompt.

shell> *stop_gui*

See Also

- start_gui
- gui_start
- gui_stop

---

stop_hosts

Stops all hosts that have been started.

Syntax

int *stop_hosts*

`[host_option_names]`

Data Types

`host_option_names` `list`

Arguments

`host_option_names`

Shut down all hosts belonging to the list of host options specified, which were previously defined by the *set_host_options* command. If you do not specify a list of host options, the command stops all host options by default.

Description

The *stop_hosts* command shuts down all hosts that have been started. The hosts could have been explicitly launched using the *start_hosts* command or implicitly launched during the execution of the *update_timing* command. Optionally, the *stop_hosts* command shuts down all hosts belonging to a list of host options by specifying the *host_option_names* argument.

In the Distributed Multi-Scenario Analysis (DMSA), stopping hosts will also remove scenarios that can no longer run from the current session. Specifically if a set of scenarios has an affinity with the host options being stopped, all scenarios in the set will be removed.

Examples

In the following example, the manager process is running on the host named ptnlm15 using a 64-bit binary and specifies several different sets of host options.

The first host options, named "my_opts1", specifies

```
- to use one process on the same host as the manager
- no upper limit on the number of cores to use so the default applies.
```

The second host options, named "my_opts2", specifies

```
- to use one process on the same host as the manager, explicitly
  mentioning the manager host by name
- to use a maximum of two cores.
```

The third host options, named "my_opts3", specifies

```
- to use one process on the host named ptnlm11, since no submit
  command is specified, "rsh" will be used to connect to ptnlm11
- to use a maximum of three cores.
```

The fourth host options named "my_opts4", specifies

```
- to use one process on the host named ptnlm12 connecting to
  ptnlm12 using the submit command "/usr/bin/rsh"
- no upper limit on the numebr of cores to use so the default applies.
```

The fifth host options named "my_opts5", specifies

```
- to use one process on an LSF farm, using the "bsub" command found
  from the environment path to submit the job, requiring 1GB of
  memory and two slots per compute server. Notice that the farm job
  must be specified with the number of slots needed to support the
  number of cores to use with the -n 2 -R span\\[ptile=2\\]
  options.
- to use the terminate command "bkill" found from the environment
  path for the termination of jobs that do not come online.
- to use a maximum of two cores.
```

The sixth host options named "my_opts6", specifies

```
- to use one process on a Grid farm, using the "qsub" command found
  from the environment path to submit the job, using the project
  named "bnormal", requiring 1GB of memory and four slots per compute
  server. Notice that the farm job must be specified with the number
  of slots needed to support the number of cores to use by targeting
  the parallel environment "mt" requesting 4 slots with the "-pe mt 4"
  options.
```

```
- to use the terminate command "qdel" found from the environment
  path for the termination of jobs that do not come online.
- to use a maximum of four cores.
```

Note: Before calling the *stop_hosts* command, all the processes report as ONLINE and after calling the *stop_hosts* command all the processes report as SHUTDOWN. The order in which the hosts shutdown is random.

Call the *set_host_options* command to specify the host options.

```
pt_shell> set_host_options -name my_opts1 -num_processes 1
1
pt_shell> set_host_options -name my_opts2 -num_processes 1 \\
          ptnlm15 -max_cores 2
1
pt_shell> set_host_options -name my_opts3 -num_processes 1 \\
          ptnlm11 -max_cores 3
Warning: no submit command specified to access remote host
 'ptnlm10'. The 'rsh' command will be used. (CMCR-004)
1
pt_shell> set_host_options -name my_opts4 -num_processes 1 \\
          -submit_command "/usr/bin/rsh" ptnlm12
1
pt_shell> set_host_options -name my_opts5 -num_processes 1 \\
          -submit_command "[sh which bsub] -n 2 -R rusage\[mem=1000\] \\
          -R span\[ptile=2\]" -terminate_command "[sh which bkill]" \\
          -max_cores 2
1
pt_shell> set_host_options -name my_opts6 -num_processes 1 \\
          -submit_command "[sh which qsub] -P bnormal -pe mt 4 \\
          -l mem_free=1G" -terminate_command "[sh which qdel]" \\
          -max_cores 4
1
```

Call the *start_hosts* command to start the worker processes.

```
pt_shell> start_hosts

stop_multi_user_client

Terminates a set of specified multi-user client sessions.

Syntax

int *stop_multi_user_client*

```
        client_names_regex
```

Data Types

```
client_names_regex      string
```

Arguments

client_name_regex

Shut down all client sessions whose name matches the specified regular expression pattern. The pattern is a required argument.

Description

The *stop_multi_user_client* command shuts down all active client sessions whose name matches the specified regex pattern. Internally, the command checks the PID of the subprocess serving the specified clients, then sends SIGTERM signals to terminate them.

The specified clients are immediately terminated, even if they are in the middle of processing a command. The client log files will not contain any explicit message indicating that the *stop_multi_user_client* command was the reason for the session termination.

This command reports the names of all clients terminated by the specified pattern.

Examples

The following multi-user server shell command terminates all clients owner by userA:

```
pt_shell> stop_multi_user_client userA*

 Information: Shutting down client 'userA.12785'
```

```
 Information: Shutting down client 'userA.14902'
 Information: Terminated 2 clients.
```

The following command terminates all clients:

```
pt_shell> stop_multi_user_client *

 Information: Shutting down client 'userB.13844'
 Information: Shutting down client 'userC.12158'
 Information: Terminated 2 clients.
```

---

stop_multi_user_server

Stops the currently active multi-user session.

Syntax

int *stop_multi_user_server*

Description

The *stop_multi_user_server* command ends the current multi-user server session. Client users will no longer be able to request access to the PrimeTime analysis using the *start_multi_user_client* script after this command is run.

All currently connected clients are immediately terminated, even if they are in the middle of processing a command. The client log files will not contain any explicit message indicating that the *stop_multi_user_server* command was the reason for the session termination.

After this command is run, the original analysis session (that was in place when the *start_multi_user_server* command was run) is restored, and the timing state of the design can again be modified.

Examples

The following example shows the current multi-user server session being stopped:

```
pt_shell> stop_multi_user_server
1
```

---

stop_profile

Stop profiling PrimeTime commands.

Syntax

status *stop_profile*

Arguments

None.

Description

The *stop_profile* command is used to stop the command level profiling in PrimeTime that you started previously using the *start_profile* command. You should use this command in conjunction with the *start_profile* command to write out profiling information for PrimeTime scripts.

Stopping a profile stops collecting information about commands for profiling and writes out profiling reports into the directory specified by *start_profile -output*. By default, the output directory name is *profile* in the current working directory.

This command succeeds all the time except when the profiling is not currently active.

Examples

The following gives an example of profiling.

```
pt_shell> start_profile
pt_shell> ....   # Usual PT script
pt_shell> stop_profile
```

See Also

- start_profile

Feedback

suppress_message

Disables printing of one or more informational or warning messages.

Syntax

string *suppress_message* [*message_list*]

`list message_list`

Arguments

message_list

A list of messages to suppress.

Description

The *suppress_message* command provides a mechanism to disable the printing of messages. You can suppress only informational and warning messages. The result of *suppress_message* is always the empty string.

A given message can be suppressed more than once. So, a message must be unsuppressed (using *unsuppress_message*) as many times as it was suppressed in order for it to be enabled. The *print_suppressed_messages* command displays the currently suppressed messages.

Examples

When the argument to the *unalias* command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to suppress the CMD-029 message:

```
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
prompt> suppress_message CMD-029
prompt> unalias q*
prompt>
```

Feedback

swap_cell

Swaps one or more cells with a new design or library cell.

Syntax

integer *swap_cell*

```
cell_list
swap_in
[-dont_preserve_constraints]
[-file file_name]
[-format db | verilog | vhdl]
```

Data Types

```
cell_list          list
swap_in            string
file_name          string
```

Arguments

cell_list

Specifies a list of cells to be swapped out.

swap_in

Specifies the name of the design or library cell to be swapped in.

-dont_preserve_constraints

Indicates that *swap_cell* is not to reapply the current design constraints after the swap.

-file *file_name*

Specifies the name of a file that contains a design that is to be swapped in.

-format db | verilog | vhdl

Specifies the format for *file_name*. Allowed values are *db* (the default), *verilog*, and *vhdl*.

Description

The *swap_cell* command replaces the cells in the *cell_list* option with *swap_in* (a new design or library cell), and incrementally relinks the design. The command checks to ensure that the pinouts of the swapped-in and swapped-out cells are the same. For example, every boundary pin of the cell being swapped out must have a counterpart with the same name in the cell being swapped in, and vice versa.

The *swap_cell* command is considered a netlist editing command. Like all other netlist editing commands, for the *swap_cell* command to succeed, all of its arguments must

succeed. If any arguments fail, the netlist remains unchanged. The *swap_cell* command returns a 1 if successful and a 0 if unsuccessful.

If you want to swap a library cell for another library cell that is just a different size, use the *size_cell* command instead of the *swap_cell* command. The *size_cell* command is more efficient than the *swap_cell* command, and it is optimized for incremental timing updates.

Library cells being swapped in must be in memory. Designs being swapped in can be in memory or can be retrieved from a file using the *-file* and *-format* options. For more information, see the "Interaction of Reading Netlists and swap_cell" section.

By default, design constraints are preserved by writing a script to the directory referenced by the *pt_tmp_dir* variable, then loading the script after the swap has completed. Use the *-dont_preserve_constraints* option only if you plan to perform several *swap_cell* commands; for example, in a loop. In this case, it is much more efficient to use the *write_script* command then the *swap_cell -dont_preserve_constraints* command, and then the *source* command in your script.

When a subdesign is swapped in or out using swap_cell, the annotated parasitics on nets connected to that cell are removed as they are no longer valid.

If a swapped cell is in the parent chain of any objects that are elements of a saved collection, these collections might be deleted based on the *collection_deletion_effort* variable. For more information, see the man pages for *collections* and associated variables.

The *swap_cell* command does not create black boxes. If the design that is swapped in contains unresolved references, the result of the swap is a partially linked design.

Interaction of Reading Netlists and swap_cell

The best way to swap in a design that is not in memory is to use the *-file* and *-format* options. When you load the new design this way, the *swap_cell* command maintains the current design, and the swap is a one-step operation. Explicitly reading a new design before swapping cells changes the current design, so you must remember to reset the current design back to the previous current design before using the *swap_cell* command. Thus, it is preferable to use the *-file* and *-format* options. Both alternatives are illustrated in the EXAMPLES section.

Interaction of Linking and swap_cell

Do not perform an explicit link after executing *swap_cell*. The *swap_cell* command implicitly relinks the part of the design you have changed; therefore, performing an explicit link after executing *swap_cell* can undo some or all of the work done by *swap_cell*.

For example, consider U2, an instance of design X, which contains instance U0, an instance of design Y. If you swap out U2/U0 for a different design, PrimeTime has modified the *instance* U2/U0; it has not modified the design Y. Therefore, an initial link causes U2/U0 to revert to the original Y (the version of Y inferred by the *link_path*).

PrimeTime does not save information about cells that have been swapped. That information persists only until the next link.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Feedback

Examples

The following example shows the optimal method for swapping in a design from a file. The design "A" is in "A.db". The *swap_cell* command replaces cells u1, u2, and u3 in TOP with the design A (in A.db).

```
pt_shell> current_design
{"TOP"}
pt_shell> swap_cell {u1 u2 u3} A -file A.db
Loading db file '/usr/designs/A.db'
 ...unlinking u1
 ...unlinking u2
 ...unlinking u3
1
pt_shell> current_design
{"TOP"}
```

The following example accomplishes the same task as the previous example, but shows the method where the design file is read explicitly.

```
pt_shell> current_design
{"TOP"}
pt_shell> read_db A.db

synchronize_attribute

Synchronizes the setting for an attribute belonging to objects in a collection, across all scenarios in command focus in DMSA mode.

Syntax

status *synchronize_attribute*

```
[-class class_name]
[-must_exist]
[-merge_type rule_name]
object_spec
attribute_name
```

Data Types

```
class_name          string
rule_name           string
object_spec         collection or string
attribute_name      string
```

Arguments

`-class class_name`

Specifies the object class of the objects whose attributes are to be synchronized, in the case where the *object_spec* is a name pattern and not a collection. It can be set to *port*, *cell*, *pin*, or *net*.

`-must_exist`

Unsets a user-defined attribute across all scenarios if the attribute is currently not set in any of these scenarios. By default, the command synchronizes the attributes as specified by the *-merge_type* option (*max* by default) without considering whether the attributes are currently set.

`-merge_type rule_name`

Specifies how to merge different attributes that come from the scenarios, either *min* or *max*. The default is *max*, which uses the maximum numeric value found, or the latest string alphanumerically, or the value *true* for a Boolean attribute. Setting this option to *min* has the opposite merging effect.

object_spec

Specifies the objects on which to set the attribute either as an object collection or a name string combined with the *-class* option. Only a single object specification is accepted.

attr_name

Specifies the name of the attribute to synchronize, either a user-defined attribute or the dont_touch application attribute. Other application attributes cannot be synchronized with this command.

Description

The *synchronize_attribute* command synchronizes the value of an attribute for all objects in a collection, across all scenarios in command focus in DMSA mode. The attribute must be a user-defined attribute or the dont_touch application attribute.

The command sets the specified attribute to the same value across all scenarios, by default choosing the largest numeric value found, or the latest string alphanumerically. For a Boolean attribute, if both of *true* and *false* settings are found, the attributes are synchronized to *true*.

For the opposite synchronization behavior, set the *-merge_type* option to *min*.

Examples

In the following DMSA example, there are multiple scenarios, one of which is called scen1. A script creates a user-defined net attribute and assigns a value to that attribute for all nets, using a different value for scenario scen1. Later, the *synchronize_attribute* command synchronizes the attribute setting to the larger value across all scenarios.

```
pt_shell> remote_execute {
    define_user_attribute -type float -class net attr_float
    if {[current_scenario] == "scen1"} {
      set_user_attribute [get_nets] attr_float 10.0
    } else {
      set_user_attribute [get_nets] attr_float 15.0
    }
  }
  ...
  pt_shell> synchronize_attribute {[get_nets]} attr_float
```

Feedback

t

test_library

Debug command to view library data in the memory.

Syntax

Boolean *test_library*

`-lib_name` *`library_name`*

Data Types

`library_name`	`string`

Arguments

`-lib_name` *`library_name`*

Indicates the library whose data user wants to view.

Description

This command opens an internal shell and user can view various options in that shell to display library data in memory.

u

unalias

Removes one or more aliases.

Syntax

string *unalias*

Feedback

patterns

Arguments

patterns

Specifies the patterns to be matched. This argument can contain more than one pattern. Each pattern can be the name of a specific alias to be removed or a pattern containing the wildcard characters * and %, which match one or more aliases to be removed.

Description

The *unalias* command removes aliases created by the *alias* command.

Examples

The following command removes all aliases.

```
prompt> unalias *
```

The following command removes all aliases beginning with f, and the alias rt100.

```
prompt> unalias f* rt100
```

See Also

- alias

---

undefine_derived_user_attribute

Remove an attribute definition defined in Tcl

Syntax

string *undefine_derived_user_attribute* -classes *class_list*

-name *attribute_name*

```
list class_list
string attribute_name
```

Arguments

-classes class_list

Remove attribute on these classes

-name attribute_name

Name of the attribute to remove

Feedback

Description

The *undefine_derived_user_attribute* command removes an attribute defined by the *define_derived_user_attribute* command.

Examples

To remove the my_attr attribute previously created with the *define_derived_user_attribute* command do the following:

```
prompt> undefine_derived_user_attribute -class cell -name my_attr
```

See Also

- define_derived_user_attribute
- get_attribute

---

undo

Reverses the effects of ECO editing commands (*size_cell*, *insert_buffer*, and *remove_buffer*).

Syntax

```
status undo
[-levels num_levels
[-check_only]
[-silent]
```

Data Types

num_levels integer

Arguments

`-levels num_levels`

Reverses the effects of the specified number of command levels. The default is 1.

`-check_only`

Causes the command to return the same status and messages it would otherwise return without actually changing anything.

`-silent`

Suppresses messages and Tcl errors.

Feedback

Description

This command undoes the effects of one or more ECO editing commands. The command can be used only if enabled in the PrimeTime GUI (ECO > Undo > Enabled). A PrimeTime-ADV-PLUS license is required.

The undone commands can be redone using the *redo* command.

Examples

The following example reverses the effects of a *size_cell* command.

```
pt_shell> size_cell InstSimple/InterNand ND2X4
  ...
pt_shell> undo
  ...
```

See Also

- redo
- undo_config

---

undo_config

Configures the undo stack.

Syntax

```
old_value undo_config
{ -enable | -disable }
```

Arguments

`-enable`

Re-enables the undo stack after it is disabled. See *-disable* option for more details.

`-disable`

Disables the undo stack. The undo is cleared and no new commands are added to the stack until it is enabled.

This option is useful if the user is about to make a large number of changes which he/she knows that they are not going to undo. Disabling in this case will not waste memory and also speed up the command processing.

Description

This command configures the undo stack.

The return value is the old value of the setting.

Examples

The following example disables undo, runs a complex command and re-enables undo:

```
shell> undo_config -disable
shell> fix_eco_drc -type max_fanout
shell> undo_config -enable
```

See Also

- undo
- redo

---

unset_rtl_to_gate_name

Specifies the signals or objects that must never be mapped, or to undo the erroneously mapped signals or objects.

Syntax

status *unset_rtl_to_gate_name*

```
        name
```

Data Types

name string

Arguments

name

Specifies the name of the RTL object that is not changed to the gate-level object by the name-mapping process.

Description

If you have done only the RTL simulation to generate the RTL backward SAIF or RTL VCD file, PrimePower tries to do the name mapping to find the gate-level objects in the RTL SAIF or VCD file. To prevent the erroneous mapping of the RTL-to-gate-level objects, use the *unset_rtl_to_gate_name* command. This command unmaps the erroneous mapping applied to the specified RTL objects.

Feedback

Examples

The following example unmaps the erroneously mapped RTL and gate-level objects. PrimePower searches the *reg_i[1]* object in the gate-level design to see if it appears in the RTL VCD or SAIF file.

```
pt_shell> unset_rtl_to_gate_name reg_i[1]
```

See Also

- set_rtl_to_gate_name

---

unsetenv

Removes a system environment variable.

Syntax

string *getenv*

```
        variable_name
```

Data Types

variable_name string

Arguments

variable_name

Specifies the name of the environment variable to be unset.

Description

The *unsetenv* command searches the system environment for the specified *variable_name* and removes variable from the environment. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the *env* Tcl array variable. The *unsetenv*, commands is a convenience function to interact with this array. It is equivalent to 'unset ::env(*variable_name*)'

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you unset the variable using the *unsetenv* command, you remove the variable value in the application and in any new child processes you initiate from the application using the *exec* command. However, the variable is still set in the parent process.

See the *set* and *unset* commands for information about working with non-environment variables.

Examples

In the following example, *unsetenv* remove the DISPLAY varible from the environment:

```
prompt> getenv DISPLAY
host:0
prompt> unsetenv DISPLAY
prompt> getenv DISPLAY
Error: can't read "::env(DISPLAY)": no such variable
        Use error_info for more info. (CMD-013)
```

See Also

- printenv
- setenv
- getenv

---

unsuppress_message

Enables printing of one or more suppressed informational or suppressed warning messages.

Syntax

string *unsuppress_message* [*messages*]

```
list messages
```

Arguments

messages

A list of messages to enable.

Description

The *unsuppress_message* command provides a mechanism to re-enable the printing of messages which have been suppressed using *suppress_message*. You can suppress only informational and warning messages, so the *unsuppress_message* command is only useful for informational and warning messages. The result of *unsuppress_message* is always the empty string.

You can suppress a given message more than once. So, you must unsuppress a message as many times as it was suppressed in order to enable it. The *print_suppressed_messages* command displays currently suppressed messages.

Feedback

Examples

When the argument to the *unalias* command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to re-enable the suppressed CMD-029 message. Assume that there are no aliases beginning with 'q'.

```
prompt> unalias q*
prompt> unsuppress_message CMD-029
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
```

See Also

- print_suppressed_messages
- suppress_message

---

update_activity

Updates activity information on the current design.

Syntax

```
status update_activity
```

Arguments

None.

Description

Updates activity for the current design without updating power. Activity is also automatically updated by command that retrieves activity results, such as the *get_switching_activity* command and most activity attributes. Note that you must set variable *power_enable_analysis* to TRUE before any power command.

PrimePower can consume either time-based (VCD file) or statistical switching activity information (SAIF file) for activity propagation. For a particular analysis mode, appropriate activity information must be provided. For example, in time_based power analysis mode, a VCD file must be provided. In averaged power analysis mode, any form of switching activity information is accepted. You can specify a VCD file by using command *read_vcd*. The statistical switching activity can be specified by using command *read_saif* or *set_switching_activity*.

In averaged power analysis mode, only averaged activity propagation will be done.

This command can be used when only activities of the design need to be refreshed. For example, this can be used for writing out saif without doing a complete power update. This command runs faster than running update_power for design and is more memory efficient.

Feedback

Examples

This example performs time-based activity propagation for time windows (0-20 and 50-end):

```
pt_shell> set power_analysis_mode time_based
pt_shell> read_vcd -rtl -time {0 20 50 -1} vcd_file.vcd
pt_shell> update_activity
```

This example performs averaged activity propagation:

```
pt_shell> set power_analysis_mode averaged
pt_shell> read_vcd vcd_file.vcd
pt_shell> update_activity
```

- power_analysis_mode
- power_enable_analysis

---

update_budget

Updates budget information on the current design.

Syntax

```
status update_budget
```

Arguments

None.

Description

Updates and compute the budget information for the current design.

Please note that the global budget allocation mode needs to be specified by *set_timing_budget* before issuing this command. pdate_budget *also needs to be explicitly called before report_budget.*

Examples

The following example updates budget information on the current design.

```
pt_shell> update_budget
```

See Also

- set_timing_budget
- report_budget

---

update_metrics

Updates RTL power related metrics on the current design.

Syntax

```
status update_metrics
```

Arguments

None.

Description

Updates RTL power metrics for the current design. This command needs to be called before reporting commands like *report_rtl_metrics*.

Note that you must set variable *power_enable_analysis* to TRUE before any power metrics command.

See Also

- update_power
- report_rtl_metrics

---

update_noise

Performs static crosstalk noise analysis for the current design.

Syntax

int *update_noise*

```
[-full]
```

Arguments

`-full`

By default, the *update_noise* command performs the noise analysis only if the design is not up to date for noise analysis. Using the *-full* option forces the *update_noise* command to perform the noise analysis regardless whether the design is out of date or not.

Description

Updates the crosstalk noise for the current design. The crosstalk noise is also automatically updated by commands or attributes that need the information, such as the *report_timing* command.

The *set_noise_parameters* command controls the settings that are used during the noise analysis update.

The noise analysis is performed at each stage of the design, by calculating the worst case noise bump that aggressors induce on the victim line when the victim line is not switching. Also, if the *-enable_propagation* option is used with the *set_noise_parameters* command, during the noise analysis, calculated noise can also propagate to the next stage and combine with the bumps induced by the aggressors of the next stage.

The induced bumps from the aggressors are calculated based on the characteristics of the driver of the victim net. If the *set_steady_state_resistance* command is specified on the library cell of the driver cell, that information would be used for the calculation of induced bumps from the aggressors. Otherwise, the steady state current-voltage (I-V) characteristics of the library cell of the driver is used. If the I-V information does not exist in the library, the steady state resistance from the library is used. If none of these are available, the steady state resistance of the victim driver is estimated from the delay and slew tables.

By default, the analysis of beyond high and low rails are disabled. If the *-include_beyond_rails* option is used with the *set_noise_parameters* command, noise analysis is also performed for beyond high and low rail during the noise update.

Examples

The following example updates the noise information for the current design.

```
pt_shell> update_noise
```

Feedback

See Also

- report_noise
- set_noise_parameters
- set_steady_state_resistance

---

update_power

Updates power information on the current design.

Syntax

```
status update_power
```

Arguments

None.

Description

Updates power for the current design. Power is also automatically updated by command that retrieves power results, such as the *report_power* command and most power attributes. Command *update_power* explicitly prepares the design for further analysis. Note that you must set variable *power_enable_analysis* to TRUE before any power command.

Starting from 2008.12 release, *update_power* can also perform power waveform generation and peak power calculation.

The *power_analysis_mode* variable can be used to specify the power analysis mode to perform. PrimePower can perform different types of power analysis based on the mode setting. The default power analysis mode is "averaged". For more information, see the *power_analysis_mode* man page.

Command *set_power_analysis_options* can be used to specify the options for power analysis. It must be set before *update_power* to take effects in power analysis. Issuing command *set_power_analysis_options* with no option can reset all the power analysis options to default. Use command *report_power_analysis_options* to get the current analysis option settings. For more information, see the *set_power_analysis_options* man page.

PrimePower can consume either time-based (VCD file) or statistical switching activity information (SAIF file) for power calculation. For a particular analysis mode, appropriate activity information must be provided. For example, in time_based power analysis mode, a VCD file must be provided. In averaged power analysis mode, any form of switching activity information is accepted. You can specify a VCD file by using command

read_vcd. The statistical switching activity can be specified by using command *read_saif* or *set_switching_activity*.

For power estimation using vector free power analysis, all primary inputs and black boxes' pins are assigned with default switching activities. You can use *set_case_analysis* or *set_switching_activity* to improve accuracy. For example, using *set_case_analysis* to set a scan enable pin to 0 gives more accurate average power for normal operating mode. Setting reasonable switching activity values for set/reset pins by using the *set_switching_activity* command is also preferred.

In averaged power analysis mode, only averaged power results will be calculated.

In time_based mode, power waveforms can be generated for the design, specific hierarchies or cells. Power waveforms are series of event-based power data calculated over time while processing VCD activity data. Meanwhile, peak power, which is the largest power value in the waveform, is also captured. The power waveforms are written into waveform files, which can later be displayed by waveform viewing tools. The peak power is saved and can be reported by *report_power*. Besides generating power waveforms, the averaged power results are also calculated.

If a gate-level zero_delay VCD (indicated by *read_vcd -zero_delay*) or a RTL VCD (indicated by *read_vcd -rtl*) is used in time_based mode, cycle accurate peak power analysis will be performed. In cycle accurate peak power analysis, the default sampling interval is the clock cycle associated with the fastest clock in the design. Within the sampling interval the power waveform is a constant which represents the total power dissipated in that cycle. Cycle accurate peak power analysis provides cycle level accurate power behavior for the design. It can report maximum cycle power and the simulation time of the cycle in which the maximum power happens. The results are shown as the peak power reported by *report_power* command and peak power attributes. The *-cycle_accurate_clock* and *-cycle_accurate_cycle_count* options of the *set_power_analysis_options* command can be used to specify the cycle for this analysis.

In leakage-variation power analysis mode, leakage variation analysis will be performed. For more information, see the *power_enable_leakage_variation_analysis* man page.

PrimePower supports UPF domain-based power report feature for multivoltage designs. You can use *set_current_power_domain* or *set_current_power_net* commands to set the domains or supply nets of interest. Only the power dissipated on the specified domains or supply nets are calculated and reported. By default (if not specified), all the domains are included in power analysis. Use *get_current_power_domain* or *get_current_power_net* to show the current settings.

Feedback

Examples

This example performs time-based power analysis for time windows (0-20 and 50-end):

```
pt_shell> set power_analysis_mode time_based
pt_shell> read_vcd -time {0 20 50 -1} dump.vcd
pt_shell> update_power
```

This example performs averaged power analysis:

```
pt_shell> set power_analysis_mode averaged
pt_shell> read_saif -instance top -input file.saif
pt_shell> update_power
```

This example performs time_based power analysis for instance u1.u2 from 100 ns to 500 ns. It also generates the results.out file with time-based power results in .out format.

```
pt_shell> set power_analysis_mode time_based
pt_shell> read_vcd -time {100 500} dump.vcd
pt_shell> set_power_analysis_options -waveform_output results
 -waveform_format out -cells {u1.u2}
pt_shell> update_power
```

The following example performs cycle accurate peak power analysis to generate a cycle accurate waveform by using an RTL VCD file as input:

```
pt_shell> set power_analysis_mode time_based
pt_shell> read_vcd myRTL.vcd -rtl
pt_shell> set_power_analysis_options -waveform_output capp_waveform
 -waveform_format out
pt_shell> update_power
```

update_timing

Updates timing information on the current design.

Syntax

string *update_timing*

```
[-full]
```

Arguments

`-full`

Indicates that the entire timing analysis is to be performed from the beginning. The default is to perform an incremental analysis, which updates only out-of-date information and runs more quickly.

Description

Updates timing for the current design. Timing is also automatically updated by commands that need the information, such as the *report_timing* command. This command explicitly prepares the design for further analysis.

By default, the *update_timing* command uses an efficient timing analysis algorithm that requires minimal computation effort and updates existing timing analysis information only where needed. You can override this default behavior using the *-full* option, which causes the entire timing update to be performed from the beginning. To avoid unnecessarily long run times, use the *-full* option only when you need to override incremental timing analysis. If the design is not timed, the *update_timing* command has the same runtime independent of the *-full* option.

If the *si_enable_analysis* variable is set to *true* and a valid PrimeTime SI license is in place, the *update_timing* command also performs crosstalk-aware timing analysis.

Examples

The following example updates timing information for the current design.

```
pt_shell> update_timing

pt_shell> update_timing -full
```

Feedback

See Also

- report_timing
- si_enable_analysis

---

upf_version

Specify the version for the UPF file and syntax checking.

Syntax

string *upf_version*

`[version_id]`

Data Types

version_id	string

Arguments

version_id

Specifies the UPF version for which the file or UPF commands are intended.

Description

As the UPF standard matures, new updated versions of the UPF standard can occur. The *upf_version* command can be used to specify the version to restrict syntax checking and semantics of UPF commands.

If called with an argument, returns the argument. If called with no argument, returns the current version number.

Currently only version 1.0 is supported. A warning is issued if you specify any other version.

Examples

Here are sample outputs when you use the *upf_version* command to query the current UPF version.

```
pt_shell> upf_version
```

Here is an example of the output that shows all UPF commands, such as commands that might be affected by a specific UPF standard.

```
pt_shell> help UPF
 connect_supply_net    # Connect supply net to supply ports and/or pins
 create_power_domain   # define power supply distribution network
 create_power_switch   # Define a switch in the power domain
```

Feedback

```
create_supply_net     # Create power or ground supply net object
create_supply_port    # Create a port on power domain
get_power_domains     # Create a collection of power domains
....
```

See Also

v

validate_ctpm

Validate the accuracy of the CTPM against the golden target library.

Syntax

string *validate_ctpm*

```
-base_lib base_lib
-side_file side_file
-ctpm_file ctpm_file
-golden_lib golden_lib
[-pre_ctpm]
[-pocv]
[-constraint]
[-pin_cap]
[-verbose]
[-verbose_table_as_csv]
```

Data Types

```
base_lib        string
side_file       string
ctpm_file       string
golden_lib     string
```

Arguments

`-base_lib base_lib`

Specifies the base library, which is characterized using original spice model.

`-side_file` *`side_file`*

Specifies the sensitivity augmented library which is the side-file of base library, as used in *define_sensitivity_lib_mapping base_lib -side_file side_file*.

`-ctpm_file` *`ctpm_file`*

Specifies the CTPM file to validate accuracy.

`-golden_lib` *`golden_lib`*

Specifies the golden library, which is characterized using target spice model.

`-pre_ctpm`

Includes pre-CTPM results.

`-constraint`

Includes constraint correlation results.

`-pocv`

Includes parameteric on-chip variation (POCV) correlation results.

`-pin_cap`

Includes pin capacitance correlation results.

`-verbose`

Reports per-lib_timing_arc error details, for both absolute and relative errors. This option applies to both pre-CTPM and post-CTPM reports.

`-verbose_table_as_csv`

Redirects verbose report to csv file(s). pre-CTPM and post-CTPM output will be two seperate files.

Description

The *validate_ctpm* command can be used to validate the acccuracy of PrimeShield SPICE2Design feature at library level. The golden_lib is characterized from target spice model, which can be a spice model representing next PDK, spot model, different spice corner.

Through ML, SPICE2Design aims to bridge the gap between the base and the target by capturing and gap through spice process parameters placed inside of a Compact Timing Power Model (CTPM) database. When CTPM is consumed in a base STA session, the QoR of this session is shifted such that to match QoR of the target.

Examples

The following script validate CTPM accuracy comparing with target library.

Feedback

```
set ps_enable_analysis true
set ps_enable_spice2design_analysis true
set base_lib base_lib.db
set side_file augmented_lib.db
set golden_lib target_golden_lib.db
validate_ctpm -base_lib $base_lib \\
  -side_file $side_file \\
  -golden_lib $golden_lib \\
  -ctpm_file pipeclean.ctpm

1
```

See Also

- read_ctpm
- ps_enable_spice2design_analysis

---

validate_implement_setup

Validates the physical setup specified by the *set_implement_options* command, and checks for consistency between the timing and physical views.

Syntax

```
status validate_implement_setup
  [-capacitance_threshold threshold_value]
  [-resistance_threshold threshold_value]
  [-slack_threshold threshold_value]
```

Data Types

threshold_value	float

Arguments

`-capacitance_threshold` *threshold_value*

Specifies the capacitance difference threshold (in library units) for validating the newly extracted parasitics from StarRC against the existing parastics in the timing sessions. If the difference is greater than this threshold, this command reports it as an error. The default value is 0.01 femto farad.

`-resistance_threshold` *threshold_value*

Specifies the resistance difference threshold (in library units) for validating the newly extracted parasitics from StarRC against the existing parastics in the timing sessions. If the difference is greater than this threshold, this command reports it as an error. The default value is 0.01 ohm.

`-slack_threshold` *`threshold_value`*

Specifies the endpoint slack difference threshold for validating the updated timing slack values (using the newly extracted parasitics) against the slack values in the original timing sessions. If the difference is greater than this threshold, this command reports it as an error. The default value is 1.0 pico second.

Description

The *validate_implement_setup* command validates that both the design and the tool environment are ready to run ECO fixing.

This validation is performed as follows:

- Check that the IC Compiler II and StarRC tools are initialized and ready for work.
- Ensure that the design data (netlist and parasitics) are consistent between PrimeECO and the physical view.
- Identify a fix for a single hold violation.
- Implement the fix in the physical view, then confirm that the fix is legalized and successful.
- Update the design data to reflect the physical changes.
- Confirm that the timing has changed as expected (the insertion endpoints are fixed, other endpoints are negligibly affected).

The *validate_implement_setup* command modifies the design in memory. After you validate your setup, exit the PrimeECO session, then start a new session to fix the full design.

If you encounter an error, correct the error condition and rerun *validate_implement_setup* in a new PrimeECO session.

By default, the command stops if a validation step fails. To force the subsequent validation steps despite a failure, set the *sh_continue_on_error* variable to *true*.

The actual command validation steps are described in the following sections.

Validation step: Initialization setup

This validation step checks if initialization with the IC Compiler II and StarRC tools is successful.

If this step fails, check whether the options specified by the *set_implement_options* command are correct. Possible causes include: incorrect path specification for the IC Compiler II or StarRC executables, incorrect path or contents in the StarRC command file.

If the *set_eco_options* command specifies incorrect physical libraries or physical blocks, the command issues an error.

Validation step: Physical block ECO readiness

This validation step checks if the physical block has any ECO cells that are not in legal locations or have legality violations.

If this validation step fails, it indicates the physical block has ECO cells (such as sized cells or inserted buffers) that have not yet been properly legalized and routed.

Open the block in IC Compiler II and legalize the ECO cells. The physical design must be a legalization and routing clean design before starting the ECO process.

Validation step: Netlist consistency

PrimeECO requires that the netlists be identical between the physical block and timing sessions.

If this validation step fails, it indicates that the netlists are not identical. In this case, PrimeECO reports the netlist differences. Review the logfile to identify the inconsistent cells, then resolve the differences.

Validation step: Parasitics consistency

PrimeECO requires that the StarRC extracted parasitics and the parasitics in the timing sessions are effectively identical. This validation step checks parasitics consistency by removing the existing parasitics, reading the newly extracted parasitics into timing sessions, and comparing the annotated total capacitances and resistances.

If this validation step fails, it indicates a mismatch in parasitics. Possible reasons are:

- StarRC version difference
- StarRC command file difference
- Netlist difference
- Routing topology difference

In this case, PrimeECO reports the nets that have parasitics differences. Review the logfile to identify the inconsistent nets, then resolve the differences.

Validation step: Timing ECO

This validation step checks if a timing ECO can be performed successfully by inserting one buffer to fix a hold violation. (This buffer is also used for the next validation step.)

Validation step: ECO implementation

This validation step checks if the buffer insertion ECO can be successfully implemented. This implementation step includes legalization, ECO routing, parasitics extraction, and timing analysis.

If this validation step fails, it indicates that one of these implementation steps has an issue.

Check if legalization was successful. If it failed, check if any legalization settings are missing in PrimeECO. Specify additional legalization settings with the *-icc2_pre_legalize_script option.*

Check how many cells have moved. PrimeECO expects only a small number of cells to move during the test ECO. If a large number of cells moved, it indicates that the legalization settings might be incorrect or that the physical block is not ready for ECO changes.

Check if ECO routing was successful. If it failed, check if any router settings are missing in PrimeECO. Specify additional router settings with the *-icc2_pre_route_script* option. Check the output of the *check_routes* command before and after ECO routing in the log. Check if the number of physical DRC violations has changed significantly after ECO routing.

Validation step: Final timing QoR consistency

This validation step checks that only expected post-ECO timing changes have occurred.

If this validation step fails, it indicates that large-scale timing changes have occurred, or that timing changes have occurred in unexpected endpoints.

PrimeECO expects that significant timing changes are limited to the endpoints in the fanout of the ECO-changed cells. It also allows for timing changes in other endpoints due to routing changes, but these changes should be minimal due to the small size of the test ECO.

Check the number of cells that moved during legalization. If a large number of cells moved, large-scale timing changes can result. Determine the cause of the cell movements.

Check the number of physical routing DRC violations before ECO routing started. If a large number of physical DRC violations existed before ECO implementation, this can result in large routing changes to fix existing routing violations unrelated to the test ECO.

Examples

The following command runs validation with default options.

```
prompt> validate_implement_setup
```

The following command runs validation with user-specified thresholds.

Feedback

```
prompt> validate_implement_setup \\
                -capacitance_threshold 0.1 \\
                -resistance_threshold 0.1 \\
                -slack_threshold 2.0
```

w

which

Locates a file and displays its pathname.

Syntax

string *which filename_list*

`list filename_list`

Arguments

`filename_list`

List of files to locate.

Description

Displays the location of the specified files. This command uses the search_path to find the location of the files. This command can be a useful prelude to read_db or link_design, because it shows how these commands expand filenames. The *which* command can be used to verify that a file exists in the system.

If an absolute pathname is given, the command searches for the file in the given path and returns the full pathname of the file.

Examples

The following examples are based on the following search_path.

prompt> *set search_path "/u/foo /u/foo/test"*

Feedback

The following command searches for the file name foo1 in the search_path.

```
prompt> which foo1
/u/foo/foo1
```

The following command searches for files foo2, foo3.

```
prompt> which {foo2 foo3}
/u/foo/test/foo2 /u/foo/test/foo3
```

The following command returns the full pathname.

```
prompt> which ~/test/designs/sub_design.db
/u/foo/test/designs/sub_design.db
```

---

win_select_objects

Creates a collection of objects equivalent to a graphical selection operation.

Syntax

string *win_select_objects*

```
[-slct_targets slct_bus]
[-slct_targets_operation operation]
[-create_slct_buses]
[-root instance]
[ -within rectangle | -line line |-at point |
  -radius r | -again_at ]
[-intersect]
[-index i]
[-visible]

string slct_bus
string operation
string instance
```

Arguments

`-slct_targets slct_bus`

Specifies the name of a selection bus to store the result in. By default the result of this command is returned in a collection. If this option is specified selection bus *slct_bus* is used instead. *slct_bus* is also returned as result of the command.

`-slct_targets_operation` *operation*

Specifies which operation should be used when storing the result in selection bus *slct_bus*. This is only allowed if you specify the -slct_targets option. Legal operations are clear, add and remove.

`-create_slct_buses`

Specifies that a new selection bus is created and used to store the result in. Using this option is equivalent to first creating a selection bus using the create_selection_bus command and then providing the created selection bus to option -slct_targets.

`-root` *instance*

Specifies a string for the instance whose component design objects and hierarchy are to be examined against the specified region criteria.

`-within` *rectangle*

Collects design objects lying within the specified rectangle.

`-line` *line*

Collects design objects intersected by specified line.

`-at` *point*

Collects design objects whose bounding box contains the specified point.

`-radius` *r*

Specifies a radius for points specified by the *-at* option. It is applicable only for *_pins* and *_ports*.

`-again_at`

Reapplies the previous *-at* option, but returns a previously-matched design object.

`-index` *i*

For point select (-at option) specifies a specific object index to select. Similar to running -again_at.

`-intersect`

Collects design objects intersecting with specified rectangle. Without this option, the command collects design objects contained in the specified rectangle.

`-visible`

Select objects marked as visible with win_set_select_class command.

Feedback

Description

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

See Also

- win_set_select_class
- win_set_filter

---

win_set_filter

Sets a filter to apply to objects selected by the *win_select_objects* command.

Syntax

```
int win_set_filter
-class class_name
[ -stop_level level ]
[ -start_level level ]
[ -z_level level ]
[ -filter expression ]
[ -layer list ]
[ -user_filter true|false ]
[ -user_filter_cmd tcl_cmd ]
[ -highlighted_only true|false ]
[ -expand_cell_types list ]
[ -part list ]
[ -visible ]
```

Arguments

`-class class_name`

Specifies a single class name for which the filter is to apply.

`-stop_level level`

Specifies the hierarchy level, up to which *win_select_objects* searches for design objects down the hierarchy. This has no effect on objects that are not collectable.

`-start_level level`

Specifies the hierarchy level, from which *win_select_objects* begins searching for design objects down the hierarchy. This has no effect on objects that are not collectable.

`-z_level` *level*

Specifies the interesting Z levels in a 3dic design. The 0 value means all chips in the current 3dic design. Other values mean only the chips on this level and the level below. For example 1 means chips on level 0 and level 1.

`-filter` *expression*

Specifies a filter expression that an object must satisfy to be returned by the *win_select_objects* command. The expression argument must be a Boolean expression based on attributes of the specified class. If this option is not specified, the filter is cleared.

`-layer` *list*

Specifies a layer number list that an object must satisfy to be returned by the *win_select_objects* command. If this option is not specified, the layer filter is cleared.

`-user_filter` *true|false*

Enables user supplied filter command.

`-user_filter_cmd` *tcl_cmd*

Specifies a tcl command for filtering.

`-highlighted_only` *true|false*

Specifies that only highlighted objects can be selected.

`-expand_cell_types` *list*

Specifies cell types for searching design objects down the hierarchy when the search level is greater than 0. This has no effect on types that is not supported or objects that are not collectable.

`-part` *list*

Specifies the object parts to select. When argument is specified only given part of a whole object will be selected by executing *win_select_objects*. The valid values for the *list* argument are *edge*, *vertex*, *centerline*, and *centervertex*.

`-visible`

Specified filters are for visible objects. By default the filters are for selectable objects.

Description

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

Feedback

---

win_set_select_class

Sets the design objects to be collected by the *win_select_objects* command.

Syntax

string *win_set_select_class*

```
{-all | class_names}
[ -visible ]
```

Arguments

`-all`

Selects all classes. The *-all* option and the *class_names* option are mutually exclusive.

`class_names`

Specifies a list of design objects. The *-all* option and the *class_names* option are mutually exclusive.

`-visible`

Specified classes are for visible objects. By default the classes are for selectable objects.

Description

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

---

write_activity_fsdb_waveform

Writes gate-level activity waveform for the design netlist in FSDB format.

Feedback

Syntax

status *write_activity_fsdb_waveform*

```
[-file file_name]
[-nets net_list]
[-rtl]
[-enable_power_calculation]
```

Data Types

file_name	string
net_list	list

Arguments

`-file file_name`

Specifies the output waveform file name.

`-nets net_list`

This option allows writing activity waveforms for specified list of nets. By default, PrimePower writes out activity waveform for all logical nets in the deisgns.

`-rtl`

This option allows writing activity waveforms for rtl objects(primary nets and blackbox outputs & sequential outputs) only. By default, PrimePower writes out activity waveform for all logical nets in the deisgns.

`-enable_power_calculation`

This option enables averaged power and activity calculation. By default power calculation is disabled with *write_activity_fsdb_waveform* command.

Description

This command writes the gate-level activity waveforms in FSDB format for whole design netlist. It works only in time-based analysis mode. The command is useful for analysis with RTL or Zero-delay FSDB/VCD. With RTL FSDB/VCD as input, PrimePower would do event based propagation throughout the design and would generate activity waveform for all design nodes.

This command supports delay-aware event propagation with RTL vector and delay-shifting of events in zero-delay event vector as input.

By default, this command only does event propagation and writing of activity waveform for the design netlist. With enable_power_calculation option it also would calculate averaged power and averaged activity for the design, however, peak power calculation would not take place. With this option, user would be able to write out gate-level SAIF file for the design after the command is run successfully.

Feedback

Examples

The following example writes the activity waveform for user specified list of nets.

```
pt_shell> write_activity_fsdb_waveform -nets [get_nets clk*] -file
 clk_nets.fsdb
```

---

write_activity_waveforms

Creates activity waveforms from the Value Change Dump (VCD).

Syntax

integer *write_activity_waveforms*

```
-interval sampling_interval
[-coverage]
[-hierarchical_levels level]
[-exclude_signals signal_list]
[-exclude_cells module_list]
[-output file_name]
[-format fsdb | out]
[-time time_list]
-vcd filename
[-verbose]
[-peak_type min | max]
[-peak_window window_size]
[-strip_path path]
```

Data Types

sampling_interval	float
level	integer
signal_list	list
module_list	list
file_name	string
time_list	list
filename	string
window_size	string
path	string

Arguments

`-interval` *sampling_interval*

Specify the sampling interval that is used for activity waveform. during each interval, activity is aggregated.

`-coverage`

Define activity to be the percentage of nets in a block that toggle at least one time during an interval. By default, the definition of activity is the number of

toggles in the block for the interval, divided by number of nets and the interval period.

`-hierarchical_levels` *level*

Create power waveforms for hierarchical cells only to the specified level from the top. The default is to create waveforms for only the top level of the design.

`-exclude_signals` *signal_list*

This option allows you to exclude some signal names from consideration. The list of signals is a list of signal names. No path should be given with the signal names; all signals with the specified names are ignored from the VCD. This option is useful for excluding signals, such as clock signals from analysis.

`-exclude_cells` *module_list*

This option allows you to exclude some module names from consideration. The list of modules is a list of module names. The names can either exclude a path to the module (such as C instead of TOP/A/B/C), or the full path can be included. If no path is given, all modules with the specified names are ignored from the VCD. The given module names can be globs, such as A*, which would exclude any module starting with 'A'. When a module is excluded, it is not included in the waveforms or the text reports (see the *-verbose* option). Also, the signals in the excluded modules are not considered in the hierarchy above the excluded module. As an exception to this, when a signal is defined in TOP/A/B and also defined in TOP/A/B/C, the signal is still counted as being in B if module C is excluded. The *-exclude_cells* option is useful for excluding macro modules or unsynthesized modules.

The given list of modules needs to be a list of module names in the VCD. It should not be a collection of cells from a design.

`-output` *file_name*

Specify the prefix of the file in which the waveform data is to be written.

`-format fsdb | out`

Specifies the format for the output file. Valid formats are *fsdb* and *out*. The default is *fsdb*.

`-time` *time_list*

Specifies the time windows for the analysis. You might want to only analyze and produce waveforms for a portion of the time in the VCD. The *-time* option accepts a list of numbers as its argument. The argument must have an even number of elements. Each consecutive pair of numbers is a time window; the first number is the start of the window, the second is the end of the window. Activity analysis is only performed on the given time windows.

The given time values are in nanoseconds. The first number in the list can use the special value -1 to represent the beginning of the VCD. The last number in the list can use the special value -1 to represent the end of the VCD.

`-vcd` *`filename`*

Specifies the file name of the VCD to be analyzed. This option is required.

`-verbose`

After analysis, a report is generated, similar to the *report_activity_waveforms* command.

`-peak_type min | max`

Specifies whether the command is to search for an interval with maximum or minimum activity (or coverage, if the *-coverage* option is also specified). By default, the command searches for an interval with maximum activity (or coverage).

`-peak_window` *`window_size`*

Specify the window size to be used when searching for the peak activity period. By default, the peak_window is the same as the interval. PrimePower searches for the peak activity period for each hierarchical block during activity file analysis. The width of the period is the peak_window. For example, the interval might be set to 10 ns, while the peak_window could be 500 ns. In this case, PrimePower looks for activity in a 500 ns window when deciding when the peak activity occurs.

Due to implementation limitations, in the example, the 500 ns window starts and interval boundaries are on. Therefore, the value specified for the *-peak_window* option must be a multiple of the interval value.

`-strip_path` *`path`*

Specifies the path to the module in the VCD of interest. All modules outside the hierarchy under the specified path are excluded. The names in the waveform file are shortened.

Description

Plots the average toggle rate for modules in the VCD over time. The toggle rate during an interval for a module is the average toggle rate for signals in the module for the interval.

No design or library needs to be loaded to use this command; only a VCD is needed.

Activity waveforms can be useful for qualifying the activity vectors. You can review the waveforms to determine if the testbench simulated as expected, and whether the vectors have covered enough of the design to be useful as inputs to power analysis.

The total VCD simulation time is partitioned into intervals, for which the average activity is calculated based on the following formula:

```
# of toggles on all the signals for the interval
Average toggle rate =
 ------------------------------------------------------
                        (# of signals) * (length of interval in
 nanoseconds)
```

You can also view the activity coverage over time to get a sense of how many of the signals are being exercised. A signal is "covered" if it has at least one toggle within the interval, so the coverage per interval is calculated as follows:

```
# of signals with at least one toggle
Coverage = ------------------------------------- * 100%
                     # of signals
```

The output format for the waveforms is either the default of .fsdb or the .out format. View either format with a waveform viewer, such as nWave.

Examples

This example outputs the file#.out text file with waveform information in the .out format:

```
pt_shell> write_activity_waveforms -output file1 -vcd my_vcd.vcd
 -interval 10
```

This example analyzes the time window from 100 to 300 and then from 1000 to the end of the vcd:

```
pt_shell> write_activity_waveforms -output file2 \\
            -vcd my_vcd.vcd -interval 10 -time {100 300 1000 -1}
```

Use the *-exclude_cells* option to exclude some modules from the waveforms and to exclude nets in the modules from being included in the totals for other modules higher in the hierarchy. For example,

```
pt_shell> write_activity_waveforms -output file3 -vcd my_vcd.vcd \\
             -interval 10 -exclude_cells {assertion_module* other_module}
```

See Also

- read_vcd
- report_activity_waveforms

---

write_analytics_data

Write out PrimeTime update_timing runtime and memory information, design parameters and timing analysis settings of the current design in .json format.

Feedback

Syntax

int *write_analytics_data*

```
-tag tag_name
[-output_dir dir_name]
```

Data Types

```
tag_name  string
dir_name  string
```

Arguments

`-tag`

The user-defined file name prefix. It should include design name, scenario name and other data that identify the session. *write_analytics_data* will append timestamp in as part of the file name. Final file name will be <tag>_<timestamp>.json

`[-output_dir`

The optional output repository directory for the output .json file.

Description

The *write_analytics_data* command write out PrimeTime update_timing runtime and memory information, design parameters and timing analysis settings of the current design .json format: <tag>_<timestamp>.json with user-defined file name prefix <tag>. Users can also define the optional output repository directory <dir_name> for the output .json file (if not provided, the default output directory will be the current working directory).

---

write_app_var

Writes a script to set the current variable values.

Syntax

string *write_app_var*

```
-output file
[-all | -only_changed_vars]
[pattern]
```

Data Types

```
file         string
pattern      string
```

Feedback

Arguments

`-output file`

Specifies the file to which to write the script.

`-all`

Writes the default values in addition to the current values of the variables.

`-only_changed_vars`

Writes only the changed variables. This is the default when no options are specified.

pattern

Writes the variables that match the specified *pattern*. The default is "*".

Description

The *write_app_var* command generates a Tcl script to set all application variables to their current values. By default, variables set to their default values are not included in the script. You can force the default values to be included by specifying the *-all* option.

Examples

The following is an example of the *write_app_var* command:

```
prompt> write_app_var -output sh_settings.tcl sh*
```

See Also

- get_app_var
- report_app_var
- set_app_var

---

write_arrival_annotations

Writes arrival and slew annotations for ILMs or contexts of the given list of instances or for all top level instances as a script of commands.

Syntax

status *write_arrival_annotations*

```
[-instances instance_list]
[-context]
[-design]
```

Feedback

Data Types

instance_list list

Arguments

-instances *instance_list*

Writes arrival annotations for the set of pins affecting the given list of instances. The tool looks for appropriate files that contain the list of aggressor driver pins inside the directories meant for these instances, and creates corresponding scripts.

-context

Specifies that the annotations are meant for the context of the block.

-design

Specifies that the annotations are meant for the entire design.

Description

This command writes arrival annotations to be used at block-level or chip-level hierarchical signal integrity analysis. This command is affected by the *pt_ilm_dir* environment variable. The tool looks for directories meant for the list of instances (or all top level instances) at the location given by the *pt_ilm_dir* environment variable. Inside the directory, it looks for wrapper.txt file or ilm.txt file depending on whether the *-context* option is used or not. Then it creates a new file called wrapper.pt.gz or ilm.pt.gz that contains the script needed to annotate the arrivals and slews at block or chip level.

If the annotations are for the chip level and the ILM is being generated for the full design (this happens if the blocks are shielded from each other and the signal integrity context of the instance is not generated), then use the *-design* option. Then, PrimeTime looks for a directory with the name of the block design and looks for ilm.txt file inside the directory.

Examples

The following example writes the annotations for contexts of all top level blocks:

```
pt_shell> write_arrival_annotations -context
```

The following example writes annotations for the ILM of instance I1:

```
pt_shell> write_arrival_annotations -instances {I1}
```

Feedback

See Also

- create_ilm
- create_si_context
- pt_ilm_dir

---

write_binary_aocvm

Creates a binary advanced on-chip variation (AOCV) file from an AOCV file.

Syntax

int *write_binary_aocvm*

```
[-compress]
aocvm_file
binary_file
```

Data Types

```
aocvm_file          string
binary_file         string
```

Arguments

`-compress`

Compresses the output binary AOCV file to reduce file size.

aocvm_file

Specifies the name of the input AOCV file.

binary_file

Specifies the name of the output binary AOCV file.

Description

The *write_binary_aocvm* command creates binary encoded AOCV files from ASCII AOCV files. This command is used to protect sensitive process related information.

The *read_aocvm* command can read binary and compressed binary AOCV files created using the *write_binary_aocvm* command. No additional arguments are required to read binary or compressed binary AOCV files.

An advanced OCV derate table imported from a binary or compressed binary file is not visible in the *report_aocvm* output.

Feedback

Examples

The following example shows how to create a binary advanced OCV file named "binary_file" from an ASCII AOCV file named "aocvm_file".

```
pt_shell> write_binary_aocvm aocvm_file binary_file
```

The following example shows how to create a compressed binary AOCV file named "small_binary_file" from an ASCII AOCV file named "aocvm_file".

```
pt_shell> write_binary_aocvm -compress aocvm_file small_binary_file
```

See Also

- read_aocvm
- remove_aocvm
- report_aocvm

---

write_changes

Writes out netlist changes performed in the current session, such as *size_cell* and *insert_buffer*.

Syntax

status *write_changes*

```
[-format ptsh | text | dctcl | icctcl | icc2tcl | eco | aprtcl]
[-output file_name]
[-reset]
```

Data Types

```
file_name     string
```

Arguments

```
-format ptsh | text | dctcl | icctcl | icc2tcl | eco | aprtcl
```

Specifies one of the following output formats:

- *ptsh* (default) - PrimeTime script
- *text* - List of changes in descriptive text format
- *dctcl* - Tcl script for Design Compiler
- *icctcl* - Tcl script for IC Compiler and IC Compiler II
- *icc2tcl* - Same as *icctcl*

- *eco* - Binary script for the PrimeTime *read_eco_changes* command
- *aprtcl* - Tcl script for third-party place-and-route tool

`-output` *`file_name`*

Writes the change list to the specified file. If you do not use this option, the change list is written to the standard output (console window).

`-reset`

Clears the change list, erasing the history of previous netlist editing commands in the current session. Note that this does not undo the effects of netlist editing; it merely clears out memory of the editing commands.

Description

The *write_changes* command writes out the netlist changes that were made to the current design after the design was linked. The output is typically formatted as a script that can be run in PrimeTime or another tool such as IC Compiler II or a third-party place-and-route tool.

By default, the output goes to the standard output (console window). To write the output to a file, use the *-output* option.

The following commands create entries in the change list:

```
connect_net
create_cell
create_net
disconnect_net
insert_buffer
remove_buffer
remove_cell
remove_coupling_separation
remove_net
rename_cell
rename_net
set_coupling_separation
size_cell
swap_cell
```

As a script, the output of the *write_changes* command is a series of scoping commands (*current_instance*) and netlist editing commands.

The *-format text* option generates one line per atomic editing operation, in order, describing in words the operation, the instance in which it occurred, and the objects involved.

The change list is not necessarily a verbatim log of the actual netlist editing commands run in the session. The change list might be different from the command history in the following situations:

- For objects specified at a higher level of the hierarchy (for example, creating a cell within u1/u2), the change list changes the scope to the lower-level cell using the *current_instance* command and then performs the operation at that level.
- Some object arguments are made explicit by wrapping them within a command that creates a collection, such as *get_pins*.
- Multiple arguments to a command such as *create_cell* are often converted into separate commands.
- Some arguments can be dropped from the change list such as superfluous arguments to the *remove_cell* command.

The *write_changes* command attempts to merge redundant operations to reduce and simplify the change list. For example, if a cell is resized multiple times, it is simplified to a single resize operation. If a buffer is inserted later removed, the associated commands are omitted. Simplification does not occur with the *-format text* option.

This simplification can cause the number of operations in the change list to be less than the number of ECO operations reported by a *fix_eco_** command.

The following commands are not written to the Design Compiler Tcl scripts (*-format dctcl*):

```
remove_coupling_separation
rename_cell
rename_net
set_coupling_separation
swap_cell
```

The following commands are not written to IC Compiler Tcl scripts (*-format icctcl*):

```
create_net -- if the net name contains a wildcard character or hierarchy
 separator
remove_coupling_separation
rename_cell
rename_net
set_coupling_separation
swap_cell
```

The aprtcl Change Format

The *-format aprtcl* option writes the changes as a set of pseudo-Tcl commands that are not specific to a particular tool. These commands can be parsed and incorporated into third-party place-and-route tools. There is no support in PrimeTime to directly replay this script. The change list file contains the list of changes in sequence and in exact order, one single operation will be performed per command.

Feedback

The *aprtcl* format is similar to the *icctcl* format, except for the following commands:

- *insert_buffer* - Insert one buffer or inverter pair per command, shows load pins driven by an inserted buffer or inverter_pair, distinguishes between ABOR and pin buffer

  Pseudo-Tcl command syntax:

  ```
  insert_buffer
    {new_lib_cell}
    [-inverter_pair]
    -new_net_names {net_name}
    -new_cell_names {buff_name}
    [-on_route]
    [-location {x y}]
      | [-location {x1 y1 x2 y2}]
    [-orientation dir]
    [-route_cut_location {x y}]
      | [-route_cut_location {x1 y1 x2 y2}]
    [-target_hier {target_hier_from_top}]
    {pin_or_port_list}
  ```

  - *{new_lib_cell}*: name of new lib_cell to insert
  - *-inverter_pair*: specifies to add inverter pair instead of buffer cell
  - *-new_net_name*: specifies the names of the new nets to add
  - *-new_cell_name*: specifies the names of the new cell to add
  - *-on_route*: specifies on-route insertion
  - *-location*: specifies physical location for a buffer {x y} or inverter pair {x1 y1 x2 y2}
  - *-orientation*: specifies the new orientation, possible values "N, W, S, E, FN, FW, FS, FE"
  - *-route_cut_location*: specifies where to cut the existing route for on-route insertion. For buffer insertion, the format is *{x y}*. For inverter pair insertion, the format is *{x1 y1 x2 y2}*.
  - *{pin_or_port_list}*: list of pins or ports that inserted buffer will drive
  - *-target_hier*: specifies the exact logical hierachy level in which the buffer or inverter pair is inserted. This option is used only in *-on-route* insertions. For details, see SolvNetPlus article 000036348.

- *size_cell* - Resize cell, one resize per command

  Pseudo-Tcl command syntax:

  ```
  size_cell
    {leaf_cell}
    {new_lib_cell}
  ```

```
[-overlap]
[-location {x y}]
[-orientation dir]
[-pin_map {pin_list}]
```

- *{leaf_cell}*: name of existing cell to be resized
- *{new_lib_cell}*: name of new library cell
- *-overlap*: specifies to allow an overlap of the resized cell with existing cells. Legalization will need to adjust the cell later to avoid overlap. Only occupied site mode can allow overlap during resizing.
- *-location*: optional
- *-orientation*: optional
- *-pin_map*: specifies all pin names of a previous and new library cell when the pin name changes due to the size_cell. *-pin_map* is only valid with the *-format aprtcl* option.

- *remove_buffer* - Removes buffer, one remove per command

  Pseudo-Tcl command syntax:

  ```
  remove_buffer {leaf_cell}
  ```

  - *{leaf_cell}*: name of leaf buffer cell to be removed

- *current_instance* - Sets the current hierarchy

  Pseudo-Tcl command syntax:

  ```
  current_instance {hier_name}
  ```

- *create_cell* - Creates a load cell instance in the current design

  Pseudo-Tcl command syntax:

  ```
  create_cell
    {load_cell_name}
    {new_lib_cell}
    [-location {x1 y1}]
    [-orientation dir]
  ```

  - *{load_cell_name}*: instance name of the new load cell created
  - *{new_lib_cell}*: library cell for new cell
  - *-location*: optional
  - *-orientation*: optional

Feedback

- *connect_net* - Connects a net to specified pins or ports

  Pseudo-Tcl command syntax:

  ```
  connect_net
    {net_name}
    {pin_or_port_list}
  ```

  - *{net_name}*: name of the net to connect
  - *{pin_or_port_list}*: list of pins or ports to be connected to the net

  The following commands are not written to *-format aprtcl* scripts:

  ```
  create_net -- if the net name contains a wildcard character or
   hierarchy separator
  remove_coupling_separation
  rename_cell
  rename_net
  set_coupling_separation
  swap_cell
  ```

  The header of the change list file includes a version string (*aprtcl_file_syntax_version*) so that external parsers can adapt to changes in the format over time. Currently, the only possible version value is *1.0*. It is recommended that parser scripts check this version for an expected value, so that future syntax upgrades do not cause unexpected behavior.

Physical ECO

After PrimeTime performs ECOs using physical data, the commands written by *write_changes -format icctcl* contain the placement locations of new buffers.

After you run an ECO using physical data, the tool disables the *ptsh* format. Because PrimeTime keeps track of physical changes internally, do not use the *-reset* option after physical data is loaded into memory. To replay changes in PrimeTime, save the changes using the *write_changes -format eco* command, which writes out the changes in binary format; and read the changes back into a PrimeTime session using the *read_eco_changes* command.

Multiply Instantiated Modules (MIM)

When the *eco_enable_mim* variable is *true*, the *write_changes* command writes one change list for the associated MIM group so that the change list can be directly implemented by the place-and-route tool.

This MIM change-collecting feature is supported by the following changelist formats:

- **`-format icctcl`**
- **`-format aprtcl`**

Feedback

Suppose a CPU module is instantiated four times in module TOP as CPU1, CPU2, CPU3, and CPU4. After fixing is completed with MIM enabled, the following command is used to write change lists:

```
pt_shell> write_changes -format icctcl -output pteco.tcl
```

This creates the following two change lists in the current directory:

```
TOP_pteco.tcl      # A change list for TOP module
CPU_pteco.tcl      # A change list for CPU module
```

The specified output file name is used as postfix after the name of the MIM. Also, the file contains the instance names of the changes to avoid any confusion.

Distributed Multi-Scenario Analysis (DMSA)

The *write_changes* command is compatible with DMSA, with or without netlist data loaded in the manager. It chooses a single scenario and executes the *write_changes* command on the netlist there. It then writes a *single* changelist file to the DMSA working directory. The behavior in DMSA is identical to that seen in a single-scenario run.

Examples

The following session shows some netlist editing commands and the change list created by *write_changes* command. The creation of cells u1 and u2 by a single *create_cell* command is converted to two *create_cell* commands in the change list.

```
pt_shell> create_cell i1/u1 class/AN2
Uniquifying 'i1' (inter) as 'inter_0'.
Information: Created cell 'u1' in 'middle/i1'. (NED-014)
1
pt_shell> size_cell i1/u1 class/AN2P
Information: Sized 'i1/u1' with 'class/AN2P'. (NED-045)
1
pt_shell> create_net i1/net1
Information: Created net 'net1' in 'middle/i1'. (NED-016)
1
pt_shell> connect_net i1/net1 i1/u1/A
Information: Connected 'i1/u1/A' to 'net1'. (NED-018)
1
pt_shell> create_cell {u1 u2} class/AN2
Information: Created cell 'u1' in design 'middle'. (NED-014)
Information: Created cell 'u2' in design 'middle'. (NED-014)
1
pt_shell> write_changes -format ptsh
#####################################
# Change list, formatted for PrimeTime
#####################################
current_instance
current_instance i1
create_cell {u1} {class/AN2}
size_cell {u1} {class/AN2P}
```

```
create_net {net1}
connect_net {net1} [get_pins {u1/A}]
current_instance
create_cell {u1} {class/AN2}
create_cell {u2} {class/AN2}
1

pt_shell> write_changes -format text
Change list, formatted as text:
  1. create_cell in i1: new cell 'u1' lib_cell 'class/AN2'
  2. size_cell in i1: 'u1' sized to 'class/AN2P'
  3. create_net in i1: new net 'net1'
  4. connect_net in i1: pin 'u1/A' to net 'net1'
  5. create_cell in <top>: new cell 'u1' lib_cell 'class/AN2'
  6. create_cell in <top>: new cell 'u2' lib_cell 'class/AN2'
1
```

The following example shows how the change list specifies the location information for IC Compiler.

```
pt_shell> write_changes -format icctcl
########################################
# Change list, formatted for IC Compiler
########################################
current_instance
add_buffer_on_route net1 -user_specified_buffers {U1 BUF1X 102.0 202.0 0}
set_cell_location -coordinates {100.0 200.0} -orientation NF \\
                  [get_cells U1]
insert_buffer U200/Z BUF2X -location {500.0 700.0}
size_cell U100 BUF4X
```

The following example shows how the change list is written for a third-party layout tool.

```
pt_shell> write_changes -format -aprtcl
################################################
# Change list, formatted for Third Party Compiler
# aprtcl_file_syntax_version : 1.0
################################################
current_instance
current_instance {u_dhm_lut}
insert_buffer BUF1X  -new_net_names {net1} -new_cell_names {U1} -on_route
 \\
                     -location {24.6240 26.7520 } -route_cut_location
 {27.512 27.588 } \\
                     -orientation FS { U20/A0 }
insert_buffer BUF1X -new_net_names {net2} -new_cell_names {U2} \\
                    -location {145.6160 112.0240} -orientation N
 { latch/GCLK }
size_cell {cell100} {BUF4X} -location {214.3200 101.9920} -orientation N
size_cell {cell150} {BUF2X} -location {208.2000 115.2300} -orientation S
 -pin_map {{A P} {B Q} {Y Y} }
remove_buffer cell200
current_instance
```

Feedback

```
create_cell {LOAD_CELL} {CLOAD1_LVT} -location {150.6320 61.8640}
 -orientation N
connect_net {u_dhm_unit_0_u_dhm_core_u_convert_64_8_N110} {LOAD_CELL}
```

write_collection

Output a machine readable report of attribute values for elements in a collection.

Syntax

write_collection

Feedback

```
collection
-file filename]
[-format format]
[-max_rows value_count]
[-columns attribute_list]
[-metadata]

string collection
string filename
string format
int value_count
list attribute_list
```

Arguments

collection

Specifies the collection on which to report. The collection may be homogeneous or heterogeneous. If the collection is very large, you may want to use the *-max_rows* option to limit the size of your output.

`-file` *filename*

This option indicates the name of the file to which the data is written.

`-format` *format*

This option accepts one of the following valid argument values: "csv" | "tsv". If the option is omitted, the default format is "csv", or command separated values. The argument "tsv" produces a tab separated values formatted data.

`-max_rows` *value_count*

This option indicates how many rows of data to include in the output. This number indicates the number of collection elements on which data is output.

`-columns` *attribute_list*

Indicates the set of attributes for which to output values, and their order in the output.

The special attribute name "object_class" may be used to include the element object class names, such as "cell" or "net", in the output.

If the option is omitted, then the object names and object class (or type) names are output by default.

`-metadata`

This option indicates that a meta data section should be included in the output.

Description

This command outputs tabular data of attribute values for elements of the given collection. The attribute values in the output are determined by the list of attributes given to the *-columns* option. The columns in the tabular report will be ordered by the order of attributes in the list. The command *list_attributes* may be called to view a list of attributes defined for an object class.

If the collection is large, the output size may be limited by indicating a *-max_rows* value. The commands *filter_collection* and *sort_collection* may be called to filter and sort a collection based on some criteria prior to creating a report for the collection elements.

By default, the output file omits the meta data section. If *-metadata* option is present, the output initiates with the meta data section which contains information such as the file generation timestamp, the product name and version and column data types. Some consumers of csv/tsv files benefit from the extra information in the meta data while other consumers do not handle it well.

Examples

The following example from IC Compiler II writes the full_name and area values of cells in a collection to a comma separated values (CSV) file named "cell_area.db".

```
icc2_shell> set cells [get_cells U*]
icc2_shell> write_collection $cells -columns {full_name area} \
              -file cell_area_pins.db
```

The next example outputs the same values to a tab separated values (TSV) file.

```
icc2_shell> write_collection $cells -columns {full_name area} \
               -format "tsv" -file cell_area_pins.db
```

The next examples limits the output to a CSV file to the first 10 objects in the collection.

```
icc2_shell> write_collection $cells -columns {full_name area} \
               -file cell_area_pins.db -max_rows 10
```

The next example first sorts the original collection of cells by the area attribute value in descending order, limiting the resulting collection to the top 10 area values. The example then outputs the full_name and area values to a CSV file named top_10_areas.db.

```
icc2_shell set sorted_cells [sort_collection -dictionary \
              $cells {area- full_name} -limit 10]
icc2_shell> write_collection $cells -columns {full_name area} \
              -file top_10_areas.db
```

The next example writes a sorted collection as in the above example but further limits the output to the first 10 objects in the collection. Note that this command may produce an output that is different from the above example. Limiting the sort to the first 10 values may produce a collection with more than 10 objects since multiple objects may share the same area value.

Feedback

```
icc2_shell set sorted_cells [sort_collection -dictionary \
              $cells {area- full_name} -limit 10]
icc2_shell> write_collection $sorted_cells -columns {full_name area} \
              -file first_10_objects_by_area.db -max_rows 10
```

The next example outputs to a CSV file which will include the meta data section.

```
icc2_shell> write_collection $cells -columns {full_name area} \
               -format "csv" -file cell_area_pins.db -metadata
```

---

write_context

Writes the timing context information for HyperScale block instances or instances characterized by the *characterize_context* command or *write_hier_data* command, producing a Tcl script or binary-format context information.

Syntax

status *write_context*

```
[-clock]
[-compress]
[-top]
[-output file_directory_name]
[-boundary_only]
[-format ptsh | sdc | dctcl | gbc]
[-exclude_upf]
[-exclude constraints_list]
[-nosplit]
[cell_block_list]
```

Data Types

cell_block_list	list
file_directory_name	string
constraints_list	string

Feedback

Arguments

`-clock`

Writes only clock information of script constraints. By default, all context information is written.

`-compress`

Generates constraint scripts in compressed format.

`-top`

Writes top-level design information only; excludes constraints from all characterized sub-instances.

`-output` *`file_directory_name`*

Specifies the name of the file or directory in which to write the context. A script for a single object is written to a file. Scripts for multiple objects are written to a directory. Binary context information (*-format gbc*) is written to a directory.

`-boundary_only`

Generates a script that includes only the boundary I/O context.

`-format ptsh | sdc | dctcl | gbc`

Specifies the output format for the script. The allowed values are:

ptsh	PrimeTime script format
sdc	Synopsys Design Constraints script format
dctcl	Design Compiler script format
gbc	binary context format

`-exclude_upf`

Excludes UPF information while writing context.

`-exclude` *`constraints_list`*

Excludes the constraint and exception commands specified in the list.

This option is not supported in interactive mode; it must be used in a script.

`-nosplit`

Disables line splitting, resulting in long lines. This option is useful for comparing different versions of generated scripts and for postprocessing the generated script.

`cell_block_list`

Specifies a list of instances or blocks for which the context is written out. If no object is given, the default is to write out all objects that have been characterized

with the *characterize_context* command. For HyperScale blocks, you must explicitly specify the instances; there is no default.

Description

This command writes the timing context of the specified instances or blocks as PrimeTime, SDC, or Design Compiler scripts; or in binary context format. It can write out the context for:

- Block instances characterized by the *characterize_context* command
- HyperScale block instances

You can use the generated context information to set the timing constraints for a block design for synthesis or logic optimization in another tool, or for performing hierarchical timing analysis in the PrimeTime tool.

You can use the command options to specify the type of script to generate and the name of the script file, or specify a directory in which to write out the context information in binary format. If you do not specify an output file or directory, the command writes out the context information to standard output.

To use context information written in script format, source the script using the appropriate tool. To use the context information written in binary format, use the *read_context* command.

Examples

The following example writes to standard output the context information for instances A1 and A2, in Design Compiler format:

```
pt_shell> write_context -format dctcl {A1 A2} -output myDC_dir
```

The following command writes the context information in PrimeTime script format to a file named A1.ptsh in the current directory:

```
pt_shell> write_context -output A1
```

The following example writes all context information for instance A1 in binary context format using the directory named A1BC:

```
pt_shell> write_context -format gbc -output A1BC A1
```

---

write_eco_design

Writes an ECO design that consumes less memory to perform ECO than the original design.

Syntax

status *write_eco_design*

```
[-type type_list]
[-endpoints endpoint_list]
[-force]
[-merge_sessions session_list]
[-verbose]
[dir_name]
```

Data Types

type_list	list
endpoint_list	list
session_list	list
dir_name	string

Arguments

`-type type_list`

Writes an ECO design that preserves the specified violation types compared to those in the original design. You can specify one or more of the following violation types:

- *setup* - Preserves setup timing results.
- *hold* - Preserves hold timing results.
- *max_transistion* - Preserves max_transition results.
- *max_capacitance* - Preserves max_capacitance results.
- *max_fanout* - Preserves max_fanout results.
- *noise* - Preserves noise results.
- *timing* - Preserves setup and hold timing results.
- *drc* - Preserves max_transition, max_capacitance, and max fanout results.

If you specify both the *setup* and *hold* violation types (the default behavior), the resulting ECO design will have setup and hold timing reports similar to those of the original design. If you specify only the *hold* violation type, the hold timing report will be similar, but the setup timing report could be different because the ECO design does not contain setup timing information. If you specify more violation types, the ECO design size becomes larger. To minimize the ECO design size, specify only necessary violation types.

`-endpoints` *`endpoint_list`*

Creates an ECO design with the specified timing endpoints. Use this option to customize your ECO design instead of creating an ECO design with violation types. For example, if you have specific timing endpoints for hold fixing but no interest in other violating endpoints, using this option creates an ECO design that preserves hold timing to only these endpoints.

This option provides great flexibility to customize your ECO design. You can write your own scripts to collect specific endpoints based on path groups, timing margins, and slacks. For more examples, see the EXAMPLES section.

`-force`

This options forces to write an ECO design even if ECO information is missing in the saved sessions.

`-merge_sessions` *`session_list`*

Creates an ECO design based on the endpoints merged from the specified PrimeTime saved sessions. Once the option is specified, the *write_eco_design* command merges endpoints from the specified directories and writes an ECO design based on the merged endpoints. Note that the *eco_save_session_data_type* must have been specified before saving the PrimeTime sessions to have violating endpoint data in the saved sessions.

This option is useful when an ECO design is generated without running DMSA, and works only in non-DMSA mode. See the details in the example section.

`-verbose`

Shows additional information such as endpoint names and progress status.

`dir_name`

Specifies a directory name in which an ECO design is created. The specified directory contains multiple files after creation. In Distributed Multi-Scenario Analysis (DMSA), the specified directory has subdirectories in which each scenario creates its own ECO design.

If you do not specify a directory name, the default is *eco_design_directory*.

Feedback

Description

This command reduces hardware requirements during timing closure ECO by creating an ECO design that requires less memory to perform ECO fixing. An *ECO design* is a small subset of the original design that contains only ECO-related design data. For example, it retains only cells and nets on critical paths and omits cells and nets on noncritical paths. Special timing and crosstalk models are created for disconnected nets and pins in the ECO design so that timing quality of results (QoR) in the ECO design is very close to the timing QoR of the original design. Its goal is to have timing QoR close enough to produce similar ECO change lists for the place-and-route tool compared to the change lists generated from the original design.

Note: it is not recommended to signoff with ECO designs. Instead, ECO designs should be used only for ECO purposes, especially when you do not have enough hardware resources to perform timing closure ECO.

Creating an ECO Design With Violation Types

The *write_eco_design* command creates an ECO design that preserves the violation type you specify with the *-type* option. If the *-type* option is not specified, setup and hold will be used as a default. The following command creates an ECO design that preserves setup and hold violations under the default directory, eco_design_directory.

```
write_eco_design
```

The command creates a new directory, eco_design_directory, which contains ECO design data. If a directory with the same name already exists, the command replaces the contents with new data. You can also specify a new directory name if you do not want to use the default name. For example, this command creates an ECO design with the name my_eco_design.

```
write_eco_design my_eco_design
```

After the command creates your new ECO design, use the *read_eco_design* command to load it and run ECO fixing. Suppose your original design consumes 100 gigabytes (GB), but the ECO design consumes only 20 GB. Although you need machines bigger than 100 GB to run static timing analysis (STA), you can perform your ECO on smaller 32-GB machines as the ECO design consumes only 20 GB. For example, after the preceding ECO design is created in the my_eco_design directory, you can log into smaller machines with less memory, run the *read_eco_design* command, and perform timing fixing with the *fix_eco_timing* command:

```
read_eco_design my_eco_design
fix_eco_timing ...
```

Use the *-type* option to specify the violation types that you are interested in to minimize your ECO design size. For example, this command preserves only hold violations:

```
write_eco_design -type hold
```

The resulting ECO design will preserve hold timing violations but might have different other timing violations such as setup and max_transition. However, hold fixing results should be close to the results of the original design because the ECO design has the same critical hold paths preserved.

Specifying more violation types increases the size of an ECO design as it includes more paths. In the following example, the first command creates a bigger ECO design than the second command because it has more violation types.

```
write_eco_design -type {setup hold max_transition max_capacitance}
write_eco_design -type hold
```

Creating an ECO Design in Distributed Multi-Scenario Analysis (DMSA)

In a DMSA flow, run the *write_eco_design* command in the manager to create an ECO design that includes all current scenarios. Suppose you are running DMSA with two scenarios, scen_1 and scen_2. In the following example, a DMSA manager creates an ECO design under the my_dmsa_eco_design directory.

```
write_eco_design my_dmsa_eco_design
```

Under the my_dmsa_eco_design directory, the command creates the scen_1 and scen_2 subdirectories, which contain ECO design data for each scenario. Next, load the ECO design by running the *read_eco_design* command in the manager. The following example launches two worker hosts automatically and loads an ECO design under the my_dmsa_eco_design directory in each scenario. For more DMSA examples, see the man page of the *read_eco_design* command.

```
read_eco_design my_dmsa_eco_design
```

Creating an ECO Design With Saved Sessions

If you perform ECO from PrimeTime sessions that were saved from individual PrimeTime STA runs, follow the steps described in this section to run the *write_eco_design* command efficiently.

First, set the *eco_save_session_data_type* variable to your desired violation types before saving sessions with the *save_session* command in individual PrimeTime STA runs. Setting this variable saves ECO information in addition to timing data while PrimeTime saves its session. The saved ECO information will be used by the *write_eco_design* command to analyze ECO data from different scenarios efficiently. This example script saves setup and hold timing ECO information.

```
set eco_save_session_data_type {setup hold}
save_session scen_1_session
```

Second, start DMSA as you normally do with your DMSA ECO. Since you are running DMSA from individually saved sessions, the following typical DMSA script example

restores saved sessions with the *-image* option of the *create_scenario* command. Suppose there are two saved sessions, scen_1_session and scen_2_session:

```
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
set_host_options -num_processes 2
start_host
current_session -all
report_global_timing
```

Third, run the *write_eco_design* command in the DMSA manager to create an ECO design that includes both scen_1 and scen_2 scenarios. In the following example, PrimeTime writes an ECO design under the default directory, eco_design_directory:

```
write_eco_design
```

Creating an ECO Design With Fewer Hosts Than Scenarios

You can use fewer hosts than scenarios to create an ECO design. This is especially useful when your machine resource is limited. For example, suppose there are four scenarios that consume 100 GB to run PrimeTime STA for each scenario. However, at the time of ECO, suppose you have only two 100-GB machines available. The following example uses only two machines to create an ECO design from four scenarios:

```
#
# Define four scenarios and their session locations
#
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
create_scenario -name scen_3 -image scen_3_session
create_scenario -name scen_4 -image scen_4_session

#
# Configure hosts with two machines
#
set_host_options -num_processes 2
start_host

#
# Create an ECO design from four scenarios
#
current_session -all
current_scenario -all
write_eco_design

#
# Exit or additional reporting
# Note that reporting incurs session swapping that may cause runtime
 penalty.
#
# report...
exit
```

It is recommended to have the *write_eco_design* command as the first command right after the *current_session* and *current_scenario* commands before any reporting commands. This avoids scenario swapping that is caused by merging reports from all scenarios.

Creating an ECO Design With Timing Endpoints

Specifying specific endpoint list for the *-endpoints* option enables PrimeTime to create an ECO design that preserves timing to those endpoints. The following example creates an ECO design that preserves timing to FF100/D and FF101/D pins.

```
write_eco_design -endpoints { FF100/D FF101/D }
```

The *-endpoints* option is a powerful tool to customize your ECO design. You can write a Tcl script that collects endpoints you are interested in and specify the endpoints for the option. For example, suppose your design has 100 hold violations, but you are interested in fixing only the 10 worst hold violations. The following example shows how to collect 10 worst hold violations and create an ECO design for them.

```
set paths [get_timing_paths -nw 1 -max 10 -delay min]
set hold_10_endpoints [get_attr $paths endpoint]
write_eco_design -endpoints $hold_10_endpoints
```

The following example creates an ECO design to perform hold fixing only for the *CLOCK_GROUP_A* clock group.

```
set paths [get_timing_paths -group CLOCK_GROUP_A -delay min]
set clk_group_a [get_attr $paths endpoint]
write_eco_design -endpoints $clk_group_a
```

Memory Reduction

After an ECO design is written, memory reduction may not be proportional to the number of reduced cells because PrimeTime's memory consumption also includes fixed memory overhead like loading library. For example, a design loaded with a large number of larger libraries shows lower memory reduction than a design loaded with one small library.

PrimeTime shows an estimated design reduction summary after the *write_eco_design* command finishes. Note that the numbers are not exact but estimated values. The purpose of the estimate is to provide rough numbers for design reduction. Exact cell, net, and pin counts as well as peak memory will be available when the *read_eco_design* command finishes.

Optimizing disk usage

If saved sessions are kept only for ECO purpose, you can reduce disk usage by removing the saved sessions after creating an ECO design. This is especially useful when there are many scenarios that take large disk space.

Creating an ECO design in non-DMSA mode

Specifying saved session directories for the *-merge_sessions* option in non-DMSA mode enables PrimeTime to merge the violating endpoints from the saved sessions and create an ECO design based on the merged endpoints. This option is designed to support to generate an ECO design without running DMSA.

Suppose there are two STA scripts as shown below.

```
# Script STA for FF running in Host1
read_verilog...
update_timing...
set eco_save_session_data_type timing
save_session $my_sessions/STA_SESSION_FF

# Script STA for SS running in Host2
read_verilog...
update_timing...
set eco_save_session_data_type timing
save_session $my_sessions/STA_SESSION_SS
```

Note that the *eco_save_session_data_type* variable is specified to store violating endpoint data in the saved sessions. After the saved sessions are created and available, the following scripts can be used to generate an ECO design under $rreco_db directory.

```
# Script to write ECO design for FF running in Host1
restore_session $my_sessions/STA_SESSIONS_FF
set sess_list "$my_sessions/STA_SESSION_FF $my_sessions/STA_SESSION_SS"
write_eco_design $rreco_db/FF -merge_sessions $sess_list

# Script to write ECO design for SS running in Host2
restore_session $my_sessions/STA_SESSIONS_SS
set sess_list "$my_sessions/STA_SESSION_FF $my_sessions/STA_SESSION_SS"
write_eco_design $rreco_db/SS -merge_sessions $sess_list
```

Note that the *write_eco_design* command specifies a subdirectory under $rreco_db so that each subdirectory is assigned to each scenario. In this directory structure, the following *read_eco_design* command can read in the ECO design in DMSA mode.

```
# Script to read RRECO design in DMSA mode
read_eco_design $rreco_db
```

Examples

This section describes a few examples to convert existing ECO scripts to new scripts utilizing the *write_eco_design* and *read_eco_design* commands.

Single-Scenario Example Scripts

The following example is a typical script for STA and ECO combined together.

```
##################################################
# FILE: run_sta_eco.tcl
#   Typical script for STA and ECO in PrimeTime.
#   Runs in 100 GB machine.
##################################################
#
# STA
#
read_verilog...
read_parasitics...
read_sdf...
update_timing...
report_timing...
#
# ECO
#
set_eco_options...
fix_eco_timing...
write_changes...
exit
```

The preceding script is separated into the two following scripts. The first script creates an ECO design after STA, and the second script loads the ECO design and performs ECO. The second script runs on smaller machines assuming peak memory is reduced from 100 GB to 20 GB.

```
##################################################
# FILE: run_sta_and_write_eco_design.tcl
#   To run STA and write_eco_design.
#   Runs in 100 GB machine.
##################################################
#
# STA
#
read_verilog...
read_parasitics...
read_sdf...
update_timing...
report_timing...
#
# Creates an ECO design
#
write_eco_design
exit

##################################################
# FILE: run_read_eco_design_and_eco.tcl
#   To run ECO.
#   Runs in 20 GB machine.
##################################################
#
# Read the ECO design
```

```
#
read_eco_design
#
# ECO
#
set_eco_options...
fix_eco_timing...
write_changes...
exit
```

Multi-Scenario Example Scripts

The following example is a typical script for DMSA ECO that restores saved sessions and performs ECO.

```
##########################################################################
# FILE: run_dmsa_eco.tcl
#   Typical script for DMSA ECO running from saved sessions.
#   Runs in four 100 GB machine assuming each scenario takes 100 GB.
##########################################################################
#
# Define four scenarios and their session locations
#
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
create_scenario -name scen_3 -image scen_3_session
create_scenario -name scen_4 -image scen_4_session
#
# Configure hosts with two machines
#
set_host_options -num_processes 4
start_host
#
# Create an ECO design from four scenarios
#
current_session -all
current_scenario -all
#
# ECO
#
fix_eco_timing...
remote_exec { write_changes... }
exit
```

The preceding script is separated into the two following scripts. The first script creates an ECO design with only one 100-GB machine, and the second script loads the ECO design and performs ECO. Assuming each scenario is reduced from 100 GB to 20 GB, all four scenarios can run in a single 100-GB machine.

The first script to create an ECO design in one host is shown below.

```
##########################################################################
# FILE: run_write_eco_design_in_one_host.tcl
#   Creates an ECO design in DMSA four scenarios with one host.
#   Runs in one 100 GB machine assuming each scenario takes 100 GB.
##########################################################################
#
# Define four scenarios and their session locations
#
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
create_scenario -name scen_3 -image scen_3_session
create_scenario -name scen_4 -image scen_4_session
#
# Configure one host
#
set_host_options -num_processes 1
start_host
#
# Create an ECO design from four scenarios
#
current_session -all
write_eco_design my_dmsa_eco_design
exit
```

The second script to run four scenarios in one 100 GB machine is shown below.

```
##########################################################################
# FILE: run_read_eco_design_and_eco_in_one_host.tcl
#   Load the ECO design with DMSA four scenarios and performs ECO.
#   Runs in one 100 GB machine running four scenarios simultaneously.
#   Assumes each scenario takes 20 GB.
##########################################################################
#
# Load the ECO design
#
read_eco_design my_dmsa_eco_design
#
# ECO
#
fix_eco_timing...
remote_exec { write_changes... }
exit
```

Feedback

write_eco_scenario_data

Writes out scenario timing data needed for ECO fixing in preparation for hybrid timing view ECO fixing.

Syntax

```
status write_eco_scenario_data
-output_directory directory_name
[-group group_list]
[-type fix_type_list]
```

Data Types

```
directory_name        string
group_list            list
fix_type_list         list
```

Arguments

`-output_directory directory_name`

Specifies the directory that will store the necessary timing information of the current scenario for hybrid timing view ECO fixing.

`-group group_list`

Writes timing information only for the specified path groups. This option applies only to the data written for the *setup* and *hold* fixing types.

`-type fix_type_list`

Specifies a list of one or more types of timing violations to fix. The valid values are *setup*, *hold*, *max_transition*, *max_capacitance*, and *noise*.

The default types are always written in the ECO data. The default list is *setup*, *hold*, *max_transition*, and *max_capacitance*. Use the *-type* option to add *noise* to this list.

Description

The *write_eco_scenario_data* command writes out all necessary timing information of the current scenario into a specified directory. This information is used in hybrid timing view ECO fixing.

In the hybrid timing view ECO flow, the PrimeECO tool uses a combination of live views for accuracy-critical ECO scenarios and static views of less critical scenarios. The static-view timing and violation information is merged into the live-view scenarios at intervals determined by the tool.

Based upon the reference information across all scenarios written by the *write_eco_scenario_data* command, the hybrid timing view ECO core engine optimizes

the combination of live views and static views, and delivers the best ECO fixing QoR using fewer machine resources.

Distributed Multi-Scenario Analysis (DMSA)

The *write_eco_scenario_data* command writes out data only for the current scenario.

Examples

The following example writes hybrid timing view ECO data for all scenarios from the DMSA manager into a directory named eco_data.

```
pt_shell> remote_execute {write_eco_scenario_data \\
            -output_directory $sh_launch_dir/eco_data/[current_scenario]}
```

The following example writes hybrid timing view ECO data including noise.

```
pt_shell> write_eco_scenario_data -output_directory S1/eco_data \\
            -type {setup hold max_transition max_capacitance noise}
```

The following session example shows how to generate hybrid timing view data for all scenarios and use that information for hybrid timing view ECO fixing.

```
create_scenario -name S1 \\
  -specific_data {specific_S2.tcl} -eco_data S1/eco_data
create_scenario -name S2 \\
  -specific_data {specific_S2.tcl} -eco_data S2/eco_data
create_scenario -name S3 \\
  -specific_data {specific_S3.tcl} -eco_data S3/eco_data

report_eco_scenarios -num_live_views 15
report_eco_scenarios -num_live_views 20
report_eco_scenarios -num_live_views 30

set_host_options -num_processes 20
start_eco_scenarios
fix_eco_timing -type setup ...
```

For scenarios S1, S2, and S3, the *write_eco_scenario_data* command generates the hybrid timing view data in directories named S1/eco_data, S2/eco_data, and S3/eco_data. This preparation step is necessary for the hybrid timing view ECO flow.

Feedback

write_eco_session

Writes PrimeTime timing and ECO data to a session, which can be read by the PrimeClosure tool to perform ECO.

Syntax

```
status write_eco_session
[-include session_data_type_list]
[-data_types fix_type_list]
[-data_format ascii | binary]
[-leakage_scenario scenario_name]
[-dynamic_scenario scenario_name]
[-pba_mode none | path | exhaustive | ml_exhaustive]
[-pt_version specific | compatible ]
[-link_session dir_name]
[-spef_data list_of_spef_files]
[-netlist_data list_of_netlist_files]
directory dir_name
```

Data Types

session_data_type_list	list
fix_type_list	list
scenario_name	list
list_of_spef_files	list
list_of_netlist_files	list
pba_mode_value	string
version	string
dir_name	string

Arguments

`-include` *session_data_type_list*

Specifies the session content types to include. Session content types are one or more of the following: pt_session, eco_data, design, netlist, spef, gpd, or libraries. The default types are pt_session and eco_data. Specifying the *design* type is the same as specifying both the netlist and SPEF design types. Specifying the *libraries* type includes libraries in the pt_session, which is equivalent to PrimeTime's *save_session* command with the *-include libraries* option specified.

`-data_types` *fix_type_list*

Specifies one or more fixing data types of setup, hold, max_transition, max_capacitance, max_fanout, power, noise, and seed. The default fixing data types are setup, hold, max_transition, and max_capacitance.

`-leakage_scenario` *scenario_name*

Specifies a leakage scenario name to generate leakage power data.

`-dynamic_scenario` *`scenario_name`*

Specifies a dynamic scenario name to generate dynmaic data.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Specifies one of the following timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode.
- *ml_exhaustive* - Performs machine learning based on exhaustive path-based analysis. This mechanism deploys machine learning techniques to trade runtime versus accuracy during the design flow. Accuracy and runtime will match the *-pba_mode exhaustive* option as the design approaches signoff.

`-pt_version specific | compatible`

Specifies whether to save a version-specific or version-compatible session

- *specific* Saves the session in a form that can be restored into the same PrimeTime release. Although this is the default, this keyword provides an explicit way to specify the default. A timing update is not needed when restoring the session.
- *compatible* Saves the session in a form that can be restored into the same or later PrimeTime releases. A timing update is always needed when restoring the session.

`-link_session` *`dir_name`*

Specifies a saved session directory name to create a symbolic link. With this option specified, the *write_eco_session* command creates a symbolic link to an existing PrimeTime session instead of creating a new session. This option is useful to save disk space. Note that this option only works in a scalar session.

`-spef_data` *`list_of_spef_files`*

Specifies a list of RC data files (SPEF or GPD) to replace the *write_eco_session* command corresponding with the RC data. This option is useful to resolve missing original RC data and for HyperScale design. Note that this option only works in a scalar session.

`-netlist_data` *`list_of_netlist_files`*

Specifies a netlist file list to replace the *write_eco_session* command with the corresponding netlist data. This option is useful for a HyperScale design. Note that this option only works in a scalar session.

`directory` *`dir_name`*

Specifies a directory path name to write a session.

Description

Use this command to create a repository of data for the PrimeClosure tool to perform ECO fixing. Use the *dir_name* option to specify the name of the directory to write the session. If the directory does not exist, a new directory is created and the data for the session is written into the new directory.

By default, the command writes PrimeTime sessions for PrimeClosure Distributed Multi Scenario Static Analysis (DMSA) mode and timing data for Single Machine Static Analysis (SMSA) mode. You can specify the *-include* option to write selected session data types. These session data types are pt_session, eco_data, design, netlist, SPEF, libraries. If the *-include* option is not specified, the default data types are pt_session and eco_data.

Scalar V.S. Distributed Multi Scenario Analysis (DMSA) mode

If the command is used in a scalar session, the directory contains the session data only. If the command is used in a DMSA session, the directory contains all scenaro sessions.

In the PrimeClosure tool, use the *read_eco_session* command to read the session written by this command. If the session is written from a DMSA session, the *read_eco_session* command reads all scenarios automatically. If the session is written from a scalar session, use the *-scenario_name* option to specify the scenario name associated with the session data.

Portability

The command uses symbolic links to existing files, such as verilog and parasitics files, instead of saving them in the session to save disk space. However, if those files are moved or deleted, the PrimeClosure tool will fail due to missing data. Also, if you want to move the session from one network to another network with different UNIX paths, the PrimeClousre tool will fail.

If you specify the 'design' type with the *-include* option, the design data, such as netlist and SPEF, are written to the session so that the session can be portable to other locations without missing data. You can specify either the netlist or SPEF design data, if needed.

Saving disk space

The command uses a PrimeTime infrastructure to save PrimeTime sessions for the PrimeClosure DMSA mode. If you have many scenarios, the pt_session can take a large

portion of disk space. You can save disk space by creating a symbolic link to existing PrimeTime sessions as long as the existing session can be assessed by the PrimeClosure tool. Use the *-link_session* option to specify the existing PrimeTime session.

Note that the *-link_session* option works only in a scalar single scenario session.

HyperScale design

If PrimeTime session contains a HyperScale design, the netlist and SPEF file paths written in the mcmm_data file under the session directory will be incomplete. If you read the session in PrimeClosure, SMSA mode considers missing blocks as black boxes. Use the *-spef_data* and *-netlist_data* options to overwrite the path list.

Note that *-spef_data* and *-netlist_data* options work only in a scalar single scenario session.

Examples

If you are running a DMSA static timing analysis (STA) session, you can run the following command in a PrimeTime manager.

```
pt_shell> write_eco_session $my_dmsa_eco_session
```

Since the command was executed in a PrimeTime master, the $my_dmsa_eco_session session directory contains multi-scenario data with subdirectories named after each scenario.

If you are running STA separately for different scenarios (scalar mode), you can still generate a session using the same *write_eco_session* command. For example:

```
pt_shell> write_eco_session $my_dir/eco_session_${scenario}
```

Suppose you have two PrimeTime scenarios, setup and hold. In the setup scenario, the following command writes a session named $my_setup_eco_session:

```
pt_shell> write_eco_session $my_setup_eco_session
```

In the hold scenario, the following command writes a session in a separate directory named $my_hold_eco_session:

```
pt_shell> write_eco_session $my_hold_eco_session
```

---

write_edge_annotation

Writes out boundary leakage edge annotation information in edge annotation file.

Syntax

status *write_edge_annotation*

```
[-edge_annotation_files file_fmt]
```

Feedback

Data Types

file_fmt	string

Arguments

`-edge_annotation_files` *file_fmt*

Specifies the name of the edge annotation file.

Description

PrimePower supports boundary leakage power analysis and reporting through edge back annotation flow. The *write_edge_annotation* command writes out boundary leakage edge annotation information in edge annotation file. The edge annotation information can be read in later in the design and boundary leakage analysis can be done using the edge annotation information.

In order to write out edge annotation information, boundary leakage analysis must be run in the design.

Examples

The following example writes out boundary leakage edge annotation information in the edge annotation file

```
pt_shell> write_edge_annotation -edge_annotation_files
 { edge_annotation }
```

- read_edge_annotation

---

write_hier_data

Writes out model data for the current design to be used for top-level HyperScale analysis, or writes out context data for HyperScale subblocks in the current design.

Syntax

status *write_hier_data*

```
[-netlist]
[-parasitics spef_format | gpd_format]
[-config]
```

```
[-exclude parasitics_data | context_data]
[-include model_reload_data | model_constraints_data]
[-script_format ptsh | sdc]
dir_name
```

Data Types

dir_name string

Arguments

`-netlist`

Writes out a netlist for the HyperScale block model interface instead of the HyperScale block model. Use this option when you want to export the HyperScale block interface netlist in Verilog format to use with other tools.

Writing out the netlist s not required in the PrimeTime HyperScale analysis flow.

`-parasitics spef_format | gpd_format`

Specifies the format, either SPEF or GPD, for the parasitic data written to the hierarchical data directory. The default is GPD. This is the parasitic data of the HyperScale block model interface.

`-config`

Writes a HyperScale configuration script instead of a HyperScale block model or block context. This script contains commands that enable HyperScale hierarchical analysis and set the hierarchical configuration (using the *set_hier_config* command). You can optionally use this script to prepare the same analysis in a future session.

`-exclude parasitics_data | context_data`

Use this option to skip writing of parasitic data for the interface nets of HyperScale block models or skip writing top-level context data for block-level analysis.

This option is typically used to save disk space when the parasitics are already available for the entire block.

When available block-level parasitics are used, it is extremely important to provide exactly the same block-level parasitics for block-level analysis that were used in top-level analysis. HyperScale top-level analysis will automatically annotate only the interface nets and ignore internal nets in the full-block parasitics data. Potential accuracy loss can occur if inconsistent block-level parasitics are used.

`-include model_reload_data | model_constraints_data`

Use the *model_reload_data* value to write out additional model reload data in tool-created directory named 'RELOAD'. You can directly load this data by using the *read_hier_data* command in a separate analysis session to check the interface data.

Use the *model_constraints_data* value to write out a constraint file that is a partial version of the full-block constraints supplied. This exports only the constraints relevant to the list of objects HyperScale considers as the block interface, either automatically by default, or as configured during block model abstraction.

The *model_reload_data* value does not affect the data in the MODEL directory; it writes out extra side data used to load the block model into a separate run with only the interface circuit in the MODEL and without providing a top-level circuit to instantiate the block model.

The *model_reload_data* option requires additional runtime and disk storage. It is recommended for debugging purposes only.

The *model_constraints_data* value must be used together with the *-netlist* option.

`-script_format ptsh | sdc`

Specifies the output format for the instance script. Allowed values are *ptsh* (the default) and *sdc* for pt_shell.

`dir_name`

Specifies the directory in which to write the block model, block model netlist, block model parasitic data, or lower-level block context. Any existing data of the same type in this directory is overwritten. For this reason, be sure to specify a different dedicated directory for each individual HyperScale block and for the top-level design.

Description

The *write_hier_data* command writes out hierarchical interface data in the discrete HyperScale analysis flow. In this flow, you use a separate analysis session for each lower-

level HyperScale block and for the top level. The data written by this command allows the exchange of interface data between the block-level and top-level analysis sessions:

- In each block-level session, the *write_hier_data* command writes out the HyperScale model for the block. In a subsequent top-level analysis session, the tool uses the HyperScale block model as directed by the *set_hier_config* command.
- In a top-level analysis session, the *write_hier_data* command writes out the context for each lower-level HyperScale block, as defined by the *set_hier_config* command. In each subsequent block-level analysis session, you read in the context data for that block by using the *read_context* command.

Block-Level and Top-Level Analysis

The current design is treated as a block-level design if it does not contain HyperScale blocks (in other words, when the *set_hier_config* command is not used in the session), or if the *read_context* command is used, or if you set the *timing_save_hier_model_data* variable to *true*. In any of these cases, the *write_hier_data* command writes out a HyperScale block model for the current design. This model can be used for analysis at the next higher HyperScale level of hierarchy.

The current design is treated as a top-level design if it contains HyperScale blocks, as specified by the *set_hier_config* command. In that case, the *write_hier_data* command writes out the context for the lower-level HyperScale blocks. The context information establishes the constraints for individual analysis of the lower-level HyperScale blocks.

A mid-level design can be both a block-level design (relative to its parent) and a top-level design (relative to its HyperScale blocks). In that case, the *write_hier_data* command writes out both a HyperScale block model for the current design and the context for the lower-level HyperScale blocks. When the *-exclude context_data* option is used, the *write_hier_data* command writes out only the model data. You can also use the *write_context* command instead.

During top-level or mid-level design analysis, there can be situations when you do not need to write out the context information for the lower-level HyperScale blocks or perform scope checking for those blocks. To save runtime, you can prevent context generation and scope checking by setting the *timing_save_hier_context_data* variable to *false*.

Hierarchical Data Directory

In each *write_hier_data* command, you must specify the directory in which to store the data. In this directory, the command writes out the HyperScale model data to a subdirectory named MODEL, or writes out the context data to a subdirectory named CONTEXT, or writes out the HyperScale model netlist and parasitic data directly. The command overwrites any existing data of the same type in the directory.

The tool automatically manages the model data stored in the model directory tree, including reading, writing, updating, and deleting of the model contents. Do not attempt to directly modify the model files or subdirectories, as this can corrupt the database.

Block Model Netlist and Parasitics

In a block-level session, you can optionally write out the netlist and parasitic data for the block model by using a separate *write_hier_data* command with the *-netlist* and *-parasitics* options. This data represents part of the block that is retained and visible in the HyperScale model for top-level analysis, roughly corresponding to the interface logic of the block. You can export this information to use with other tools; it is not needed in the HyperScale analysis flow.

The netlist and parasitic data can be written only with no subblocks loaded as HyperScale blocks, and only after a timing update. The netlist is written in Verilog format and the parasitic data is written in Galaxy Parasitic Database (GPD) or SPEF format, as specified by the *-parasitics* argument. Text files are written in compressed gzip format.

Block-Level UPF Data

In a block-level session, the *write_hier_data* command automatically extracts any UPF data for the HyperScale block model. During top-level analysis, the tool automatically loads the extracted block UPF data along with the rest of the HyperScale model data, and it ignores any attempt to load UPF data for HyperScale blocks using the *load_upf* command.

Usage Notes

In a top-down hierarchical flow, from a top-level analysis, you might want to generate the only the constraints (rather than the full context) for lower-level blocks for which there are not yet any HyperScale models. In that case, do not use the *write_hier_data* command. Instead, set the *hier_characterize_context_mode* variable to *constraints_only*, and then use the *characterize_context* and *write_context* commands to generate and write out the initial constraints for the lower-level blocks.

Examples

In a discrete hierarchical analysis flow, you analyze each HyperScale block and the top-level in a separate session. The *write_hier_data* command writes out the hierarchical data from each session, allowing the tool to exchange data between sessions at different hierarchical levels.

In the following example, a top-level design called TOP contains two HyperScale blocks, BLKA and BLKB.

BLKA block-level analysis session:

```
set_app_var hier_enable_analysis true
 ...
read_verilog BLKA.v
```

```
link_design BLKA
 ...
# Read context data from top-level analysis session, if available
read_context $topContextDir
 ...
update_timing
 ...
# Write HyperScale block model data for BLKA
write_hier_data $model_A
# Write block model interface netlist & parasitics (optional)
write_hier_data -netlist -parasitics spef_format $model_A
```

BLKB block-level analysis session:

```
set_app_var hier_enable_analysis true
 ...
read_verilog BLKB.v
link_design BLKB
 ...
# Read context data from top-level analysis session, if available
read_context $topContextDir
 ...
update_timing
 ...
# Write HyperScale block model data for BLKB
write_hier_data $model_B
# Write block model interface netlist & parasitics (optional)
write_hier_data -netlist -parasitics spef_format $model_B
```

Top-level analysis session using HyperScale BLKA/BLKB models:

```
set_app_var hier_enable_analysis true
 ...
set_hier_config -block BLKA -path $model_A
set_hier_config -block BLKB -path $model_B
 ...
read_verilog TOP.v
link_design TOP
 ...
update_timing
 ...
# Write context data for BLKA and BLKB
write_hier_data $topContextDir
```

You can run these scripts multiple times to analyze design changes or refine the constraints. The block-level and top-level analysis sessions exchange hierarchical data by using the *write_hier_data*, *read_context*, and *set_hier_config* commands.

---

write_ilm_netlist

Writes out a flattened Verilog netlist corresponding to the interface logic for the current design.

Syntax

int *write_ilm_netlist*

```
[-include_all_net_pins]
[-verbose]
file_name
```

Data Types

file_name	string

Arguments

`-include_all_net_pins`

Indicates that all pins on nonclock interface logic nets and propagated clock interface logic nets are to be included in the netlist. By default, only pins that have the *is_interface_logic_pin* attribute are written out in the Verilog netlist. Use this option if the interface logic model (ILM) is used in non-SDF flows and delay calculation is performed using the information contained in the ILM. Preserving all pins on a net maintains correct pin capacitance information for the net. This option does not affect nonpropagated clock nets; that is, nets in the clock network that have user-specified source latency.

`-verbose`

Indicates that information about the number of cells and nets in the original design and in the ILM netlist is to be written to standard output.

file_name

Specifies the name of the output file containing the flattened Verilog netlist information.

Description

Writes out a flattened Verilog netlist corresponding to the interface logic on the current design. This represents the netlist of the interface logic model (ILM).

Use the *-include_all_net_pins* option if the ILM is used in the non-SDF flows. You can use the *-verbose* option for approximating the reduction of the ILM size when compared with the original netlist.

For a discussion of ILM creation and the associated commands, see the *identify_interface_logic* man page.

Examples

The following example writes out a Verilog netlist that includes statistics comparing the ILM with the original netlist.

```
pt_shell> write_ilm_netlist -verbose model.v
```

The following example writes out a Verilog netlist while keeping all pins on interface logic nets in the netlist.

```
pt_shell> write_ilm_netlist -include_all_net_pins model.v
```

---

write_ilm_parasitics

Writes out in Standard Parasitic Exchange Format (SPEF) or Synopsys Binary Parasitic Format (SBPF) all annotated parasitics on the interface logic for the current design.

Syntax

int *write_ilm_parasitics*

```
[-input_port_nets]
[-constant_nets]
[-compress compression]
[-format SPEF | SBPF]
file_name
```

Data Types

compression	string
file_name	string

Arguments

`-input_port_nets`

Indicates that parasitic information is to be written out for nets connected to the input ports on the current design. By default, this information is not written out.

`-constant_nets`

Indicates that parasitic information is to be written out for constant nets. By default, this information is not written out.

`-compress` *compression*

Specifies that the file should be compressed. The only valid value for *compression* is *gzip*.

`-format SPEF | SBPF`

Specifies the format of the file. The valid values are *SPEF* and *SBPF*. The default is *SPEF*.

file_name

Specifies the name of the output SPEF file.

Description

This command writes out in SPEF format all annotated parasitics on the current design that are defined on its interface logic. This information is used as back-annotation information for the interface logic model (ILM).

For a discussion of ILM creation and the associated commands, see the *identify_interface_logic* man page.

Examples

The following example writes to the SPEF file model.spef the parasitics that apply to interface logic.

```
pt_shell> write_ilm_parasitics model.spef
```

The following example includes parasitic information for the input ports and writes all parasitic information to the SPEF file model.spef.

```
pt_shell> write_ilm_parasitics -input_port_nets model.spef
```

See Also

- write_ilm_sdf

---

write_ilm_script

Writes constraints, assertions and exceptions for interface logic as a script for PrimeTime or Design Compiler.

Syntax

int *write_ilm_script*

```
[-instance]
[-format ptsh | dcsch | dctcl]
[-compress compression]
[-nosplit]
file_name
```

Data Types

compression	string
file_name	string

Arguments

`-instance`

Indicates that the script written out should be appropriate for use when the interface logic is instantiated at the chip level. That is, assertions and exceptions must refer to boundary pins on a block instead of referring to ports on a design. The script does not include environment information because that is defined by the chip-level design. Do not use this option to generate a script for verifying the standalone ILM against the original design.

`-format ptsh | dcsch | dctcl`

Specifies the output format for the script. Allowed values are *ptsh* (the default) for pt_shell, *dcsh* for dc_shell, and *dctcl* for dc_shell-t.

`-compress` *`compression`*

Specifies that the script is to be compressed; by default, the script is written as standard text. The only valid value for the *compression* option is *gzip*.

`-nosplit`

The *-nosplit* option prevents line-splitting. This is most useful for doing diffs on previous scripts, or for postprocessing the script.

`file_name`

Specifies the name of the script file to write. If the *-compress* option is also specified, the extension ".gz" is added if it is not already present.

Description

Writes constraints, assertions and exceptions for interface logic as a script for pt_shell, dc_shell, or dc_shell-t.

For a discussion of ILM creation and the associated commands, see the manual page for the *identify_interface_logic* command.

Examples

The following example writes out in ptsh format the assertions and exceptions that apply to interface logic, to the file model.pt. This script would be used to verify an ILM against the original netlist.

```
pt_shell> write_ilm_script model.pt
```

The following example writes out the assertions and exceptions that can be applied to the ILM when it is instantiated at the chip level.

```
pt_shell> write_ilm_script -instance model.pt
```

---

write_ilm_sdf

Writes out a Version 2.1-compliant Standard Delay Format (SDF) back-annotation file for the interface logic of the current design.

Syntax

integer *write_ilm_sdf*

```
[-input_port_nets]
[-output_port_nets]
[-significant_digits digits]
[-annotated]
[-no_edge]
[-compress compression]
[-version sdf_version]
file_name
```

Data Types

digits	integer
compression	string
sdf_version	string
file_name	string

Arguments

`-input_port_nets`

Indicates that the SDF file is to include delays of nets connected to input ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available.

`-output_port_nets`

Indicates that the SDF file is to include delays of nets connected to output ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available.

`-significant_digits` *digits*

Specifies the number of digits to the right of the decimal point that are to be written in SDF delay triplets. Allowed values are 0-13; the default is 3.

`-annotated`

Indicates that the SDF is to include only timing arcs that have been annotated with the *read_sdf*, *set_annotated_delay*, or *set_annotated_check* commands.

`-no_edge`

Indicates that the generated SDF is not to include any edges (posedge or negedge) for combinational IOPATHs.

`-compress` *`compression`*

Specifies that the file should be compressed. The only valid value for *compression* is *gzip*.

`-version` *`sdf_version`*

Selects which SDF version to use. Supported SDF versions are 1.0, 2.1, and 3.0. SDF version 2.1 is the default.

`file_name`

Specifies the name of the SDF file to write. If the *-compress* option is also specified, the extension ".gz" is added if it is not already present.

Description

This command writes out in SDF format information on cell and net delays for the interface logic on the current design.

For information about ILM creation and the associated commands, see the *identify_interface_logic* man page.

Examples

The following example writes out SDF information that applies to the interface logic; only SDF data that was previously back-annotated on a design is written out.

```
pt_shell> write_ilm_sdf -annotated model.sdf
```

The following example writes out an SDF file, model.sdf, for the interface logic. All delay values are included whether or not they had been back-annotated. Information is included for the input and output ports on the design. Four significant digits to the right of the decimal point are written in SDF delay triplets.

```
pt_shell> write_ilm_sdf -input_port_nets -output_port_nets
 -significant_digits 4 model.sdf
in -0.25in
```

---

write_implement_changes

Writes out ECO changes performed in the current session in DEF, Verilog, or IC Compiler II Tcl script format.

Syntax

status *write_implement_changes*

```
-format icc2tcl | verilog | def
-output file_name
```

Data Types

```
file_name     string
```

Arguments

`-format icc2tcl | verilog | def`

Specifies one of the following output formats:

- *icc2tcl* - A change list script in IC Compiler II Tcl command format that implements the netlist changes
- *verilog* - The ECO-modified design netlist in Verilog format
- *def* - The ECO-modified physical design in Design Exchange Format (DEF)

`-output file_name`

Specifies the name of the output file (Tcl script, Verilog, or DEF file).

Description

The *write_implement_changes* command writes out the ECO changes that were made to the specified ECO block. The *-format* option specifies whether to write out the changes as a Tcl script file that can be run in the IC Compiler II tool, a Verilog netlist, or DEF physical data file. You can use a Verilog netlist and DEF file to export the design to other tools.

The *write_implement_changes* command attempts to merge redundant operations to reduce and simplify the change list. For example, if a cell is resized multiple times, it is simplified to a single resize operation. If a buffer is inserted later removed, the associated commands are omitted.

Feedback

Examples

The following command writes out the change list file as an IC Compiler II Tcl script. Running the script in IC Compiler II performs all the ECO netlist changes and physical changes of the session.

```
prompt> write_implement_options -format icc2tcl -name my_eco_changes.tcl
```

The following commands write out the ECO-modified design netlist in Verilog format and the ECO-modified physical design in DEF format.

```
prompt> write_implement_changes -format verilog -name post_eco.v

prompt> write_implement_changes -format def -name post_eco.def
```

See Also

- implement_eco
- set_implement_options
- write_changes

---

write_interface_timing

Generates an interface timing ASCII report for a gate-level netlist or an extracted timing model (ETM) design.

Syntax

int *write_interface_timing*

```
file_name
[-ignore_ports port_list]
[-significant_digits digits]
[-nosplit]
[-timing_type slack | arc]
[-verbose]
[-include incl_list]
[-latch_level level]
[-sms_scenarios sms_scenarios_list]
```

Data Types

digits	int
file_name	string
incl_list	list
level	int
port_list	list
sms_scenarios_list	collection

Feedback

Arguments

file_name

Specifies the name of the file to which the interface timing information is to be written.

-ignore_ports *port_list*

Specifies a list of ports that are to be excluded from the timing file. By default, all ports are included.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported following the method used in the *report_timing* command. Allowed values are 0-13.

The default is the maximum of six and the value of the *report_default_significant_digits* variable. Use this option if you want to override the default. Fixed-precision floating-point arithmetic is used for delay calculation; thus, the actual precision might depend on the platform.

-nosplit

Prevents line-splitting. This is most useful for doing diffs on previous scripts or for postprocessing the script.

-timing_type slack | arc

Selects the type of timing data section to be reported.

- *slack* (default) - Reports the slack associated with interface timing relationships.
- *arc* - Reports the timing arc values for interface timing relationships.

Slack values are a function of the external environment (clocks, arrival times), but arc values are not.

If you are validating an ETM that gave a MEXT-54 warning when generated, do not use arc values. When the MEXT-54 warning is given, some of the ETM arcs have been adjusted by a multiple of the clock period and does not match the arc values of the original netlist.

-verbose

Shows details of the progress of the *write_interface_timing* command and provides data on CPU time and memory usage. For longer runs, it shows a time estimate of completion.

`-include` *`incl_list`*

Selects the type of data to analyze. You can specify the following values for the *incl_list*:

- *timing* (default) - Reports the slack/arc, capacitance, transition time, and design rules sections.

`-latch_level` *`level`*

Specifies the number of levels of latch borrowing that are to occur at the interface of a design. The default is 12.

`-sms_scenarios` *`sms_scenarios_list`*

Writes interface timing only for the specified SMVA/SMS scenarios. This collection is created by the *get_sms_scenarios* command. The default is to write interface timing for all SMS scenarios relevant to the design.

In an SMVA/SMS analysis, the *write_interface_timing* command creates a separate file for each SMS scenario, augmenting the file name with a description of the voltage configuration as follows:

```
  <name>_<supply_group1>_<ref_name1>[..._<supply_groupN>_<ref_nam
eN>]
```

where *supply_group1,.,supply_groupN* are the supply groups included in the voltage configuration, and *ref_name1,..ref_nameN* are their corresponding voltage reference names specified with the *set_voltage_levels* command.

Description

This command generates an interface timing ASCII report for a gate-level netlist, or an extracted timing model (ETM) design. The report is a file containing interface timing, slew, capacitance, design rule, and noise information for a gate-level netlist or an ETM design. The command performs an implicit *update_timing* and *update_noise*, if necessary, for the selected data sections. A return code of *1* indicates that the command ran to completion; a return code of *0* indicates an error.

The output report file contains the following sections:

Slack - Shows worst-case slacks for combinational paths from an input port to an output port, for input-to-register paths from an input port to each clock used to clock the input port, and for output-to-register paths from each clock used to clock an output port to the output port.

For each port-to-port, register-to-port, and port-to-register timing relationship, it reports slacks for the following possible arc types: *min_seq_delay*, *max_seq_delay*,

min_combo_delay, *max_combo_delay*, *setup*, *hold*, *recovery*, *removal*, *clock_gating_setup*, and *clock_gating_hold.*

Arc - Shows worst-case setup/hold/delay arc values for combinational paths from an input port to an output port, for input-to-register paths from an input port to each clock used to clock the input port, and for output-to-register paths from each clock used to clock an output port to the output port.

For each port-to-port, register-to-port, and port-to-register timing relationship, it reports arc values for the following possible arc types: *min_seq_delay*, *max_seq_delay*, *min_combo_delay*, *max_combo_delay*, *setup*, *hold*, *recovery*, *removal*, *clock_gating_setup*, and *clock_gating_hold.*

Transition Time - Shows actual transition times on all ports for the four delay types: *min_fall*, *min_rise*, *max_fall*, and *max_rise*.

Input Capacitance - Shows actual total (lumped) or effective capacitances on boundary nets connected to each port.

Design Rule - Shows design rule information for all ports: max_capacitance, min_capacitance, max_transition, max_fanout, and fanout_load.

Noise Detection - Shows noise slack information for all input ports for the four noise regions: below low, above low, below high, above high.

Noise Calculation - Shows driver steady-state resistance for all output ports for the four noise regions: below low, above low, below high, above high.

To compare two report files generated by the *write_interface_timing* command, use the *compare_interface_timing* command.

Examples

The following example writes timing information for the current design to the model.rpt file.

```
pt_shell> write_interface_timing -timing_type arc model.rpt
```

See Also

- compare_interface_timing
- update_noise
- update_timing
- report_default_significant_digits

---

write_parasitics

Writes out annotated parasitics information for the current design.

Feedback

Syntax

status *write_parasitics*

```
-format SPEF | GPD
-no_name_mapping
-nets net_list
file_name
```

Data Types

net_list	list
file_name	string

Arguments

`-format SPEF | GPD`

Specifies the format of the output parasitics file. Currently, the only allowed values are Standard Parasitic Exchange Format (*SPEF*) and Galaxy Parasitics Database (*GPD*).

`-no_name_mapping`

This option is only for SPEF. When specified for SPEF, it means that name maps should not be used for generating SPEF file. By default, a name map section is always generated.

`-nets net_list`

Specifies the list of nets to output parasitics in the parasitics file. This option is supported for both SPEF and GPD.

file_name

Specifies the name of the output parasitics file.

Description

The *write_parasitics* command writes all parasitics annotated on the current design to the file specified in the *file_name* argument. This command supports the SPEF and GPD formats, and a *PrimeTime SI* license is required for GPD.

Binary parasitics are useful for analysis iterations. You can read parasitics in one format (for example, SPEF), then use the *write_parasitics* command to output the parasitics in GPD format, which loads much faster than ASCII formats and is much more compact. The *write_parasitics* command can write detailed RC, PI model, and lumped-capacitance networks.

SPEF writing can be useful for debugging if you read parasitics into PrimeTime through GPD.

Feedback

Examples

The following example reads the top.spef parasitics file and then writes it out in GPD format:

```
pt_shell> read_parasitics top.spef
****************************************
Report : read_parasitics /u/designs/top.spef
Design : TOP
****************************************
        0 error(s)
        Format is SPEF
        Number of annotated nets          :        66
        Number of annotated capacitances  :      1390
        Number of annotated resistances   :      1333
        Number of annotated RC pi models  :         0
        Number of annotated Elmore delays :         0
1
pt_shell> write_parasitics -format GPD top.gpd
1
pt_shell> write_parasitics -format SPEF top.spef
1
```

See Also

- read_parasitics

---

write_physical_annotations

Writes annotated delays and parasitics for a hierarchical cell.

Syntax

string *write_physical_annotations*

```
[-sdf sdf_file]
[-version sdf_version]
[-nets_only]
[-cells_only]
[-boundary_nets]
[-parasitics parasitics_file]
[-append script_file]
[-format ptsh | dcsh | dctcl]
cell
```

Data Types

```
sdf_file              string
sdf_version           string
parasitics_file       string
```

```
script_file             string
cell                    string
```

Arguments

`-sdf` *sdf_file*

Indicates that annotated delays are to be written in Standard Delay Format (SDF) to the specified *sdf_file*. You must specify either *-sdf* or *-parasitics*, but you cannot specify both. If you specify either the *-version*, *-nets_only*, or *-cells_only* option, you must also specify the *-sdf* option.

`-version` *sdf_version*

Specifies the version of the SDF to use. Allowed values are *1.0* and *2.1* (the default). If you specify the *-version* option, you must also specify the *-sdf* option.

`-nets_only`

Indicates that only delays annotated on nets be written out as SDF. By default, all annotated delays are written out. If you specify the *-nets_only* option, you must also specify the *-sdf* option.

`-cells_only`

Indicates that only delays and timing checks annotated on cells be written out as SDF. By default, all annotated delays are written out. If you specify the *-cells_only* option, you must also specify the *-sdf* option.

`-boundary_nets`

Indicates that parasitics annotated on boundary nets of the specified cell must also be written out to the parasitics file. By default, only the annotated parasitics of internal nets are written out. Do not use this option if you issue this command in conjunction with the *characterize_context* command to avoid overwriting characterized capacitance on boundary nets. If you specify the *-boundary_nets* option, you must also specify the *-parasitics* option.

`-parasitics` *parasitics_file*

Indicates that annotated capacitance and resistance on nets are to be written to the specified *parasitics_file* as a script. Annotated capacitance is written out as a *set_load* command for for pt_shell and dc_shell. Annotated resistance is written out as a *set_resistance* command. You must specify either the *-sdf* or *-parasitics* option, but you cannot specify both options. If you specify the *-boundary_nets* option, you must also specify the *-parasitics* option.

`-append` *script_file*

Appends commands to import the generated files in the given script file. The SDF file is read using the *read_sdf* command in pt_shell and the *read_timing* command in dc_shell. The parasitics file is included in the script file.

`-format ptsh | dcsh | dctcl`

Specifies the format in which to output the commands in the script file and the parasitics file. Allowed values are *ptsh* (the default), *dcsh*, or *dctcl*.

cell

Specifies the name of the cell for which to export the annotations. The cell must be hierarchical.

Description

The *write_physical_annotations* command writes physical information for a hierarchical block in the design. The exported information includes annotated net and cell delays using the Standard Delay Format (SDF). Annotated parasitics can also be exported as a series of pt_shell or dc_shell commands.

The *write_physical_annotations* command is most commonly used in conjunction with the *characterize_context* and *write_context* commands to export timing and physical information for a block from the chip-level environment to module level tools. A typical sequence of commands is to first characterize the timing environment of a block using the *characterize_context* command and write this information as a dc_shell script using the *write_context* command. The *write_physical_annotations* command is then used to export annotated delays and parasitics for internal nets of the block.

To avoid overwriting characterized capacitance on boundary nets, do not specify the *-boundary_nets* option. You can use the *-append* option to append commands to read the SDF and include the parasitics script at the end of the script file generated by the *write_context* command.

Examples

The following command writes the annotated delays on nets for the hierarchical cell 'I1':

```
pt_shell> write_physical_annotations \\
            -sdf I1.sdf -nets_only I1
```

The following command is used in conjunction with the *characterize_context* and *write_context* commands to export the timing and physical environment for cell 'I2' as a dc_shell script. The command uses the *append* option to augment the script generated by the write_context command with commands to import the generated delay and parasitic files.

```
pt_shell> characterize_context I2

pt_shell> write_context -format dcsh \\
          -out I2.dcsh I2

pt_shell> write_physical_annotations \\
          -sdf I2.sdf -parasitics I2.rc \\
```

```
-format dcsh -append I2.dcsh \\
I2
```

---

write_rh_file

Writes timing input file for ANSYS RedHawk solution.

Syntax

string *write_rh_file*

```
[-filetype irdrop | jitter ]
[-significant_digits digits]
-output file_name
```

Data Types

digits	int
file_name	string

Arguments

`-significant_digits` *digits*

Specifies the number of digits to the right of the decimal point that are to be written in the file. The default is the value of variable *report_default_significant_digits*.

`-filetype irdrop | jitter`

The filetype to be written out. If not specified, the irdrop file will be written.

file_name

Specifies the name of the timing file to be written for ANSYS RedHawk

Description

This command writes the timing input file for ANSYS RedHawk to a compressed disk file with ".gz" suffix.

Examples

The following example writes timing information for the current design of current scenario to a disk file called test_rh.irdrop.gz

```
prompt> write_rh_file -output test_rh.irdrop
```

---

write_rh_power_file

Writes an instance power file for the ANSYS RedHawk solution.

Syntax

string *write_rh_power_file*

```
[-output file_name]
[-extended_rh_file]
[-exclude cell_list]
[-compress]
[-exclude_pg_type pg_type_list]
[-include_ground_current]
```

Data Types

```
file_name     string
cell_list list
pg_type_list list
```

Arguments

`-output file_name`

Specifies the name of the instance power file to be written for ANSYS RedHawk solution.

`-extended_rh_file`

Supports the more comprehensive 9-column format.

`-exclude cell_list`

Excludes cells (memory or macros, etc) from being in the instance power file.

`-compress`

Writes the instance power file in the compressed (.gz) format.

`-exclude_pg_type`

Excludes PG pin types (bias, internal_power, or both) from being including the instance power file. Valid values are *bias* and *internal_power*.

`-include_ground_current`

Includes the ground current information in the instance power file.

Description

This command writes the instance power file for the ANSYS RedHawk solution.

Examples

The following example writes power information for the current design to a disk file called test_rh.ipf, excluding a list of cells using the -exclude option.

```
pt_shell> write_rh_power_file -output test_rh.ipf -exclude [get_cell *]
```

The following examples write the instance power file in the compressed format.

```
pt_shell> write_rh_power_file -output test_rh.ipf -compress

pt_shell> write_rh_power_file -output test_rh.ipf.gz -compress
```

The following examples write the instance power file excluding PG pin types of bias, internal_power or both.

```
pt_shell> write_rh_power_file -output test_rh.ipf -exclude_pg_type {bias}

pt_shell> write_rh_power_file -output test_rh.ipf -exclude_pg_type
 {internal_power}

pt_shell> write_rh_power_file -output test_rh.ipf -exclude_pg_type {bias
 internal_power}
```

The following example runs the *write_rh_power_file* command with the -include_ground_current and -extended_rh_file options and generates an instance power file which lists the instance power and current values by different power and current types per power and ground pins.

```
pt_shell> write_rh_power_file -output test -include_ground_current
 -extended_rh_file

Instance Pin   Power/  Toggle Fre-   Total     Switching Internal Leakage
Name     Name  Ground  Rate   quency Power/    Power/    Power/   Power/

---

write_saif

Writes a backward Switching Activity Interchange Format (SAIF) file.

Syntax

int *write_saif*

```
file_name
[-cells cell_list]
[-derate_glitch value]
[-rtl]
[-propagated]
[-exclude_sdpd]
[-no_hierarchy]
[-compress compression]
[-conflict]
[-event_based]
[-include_sequential_inputs]
[-exclude_hier_pins]
[-keep_input_saif_sdpd_info]
```

Data Types

file_name	string
cell_list	list
value	float

Arguments

file_name

Specifies the name of the output SAIF file.

`-cells` *`cell_list`*

Specifies an optional list of hierarchical instances for which the SAIF file is generated. If this argument is not specified, the SAIF file is generated for the current instance.

`-derate_glitch` *`value`*

Specifies a derating factor value to be used for converting part of glitches into inertial glitches. If this argument is not specified, a default derating factor of 0.5 is used.

`-rtl`

Specifies that the generated SAIF file contains the switching activity for the synthesis invariant objects. These are the design ports, hierarchical cell pins, and outputs of sequential and tri-state cells. Note that you should not use the *-rtl_direct* option of the *read_saif* command when reading SAIF files generated by the *write_saif* command.

`-propagated`

Propagates the user-annotated switching activity to estimate the switching activity of unannotated objects, and generates a SAIF file containing both the annotated and estimated switching activity. When this option is not specified, the *write_saif* command generates a SAIF file containing only the user-annotated switching activity.

`-exclude_sdpd`

Inhibits the state-dependent and path-dependent (SDPD) switching activity generation. If you do not specify this option, the *write_saif* command outputs SDPD information by default. When the *write_saif* command is called with the *-propagated* option, the estimated SDPD information is included in the SAIF file.

`-no_hierarchy`

Specifies that the SAIF file contains switching activity information for only the top-level design objects. When this option is not specified, the *write_saif* command generates a SAIF file containing switching activity information for all the objects in the hierarchy.

`-compress`

Specify that the output saif file should be compressed. The only valid value for compression is gzip.

`-conflict`

Specify that the output saif file contains conflict switching activities only. This option is valid under merged fsdb/saif flow which is enabled when

power_enable_merged_fsdb variable is *true*. Also user should specify conflict instances using *set_power_analysis_options -conflict_activity_cells*.

`-event_based`

Writes event based saif file from RTL fsdb. update_power has to be done before using this option. *-propagated* is mandatory to be mentioned along with this option.

`-include_sequential_inputs`

This option enables writing toggle information of input pins for sequential devices. update_power has to be done before using this option. *-rtl* is mandatory to be mentioned along with this option.

`-exclude_hier_pins`

This option enables skipping writing of toggle information of hierarchical pins. update_power has to be done before using this option. *-rtl* is mandatory to be mentioned along with this option.

`-keep_input_saif_sdpd_info`

This option enables retaining the sdpd information of sequential and memory cells from the input saif read when used with '-rtl' option. *-rtl* is mandatory to be mentioned along with this option.

Description

The *write_saif* command generates a backward SAIF file containing the user-annotated and propagated simple and SDPD switching activity in the current design.

The top-level instance name in the generated SAIF file is the current instance name. You must specify this name as the instance name when reading the SAIF file with the *read_saif* command.

By default, the saif file is written as simple text. Optionally, the file can be compressed using the -compress option.In some cases, a file extension is appended to file_name if it is omitted. For example, with gzip formatted files, if file_name does not end with ".gz", then ".gz" is appended to the file name.

Examples

The following example shows how a SAIF file containing the user-annotated switching activity information on all design objects:

```
pt_shell> write_saif file
```

The following example shows how a SAIF file containing both user- annotated and propagated non-SDPD switching activity information can be generated:

```
pt_shell> write_saif file -propagated -exclude_sdpd
```

Feedback

The following example shows how a SAIF file can be compressed.

```
pt_shell> write_saif file -compress gzip
```

The following example shows how an event based SAIF file can be written from RTL fsdb.

```
pt_shell> write_saif file -propagated -event_based
```

The following example shows how to enable additional writing of toggle information of input pins of sequential devices to saif.

```
pt_shell> write_saif file -rtl -include_sequential_inputs
```

```
pt_shell> write_saif file -rtl -exclude_hier_pins
```

The following example shows how to retain sdpd information of memory/sequential cells from the read input saif.

```
pt_shell> write_saif file -rtl -keep_input_saif_sdpd_info
```

The following example shows how a SAIF file on a synthesized design object can be generated by the *write_saif* command and read back using the *read_saif* command:

```
pt_shell> current_design top
pt_shell> current_instance U1
pt_shell> write_saif design.saif
pt_shell> reset_switching_activity
pt_shell> read_saif design.saif
```

---

write_script

Writes design constraints as a script of commands for PrimeTime or Design Compiler.

Feedback

Syntax

int *write_script*

```
[-no_annotated_delay]
[-no_annotated_check]
[-format ptsh | dctcl]
[-output file_name]
[-compress gzip]
[-include category_list]
[-exclude category_list]
[-nosplit]
[-print_command_types]
```

Data Types

category_list	list
compression	string
file_name	string

Arguments

`-no_annotated_delay`

Specifies that *set_annotated_delay* commands are not to be written, which means that delay annotations are ignored.

`-no_annotated_check`

Specifies that *set_annotated_check* commands are not to be written, which means that check annotations are ignored.

`-format ptsh | dctcl`

Specifies the output format for the script. Valid values are *ptsh* (the default) for pt_shell and *dctcl* for dc_shell.

`-output file_name`

Specifies the name of a file to which output is to be written. The default is the standard output. If the *-compress* option is also specified, the extension ".gz" is added if it is not already present.

`-compress gzip`

Specifies that the script is to be compressed. By default, the script is written as standard text. The only valid value is *gzip*. If you specify this option, you must also specify the *-output* option.

`-include category_list`

Writes specified command categories only. The only valid values for *category_list* are *exceptions*, *derate*, *drv*, *case_analysis*, *max_time_borrow*, *clock*, *clock_gating_check*, *clock_transition*, *min_pulse_width*,*clock_latency*,

input_delay, *output_delay*, *edrc*, *cell_mode*,*disable_timing*, *clock_group*, *clock_uncertainty*, *clock_sense*, *load*, *path_group*, *drive_info*, *net_resistance*, *annotation*, *ideal_network*, *data_check*, *pvt*, *pvt_dynamic*, *false_path*,*min_delay*, *max_delay*, *multicycle_path*, *latch_loop_breaker*, *size_only*, *target_library_subset*, *clock_jitter*, *aocvm_coefficient*, *aocvm_coefficient_lib_cell*.

The *drv* category includes set_input_transition, set_driving_cell, set_load, set_max_transition, and set_max_capacitance commands.

The *exceptions* category writes only exceptions to the file.

The *cell_mode* category writes only set_cell_mode command.

The *derate* category writes only set_timing_derate command.

The *path_group* category writes only group_path command.

The *max_time_borrow* category writes only set_max_time_borrow command.

The *data_check* category writes only set_data_check command.

The *load* category writes only set_load command.

The *net_resistance* category writes only set_resistance command.

The *clock_transition* category writes only set_clock_transition command.

The *clock_gating_check* category writes only set_clock_gating_check command.

The *case_analysis* category writes only set_case_analysis command.

The *disable_timing* category writes only set_disable_timing command.

The *clock_group* category writes only set_clock_groups command.

The *clock_uncertainty* category writes only set_clock_uncertainity command.

The *clock_sense* category writes only set_sense command.

The *min_pulse_width* category writes only set_min_pulse_width command.

The *input_delay* category writes only set_input_delay command.

The *output_delay* category writes only set_output_delay command.

The *ideal_network* category writes only set_ideal_network command.

The *pvt* category writes only set_voltage command.

The *pvt_dynamic* writes only set_operating_conditions command.

The *drive_info* writes set_drive and set_driving_cell command.

The *clock* writes create_clock and create_generated_clock command.

The *clock_latency* writes set_clock_latency and set_propagated_clock command.

The *edrc* writes set_max_capacitance, set_min_capacitance, and set_max_transition command.

The *annotation* writes set_ideal_latency, set_ideal_transition, set_annotated_transition, and set_annotated_delay command.

The *false_path* writes set_false_path command.

The *min_delay* writes set_min_delay command.

The *max_delay* writes set_max_delay command.

The *multicycle_path* writes set_multicycle_path command.

The *latch_loop_breaker* writes set_latch_loop_breaker command.

The *size_only* writes set_size_only command.

The *target_library_subset* writes set_target_library_subset commad.

The *clock_jitter* writes set_clock_jitter command.

The *aocvm_coefficient* writes set_aocvm_coefficient command.

The *aocvm_coefficient_lib_cell* writes set_aocvm_coefficient command.

`-exclude` *`category_list`*

Excludes specified command categories. The only valid values for *category_list* are *exceptions*, *derate*, *case_analysis*, *max_time_borrow*, *clock*, *clock_gating_check*, *clock_transition*, *min_pulse_width*,*clock_latency*, *input_delay*, *output_delay*, *edrc*, *cell_mode*,*disable_timing*, *clock_group*, *clock_uncertainty*, *clock_sense*, *load*, *path_group*, *drive_info*, *net_resistance*, *annotation*, *ideal_network*, *data_check*, *pvt*, *pvt_dynamic*, *false_path*,*min_delay*, *max_delay*, *multicycle_path*, *latch_loop_breaker*, *size_only*, *target_library_subset*, *clock_jitter*, *aocvm_coefficient*, *aocvm_coefficient_lib_cell*.

The *exceptions* category excludes only exceptions to the file.

The *cell_mode* category excludes only set_cell_mode command.

The *derate* category excludes only set_timing_derate command.

The *path_group* category excludes only group_path command.

Feedback

The *max_time_borrow* category excludes only set_max_time_borrow command.

The *data_check* category excludes only set_data_check command.

The *load* category excludes only set_load command.

The *net_resistance* category excludes only set_resistance command.

The *clock_transition* category excludes only set_clock_transition command.

The *clock_gating_check* category excludes only set_clock_gating_check command.

The *case_analysis* category excludes only set_case_analysis command.

The *disable_timing* category excludes only set_disable_timing command.

The *clock_group* category excludes only set_clock_groups command.

The *clock_uncertainty* category excludes only set_clock_uncertainity command.

The *clock_sense* category excludes only set_sense command.

The *min_pulse_width* category excludes only set_min_pulse_width command.

The *input_delay* category excludes only set_input_delay command.

The *output_delay* category excludes only set_output_delay command.

The *ideal_network* category excludes only set_ideal_network command.

The *pvt* category excludes only set_voltage command.

The *pvt_dynamic* excludes only set_operating_conditions command.

The *drive_info* excludes set_drive and set_driving_cell command.

The *clock* excludes create_clock and create_generated_clock command.

The *clock_latency* excludes set_clock_latency and set_propagated_clock command.

The *edrc* excludes set_max_capacitance, set_min_capacitance, and set_max_transition command.

The *annotation* excludes set_ideal_latency, set_ideal_transition, set_annotated_transition, and set_annotated_delay command.

The *false_path* excludes set_false_path command.

The *min_delay* excludes set_min_delay command.

The *max_delay* excludes set_max_delay command.

The *multicycle_path* excludes set_multicycle_path command.

The *latch_loop_breaker* excludes set_latch_loop_breaker command.

The *size_only* excludes set_size_only command.

The *target_library_subset* excludes set_target_library_subset commad.

The *clock_jitter* excludes set_clock_jitter command.

The *aocvm_coefficient* excludes set_aocvm_coefficient command.

The *aocvm_coefficient_lib_cell* excludes set_aocvm_coefficient command.

`-nosplit`

Prevents line splitting. This is used for performing diffs on previous scripts or for postprocessing the script.

`-print_command_types`

Prints the option category present in the design along and the associated commands along with their respective counts. This is used for performing the write_script -include and -exclude operations. This is employed to quickly list out the option category present in the design, associated commands, and their respective count. The write_script file is extensive, user can extract specific commands of interest from the table.

While executing write_script -print_command_types, the information is automatically written out to the command.txt file. Executing write_script -print_command_types -output script.log, results in the information being written to the command_script.log file. script.log have the information related to the write_script.

Description

This command writes design constraints as a script of commands for PrimeTime or Design Compiler. The script is used to re-create design intent.

The *write_script* command writes the following information:

- Clock information: clock creation, generated clock creation, clock latency, clock uncertainty, interclock uncertainty.
- Timing information: disable timing, max time borrow. Disable timing set on library objects is written by default, but can be suppressed by setting the *write_script_include_library_constraints* variable to *false*.
- Point-to-point exceptions: false paths, min delay, max delay, multicycle paths, group path, input delay, output delay, annotated delay, and annotated checks.

Feedback

- Net attributes: capacitance, resistance. These are no longer written by default. For more information, see the man page for the *write_script_output_lumped_net_annotation* variable.
- Port attributes: fanout, capacitance, and resistance.
- Design environment: wire load model, operating condition, drive, driving cell, and input transition.
- Design rules: minimum capacitance, maximum capacitance, minimum transition, maximum transition, minimum fanout, and maximum fanout.

Examples

The following example writes the script in ptsh format to the des.pt file:

```
pt_shell> write_script -output des.pt
```

See Also

- characterize_context
- write_context
- write_script_output_lumped_net_annotation

---

write_sdc

Writes out a script in Synopsys Design Constraints (SDC) format.

Syntax

int *write_sdc*

```
file_name
[-version sdc_version]
[-compress compression]
[-include categories_list]
[-exclude category_list]
[-nosplit]
```

Data Types

```
file_name           string
sdc_version         string
compression         string
categories_list     list
```

Feedback

Arguments

file_name

Specifies the name of the file to which the SDC script is to be written.

-version *sdc_version*

Specifies the version of SDC to write. Allowed values are: *1.2*, *1.3*, *1.4*, *1.5*, *1.6*, *1.7*, *1.8*, *1.9*, *2.0*, and *latest* (the default).

-compress *compression*

Specifies that the script must be compressed. The only valid value for *compression* is *gzip*.

-include *categories_list*

Write specified command categories only. The only valid values for *categories_list* are *exceptions*, *sourcefile_refs*,*derate*,*case_analysis*, *max_time_borrow*, *clock*, *clock_gating_check*, *clock_transition*, *min_pulse_width*,*clock_latency*, *input_delay*, *output_delay*, *edrc*,*disable_timing*, *clock_group*, *clock_uncertainty*, *clock_sense*, *load*, *path_group*, *drive_info*, *net_resistance*, *annotation*, *ideal_network*, *data_check*, *pvt*, *pvt_dynamic*.

The *exceptions* category writes only exceptions to the file.

The *sourcefile_regs* category includes information about the original script location of the constraint or exception. This requires that the *sdc_save_source_file_information* variable was set to *true* when the original constraints were read. For details, see the man page.

The *derate* category writes only set_timing_derate command.

The *path_group* category writes only group_path command.

The *max_time_borrow* category writes only set_max_time_borrow command.

The *data_check* category writes only set_data_check command.

The *load* category writes only set_load command.

The *net_resistance* category writes only set_resistance command.

The *clock_transition* category writes only set_clock_transition command.

The *clock_gating_check* category writes only set_clock_gating_check command.

The *case_analysis* category writes only set_case_analysis command.

The *disable_timing* category writes only set_disable_timing command.

The *clock_group* category writes only set_clock_groups command.

The *clock_uncertainty* category writes only set_clock_uncertainity command.

The *clock_sense* category writes only set_sense command.

The *min_pulse_width* category writes only set_min_pulse_width command.

The *input_delay* category writes only set_input_delay command.

The *output_delay* category writes only set_output_delay command.

The *ideal_network* category writes only set_ideal_network command.

The *pvt* category writes only set_voltage command.

The *pvt_dynamic* writes only set_operating_conditions command.

The *drive_info* writes set_drive and set_driving_cell command.

The *clock* writes create_clock and create_generated_clock command.

The *clock_latency* writes set_clock_latency and set_propagated_clock command.

The *edrc* writes set_max_capacitance, set_min_capacitance, and set_max_transition command.

The *annotation* writes set_ideal_latency, set_ideal_transition, set_annotated_transition, and set_annotated_delay command.

`-exclude` *`category_list`*

Excludes specified command categories.

`-nosplit`

The *-nosplit* option prevents line-splitting. This is most useful for doing a diff against previous scripts or for postprocessing the script.

Description

The *write_sdc* command writes out a script file in the latest Synopsys Design Constraints (SDC) format. This script contains commands that can be used with PrimeTime or with Design Compiler. SDC is also licensed by external vendors through the Tap-in program. SDC formatted script files are read into Synopsys tools using the *read_sdc* command.

By default, the script is written as simple text. Optionally, the script can be compressed using the *-compress* option. In some cases, a file extension is appended to *file_name* if it is omitted. For example, with gzip formatted files, if *file_name* does not end with ".gz", then ".gz" is appended to the file name.

By default, the latest version of SDC is written. Some earlier versions of SDC can be written using the *-version* option.

SDC is a subset of the commands already supported by PrimeTime and the synthesis tools. Of the commands supported in the latest SDC version, the following can be written by *write_sdc*. Those added for versions 1.3 and later are noted.

General Purpose Commands:

```
list
```

Object Access Functions:

```
current_design
current_instance
get_cells
get_clocks
get_libs
get_lib_cells
get_lib_pins
get_nets
get_pins
get_ports
set_hierarchy_separator
```

Basic Timing Assertions:

```
create_clock
create_generated_clock      (1.3)
set_clock_gating_check
set_clock_latency
set_clock_transition
set_clock_uncertainty
set_false_path
set_input_delay
set_max_delay
set_min_delay
set_multicycle_path
set_output_delay
set_propagated_clock
set_min_pulse_width         (2.0)
```

Secondary Assertions:

```
set_disable_timing
set_max_time_borrow
set_data_check              (1.4)
set_timing_derate           (1.5)
```

Environment Assertions:

```
set_case_analysis
set_drive
set_driving_cell
set_fanout_load
set_input_transition
```

```
set_load
set_max_area
set_max_capacitance
set_max_fanout
set_max_transition
set_min_capacitance
set_min_fanout
set_operating_conditions
set_port_fanout_number
set_resistance
set_wire_load_min_block_size
set_wire_load_mode
set_wire_load_model
set_wire_load_selection_group
```

Similar to the *write_script* command, the *write_sdc* command writes out commands relative to the top of the design, regardless of the current instance. SDC files written by the *write_sdc* command must be read in from the top of the design.

For a complete guide to using SDC with Synopsys applications, see the *Using the Synopsys Design Constraints Format Application Note*, which is available at http://solvnet.synopsys.com.

The usage of some of these commands is restricted when reading SDC. In some cases, some options are not allowed. The *write_sdc* command supports the restricted usage by restricting what is written. The following restriction apply for SDC Version 1.3 or later:

Note: For the *set_port_fanout_number* command, the *-min* and *-max* options are not supported.

When hierarchy has been partially flattened, embedded hierarchy separators can make names ambiguous - it is unclear which hierarchy separator characters are part of the name and which are real separators. Beginning with SDC version 1.2, hierarchical names can be made unambiguous using the *set_hierarchy_separator* SDC command or the *-hsc* option available from the *get_cells*, *get_lib_cells*, *get_lib_pins*, *get_nets*, and *get_pins* SDC object access commands.

By default, PrimeTime and the synthesis tools write an SDC file using these features to create unambiguous names. It is recommended that you write SDC files that contain unambiguous names. However, if you are using a third-party application that does not fully support SDC 1.2 or later (that is, it does not support the unambiguous hierarchical names features of SDC), you can suppress these features by setting the *sdc_write_unambiguous_names* variable to *true*.

The following features are added for SDC Version 1.5 or later:

- *-clock* option of the *set_clock_latency* command
- *set_timing_derate* command with all options

Feedback

- *-clock_path -data_path -rise -fall* options of the *set_max_transition* command
- *-rise_from*, *-rise_to*, *-fall_from*, *-fall_to* options, of the *set_clock_uncertainty* command
- *-object_list* option of the *set_operating_conditions* command
- Synonyms for all of the *get_object* commands
- *get_objects -nocase* support independently with the *-regexp* option
- *get_objects -regexp* support
- *get_objects -of_objects* support for *get_cells/get_nets/get_pins*

The following features are added for SDC Version 2.0 or later:

- *-reference_pin* option of the *set_input_delay* and *set_output_delay* commands
- The *set_min_pulse_width* command

Examples

The following command writes the SDC script to the file top.sdc.

```
prompt> write_sdc top.sdc
```

[-delay_calculation_only_mode]
[-exclude_cells cell_list]
[-no_derates]
[-objects]
[-all_scenarios]
[-sms_scenarios sms_scenarios_list]
file_name
```

Data Types

arc_type_list	list
cell_list	list
compression	string
digits	int
exclude_list	list
file_name	string
include_list	list
inst_name	string
level	int
sdf_map_file_list	list
sdf_version	string
sms_scenarios_list	collection
values_list	list

Arguments

`-version` *sdf_version*

Selects the SDF version to use. Supported SDF versions are *2.1* (default) and *3.0*.

`-no_cell_delays`

Indicates that no cell delays are be written in the SDF file. By default, all cell pin-to-pin delays are written to the SDF file. Cell delays include the load delay of the cell. Following the SDF conventions, only cell input pin to cell output pin delays are written. For unbuffered cell output pins, delays are usually represented in libraries by a delay from an output pin to another output pin. Because this is not allowed by the SDF convention, the SDF delay for an unbuffered output is specified from cell inputs.

`-no_timing_checks`

Indicates that no cell timing checks are to be written in the SDF file. By default, all cell timing checks (for example, setup, hold, recovery, and removal) are written to the SDF file.

`-no_net_delays`

Indicates that no net delays are to be written in the SDF file. By default, all net pin-to-pin delays are written to the SDF file. If the *-input_port_nets* or *-output_port_nets* options are also specified, then only the net delays connected to the corresponding ports will be printed.

`-input_port_nets`

Indicates that the SDF file is to include delays of nets connected to input ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available. If the *-instance* option is specified, all net delays across the instance boundary leading to a pin inside the instance are included instead. If the *-levels level* option is specified, the pin must be found on any levels 1 to *level* of hierarchy.

`-output_port_nets`

Indicates that the SDF file is to include delays of nets connected to output ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available. If the *-instance* option is specified, then all net delays across the instance boundary leading from a pin inside the instance are included instead. If the *-levels* option is specified, the pin must be found on any of levels 1 to *level* of hierarchy.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point that are to be written in SDF delay triplets. Allowed values are 0-13; the default is 3.

`-enabled_arcs_only`

Indicates that the SDF file is to contain only delays of enabled timing arcs, and is not to include delays of currently-disabled timing arcs. By default, delays of all timing arcs in the design are written to the SDF file, whether they are disabled or enabled.

`-no_internal_pins`

Indicates that the SDF file is not to include delay timing arcs from or to internal pins. Timing arcs to or from internal pins are expanded into delays from and to primary input and output of the given cell.

`-instance` *`inst_name`*

Specifies that the SDF file is to be written only for the instance named *inst_name*. By default, all pin names are relative to the *inst_name*. However, if boundary net delays are included (using the *-input_port_nets* or *-output_port_nets* option) all pin names are relative to the top design. Note that in general, if the *-input_port_nets* or *-output_port_nets* option is specified, boundary nets are written leaf-to-leaf and do not start or end on hierarchical pins. If boundary nets are required to start or end on hierarchical pins, see the *write_physical_annotations* command.

`-context none | verilog | vhdl`

Specifies the context for writing bus names in SDF. Valid values are *verilog*, *vhdl*, or *none* (the default). In the Verilog context, when pin names are displayed, the last two square bracket characters ("[" and "]") are not escaped. In the VHDL context, the last two parenthesis characters ("(" and ")") in a pin name are not escaped. In the default *none* context, all bus-delimiting characters are escaped with a backslash character ("\\"). In any context, bus-delimiting characters in instance names are always escaped. When used with the *-map* option, the *-context* option also affects the way names are printed in mapped SDF files. In the Verilog context, names are printed in %s[%d] format; in the VHDL context, names are printed in %s(%d) format.

Note: Names are affected only if they are mapped using the bus(name_to_be_changed) function in the mapping file.

`-map` *`sdf_map_file_list`*

Specifies a list of mapping files the SDF writer is to use when writing out the SDF file. A mapping file contains a user-specified format for printing SDF cell delays and constraints. When writing out SDF for a cell, the SDF writer takes the user-specified mapping, if present, to print out SDF for the cell. If no user-specified mapping is present for a cell, the SDF writer writes out SDF in the normal way.

`-annotated`

Indicates that the SDF is to include only timing arcs that have been annotated with the *read_sdf*, *set_annotated_delay*, or *set_annotated_check* command.

`-levels` *`level`*

Specifies the number of levels of hierarchy for which the SDF is written out. Level 1 means only the top design or *inst_name*. Value of N means all levels of hierarchy, 1 to N. By default, all levels of hierarchy are written out. Note that boundary net delays (using the *-input_port_nets* or *-output_port_nets* options) typically have some net arcs from or to pins outside the *inst_name* option. The location of such outside pins is not limited by the *-levels* option. That is, the

-levels and *-instance* options let you choose which boundary arcs are included, but do not restrict where the arcs lead outside of the *inst_name* option.

`-no_edge`

Indicates that the generated SDF is not to include any edges (posedge or negedge) for both combinational and sequential IOPATHs.

`-compress` *`compression`*

Specifies a format to be used to compress the file. The only valid value for *compression* is *gzip*. By default, files are not compressed.

`-include` *`include_list`*

Specifies a list of constructs and specifiers to include in the SDF file; you can specify one or more of the following:

- *SETUPHOLD* - Indicates that all SETUP and HOLD constructs are to be replaced by SETUPHOLD constructs. If a pair of setup and hold arcs are found between the same pin edges, timing information for the/both arc/arcs is written in a single SETUPHOLD construct. If a single setup/hold arc is found, then the arc will be written in a single SETUPHOLD construct with no timing information for the hold/setup portion. SETUPHOLD supports negative values.
- *RECREM* - Indicates that all RECOVERY and REMOVAL constructs are to be replaced by RECREM constructs. If a pair of recovery and removal arcs are found between the same pin edges, timing information for both arcs is written in a single RECREM construct. If a single recovery/removal arc is found, then the arc will be written in a single RECREM construct with no timing information for the removal/recovery portion. RECREM supports negative values and can be written only for version 3.0.
- *edge_specific_preset_clear* - Indicates that the generated SDF is to include the appropriate edges (posedge or negedge) for preset and clear arcs. The default behavior is not to include edge specifiers for preset and clear arcs.

`-exclude` *`exclude_list`*

Specifies a list of timing values of construct types to be either excluded from the SDF file in order to reduce its size, or to be replaced by another construct, as in the case of condelse. Allowed values are one or more of the following:

- *constant_nets* - Indicates that nets are to be omitted from the SDF file if they propagate a constant.
- *constant_delay_arcs* - Indicates that delay arcs are to be omitted from the SDF file if they propagate a constant, either from case analysis or logical inputs.

- *default_cell_delay_arcs* - Indicates that all default cell delay arcs are to be omitted from the SDF file if conditional delay arcs are present. If there are no conditional delay arcs, the default cell delay arcs are written to the SDF file.
- *wlm_load_delay* - Indicates that net delays and cell delays calculated using WLM are to be omitted from the SDF.
- *checkpins* - When Library Compiler finds both combinational and sequential arcs between pins, a checkpin is created so that all arcs are expanded in the db so that a single arc pinA->pinB is replaced by the combination of a positive unate arc pinA->pinAcheckpin1 with zero delay and an arc pinAcheckpin1->pinB with the same sense and values as the original arc. When this option is set the SDF is written out as if all checkpins were never created.
- *no_condelse* - Indicates that PrimeTime will not use the condelse statement to write out default iopaths. By default PrimeTime will replace default iopaths with the condelse construct. Specifying this option will result the condelse statement being replaced by a default iopath. This option should be used for generating simulator compatible SDF.
- *clock_tree_path_models* - Indicates that arcs that model clock tree paths are to be omitted from the SDF file.

`-mask_violations` *`violation_type`*

Adjusts the delays in the SDF so that when it is annotated back it will result in zero setup and/or hold time violations even if actual timing violations are present in the design. The SDF generated with this option should not be used for signoff purposes.

`-no_negative_values` *`values_list`*

Specifies a list of timing value types whose negative values are to be zeroed out when writing to the SDF file. Allowed values for timing values are timing checks, cell delays and net delays. This option should be used when the SDF file is intended for simulator use. Using this option leads to inaccurate delay estimation in PrimeTime, so the user should use caution with this option.

`-no_edge_merging` *`arc_type_list`*

Specifies a list of arc types that are not to be compressed in the SDF file through edge merging. When this option is not selected PrimeTime merges the posedge/negedge arcs only if they are identical to within a tolerance of 0.00001 times the absolute value of the smaller delay.

Allowed values are one or more of the following.

- *timing_checks* - Indicates that timing checks are not to be compressed in the SDF file through edge merging.
- *cell_delays* - Indicates that cell delays are not to be compressed in the SDF file through edge merging.

`-delay_calculation_only_mode`

This option is intended for speeding-up flows that use PrimeTime for delay calculation. The *write_sdf* command first checks if the design is in the updated state. If it is, it simply writes the already computed delays and leaves the design in the updated state, regardless of the presence of the *-delay_calculation_only_mode* option. If the design is not in the updated state, by default, the command triggers the *update_timing* command, which brings the design in the updated state. However, if the *-delay_calculation_only_mode* option is used, PrimeTime does not trigger the *update_timing* command; it triggers only the operations that are necessary for writing the SDF file; the design is left in the not-updated state.

`-exclude_cells` *`cell_list`*

Specifies a list of cells that are not to be included in the SDF file. The net delays of the excluded cell's boundary pins are not excluded.

`-no_derates`

Specifies not to apply a derate to any delay in the generated SDF file.

`-objects`

Specifies that only cells that have the user-defined attribute *is_write_sdf_object* set to *true* will be included in the SDF file. Net arcs will be included in the SDF if they meet at least one of the following three conditions:

- The net arc is between two cells that both have attribute *is_write_sdf_object* set to *true*.
- The net arc is between a cell that has attribute *is_write_sdf_object* set to *true* and a port.
- The net arc belongs to a net that has attribute *is_write_sdf_object* set to *true*.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios (from the *get_sms_scenarios* command) to analyze. The worst (min/max) delays across the specified SMS scenarios are printed. This option is only available with SMVA or SMC analysis.

`-all_scenarios`

Automatically creates a separate SDF file for every fully different voltage configuration in SMVA analysis. All possible voltage configuration combinations are captured. This option is only available with SMVA analysis.

`file_name`

Specifies the name of the SDF file to be written.

Description

This command writes leaf cell pin-to-pin timing information to a disk file. Timing information is written in SDF format using versions v2.1 or v3.0. The timing file contains data associated with the netlist from which it is created.

By default, the file is written as simple text; you can use the *-compress* option to compress the file. In some cases, if you omit the file extension, the *write_sdf* command appends it to *file_name*. For example, for gzip formatted files, the *write_sdf* command appends .gz to the file name if .gz was not specified.

Use the *write_sdf* command only when the instance names in the design agree with the naming conventions of the system to which the timing file is written.

Timing information can be written in multiples of ns, ps, and us. The time unit in the SDF file is that specified in the logic library, and is written in the timing file under "timescale". If there is no time unit in the library, the unit is assumed to be a multiple of nanoseconds.

For efficiency, PrimeTime merges rise/fall delay triplets in SDF, if they are identical to within a very small tolerance.

Examples

The following example writes timing information for the *MULT16* design to a disk file called mult16.sdf, using SDF version 2.1:

```
pt_shell> write_sdf -version 2.1 mult16.sdf
```

You can use the *-level* option to write out interblock net delays. Assume a design with three hierarchical cells, h, h/h1, and h/h2; and two leaf cells, h/h1/u1 and h/h1/u2. The following command writes out all arcs that begin or end inside h but outside h/h1 and h/h2:

```
pt_shell> write_sdf -levels 1 -instance h h.sdf
```

The following example writes out the same arcs as the previous example, plus arcs that cross the boundary of h. Note that either the from or the to pin must be outside h and the other inside h. Therefore, the command does not write a feedthrough net through h on this particular design. Similarly, a net arc representing net h/h1/u1/Y -> h/h1/out -> h/h1/in -> h/h1/u2/A is not written out, because both pins h/h1/u1/Y and h/h1/u2/A are inside h/h1; that is, both are outside the region defined by the *-level 1 -instance h* option.

Feedback

```
pt_shell> write_sdf -levels 1 -instance h -input_port_nets \\
            -output_port_nets h.sdf
```

---

write_session_settings

Writes current session settings to an encrypted file, which can be later sourced with the *source* command.

Syntax

status *write_session_settings*

`-output` *file_name*

Data Types

file_name	string

Arguments

`-output` *file_name*

Writes current session settings to the specified file.

Description

The *write_session_settings* command writes current session settings to a file in Tcl byte code (TBC) binary format. The session settings include application variables and other design-independent settings. This enables porting settings from one session to another. For example, you can write out the settings from one session and source the file in the other session to restore the same settings.

Note that the *write_session_settings* command does not write any design-specific settings such as design data and constraints. Those can be saved by the *save_session* command.

Feedback

Examples

The following example changes the *timing_crpr_threshold_ps* variable setting from the default value to 10 and writes it to a file along with other variable settings.

```
pt_shell> set_app_var timing_crpr_threshold_ps 10
  ...
pt_shell> write_session_settings -output my_session.tbc
```

In a new PrimeTime session, the following example sources the my_session.tbc file. After sourcing, the *timing_crpr_threshold_ps* application variable has changed from the default value to 10.

```
pt_shell> source my_session.tbc
pt_shell> printvar timing_crpr_threshold_ps
timing_crpr_threshold_ps = "10"
```

write_spice_deck

Writes out a SPICE deck for the timing paths or arcs collected by the *get_timing_paths* or *get_timing_arcs* command.

Syntax

status *write_spice_deck*

```
[-align_aggressors]
[-analysis_type type]
[-ground_coupling_capacitors]
[-header header_file_name]
[-initial_delay delay]
[-logic_one_name v1name]
[-logic_one_voltage v1]
[-logic_zero_name v0name]
[-logic_zero_voltage v0]
[-minimum_transition_time trans]
[-output file_name]
[-sub_circuit_file spice_sub_circuit_file]
[-sweep_exhaustive]
[-sweep_size number_of_points]
[-sweep_step num]
[-sample_size number_of_samples]
[-time_precision precision]
[-transient_size tran_size]
[-transient_step tran_step]
```

```
[-use_probe]
[-user_measures user_measure_list]
[-variation]
[-mc_sample_size number_of_mc_samples]
paths_arcs_list
```

Data Types

type	list
header_file_name	string
delay	float
v1name	string
v1	float
v0name	strong
v0	float
trans	float
file_name	string
spice_sub_circuit_file	string
number_of_points	unsigned
num	float
number_of_samples	integer
precision	unsigned
tran_size	float
tran_step	float
user_measure_list	list
number_of_mc_samples	integer
paths_arcs_list	collection

Arguments

`-align_aggressors`

Aligns multiple aggressor transitions to apply the worst-case crosstalk effects on each victim net for the conditions specified by the *-analysis_type* option. The *-align_aggressors* option applies only to a *net* timing arc (gathered by the *get_timing_arcs* command) with an annotated RC network.

The relative switching times of active aggressors on the net arc computed by crosstalk delay or noise analysis are written out in the corresponding piecewise linear (PWL) statement. The victim net switches after the initial delay specified by the *-initial_delay* option and the active aggressors switch relative to that. The tool uses the calculation engine to get the worst-case alignment and uses a similar setup so that the relative alignment is valid. For example, filtered aggressors are not considered effective during calculation and so their coupling capacitors are grounded.

`-analysis_type` *type*

Specifies the type of crosstalk or noise analysis performed in the SPICE deck for a timing arc:

- Crosstalk: *max_rise* (the default), *max_fall*, *min_rise*, or *min_fall*
- Noise: *above_high*, *above_low*, *below_high*, or *below_low*

This option applies only to a timing arc, not a timing path.

`-ground_coupling_capacitors`

Prevents crosstalk analysis in the SPICE simulation. Coupling capacitors are connected to ground with a factor of 1, and aggressors of the timing path or timing arc are not written to the SPICE deck.

`-header` *header_file_name*

Specifies the path to the user header file. The file content is copied to the generated SPICE deck. You can use this file to identify the SPICE deck, to include library files, or for any other purposes to support the SPICE run.

`-initial_delay` *delay*

Specifies the initial delay, in library time units, added to all PWL statements. The default is the longest clock period, or 1.0 library unit for asynchronous designs.

Setting the delay to zero makes generating a ramp difficult and is therefore not recommended.

`-logic_one_name` *v1name*

Specifies the name of the upper rail voltage source. The default is VDD.

`-logic_one_voltage` *v1*

Specifies the upper rail voltage of the gate input pins. This is used in the PWL and voltage sources generated by the command. The default is main library voltage.

`-logic_zero_name` *v0name*

Specifies name of the default lower rail voltage source. The default is VSS.

`-logic_zero_voltage` *v0*

Specifies the lower rail voltage of the gate input pins. The default is 0 volts.

`-minimum_transition_time` *trans*

Specifies the minimum transition time in nanoseconds (ns), which is used in generated PWL transitions where the transition time computed by the PrimeTime tool is less than the specified minimum value. The default is 0.001 ns. Transition times less than 0.0001 ns are not recommended.

`-output` *name*

Specifies the name of the SPICE deck file written by the command. If multiple files are generated, they are named by appending characters to the specified name. If the *-sample_size* option is used, the *-output* option specifies the name of the directory created to hold the generated SPICE deck files.

If you do not specify an output name, the command writes the SPICE deck to the screen.

`-sub_circuit_file` *spice_sub_circuit_file*

Specifies the path to the file that contains all the SPICE .subckt definitions of logic gates in the timing paths. By default, a subcircuit call uses the pin order in the Synopsys .lib file. Use this option if the SPICE subcircuit has a different pin order from that of the .lib file.

`-sweep_exhaustive`

If the *-sample_size* option and *-align_aggressors* option are set, then by default, sweeping is done for all aggressors in the same way to avoid excessive simulation runtime. If this option is set, sweeping is done in an exhaustive manner.

With exhaustive sweeping, the number of SPICE simulations grows geometrically as the number of active aggressors increases. For example, using *-sweep_exhaustive -sample_size 3* for five active aggressors results in 3^5 (243) simulations.

`-sweep_size` *number_of_points*

Specifies the number of sweep points generated for each active aggressor of the net arc. By default, the sweep table size is equal to the specified number of points.

With the *-sweep_exhaustive* option, the number of simulations increases geometrically with the number of the active aggressors.

The specified number of points can be no more than 20 the *-sweep_exhaustive* option is set.

Use this option with the *-align_aggressors* option.

`-sweep_step` *num*

Specifies the maximum time interval between sweep points generated for each active aggressor of the net arc. The unit size is nanoseconds. The default is 0.1 ns. Use this option with the *-align_aggressors* and *-sweep_size* options.

`-sample_size` *`number_of_samples`*

Specifies the number of SPICE deck files to be created for variation-aware timing analysis. This option takes the name of the directory specified by the *-output* option and creates multiple SPICE deck files that correspond to various samples of the variations defined.

`-time_precision` *`precision`*

Specifies the number of digits written out for time values in the PWL statements. The default is 6. The allowed range is from 1 to 20.

`-transient_size` *`tran_size`*

Specifies the total transient time used in the SPICE .tran statement. The unit size is nanoseconds.

`-transient_step` *`tran_size`*

Specifies the transient step size used in the SPICE .tran statement. The unit size is nanoseconds. The default is 0.001 ns.

`-use_probe`

Uses the .probe statement to output the node voltage instead of the .print statement.

`-user_measures` *`user_measure_list`*

Uses the user-specified measures instead of the ones generated automatically by the SPICE deck. To remove all automatically generated .measure and .print statements from the SPICE deck, specify *-user_measures {}*.

`-variation`

Generates a SPICE deck for Monte Carlo based simulation for path arrival. The number of Monte Carlo samples follows the *-mc_sample_size* option. This option only works for a timing path, not a timing arc.

`-mc_sample_size` *`number_of_mc_samples`*

Specifies the number of Monte Carlo samples in the SPICE deck. By default, *number_of_mc_samples* is 5000. This option has impact only with the *-variation* option.

`paths_arcs_list`

Specifies a collection of timing paths gathered by the *get_timing_paths* command or a timing arc collection gathered by the *get_timing_arcs* command. A SPICE deck is generated for each path or arc in the collection.

Feedback

Description

This command writes out SPICE deck files, one file for each timing path or timing arc from a collection generated by the *get_timing_paths* or *get_timing_arcs* command. The SPICE deck file contains the circuit elements, parasitic components, and side pin voltages of the path or arc. For a timing arc, the SPICE deck can include simulation of crosstalk effects through parasitic capacitors with worst-case alignment of aggressor transitions.

Using the generated data files and a SPICE circuit simulator such as HSPICE, you can run a simulations of signal transitions propagated through the timing path or timing arc. The simulation results confirm the accuracy of PrimeTime static timing analysis.

The names of multiple SPICE deck files are based on the string provided by the *-output* option. For example, if you specify *-output timing_path.spo*, the first file name is timing_path.spo, the second is timing_path_00001.spo, the third is timing_path_00002.spo, and so on.

The *write_spice_deck* command also puts the corresponding stimulus data, such as PWL and PULSE statements, in separate stimulus files. The example, the stimulus file names can be timing_path_stim.spo, timing_path_00001_stim.spo, and so on. A stimulus file is included in the main circuit file by means of the SPICE .include statement.

If you specify a subcircuit file using the *-sub_circuit_file* option, all lines except .include and .subckt are ignored. The file on the .include line is further opened and parsed for other .include and .subckt lines. The pin order of each .subckt line is recorded and applied when a subcircuit call is generated. If a gate used is not in the subcircuit file, the .lib pin order is used. A warning is generated if a pin in the subcircuit definition is not found in the .lib file. This mismatched pin is written out to the SPICE deck in the same order as it appears in the subcircuit file. An error message is generated when a .lib gate pin is not found in the subcircuit definition.

Note that side input pins are sensitized locally.

The timing PWL voltage sources are defined by the *set_library_driver_waveform* command. The default is the standard Synopsys predriver waveform. The *set_library_driver_waveform* command defines the waveform shape used to characterize the timing library. If advanced waveform propagation is enabled and a distorted waveform is available, the actual waveform is used to define the shape of the PWL voltage sources instead. If you want to use the library waveform shape, use the *set_annotated_transition* command to apply the transition slew value on the pin.

The *-align_aggressors* option applies only to active aggressors of net timing arcs. The inactive or filtered aggressors are set to be quiet and their coupling capacitors grounded. To report the active aggressors of a victim, use *report_delay_calculation -crosstalk* or *report_noise_calculation*.

While the *-aligned_aggressors* option is set, the *-sweep_size* option set to more than zero sweeping points writes out the PWL in sweep form. A third file with the sweep data is

generated, for example named timing_arc_sweep.spo, which is also included in the main circuit file by means of the SPICE .include statement

Under most circumstances, the *-align_aggressors* option writes out the alignment to produce the worst-case stage delay. However, under some corner cases, for example when the crosstalk bump is very large, the *-sweep_size* option should be used in conjunction with *-align_aggressors* to obtain the worst-case alignment.

The sweep points center around the aligned aggressor switching time generated without the *-sweep_size* option. If an even number is given, one more sweep point on the smaller switch time side is generated. The time difference between the sweep points is controlled by the *-sweep_step* and *-sweep_size* options, and the aggressor sweep range is computed by the crosstalk delay engine. The command uses the lesser of the (sweep_range)/(number_of_sweep_points-1) for each aggressor or the *-sweep_step* option.

Use the *-user_measures* option to create specific measure statements instead of automatically generating them. The *user_measure_list* argument is a list of user-defined measures. Each user-defined measure can be one of the following types.

```
{delay from_pin/port_name to_pin/port_name [meas_name]}
{slew pin_or_port_name [meas_name]}
{noise_peak pin_or_port_name [meas_name]}
{user_string "user_defined_string"}
```

The *write_spice_deck* command uses these user-defined measure instructions and creates SPICE .measure statements with proper trip points and switching directions. The SPICE measures are in the same order as the measure generated when using the *user_measure_list* option. When this option is provided, the user-defined measure overrides the automatic .measure and .print statements.

You can specify zero or more measures in the list. When there is no user-defined measure in the list, for example, using *-user_measures { }*, the SPICE deck does not have any kind of .measure or .print statements. You can also insert user-specific measures in the user-defined string, which is inserted verbatim. For the *delay*, *slew*, and *noise_peak* types, you can give a name to the measurement as *meas_name*. If it is missing, the *write_spice_deck* command automatically generates a name for the measurement. A user-defined measure must match with one of the previous formats.

If you specify the *-sample_size* option while performing variation-aware timing analysis, the command creates a directory and writes multiple SPICE deck files inside it.

To use the *write_spice_deck* command, you must have a PrimeTime SI license.

Examples

The following example writes a SPICE deck for timing paths gathered by the *get_timing_paths* command, using the my_subckt.sp file as the source of all SPICE .subckt definitions of all gates in the timing path.

Feedback

```
pt_shell> write_spice_deck -output path.spo \\
            -sub_circuit_file my_subckt.sp [get_timing_paths]
```

The following example writes a SPICE deck for a timing arc gathered by the *get_timing_arcs* command.

```
pt_shell> write_spice_deck -output path.spo \\
            -analysis_type above_low \\
            -sub_circuit_file my_subckt.sp [get_timing_arcs -from U1/A]
```

The following example writes a SPICE deck for a timing arc, including crosstalk with sweep analysis to find the worst aggressor alignment.

```
pt_shell> write_spice_deck -output ./arc.spi \\
            -analysis_type max_rise \\
            -align_aggressors -sweep_size 3 -sweep_step 0.01 \\
              [get_timing_arcs -from I1_1/Z -to I1_2/A ]
```

The following example generates measure statements to measure the slew at the path output and delay from input to output.

```
pt_shell> write_spice_deck [get_timing_paths -from [get_port i2] \\
            -to [get_port o2]] -user_measures { {slew o2 my_out_slew } \\
            {delay i2 o2 path_delay} {user_string ".print o2"} }
```

```
.measure tran my_out_slew
+ trig v(o2) val = 2.16 td = 7.5e-09 fall = 1
+ targ v(o2) val = 0.54 td = 7.5e-09 fall = 1
.measure tran path_delay
+ trig v(i2) val = 1.35 td = 7.5e-09 fall = 1

---

write_training_data

Writes out training data recorded after the *record_training_data* command for faster power recovery in future sessions using similar design data.

Feedback

Syntax

status *write_training_data*

```
-output file_name
[-force]
```

Data Types

```
file_name     string
```

Arguments

`-output file_name`

Specifies the name of the file to use for writing out the training data. You can specify an absolute or relative path the to file. Specifying a relative path writes out the training data to the current working directory.

To invoke accelerated ECO power recovery in future sessions, specify the training data file using the *-training_data* option of the *fix_eco_power* command.

`-force`

Overwrites the specified file if the file already exists. Without this option, the command does not save the training data if the specified file already exists.

Description

The *write_training_data* command writes training data to a file after you run the *record_training_data* command and perform cell sizing operations for power recovery using the *size_cell* commands.

In future PrimeTime sessions, you can invoke the same cell sizing operations during ECO power recovery for cells in the same or similar design context. When you use the *fix_eco_power* command, use the *-training_data* option to specify the names of the files previously generated by the *write_training_data* command, or use the *training_data_directory* variable to specify the directory where the training data files can be found.

In this flow, the PrimeTime tool does not check or evaluate the quality or benefit of the *size_cell* commands. It simply records the cell sizing changes and saves the timing and topological conditions surrounding those changes for future use during ECO power recovery.

Examples

The following example starts power optimization training, performs cell sizing for power recovery, and writes the session training data into a file in a specified absolute path.

```
pt_shell> record_training_data
pt_shell> size_cell U100 ...
```

```
 ...
pt_shell> source my_eco_changes.tcl  # Cell sizing for power recovery
 ...
pt_shell> size_cell U200 ...
 ...
pt_shell> write_training_data -output /home/train_dir/my_training.td
```

In a future PrimeTime session using the same design or a similar design, the following command invokes the same cell sizing operations for power optimization using the previously saved training data.

```
pt_shell> fix_eco_power -training_data /home/train_dir/my_training.td ...
```

Alternatively, use the *training_data_directory* variable to specify the directory where the training data files can be found:

```
pt_shell> set_app_var training_data_directory /home/train_dir
/home/train_dir
pt_shell> fix_eco_power ...
```

---

write_tsv_timing

Generate TSV feedthrough path timing data at the die(block) level.

Syntax

```
int write_tsv_timing
  [-corner_id id]
  [-output file_name]
```

Data Types

id	int
file_name	string

Arguments

`-corner_id` *id*

Specifies the corner id in integer.

`-output` *filename*

Specify the name of the tsv path timing data file to be written.

Feedback

Description

The *write_tsv_timing* command writes out a tsv feedthrough path timing data file in binary format at the die level for the specified corner.

Note: update_timing -full needs to be done before you use this command.

Examples

The following example writes a tsv feedthrough path timing data file tsv.dat at the die level for the specified corner 1.

```
prompt> write_tsv_timing -corner_id 1 -output tsv.dat
```

---

write_vectors

Generate vectors in form of a VCD file.

Syntax

status *write_vectors*

```
[-format file_format]
file_name
```

Data Types

```
file_format          string
file_name            string
```

Arguments

file_format

Specifies the file format for writing out vectors. Supported format is VCD/vcd or FSDB/fsdb. Default is VCD.

file_name

Specifies the name of the file to which the VCD is to be written.

Description

The *write_vectors* command writes events generated from vector free vector generation into a VCD or FSDB file. By default, a RTL VCD file is written out, which means only events on synthesis invariant points are written out.

The command *set_vector_generation_options* is used to set options on how vectors are generated. There are three different types of vectors can be generated, and each one can be specified by corresponding option in the command *set_vector_generation_options*. Default is single clock cycle vector generation. The second one is multi-cycle vector generation, which is enabled by the option *-number_of_cycles*. The third one is special mode vector generation for single cycle, which is enabled by the option *-special_nets*.

Examples

The following example writes a RTL VCD file after average power analysis:

```
pt_shell> set_power_analysis_options -through_mode
pt_shell> update_power
pt_shell> write_vectors rtl.vcd
```

The following example sets a clock gating percentage 30% rather than default 50%, and then writes a RTL VCD file:

```
pt_shell> set_power_analysis_options -through_mode
pt_shell> update_power
pt_shell> set_clock_gating_percentage -value 0.3
pt_shell> write_vectors rtl.vcd
```

The following example writes a RTL FSDB file after average power analysis:

```
pt_shell> set_power_analysis_options -through_mode
pt_shell> update_power
pt_shell> write_vectors -format FSDB rtl.fsdb
```

The following example reads patterns from a VCD file for all control nets, and sets one hot mode for a list of bus nets. For all primary input, constraint mode is applied. Then the command *write_vectors* is invoked to generate 100 cycle VCD.

```
pt_shell> set_vector_generation_options -number_of_cycles 100
pt_shell> set_net_pattern -file control.vcd -format VCD -strip_path tb
 -object_list [get_nets control*]
pt_shell> set_net_pattern -mode one_hot -object_list [get_nets mbus[*]]
pt_shell> set_net_pattern -object_list [get_nets -of [get_ports]] -mode
 constraint
pt_shell> write_vectors 100_cycle.vcd
```

The following example shows how to generate a special mode VCD file, where all nets are considered as special nets, and 75% of those nets are toggling. At the same time, state 0 is set on all clock gating cell enable nets through command *set_net_pattern*.

```
pt_shell> set_vector_generation_options -special_nets [get_nets -hier]
pt_shell> set_vector_generation_options -toggle_percentage 0.75
pt_shell> set_net_pattern -pattern 0 -object_list [get_nets -of [get_pins
 icg_*/enble]
pt_shell> write_vectors special_mode_75.vcd
```

---

write_waiver

Writes existing waivers into an output file. The file can be sourced to restore waivers in a new session.

Syntax

Boolean *write_waiver*

```
-output output_file
[-force]
```

Data Types

```
output_file     string
```

Arguments

`-output output_file`

Writes all existing waivers into the given output file.

`-force`

Overwrites the output file if it already exists.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Writes existing waivers into an output waiver file. To restore waivers from the *write_waiver* output, you need to source the waiver file in each scenario. Sourcing a waiver file in one scenario restores only the waivers active in that scenario, and waivers for scenario-independent rules.

Feedback

write_xdomain_design

Writes a cross-domain design that consumes less memory to perform SMVA than the original design.

Syntax

status *write_xdomain_design*

[*dir_name*]

Data Types

dir_name	string

Arguments

dir_name

Specifies a directory name in which a cross-domain design is created. The specified directory contains multiple files after creation.

If you do not specify a directory name, the default is *xdomain_design_directory*.

Description

This command reduces hardware requirements by creating a cross-domain design that requires less memory to perform SMVA. A *cross-domain design* is a small subset of the original design that contains only paths crossing voltage domains. For example, it retains only cells and nets on cross-domain paths and omits cells and nets on non cross-domain paths. Special timing and crosstalk models are created for disconnected nets and pins in the cross-domain design so that timing quality of results (QoR) in the cross-domain design is very close to the timing QoR of the original design. Its goal is to have timing QoR close enough to produce similar SMVA run for path crossing domains compared to the cross-domain design generated from the original design.

Memory Reduction

After a cross-domain design is written, memory reduction may not be proportional to the number of reduced cells because PrimeTime's memory consumption also includes fixed memory overhead like loading library. For example, a design loaded with a large number of larger libraries shows lower memory reduction than a design loaded with one small library.

PrimeTime shows an estimated design reduction summary after the *write_xdomain_design* command finishes. Note that the numbers are not exact but estimated values. The purpose of the estimate is to provide rough numbers for design reduction. Exact cell, net, and pin counts as well as peak memory will be available when the *read_xdomain_design* command finishes.

Feedback

Examples

This section describes an example to convert existing SMVA scripts to new scripts utilizing the *write_xdomain_design* and *read_xdomain_design* commands.

Example Scripts

The following example is a typical script for STA and SMVA combined together.

```
################################################
# FILE: run_sta_and_write_xdomain_design.tcl
#   To run STA and write_xdomain_design.
#   Runs in 100 GB machine.
################################################
#
# STA
#
set timing_enable_cross_voltage_domain_analysis true
set timing_cross_voltage_domain_analysis_mode capture_reduced_model
read_verilog...
read_parasitics...
read_sdf...
update_timing...
report_timing...
#
# Creates an xdomain design
#
write_xdomain_design
exit

################################################
# FILE: run_read_xdomain_design_and_xdomain.tcl
#   To run cross-domain.
#   Runs in 20 GB machine.
################################################
#
# Read the cross-domain design
#
set timing_cross_voltage_domain_analysis_mode full
read_xdomain_design

update_timing...
report_timing...
exit
```
