PrimeTime Suite Tool Commands

This document describes the tool commands supported by the PrimeTime Suite tool.

a

add_command_hook

Add hook into command execution

Syntax

string *add_command_hook* -before *script*

-after *script* -replace *script* [-name *name*] *commandName*

```
string script
string script
string script
string name
string commandName
```

Arguments

`-before script`

Hook runs before command.

`-after script`

Hook runs after command.

`-replace script`

Hook runs in place of command.

`-name name`

Name of hook. If no name is specified a name is automatically generated.

`commandName`

Command to update.

Feedback

Description

The *add_command_hook* adds a customization point into the execution of an application command. For example, these hooks can be used to either run a report or gather statistics before and after an application command is run.

Within the body of any hook the get_current_hook_command can be used to query the command and its arguments. For example, a before and after hook may use this information if the hook actions should only happen when specific options are specified. In a replace hook the hook can run the replaced command possibly updating the command options.

This command returns the name of the hook which can be used to remove the hook from the command if desired.

Examples

Arrange for report timing to be executed every time place_opt_is run.

```
prompt> add_command_hook place_opt -before report_timing
before0
```

Force all report_timing calls to use the -nosplit option.

```
prompt> add_command_hook report_timing -replace {eval
 [get_current_hook_command] -nosplit}
replace0
```

See Also

- get_command_hooks
- remove_command_hook
- get_current_hook_command

---

add_eco_scenario_data

Specifies additional ECO data (beyond the *create_scenario* definition) for hybrid view determination by *report_eco_scenarios* and *start_eco_scenarios*.

Syntax

```
status add_eco_scenario_data
-scenario scenario_name
-eco_data directory_name
[-path prefix_list]
```

Feedback

Data Types

```
directory_name  string
prefix_list     list
scenario_name   string
```

Arguments

`-scenario`

Specifies a scenario name for the additional ECO data to be applied to.

`-eco_data`

Specifies the ECO data directory used to determine hybrid views.

`-path` *`prefix_list`*

Specifies a list of relative paths to the instance names of the current design from a higher-level design that includes the current design.

By default, absolute path names are used. Use this option if the ECO data is generated from a higher-level design that includes the current design, and you want to use the higher-level design timing to determine the hybrid views for the current design. If more than one prefix is supplied, all of the instances of the design are considered.

Description

The *add_eco_scenario_data* command is used to import ECO timing data from a source other than the current design analysis.

For example, you might have a top-level design that includes the current design as one of its subblocks, and the top-level analysis has more accurate timing for the interface paths at the block boundary. In this case, use this command to add the ECO data generated at the top level to the current ECO data specified by the *create_scenario* command.

Examples

Suppose the current design 'Block_A' is instantiated as 'Block_A1' and 'Block_A2' at the top level design 'Top'. In other words, the design 'Top' has two sub blocks 'Block_A1' and 'Block_A2'. All designs have two scenarios, 'ss' and 'ff'. The following commands write ECO data from the top-level analysis.

In 'ss' scenario at the top level:

```
pt_shell> write_eco_scenario_data -output top_eco_data/ss
```

In 'ff' scenario at the top level:

```
pt_shell> write_eco_scenario_data -output top_eco_data/ff
```

At the block level, the following commands add the top-level ECO data, assuming the 'Block_A' directory contains ECO data for the current design.

```
pt_shell> create_scenario -name ss -image ss_session -eco_data Block_A/ss
pt_shell> create_scenario -name ff -image ss_session -eco_data Block_A/ff
pt_shell> add_eco_scenario_data -scenario ss \\
            -eco_data top_eco_data/ss \\
            -path { Top/Block_A1 Top/Block_A2 }
pt_shell> add_eco_scenario_data -scenario ff \\
            -eco_data top_eco_data/ff \\
            -path { Top/Block_A1 Top/Block_A2 }
```

- start_eco_scenarios

---

add_power_state

Adds state information to a supply set or a group or a domain.

Syntax

status *add_power_state*

```
[-supply | -group | -domain] object_name
[-simstate  {simstate}]
[-update]
[-state state_name {[-supply_expr {supply_expression}]
                           [-logic_expr  {logic_expression}]
                           [-simstate    {simstate}] }]
```

Data Types

```
object_name          string
simstate             string
state_name           string
supply_expression    string
logic_expression     string
```

Arguments

`-supply | -group | -domain` *object_name*

Specifies the name of a supply set, or the name of a group created with the *create_power_state_group* command or the name of a domain. The name should be a simple (nonhierarchical) name.

`-state state_name`

Specifies the name of the state to add to the supply set or the group or the domain. The name should be a simple (nonhierarchical) name. This option can be specified multiple times in the same command.

`-supply_expr {supply_expression}`

Specifies a Boolean expression in terms of nets and their netstates. This option can only be specified when the *object_name* is a supply set. The only operator allowed in the Boolean expression is && (AND operator). Each subexpression in the Boolean expression specifies the net and netstate definitions using the following syntax:

```
net == netstate
```

The *net* can be power or ground, and the *netstate* syntax must be one of the following:

```
status
{status}
{status nom_voltage}
```

- *status* can be OFF or FULL_ON
- If the *status* is FULL_ON, the voltage value must be defined while assigning status to a net or later with the *-update* option.

`-logic_expr {logic_expression}`

If the *object_name* is a group or a domain, then this option specifies a Boolean expression in terms of supply sets and their states. The only operator allowed in the Boolean expression is &&.

If the *object_name* is a supply set, then this option specifies a SystemVerilog Boolean expression in terms of logic nets and supply nets. The -logic_expr option does not affect implementation and is intended to be used by simulation tools. It is read and ignored by the tool.

`-simstate {simstate}`

Specifies a simstate for the power states associated with a supply set. The -simstate option does not affect implementation and is intended to be used by simulation tools. It is read and ignored by the tool.

`-update`

Updates *object_name* with the state information specified in this command run without overwriting the existing power state definition.

Feedback

Description

This command adds state information to a supply set or a group or a domain.

If the specified object is a supply set, the command sets power states on the nets of a supply set and uses them as supplies for the power state table. If the supply set does not already exist, this command issues an error.

If the specified object is a group, the command creates the power state table by using supply sets that are specified by the -logic_expr option. The group should have been previously created using the *create_power_state_group* command; otherwise, the command issues an error.

When adding power states to a supply set, the *-update* option is supported for adding the new state definition but it's optional. For instance, to add SS1_state1 to the SS1 supply net set, use the following command:

```
prompt > add_power_state SS1 -state SS1_state1 ...
```

To add another power state SS1_state2, use either of the following commands:

```
prompt > add_power_state SS1 -state SS1_state1 ... -state SS1_state2 ...
prompt > add_power_state SS1 -state SS1_state2 ...
prompt > add_power_state SS1 -state SS1_state2 ... -update
```

For adding group power states, the *-update* option is mandatory for adding new state definition. For example, to add A_state2 to GroupA which was set with the A_state1 state, use either of the following commands:

```
prompt > add_power_state -group GroupA -state A_state1 ... -state
 A_state2 ...
prompt > add_power_state -group GroupA -state SS1_state2 ... -update
```

In the previous example, the second *add_power_state* command must be run with the *-update* option. Otherwise, the tool issues an error.

The *-update* option is supported for sub-state conjunctions when adding power states to a supply set. For example, you can add power states without the *-update* option:

```
prompt > add_power_state SS1 \\
         -state HPg {-supply_expr {power == {OFF} && ground =={FULL_ON
 0}}}
```

Or use the *-update* option:

```
prompt > add_power_state SS1 \\
         -state HPg {-supply_expr {power == {OFF}}
prompt > add_power_state SS1 \\
         -state HPg {-supply_expr {ground =={FULL_ON 0}}} -update
```

The tool issues an error when the *-update* option is not specified in the previous example because of duplicate definition of the state HPg.

You can assign a voltage value to the functional net's state with the *-update* option later:

e.g.

```
prompt > add_power_state SS1 \\
         -state HPg {-supply_expr {power =={FULL_ON}}}
prompt > add_power_state SS1 \\
         -state HPg {-supply_expr {power =={FULL_ON 0.8}}} -update
```

The *-update* option is also supported for sub-state conjunctions when adding group power states. For example, you can add group power states without the *-update* option:

```
prompt> add_power_state group_A -group \\
        -state lo2 {-logic_expr {SS1 == HPg && SS2 == HVp}
```

Or use the *-update* option:

```
prompt > add_power_state group1 \\
         -state lo2 {-logic_expr {SS1 == Hpg}}
prompt > add_power_state group1 \\
         -state lo2 {-logic_expr {SS2 == HVp}} -update
```

You can create an empty power state first, and then update it later:

```
prompt> add_power_state SS1 -state ON {}
prompt> add_power_state SS1 -state ON {-supply_expr {power == FULL_ON}}
 -update
```

Examples

The following example defines a state ON for the supply set SS1 where the supply_expression is a Boolean expression of power and ground.

```
prompt> add_power_state -supply SS1\\
        -state ON  {-supply_expr {power == {FULL_ON 0.8} && ground ==
 {FULL_ON 0}}}
```

The following example defines two states, ON and OFF, for the supply set SS2.

```
prompt> add_power_state -supply SS2\\
        -state ON  {-supply_expr {power == {FULL_ON 0.8} && ground ==
 {FULL_ON 0}}}\\
        -state OFF {-supply_expr {power == {OFF} && ground == {FULL_ON
 0}}}
```

The following shows how to add power states to a PST group PST_GROUP. The system is in state RUN when both supply sets SS1 and SS2 are in state ON; and the system is in state SLEEP when the supply set SS1 is in state ON while the supply set SS2 is in state OFF.

Feedback

```
prompt> create_power_state_group PST_GROUP
prompt> add_power_state -group PST_GROUP \\
        -state RUN   {-logic_expr {SS1 == ON && SS2 == ON}}\\
        -state SLEEP {-logic_expr {SS1 == ON && SS2 == OFF}}
```

See Also

- create_power_state_group
- create_supply_set

---

add_pst_state

Defines the states of each of the supply nets for one possible state of the design.

Syntax

status *add_pst_state*

```
state_name
-pst table_name
-state supply_states
```

Data Types

state_name	string
table_name	string
supply_states	list

Arguments

state_name

Specifies the name of the power state.

-pst *table_name*

Specifies the power state table (PST) to which this state applies.

-state *supply_states*

Lists the supply net state names in the corresponding order of the *-supplies* option listing in the *create_pst* command.

Description

The *add_pst_state* command defines the states of each of the supply nets for one possible state of the design. It is an error if the number of supply state names is different from the number of supply nets within the power state table.

Feedback

Examples

The following example defines the supply net state names for the s1, s2 and s3 power states:

```
create_pst pt -supplies { PN1 PN2 SOC/OTC/PN3 }
add_pst_state s1 -pst pt -state { s08 s08 s08 }
add_pst_state s2 -pst pt -state { s08 s08 off }
add_pst_state s3 -pst pt -state { s08 s09 off }
```

See Also

- create_pst

---

add_to_collection

Adds objects to a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *add_to_collection*

```
[-unique]
collection1
object_spec
```

Data Types

collection1	collection
object_spec	list

Arguments

`-unique`

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

collection1

Specifies the base collection to which objects are to be added. This collection is copied to the result collection, and objects matching *object_spec* are added to the result collection. The *collection1* option can be the empty collection (empty string), subject to some constraints, as explained in the DESCRIPTION section.

object_spec

Specifies a list of named objects or collections to add.

If the base collection is heterogeneous, only collections can be added to it.

If the base collection is homogeneous, the object class of each element in this list must be the same as in the base collection. If it is not the same class, it is ignored. From heterogeneous collections in the *object_spec*, only objects of the same class of the base collection are added. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

The *object_spec* has some special rules when the base collection is empty, as explained in the DESCRIPTION section.

Description

The *add_to_collection* command allows you to add elements to a collection. The result is a new collection representing the objects in the *object_spec* added to the objects in the base collection.

Elements that exist in both the base collection and the *object_spec*, are duplicated in the resulting collection. Duplicates are not removed unless you use the *-unique* option. If the *object_spec* is empty, the result is a copy of the base collection.

If the base collection is homogeneous, the command searches in the database for any elements of the *object_spec* that are not collections, using the object class of the base collection. If the base collection is heterogeneous, all implicit elements of the *object_spec* are ignored.

When the *collection1* argument is the empty collection, some special rules apply to the *object_spec*. If the *object_spec* is non-empty, there must be at least one homogeneous collection somewhere in the *object_spec* list (its position in the list does not matter). The first homogeneous collection in the *object_spec* list becomes the base collection and sets the object class for the function. The examples show the different errors and warnings that can be generated.

The *append_to_collection* command has similar semantics as the *add_to_collection* command; however, the *append_to_collection* command can be much more efficient in some cases. For more information about the command, see the man page.

For background on collections and querying of objects, see the *collections* man page.

Examples

The following example uses the *get_ports* command to get all of the ports beginning with 'mode' and then adds the "CLOCK" port.

```
prompt> set xports [get_ports mode*]
{mode[0] mode[1] mode[2]}
prompt> add_to_collection $xports [get_ports CLOCK]
{mode[0] mode[1] mode[2] CLOCK}
```

The following example adds the cell u1 to a collection containing the SCANOUT port.

Feedback

```
prompt> set so [get_ports SCANOUT]
{SCANOUT}
prompt> set u1 [get_cells u1]
{u1}
prompt> set het [add_to_collection $so $u1]
{u1}
prompt> query_objects -verbose $het
{{port SCANOUT} {cell u1}}
```

The following examples show how the *add_to_collection* command behaves when the base collection is empty. Adding two empty collections yields the empty collection. Adding an implicit list of only strings or heterogeneous collections to the empty collection generates an error message, because no homogeneous collections are present in the *object_spec* list. Finally, if one homogeneous collection is present in the *object_spec* list, the command succeeds, even though a warning message is generated. The example uses the variable settings from the previous example.

```
prompt> sizeof_collection [add_to_collection "" ""]
0

prompt> set A [add_to_collection "" [list a $het c]]
Error: At least one homogeneous collection required for argument
 'object_spec'
        to add_to_collection when the 'collection' argument is empty
 (SEL-014)

prompt> add_to_collection "" [list a $het $sp]]
Warning: Ignored all implicit elements in argument 'object_spec'
         to add_to_collection because the class of the base collection
         could not be determined (SEL-015)
{SCANOUT u1 SCANOUT}
```

- sizeof_collection

---

alias

Creates a pseudo-command that expands to one or more words, or lists current alias definitions.

Feedback

Syntax

string *alias* [*name*] [*def*]

Data Types

name	string
def	string

Arguments

name

Specifies a name of the alias to define or display. The name must begin with a letter, and can contain letters, underscores, and numbers.

def

Expands the alias. That is, the replacement text for the alias name.

Description

The *alias* command defines or displays command aliases. With no arguments, the *alias* command displays all currently defined aliases and their expansions. With a single argument, the *alias* command displays the expansion for the given alias name. With more than one argument, an alias is created that is named by the first argument and expanding to the remaining arguments.

You cannot create an alias using the name of any existing command or procedure. Thus, you cannot use *alias* to redefine existing commands.

Aliases can refer to other aliases.

Aliases are only expanded when they are the first word in a command.

Examples

Although commands can be abbreviated, sometimes there is a conflict with another command. The following example shows how to use *alias* to get around the conflict:

```
prompt> alias q quit
```

The following example shows how to use *alias* to create a shortcut for commonly-used command invocations:

```
prompt> alias include {source -echo -verbose}

prompt> alias rt100 {report_timing -max_paths 100}
```

After the previous commands, the command *include script.tcl* is replaced with *source -echo -verbose script.tcl* before the command is interpreted.

The following examples show how to display aliases using *alias*. Note that when displaying all aliases, they are in alphabetical order.

```
prompt> alias rt100
rt100  report_timing -max_paths 100

prompt> alias
include  source -echo -verbose
q  quit
rt100  report_timing -max_paths 100
```

See Also

- unalias

---

all_clocks

Creates a collection of all clocks in the current design. You can assign these clocks to a variable or pass them into another command.

Syntax

collection *all_clocks*

Arguments

None.

Description

The *all_clocks* command creates a collection of all clocks in the current design. If you do not define any clocks, the empty collection (empty string) is returned.

If you want only certain clocks, use *get_clocks* to create a collection of clocks matching a specific pattern and optionally pass in filter criteria.

Examples

The following example applies the *set_propagated_clock* command to all clocks in the design.

pt_shell> *set_propagated_clock [all_clocks]*

See Also

- collections
- create_clock
- derive_clocks

- get_clocks
- set_propagated_clock

---

all_connected

Creates a collection of objects connected to a net, pin, or port object. You can assign this collection to a variable or pass it into another command.

Syntax

collection *all_connected*

```
[-leaf]
object_spec
```

Data Types

object_spec	list

Arguments

`-leaf`

Specifies that the connections of the net that are being returned should be global or leaf pins. When specified, this gives the leaf pins of a hierarchical net. For non-hierarchical nets, there is no difference in output.

object_spec

Specifies the object whose connections are returned. This is a collection of one element which is a net, pin, or port collection, or the name of a net, pin, or port.

Description

The *all_connected* command creates a collection of objects connected to a specified net, pin, or port. The *object_spec* option is either a collection of exactly one net, pin, or port object, or a name of an object. If it is a name, PrimeTime searches for a net, pin, or port, in that order. If the *object_spec* refers to a net, you can use the *-leaf* option to get the global leaf pins of the net.

The command returns a collection. The collection can contain nets, ports, pins, or a combination of ports and pins. In the latter case, the ports are first and they are followed by the pins.

When issued from the command prompt, the *all_connected* command behaves as though the *query_objects* command has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

Feedback

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example shows all objects connected to net "CLOCK":

```
pt_shell> query_objects -verbose [all_connected [get_nets CLOCK]]
{"port:CLOCK", "pin:U1/CP", "pin:U2/CP", "pin:U3/CP", "pin:U4/CP"}
```

See Also

- collections
- get_nets
- get_pins
- query_objects
- collection_result_display_limit

---

all_fanin

Creates a collection of pins, ports, or cells in the fanin of specified objects.

Syntax

collection *all_fanin*

```
[-from from_list]
[-through through_list]
-to to_list
[-startpoints_only]
[-only_cells]
[-flat]
[-quiet]
[-step_into_hierarchy]
[-levels level_count]
[-pin_levels pin_count]
[-trace_arcs timing | enabled | all]
[-continue_trace pin_types]
```

Data Types

```
from_list        list
through_list     list
to_list          list
level_count      int
pin_count        int
pin_types        string
```

Feedback

Arguments

`-from` *`from_list`*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanin of each object in *to_list* becomes part of the resulting collection only if it is in the fanout cone of at least one object in *from_list*. If a net is specified, the effect is the same as listing all load pins on the net.

`-through` *`through_list`*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified, the fanin of each object in *to_list* is restricted to objects on paths through the pins, ports or nets in *through_list*.

`-to` *`to_list`*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanin of each object in *to_list* becomes part of the resulting collection. If a net is specified, the effect is the same as listing all driver pins on the net. This argument is required.

`-startpoints_only`

Includes only the timing startpoints in the result.

`-only_cells`

Includes only cells in the timing fanin of the *to_list* and not pins or ports.

`-flat`

There are two major modes in which this command functions: hierarchical (the default) and flat. When in hierarchical mode, only objects within the same hierarchical level as the current *to_list* object are included in the result. In flat mode, the relevant leaf objects through design hierarchy are included; the only non-leaf objects in the result are any specified hierarchical *to_list* objects.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-step_into_hierarchy`

You can use this option only in hierarchical mode and with either the *-levels* or *-pin_levels* option. Without this option, a hierarchical block at the same level of hierarchy as the current object is considered to be a cell; the input pins are considered a single level away from the related output pins, regardless of what is inside the block.

With the switch enabled, the counting is performed as though the design were flat, and although pins inside the hierarchy are not returned, they determine the depth of the related output pins.

`-levels` *`level_count`*

The traversal stops when reaching a depth of search of *cell_count* hops, where the counting is performed over the layers of cells of same distance from the object in *to_list*.

`-pin_levels` *`pin_count`*

The traversal stops when reaching a depth of search of *pin_count* hops, where the counting is performed over the layers of pins of same distance from the object in *to_list*.

`-trace_arcs timing | enabled | all`

Specifies the type of combinational arcs to trace during the traversal:

- *timing* (the default) - Permits tracing of valid timing arcs only -- that is, arcs that are neither disabled nor invalid due to case analysis.
- *enabled* - Permits the tracing of all enabled arcs and disregards case analysis values.
- *all* - Permits the tracing of all combinational arcs regardless of case analysis or arc disabling.

`-continue_trace` *`pin_types`*

This option permits the user to override the default behavior of the traversal which is to stop at all timing startpoints. When used, the travsal is permitted through startpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- *generated_clock_source* - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

Description

The *all_fanin* command creates a collection of objects in the timing fanin of specified "to" pins, ports, or nets in the design. A pin is considered to be in the timing fanin of an object in *to_list* if there is a timing path through combinational logic from the pin to that object (see also the *-trace_arcs* option). The fanin stops at input ports and the clock pins of registers (sequential cells).

If the current instance in the design is not the top level of hierarchy, only objects within the current instance are returned.

The fanin cone can be topologically restricted by using the *-from* and *-through* options.

Feedback

Examples

This example shows the timing fanin of a port in the design. The fanin includes a register, reg1.

```
pt_shell> query_objects [all_fanin -to out_1]
{"out_1", "reg1/Q", "reg1/CP"}
```

This example shows the flat mode of *all_fanin*. The object in *to_list* is an input pin of a hierarchical cell, H1, which is connected to an output pin of another hierarchical cell, H2. H2 contains additional hierarchy and eventually, a leaf cell with 2 inputs, each of which has a top level register in its fanin.

```
pt_shell> query_objects [all_fanin -to H1/a -flat]
{"H1/a", "H2/U1/n1/Z", "H2/U1/n1/A", "H2/U1/n1/B",
 "reg1/Q", "reg2/Q", "reg1/CP", "reg2/CP"}
```

This example shows the timing fanin of an output port that passes through pin U1/Z or pin U2/Z.

```
pt_shell> query_objects [all_fanin -to out -through {U1/Z U2/Z}]
{"out", "U3/Z", "U3/A", "U3/B", "U1/Z", "U1/A", "U2/Z", "U2/Z",
 "reg1/Q", "reg2/Q", "reg1/CP", "reg2/CP"}
```

This example shows the timing fanin of an output port the passes through pin U1/Z and pin U3/A.

```
pt_shell> query_objects [all_fanin -to out -through U1/Z -through U3/A]
{"out", "U3/Z", "U3/A", "U1/Z", "U1/A", "reg1/Q", "reg1/CP"}
```

---

all_fanout

Creates a collection of pins, ports, or cells in the fanout of the specified objects.

Syntax

collection *all_fanout*

```
-from from_list
   | -clock_tree
[-through through_list]
```

```
[-to to_list
[-endpoints_only]
[-only_cells]
[-flat]
[-quiet]
[-step_into_hierarchy]
[-levels level_count]
[-pin_levels pin_count]
[-trace_arcs timing | enabled | all]
[-continue_trace pin_types]
```

Data Types

from_list	list
through_list	list
to_list	list
level_count	int
pin_count	int
pin_types	string

Arguments

`-from` *from_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each object in *from_list* becomes part of the resulting collection. If a net is specified, the effect is the same as listing all load pins on the net.

This option is mutually exclusive with the *-clock_tree* option. At least one must be specified.

`-through` *through_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified, the fanout of each object in *from_list* is restricted to objects on paths through the pins, ports or nets in *through_list*.

`-to` *to_list*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each object in *from_list* becomes part of the resulting collection only if it is in the fanin cone of at least one object in *to_list*. If a net is specified, the effect is the same as listing all driver pins on the net.

`-clock_tree`

Specifies that all clock source pins and ports in the design are used as objects in the *from_list*. Clock sources are specified using *create_clock*. If there are

no clocks, or if the clocks have no sources, the command returns an empty collection. This option constrains the search to objects in the clock network only.

This option is mutually exclusive with the *-from* option. At least one must be specified.

`-endpoints_only`

Includes only the timing endpoints in the result.

`-only_cells`

Includes only cells in the timing fanout of the *from_list* and not pins or ports.

`-flat`

There are two major modes in which this command functions: hierarchical (the default) and flat. When in hierarchical mode, only objects within the same hierarchical level as the current *from_list* object are included in the result. In flat mode, the relevant leaf objects through design hierarchy are included; the only non-leaf objects in the result are any specified hierarchical *from_list* objects.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-step_into_hierarchy`

You can use this option only in hierarchical mode and with either the *-levels* or *-pin_levels* option. Without this option, a hierarchical block at the same level of hierarchy as the current object is considered to be a cell; the output pins are considered a single level away from the related input pins, regardless of what is inside the block. With the switch enabled, the counting is performed as though the design were flat, and although pins inside the hierarchy are not returned, they determine the depth of the related input pins.

`-levels` *`level_count`*

The traversal stops when reaching a depth of search of *cell_count* hops, where the counting is performed over the layers of cells of same distance from the object in *from_list*.

`-pin_levels` *`pin_count`*

The traversal stops when reaching a depth of search of *pin_count* hops, where the counting is performed over the layers of pins of same distance from the object in *from_list*.

`-trace_arcs timing | enabled | all`

Specifies the type of combinational arcs to trace during the traversal:

- *timing* (the default) - Permits tracing of valid timing arcs only -- that is, arcs that are neither disabled nor invalid due to case analysis.
- *enabled* - Permits the tracing of all enabled arcs and disregards case analysis values.
- *all* - Permits the tracing of all combinational arcs regardless of case analysis or arc disabling.

`-continue_trace` *`pin_types`*

This option permits the user to override the default behavior of the traversal which is to stop at all timing endpoints. When used, the travsal is permitted through endpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- *generated_clock_source* - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

Description

The *all_fanout* command creates a collection of objects in the timing fanout of specified "from" pins, ports, or nets in the design. A pin is considered to be in the timing fanout of an object in *from_list* if there is a timing path through combinational logic from that object to the pin (see also the *-trace_arcs* option). The fanout stops at output ports and the inputs to registers (sequential cells). The from objects are specified using either *-clock_tree* or *-from from_list*.

If the current instance in the design is not the top level of hierarchy, only objects within the current instance are returned.

The fanout cone can be topologically restricted by using the *-through* and *-to* options.

Examples

This example shows the timing fanout of a port in the design. The fanout includes the reg3 register.

```
pt_shell> query_objects [all_fanout -from in1]
{"in1", "reg3/D"}
```

This example shows the difference between the hierarchical and flat modes of *all_fanout*. The object in the *from_list* is the H3/z1 output pin of a hierarchical cell, which is connected to the H4/a input pin of another hierarchical cell. H4 contains the U1 leaf cell with input A and output Z. The first command is in hierarchical mode and shows that hierarchical pins are included in the result. The second command is in leaf mode, and leaf pins from the lower level are included.

```
pt_shell> query_objects [all_fanout -from H3/z1]
{"H3/z1", "H4/a", "H4/z", "reg2/D"}

pt_shell> query_objects [all_fanout -from H3/z1 -flat]
{"H3/z1", "H4/U1/A", "H4/U1/Z", "reg2/D"}
```

This example shows how to get the fanout of reg1/CP on paths passing through u1/Z and U3/Z.

```
pt_shell> query_objects [all_fanout -from reg1/CP -through U1/Z \\
          -through U3/A]
{"out", "U3/Z", "U3/A", "U1/Z", "U1/A", "reg1/Q", "reg1/CP"}
```

---

all_inputs

Creates a collection of all input ports in the current design. You can assign these ports to a variable or pass them into another command.

Syntax

collection *all_inputs*

```
[-level_sensitive]
[-exclude_clock_ports]
[-edge_triggered]
[-clock clock_name]
```

Data Types

clock_name list

Arguments

`-level_sensitive`

Only considers ports with level-sensitive input delay. This is specified by the *set_input_delay 2 -clock CLK -level_sensitive IN1* command.

`-exclude_clock_ports`

Excludes input ports which serve as clock sources.

`-edge_triggered`

Only considers ports with edge-triggered input delay. This is specified by *set_input_delay 2 -clock CLK IN2*.

`-clock` *`clock_name`*

Only considers ports with input delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

Description

The *all_inputs* command creates a collection of all input or inout ports in the current design. You can limit the contents of the collection by specifying the type of input delay that must be on a port.

You can remove clock source ports from the resulting collection by specifying *-exclude_clock_ports* option.

If you want only certain ports, use the *get_ports* command to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, the *all_inputs* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example specifies a driving cell for all input ports.

```
pt_shell> set_driving_cell -lib_cell FFD3 -pin Q [all_inputs]
```

See Also

- collections
- get_ports
- report_port
- query_objects
- set_driving_cell
- set_input_delay
- collection_result_display_limit

Feedback

all_instances

Creates a collection of all instances of a specific design or library cell in the current design, relative to the current instance. You can assign the resulting collection of cells to a variable or pass it into another command.

Syntax

collection *all_instances*

```
[-hierarchy]
object_spec
```

Data Types

```
object_spec     string
```

Arguments

`-hierarchy`

Searches for instances in all levels of instance hierarchy below the current instance. By default, only instances from the current level of hierarchy are considered.

object_spec

Specifies the target design or library cell. This can be a design collection, lib_cell collection, or name.

Description

The *all_instances* command creates a collection of cells that are instances of a design or library cell. The search for instances is made relative to the current instance within the current design. By default, *all_instances* considers only instances at the current level of the hierarchy. If you use the *-hierarchy* option, the search continues throughout the hierarchy.

The *object_spec* can be a simple name. In this case, any instance of a design or lib_cell with that name will match. Alternatively, the *object_spec* can be a collection of exactly one design or one library cell. Any other collection results in an error message. Using the collection can help focus the search for instances of specific designs or lib_cells, especially after *swap_cell* has been used.

When issued from the command prompt, *all_instances* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum using the *collection_result_display_limit* variable.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Examples

The following example uses *all_instances* to get the instances of the design 'low' in the current level of hierarchy.

```
pt_shell> all_instances low
{"U1", "U3"}
```

The following example uses *-hierarchy* to display instances of a design across multiple levels of hierarchy.

```
pt_shell> query_objects [all_instances low -hierarchy]
{"U1", "U2/U1", "U3"}
```

In the following example, there are two instances of design "inter". One of them is swapped for a new design. The difference between using *all_instances* with a name and a collection of one design is shown.

```
pt_shell> swap_cell i1 inter_2.db:inter
 ...unlinking i1
1
pt_shell> all_instances inter
{"i1", "i2"}
pt_shell> all_instances [get_designs inter_2.db:inter]
{"i1"}
```

---

all_outputs

Creates a collection of all output ports in the current design. You can assign these ports to a variable or pass them into another command.

Feedback

Syntax

collection *all_outputs*

```
[-level_sensitive]
[-edge_triggered]
[-clock clock_name]
```

Data Types

clock_name	list

Arguments

`-level_sensitive`

Only considers ports with level-sensitive output delay. This is specified by *set_output_delay 2 -clock CLK -level_sensitive IN1*.

`-edge_triggered`

Only considers ports with edge-triggered output delay. This is specified by *set_output_delay 2 -clock CLK IN2*.

`-clock clock_name`

Only considers ports with output delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

Description

The *all_outputs* command creates a collection of all output or inout ports in the current design. You can limit the contents of the collection by specifying the type of output delay that must be on a port.

If you want only certain ports, use *get_ports* to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, *all_outputs* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable *collection_result_display_limit*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example specifies a pin capacitance for all output ports.

```
pt_shell> set_load 4.56 [all_outputs]
```

Feedback

The following example shows the names all of the output ports with output delay relative to PHI1.

```
pt_shell> all_outputs -clock PHI1
```

See Also

- collections

---

all_registers

Creates a collection of register cells or pins. You can assign the resulting collection to a variable or pass it to another command.

Syntax

collection *all_registers*

```
[-clock clock_name]
[-rise_clock rise_clock_name]
[-fall_clock fall_clock_name]
[-cells]
[-data_pins]
[-clock_pins]
[-slave_clock_pins]
[-async_pins]
[-output_pins]
[-level_sensitive]
[-edge_triggered]
[-master_slave]
[-no_hierarchy]
```

Data Types

```
clock_name              list
rise_clock_name         list
fall_clock_name         list
```

Arguments

`-clock` *`clock_name`*

Considers all registers clocked by *clock_name*. This is either the name of a clock, or a collection containing a clock or clocks. For example, all registers whose clock pins are in the fanout of the specified clock or clocks.

`-rise_clock` *`rise_clock_name`*

Considers all registers clocked by *rise_clock_name* and having open edge effectively the rising clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops without any inversion on the clock path or falling edge triggered flip-flops with inversion on the clock path.

`-fall_clock` *`fall_clock_name`*

Considers all registers clocked by *fall_clock_name* and having open edge effectively falling the clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops with inversion on the clock path or falling edge triggered flip-flops without any inversion on the clock path.

`-cells`

Collects cells; this is the default behavior of this command. The cells are registers and are further limited by other command options.

`-data_pins`

Collects register data pins. The collection can be limited by other command options.

`-clock_pins`

Collects register clock pins. The collection can be limited by other command options.

`-slave_clock_pins`

Collects register slave clock pins (the slave clock pins of master-slave registers). Specify slave clock pins as *clocked_on_also* in the library.

`-async_pins`

Collects asynchronous preset or clear pins.

`-output_pins`

Collects register output pins.

`-level_sensitive`

Considers only level-sensitive latches.

`-edge_triggered`

Considers only edge-triggered flip-flops.

`-master_slave`

Considers only master or slave register cells.

`-no_hierarchy`

Considers only the current instance; does not descend the hierarchy.

Description

The *all_registers* command creates a collection of pins or cells related to registers.

When issued from the command prompt, *all_registers* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; to change this maximum, set the *collection_result_display_limit* variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

This example performs a trace from a port to all register clock pins which are clocked by CLK.

```
pt_shell> report_timing -from [get_ports {CLK}] \\
          -to [all_registers -clock CLK -clock_pins]

****************************************
Report : timing
        -path full
        -delay max
        -max_paths 1
Design : counter
 ...
****************************************

  Startpoint: CLK (input port clocked by CLK)
  Endpoint: ffa/CP (internal pin)
  Path Group: (none)
  Path Type: max

  Point                                    Incr       Path
  -----------------------------------------------------------
  input external delay                     0.00       0.00 r
  CLK (in)                                 0.00       0.00 r
  ffa/CP (FD2)                             0.00       0.00 r
  data arrival time                                   0.00
  -----------------------------------------------------------
  (Path is unconstrained)
```

Feedback

The following example performs a trace from all registers clock pins, which are triggered by clock rising edge.

```
pt_shell> report_timing -from [all_registers -rise_clock \\
            CLK -clock_pins]

Feedback

annotate_trace

Control annotation of traced command execution to the shell output.

Syntax

annotate_trace [-start|-stop] [-profile profile_annotation_type] [-log log_string] [-quiet]

string *log_string* string *profile_annotation_type*

Arguments

`-start`

This option is mutually exclusive with -stop. The option starts the annotation of traced command execution to the shell output. Each executed command string is annotated to the output prepended with ";## ".

`-stop`

This option is mutually exclusive with -start. This option stops annotation of traced command execution to the shell output.

`-profile` *`profile_annotation_type`*

This option selects the profile data output behavior for command annotation. This option is only meaningful when given with the -start option. The argument is one of: on, with_start, off. The /fIon/fP value starts annotation with profile data output enabled in the default mode which is to output the data only at the end of a command invocation. The data is output only if the delta values from the beginning of the command invocation meet or exceed the thresholds set for each of the reported metrics. The /fIwith_start/fP value starts annotation with profile data output both at the beginning and at the end of a command invocation. The profile data is output at the beginning irregardless of any thresholds since delta values cannot be calculated at the beginning of the invocation. The profile data output at the end of command invocation is controlled by thresholds. The /fIoff/fP value disables profile data output. If profile data annotation is enabled but profile metric gathering has not been enabled with set_trace_option, all profile metrics are auto-enabled. If omitted, annotation is started without profile data output.

`-log` *`log_string`*

This option outputs the given log_string to the shell output prepended with ";## ". If the given string contains newline characters, each line is prendended with ";## ".

Feedback

`-quiet`

If given, this option causes the command to ignore error conditions such as an attempt to log a comment string before annotation is started. The command will exit quietly when it encounters an error condition.

Description

The *annotate_trace* command performs operations related to annotating traced command execution to the shell output. If the application creates an output log, the annotation is made also to the output log. The command strings which are annotated to the output are those that are traced for creating a traced command replay log.

The *annotate_trace* with no options will report on the current status of annotation: on or off.

Examples

The following example starts annotation of executed commands to the output. Then the command is invoked again with no options to report on the status.

```
prompt> annoate_trace -start
prompt> annoate_trace
on
```

The following example configures profile metrids, then starts annotation of executed commands to the output along with the profile data.

```
prompt> set_trace_topion -profile all
prompt> set_trace_topion -memory_threshold 10
prompt> set_trace_topion -cpu_threshold 0
prompt> annotate_trace -start -profile with_start
```

---

append_to_collection

Adds objects to a collection and modifies a variable.

Syntax

collection *append_to_collection* [-dict *dict_var*]

```
[-unique]
var_name
object_spec
```

Feedback

Data Types

var_name	variable referencing a collection
dict_var	variable referencing a dict
object_spec	list

Arguments

`-unique`

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

var_name

Specifies a variable name. The objects matching *object_spec* are added into the collection referenced by this variable.

`-dict` *dict_var*

Specifies a variable name referencing a dict object. When this is specified the *var_name* argument specifies the key in the dict to update.

object_spec

Specifies a list of named objects or collections to add.

Description

The *append_to_collection* command allows you to add elements to a collection. This command treats the variable name given by the *var_name* option as a collection, and it appends all of the elements in *object_spec* to that collection. If the variable does not exist, it is created as a collection with elements from the *object_spec* as its value. If the variable does exist and it does not contain a collection, it is an error.

Alternatively this command may also update a value in a dict. When *-dict* is specified the *dict_var* is treated as a dict and the key specified by *var_name* is updated. If the dict variable is unset the dict is created. If the value referenced by the variable is not a dict it is an error.

The result of the command is the collection that was initially referenced by the *var_name* option (or dict key value), or the collection created if the variable did not exist.

The *append_to_collection* command provides the same semantics as the common use of the *add_to_collection* command; however, this command shows significant improvements in performance.

An example of replacing the *add_to_collection* command with the *append_to_collection* command is provided below. For example,

```
set var_name [add_to_collection $var_name $objs]
```

Feedback

Using the *append_to_collection* command, the command becomes:

```
append_to_collection var_name $objs
```

Updating a key in a dictionary:

```
append_to_collection -dict drivers $pinName $newDrivers
```

The *append_to_collection* command can be much more efficient than the *add_to_collection* command if you are building up a collection in a loop. The arguments of the command have the same restrictions as the *add_to_collection* command. For more information about these restrictions, see the *add_to_collection* man page.

Examples

The following example from PrimeTime shows how a collection can be built up using the *append_to_collection* command:

```
pt_shell> set xports
Error: can't read "xports": no such variable
        Use error_info for more info. (CMD-013)
pt_shell> append_to_collection xports [get_ports in*]
{"in0", "in1", "in2"}
pt_shell> append_to_collection xports CLOCK
{"in0", "in1", "in2", "CLOCK"}
```

---

apply_power_model

Binds power models to instances in the design and connects the interface supply set handles and logic ports of a previously loaded power model.

Syntax

string *apply_power_model*

Feedback

```
[model_name]
[-elements instance_name_list]
[-supply_map {{instance_scope_supply_set current_scope_supply_set}*}]
[-port_map {{instance_scope_logic_port current_scope_logic_net}*}]
[-parameters {{power_model_ parameter design_object}*}]
```

Data Types

```
instance_name_list                                  list
{instance_scope_supply_set current_scope_supply_set}  list
{instance_scope_logic_port current_scope_logic_net}   list
{power_model_ parameter design_object}              list
```

Arguments

`model_name` *string*

PrimeTime reads and ignore this option. Complete support will be available in future releases.

`-elements` *instance_name_list*

PrimeTime reads and ignore this option. Complete support will be available in future releases.

`-supply_map` *{{instance_scope_supply_set current_scope_supply_set}*}*

PrimeTime reads and ignore this option. Complete support will be available in future releases.

`-port_map` *{{instance_scope_logic_port current_scope_logic_net}*}*

PrimeTime reads and ignore this option. Complete support will be available in future releases.

`-parameters` *{{power_model_ parameter design_object}*}*

PrimeTime reads and ignore this option. Complete support will be available in future releases.

Description

PrimeTime reads and ignore this command. Complete support will be available in future releases.

Examples

The following command instantiates power model named MODEL.

```
prompt> apply_power_model MODEL -elements {.}
1
```

---

apropos

Searches the command database for a pattern.

Syntax

string *apropos*

```
[-symbols_only]
pattern
```

Data Types

```
pattern      string
```

Arguments

`-symbols_only`

Searches only command and option names.

pattern

Searches for the specified *pattern*.

Description

The *apropos* command searches the command and option database for all commands that contain the specified *pattern*. The *pattern* argument can include the wildcard characters asterisk (*) and question mark (?). The search is case-sensitive. For each command that matches the search criteria, the command help is printed as though *help -verbose* was used with the command.

Whereas *help* looks only at command names, *apropos* looks at command names, the command one-line description, option names, and option value-help strings. The search can be restricted to only command and option names with the *-symbols_only* option.

When searching for dash options, do not include the leading dash. Search only for the name.

Examples

In the following example, assume that the *get_cells* and *get_designs* commands have the *-exact* option. Note that without the *-symbols_only* option, the first search picks up commands which have the string "exact" in the one-line description.

```
prompt> apropos exact
 get_cells            # Create a collection of cells
```

```
    [-exact]                (Wildcards are considered as plain characters)
    patterns                (Match cell names against patterns)

  get_designs           # Create a collection of designs
    [-exact]                (Wildcards are considered as plain characters)
    patterns                (Match design names against patterns)

  real_time             # Return the exact time of day

prompt> apropos exact -symbols_only
  get_cells             # Create a collection of cells
    [-exact]                (Wildcards are considered as plain characters)
    patterns                (Match cell names against patterns)

  get_designs           # Create a collection of designs
    [-exact]                (Wildcards are considered as plain characters)
    patterns                (Match design names against patterns)
```

---

as_collection

Find a collection by name

Syntax

string *as_collection* [-check] *collection1*

```
string collection1
```

Arguments

`-check`

Return 1 if collection1 is a collection

collection1

The collection to convert

Description

This command looks up a string value and returns it as a collection it the collection is still live. All other values are passed through this command unmodified.

This command is also provides a simple way to check if the input is a collection.

Feedback

Examples

Check if a value is a collection:

```
shell> as_collection -check [get_cells]
1
shell> as_collection -check hello
0
```

See Also

- collections
- foreach_in_collection

---

associate_supply_set

Associates a supply set handle to another supply set handle or supply set reference.

Syntax

status *associate_supply_set*

```
-handle supply_set_handle
supply_set_name
```

Data Types

```
supply_set_handle     string
supply_set_name       string
```

Arguments

`-handle` *supply_set_handle*

Specifies the supply set handle on which the action is performed.

This is a required argument.

supply_set_name

Specifies the name of the supply set to which the supply set handle is associated. The name can be the name of a supply set or a supply set handle.

This is a required argument.

Description

The *associate_supply_set* command associates the supply set handle specified with the *-handle* option to the specified supply set. After the association, the tool treats corresponding functions in each supply set to be virtually connected. Therefore, the supply

sets inherit common switching behavior and must eventually be resolved to the same physical supply net.

A supply set is an abstract collection of supply nets, consisting of two supply functions, power and ground.

Examples

The following example associates primary supply handle of domain PD1 to the SS1 supply set.

```
prompt> associate_supply_set SS1 -handle PD1.primary
1
```

See Also

---

cache_distributed_attribute_data

Collects and stores remotely accessible attribute data locally in the manager process.

Syntax

string *cache_distributed_attribute_data*

```
[-class class_name]
[-attributes attribute_list]
```

Data Types

class_name	string
attribute_list	list

Arguments

`-class` *class_name*

Specifies the type of object: *port*, *cell*, *pin*, *net*. Use this option to specify the name of the class/object.

`-attributes` *attribute_list*

Store only the specified list of attributes for each object in the manager process.

Feedback

Description

The *cache_distributed_attribute_data* stores the value for the specified attributes locally in the manager process, such that when any attribute query is made for the remotely accessible attributes, the attributes will be available locally in the manager process. The command is supported in *Distributed Static Timing Analysis (DSTA)* and *Distributed Multi-Scenario Analysis (DMSA)* mode.

Examples

The following example shows the usage of cache_distributed_attribute_data command in Distributed Static Timing Analysis *(DSTA)* mode.

```
pt_shell> cache_distributed_attribute_data -class pin -attributes
 {min_rise_slack max_rise_slack}

Start of Manager/Worker Task Processing
----------------------------------------
Started    : Task execution on 'partition2' (Hid=2)
Started    : Task execution on 'partition4' (Hid=1)
Started    : Task execution on 'partition1' (Hid=3)
Started    : Task execution on 'partition0' (Hid=4)
Started    : Task execution on 'partition3' (Hid=5)
Successful : Task execution on 'partition3' (Hid=5)
Successful : Task execution on 'partition0' (Hid=4)
Successful : Task execution on 'partition1' (Hid=3)
Successful : Task execution on 'partition2' (Hid=2)
Successful : Task execution on 'partition4' (Hid=1)
----------------------------------------
End of Manager/Worker Task Processing
```

```
The following example shows the usage of cache_distributed_attribute_data
 command in
Distributed Multi-Scenario Analysis (DMSA) mode.

pt_shell> cache_distributed_attribute_data -class pin -attributes
 {min_rise_slack max_rise_slack}

Start of Manager/Worker Task Processing
-----------------------------------
Started    : Command execution in scenario 'scen1'
Started    : Command execution in scenario 'scen2'
Succeeded  : Command execution in scenario 'scen2'
Succeeded  : Command execution in scenario 'scen1'
-----------------------------------
End of Manager/Worker Task Processing

Restoring Attribute data at Manager
```

Feedback

cell_of

Creates a collection of cells of the given pins. The *cell_of* command is a DC Emulation command provided for compatibility with Design Compiler.

Syntax

string *cell_of*

```
        object_list
```

Data Types

object_list	list

Arguments

object_list

Creates a list of pins for which cells to get.

Description

The *cell_of* command creates a collection of cells owned by a list of pins. The command exists in PrimeTime for compatibility with Design Compiler. Complete information about the *cell_of* command can be found in the Design Compiler documentation. The supported method for getting pins of cells is to use the *get_cells* command with the *-of_objects* option.

See Also

- get_cells

change_selection

Changes the selection in the GUI, taking a collection of objects and changing the selection according to the type of change specified.

Syntax

int *change_selection*

```
[-name slct_bus]
[-replace]
[-add]
[-remove]
[-toggle]
[-push]
[-undo]
```

```
[-type object_type]
collection
```

Data Types

```
slct_bus              string
object_type           list
collection            list
```

Arguments

`-name slct_bus`

Specifies to change the selection bus by using the value of *slct_bus*. By default, the command changes the selection bus by using the name *global*.

`-replace`

Replaces the current selection with the objects in the collection. This is the default behavior of the command if you do not specify any optional parameter.

`-add`

Adds the objects in the collection to the current selection. By default, this option is off.

`-remove`

Removes the objects that are specified in the collection from the current selection. By default, this option is off.

`-toggle`

Adds each item that is specified in the collection to the selection bus if it is not currently contained there. If it is currently contained in the selection bus, remove it. By default, this option is off.

`-push`

Pushes current selection onto selection stack before changing the selection.

`-undo`

Undo to previous selection.

Undo is single level so running undo twice will return to original selection.

`-type object_type`

Specifies the type to change. Only those items from the collection that are of the type specified by *object_type* are used to change the selection. The valid values are *design*, *port*, *net*, *cell*, *pin*, and *path* (timing path). By default, the command uses the entire collection.

collection

Specifies the collection of objects to use to change the selection. The type of change that is applied to the current selection with the *collection* is specified by the optional parameters listed above. By default, this option is off.

Description

The *change_selection* command changes the selection in the GUI. When selections are changed, the GUI updates all relevant windows to reflect it.

A collection of objects and the type of change are given as input to the command. The collection of objects might be returned as the result of another command such as the *get_designs* command. If the collection is empty and you use the *-replace* option (or let the command default by specifying no option), the current selection is cleared.

If you use the *-type* option, only the type of objects specified are used to change the current selection. For example, if you use *-type design*, the command uses only the design objects in the collection to change the current selection. If you do not use *-type* option, all objects in the collection are used to change the current selection. For example, if you use the *-add* option without using the *-type* option, all objects, regardless of their type, are added to the current selection.

For information about collections, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example replaces the current selection with the collection of design objects, regardless of type.

```
prompt> change_selection [get_designs]
```

The following example adds a cell named U5 to the selection made in the example above.

```
prompt> change_selection -add [get_cells U5]
```

The following example removes all pin objects from the current selection.

```
prompt> change_selection -remove -type pin [get_selection]
```

The following example clears the selection.

```
prompt> change_selection ""
```

The following example creates a new selection bus and adds a net named n1 to the selection.

Feedback

```
prompt> set slct [create_selection_bus]
prompt> change_selection  -name $slct [get_nets 1]
```

---

characterize_context

Captures the timing context of a list of instances for hierarchical analysis.

Syntax

string *characterize_context*

```
-block block_name
[-top]
[-instances cell_list]
[-name mim_group_name]
[-mim_reference mim_ref_instance]
```

Data Types

```
block_name       string
cell_list        list
mim_group_name   string
mim_ref_instance string
```

Arguments

`-block block_name`

Specifies the name of the reference subblock design. One or more instances of this block are characterized.

`-top`

Specifies top design is characterized for top only context writing. In top only mode, the tool only writes out the top level constraints and excludes all constraints from characterized sub-instances.

`-instances` *`cell_list`*

Specifies a list of one or more instances in the current design to be characterized. They must be instances of the reference block specified by the *-block* option.

If you omit this option, the command tries to merge all instances of the block specified by the *-block* option. If all the instances cannot be merged due to differences in context, the command merges the largest mergeable cluster of instances with similar context.

`-name` *`mim_group_name`*

Specifies the name of the instance group subset of multiply instantiated modules (MIMs). The instances specified in *-instances* have their context merged for a single common block-level analysis. To perform merging, using the *-name* option is mandatory if *-instances* is used, unless the given instances cover all the instances of the given block.

`-mim_reference` *`mim_ref_instance`*

Specifies the instance name of the MIM reference used for context merging. By default, MIM context merging automatically chooses a reference instance from the largest mergeable instance cluster. With this option, the specified instance is used for context merging, possibly overriding the default.

Description

The *characterize_context* command captures the timing context of instances of subdesigns from the chip-level timing environment to support hierarchical analysis. You can use the characterization data to analyze the timing behavior of the block instance by itself, in the context of the top-level design where it is used.

The timing context of an instance includes waveforms of the clocks affecting this instance, input arrival times, output required times, timing exceptions, design rules, propagated constants, input drives, and capacitive loads. You can report the context data using the *report_context* command.

To write out the context information for other PrimeTime sessions or other tools, use the *write_context* command.

Examples

The following script derives, reports, and writes out the context for instance U12 of block BLKA. The next PrimeTime session reads in the block and block context, and then analyzes the timing of the block by itself in the context of top-level design where the block is used.

```
characterize_context -block blkA -instances U12
report_context U12
write_context -format psth -output U12_context [get_cells U12]
```

```
------------------------

read_verilog block BLKA.v
link_design BLKA
 ...
read_context U12_context
update_timing
```

The following script characterizes the context for four instances of the block BLKA. It merges the constraints for instances U1 and U3 into a single context description and merges the constraints for instances U2 and U4 into another context description.

```
characterize_context -block BLKA -instances {U1 U3} -name BLKAodd
characterize_context -block BLKA -instances {U2 U4} -name BLKAeven
update_timing
write_context {U1 U3 U2 U4} -format gbc BLKA_context_dir
```

See Also

- remove_context
- report_context
- write_context

---

check_activity

Check the VCD and FSDB file and reports any unannotated, X, Z, or unconnected states of the input signals.

Syntax

bool *check_activity*

```
[-trace_fanin]
[-show_pins]
pin_list | net_list
```

Data Types

pin_list | *net_list* list

Arguments

`-trace_fanin`

Check the fanin of the pins specified in the pin list for X or Z states.

`-show_pins`

report the pins specified in the net list for X or Z states.

pin_list | net_list

List of pins or nets on which the activity checker needs to be performed.

Description

Use the *check_activity* command to check if a pin is in X, Z, unannotated, or unconnected states in the VCD/FSDB file. The command can only be used in the time-based power analysis. This command updates the "activity_checker_status" attribute on the pin.

If the initial state of a pin is not annotated, the pin is simply reported as unannotated.

All constant pins (connected to constant logic including TieHI and TieLO cells) are reported as Pass.

Similarly, internal pins of a cell are also marked as Pass. For example, in case of an ICG cell, the output pin of the latch is directly connected to an AND gate inside the ICG hierarchical cell. This internal pin is marked as Pass by the activity checker.

Any unconnected pin which does not have a driver is marked as unconnected by the checker.

If a pin has X value in time (0, 30), then switches to Z in time (30, 60), the initial state of the pin is always used and reported in summary as X. The final Z value is not used for reporting.

Also, activity checker only checks for events in the time interval specified during "read_vcd" command. If VCD/FDSB is partially read, then activity checker can only report status for events during that period.

So, for example, when you read events in (0, 30) time interval using the "read_vcd" command. The pin status is initialized as 'X' in VCD. Therefore, the activity checker only knows about the pin status and reports it as 'X' for the period.

It might be possible that the pin state later changes to Z at 40 ns and remains at Z until end of VCD. After reading events for period "0 - 30 ns", it is not possible to know if the pin state ever changes in the rest of VCD/FSDB. So, activity checker reports the current output of pin as 'X' from (0, unknown) after reading events from "0 - 30 ns". This simply means the pin never changed state during the time interval specified in "read_vcd".

Examples

The following examples show how to use activity checker in PrimePower.

The following example reads a VCD file mini.vcd from the disk and uses the first 30 time unit of the events in the file. If the time unit is ns, this command reads first 30 ns of events from VCD.

```
pwr_shell> read_vcd $test_dir/mini.vcd  -strip_path testmini/mini -time
 {0 30} -rtl
```

```
============================================================================
Summary:
Total number of nets = 9
Number of annotated nets = 8 (88.89%)
Total number of leaf cells = 4
Number of fully annotated leaf cells = 4 (100.00%)
============================================================================

Information: Total number of synthesis invariant points = 6 ,
annotated synthesis invariant points = 6, annotation_ratio = 100.00%
1
```

The following example shows how to use the activity checker after reading "mini.vcd" from the previous command. The summmary report shows one pin (q) in X state, and one pin in Z state (in2), while the rest of the pins are in Pass state during (0 - 30 ns) time period.

The detailed report shows that "in2" pin becomes Z at 10 ns and then stays at Z until 30 ns, while "q" pin started with X state and never changed state during (0, 30) time period.

```
pwr_shell> check_activity
[get_pins -of_object [get_cells * -hier -filter "is_hierarchical ==
 false"]]

check_constraints

Checks constraints of the current design and reports potential problems.

Syntax

int *check_constraints*

```
[-verbose]
```

Arguments

`-verbose`

Print verbose report of constraint errors.

Description

Invokes constraint consistency to check constraints of the current design for potential problems.

Feedback

Examples

The following example shows a constraint checking report:

```
pt_shell> check_constraints -verbose

---

check_eco

Reads in the LEF/DEF or IC Compiler II physical library and design information and checks the data for correctness and consistency with the logical netlist.

Syntax

```
status check_eco
```

Arguments

None

Description

The *check_eco* command reads physical library and design files in either LEF/DEF or IC Compiler II format as previously specified by the *set_eco_options* command, and checks the data for correctness and consistency with the logical netlist previously read by the *read_verilog* command.

The *check_eco* command reports any errors, warnings, or missing LEF macros in the log file specified by the *set_eco_options* command. Be sure to resolve any reported errors. See the man pages for the reported error codes as needed. After you fix the errors, rerun *check_eco* to repeat the checking process.

If physical LEF or DEF files are missing, you can run *reset_eco_options* to reset the previous *set_eco_options* settings. Then you can specify all physical information files with *set_eco_options* and rerun *check_eco*.

A successful *check_eco* run loads the physical information in PrimeTime. Subsequent physically aware ECO commands (*fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power*) operate on the physical information in memory; they do not reload the physical information.

To view the chip layout in the GUI, choose Window > Layout Window. This opens a new layout window showing any ECO changes. From this window, you can perform further ECO operations manually using the following commands:

```
ECO > Insert Buffer
ECO > Size Cell
ECO > Remove Buffer
ECO > Create Placement Blockage
```

You can also display color-coded maps using the following commands:

```
View > Map > Cell Density
View > Map > Pin Density
View > Map > Cell Power Density
```

PrimeECO flow

In the context of the PrimeECO physical signoff closure flow, the *check_eco* command performs designated tasks. In that flow, you must specify the following information:

```
set_eco_options \\
  -physical_icc2_lib my_NDM \\
  -physical_icc2_blocks CPU_after_route

set_implement_options \\
  -icc2_exec icc2_shell \\
  -starrc_exec StarXtract
```

PrimeECO enables incremental ECO operation by keeping the PrimeTime-ECO, IC Compiler II, and StarRC tools synchronized. For that purpose, the *check_eco* command does the following:

- Invokes IC Compiler II to load a working view of the design block specified by the *set_eco_options -physical_icc2_block* option, and starts recording ECO changes
- Reads physical data to enable physically aware optimization by *fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power*
- If StarRC incremental extraction is enabled, runs full extraction with StarRC to establish a baseline for subsequent incremental extraction

For more details about the PrimeECO flow, see the man page for the *implement_eco* command.

Examples

The following script specifies the physical library and design data in LEF/DEF format. The *check_eco* command loads the physical data and checks it for correctness and consistency with the logical netlist. The *gui_start* command opens the GUI main window, from which you can use the Window > Layout Window command to display any physical ECO changes.

```
set_eco_options \\
  -physical_tech_lib_path LEF_tech_file_list \\
  -physical_lib_path LEF_lib_file_list \\
  -physical_design_path DEF_design_file_list
check_eco
gui_start
```

Feedback

The following script specifies the physical library and design data in IC Compiler II format, loads and checks the physical data, and starts the GUI.

```
set_eco_options \\
  -physical_icc2_lib icc2_lib_directory_path \\
  -physical_icc2_blocks icc2_block_name_list
check_eco
gui_start
```

---

check_level_shifters

Alias for the *check_timing -override_defaults {signal level}* command.

Syntax

string *check_level_shifters*

```
[-verbose]
```

Arguments

`-verbose`

Prints a detailed report of all possible violations.

Description

In PrimeTime, the *check_level_shifters* command is an alias for:

```
check_timing -override_defaults {signal_level}
```

See Also

- check_timing

Feedback

check_noise

Checks that the necessary data is available to run the *update_noise* command.

Syntax

int *check_noise*

```
[-verbose]
[-beyond_rail]
[-nosplit]
[-include noise_driver | noise_immunity]
```

Arguments

`-verbose`

Enables verbose mode showing detailed information and pin names; shows cell and pin names that have no model or invalid models.

`-beyond_rail`

Enables beyond_rail noise analysis check. By default, *check_noise* performs only within_rail analysis.

`-nosplit`

Prevents line-splitting and facilitates writing software to extract information from the report output, because most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

`-include noise_driver | noise_immunity`

Specifies one of the following types of checking: *noise_driver* and *noise_immunity* (the default).

Description

It is possible to have invalid noise models in a library and run noise analysis without detecting them. This might result in inaccurate results. If the design is large, and it takes a long time to finish the noise analysis, it also causes longer turnaround time. Moreover, it is very important that all pins in the design have correct noise immunity information. Otherwise, when the noise analysis is over, violations are not reported even if noise bumps are large enough to create violations.

To validate the correctness of a design with respect to the noise analysis, run the *check_noise* command before performing noise analysis. It checks any invalid noise model, any pin without a model from the library, and the design. It checks if all pins in the design are 'noise constrained', for example, so their noise immunity can be calculated.

The command might produce different results before and after *update_timing*. For example, case analysis can disable noise models, and pins can be unconstrained after *update_timing*. It is recommended that you run the *check_noise* command after *update_timing* to consider design context.

Examples

The following example shows the noise immunity check.

```
pt_shell> check_noise

  Noise immunity type            above_low  below_high
  ------------------------------------------------------
  user hyperbolic curve                  8           8
  user margin                            1           1
  library immunity table                 0           0
  library hyperbolic curve               0           0
  library CCS noise immunity          3245        3245
  none                                   0           0
```

The following example shows the noise driver check.

```
pt_shell> check_noise -include "noise_driver"

Noise driver check:

  Noise driver type              above_low    below_high
  ------------------------------------------------------
  CCS noise                            520         520
  library IV curve                     121         121
  library resistance                     0           0
  equivalent library pin                 1           1
  user resistance                        1           1
  none                                   1           1
```

The verbose mode shows which pin is not constrained.

```
pt_shell> check_noise -include "noise_driver" -verbose

Noise driver check:

  library pin name                             Region           Status

 ------------------------------------------------------------------------
----
  top/inv1/Z                                   above_low        None

  Noise driver type              above_low    below_high
  ------------------------------------------------------
  CCS noise                            520         520

---

check_power

Shows possible power problems for design and specific cell object_list.

Syntax

string *check_power*

```
[-verbose]
[-significant_digits digits]
[-override_defaults check_list]
[-include check_list]
[-exclude check_list]
[-max_fanout fanout]
[-max_slew   slew]
[-max_cap    cap]
[-max_delay  delay]
[object_list]
```

Data Types

```
digits        integer
check_list    list
fanout        integer
slew          float
cap           float
delay         float
```

Arguments

`-verbose`

Shows detailed information about potential problems.

`-significant_digits digits`

Specifies the number of digits of precision to be displayed by warnings that show floating point numbers. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, whose default value is 2. Use this option if you want to override the default.

`-override_defaults` *check_list*

Overrides the checks in *power_check_defaults* variable with those listed in *check_list*. The allowed checks are:

```
no_arrival_window
no_base_clock
out_of_table_range
missing_table
missing_function
```

`-include` *check_list*

Adds the checks listed in *check_list* to the checks in *power_check_defaults*.

`-exclude` *check_list*

Subtracts the checks listed in *check_list* from the checks in *power_check_defaults*.

`-max_fanout` *fanout*

Specifies maximum fan-out limit for checking fan-out for each of driver nets.

`-max_slew` *slew*

Specifies maximum slew limit in library time units for checking slew for each of the input pins.

`-max_cap` *cap*

Specifies maximum capacitance limit in library cap units for checking capacitance for each of the driver nets.

`-max_delay` *delay*

Specifies maximum delay limit in library time units for checking delay for each of the arcs.

`object_list`

Accepts a collection of cell or library cell objects.

Description

The check_power command checks structure of the design for potential power violations. This command is used to identify possible power calculation problems before updating power or before generating power reports.

This command also prints which checks it performs. If a check reveals a violation, then the command also prints a message about the violation. By default, the message contains a summary of the violation. To get more information about violations, use the *-verbose* option.

This command without any options performs the checks defined by the *power_check_defaults* variable. To change the value of this variable, either redefine it or use the *-override_defaults* option. If the *-override_defaults* option is not used, the final list of checks to be performed is the checks in *power_check_defaults* plus the list of checks given by the *-include* option minus the list of checks given by the *-exclude* option. If the *-override_defaults* option is used with a check_list, the final list of checks to be performed is the checks in the check_list given by the option plus the list of checks given by the *-include* option minus the list of checks given by the *-exclude* option.

The alphabetically ordered list below shows the meaning of each check:

missing_function

Checks if library cells have function statements. The function statements are used during toggle propagation and event simulation.

missing_table

Checks if library cells have leakage power tables and dynamic power tables.

no_arrival_window

Checks whether pins have arrival window or not. This check helps to generate accurate cycle-based average waveform, zero delay VCD power analysis, and RTL VCD power analysis. In order to save the arrival windows user should set the variable timing_save_pin_arrival_and_slack to true before update_timing/ update_power. Users seeing this violation are directed to check if timing is correct by using the *check_timing* command.

no_base_clock

Checks whether nets have power base clock or not. During updating power, the fastest clock is used as power base clock for these nets that do not have power base clock. However, this exposes some potential accuracy problem. Users seeing this violation are directed to check if timing is correct by using the *check_timing* command.

out_of_table_range

Checks if there are out-of-range ramp or load violations when looking up power tables for each cells. The out of range values together with cell name, pin name, and library cell name and its range is displayed if the "-verbose" option is used.

Examples

The following example sets maximum slews as 0.4, maximum capacitance as 0.25, maximum delay as 0.2 and maximum fan-out as 200 and shows detailed information on potential problems in the design.

```
pt_shell> check_power -max_slew 0.4 -max_cap 0.25 -max_delay 0.2
 -max_fanout 200 -verbose
```

---

check_routes

Verifies and reports routing design rule checking (DRC) violations, net opens, antenna rule violations, voltage-area rule violations, and via conversion rates.

Syntax

```
status check_routes
```

Arguments

None

Description

This command verifies, checks, and reports routing statistics for the current design block. Only signal routes are included in the check; PG routes are ignored.

The PrimeECO *check_routes* command works like the *check_routes* command in IC Compiler II with the default command options. For details, see the IC Compiler II man page for the *check_routes* command.

Examples

The following example reports physical routing DRC violations for all nets in the block.

```
prompt> check_routes

  ...

DRC-SUMMARY:
  @@@@@@@ TOTAL VIOLATIONS = 94
  Diff net spacing : 42
  Edge-line via spacing : 1
  End of line spacing : 3
  Fat wire via keepout enclosure : 48
```

check_rtl_power

Checks for potential redundancies or issues in RTL design.

Syntax

status *check_rtl_power*

```
[-check_type rtl_check_list]
[-check_group group_list]
[-topN number]
[-level number]
[-csv csv_file]
[-root hier_cell_list]
[-hier hier_cell_list]
[-exclude_hier hier_cell_list]
[-clock clock_list]
[-file file_list]
[-verbose]
[-parent_reference]
[object_list]
```

Data Types

```
rtl_check_list    list
group_list        list
number            number
csv_file          string
hier_cell_list    list
clock_list    list
file_list    list
```

Arguments

`-check_type rtl_check_list`

Specifies the rtl checks to be performed on the design.

Check group type Lint checks

ClockGating CICG, FICG, RICG, SCECG, UCGREG, UCNREG, IFRREG, INSREG, BTHREG, CCGREG and XORREG

ConstantInput ENHREG and ENLREG

SeqOpt DUPREG, CNDREG, CNRREG, UNOREG, CNDLCH, CNELCH and UNOLCH

Memory MCCG, UCGMEM, CGPMEM, ENHMEM, ENLMEM and ODCMEM

Glitch OPRMUX and OPRDPT

By default all checks are performed.

`-check_group` *`group_list`*

Report all the lint checks belonging to the specified group list. Allowed values are : ClockGating, ConstantInput, SeqOpt, Memory, Glitch.

`-topN` *`number`*

When used with verbose mode, print only this number of violations for each tag. Useful to limit the file size for designs with a large violation count.

`-level` *`number`*

Specifies the depth (n) for reporting registers with clock enable depth > n or operators with input depth difference > n. By default depth > 5 are reported.

`-csv` *`csv_file`*

This option specifies that the report is written out in a comma-separated value format. The *csv_file* specifies the csv file name for the report.

`-root` *`hier_cell_list`*

Report lint checks only for the cells inside the specified hierarchical cells.

`-hier` *`hier_cell_list`*

Report lint checks only for the cells inside the specified hierarchical cells.

`-exclude_hier` *`hier_cell_list`*

Skip lint checks for the cells inside the specified hierarchical cells.

`-clock` *`clock_list`*

Report lint checks only for the cells that belong to specified clock domains.

`-file` *`file_list`*

Report lint checks only for the cells originating from specified rtl files.

`-verbose`

Specifies to display detailed report

`-parent_reference`

Report the file name and line number for the parent hierarchy along with the file name and line number of the cell. This option can be provided only if the -verbose option is enabled.

Description

The *check_rtl_power* command flags off the potential redundancies and issues in RTL design. It generates detailed instance level report when *-verbose* option is given.

User can specify one or more checks through *-check_type* option. The following types of check are supported :

- *CICG* - Constant ICG inputs i.e at least one of EN or CLK pins of ICG is tied to high/low. Specify using *-check_type constant_icg*.
- *FICG* - Floating ICG i.e ICG output is not driving any cell. Specify using *-check_type floating_icg*.
- *RICG* - Redundant cascaded ICGs. Specify using *-check_type redundant_icg*.
- *SCECG* - ICGs having common enable and clock. Specify using *-check_type same_clock_enable_cg*.
- *DUPREG* - Duplicate registers i.e. registers having common data and clock. Specify using *-check_type duplicate_reg*.
- *UCGREG* - Ungated register count. Specify using *-check_type UCGREG*.
- *UCNREG* - Untraced register count. Specify using *-check_type UCNREG*.
- *IFRREG* - Inferred only gated register count. Specify using *-check_type IFRREG*.
- *INSREG* - Instantiated only gated register count. Specify using *-check_type INSREG*.
- *ENHREG* - Registers with tied-high clock enables. Specify using *-check_type ENHREG*.
- *ENLREG* - Registers with tied-low clock enables. Specify using *-check_type ENLREG*.
- *CCGREG* - Registers with clock enable depth > n. Specify using *-check_type CCGREG -level n*. Default value of n is 5.
- *XORREG* - Registers with XOR based self gating. Specify using *-check_type XORREG*.
- *UCGMEM* - Ungated memory clock ports. Specify using *-check_type UCGMEM*.

- *CGPMEM* - Clock-gated memory clock ports. Specify using *-check_type CGPMEM*.
- *ENHMEM* - Memories with tied-HIGH enables. Specify using *-check_type ENHMEM*.
- *ENLMEM* - Memories with tied-LOW enables. Specify using *-check_type ENLMEM*.
- *CNDREG* - Number of registers optimized due to DATA constant. Specify using *-check_type CNDREG*.
- *CNRREG* - Number of registers optimized due to RESET constant. Specify using *-check_type CNRREG*.
- *UNOREG* - Number of registers optimized due to OUTPUT unused. Specify using *-check_type UNOREG*.
- *CNDLCH* - Number of latches optimized due to DATA constant. Specify using *-check_type CNDLCH*.
- *CNRLCH* - Number of latches optimized due to RESET constant. Specify using *-check_type CNRLCH*.
- *UNOLCH* - Number of latches optimized due to OUTPUT unused. Specify using *-check_type UNOLCH*.
- *BTHREG* - Inferred & Instantiated gated register count. Specify using *-check_type BTHREG*.
- *ODCMEM* - Memories with ODC Condition. Specify using *-check_type ODCMEM*.
- *OPRMUX* - Operators with mux driving the input. Specify using *-check_type OPRMUX*.
- *OPRDPT* - Operators with input depth difference > n. Specify using *-check_type OPRDPT -level n*. Default value of n is 5. -

User can specify one or more check group type through *-check_group* option to report all lint checks belonging to it. The following types of check groups are supported (along with the lint checks) :

- *ClockGating* - Report for Lint Checks : CICG, FICG, RICG, SCECG, UCNREG, UCGREG, IFRREG, INSREG, BTHREG, CCGREG, XORREG.
- *ConstantInput* - Report for Lint Checks : ENHREG, ENLREG.
- *SeqOpt* - Report for Lint Checks : DUPREG, CNDREG, CNRREG, UNOREG, CNDLCH, CNELCH, UNOLCH.
- *Memory* - Report for Lint Checks : MCCG, UCGMEM, CGPMEM, ENHMEM, ENLMEM, ODCMEM.
- *Glitch* - Report for Lint Checks : OPRMUX, OPRDPT.

check_script

Statically check a script using the a static Tcl syntax checker based on TclPro Procheck and the Synopsys checking extensions for this tool.

Syntax

string *snpsTclPro::check_script* [-no_tclchecker_warning]

[-quiet] [-onepass] [-verbose] [-suppress *messageID*] [-application *appName*] [-W1] [-W2] [-W3] [-Wall] *filePattern*

```
string messageID
string appName
string filePattern
```

Arguments

`-no_tclchecker_warning`

Don't warn that TclDevKit cannot be found

`-quiet`

prints minimal error information

`-onepass`

perform a single pass without checking proc args

`-verbose`

prints summary information

`-suppress messageIDs`

prevent given messageIDs from being printed

`-application appName`

Check script against application other than this one

`-W1`

print only error messages

`-W2`

print only error and usage warnings

`-W3`

print all errors and warnings

`-Wall`

print all types of messages (same as W3)

`filePattern`

file(s) to be checked

USING THE PACKAGE

The *check_script* command is in the snpsTclPro Tcl package, and all of the commands in this package are defined in the namespace snpsTclPro. The way to use this command is to load the package, which will import the commands it exports into the global namespace. This is shown below.

```
shell> package require snpsTclPro
1.0
```

These commands can be added to the .synopsys setup file for the system, user, or current directory, or the commands can be typed when the package is needed.

Description

The *check_script* command simplifies running the TclDevKit tclchecker program. This application is available for purchase from ActiveState (http://www.activestate.com). If the TclDevKit is not available then there is a limited Synopsys Tcl syntax checker that is used by this command. The Synopsys version of this code does not understand Tcl8.4 constructs, and some other checking is limited.

These checkers will check builtin Tcl commands, as well as the Synopsys extension commands which are found in the script. *check_script* will locate the Synopsys checking extensions for the application and will then invoke the checker. The limited checker does not require any external license. It is part of the Synopsys installation.

The *check_script* command will raise a Tcl error if the checker detects errors in the scripts being checked.

The *check_script* command is provided as a convenience to streamline the use of the syntax checker within Synopsys applications. The checker can also be called directly on scripts, without requiring a license for the Synopsys application whose script is being checked. This checker script is available in the auxx/tcllib/bin/check_script in the installation directory of your application. When run standalone the -application option must be specified.

Synopsys Checker Extensions

The Synopsys extensions to the TclPro checker define a number of new warnings and errors. These messages are listed below, along with a short explanation of them.

Feedback

Error *MisVal*

An option to a command which requires a value is missing its value.

Error *MisReq*

A required option or argument was not specified.

Error *Excl*

Two options which are mutually exclusive were both specified.

Error *ExtraPos*

An extra positional argument was specified to a command.

Error *BadRange*

The value specified for a given argument was outside of the legal range.

Error *UnkCmd*

The command specified is not known by the application.

Error *UnkOpt*

The specified option is not legal for the command.

Error *AmbOpt*

The option specified is not complete and matches 2 or more options for the command.

Warning *NotLit*

This warning indicates that the argument specified to an option was not a literal and therefore could not be checked. This message is suppressed by default. It can be enabled by setting the environment variable SNPS_TCL_NOLITERALWAN to true.

Warning *DupIgn*

An option was specified multiple times to the command, and the first value specified will be the one used. The other values will be ignored.

Warning *DupOver*

An option was specified multiple times to the command, and the last value specified will be the one used. The other values will be ignored.

check_signal_em

performs signal nets electromigration analysis

Syntax

status *check_signal_em*

```
[net_list]
-skip_filter
```

Data Types

```
net_list      list
```

Feedback

Arguments

net_list

The nets list to perform signal electromigration analysis. If the list is empty, all signal nets are checked.

-skip_filter

Skip fast filtering step. The command has two major steps. The first one is faster filtering step. This step identifies signal nets which may have EM violations, then pass these nets to step 2. The second step performs detailed EM analysis and prepares analysis result for *report_signal_em_violation* command. This option skips the faster filtering step, then all signal nets will perform detail EM analysis.

Description

The command performs electromigration analysis on given signal nets. Electromigration analysis is used to determine whether the current density at a location in the circuit exceeds the defined electromigration rule limits. The current density limits are intended to control the risk that current-carrying geometries is degraded by excessive current flow. High current densities damage the wires and damaged current-carrying wires can ultimately lead to shorts and opens within the metal, causing circuit failure.

Note that you must set variable *power_enable_signal_em_analysis* to TRUE before *check_signal_em* and *read_parasitics* command.

The foundries set the current density limit rules of their related metallurgy to ensure reliability. Before you run this command, you must load electromigration rule file by *read_signal_em_rules* command. See the *read_signal_em_rules* man page for more details.

The command gets signal net geometries from tail comments of parasitics netlist written by StarRC. Before you run this command, you must load signal net parasitics by *read_parasitics* command. It is recommended to use *-format SPEF* of *read_parasitics*, since it has better tail comment support.

To output SPEF parasitics netlist for signal electromigration analysis, the recommend StarRC options are listed below:

```
EXTRACTION: RC
REDUCTION: NO
NETS: *
NETLIST_CONNECT_OPENS: !*
NETLIST_NODE_SECTION: YES
NETLIST_TAIL_COMMENTS: YES
EXTRA_GEOMETRY_INFO: NODE RES
SHORT_PINS: NO
KEEP_VIA_NODES: YES
EM_EXTARCTION: YES
```

Feedback

You can use *set_signal_em_analysis_options* command to set options of signal electromigration analysis. Refer to *set_signal_em_analysis_options* man page for option details.

You can use *report_signal_em* command to report signal electromigration violations. Refer to *report_signal_em* man page for more details.

Examples

The following command invokes signal em analysis for all signal nets.

```
pt_shell> check_signal_em
```

The following command invokes signal electromigration analysis for net net001.

```
pt_shell> check_signal_em {net001}
```

---

check_timing

Reports possible timing problems in the design.

Syntax

string *check_timing*

```
[-verbose]
[-significant_digits digits]
[-ms_min_separation delta]
[-override_defaults check_list]
[-include check_list]
[-exclude check_list]
[-sms_scenarios sms_scenarios_list]
```

Data Types

digits	int
delta	float
check_list	list
sms_scenarios_list	collection

Arguments

`-verbose`

Shows detailed information about potential problems.

`-significant_digits` *`digits`*

Specifies the number of digits of precision to be displayed by warnings that show floating point numbers. Allowed values are 0-13. The default is determined by the *report_default_significant_digits* variable, which has a default of 2. Use this option if you want to override the default.

`-ms_min_separation` *`delta`*

Minimum separation value between master and slave clocks. The default minimum separation is 0.0.

`-override_defaults` *`check_list`*

Overrides the checks in the *timing_check_defaults* variable using the *check_list* option. For default information, see the *timing_check_defaults* man page.

`-include` *`check_list`*

Adds the checks specified in the *check_list* to the checks in *timing_check_defaults* variable.

`-exclude` *`check_list`*

Subtracts the checks specified in the *check_list* from the checks in *timing_check_defaults* variable.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only timing problems related to the specified SMS scenarios collection are reported. This option is supported only with *operating_conditions* check. This collection is created by *get_sms_scenarios* command.

Description

Checks the assertions and structure of the design for potential timing violations. This command is used to identify possible problems before generating timing or constraint reports.

This command also prints which checks it performs. If a check reveals a violation, the command also prints a message about the violation. By default, the message contains a summary of the violation. To get more information about violations, use the *-verbose* option.

This command without any options performs the checks defined by the *timing_check_defaults* variable. To change the value of this variable, either redefine it or use the *-override_defaults* option. If the *-override_defaults* option is not used, the final list of checks to be performed is the checks in the *timing_check_defaults* variable plus the list of checks given by the *-include* option minus the list of checks given by the *-exclude* option. If the *-override_defaults* option is used with a *check_list*, the final list of checks to

be performed is the checks in the *check_list* given by the option plus the list of checks given by the *-include* argument minus the list of checks given by the *-exclude* argument.

You can specify the following checks in the *check_list* argument:

- *clock_crossing* - Checks clock interactions when there are multiple clock domains. If a clock launches one or more paths, which are captured by other clocks, it is listed in clock crossing report. If all paths between two clocks are false paths or they are exclusive/asynchronous clocks, the path is marked by *. If only part of paths are set as false paths or exclusive/asynchronous clocks, the path is marked by #.
- *data_check_multiple_clock* - Warns if multiple clocked signals reach a data check register reference pin. The analysis is performed for each of the clocked domain separately.
- *data_check_no_clock* - Warns if no clocked signal reaches a data check register reference pin. In this case, no setup or hold checks are performed on the constrained pin.
- *generated_clocks* - Checks generated clock network. The master must be driven by a clock source. There cannot be loops of generated clocks. For example, the source of generated clock CLK1 cannot be used to generate clock CLK2 if CLK2 also is used to generate CLK1. Also checks for muxes with clock propagated to both input and select pins. It is possible to stop clock signals from propagating through the mux select pin by using: set_sense -stop_propagation[get_pin $select_pin]
- *generic* - Warns about generic (unmapped) cells in the design. The timing of paths through generic cells is inaccurate because generic cells have zero delay.
- *ideal_clocks* - Shows the clocks that are not defined as propagated using the *set_propagated_clock* command. Generally, all clocks should be propagated so that the clock network timing is accurately calculated. Especially, in presence of crosstalk, the delay changes induced by other nets on the clock network are not reflected in the calculated slacks in the design.
- *latch_fanout* - Checks fanout of level-sensitive latches. A warning is issued if a level-sensitive latch fans out to itself. An information message also appears for a latch that fans out to a latch of the same clock (PHI1 to PHI1 path).
- *latency_override* - Warns of clock latency specification conflicts. If clock source latency is defined for both a clock and its port (source pin), the source latency for clock object is ignored. If input_delay is set on clock port, which also has source latency specified, the input_delay is ignored as a source latency. Also warns if more than one clock latency fan out to any latch clock pin.
- *loops* - Warns of nonconstant combinational feedback loops. Combinational feedback loops are not analyzed. If the feedback loop is not broken by *set_disable_timing*, it is automatically broken by disabling one or more timing arcs.

- *constant_loops* - Warns of constant combinational feedback loops. A constant combinational feedback loop is a loop where all the pins in the loop have a case value 0, 1, or S. Combinational feedback loops are not analyzed. If the feedback loop is not broken by *set_disable_timing*, it is automatically broken by disabling one or more timing arcs.
- *ms_separation* - Checks minimum separation of master and slave clock pulses on master/slave latches.
- *no_clock* - Warns if no clock reaches a register clock pin. In this case, no setup or hold checks are performed on data pins related to that clock pin, and the path starting at the clock pin is not relative to a clock.
- *no_driving_cell* - Warns if a port does not have any driving cell. This warning is issued only when the net connected to the port has parasitics. In such case, the accuracy of delay calculation could be affected, as a default strong driver is assumed in absence of driving cell definition. Especially, in presence of crosstalk, a port with no driving cell could act as a strong aggressor which could lead to significant amount of pessimism in the analysis. Also, a port with no driving cell could act as a string victim, which could underestimate the crosstalk effect.
- *no_input_delay* - Warns if no clock related delay specified on an input port, where it propagates to a clocked latch or output port. With *-verbose*, the port name is listed.
- *operating_conditions* - When the design has scaling groups defined by the *define_scaling_lib_group* command, this operating condition check detects improperly set process, voltage, temperature, rail, and operating conditions. Warning are issued for
  - Extrapolation outside the PVT rail operating condition range covered by the scaling group.
  - If *-exact_match_only* is specified in the *define_scaling_lib_group* command, it warns on exact-match failures when the design cell instance operating condition does not match with any of the corner library operating condition.
  - When a design cell instance does not have an associated scaling group, it warns when the operating condition does not match with that of the linked library operating condition.
- *partial_input_delay* - Warns if any port has partially defined input delay. This happens when *set_input_delay -min* is applied on a port to set the min input delay with respect to a clock, however no *set_input_delay -max* is applied to that port to specify the max delay, or vice versa. As a result, some paths starting from the port with partially defined input delay might become unconstrained and some potential violations could be missed.

- *pll_configuration* - Warns if a problem is detected in the configuration of any phase locked loop (PLL) cells. For a PLL to be correctly configured, the PLL output clock should reach the PLL feedback pin. If a PLL is not correctly configured, it does not show any phase adjustment on the PLL output clock.
- *pulse_clock_no_pulse_generator* - Warns if the pulse clock constraints cannot be honored. This could be because pulse clock constraints have been set on clocks that do not drive pulse generators, or the design might not have any pulse generators.
- *pulse_clock_non_pulse_clock_merge* - Warns if pulse clock and normal clock propagate to the same network.
- *retain* - Warns if any of the RETAIN values is larger than its corresponding delay value. The RETAIN values should be less than their corresponding delay values so that they be considered for hold violations. Otherwise, they might be considered for setup violations.
- *signal_level* - Checks that the driver signal level matches the load signal level. The signal levels are determined from the cell specific operating conditions and rail voltages (or UPF), and from the following library attributes: input_signal_level, output_signal_level, input_voltage, output_voltage. The check is performed on all input pins that have input_voltage defined in the timing library. If the driver pin does not have output_voltage defined in the library then the voltage of the rail powering the driver pin is used as the output signal level. With PG libraries the signal level is determined from input/output_signal_level_high (exact voltage in .lib) first, then input/output_signal_level (reference to voltage_map in .lib) if the related_power_pin uses a different_voltage map, and finally from the instance specific voltage of the related power PG pin. If the load pin does not have input_voltage then matching is done based on driver and load rail voltages. Such matching (without library attributes input/output_voltage) is subject to tolerances set by *set_level_shifter_threshold* and *set_level_shifter_strategy* commands. By default the number of mismatches is reported. With *-verbose* the mismatching driver, load and voltage difference are reported.
- *supply_net_voltage* - Checks that each segment of UPF supply nets has voltage assigned to it by *set_voltage* command. It warns about mismatching voltage between port supply voltage against port driving cell voltage. It also warns about mismatching port supply against visible logic. The port supply refers to port supply attributes specified on port objects through the *set_port_attributes* command.
- *unconnected_pg_pins* - Checks that each power and ground pin is connected to a UPF supply net. The connection can be implicit (for example, power domain) or explicit (for example, *connect_supply_net*).
- *unconstrained_endpoints* - Warns about unconstrained timing endpoints. This warning identifies timing endpoints (output ports and register data pins) that are not constrained for maximum delay (setup) checks. To be reported as unconstrained, the endpoints must have a valid timing signal arriving at it. In this context, a valid timing signal

is one that has a valid launch clock and is not a user-designated false path. If the endpoint is a register data pin, it can be constrained by using *create_clock* for the appropriate clock source. You can constrain output ports using the *set_output_delay* or *set_max_delay* commands.

- *no_arrival_endpoints* - Warns about timing endpoints (output ports and register data pins) that have a valid clocked constraint requirement but no valid timing signal to capture. In this context, a valid timing signal is one that has a valid launch clock and is not a user-designated false path.
- *unexpandable_clocks* - Warns if there are sets of clocks for which periods are not expandable with respect to each other. The checking is only done for the related clock domains, such as ones where there is at least one path from one clock domain to the other. This could be because of an incorrectly defined clock period for one or more of the clocks. Another possibility is when asynchronous clocks with unexpandable periods are interacting where they should have been defined in different clock domains.
- *supply_net_without_associated_supply_port* - Warns if there are supply nets without an associated supply port.
- *dangling_startpoints* - Warns about network startpoints which are inactive from a timing point of view (i.e. electrically inactive). This excludes cases where the inactivity is due to *set_disable_timing* or an unclocked register. Examples of such startpoints include: pins without backward arcs, hierarchical pins without fanin nets, input ports without input delays.
- *voltage_level* - Performs the same checks as the *operating_conditions* check, along with the following additional check:
  - If DCALM (*define_cell_alternative_lib_mapping*) is used, it warns of mismatches between the library voltage expected by the DCALM specification and the actual voltage supplied by the *set_voltage* supply specification.

Examples

The following example checks timing of the current design and shows summary information of potential problems. The checks performed are those defined by *timing_check_defaults*.

```
pt_shell> check_timing

Information: Checking 'no_clock'.
Warning: There are 4 register clock pins with no clock.

Information: Checking 'no_input_delay'.

Information: Checking 'unconstrained_endpoints'.
Warning: There are 10 endpoints which are not constrained for maximum
 delay.
```

```
Information: Checking 'generic'.

Information: Checking 'latch_fanout'.
Warning: There are 2 level-sensitive latches which fanout to themselves.
Information: There are 2 level-sensitive latches which fanout to latches
 of the same clock.

Information: Checking 'loops'.
Warning: There are 6 timing loops in the design.

Information: Checking 'generated_clocks'.
```

The following example adds the *clock_crossing* check to the list of checks in *timing_check_defaults*.

```
pt_shell> check_timing -include {clock_crossing}

Information: Checking 'no_clock'.
Warning: There are 4 register clock pins with no clock.

Information: Checking 'no_input_delay'.

Information: Checking 'unconstrained_endpoints'.
Warning: There are 10 endpoints which are not constrained for maximum
 delay.

Information: Checking 'generic'.

Information: Checking 'latch_fanout'.
Warning: There are 2 level-sensitive latches which fanout to themselves.
Information: There are 2 level-sensitive latches which fanout to latches
 of the same clock.

Information: Checking 'loops'.
Warning: There are 6 timing loops in the design.

Information: Checking 'generated_clocks'.

Information: Checking 'clock_crossing'.

Information: Checking 'pll_configuration'.
```

The following example adds the *clock_crossing* check to the list of checks in *timing_check_defaults* and removes the *loops* check from the same list.

```
pt_shell> check_timing -include {clock_crossing} -exclude {loops}

Information: Checking 'no_clock'.
Warning: There are 4 register clock pins with no clock.

Information: Checking 'no_input_delay'.

Information: Checking 'unconstrained_endpoints'.
```

```
Warning: There are 10 endpoints which are not constrained for maximum
 delay.

Information: Checking 'generic'.

Information: Checking 'latch_fanout'.
Warning: There are 2 level-sensitive latches which fanout to themselves.
Information: There are 2 level-sensitive latches which fanout to latches
 of the same clock.

Information: Checking 'generated_clocks'.

Information: Checking 'clock_crossing'.
```

The following example removes the *retain* option from the list of checks in *timing_check_defaults*. Assuming that this check is not included in *timing_check_defaults*, there is nothing to remove. The output in this example is the same as running the command without the *-exclude* option.

```
pt_shell> check_timing -exclude {retain}

Information: Checking 'no_clock'.
Warning: There are 4 register clock pins with no clock.

Information: Checking 'no_input_delay'.

Information: Checking 'unconstrained_endpoints'.
Warning: There are 10 endpoints which are not constrained for maximum
 delay.

Information: Checking 'generic'.

Information: Checking 'latch_fanout'.
Warning: There are 2 level-sensitive latches which fanout to themselves.
Information: There are 2 level-sensitive latches which fanout to latches
 of the same clock.

Information: Checking 'loops'.
Warning: There are 6 timing loops in the design.

Information: Checking 'generated_clocks'.
```

The following example checks only latch fanout and shows detailed information.

```
pt_shell> check_timing -verbose -override_defaults {latch_fanout}
Warning: There are 2 level-sensitive latches which fanout to themselves.

Latch data pin
------------------------------------------------------------
l3/D
l4/D
```

```
Information: There are 2 level-sensitive latches which fanout to latches
 of the same clock.

From Pin            To Pin              Clock         Level
-------------------------------------------------------------------------
------
l1/G                l2/D                C1            positive
l1/G                l3/D                C1            positive
```

The following example gives a list of supply nets without associated supply port and shows detailed information.

```
pt_shell> check_timing -override
 supply_net_without_associated_supply_port
Information: Checking 'supply_net_without_associated_supply_port'.
Warning: There are '4' supply nets without associated supply port.
 (UPF-747)

close_drc_error_data

Closes a physical DRC error data collection.

Feedback

Syntax

```
status close_drc_error_data
drc_error_data
[-save]
[-force]
```

Data Types

```
drc_error_data        collection
```

Arguments

drc_error_data

Specifies the collection of physical DRC error data objects to close.

-save

Saves the pending changes in the exported physical DRC error data before closing the error data file.

The *-save* and *-force* options, are mutually exclusive; you can specify only one.

-force

Closes the specified collection of physical DRC error data, discarding any unsaved pending changes.

The *-save* and *-force* options, are mutually exclusive; you can specify only one.

Description

The *close_drc_error_data* command decrements the open count of the specified error data collection.

The tool increments the open count for an error data file each time you run the *open_drc_error_data* or *create_drc_error_data* command for the error data file. The tool decrements the open count for an error data file each time you run the *close_drc_error_data* command. The error data collection is removed from memory when the open count reaches zero.

If the error data has unsaved pending changes, the command fails unless you use the *-save* or *-force* option.

Examples

The following example opens the external physical DRC error data file named my_design_dppinassgn.err, and then closes it.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
```

Feedback

```
prompt> close_drc_error_data $data
1
```

---

collections

Describes the methodology for creating collections of objects and querying objects in the database.

Description

Synopsys applications build an internal database of objects and attributes applied to them. These databases consist of several classes of objects, including designs, libraries, ports, cells, nets, pins, clocks, and so on. Most commands operate on these objects.

By definition:

A collection is a group of objects exported to the Tcl user interface.

Collections have an internal representation (the objects) and, sometimes, a string representation. The string representation is generally used only for error messages.

Collections represent an ordered sequence of database objects. These collections provide constant time random access to the objects contained in the sequence.

A set of commands to create and manipulate collections is provided as an integral part of the user interface. The collection commands encompass two categories: those that create collections of objects for use by another command, and one that queries objects for viewing. The result of a command that creates a collection is a Tcl object that can be passed along to another command. For a query command, although the visible output looks like a list of objects (a list of object names is displayed), the result is an empty string.

An empty string "" is equivalent to the empty collection, that is, a collection with zero elements.

To illustrate the usage of the common collection commands, the man pages have examples. Most of the examples use PrimeTime as the application. In all cases, the application from which the example is derived is indicated.

Homogeneous and Heterogeneous Collections

A homogeneous collection contains only one type of object. A heterogeneous collection can contain more than one type of object. Commands that accept collections as arguments can accept either type of collection.

Lifetime of a Collection

Collections are active only as long as they are referenced. Typically, a collection is referenced when a variable is set to the result of a command that creates it or when it is passed as an argument to a command or a procedure. For example, in PrimeTime, you can save a collection of design ports by setting a variable to the result of the *get_ports* command:

```
pt_shell> set ports [get_ports *]
```

Next, either of the following two commands deletes the collection referenced by the *ports* variable:

```
pt_shell> unset ports
pt_shell> set ports "value"
```

Collections can be implicitly deleted when they go out of scope. Collections go out of scope for various reasons. An example would be when the parent (or other antecedent) of the objects within the collection is deleted. For example, if our collection of ports is owned by a design, it is implicitly deleted when the design that owns the ports is deleted. When a collection is implicitly deleted, the variable that referenced the collection still holds a string representation of the collection. However, this value is useless because the collection is gone, as illustrated in the following PrimeTime example:

```
pt_shell> current_design
{"TOP"}

pt_shell> set ports [get_ports in*]
{"in0", "in1"}

pt_shell> remove_design TOP
Removing design 'TOP'...

pt_shell> query_objects $ports
Error: No such collection '_sel26' (SEL-001)
```

Iteration

To iterate over the objects in a collection, use the *foreach_in_collection* command. You cannot use the Tcl-supplied *foreach* iterator to iterate over the objects in a collection, because the *foreach* command requires a list, and a collection is not a list. In fact, if you use the *foreach* command on a collection, it destroys the collection.

The arguments of the *foreach_in_collection* command are similar to those of foreach: an iterator variable, the collection over which to iterate, and the script to apply at each iteration. Note that unlike the *foreach* command, the *foreach_in_collection* command does not accept a list of iterator variables.

The following example is an iterative way to perform a query in PrimeTime. For more information, see the *foreach_in_collection* man page.

```
pt_shell> \\
foreach_in_collection s1 $collection {
  echo [get_object_name $s1]
  }
```

Manipulating Collections

A variety of commands are provided to manipulate collections. In some cases, a particular command might not operate on a collection of a specific type. This is application-specific. Consult the man pages from your application.

- *add_to_collection* - This command creates a new collection by adding a list of element names or collections to a base collection. The base collection can be the empty collection. The result is a new collection. In addition, the *add_to_collection* command allows you to remove duplicate objects from the collection by using the *-unique* option.
- *append_to_collection* - This command appends a set of objects (specified by name or collection) to an existing collection. The base collection is passed in through a variable name, and the base collection is modified directly. It is similar in function to the *add_to_collection* command, except that it modifies the collection in place; therefore, it is much faster than the *add_to_collection* command when appending.
- *remove_from_collection* - This command removes a list of element names or collections from an existing collection. The second argument is the specification of the objects to remove and the first argument is the collection to have them removed from. The result of the command is a new collection. For example, in PrimeTime:

  ```
  pt_shell> set dports \\
  [remove_from_collection [all_inputs] CLK]
  {"in1", "in2", "in3"}
  ```

- *compare_collections* - This command verifies that two collections contain the same objects (optionally, in the same order). The result is "0" on success.
- *copy_collection* - This command creates a new collection containing the same objects in the same order as a given collection. Not all collections can be copied.
- *index_collection* - This command extracts a single object from a collection and creates a new collection containing that object. The index operation is done in constant time - it

is independent of the number of elements in the collection, or the specific index. Not all collections can be indexed.

- *sizeof_collection* - This command returns the number of objects in a collection.

Filtering

In some applications, you can filter any collection by using the *filter_collection* command. This command takes a base collection and creates a new collection that includes only those objects that match an expression.

Some applications provide a *-filter* option for their commands that create collections. This allows objects to be filtered out before they are ever included in the collection. Frequently this is more efficient than filtering after the they are included in the collection. The following examples from PrimeTime filters out all leaf cells:

```
pt_shell> filter_collection \\
[get_cells *] "is_hierarchical == true"]
{"i1", "i2"}
pt_shell> get_cells * -filter "is_hierarchical == true"
{"i1", "i2"}
```

The basic form of a filter expression is a series of relations joined together with AND and OR operators. Parentheses are also supported. The basic relation contrasts an attribute name with a value through a relational operator. In the previous example, *is_hierarchical* is the attribute, **==** is the relational operator, and *true* is the value.

The relational operators are

```
==   Equal
!=   Not equal
>    Greater than
<    Less than
>=   Greater than or equal to
<=   Less than or equal to
=~   Matches pattern
!~   Does not match pattern
```

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only true or false.

Additionally, existence relations determine if an attribute is defined or not defined, for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
```

These operators apply to any attribute as long as it is valid for the object class. See the appropriate man pages for complete details.

Sorting Collections

In some applications, you can sort a collection by using the *sort_collection* command. It takes a base collection and a list of attributes as sort keys. The result is a copy of the base collection sorted by the given keys. Sorting is ascending, by default, or descending when you specify the *-descending* option. In the following example from PrimeTime, the command sorts the ports by direction and then by full name.

```
pt_shell> sort_collection [get_ports *] \\
{direction full_name}
{"in1", "in2", "out1", "out2"}
```

Implicit Query of Collections

In many applications, commands that create collections implicitly query the collection when the command is used at the command line. Consider the following examples from PrimeTime:

```
pt_shell> set_input_delay 3.0 [get_ports in*]
1
pt_shell> get_ports in*
{"in0", "in1", "in2"}
pt_shell> query_objects -verbose [get_ports in*]
{"port:in0", "port:in1", "port:in2"}
pt_shell> set iports [get_ports in*]
{"in0", "in1", "in2"}
```

In the first example, the *get_ports* command creates a collection of ports that is passed to the *set_input_delay* command. This collection is not the result of the primary command (*set_input_delay*), and as soon as the primary command completes, the collection is destroyed. The second example shows how a command that creates a collection automatically queries the collection when that command is used as a primary command. The third example shows the verbose feature of the *query_objects* command, which is not available with an implicit query. Finally, the fourth example sets the variable iports to the result of the *get_ports* command. Only in the final example does the collection persist to future commands until iports is overwritten, unset, or goes out of scope.

- as_collection

Feedback

compare_collections

Compares the contents of two collections. If the same objects are in both collections, the result is "0" (like string compare). If they are different, the result is nonzero. The order of the objects can optionally be considered.

Syntax

int *compare_collections*

```
[-order_dependent]
collection1
collection2
```

Data Types

collection1	collection
collection2	collection

Arguments

`-order_dependent`

Indicates that the order of the objects is to be considered; that is, the collections are considered to be different if the objects are ordered differently.

collection1

Specifies the base collection for the comparison. The empty string (the empty collection) is a legal value for the *collection1* argument.

collection2

Specifies the collection with which to compare to *collection1*. The empty string (the empty collection) is a legal value for the *collection2* argument.

Description

The *compare_collections* command is used to compare the contents of two collections. By default, the order of the objects does not matter, so that a collection of cells u1 and u2 is the same as a collection of the cells u2 and u1. By using the *-order_dependent* option, the order of the objects is considered.

Either or both of the collections can be the empty string (the empty collection). If two empty collections are compared, the comparison succeeds (that is, *compare_collections* considers them identical), and the result is "0".

Examples

The following example from PrimeTime shows a variety of comparisons. Note that a result of "0" from *compare_collections* indicates success. Any other result indicates failure.

```
pt_shell> compare_collections [get_cells *] [get_cells *]
0
pt_shell> set c1 [get_cells {u1 u2}]
{"u1", "u2"}
pt_shell> set c2 [get_cells {u2 u1}]
{"u2", "u1"}
pt_shell> set c3 [get_cells {u2 u4 u6}]
{"u2", "u4", "u6"}
pt_shell> compare_collections $c1 $c2
0
pt_shell> compare_collections $c1 $c2 -order_dependent
-1
pt_shell> compare_collections $c1 $c3
-1
```

The following example builds on the previous example by showing how empty collections are compared.

```
pt_shell> set c4 ""
pt_shell> compare_collections $c1 $c4
-1
pt_shell> compare_collections $c4 $c4
0
```

- collections

Feedback

compare_interface_timing

Compares two reports generated by the *write_interface_timing* command.

Syntax

```
int compare_interface_timing
ref_timing_file
cmp_timing_file
[-output file_name]
[-absolute_tolerance atol_list]
[-percent_tolerance ptol_list]
[-capacitance_tolerance ctol_list]
[-ignore ign_list]
[-include cmp_list]
[-quiet]
[-nosplit]
[-sort_by_worst]
[-session session_name]
[-significant_digits digits]
```

Data Types

ref_timing_file	string
cmp_timing_file	string
file_name	string
atol_list	list
ptol_list	list
ctol_list	list
ntol_list	list
ign_list	list
cmp_list	list
session_name	string
digits	int

Arguments

ref_timing_file

Specifies the name of the timing file to be used as the reference in the comparison.

cmp_timing_file

Specifies the name of the timing file to be compared to the reference timing file.

-output *file_name*

Specifies the name of the output file where the results of the comparison information is written. The information written to *file_name* specifies PASS/FAIL status for every parameter compared by the command.

By default, these results are written to the session transcript. All informational, warning, or error messages are still directed to the session transcript, even if this option is specified.

`-absolute_tolerance` *`atol_list`*

Specifies the absolute error tolerance for time data. The default is zero. See below for a description of the tolerance format. If you specify this option together with the *-percent_tolerance* option, both tolerances must be exceeded to cause a FAIL. See the *-capacitance_tolerance* options for other absolute tolerances.

`-percent_tolerance` *`ptol_list`*

This option is similar to the *-absolute_tolerance* option except that it uses the percent relative error instead of an absolute error. The exception is that slack data ignores this option and uses only the absolute tolerance. The default is zero.

See below for a description of the tolerance format. If you specify this option together with either the *-absolute_tolerance*, or *-capacitance_tolerance* option, both tolerances must be exceeded to cause a FAIL.

`-capacitance_tolerance` *`ctol_list`*

Specifies the absolute error tolerance for capacitance data. The default is zero.

See below for a description of the tolerance format. If you specify this option together with the *-percent_tolerance* option, both tolerances must be exceeded to cause a FAIL. *-noise_tolerance* options. For other absolute tolerances, see the *-absolute_tolerance* options.

`-ignore` *`ign_list`*

Specifies a list of categories of slack or arc data to be excluded from the comparison. The following list describes the valid values:

max - Excludes all max_rise and max_fall delay type arcs from the slack and transition_time sections. The capacitance section is not examined because it contains only maximum information.

min - Excludes all min_rise and min_fall delay type arcs from the slack and transition_time sections.

unconstrained - Excludes all paths that are unconstrained for both reference and compare data files.

pass - Excludes all passing comparisons, so only fails are displayed.

async_default - Excludes the comparison of paths in the async_default path group. This option is obsolete and is replaced by specifying the *recover* and *removal* values of the *-include* option.

clock_gating - Excludes comparison of paths with the clock_gating_default path group. This option is obsolete and is replaced by specifying the *clock_gating_setup* and *clock_gating_hold* of the *-include* option.

input_to_register - Excludes comparison of input-to-register paths. This option is obsolete and is replaced by specifying the *setup* and *hold* values of the *-include* option.

register_to_output - Excludes comparison of register-to-output path. This option is obsolete and is replaced by specifying the *max_seq_delay* and *min_seq_delay* of the *-include* option.

input_to_output - Excludes comparison of combinational paths. This option is obsolete and is replaced by specifying the *max_combo_delay* and *min_combo_delay* of the *-include* option.

`-include` *`cmp_list`*

Specifies a list of data sections from the *write_interface_timing* command output to be included in the comparison; only those sections are compared. By default, all sections are compared. The following list describes the keywords that are accepted in the *cmp_list* as valid:

slack - Specifies that only worst-case slacks are to be compared.

arc - Specifies that only arc values are to be compared.

transition_time - Specifies that only actual transition times on ports are to be compared.

capacitance - Specifies that only actual capacitances on ports are to be compared.

design_rules - Specifies that only design rules on ports are to be compared.

missing_arcs - Specifies that only arcs in the reference timing file that are missing from the compare timing file are to be included in the report. If it is used together with other sections, the report includes the intersection of *missing_arcs* and the other specified sections, not the union of them.

max_combo_delay - Specifies that only maximum combination delay arc type paths are to be reported.

min_combo_delay - Specifies that only minimum combination delay arc type paths are to be reported.

max_seq_delay - Specifies that only maximum sequential delay arc type paths are to be reported.

min_seq_delay - Specifies that only minimum sequential delay arc type paths are to be reported.

setup - Specifies that only setup arc type paths are to be reported.

hold - Specifies that only hold arc type paths are to be reported.

recovery - Specifies that only recovery arc type paths are to be reported.

removal - Specifies that only removal arc type paths are to be reported.

clock_gating_setup - Specifies that only clock gating setup arc type paths are to be reported.

clock_gating_hold - Specifies that only clock gating hold arc type paths are to be reported.

`-quiet`

Specifies an obsolete option. This option is now obsolete and has been replaced by the *-session quiet* option.

`-nosplit`

Prevents line-splitting. This is most useful for performing difference comparisons on previous scripts or for post processing the script.

`-sort_by_worst`

Specifies that the output is to be sorted from negative to positive, with the worst failure first. After the FAIL section, all PASS lines are sorted alphabetically within each path attribute. By default, the output follows the order of the reference write_interface_timing data, which is sorted alphabetically within each path attribute (c paths, i paths including a and g, then o paths).

`-session` *`session_name`*

Controls the information that is printed to the session transcript. Note that this option affects only the session transcript, not the information written to the output file. The following list describes the keywords that are accepted for *session_name*:

quiet - Prevents information, warning, and error messages from appearing in the session transcript. Use this option when you want to see only the success/failure return code without any MV messages. The *-session* option used with this keyword replaces the now-obsolete *-quiet* option.

summary - Prints only the summary pass/fail count to the session transcript.

full - Prints the detailed report either to the session transcript or to a file if you specify the *-output* option. This is the default behavior.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point that are to be reported following the method used in the *report_timing* command. Allowed

values are 0-13. The default is 2. Use this option if you want to override the default. See below for a more detailed description of significant digits.

Description

This command compares two interface timing files (called the "reference" and "comparison" files) previously generated by the *write_interface timing* command. The result is PASS if the timing parameter values in the two files are the same or within a specified tolerance. The result is FAIL if both columns have data and the tolerance is exceeded. If all comparisons in the report are PASS, the return code for the *compare_interface_timing* command is 0. If one or more comparisons result in FAIL, the return code is 1. Any other return code (or no return code) indicates a command error. If either file format does not conform to the *write_interface_timing* standard, the command issues a warning message.

The *compare_interface_timing* command lets you specify the input and output files for the comparison, the types of paths and timing parameters to compare or not compare, and the allowed tolerance levels that trigger comparison failures.

If the reference and comparison files were generated using different contexts then the two files might contain different timing arcs along with different slacks. If an arc exists in the comparison file but not in the reference file, the *compare_interface_timing* command ignores the extra arcs. If an arc exists in the comparison file but not in the reference file, the *compare_interface_timing* command reports the slack value for the reference file, but either "N.C." or "----" for the comparison file slack. The slack difference is marked as "----", and the status is FAIL. The comparison slack is marked as "----" if the arc is not clock gating or recovery or removal.

The slack for a missing arc is mark as "N.C.", meaning not critical, if it exists in the reference but not in the comparison file, and the arc type is clock gating or recovery or removal. These arcs fall into the **clock_gating_default** or **asynchronous_default** clock groups, respectively. Each of these groups can have several clocks in them, and under certain circumstances the *write_interface_timing* command sees the path to one clock as critical for the reference view and report that arc and slack, but another clock as critical in the comparison view and report that arc and slack.

The *compare_interface_timing* command deals with significant digits in two distinct ways. First, the internal computations are limited to the minimum precision of the two input files. This means that if the *ref_timing_file* was generated with three digits and the *cmp_timing_file* with four, the *compare_interface_timing* command uses three digits for all internal computations.

It is important to make the tolerances larger than a unit of the computational significant digits, or the *compare_interface_timing* command could generate false FAIL and PASS messages. This can happen because of rounding. For example, if the internal significant digits is two, and the absolute tolerance is set to 0.01, a difference of 0.014 is rounded to 0.01 and reported as a PASS even though it is outside the tolerance. Similarly, if the

absolute tolerance is set to 0.009, a difference of 0.009 is rounded to 0.01 and reported as FAIL even though it is within tolerance. You should ensure that the number of digits of accuracy of the input files is greater than the accuracy of the tolerances.

A second use of significant digits is in report generation, which is limited to the minimum of the input precision and the significant digits that you specified. You specify the significant digits for the report through the *-significant_digits* option. For example, if the value for the *-significant_digits* option is five but the *ref_timing_file* was generated with four digits, the report is limited to four digits. Note that this use of significant digits does not affect the PASS or FAIL status, but a reported difference could look like it should have a different status if the difference is close to a tolerances and the difference rounded when writing the report.

Each tolerance is a list of either one or two floating point numbers. All tolerances are inclusive, and the sign of the values has no effect. If there is only one number, it serves to specify both the plus and minus tolerances. The plus tolerance is the absolute value of the number, and the minus tolerance is the inverse of the plus. For example, *atol_list* equal to *0.1* indicates that time differences of less than 0.1 and greater than -0.1 are considered to be passing.

If there are two numbers, the first specifies the minus bound and the second the plus. The minus tolerance is the inverse of the absolute value of the first number, and the plus tolerance is the absolute value of the second number. Having a pair of numbers allows different tolerances to be applied for negative and positive errors, which can be interpreted as optimism and pessimism depending on the arc type. For example, an *atol_list* equal to *{0.2 -0.3}* indicates that data differences of less than 0.3 and greater than -0.2 are considered passing.

Examples

The following example shows a variety of comparisons. Each item in parentheses (for example, L1, L2) represents the latch level associated with the slack number directly to the left. These values are included in the report wherever there is an *L#* attribute in the *write_interface_timing* output. At the end of the report is a summary of the total comparisons passed and failed broken down by data section.

```

compile_scaling_library_group_data

Generates the scaling.db file for the library passed in.

Syntax

string *compile_scaling_library_group_data*

```
library_name
[-config_file DBFile_name]
```

Feedback

Data Types

library_name	list
config_file	string

Arguments

library_name

Collection of libraries in memory for which the companion.db files are to be created.

-config_file *DBFile_name*

Specifies writing data to DBFile.

Description

The *compile_scaling_library_group_data* command pre-computes all derived library data that is needed during *update_timing* and deposits it a "scaling.db" file. This file is consumed in *update_timing* if it can be found in the *search-path* and allows to use the precomputed derived libray data instead of computing it on the fly.

The scaling.db file is generated in the current directory.

Examples

The following snippet would typically be used during library data prep to generate the scaling.db file

```
pt_shell> compile_scaling_library_group_data 1.db -config_file 1_fusion
```

---

complete_net_parasitics

Completes partial parasitics annotated on all nets of the current design.

Syntax

string *complete_net_parasitics*

[-complete_with *completion_type*]

Data Types

completion_type	string

Arguments

-complete_with *completion_type*

Indicates that a net with partially annotated parasitics and missing segments is to be completed by inserting capacitances and resistances according to the *completion_type* value. Allowed values are *zero* (the default), which completes

the net by inserting zero capacitances and resistances, and *wlm*, which completes the net by inserting capacitances and resistances derived from wire load models.

This option is equivalent to the *read_parasitics -complete_with* command.

Description

This command completes all nets in the design that have incomplete RC networks annotated from SPEF or SPF files.

If lumped parasitics (set using the *set_load* or *set_resistance* command) already exist on any of the nets, they are not overwritten; however, a warning message is issued.

In a hierarchical flow where you read in multiple parasitics files, do not use this command until all parasitics files are read in, or you will create incorrect data for temporarily incomplete networks at block boundaries.

Note: The *complete_net_parasitics* and *read_parasitics -complete_with* commands complete a net only if all missing segments are between two pins, and only if the nets are partially annotated. Nets are not affected if they are fully annotated or have no annotation at all. Also, the net must be hierarchical, so that if the parasitics for the block-level parts of a net are missing, those parasitics could exist in the top-level net. If any of these conditions are not met, you must manually correct the SPEF or DSPF file.

Use the *report_annotated_parasitics* command to view how the parasitics are completed.

After the completion of the nets, there is no direct way to remove only the completed segments. You can remove all parasitics read and annotated with the *read_parasitics* and *complete_net_parasitics* commands using the *remove_annotated_parasitics* command. You then reread the previously annotated parasitics using the *read_parasitics* command. The *reset_design* command removes all attributes from the current design, including annotated parasitics.

Examples

The following example completes the partially annotated parasitics from the file speffile.spef, by inserting zero capacitances and resistances.

```
pt_shell> read_parasitics speffile.spef
pt_shell> complete_net_parasitics -complete_with zero
```

The following example completes any partially annotated parasitics after reading in hierarchical parasitics.

```
pt_shell> read_parasitics blkA.spf -path blkA
pt_shell> read_parasitics blkB.spf -path blkB
pt_shell> read_parasitics top_level.spf
pt_shell> complete_net_parasitics -complete_with zero
```

---

compute_metrics

Performs RTL Power analysis.

Syntax

string *compute_metrics*

```
[-power]
[-elaborated_block eblock]
[-reuse workspace]
```

Data Types

```
eblock      block_name
workspace      directory
```

Arguments

`-power`

This option performs FAST compile in a separate RTL Architect process (under the hood) and then calculates RTL power metrics for the compiled design.

`-elaborated_block eblock`

This option compiles the elaborated block *eblock* and does RTL power analysis for the block.

`-reuse workspace`

This option loads a previous existing *workspace* directory and automatically performs RTL power analysis.

Description

This is a high level command that performs power analysis starting from rtl.

Feedback

- update_power
- update_metrics
- report_rtl_metrics

---

configure_sms_scenarios

Configures SMS scenarios for selective SMVA/SMS analysis.

Syntax

string *configure_sms_scenarios*

```
[-disable sms_scenarios_list]
[-enable sms_scenarios_list]
```

Data Types

```
sms_scenarios_list       collection
```

Arguments

`-disable sms_scenarios_list`

Specifies a collection of SMS scenarios to disable. The specified SMS scenarios will be ignored during timing analysis and reporting. This collection is created by *get_sms_scenarios*.

`-enable sms_scenarios_list`

Specifies a collection of SMS scenarios to re-activate. The specified SMS scenarios will be re-activated for a subsequent full timing analysis and reporting. Only previously disabled SMS scenarios can be specified for re-activation. This collection is created by *get_sms_scenarios*.

Description

The *configure_sms_scenarios* command configures SMS scenarios for selective SMVA/SMC analysis. PrimeTime analyzes by default all relevant and active SMS scenarios. Specific scenarios can be disabled using the -disable command option, thus reducing the SMS scenarios analysis space. Disabled scenarios are not considered for timing analysis and subsequent reporting. Disabled scenarios can be re-activated for analysis using the -enable command option. This command is only available with SMVA/SMC analysis.

Examples

The following example specifies 3 voltage reference names {high,low,typ} for each one of the supply groups SN1 and SN2. PrimeTime automatically considers all the

relevant combinations of voltage levels, in this case up to nine prior the use of the configure_sms_scenarios command. The example disables all SMS scenarios for which the supply group SN1 is at 'typ' voltage and SN2 is at 'typ' voltage.

```
pt_shell> set_voltage_levels SN1 -reference_names { high low typ }
pt_shell> set_voltage -o SN1 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN1 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN1 -reference_name typ 0.9 -min 1.0
pt_shell> set_voltage_levels SN2 -reference_names { high low typ }
pt_shell> set_voltage -o SN2 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN2 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN2 -reference_name typ 0.9 -min 1.0

---

connect_net

Connects a net to specified pins or ports.

Syntax

int *connect_net*

net
object_spec

Data Types

net	string
object_spec	list

Arguments

net

Specifies the name of the net to which the pins and ports are to be connected.

object_spec

Specifies a list of pins or ports to connect to *net*.

Description

Connects pins and ports to a *net* in the current design. Like all other netlist editing commands, for the *connect_net* command to succeed, all of its arguments must succeed.

If any arguments fail, the netlist remains unchanged. The *connect_net* command returns a 1 if successful and a 0 if unsuccessful.

The *net* and each pin and port specified in the *object_spec* must be in scope; that is, at or below the current instance.

There are two rules for the *connect_net* command:

- You cannot connect *net* to a pin that is already connected.
- You cannot connect across a hierarchical boundary. For example, you cannot connect a port to a net at a hierarchical level other than the top of the design.

Examples

The following example creates a cell and a net and then connects the new net to the output of the new cell:

```
pt_shell> create_net new_net1
Information: Created net 'new_net1' in design 'top'. (NED-016)
1

pt_shell> create_cell u1 class/AN2
Information: Created cell 'u1' in design 'top'. (NED-014)
1

pt_shell> connect_net new_net1 u1/Z
Information: Connected 'u1/Z' to 'new_net1'. (NED-018)
1
```

connect_power_domain

Connects power net information for the specified power domains.

Feedback

Syntax

status *connect_power_domain*

```
power_domains
[-primary_power_net power_net]
[-primary_ground_net ground_net]
[-backup_power_net power_net]
[-backup_ground_net ground_net]
[-internal_power_net internal_power_net]
[-internal_ground_net internal_ground_net]
```

Data Types

power_domains	collection
power_net	string
ground_net	string
internal_power_net	string
internal_ground_net	string

Arguments

power_domains

Specifies the power domains for which to make the power net information connections.

-primary_power_net *power_net*

Specifies the primary power net information for the power domains.

-primary_ground_net *ground_net*

Specifies the primary ground net information for the power domains.

-backup_power_net *power_net*

Specifies the backup power net information for the power domains.

-backup_ground_net *ground_net*

Specifies the backup ground net information for the power domains.

-internal_power_net *internal_power_net*

Specifies the internal power net information for the power domains.

-internal_ground_net *internal_ground_net*

Specifies the internal ground net information for the power domains.

Description

The *connect_power_domain* command creates logical power connections for the specified power domains. All cells in the power domain inherit the power connections. You can

Feedback

override the inherited power connections for a cell by using the *connect_power_net_info* command.

The primary power and ground nets are used to define the main power connections for the power domain.

The backup power and ground nets are used to define power connections for always-on logic, retention registers, isolation cells, and enable-level shifter cells.

The internal power and ground nets are used to connect power nets to the switching cells present inside the power domain.

Examples

The following example connects power net information to the TOP_DOMAIN and SUB_DOMAIN power domains.

```
prompt> connect_power_domain TOP_DOMAIN \\
   -primary_power_net T_VDD \\
   -primary_ground_net T_VSS
1
prompt> connect_power_domain SUB_DOMAIN \\
   -primary_power_net A_VDD  \\
   -primary_ground_net A_VSS \\
   -backup_power_net VDD_Backup \\
   -backup_ground_net VSS_Backup
1
```

---

connect_power_net_info

Connects the specified power net information to the specified power pins.

Syntax

status *connect_power_net_info*

```
object_list
-power_pin_name power_pin_name
-power_net_name power_net_name
```

Feedback

Data Types

```
object_list         list
power_pin_name      string
power_net_name      string
```

Arguments

object_list

Specifies the leaf cells for which the power net information connections are made.

-power_pin_name *power_pin_name*

Specifies the name of the power pin.

-power_net_name *power_net_name*

Specifies the name of the power net.

Description

The *connect_power_net_info* command makes power net information connections for a specific power pin of a leaf cell. The pin-level connection overrides the domain-level connections made with the *connect_power_domain* command.

See the *report_power_pin_info* man page for more information.

Examples

The following example connects the power net information for the PWR pin of the PD0_INST/I0 cell.

```
prompt> connect_power_net_info PD0_INST/I0 \\
   -power_pin_name PWR -power_net_name exp_VDD
1
```

See Also

- connect_power_domain
- report_power_pin_info

---

connect_supply_net

Connects the supply net to specified supply ports or pins. This command is part of UPF definition of virtual power and ground network.

Feedback

Syntax

```
status connect_supply_net
  -ports list
  supply_net_name
```

Data Types

```
list                list
supply_net_name     string
```

Arguments

`-ports list`

Specifies supply ports to be connected to the supply net. The name is hierarchical name.

`supply_net_name`

Specifies the name of the supply_net to be connected. The name should be a simple (nonhierarchical) name. The net must exist in the current scope. This argument is required. If you use this option in UPF mode, it specifies which supply ports or instance power ground pins are to be connected with the supply net.

Description

This command provides an explicit connect of a supply net to any supply ports or pins and overrides (has higher precedence than) the auto-connection semantics that might otherwise apply. If a design element is not connected explicitly to any supply net using the *connect_supply_net* command, it shares the primary power/ground supply net with the power domain it belongs to.

The instance that contains the pin must also be in the extend of the same power domain. A supply port cannot connect to two nets in the same domain. Note that the commands does not specify whether the net connects to the inside or outside side of the port. The port side is auto-derived from the net domain and port scope.

Note that explicit connections cannot be made to cell PG pins that are created based on default PG pin names by the tool.

Examples

The following example connects a VSS supply net with VSS supply port and ground pin of cell INST_1/u1:

```
prompt> create_power_domain PD1 -elements INST_1
PD1
prompt> create_supply_net VSS -domain PD1
VSS
prompt> create_supply_port VSS -domain PD1
```

```
VSS
prompt> connect_supply_net VSS -ports VSS
1
prompt> connect_supply_net VSS -ports INST_1/u1/GND
1
```

---

convert_spef_to_gpd

Converts a SPEF file into the GPD (Galaxy Parasitics Database) binary format.

Syntax

status *convert_spef_to_gpd*

```
spef_file_name
  gpd_dir
```

Data Types

```
spef_file_name      string
gpd_dir             string
```

Arguments

spef_file_name

Specifies the SPEF file to be converted to GPD. Input SPEF file can be compressed/uncompressed.

gpd_dir

Specifies the directory where the GPD data files are written.

Description

This command converts a SPEF file into the GPD (Galaxy Parasitic Database) format, which is written as a set of files in the output directory.

Feedback

Examples

The following example converts a compressed SPEF file xx.spef.gz and generates the output GPD in the mygpd directory.

```
pt_shell> convert_spef_to_gpd xx.spef.gz mygpd
```

copy_collection

Duplicates the contents of a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *copy_collection*

```
        collection1
```

Data Types

```
collection1          collection
```

Arguments

collection1

Specifies the collection to be copied. If an empty string is used for the *collection1* argument, the command returns the empty string (a copy of the empty collection is an empty collection).

Description

This command is no longer needed and is provided only to make old scripts work without modification.

Examples

The following example from PrimeTime shows the result of copying a collection. Functionally, it is not much different that having multiple references to the same collection, except it is slower.

```
pt_shell> set c1 [get_cells "U1*"]
{"U1", "U10", "U11", "U12"}
pt_shell> set c2 [copy_collection $c1]
{"U1", "U10", "U11", "U12"}
```

```
pt_shell> unset c1
pt_shell> query_objects $c2
{"U1", "U10", "U11", "U12"}
```

---

cputime

Retrieves the overall user time associated with the current pt_shell process.

Syntax

float *cputime*

[*format*]

Data Types

format string

Arguments

format

This argument takes a *print* style formatting string for a floating point number.

Description

This command returns the accumulated user time, in seconds, for the current pt_shell process. If the *format* string is omitted, an integer number of seconds is returned. If the *format* string is specified, a floating point number is returned. The number includes fractions of a second elapsed and is formatted in accordance with given specifier. For detailed information about formatting a floating point argument, see the *print* UNIX man page.

Examples

```
pt_shell> cputime "%g"
3.74
```

- mem

---

create_cell

Creates cells in the current design.

Feedback

Syntax

```
status create_cell
  [-libraries lib_spec]
  [-exact]
  cell_list
  lib_cell
```

Data Types

```
lib_spec          string
cell_list         list
lib_cell          string
```

Arguments

`-libraries lib_spec`

If this option is specified, PrimeTime resolves the *lib_cell* option from the libraries contained in only the *lib_spec* option. Libraries are searched in the order in which they appear in *lib_spec*. The *lib_spec* value can be a list of library names or collections of libraries loaded into PrimeTime. You can obtain the latter by using the *get_libs* command. You cannot specify this option if a full library cell name has been specified.

`-exact`

Indicates that names are to be used exactly as specified. Use this option if you want to create a cell that contains a hierarchy or wildcard character as part of the cell name. For more information, see the Naming Cells With Special Characters section.

cell_list

Specifies a list of cells to be created.

lib_cell

Specifies the name of the library cell to which the specified cells are to be linked. The *lib_cell* option can be a library cell object or the name of a library cell. You can obtain the former by using the *get_lib_cells* command. The latter can either be the full library cell name, such as *lib_name/lcell_name*, or the just the base name of the library cell, such as *lcell_name*. You cannot specify the *-libraries* option and explicitly specify the full library cell name. If you invoke PrimeTime with the *-multi_scenario* option, only the library cell base name must be used. For more information, see the Resolved Library Cells section.

Description

This command creates new cells in the current design. Like all other netlist editing commands, for the *create_cell* command to succeed, all of its arguments must succeed. If

any arguments fail, the netlist remains unchanged. The *create_cell* command returns a 1 if successful and a 0 if unsuccessful.

Cells are created in scope; that is, at or below the current instance. Cell names are specified as for other commands, using the full hierarchical name relative to the current instance, as in the following example:

```
create_cell u1/u2/u3 class/AN2
```

This command attempts to create a cell named u3 in the hierarchical block u1/u2. The name to the right of the last hierarchical separator is the actual cell name, and the remainder is sent to a *search engine* to find a hierarchical block in which to create the new cell. The operation fails if any of the following are true:

- The search engine cannot find u1/u2.
- The search engine finds multiple blocks that match u1/u2.
- The search engine finds a leaf cell matching u1/u2.

Currently, you cannot create new hierarchy; that is, you cannot create a cell that is an instance of a design. The *lib_cell* must be a leaf library cell.

After creating a cell, you can connect nets to its pins with the *connect_net* command. You can remove cells with the *remove_cell* command.

Resolving Library Cells

If the *lib_cell* has been specified in base name only format, such as without a library from which to resolve it from, PrimeTime resolves the library cell according to the following methodology.

If the *-libraries* option is specified, PrimeTime searches for library cells only in the libraries contained within the *lib_spec*.

Alternatively, if the *-libraries* option is not specified, PrimeTime searches for the library cell in the libraries contained within the *link_path* variable.

The first library cell that is found is used.

Naming Cells With Special Characters

If you want to create a cell whose name contains the current hierarchical separator or wildcard characters used by the search engine, you must do the following:

- Use the *current_instance* command to change the scope to the block in which you want the new cell created.
- Use the *create_cell -exact* command to create the cell.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Feedback

Examples

In the following example, cells are created in the current instance, and at a level below the current instance. Currently, u1 is an instance of a design that has multiple instances. Therefore, it is uniquified as part of the editing operation.

```
pt_shell> create_cell t1 class/AN2
Information: Created cell 't1' in design 'top'. (NED-014)
1

pt_shell> create_cell u1/t1 class/AN2
Uniquifying 'u1' (block1) as 'block1_0'.
Information: Created cell 't1' in 'top/u1'. (NED-014)
1
```

The following example creates cell a/b in the hierarchical block u1/u2. The first attempt fails, because the *exact* option was omitted. Here, u1/u2 is an instance of a design that has multiple instances; therefore, it is uniquified as part of the editing operation. The u1 was already uniquified in the previous example.

```
pt_shell> current_instance u1/u2
u1/u2

pt_shell> create_cell  a/b class/AN2
Error: Could not create cell 'a/b':
        a not found. (NED-041)
Error: No changes made. (NED-040)
0

pt_shell> create_cell a/b class/AN2  -exact
Uniquifying 'u1/u2' (block2) as 'block2_0'.
Information: Created cell 'a/b' in 'top/u1/u2'. (NED-014)
1
```

In the following example, multiple cells are created using library cells chosen from user-specified libraries using only the library cell base name. The 'lib1' library is searched first as it appears in the *lib_spec* list first and then 'lib2' is searched.

```
pt_shell> create_cell -libraries {lib1 lib2} {u1 u2 u3} ND2
Information: Created cell 'u1' in design 'middle' with 'lib1/ND2'.
 (NED-014)
Information: Created cell 'u2' in design 'middle' with 'lib1/ND2'.
 (NED-014)
Information: Created cell 'u3' in design 'middle' with 'lib1/ND2'.
 (NED-014)
1
```

---

create_clock

Creates a clock object.

Syntax

string *create_clock*

```
-period period_value
[-name clock_name]
[-waveform edge_list]
[-add]
[-sms_scenarios sms_scenarios_list]
[-comment comment_string]
[source_objects]
```

Data Types

period_value	float
clock_name	string
edge_list	list
source_objects	list
sms_scenarios_list	collection
comment_string	string

Arguments

`-period period_value`

Specifies the clock period in library time units. This is the minimum time over which the clock waveform repeats. The *period_value* type must be greater than or equal to zero.

`-name` *clock_name*

Specifies the name of the clock being created. If you do not use this option, the clock gets the same name as the first clock source specified in the *source_objects* list. If you did not specify the *source_objects* list, you must use the *-name* option, which creates a virtual clock not associated with a port or pin. You can use both the *-name* and *source_objects* options to give the clock a more descriptive name than the first source pin or port. If you specify the *-add* option, you must use the *-name* option and the clocks with the same source must have different names.

`-waveform` *edge_list*

Specifies the rise and fall edge times of the clock waveforms of the clock, in library time units, over an entire clock period.

The first time in the *edge_list* is a rising transition, typically the first rising transition after time zero. There must be an even number of edges, and they are assumed to be alternating rise and fall.

The edges must be monotonically increasing, except for a special case with two edges, where fall can be less than rise. The numbers should represent one full clock period.

If you do not specify this option, a default waveform is assumed, which has a rise edge of 0.0 and a fall edge of *period_value*/2.

`-add`

Specifies whether to add this clock definition to the existing clock or to overwrite it. Use this option to capture the case where multiple clocks must be specified on the same source for simultaneous analysis with different clock waveforms. When you specify this option, you must also use the *-name* option.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because PrimeTime must explore all possible combinations of launch and capture clocks. Use the *set_clock_groups* or *set_false_path* command to disable unwanted clock combinations.

`-comment` *comment_string*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC, such as to track the methodology or tool that originated the command.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios for which this clock specification is analyzed. When this option is not given, the clock specification applies for all SMS scenarios. PrimeTime requires that clock waveforms to be specified

for all applicable SMS scenarios. It is thus recommended to first specify the clock waveforms without this option, followed by the desired waveforms at specific SMS scenarios using this option. This collection is created by *get_sms_scenarios*.

`source_objects`

Specifies the objects used as sources of the clock. The sources can be ports, pins, or nets in the design. If you do not use this option, you must use the *-name* option, which creates a virtual clock not associated with a port, pin, or net. If you specify a clock on a pin that already has a clock, the new clock replaces the old one unless you use the *-add* option. When a net is used as the source, the first driver pin of the net is the actual source used in creating the clock.

Description

Creates a clock object. It is created in the current design and is applied to the specified *source_objects* list. If you do not specify a *source_objects* list, but give a *clock_name* value, a virtual clock is created. You can create a virtual clock to represent an off-chip clock for input or output delay specification. For more information about input and output delay, see the *set_input_delay* and *set_output_delay* man pages.

If one of the *source_objects* values is already the source of a clock, the source is removed from that clock. This clock is eliminated if it has just one source.

The *create_clock* command also defines the waveform for the clock. The clock can have multiple pulses per period.

The *create_clock* command is used together with the *set_clock_latency*, *set_clock_uncertainty*, *set_propagated_clock*, and *set_clock_transition* commands to specify properties of clock networks. By default, a new path group is created for the clock. This new path group brings together the endpoints related to this clock for cost function calculation. To remove the clock from its assigned group, use the *group_path* command to reassign the clock to another group or to the default path group. For more information, see the *group_path* man page.

The new clock has ideal clock latency and transition time; no propagated delay through the clock network is assumed and a transition time of zero is used at the clock source pin. To enable propagated latency for a clock network, use the *set_propagated_clock* command. To set an estimated latency, use the *set_clock_latency* command.

To show information about clocks in the design, use the *report_clock* command. To create a collection of clocks matching a pattern and optionally matching filter criteria, use the *get_clocks* command.

To undo *create_clock*, use the *remove_clock* command.

Feedback

Examples

The following example creates a clock on a port named *PHI1* with a period of *10.0*, a rise at *5.0*, and a fall at *9.5*.

```
pt_shell> create_clock PHI1 -period 10 -waveform { 5.0 9.5 }
```

The following example shows a clock named *PHI2* with a falling edge at *5* and a rising edge at *10* with a period of *10*. Because the edges for the *-waveform* option should be ordered as first rise, then fall, and should increase in value, the fall edge can be given as *15*. This places the next falling edge after the first rise edge at *10*.

```
pt_shell> create_clock PHI2 -period 10 -waveform { 10 15 }
```

The following example creates a virtual clock *PHI2* with a period of *10.0*, a rise at *0.0*, and a fall at *5.0*.

```
pt_shell> create_clock -name PHI2 -period 10 -waveform {0.0 5.0}
```

The following example creates a clock named *clk2* with multiple sources.

```
pt_shell> create_clock -name clk2 -period 10 \\
-waveform {2.0 4.0} {clkgen1/Z clkgen2/Z clkgen3/Z}
```

The following example creates a clock named *CLK* on pin *u13/Z* with a period of *25*, a fall at *0.0*, a rise at *5.0*, a fall at *10.0*, a rise at *15.0*, and so on.

```
pt_shell> create_clock u13/Z -name CLK -period 25 -waveform { 5 10 15 25}
```

Feedback

create_command_group

Creates a new command group.

Syntax

string *create_command_group* [-info *info_text*] *group_name*

Arguments

`-info` *info_text*

Help string for the group

group_name

Specifies the name of the new group.

Description

The *create_command_group* command is used to create a new command group, which you can use to separate related user-defined procedures into functional units for the online help facility. When a procedure is created, it is placed in the "Procedures" command group. With the *define_proc_attributes* command, you can move the procedure into the group you created.

The *group_name* can contain any characters, including spaces, as long as it is appropriately quoted. If *group_name* already exists, *create_command_group* quietly ignores the command. The result of *create_command_group* is always an empty string.

Examples

The following example demonstrates the use of the *create_command_group* command:

```
prompt> create_command_group {My Procedures} -info "Useful utilities"

prompt> proc plus {a b} { return [expr $a + $b] }

prompt> define_proc_attributes plus -command_group "My Procedures"

prompt> help
My Procedures:
  plus

 ...
```

See Also

Feedback

create_drc_error

Creates a physical DRC error object.

Syntax

```
collection create_drc_error
-error_data drc_error_data
-error_type drc_error_type
[-status error | fixed | ignored | waived]
[-polygons shape_list]
[-polylines shape_list]
[-endpoints coord_list]
[-points shape_list]
[-objects objects]
[-must_fix]
[-direction direction]
[-required_spacing distance]
[-actual_spacing distance]
[-width_required distance]
[-height_required distance]
[-shape_uses shape_uses]
[-pin_edge pin_edge]
[-information information]
```

Data Types

```
drc_error_data  collection
drc_error_type  collection
shape_list      list
coord_list      list
objects         collection
direction       string
distance        float
shape_uses      list
pin_edge        integer
information     string
```

Arguments

`-error_data drc_error_data`

Specifies the error data in which to create the physical DRC error.

`-error_type drc_error_type`

Specifies the error type for which to create the physical DRC error. The error type value becomes available as the *error_type* attribute for the error.

`-status error | fixed | ignored | waived`

Sets the initial status of the new error. Available values are: *error, fixed, ignored,* and *waived*. If omitted, the status value *error* is used. The status value becomes available as the *status* attribute for the error.

`-polygons` *`shape_list`*

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

`-polylines` *`shape_list`*

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polylines* attribute for the error.

`-endpoints` *`coord_list`*

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This option is a required option when create open error. The coordinates become available as the *endpoints* attribute for the error.

`-points` *`shape_list`*

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the *points* attribute for the error.

`-objects` *`objects`*

Specifies design objects associated with the new error. The objects become available as the *objects* attribute for the error.

`-must_fix`

Sets the *must fix* flag on the error. The default is false. The must fix value becomes available as the *must_fix* attribute for the error.

`-direction` *`direction`*

Sets the direction of a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The direction is used in rendering the spacing violation in the GUI layout view. The direction value becomes available as the *direction* attribute for the error.

`-required_spacing` *`distance`*

Sets the required spacing distance which was not met in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The required distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The required spacing value becomes available as the *required_spacing* attribute for the error.

`-actual_spacing` *`distance`*

Sets the actual spacing distance which did not meet requirements in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The actual distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The actual spacing value becomes available as the *actual_spacing* attribute for the error.

`-width_required` *`distance`*

Sets the required width of the drc_error object, which is the required width of the violating object. The required width has meaning in the context of a violation in the "size" error_class, where the width of the object does not meet the requirement.

`-height_required` *`distance`*

Sets the required height of the drc_error object, which is the required height of the violating object. The required height has meaning in the context of a violation in the "size" error_class, where the height of the object does not meet the requirement.

`-shape_uses` *`shape_uses`*

Sets the shape uses associated with the error. The *shape_uses* values can be used to filter errors in the GUI error browser where the attribute is called "route types". The *shape_uses* become available as the *shape_uses* attribute for the error.

`-pin_edge` *`pin_edge`*

Sets the pin edge associated with the error. Given any shape, rectangular or rectilinear shape, the edge numbers are a list of positive integers that start from 1. The lower left-most vertical edge is the starting edge with side number 1. Going clockwise, the side numbers of the next edges are 2, 3, and so on. The pin edge is reported as a part of the detailed textual report in the GUI error browser. The pin edge value becomes available as the *pin_edge* attribute for the error.

`-information` *information*

Sets the error instance specific information string attribute. Information for an error instance is generally set by setting the brief_info and verbose_info attributes of the owning error type and formatting error instance specific data into these strings. However, there are times that information specific to an error instance must be set. In this case, use this attribute to set the information string.

Description

The *create_drc_error* command creates a physical DRC error object in the given error data for the given error type. Additional shapes can be added to a drc_error object after creation by using the *create_drc_error_shapes* command.

Most of the attributes associated with a drc_error object are read-only and can only be set at the time of creation. Exceptions to this is the error status, which can be modified using the *set_attribute* command. All attribute values set at creation can then be accessed with the *get_attribute* command. In addition, the attribute values are displayed in the GUI error browser and the GUI layout view.

Brief and verbose information strings are accessible for each drc_error object as the *brief_info* and the *verbose_info* attributes, respectively. These strings are also displayed in the GUI error browser. These information strings are not attached to the drc_error object in the database, but rather with the drc_error_type associated with the drc_error object. A message construction service customizes the information strings for each drc_error object by substituting attribute values from the drc_error object into the strings. A detailed description of the message construction is provided in the man page for *create_drc_error_type*.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the spacing class. A DRC error instance is then created for the new type.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \\
    -name "route spacing" -error_class spacing \\
    -required_objects {net net} \\
    -brief_info "A spacing violation between net %net:0% and net %net:1%
 was detected." \\
    -brief_format message \\
    -severity error]
{"route short"}

prompt> create_drc_error -error_data $data \\
    -error_type $type -objects [get_nets {"F_12_" "F_11_"}] \\
```

Feedback

```
    -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200}
 {78.8600 186.3200}} \\
    -status error -direction vertical \\
    -required_spacing 3.400 -actual_spacing 31.400
{"123"}
```

See Also

---

create_drc_error_data

Creates an error data file and returns a collection that contains the error data object.

Syntax

```
collection create_drc_error_data
[-file_name file_name]
-checker_name checker_name
[-checker_version version_string]
[-information info_string]
```

Data Types

```
file_name           string
checker_name        string
checker_version     string
information         string
```

Arguments

`-file_name file_name`

Specifies the name of the external error data file.

The naming convention for an error data file is to append an underscore, the checker name, and the ".err" suffix to the design name. For example, for a design named "my_design" and a checker named "test", the error data file name is named "my_design_test.err".

`-checker_name checker_name`

Specifies the name of the rule checking engine creating the error data file.

For example, for the route check performed by the router, the engine name might be "zroute".

`-checker_version` *version_string*

Specifies the version string for the checker engine.

`-information` *info_string*

Specifies an informative message to associate with the error data.

Description

The *create_drc_error_data* command creates the specified error data file. The command fails if the specified error data file already exists.

If created with the *-file_name* option, the error data file is written to disk. The created error data file is opened in read/write mode. To save an error data file created in this manner, run the *save_drc_error_data* command.

The command returns a collection that contains the error data object associated with the error data file. If no error data object is created, the command returns an empty string.

The *create_drc_error_data* command increments the open count for the error data object. The *create_drc_error_data* (and *open_drc_error_data*) commands must be balanced by an equal number of *close_drc_error_data* commands to close the error data object.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example creates an external error data file named "my_design_dppinassgn.err", with a checker name of "dppinassgn", and a short information string.

```
prompt> set data [create_drc_error_data \\
   -file_name my_design_dppinassgn.err \\
   -checker_name dppinassgn \\
   -information "This error data contains pin assignment and \\
      placement errors for the my_design design"]
{"my_design_dppinassgn.err"}
```

Feedback

create_drc_error_shapes

Creates shapes and adds to a physical DRC error object.

Syntax

```
status create_drc_error_shapes
-error_data error_data
drc_error
[-polygons shape_list]
[-polylines shape_list]
[-endpoints coord_list]
[-points shape_list]
```

Data Types

```
error_data      collection
drc_error       collection
shape_list      list
coord_list      list
```

Arguments

`-error_data error_data`

Specifies the error data in which to find the physical DRC error to modify.

drc_error

Specifies the error to which to add the shapes.

`-polygons shape_list`

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

`-polylines shape_list`

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polylines* attribute for the error.

`-endpoints coord_list`

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This option is a required option when create open error. The coordinates become available as the *endpoints* attribute for the error.

Feedback

`-points` *shape_list*

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the *points* attribute for the error.

Description

The *create_drc_error_shapes* command adds additional shapes to an existing physical DRC error object in the given error data. Shapes are added to the DRC error object at the time of creation. If more than one shape is required to describe the error, use the *create_drc_error_shapes* command to add the additional shapes. The command requires at least one of shape options be specified.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the basic class. A DRC error instance is then created for the new type. Additional shapes are then added.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \\
    -name "shapely error" -error_class basic \\
    -required_objects {net} \\
    -severity error]
{"route short"}

prompt> set error [create_drc_error -error_data $data \\
    -error_type $type -objects [get_nets {F_12_}] \\
    -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200}
 {78.8600 186.3200}}
{"45"}

prompt> create_drc_error_shapes -error_data $data $error\\
    -polygons {{74.8600 189.4600} {75.8800 189.4600} {75.8800 186.3200}
 {74.8600 186.3200}}
```

Feedback

create_drc_error_type

Creates a physical DRC error type object.

Syntax

```
collection create_drc_error_type
-error_data drc_error_data
-name type_name
-error_class base | spacing | short | open_locator
[-brief_info info_string]
[-brief_format ascii | message]
[-verbose_info info_string]
[-verbose_format ascii | message]
[-severity error | information | recommendation | warning]
[-required_objects {net pin port cell pinGuide}]
[-num_detected_errors num_errors]
```

Data Types

```
drc_error_data  collection
type_name       string
info_string     string
num_errors      integer
```

Arguments

`-error_data drc_error_data`

Specifies the error data in which to create the physical DRC error type.

`-name type_name`

The name for the error type being created. Names must be unique in the scope of the owning error data.

`-error_class base | spacing | short | open_locator`

Specifies the kind of errors represented by the new error type. The error class determines how the shapes of the associated DRC error instances are rendered in the GUI layout view. It also determines some expected attributes for its error instances. Available values are: base, spacing, short, and open_locator.

The *base* class allows its types to define required associated design objects. The *spacing* class allows its types to define required associated design objects and the error instances to describe a mismatch in actual and required spacing distance. Spacing errors can also be defined with a direction. The *short* class allows its types to define required associated design objects and is rendered with a diagonal cross inside of its shape. The *open_locator* class is for open nets and expects to be associated with a single net and to have two endpoints describing an open in a net as its shape description.

`-brief_info` *`info_string`*

Specifies a brief information string for display. Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The brief information string is expected to be a compact description that is suitable for display in a tabular format in the GUI error browser.

`-brief_format ascii | message`

Specifies the display format of the brief information string specified with *-brief_info*. If the format is *ascii*, the brief info string is displayed exactly as specified with the *-brief_info* option, without modification. If the format is *message*, the brief info string is parsed for special tokens. The tokens are replaced with error instance attribute values before display.

`-verbose_info` *`info_string`*

Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The verbose information string should be a detailed description that is suitable for display in a report format in the GUI error browser.

`-verbose_format ascii | message`

Specifies the display format of the verbose information string specified with *-verbose_info*. The format can be one of: *ascii* or *message*. If the format is *ascii*, the verbose info string is displayed exactly as specified with the *-verbose_info* option, without modification. If the format is *message*, then the verbose info string is parsed for special tokens. The tokens are replaced with error instance attribute value before display.

`-severity error | information | recommendation | warning`

Specifies the severity of the message associated with instances of this type.

`-required_objects {net pin port cell pinGuide}`

Specifies the required object classes associated with this error. A type might require that a specific number of design objects be associated with its error instances. For example, a route spacing type error might require that all of its instances have two associated nets. If the spacing violation is between shapes

of the same net, the same net can be repeated twice. By specifying required objects, the type allows instances to be filtered for null object association.

The required objects are specified with a list of the design object class names. If multiple instances of a design object type are required, the class name can be repeated. For example, to specify that two nets are required, use the option argument *{net net}*.

While this option allows definition of the required design object types, additional objects can be associated with an error instance in addition to the required design object types.

`-num_detected_errors` *num_errors*

Specifies the maximum number of detected errors that are allowed. Some checkers allow you to specify a limit on the number of errors detected per type. The checker can add information about how many errors were detected, vs. how many errors were added into the error database, by using this option.

Description

The *create_drc_error_type* command creates physical DRC error objects in the specified error data. Error types must have unique names in the scope of the owning error data and error types must be defined with an error class.

The command supports brief and verbose information strings for error type objects. These strings are displayed for each error instance in the GUI error browser. The strings can be customized with attribute values of an error instance by using the *message* format along with replacement of special tokens with attribute values.

A message construction service parses the error message for delimited tokens. If found, the command substitutes them with attribute values to construct a message appropriate for a specific DRC error instance. The token delimiter is the percent (%) character. To pass a percent symbol directly to the output message without modification, escape the character with a backslash: \\%. A token has the form *%<error instance attribute name[:<ordinal value>]>[.<attribute name>]%* Error instance attributes are named as described below.

For associated design objects, the attribute name is the object type name. If there are multiple objects of the same object type, the specific associated object is identified with the ":<ordinal value>" qualifier. The value starts at zero for the first identified object. For example "pin:0" identifies the first associated pin and "pin:2" identifies the third pin associated with the error instance. If the ordinal value qualifier is omitted, the first object of that type is default. The special character "*" can be used in place of the ordinal value to mean all objects of the given type. The supported object type names are: *net, pin, port, cell,* and *pinGuide*.

In addition, the attribute name *type* can be used to denote the associated error type. Append a period character (.) delimiter to the optional attribute name to access a specific

attribute for the identified object. If the attribute qualifier is omitted, the object's name is used. Attribute names supported with the associated object are: name and full_name. In addition, pin and port objects support the attribute name *cell* which will print the name of the cell associated with the pin or port. Attribute names supported with the associated error type are: name, severity, and class.

For other error instance attribute fields, access an attribute value by using the attribute name for the object. For example, use *actual* for the actual distance in a spacing violation and *direction* for the direction of a spacing violation. Some of these attributes can also be given with the *:<ordinal value>* qualifier. For example, there can be multiple route types associated with an error. As with design objects, if the ordinal value qualifier is omitted, the first one is selected by default. The * glob character can be used to specify all values. The currently supported error instance attributes are: *status, shapes, bbox, direction, actual, required, routeType,* and *endpoint*.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the short class.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> create_drc_error_type -error_data $data \\
    -name "route short" -error_class short \\
    -required_objects {net net} \\
    -brief_info "A short between net %net:0% and net %net:1% was
 detected." \\
    -brief_format message \\
    -severity error
{"route short"}
```

---

create_generated_clock

Creates a generated clock object.

Syntax

string *create_generated_clock*

Feedback

```
[-name clock_name]
-source master_pin
[-divide_by divide_factor | -multiply_by multiply_factor |
 -edges edge_list]
[-combinational]
[-duty_cycle percent]
[-invert]
[-preinvert]
[-edge_shift edge_shift_list]
[-add]
[-master_clock clock]
[-pll_output output_pin]
[-pll_feedback feedback_pin]
[-sms_scenarios sms_scenarios_list]
[-comment comment_string]
source_objects
```

Data Types

clock_name	string
master_pin	list
divide_factor	int
multiply_factor	int
edge_list	list
percent	float
edge_shift_list	list
clock	string
output_pin	list
feedback_pin	list
sms_scenarios_list	collection
comment_string	string
source_objects	list

Arguments

`-name clock_name`

Specifies the name of the generated clock. If you do not use this option, the clock receives the same name as the first clock source specified in the *-source* option.

If you specify the *-add* option, you must use the *-name* option and the clocks with the same source must have different names.

`-source master_pin`

Specifies the master clock source pin. This pin is used to determine the following:

- The identity of the master clock
- The sense of the master clock (inverted or non-inverted) used as input for the generated clock

This pin does not restrict the generated clock's source latency computation; the tool considers all paths between the master clock's actual source pin and the generated clock that provide the required edge relationships. (This pin can even be outside the fanin of the generated clock's own source pin, as long as it provides the identity and sense of the desired master clock.)

If more than one potential master clock exists at the specified pin, use the *-master_clock* option to specify which clock to use.

`-divide_by` *`divide_factor`*

Specifies the frequency division factor. For example, *-divide_by 2* specifies that the generated clock period is twice as long as the master clock period.

`-multiply_by` *`multiply_factor`*

Specifies the frequency multiplication factor. For example, *-multiply_by 3* specifies that the generated clock period is one-third of the master clock period.

`-edges` *`edge_list`*

Specifies a list of integers that represents edges from the source clock that are to form the edges of the generated clock. The edges are interpreted as alternating rising and falling edges and each edge must be not less than its previous edge. The number of edges must be an odd number and not less than 3 to make one full clock cycle of the generated clock waveform. For example, *1* represents the first source edge, *2* represents the second source edge, and so on.

`-combinational`

Causes the source latency path for a *-divide_by 1* generated clock to include only the logic that is propagated from the master clock through combinational logic. The source latency path does not flow through sequential element clock pins, transparent latch data pins, or source pins of other generated clocks.

`-duty_cycle` *`percent`*

Specifies the duty cycle, in percent, if frequency multiplication is used. It is the percentage of the clock period that the clock is high. The default is 50 percent.

`-invert`

Inverts the generated clock signal (in the case of frequency multiplication and division). This option first creates the generated clock from the original clock signal and then inverts the generated clock.

`-preinvert`

Creates a generated clock based on the inverted clock signal. This option first inverts the original clock signal and then creates the generated clock signal based on the inverted original clock.

`-edge_shift` *`edge_shift_list`*

Specifies a list of floating-point numbers that represent the amount of shift, in library time units, of the specified edges to yield the final generated clock waveform. The number of edge shifts specified must be equal to the number of edges specified by the *-edges* option. The values can be positive or negative, representing shifts later or earlier in time, respectively. For example, the value 1.0 shifts the corresponding edge later by one library time unit. Use this option to specify shifts resulting from the logic of the design, not to model latency effects.

`-add`

Specifies whether to add this clock to the existing clock or to overwrite it. Use this option to capture the case where multiple generated clocks must be specified on the same source, because multiple clocks fan into the master pin. Ideally, one generated clock must be specified for each clock that fans into the master pin.

If you specify this option, you must also use the *-name* and *-master_clock* options.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because PrimeTime must explore all possible combinations of launch and capture clocks. Use the *set_false_path* command to disable unwanted clock combinations.

`-master_clock` *`clock`*

Specifies the master clock to be used for this generated clock if multiple clocks fan into the master pin.

If you specify this option, you must also use the *-add* option.

`-pll_output` *`output_pin`*

Specifies the output pin of the PLL that is connected to the feedback pin. For a single-output PLL, this pin is same as the pin on which the generated clock is defined.

`-pll_feedback` *`feedback_pin`*

Specifies the feedback pin of the PLL. There should be a path in the circuit connecting one of the outputs of the PLL to this feedback pin.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which this generated clock specification is analyzed. When this option is not given the generated clock specification applies for all SMS scenarios. PrimeTime requires clock waveforms to be specified for all applicable SMS scenarios. It is thus recommended to first specify the generated clock waveforms without this option, followed by the

desired waveforms at specific SMS scenarios using this option. This collection is created by *get_sms_scenarios*.

PrimeTime currently supports this option for only a single clock in a generated clock hierarchy. For example, if this option is used for a master clock, none of its generated clock children can use this option.

`-comment` *`comment_string`*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

`source_objects`

Specifies a list of ports, pins, or nets defined as generated clock source objects. When a net is used as the source, the first driver pin of the net is the actual source used to create the generated clock.

Description

The *create_generated_clock* command creates a generated clock object in the current design and also defines a list of objects as generated clock sources in the current design. You can specify a pin or a port as a generated clock source object. The command also specifies the original master clock source from which the new clock is generated. When the master clock changes, the generated clock automatically changes.

The generated clock can be created as one of the following:

- A frequency divided clock, using the *-divide_by* option
- A frequency multiplied clock, using the *-multiply_by* option
- A special divide-by-1 clock, using the *-combinational* option
- An edge-derived clock, using the *-edges* option

To invert a frequency-divided or frequency-multiplied clock, use the *-invert* or *-preinvert* option. To shift the edges of an edge-derived clock by specified amounts of time, use the *-edge_shift* option.

The number of edges specified by the *-edges* option must be an odd number of at least 3. Consider the following example:

```
create_generated_clock -source clk -edges {1 3 5} [get_pins U82/Q]
```

The first, third, and fifth edges of the source clock determine the times at which the first, second, and third edges (rising-falling-rising) occur for the generated clock. The period of the generated clock is determined by the final entry in the edge list.

Non-increasing edges as in *-edges { 1 1 3 }* are allowed and usually used with the *-edge_shift* option to produce a generated clock pulse independent of the duty cycle of the master clock itself.

If a generated clock is specified with a *divide_factor* value that is a power of 2 (1, 2, 4, ...), the rising edges of the master clock are used to determine the edges of the generated clock. If the *divide_factor* value is not a power of two, the edges are scaled from the master clock edges.

Using the *create_generated_clock* command on an existing generated_clock object overwrites the existing object attributes. The generated_clock objects are expanded to real clocks at the time of analysis.

The *set_clock_latency*, *set_clock_uncertainty*, *set_propagated_clock*, and *set_clock_transition* commands can reference the generated clock.

For internally generated clocks, the tool automatically computes the clock source latency if the master clock of the generated clock has propagated latency and no user-specified value for generated clock source latency exists. If the master clock is ideal and has source latency and there is no user-specified value for the generated clock's source latency, zero source latency is assumed.

To display information about generated clocks, use the *report_clock* command.

Examples

The following example creates a frequency divide-by 2 generated clock.

```
pt_shell> create_generated_clock -divide_by 2 \\
            -source [get_pins CLK] [get_pins pinf]
```

The following example creates a frequency divide-by 3 generated clock. If the master clock period is 30, and master waveform is {24 36}, the generated clock period is 90 with waveform {72 108}.

```
pt_shell> create_generated_clock -divide_by 3 \\
            -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a frequency multiply-by 2 generated-clock with a duty cycle of 60%.

```
pt_shell> create_generated_clock -multiply_by 2 -duty_cycle 60 \\
            -source [get_pins CLK] [get_pins pinf1]
```

The following example creates a frequency multiply-by 3 generated-clock with a duty cycle equal to the master clock duty cycle. If the master clock period is 30, and master waveform is {24 36}, the generated clock period will be 10 with waveform {8 12}.

```
pt_shell> create_generated_clock -multiply_by 3 \\
            -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a generated clock with edges at first, third, and fifth edges of the master clock source.

```
pt_shell> create_generated_clock -edges {1 3 5} \\
            -source [get_pins CLK] [get_pins pinf2]
```

The following example creates a generated clock like the previous example, but with each derived edge shifted later by one time unit.

```
pt_shell> create_generated_clock -edges {1 3 5} -edge_shift {1.0 1.0 1.0}
 \\
            -source [get_pins CLK] [get_pins pinf2]
```

The following example creates a generated clock that is inverted with respect to the source clock and has the same period.

```
pt_shell> create_generated_clock -divide_by 1 -combinational -invert \\
            -source [get_pins CLK] [get_pins pinf2]
```

The following example creates a rising-pulse clock with a width of 5.0 time units, with the pulse triggered by the rising edge of the master clock, and the period determined by the third edge of the master clock.

```
pt_shell> create_generated_clock -edges {1 1 3} -edge_shift {0 5.0 0}  \\
            -source [get_pins CLK] [get_pins pinf2]
```

The following example creates a falling-pulse clock triggered by the rising edge of its master clock.

```
pt_shell> create_generated_clock -edges {1 1 3} -edge_shift {0 5.0 0} \\
            -invert -source [get_pins CLK] [get_pins pinf2]
```

The following example creates a frequency doubling pulse. A rising pulse is triggered by both rising and falling edges of its master clock.

```
pt_shell> create_generated_clock -edges {1 1 2 2 3} -edge_shift {0 2.5 0
 2.5 0} \\
            -source [get_pins CLK] [get_pins pinf2]
```

create_histogram

Creates a custom histogram graph.

Syntax

status *create_histogram*

```
[-numbins number_of_bins]
[-min min_value]
[-max max_value]
[-greater_than gt_value]
[-less_than lt_value]
[-midpoint mid_value]
[-worst worst_side]
[-title title_label]
[-xlabel x_axis_label]
[-ylabel y_axis_label]
[-object_name object_name]
[-value_label value_label]
[-attribute attribute_name]
[-tcl_cmd tcl_command]
[-name name_histogram]
[-view view_name]
[-width window_width]
[-height window_height]
[-bin_range bin_range]
[-max_num_bins max_num_bins]
[-grid grid_view]
-collection object_list
[-infile debug_input]
[-outfile debug_output]
[-core_infile debug_core_input]
[-core_outfile debug_core_output]
```

Data Types

number_of_bins	integer

```

Arguments

`-numbins` *number_of_bins*

An integer in the range of 1 to 300, that specifies the number of bins to use in creating the histogram. The default is 8.

`-min` *min_value*

Specifies the minimum value to use in binning objects; the default is the smallest value used in binning the objects, or the value of *-greater_than*, if specified. Any object whose associated value is less than this value is to be dropped from the histogram with a warning message.

`-max` *max_value*

Specifies the maximum value to use in binning objects; the default is the largest value used in binning the objects, or the value of *-less_than*, if specified. Any object whose associated value is greater than this value is to be dropped from the histogram with a warning message.

`-greater_than` *gt_value*

Specifies the non-inclusive least value limit to use in binning objects; by default, there is no filtering of data on the min end of the value range. If *-min* is specified and *-greater_than* is not, the value given for *-min* is used. Any object whose associated value is less than or equal to this value is to be dropped from the histogram with a warning message.

`-less_than` *`lt_value`*

Specifies the non-inclusive greatest value limit to use in binning objects; by default, there is no filtering of data on the max end of the value range. If *-max* is specified and *-less_than* is not, the value given for *-max* is used. Any object whose associated value is greater than or equal to this value is to be dropped from the histogram with a warning message.

`-midpoint` *`mid_value`*

Specifies the midpoint value to use in interpreting histogram bins; by default, no midpoint is used. An x-axis tick mark is placed on the midpoint value and all bins to the *worst* side of the midpoint are colored red while all bins to the other side of the midpoint are colored green. The *worst* side is *none* by default but can be set to *left* or *right* using the *-worst* option.

`-worst` *`worst_side`*

Specifies whether values less than or greater than the midpoint are to be considered "worst." Allowed values are *left*, meaning that values less than midpoint are worse; *right*, meaning that values greater than the midpoint are worse; and *none* (the default), meaning that neither is worse.

`-title` *`title_label`*

Specifies the label to place at the top of the histogram graph. If not specified, a default title is constructed by concatenating the *object_name* label and the *value_label* label.

`-xlabel` *`x_axis_label`*

Specifies the label to place along the x-axis of the histogram graph. If not specified, the default x-axis label is the *value_label* label.

`-ylabel` *`y_axis_label`*

Specifies the label to place along the y-axis of the histogram graph. If not specified, the default y-axis label is constructed with the string "Number of *object_name*" where *object_name* is replaced with the *object_name* label.

`-object_name` *`object_name`*

Specifies the label to place at the head of the object name column in the list view accompanying the histogram. If not specified, the default is the standard type name for the type of objects found in the object list supplied for the *-collection* argument. For example, if the list consists of pins, the label "Pin" is placed at the head of the object name column. If the object list consists of multiple types of objects, the label "Object" is used. This label can also be used to construct the default title and y-axis labels.

`-value_label` *`value_label`*

Specifies the label to place at the head of the value column in the list view accompanying the histogram. If not specified, the default is the attribute name specified for the *-attribute* option, or the Tcl command string specified for the *-tcl_cmd* option, whichever is used. This label can also be used to construct the default title and x-axis labels.

`-attribute` *`attribute_name`*

Specifies the name of the attribute to use in constructing the histogram. The value of the named attribute is fetched for each object in the object list specified by the *-collection* argument. These values are then used to bin the objects to construct the histogram. If the attribute value is not defined for any object in the list, a warning message is issued and the object is excluded from the histogram. You must specify either *-attribute* or *-tcl_cmd*, but not both.

`-tcl_cmd` *`tcl_command`*

Specifies the Tcl command to use in constructing the histogram. The Tcl command is evaluated for each object in the object list specified by the *-collection* argument. These values are then used to bin the objects to construct the histogram. If the Tcl command evaluation fails for any object in the list, a warning message is issued and the object is excluded from the histogram. You must specify either *-attribute* or *-tcl_cmd*, but not both.

For a description of how the object in the object list is passed to the Tcl command, see the DESCRIPTION section.

`-name` *`name_histogram`*

Specifies the name of the new histogram view.

`-view` *`view_name`*

Specifies an existing histogram view to use for the new histogram.

`-width` *`window_width`*

Specifies the width of the window in number of pixels. The default is the width of the last histogram window closed when PrimeTime was last run.

`-height` *`window_height`*

Specifies the height of the window in number of pixels. The default is the height of the last histogram window closed when PrimeTime was last run.

`-bin_range` *`bin_range`*

Specifies the size of the value range per bin.

`-max_num_bins` *`max_num_bins`*

Specifies the maximum number of bins allowed when value range per bin is specified. The value must be greater than or equal to 1.

`-grid` *`grid_view`*

Specifies an existing grid view to use with the new histogram.

`-collection` *`object_list`*

Specifies the object collection to bin and graph.

`-infile` *`debug_input`*

Specifies the file to read data from on the GUI side.

`-outfile` *`debug_output`*

Specifies the file to write data to on the GUI side.

`-core_infile` *`debug_core_input`*

Specifies the file to read data from on the core side.

`-core_outfile` *`debug_core_output`*

Specifies the file to write data to on the core side.

Description

The *create_histogram* command constructs a histogram by binning the objects in the given object list using values evaluated with the given attribute name or Tcl command. You can issue *create_histogram* only while the GUI is active. Type the command into the command line field at the bottom of the GUI console window.

The object in the object list is passed to the Tcl command using the following conventions.

For each object the following is appended to the supplied Tcl command string: "-collection *collection_name* -index *index_of_object*" where *collection_name* is replaced by the name of the list given to the *create_histogram* command and the *index_of_object* is replaced with the zero-based index of the current object under evaluation in that list.

If the object is not a timing path, timing arc, or library timing arc, the following is further appended after the *-collection* and *-index* arguments: "-object *object*" where *object* is replaced with the name of a one-object collection that contains the current object under evaluation from the object list.

Note that you cannot use the *index_collection* command as the *-tcl_cmd* argument for lists of timing paths, timing arcs, library timing arcs, and timing points.

The histogram is graphed in a histogram view accompanied by a two-column table view that displays members of a selected bar. You can select a bar in the histogram by clicking the left mouse button over the bar. When a bar is selected, the accompanying table view

displays the objects in the bar. The left column displays the object names, while the right column displays the values associated with the objects used to created the histogram.

Examples

These examples show creation of custom histograms using the *create_histogram* command. All command strings must be entered in the command line field at the bottom of the GUI console window.

The following example shows creation of a histogram using the *-attribute* flag to retrieve an attribute value for each object in a collection. In this example, the *fanout_load* attribute value is used to bin all pins in the design. The graph is labeled with the title string "Pin Fanout" using the *-title* option. A new window frame is created for the new histogram by default because no view is given with a *-view* option. The new histogram view is named *view1* using the *-name* option,

```
pt_shell> create_histogram -name view1 -attribute fanout_load \\
                -title "Pin Fanout" -collection [get_pins *]
1
```

The following example shows creation of another histogram binning cells by area, with the graph reusing the histogram view named *view1* created in the previous example. The histogram will have the default title "Cell area", default x-axis label "area" and y-axis label "Number of cells".

```
pt_shell> create_histogram -view view1 -attribute area \\
                -collection [get_cells *]
1
```

The following example shows creation of a histograms using the *-tcl_cmd* flag to use a user-defined Tcl procedure to retrieve a value for each object in a collection. First, a Tcl script file named "myscript.tcl" containing the following lines is created to define a Tcl procedure named "myproc" that retrieves the *fanout_load* attribute value for the object that is passed in the procedure arguments:

```
proc myproc {flag1 clct flag2 idx flag3 obj} {
    set result [get_attribute $obj fanout_load]
    return $result
}
```

The disregarded strings flag1, flag2, and flag3 are placeholders for the *-collection*, *-index*, and *-object* option flags, respectively, preceding the three arguments.

You can identify the object by directly using the object in the third argument as in the preceding myproc procedure, or by using the collection name and the object index in the first and second arguments, respectively. The following procedure, myproc2, performs the same function as myproc but retrieves its objects using the first and second arguments:

```
proc myproc2 {flag1 clct flag2 idx flag3 obj} {
    set mypin [index_collection $clct $idx]
```

```
    set result [get_attribute $mypin fanout_load]
    return $result
}
```

You can now source the script file to define the procedures within the PrimeTime Tcl interpreter context:

```
pt_shell> source myscript.tcl
1
```

After you define the procedures, you can reference them by running *create_histogram -tcl_cmd* as in the following example.

```
pt_shell> create_histogram -name view1 -tcl_cmd myproc \\
          -title "Pin Fanout" -collection [get_pins *]
1
```

In this example, the embedded command *[get_pins *]* is first interpreted to create a collection of all pins in the design. The Tcl procedure "myproc" is then invoked for each pin object in the collection to retrieve a value per pin to use in creating the histogram.

---

create_ilm

Creates an interface logic model and writes it to a new directory. Also, sets the *is_interface_logic_pin* attribute on pins of the current design that are part of its interface logic model.

Syntax

int *create_ilm*

```
[-script_format ptsh | dcsh | dctcl]
[-instances instance_list]
[-ignore_ports port_list]
[-auto_ignore]
[-verbose]
[-ignore_boundary_pins boundary_pin_list]
[-include incl_list]
[-verification_script]
[-latch_level levels]
[-context_borrow]
[-keep_ignored_fanout]
[-include_pins pin_list]
[-critical_pins]
[-traverse_disabled_arcs]
[-parasitics_options para_options]
```

```
[-sdf_options sdf_options]
[-validate valid_list]
```

Data Types

```
instance_list       list
port_list           list
boundary_pin_list   list
incl_list           list
levels              int
pin_list            list
para_options        list
sdf_options         list
scenario_name       string
valid_list          string
```

Arguments

`-script_format ptsh | dcsh | dctcl`

Specifies the output format for the script. Allowed values are *ptsh* (the default) for pt_shell, *dcsh* for dc_shell, and *dctcl* for dc_shell-t.

`-instances instance_list`

Specifies the list of instances for which ILMs need to be generated. Separate ILMs are generated for each instance and written out to directories named after the instance name.

`-ignore_ports port_list`

Specifies a list of input or output ports whose fanout or fanin is to be ignored when setting the *is_interface_logic_pin* attribute. Clock ports are automatically ignored; you do not have to specify them in this list.

You can use this option to exclude the fanout of ports connected to chip-level nets (for example, scan enable and reset) from affecting the contents of interface logic. If these nets are not explicitly ignored, they cause unnecessary logic (for example, internal registers) to be part of the interface logic on the current design. You can also use this option to selectively generate the interface logic for a subset of the ports on a block; for example, an interface logic model (ILM) can model only the timing behavior on a subset of the ports on a block.

By default, all nonclock input and all output ports are used in identifying the contents of interface logic. The *-ignore_ports*, *-ignore_boundary_pins*, and *-auto_ignore* options are mutually exclusive.

`-auto_ignore`

Enables automatic determination of ports whose fanout should be ignored when setting the *is_interface_logic_pin* attribute. A port is ignored if the percentage of the total registers in the design in the transitive fanout of the port exceeds a

specified threshold percentage contained in the *ilm_ignore_percentage* variable (default 25).

You can use this option to help you identify the test enable and reset ports of your design. Before using it, examine the current value of the *ilm_ignore_percentage* variable and reset it, if necessary. Note that the *-auto_ignore* option might potentially ignore ports you do not want to ignore, or fail to ignore ports you want to ignore. Carefully read the messages issued by this command when you use this option to see which ports have been ignored and what percentage of registers to which they fanned out.

The *-ignore_ports*, *-ignore_boundary_pins* and *-auto_ignore* options are mutually exclusive.

`-verbose`

Indicates that information about the number of cells and nets in the original design and in the ILM netlist is to be written to standard output.

`-ignore_boundary_pins` *`boundary_pin_list`*

Specifies a list of boundary pins whose fanout or fanin is to be ignored when placing the is_interface_logic_pin attribute while extracting an instance ILM. Works similar to the *-ignore_ports* option but works for instance ILMs. This option can only be used along with the *-instances* option.

The *-ignore_ports*, *-ignore_boundary_pins* and *-auto_ignore* options are mutually exclusive.

`-include` *`incl_list`*

Includes specified elements in the ILM. You can specify these values:

- *net_pins* - Includes all pins on nonclock interface logic nets and propagated clock interface logic nets. Use this option if the interface logic model (ILM) is used in non-SDF flows and delay calculation is performed using the information contained in the ILM. Preserving all pins on a net maintains correct pin capacitance information for the net. The *net_pins* does not affect unpropagated clock nets; that is, nets in the clock network that have user-specified source latency.
- *boundary_cells* - Includes the boundary cells for all input ports. By default, the boundary cells would be present for all inputs except for the ignored ports. This option includes boundary cells for the ignored input ports also so that DRC checks can be performed at top level.

- *si_delay_pins* - Includes additional logic required to perform crosstalk delay analysis at the chip-level. Since the crosstalk flow involves detailed parasitics, the *si_delay_pins* argument also turns the *net_pins* argument on.
- *si_noise_pins* - Includes additional logic required to perform noise analysis at the chip-level. Since the noise flow involves detailed parasitics, the *si_noise_pins* argument also turns the *net_pins* argument on.

`-verification_script`

Specifies that a script needs to be generated that can be used for the verification of ILM. By default, *create_ilm* command generates a script that can be used when the ILM is instantiated at upper level of hierarchy. This option additionally generates a script that can be used to validate the ILM against the original block from which the ILM was generated.

`-latch_level` *`levels`*

Specifies the number of logic levels over which time borrowing can occur for latch chains that are a part of the interface logic. Substitute the number of levels you want for the *levels* option. By default, all latches found in interface logic are assumed to be potential borrowers. Thus, all logic from I/O ports to flip-flops or output ports are identified as belonging to interface logic.

When you use this option, note that the value of the *levels* argument must account for the borrowing behavior of latches only on interface timing paths. If *n* represents a latch level, then *n* + 1 represents the number of latches maintained in latch chains that originate at input ports. The *n* + *1*th latch functions as an edge-triggered register and decouples I/O paths from internal paths. Use this option only when there are latches in the interface logic for a block. Specifying this option might potentially result in less accurate models, because not all latches are allowed to borrow. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-context_borrow`

Specifies that latch borrowing at the interface should be established based on the current context defined for the design. So, latches that borrow based on arrival times defined on input ports and clocks defined on the design are traced through, but path tracing stops at nonborrowing latches. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-keep_ignored_fanout`

Specifies that the fanout from ignored input ports to interface logic is to be maintained in the model. Thus, ignored ports are not used to identify interface logic, but connections between ignored ports and interface logic are preserved. Timing slacks for ignored ports might differ from those reported on the original

netlist because connections from ignored ports to internal registers are not preserved in the model.

`-include_pins` *`pin_list`*

Specifies a list of pins that must be included in the interface logic. Substitute the list of pins you want for the *pin_list* option. This option can be used to optionally add internal pins to the interface logic. After the interface logic is determined, this list of pins is added to the interface logic. Use this option to define additional interface logic pins that are otherwise removed in the model. There is not any affect on pins that are already in the interface logic. Use this option in conjunction with the *all_fanin* and *all_fanout* commands to include a particular cone of logic in the model.

`-critical_pins`

Specifies that critical pins interface logic must be identified. This option allows you to extract a model that keeps only the pins in the critical paths of the design.

You can use this option to extract a critical pins interface logic. The model generated contains the interface logic pins in the critical paths of the design. The model is compact compared to normal interface logic models, but might not be as accurate outside of the current context. This model can be used only to do critical path analysis. It might take much longer to generate this model than the normal model.

The *-include {si_delay_pins}* option is not currently supported for critical pins ILM.

`-traverse_disabled_arcs`

Specifies that the interface logic should not be affected by disabled arcs/pins on the design. If specified, this option forces the traversal of disabled arcs while determining interface logic.

`-parasitics_options` *`para_options`*

Writes parasitic data for the net pins of the ILM in addition to the following options:

- *spef_format* - Writes parasitic data in SPEF format.
- *sbpf_format* - Writes parasitic data in SBPF format.
- *input_port_nets* - Writes parasitic data for nets connected to the input ports on the current design.
- *constant_nets* - Writes parasitic data for constant nets.

`-sdf_options` *`sdf_options`*

Writes SDF data for the ILM with the following options:

- *annotated* - Includes only timing arcs that have been annotated with the *read_sdf*, *set_annotated_delay*, or *set_annotated_check* commands.
- *no_edge* - Omits any edges (posedge or negedge) for combinational I/O paths.
- *2.1_version* - Writes the output as SDF version 2.1. This is the default.
- *3.0_version* - Writes the output as SDF version 3.0.
- *input_port_nets* - Includes delays of nets connected to input ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available.
- *output_port_nets* - Includes delays of nets connected to output ports of the current design. By default, these delays are not written to the SDF file because the external connectivity information for ports is not available.

`-validate` *`valid_list`*

Specifies what should be validated after the model is created. The allowed value is *timing*.

Description

Extracts an interface timing model (ILM) for the design or given list of instances. The ILM is written to a directory with name of the design, or the hierarchical name of instance with forward slash (/) replaced by underscore (_). The location of this potentially new directory is given by the *pt_ilm_dir* variable.

The command generates the following files:

- *dir_name*/ilm.v (Verilog design for the ILM)
- *dir_name*/ilm_inst.pt.gz (script to apply the instance constraints)

Additionally, the command might generate:

- *dir_name*/ilm.{sbpf, spef.gz} (Parasitics if *-parasitics_options* is given)
- *dir_name*/ilm.sdf (SDF file if *-sdf_options* is given)
- *dir_name*/ilm_verif.pt.gz (verification script for the design)
- *dir_name*/ilm.txt (list of aggressor annotation pins if *-include {si_delay_pins}* is given)

Also, the command sets the *is_interface_logic_pin* attribute on pins of the current design that are part of its interface logic.

The interface logic on a block contains all cells whose timing is affected by, or affects, the external environment of a block:

- All cells in timing paths that lead from input ports to registers or output ports that terminate the paths.
- All cells in timing paths that lead to output ports from registers or input ports that originate the paths.
- Clock trees that drive interface registers; including any registers in the clock tree. Clock-gating circuitry is part of interface logic if it is driven by external ports, but not if it is driven by registered outputs on a block.

Notice that interface logic does not include internal register-to-register paths and logic on a block associated only with these paths.

To include additional logic, use the *-include_pins* option. If the *-include {si_delay_pins}* option is given, additional register-to-register logic can be pulled in that is needed for crosstalk analysis at chip level.

This command implicitly performs an update_timing on the design if required. You can review the objects you have identified as interface logic by using the *get_ilm_objects* command.

If the *-validate* option is given, and the *hier_modeling_version* variable is set to 2.0, the model is validated automatically after the model is created.

Examples

The following example extracts ILM and sets the *is_interface_logic_pin* attribute on all nonclock pins in the current design, except for pins in the fanin/fanout of ports port1, port2, and port3.

```
pt_shell> create_ilm -ignore_ports [get_ports {port1 port2 port3}]
```

The following example extracts ILM for instance I1, additionally includes three levels of logic from internal pin I1/ff/Q and also includes internal crosstalk pins needed for top-level crosstalk analysis.

```
pt_shell> set ilm_pins [all_fanout -level 3 \\
          -flat [get_pin I1/ff/Q]]

pt_shell> create_ilm -instances {I1} \\
          -include_pins $ilm_pins -include {si_delay_pins}
```

The following example extracts a critical pins interface timing model.

```
pt_shell> create_ilm -critical_pins -include {net_pins}
```

The following example extracts ILM by placing the *is_interface_logic_pin* attribute on all nonclock pins in the current design, except for pins identified by the *-auto_ignore* option.

Feedback

Because the value of the *ilm_ignore_percentage* variable is currently 35, pins are ignored if the percentage of the total design registers in their transitive fanout is greater than 35. The *-latch_level* option with a value of 1 states that the first latch encountered in I/O paths might potentially borrow, but the second latch can be treated as an edge-triggered device. Thus, two levels of latches are maintained in the interface logic.

```
pt_shell> printvar ilm_ignore_percentage
ilm_ignore_percentage = "35"

pt_shell> create_ilm -auto_ignore -latch_level 1
```

---

create_merged_modes

Merges modes from the defined scenarios so that the timing scenarios are reduced.

Syntax

status *create_merged_modes*

```
[-test_only]
[-interactive]
[-keep_all_clocks]
[-match_clock_names]
[-target_eco]
[-value_tolerance tolerance]
```

Data Types

tolerance	float

Arguments

`-test_only`

Generates a mode merging report on which modes are merged and why certain modes are not be merged, without performing the actual merging.

`-interactive`

Determines which modes are merged and why certain modes are not merged by doing *-test_only* analysis, and opens the report in a GUI for interactive debugging.

`-keep_all_clocks`

Keeps all clocks separately. If you do not specify this option, mode merging adds only one clock into the merged mode when identical clocks (with the same waveform and sources) are present in more than one individual mode.

`-match_clock_names`

Specifies that clock names should also be matched in addition to the waveform and sources. If you do not specify this option, mode merging adds only one clock into the merged mode when identical clocks (with the same waveform and sources) are present in more than one individual mode.

`-target_eco`

Specifies that the merged modes are targeted for use in ECO flow. If you specify this option, mode merging automatically resolves merge conflicts wherever possible to improve mergeability. In addition, only the clocks that contribute to worst slack in the merged mode are kept and all other clocks are pruned.

`-value_tolerance` *tolerance*

When two modes have constraint values (for example, *set_clock_uncertainty*, *set_input_delay*, and so on) that differ by more than certain fraction, the two modes are not merged. By default, a tolerance value of 0.01 is used, which means that if the values are different by more than 1 percent, then the modes are not merged. You can use this option to change the tolerance value, thereby allowing for tradeoff between level of mode reduction and pessimism. A higher (or lower) tolerance value leads to more (or less) reduction but more (or less) pessimism in merged constraints.

Description

The *create_merged_modes* command merges modes from the defined scenarios so that the timing scenarios are reduced. For mode merging, the scenarios must have been created previously using *-mode* and *-corner* options of *create_scenario*. This command is only available in multi-scenario analysis.

After the modes are merged, the merged modes should be used with the same *-corner* option as was used for individual modes. Merged mode constraints are created under *multi_scenario_working_directory* with the name *merged_constraints*. Constraints are also written for unmerged modes in the directory. In addition, details of mode merging results, including why certain modes could not be merged, are written to a text file named *mode_merging_report.txt* in the *merged_constraints* directory.

Next, you describe how various commands are dealt with for mode merging. Mode merging merges pure mode commands (such as *create_clock*) and scenario (combination of mode and corner) commands. For scenario commands (such as *set_input_delay*), it is assumed that the command is present in all corners of a given mode but the values can

differ in each mode. For pure corner commands, it assumes that the command is present in all modes of the same corner.

Mode merging handles the following pure mode and scenario commands:

- create_clock • create_generated_clock • group_path • set_annotated_transition • set_case_analysis • set_clock_gating_check • set_clock_groups • set_clock_latency • set_clock_sense • set_clock_transition • set_clock_uncertainty • set_disable_timing • set_drive_resistance • set_driving_cell • set_false_path • set_fanout_load • set_ideal_latency • set_ideal_network • set_ideal_transition • set_input_delay • set_input_transition • set_load • set_max_capacitance • set_max_delay • set_max_fanout • set_max_time_borrow • set_max_transition • set_min_delay • set_mode • set_multicycle_path • set_output_delay • set_propagated_clock • set_sense

Although mode merging does not merge the following pure corner commands, the tool captures and writes these commands to merged mode scripts:

- create_operating_conditions • set_annotated_check • set_annotated_clock_network_power • set_annotated_delay • set_annotated_power • set_aocvm_coefficient • set_aocvm_table_group • set_connection_class • set_coupling_separation • set_cross_voltage_domain_analysis_guardband • set_domain_supply_net • set_dont_override • set_dont_touch • set_dont_touch_network • set_equal • set_input_noise • set_isolation • set_isolation_control • set_level_shifter_strategy • set_level_shifter_threshold • set_lib_rail_connection • set_library_driver_waveform • set_max_area • set_min_capacitance • set_min_pulse_width • set_noise_derate • set_noise_immunity_curve • set_noise_lib_pin • set_noise_margin • set_noise_parameters • set_operating_conditions • set_opposite • set_port_fanout_number • set_power_derate • set_rail_voltage • set_related_supply_net • set_resistance • set_retention • set_retention_control • set_setup_hold_pessimism_reduction • set_si_aggressor_exclusion • set_si_delay_analysis • set_si_noise_analysis • set_si_noise_disable_statistical • set_steady_state_resistance • set_supply_net_probability • set_switching_activity • set_temperature • set_timing_derate • set_voltage • set_wire_load_min_block_size • set_wire_load_mode • set_wire_load_model • set_wire_load_selection_group

For pure corner commands, any nested command is replaced by its output. For example, if the input constraints have the command "set_resistance 0.5 [get_nets n1]", the merged constraints have "set_resistance 0.5 {n1}". If net n1 does not exist, the merged constraints have "set_resistance 0.5", which is invalid syntax, leading to an error. It recommended that you check for and fix any errors in the input constraints on the pure corner commands.

The following list shows scenario commands that might need user intervention. Check these commands for correctness. For example, some clock names might need to be changed based on MMODE-008 messages.

Feedback

- set_power_clock_scaling • set_pulse_clock_max_transition • set_pulse_clock_max_width • set_pulse_clock_min_transition • set_pulse_clock_min_width

The following commands are not supported in mode merging.

- read_ddc • read_milkyway • set_active_clocks

Examples

In the following example, an iterative loop creates a set of scenarios. The same single.tcl script is used for all scenarios but the corner variables distinguishes the scenarios. Finally, the modes are merged using the *create_merged_modes* command. Modes M1 and M2 are merged to the new mode merged_1. Mode M3 is not merged.

```
pt_shell> foreach corner {bc tc wc} {
  foreach mode {M1 M2 M3} {
    create_scenario \
     -mode ${mode} \
     -corner ${corner} \
     -common_variables {mode corner} \
     -common_data "single.tcl"
  }
}

pt_shell> create_merged_modes
 ...
          Merged Mode Generation Summary
Original Modes              Merged Mode    Corners
-----------------------------------------------------
M1, M2                      merged_1       bc, tc, wc
M3                          M3             bc, tc, wc
```

- create_scenario

---

create_net

Creates nets in the current design.

Syntax

status *create_net*

```
[-exact]
net_list
```

Data Types

```
net_list     list
```

Feedback

Arguments

`-exact`

Indicates that names are to be used exactly as specified. Use this option if you want to create a net that contains a hierarchy or wildcard character as part of the net name. For more information, see "Naming Nets with Special Characters".

`net_list`

Specifies a list of nets to be created.

Description

The *create_net* command creates new nets in the current design. Like all other netlist editing commands, for the *create_net* command to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. The *create_net* command returns a 1 if successful and a 0 if unsuccessful.

The *create_net* command behaves almost identically to the *create_cell* command. Nets are created in scope; that is, at or below the current instance. Net names are specified as for other commands, using the full hierarchical name relative to the current instance, as in the following example:

```
create_net u1/u2/new_net class/AN2
```

This command attempts to create a net named new_net in the hierarchical block u1/u2. The name to the right of the last hierarchical separator is the actual net name, and the remainder is sent to the search engine to find a hierarchical block in which to create the new net. The operation fails if any of the following are true:

- The search engine cannot find "u1/u2".
- The search engine finds multiple blocks that match "u1/u2".
- The search engine finds a leaf cell matching "u1/u2".
- The search engine finds a net, port or hierarchical pin matching "u1/u2/new_net".

Naming Nets With Special Characters

If you want to create a net whose name contains the current hierarchical separator or wildcard characters used by the search engine, you must do the following:

- Use *current_instance* to change the scope to the block in which you want the new net created.
- Use *create_net -exact* to create the net.

For examples, see the EXAMPLES section.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Feedback

Examples

The following example creates nets in the current instance, and at a level below the current instance. Currently, u1 is an instance of a design that has multiple instances. Therefore, it is uniquified as part of the editing operation.

```
pt_shell> create_net new_net1
Information: Created net 'new_net1' in design 'top'. (NED-016)
1

pt_shell> create_net u1/new_net1
Uniquifying 'u1' (block1) as 'block1_0'.
Information: Created net 'new_net1' in 'top/u1'. (NED-016)
1
```

The following example creates net a/b in the hierarchical block u1/u2. The first attempt fails, because the *-exact* option was omitted. Here, u1/u2 is an instance of a design that has multiple instances; therefore, it is uniquified as part of the editing operation. u1 was already uniquified in the previous example.

```
pt_shell> current_instance u1/u2
u1/u2

pt_shell> create_net a/b
Error: Could not create net 'a/b':
        a not found. (NED-041)
Error: No changes made. (NED-040)
0

pt_shell> create_net a/b -exact
Uniquifying 'u1/u2' (block2) as 'block2_0'.
Information: Created net 'a/b' in 'top/u1/u2'. (NED-016)
1
```

---

create_operating_conditions

Creates a new set of operating conditions in a library.

Feedback

Syntax

int *create_operating_conditions*

```
-name name
-library library_name
-process process_value
-temperature temperature_value
-voltage voltage_value
[-tree_type tree_type]
[-calc_mode calc_mode]
[-rail_voltages rail_value_pairs]
```

Data Types

name	string
library_name	string
process_value	float
temperature_value	float
voltage_value	float
tree_type	string
calc_mode	string
rail_value_pairs	list

Arguments

`-name` *name*

Specifies the name of the new set of operating conditions.

`-library` *library_name*

Specifies the name of the library for the new operating conditions.

`-process` *process_value*

Specifies the process scaling factor for the operating conditions. Allowed values are 0.0 through 100.0.

`-temperature` *temperature_value*

Specifies the temperature value, in degrees Celsius, for the operating conditions. Allowed values are -300.0 through +500.0.

`-voltage` *voltage_value*

Specifies the voltage value, in volts, for the operating conditions. Allowed values are 0.0 through 1000.0.

`-tree_type` *tree_type*

Specifies the tree type for the operating conditions. Allowed values are *best_case_tree*, *balanced_tree* (the default), or *worst_case_tree*. The tree type is used to estimate interconnect delays by providing a model of the RC tree.

`-calc_mode` *`calc_mode`*

For use only with DPCM libraries. Specifies the DPCM delay calculator mode for the operating conditions; analogous to the *-process* option used in Synopsys libraries. Allowed values are *unknown* (the default), *best_case*, *nominal*, or *worst_case*. The default behavior (*unknown*) is to use worst case values during analysis similarly to worst_case. If *-rail_voltages* are specified, the command sets all (worst_case, nominal, and best_case) voltage values.

`-rail_voltages` *`rail_value_pairs`*

Specifies a list of name-value pairs that defines the voltage for each specified rail. The name is one of the rail names defined in the library; the value is the voltage to be assigned to that rail. By default, rail voltages are as defined in the library; use this option to override the default voltages for specified rails.

Description

This command creates a new set of operating conditions in the specified library. A technology library contains a fixed set of operating conditions; this command allows you to create new, additional operating conditions.

To see the operating conditions defined for a library, use the *report_lib* command.

To set operating conditions on the current design, use the *set_operating_conditions* command.

Examples

The following example creates a new set of operating conditions called WC_CUSTOM in the library "tech_lib", specifying new values for process, temperature, voltage, and tree type. By default, rail voltages remain as defined in the library.

```
pt_shell> create_operating_conditions -name WC_CUSTOM \\
-library tech_lib -process 1.2 -temperature 30.0 -voltage 2.8 \\
-tree_type worst_case_tree
```

The following example creates a new set of operating conditions called OC3, in the library "IBM_CMOS5S6_SC", specifying new values for process, temperature, voltage, and rail voltages for rails VTT and VDDQ. By default, the tree type *balanced_tree* is used.

```
pt_shell> create_operating_conditions -name OC3 \\
-lib IBM_CMOS5S6_SC -proc 1.0 -temp 100.0 -volt 4.0 \\
-rail_voltages {VTT 3.5 VDDQ 3.5}
```

See Also

- set_operating_conditions

Feedback

create_path_tag_set

Associates a named tag with timing paths in a collection.

Syntax

```
status create_path_tag_set
  [path_collection]
  [-append]
  [-name tag_name]
```

Data Types

```
path_collection     collection
tag_name            string
```

Arguments

path_collection

Specifies a collection of timing paths to tag. If not specified, an empty tag set is created.

`-name` *tag_name*

Specifies the tag name. Without this option, the command uses the name "default".

`-append`

Adds the specified paths to the existing tag set. Without this option, the command overwrites an existing tag set with the same name.

Description

The *create_path_tag_set* command provides a capability to tag collections of timing paths. Tagged timing paths can be excluded from appearing in the output of subsequent calls to *get_timing_paths* or *report_timing*.

You can specify the name of the tag using the *-name* option. The default name is "default".

If *path_collection* option is not specified, the command creates a new empty tag set if there is not already a tag set of the specified name.

Limitations

Collection tagging only applies to collections of timing paths.

Feedback

Examples

The following example tags a collection of timing paths and excludes the tagged timing paths from a subsequent *get_timing_paths* command:

```
pt_shell> set_app_var enable_path_tagging true
true
pt_shell> set mypaths [get_timing_paths ...]
pt_shell> create_path_tag_set $mypaths -name tag1
1
pt_shell> set more_paths [get_timing_paths -nworst 5 -max 5 -exclude
 tag1]
_sel2
```

The following example shows an iterative process where timing paths are analyzed in batches of 1000 and previously analysed paths are excluded from new results. When the *create_path_tag_set* command is used with the name of an existing tag set, the *-append* option causes the paths to be added to the existing tag set.

```
pt_shell> set path_set1 [get_timing_paths -max_paths 1000]
_sel1
pt_shell> report_timing -pba_mode path $path_set1
pt_shell> create_path_tag -name Alrdy_analyzed $path_set1
pt_shell> set path_set2 \\
 [get_timing_paths slack 0 max_paths 1000 -exclude Alrdy_analyzed]
_sel2
pt_shell> report_timing -pba path $path_set2
pt_shell> create_path_tag -append -name Alrdy_analyzed $path_set2
pt_shell> report_path_tag_set
****************************************
Report : Timing Path Tag Sets
 ...
****************************************

Tag name              |  Number of paths
------------------------------------------
Alrdy_analyzed        |  2000

1
```

Feedback

create_placement_blockage

Creates a new placement blockage.

Syntax

status *create_placement_blockage*

```
-bbox coordinate_list
[-name blockage_name]
```

Data Types

```
coordinate_list   list
blockage_name     string
```

Arguments

`-bbox coordinate_list`

Specifies the lower-left and upper-right coordinates (in microns) of the bounding box of the placement blockage in the following format: {*lower_left_x lower_left_y upper_right_x upper_right_y*}.

`-name blockage_name`

Specifies the optional name of the blockage.

Description

This command creates a new placement blockage that controls the placement of ECO cells when you use the *fix_eco_drc* or *fix_eco_timing* command with the *-physical_mode* option. PrimeTime does not resize cells or insert buffers within placement blockages.

You can create a placement blockage only after PrimeTime loads the physical database. To specify the file that contains *create_placement_blockage* commands, use the *set_eco_options* command with the *-physical_constraint_file* option. When you use this option, PrimeTime loads the physical database, reads the constraint file, and creates blockage areas before fixing violations.

Examples

The following example creates a placement blockage named placeblockage_10.

```
pt_shell> create_placement_blockage -bbox {0 0 100 100} -name
 placeblockage_10
```

---

create_power_domain

Creates a power domain at the specified scope, which provides a power supply distribution network.

Syntax

string *create_power_domain*

```
domain_name
[-elements element_list]
[-exclude_elements exclude_list]
[-include_scope]
[-scope instance_name]
[-supply supply_set_handle_or_ref]
[-available_supply supply_set_handle_or_ref]
[-update]
[-atomic]
```

Data Types

domain_name	string
element_list	list
exclude_list	list
instance_name	string
supply_set_handle_or_ref	string

Arguments

domain_name

Specify the name of the power domain to be created. The name should be a simple (non-hierarchical) name. You must specify this argument.

If there is a power domain with the same name in the specified scope, the power domain cannot be created. If there is a hierarchical/leaf cell instance or port with the same name in the specified scope, the power domain cannot be created either.

-elements *element_list*

Specify a list of cells which are added as the extent of the power domain. The list of cells should be hierarchical, macro, or I/O pad cells, but PrimeTime accepts any cell. Specified cells cannot be added in other power domains of the same scope.

If neither *-elements* nor *-include_scope* is specified, the power domain consists of the current scope and any of its children not specified as elements in another *create_power_domain* command.

`-exclude_elements` *`exclude_list`*

Specify a list of design elements to exclude from the effective_element_list.

`-include_scope`

If this option is specified, the scope of the power domain is also included in the extent of the power domain. This means all elements within the current scope get the supply as the power domain.

`-atomic`

Defines the minimum extent of the power domain. PrimeTime currently reads and ignores this option.

`-scope` *`instance_name`*

Specify in which scope the power_domain is going to be created. The instance name is the name of a hierarchical cell.

If this option is not specified, the power domain is created in the current scope.

`-supply` *`supply_set_handle_or_ref`*

Specifies the *supply_set_ref* for the domain. *supply_set_handle_or_ref* follows the following format : {*supply_set_handle* [*supply_set_ref*]}. If *supply_set_ref* is also specified, the domain supply_set_handle is associated with the specified supply_set_ref. This option can be specified multiple times.

`-available_supply` *`supply_set_handle_or_ref`*

PrimeTime currently reads and ignores this option.

Either predefined or user-defined handle names can be used. The predefined supply_set_handles are:

- *primary*: primary supply set of this power domain
- *default_isolation*: default isolation supply set for any isolation strategy applied to this power domain if the isolation power or ground is not specified in the strategy
- *default_retention*: default retention supply set for any retention strategy applied to this power domain if the retention power or ground is not specified in the strategy

Handles of the form *extra_supplies_[0-9]+* are accepted but ignored in PrimeTime.

`-update`

Updates the supply set association of an existing power domain.

The *-update* option is used along with and only with the *domain_name* and *-supply* options. It is an error to use the *-update* option with any other option.

This option allows you to

- Add a new supply set handle name without explicitly defining a supply set association
- Add a supply set to be associated with a previously declared supply set handle
- Add a new supply set handle and a supply set association in a single command
- Add cells to a previously created domain.

NOTE: It is an error to update a supply set handle that you have already associated with a supply set. It is an error to add cells that are already root cells of the domain.

Description

The *create_power_domain* command enables you to create a power domain in the specified scope. A power_domain is a collection of design elements that share a primary power and ground power net. The logic hierarchy level where a power domain is created is called the scope of the power domain. Any design elements that belong to a power domain are said to be in the extent of that power domain. While a design element can be in the scope of a number of power domains, if can only be in the extent of one power domain.

A power domain could have several supply_nets, supply_nets are connected to power_domain via supply_port. And a power_switch of a power_domain could be used to turn on/off the power supply of part/whole power domain. The supply net, supply port, and power switch can be created using the *create_supply_net*, *create_supply_port* and *create_power_switch* commands respectively.

This command returns collection object (the newly created power domain). It returns null string if it failed.

Non-UPF Mode (Power Domains Mode): This command works in power domains mode as well, and take following options instead.

string *create_power_domain*

```
domain_name
[-power_down]
[-power_down_ctrl list]
```

```
[-power_down_ack list]
[-power_down_ctrl_sense <0 or 1>]
[-object_list list]
```

-power_down

Use this to specify the new power domain is a power down domain. This option is a prerequisite for the *-power_down_ctrl* option.

-power_down_ctrl *list*

Use this to specify the power down control net for the new power domain. The *-power_down* option is required in order to use this option. It is also a prerequisite for the *-power_down_ack* option.

-power_down_ack *list*

Use this to specify the power down acknowledge net for the new power domain. The *-power_down_ctrl* option is required in order to use this option.

-power_down_ctrl_sense *<0 or 1>*

Use this to specify the sense of the power down control net for the new power domain. It take values of 0 or 1. It specifies the active low or active high sense type for power control signal. The *-power_down_ctrl* option is required in order to use this option.

-object_list *list*

A list of hierarchical cells that are associated with the new power domain. When this option is absent, the new power domain is assumed to be the top level domain. For each design, there can only be one top-level domain. Also, each hierarchical cell can only be associated with one power domain.

The *create_power_domain* command creates a new power domain for the current design. The power domains for each design must be uniquely named. There can be only one design-wise top level power domain.

Use *-power_down* to specify a new domain is a power down domain. An always-on power domain is created without this switch. For a power down domain, use *-power_down_ctrl* to specify an optional power down control net; use *-power_down_ack* to specify an optional power down acknowledge net.

Use *-object_list* to associate a list of hierarchical cells with the new power domain. When this option is not used, the new power domain is considered as top-level power domain. Each hierarchical cell can only belong to one power domain.

By default, power down control and power acknowledge signals are marked dont touch. Set the *dont_touch_power_domain_control_nets* variable to false if you do not want these signal marked dont_touch.

Feedback

Examples

UPF Mode:

The following example creates two power_domains in scope INST1:

```
pt_shell> create_power_domain PD1 -elements INST1/SUB_INST -scope INST1
{"INST1/PD1"}

pt_shell> create_power_domain PD2 -elements INST1/SUB_INST -scope INST1
Error: Cell 'INST1/SUB_INST' is already in the extent of power domain
 'PD1'. (UPF-001)

pt_shell> create_power_domain PD2 -scope INST1 -include_scope
{"INST1/PD2"}
```

The following example excludes instance INST1 specified in -exclude_elements option from the effective element list:

```
pt_shell> create_power_domain PD_TOP -elements {INST1 INST2}
 -exclude_elements {INST1}
```

The following example creates a power domain in scope INST1, and uses a supply set to provide the default primary power and ground, and a different supply set to provide the default retention power and ground nets.

```
pt_shell> create_power_domain PD3 -scope INST1 -supply {primary set1} \\
            -supply {default_retention set2}
```

The following example updates an existing power domain with the *-supply* option.

```
prompt> create_power_domain PD_MID -scope mid1 -supply {abc}
mid1/PD_MID
prompt> create_power_domain PD_MID -scope mid1 -update \\
    -supply {primary SS1} -supply {abc SS1}
mid1/PD_MID
```

Non-UPF Mode:

The following examples use the command to create power domains.

```
pt_shell> create_power_domain TOP_DOMAIN
1

pt_shell> create_power_domain SUB_DOMAIN -power_down \\
                  -power_down_ctrl [get_nets pd_ctrl] \\
                  -power_down_ack [get_nets pd_ack] \\
                  -object_list [get_cells mid1]
1
```

---

create_power_group

Creates a power group of cells in the current design.

Syntax

int *create_power_group*

```
-name group_name
-default
object_list
```

Data Types

group_name	string
object_list	list

Arguments

`-name` *group_name*

Specifies the name for the power group. The name should not conflict with names of existing power groups.

`-default`

Indicates that the specified power group is predefined and the default list of cells are to be included in the power group. This option is mutual exclusive with the *object_list* option.

object_list

Specifies a list of cells to be included in this power group. This option is mutual exclusive with the *-default* option.

Description

Group a list of cells of special interests (not necessarily in the same hierarchy) to form a power group. The *update_power* and *report_power* commands are able to generate power waveform and power report for this power group.

The cells contained in power groups are leaf cells. If a hierarchical cell is specified in the *object_list* option, all the leaf cells contained by the hierarchical cell, instead of the hierarchical cell itself, are added to the power group.

There are several power groups predefined and automatically created by the tool. However, if a predefined power group has been removed, the *-default* option can be used to regenerate it.

The following is a list of the predefined power groups ordered by priority from high to low. Note that the predefined power groups are not supposed to be overlapping with one another. If one cell happens to belong to more than one group, it is put into the group with the higher priority.

- *io_pad* - All I/O PAD cells.
- *memory* - All memory cells.
- *black_box* - All black boxes.
- *clock_network* - Cells in the clock network. The contents is consistent with the results from the *get_clock_network_objects -type cell* command. If the *power_clock_network_include_clock_gating_network* variable is set to *true*, the contents is consistent with the results from the *get_clock_network_objects -type cell -include_clock_gating_network* command.
- *register* - The latches, flip-flops driven by the clock network. The contents is consistent with the results from the *get_clock_network_objects -type register* command. If the *power_clock_network_include_clock_gating_network* variable is set to *true*, the contents is consistent with the results from the *get_clock_network_objects -type register -include_clock_gating_network* command.
- *sequential* - All other sequential cells.
- *combinational* - All other combinational cells.

To move cells from one predefined group to another, add the power_cell_type attribute and assign the value to the desired predefined group. The power_cell_type attribute takes precedence over the rules used to determine which group a cell belongs to.

Examples

In the following example, a power group called clock_tree is created to accommodate all the clock tree cells.

```
pt_shell> create_power_group -name clock_tree [get_clock_network_objects
 -type cell]
1
```

In the following example, the predefined power group clock_network has been removed earlier, now you want to create it again with the default list of cells.

```
pt_shell> create_power_group -name clock_network -default
1
```

---

create_power_net_info

Creates a power net.

Syntax

int *create_power_net_info*

```
power_net_name
-power
-gnd
[-switchable]
[-nominal_voltages nominal_voltage_list]
[-voltage_ranges voltage_range_list]
```

Data Types

```
power_net_name          string
nominal_voltage_list    list
voltage_range_list      list
```

Arguments

power_net_name

The name of the new power net info to be created.

-power

Specifies the type of the new power net is "power". Mutually exclusive with -gnd option.

-gnd

Specifies the type of the new power net is "gnd". Mutually exclusive with -power option.

Feedback

`-switchable`

Specifies that this power net is switchable (can be cut off externally, or, if driven by an internal switch, cut off internally). This option can only be used with -power.

`-nominal_voltages` *`nominal_voltage_list`*

Specifies the list of nominal voltages this power net has been designed to operate. The actual operating voltage of the power net can deviate from the nominal within a certain tolerance as specified by *voltage_ranges_list*. This optional argument must be specified together with *voltage_ranges_list*. This option can only be used with -power.

`-voltage_ranges` *`voltage_range_list`*

Specifies the list of allowed voltage ranges around the nominal voltages that this power net has been designed to operate. This optional argument must be specified together with *nominal_voltages_list*. This option can only be used with -power.

Description

The *create_power_net_info* command creates a new power net info for the current design. The power net is either of type power or of type gnd.

Examples

The following examples use the command to create power nets.

```
prompt> create_power_net_info VSS_net -gnd
1
prompt> create_power_net_info VDD1_net -power
1
prompt> create_power_net_info VDD2_net -power \\
   -switchable -nominal_voltages {0.9 1.08} \\
   -voltage_ranges {0.88 0.92 1.05 1.10}
1
```

---

create_power_rail_mapping

Maps the power rails defined in the libraries to the physical power rails existing in the design.

Feedback

Syntax

status create_power_rail_mapping

```
[-lib_rail_name power_rail_name]
[-cells cell_list]
[-off_condition condition]
[-default]
design_rail
```

Data Types

power_rail_name	string
cell_list	list
condition	string
design_rail	string

Arguments

`-lib_rail_name` *power_rail_name*

Specifies the power rail defined in the library. It can take the power rail name defined in the library and also take "all". The power rail name can be the name of the *voltage_map* command defined in the library. By using the *-lib_rail_name all* option, the mapping is applied to all the power rails in each library associated with the library cells. If the *-lib_rail_name* option is not used, the mapping is applied to the default library power rail in each library associated with the library cells.

`-cells` *cell_list*

Specifies the instance names or collections of instances. The instance can be hierarchical or leaf instances. For an instance block, only the top instance needs to be specified. All the instances inside such block will be affected by the mapping. Without this option, the mapping will be created for the whole design.

`-off_condition` *condition*

Specifies the power-off condition for the design power rail. At power-off state, the portion of design that is powered off by the specific design power rail will not contribute any dynamic or static power. The Boolean expression takes net names plus operators. The operators supported are: (,), !, +, *, &, |, ^, '. When the expression is evaluated to be "1", the design power rail is in power-off state. If the expression is evaluated to be "0" or any unknown state, the design power rail is in power-on state. Ensure that the states of the nets used in the Boolean expression are clearly defined to avoid any unexpected results. If the *-power_off* option is omitted, the design power rail is assumed to be on all the time.

When switching activity information is specified by the VCD file, the state of the power control signal nets are monitored. The power-off expression is evaluated if there is any state change on these control nets. When a specific power rail is

powered-off, neither dynamic nor static power will be dissipated on the cell (or part of cell) powered by this rail.

When switching activity information is specified by statistical toggle rate and state probability, the state probability of the power rail being on is calculated. As a default, only leakage power is scaled by the state probability of the associated power rail being on. Set the *power_scale_dynamic_power_at_power_off* variable to true, if dynamic power needs to be scaled too. Dynamic power scaling is only needed if the statistical switching activity includes toggles happened when the rail is being powered off.

`-default`

Specifies the design power rail to be the default rail in the design. If not specified, the design power rail defined by the first *create_power_rail_mapping* command is assigned as the default design rail.

`design_rail`

Defines the power rail used in the design.

Description

Use this command to map the power rails defined in the libraries to the physical power rails existing in the design. Such rail mapping is done at cell (instance) level, which gives you the flexibility to connect the same library cell to different physical power rails in a design. The design power rails specified in this command are virtual power rails, which means that the rail connections do not actually exist in the netlist. No voltage level violation will be checked for such virtual rail connections. It is allowed to connect cells with different voltages to the same virtual design power rail. This command enables PrimePower to create collections of instances on different power rails. Thus, provides the capability and flexibility to create rail-based power reporting at design level. This command also enables PrimePower to be sensitive to the power-on/off control signals associated with the design power rails.

Single-rail or multi-rail cell in PrimePower is based on its cell definition in logic library. A multi-rail cell can have rail specific internal or leakage power tables defined in the library. So that power consumption can be reported for different rails.

This command can create the rail mapping for the whole design or for specific instances (hierarchical or leaf-level). Multiple *create_power_rail_mapping* commands can be issued, the latter overwrites the previous settings if it overlaps.

For single-rail design, if not specified, the default library rail will be mapped to the default design rail internally.

The *report_power_rail_mapping* command can be used to report existing power rail mapping information.

Feedback

Examples

The following example shows how to create rail mapping and generate rail-based power reports for a multi-rail design. There are three instance blocks in this design: block1, block2 and ls_block. Block block1 and block2 are both single-rail instance blocks with all the leaf cells powered by the default library power rail defined in each associated logic library. Block block1 is connected to design power rail VDD1 in the design while block block2 is connected to design power rail VDD2 in the design. Block ls_block is a dual-rail instance block with rail V1 and V2 defined in its cells' logic library. Library power rail V1 is connected to design power rail VDD1 and library power rail V2 is connected to design power rail VDD2. The *current_power_rail* command can select the rail of interest and the *update_power* command can generate the power analysis results just for the interested rails. As a result, report Power_VDD1.rpt file will only contain the power consumed on design power rail VDD1 and report Power_VDD2.rpt will only contain the power consumed on design power rail VDD2. Since the *current_power_rail all* command will mark all the design power rails to be interested, report Power_all.rpt file will contain the total power consumed for entire design.

```
pt_shell> create_power_rail_mapping VDD1 -cells block1
pt_shell> create_power_rail_mapping VDD2 -cells block2
pt_shell> create_power_rail_mapping VDD1 -lib_rail_name V1 -cells
 ls_block
pt_shell> create_power_rail_mapping VDD2 -lib_rail_name V2 -cells
 ls_block
pt_shell> current_power_rail VDD1
pt_shell> update_power
pt_shell> report_power > Power_VDD1
pt_shell> current_power_rail VDD2
pt_shell> update_power
pt_shell> report_power > Power_VDD2
pt_shell> current_power_rail all
pt_shell> update_power
pt_shell> report_power > Power_all
```

---

create_power_state_group

Defines a group name to be used in the *add_power_state* command.

Syntax

status *create_power_state_group*

```
        group_name
```

Data Types

group_name	string

Arguments

group_name

Specifies the name of the group to create. It must use a simple name.

Description

The *create_power_state_group* command defines a group in the active scope that can be used with the *-group* option of the *add_power_state command*.

Use a group to collect related power states defined by the *add_power_state* command. The legal power states of a group define the legal combinations of power states of other objects in this scope or the descendant subtree, that is, those combinations of states of those objects that can exist at the same time during operation of the design.

It is an error if the specified group name already exists in the active scope.

Examples

The following example shows how to define a power state group.

```
prompt> create_power_state_group PST_GROUP
```

See Also

- add_power_state

Feedback

create_power_switch

Creates a power switch at the specified power domain. This command is supported only in the UPF mode.

Syntax

status *create_power_switch*

```
switch_name
-domain domain_name
-output_supply_port {port_name supply_net_name}
-input_supply_port  {port_name supply_net_name}
-control_port {port_name net_name}
-on_state {state_name input_supply_port {boolean_function}}
[-off_state {state_name {boolean_function}}]
[-on_partial_state {state_name input_supply_port {boolean_function}}]
[-error_state {state_name {boolean_function}}]
[-ack_port {port_name net_name [{boolean_function}]}]
[-ack_delay {port_name delay}]
[-supply {port_name supply_net_name}]
```

Data Types

```
switch_name           string
domain_name           string
port_name             string
supply_net_name       string
net_name              string
state_name            string
input_supply_port     string
boolean_function      list
delay                 string
supply_net_name                string
```

Arguments

switch_name

Specifies the power switch to create. The name should be a simple (nonhierarchical) name. You cannot create a power switch with the same name as the existing power switch in a specified power domain. This option is required.

-domain *domain_name*

Specifies the power domain that contains the power switch. If the power domain with the specified name does not exist in the current scope, the command fails. This option is required.

`-output_supply_port {port_name supply_net_name}`

Specifies the output port of the power switch and the supply net where the port connects. The command fails when,

- A port exists with the same name on the power switch.
- A supply net with the same name does not exist in the current scope. This option is required.

`-input_supply_port {port_name supply_net_name}`

Specifies the input port of the power switch and the supply net where the port connects. The command fails when,

- A port exists with the same name on the power switch.
- A supply net with the same name does not exist in the current scope. This option is required.

`-control_port {port_name net_name}`

Specifies the control port of the power switch and the logical net where this port connects. The command fails when,

- A port with the specified name already exists on the power switch.
- A net with the specified name does not exist. This option is required. You can specify this option more than one time. One power switch can have multiple control ports.

`-on_state {state_name input_supply_port {boolean_function}}`

Specifies the on state, the relevant input supply port, and its Boolean function. You can specify this option multiple times.

`-off_state {state_name {boolean_function}}`

Specifies the off state and its relevant Boolean function. This option is currently ignored by the PrimeTime tool.

`-on_partial_state {state_name input_supply_port {boolean_function}}`

Specifies the partial state and its relevant Boolean function. This option is currently ignored in the PrimeTime tool.

`-error_state {state_name {boolean_function}}`

Specifies the error state and its relevant Boolean function. This option is currently ignored by the PrimeTime tool.

`-ack_port {port_name net_name [{boolean_function}]}`

Specifies the acknowledge port of the power switch and the logical net where this port connects. The command fails when,

- A port with the specified name already exists on the power switch.
- A net with the specified name does not exist. You can specify a Boolean function. This option is currently ignored by the PrimeTime tool.

`-ack_delay {port_name delay}`

Specifies the acknowledge port on the switch and the corresponding delay. This option is currently ignored by the PrimeTime tool.

`-supply {port_name supply_net_name}`

PT currently reads and ignores this option.

Description

This command enables you to create a power switch at the specified power domain. The switch is created within the scope of the power domain. Each power switch must be connected with an input supply net and an output supply net. The power switch can be connected with an acknowledge net and several control nets through a switch port. The switch ports are created if the power switch is created successfully, otherwise generates an appropriate error message.

Examples

The following example creates power switch, SW1 within power domain, PD1:

```
pt_shell> create_power_switch SW1 -domain PD1 \\
          -output_supply_port {vout VNO2} \\
          -input_supply_port {vin1 VNI1} \\
          -control_port {ctrl_small ON1}  \\
          -on_state {full_s vin1 {ctr_small}}
```

The following example generates an error message, when the command fails.

```
pt_shell> create_power_switch sw1 -domain ADD1 \\
          -control_port {ctrl power_down} \\
          -input_supply_port {in VDD1} \\
          -output_supply_port {out VDD1_ADD} \\
          -on_state {state_2001 in {!ctrl}}
Warning: Nothing implicitly matched 'ADD1' (SEL-003)
Error: Nothing matched for collection (SEL-005)
Error: The '-domain' option of create_power_switch command must specify
exactly one power domain object. (UPF-004)
0
```

Feedback

---

create_pst

Creates a power state table (PST), using a specific order of supply nets.

Syntax

string *create_pst*

```
table_name
-supplies list
```

Data Types

```
table_name          string
list                list
```

Arguments

table_name

Specifies the name of the power state table.

This argument is required.

-supplies *list*

Specifies a list of supply nets to include in each power state table in the design.

This option is required.

Description

The *create_pst* command creates a power state table using a specific order of supply nets. A power state table is used for implementation specifically for synthesis, analysis, and optimization. The power state table defines the legal combinations of states, which are those combinations of states that can exist at the same time during the operation of the design.

An error occurs if a specified supply net has not been created before the *create_pst* command is run.

Examples

The following is an example of the *create_pst* command:

```
prompt> create_pst MyPowerStateTable -supplies {PN1 PN2 SOC/OTC/PN3}
```

Feedback

See Also

---

create_qtm_constraint_arc

Creates a constraint arc for a quick timing model.

Syntax

string *create_qtm_constraint_arc*

```
[-name arc_name]
[-setup]
[-hold]
[-recovery]
[-removal]
-from port_name
[-to port_spec]
-edge rise | fall
[-signal_edge rise | fall]
[-path_type name]
[-path_factor multiplication_factor]
[-value constraint_value]
```

Data Types

arc_name	string
port_name	string
port_spec	list
name	string
multiplication_factor	float
constraint_value	float

Arguments

`-name arc_name`

Specifies the name of the constraint arc.

`-setup`

Creates a setup arc.

`-hold`

Creates a hold arc.

`-recovery`

Creates a recovery arc.

`-removal`

Creates a removal arc.

`-from` *`port_name`*

Specifies the constraining port name. Define this port as a clock port.

`-to` *`port_spec`*

Specifies the constrained port. Define this port as an input/inout port.

`-edge rise | fall`

Specifies the triggering edge of the clock (rise or fall).

`-signal_edge rise | fall`

Specifies the direction of the signal at the constrained port specified by the *-to* option.

If you do not specify this option, the tool creates constrinats for both signal rise and signal fall.

`-path_type` *`name`*

Specifies the path type that you want to use to set the delay.

`-path_factor` *`multiplication_factor`*

Specifies the multiplication factor for the path type.

`-value` *`constraint_value`*

Specifies the delay value in terms of the time units you use for the model.

Description

This command allows you to create a constraint arc in a quick timing model. The *-from* port denotes the constraining port, and the *-to* port denotes the constrained port. The *-from* port must be defined as a clock port and the *-to* port must be an input or inout port. You can use *-signal_edge* option to specify the the direction of the signal at the constrained port specified by the *-to* option.

Use the *-setup*, *-hold*, *-recovery* and *-removal* options to specify a setup, hold, recovery or removal arc. You must use one of the switches, but you cannot use them simultaneously. To specify the triggering edge of the clock, use the *-edge* option and specify *rise* or *fall*.

To specify the delay value, use the *-path_type* option. You can specify the delay as a value in terms of the time units used in the design. Use either the *-path_type* or the *-value* option; you cannot use both simultaneously.

If the constraint arc is a setup/hold/recovery/removal arc, the quick timing model (QTM) parameter global setup/hold/recovery/removal time is added to the value of the specified

Feedback

type correspondingly. You must define the global setup/hold/recovery/removal time before creating any arc of the correspongin type. The command checks to see if these parameters are defined. Global setup/hold/recovery/removal time are defined using the *set_qtm_global_parameter* command.

To see the information about the current quick timing model, use the *report_qtm_model* command.

For a basic description about quick timing models, see the *create_qtm_model* man page.

Examples

The following command creates a setup arc from the positive edge of constraining pin CLK to IN1 (constrained pin) with a delay equivalent to 2 times that of path type path1.

```
pt_shell> create_qtm_constraint_arc -setup -edge rise -from CLK -to IN1
            -path_type path1 -path_factor 2
```

The following command creates a hold arc from the positive edge of constraining pin CLK to IN1 (constrained pin) with a delay equivalent to 2 times that of path type path1.

```
pt_shell> create_qtm_constraint_arc -hold -edge rise -from CLK -to IN1
            -path_type path1 -path_factor 2
```

The following command creates a hold arc from the positive edge of constraining pin CLK to IN1 (constrained pin) with a delay of 3 time units.

```
pt_shell> create_qtm_constraint_arc -hold -edge rise -from CLK -to IN1
 -value 3.0
```

---

create_qtm_delay_arc

Creates a delay arc for a quick timing model (QTM).

Feedback

Syntax

string *create_qtm_delay_arc*

```
[-name arc_name]
-from port_spec
-to port_spec
[-edge rise | fall]
[-from_edge rise | fall]
[-to_edge rise | fall]
[-path_type path_type]
[-path_factor multiplication_factor]
[-value delay_value]
[-total_value total_value]
```

Data Types

arc_name	string
port_spec	list
path_type	string
multiplication_factor	float
delay_value	float
total_value	float

Arguments

`-name` *arc_name*

Specifies the name of the delay arc.

`-from` *port_spec*

Specifies the QTM port name or a collection of QTM ports, which is the startpoint of the delay arc. For an edge triggering arc this must be a clock.

`-to` *port_spec*

Specifies the QTM port name or a collection of QTM ports. This port must be output or inout type.

`-edge rise | fall`

Specifies the triggering edge (rise or fall)

`-from_edge rise | fall`

Specifies the triggering edge (rise or fall) for clock start points or the signal direction for data startpoints. If you do not use this option, the command creates delay arcs from both rise and fall edges at the start points.

`-to_edge rise | fall`

Specifies the signal direction at the data endpoints. If you do not use this option, the command creates delay arcs to both rise and fall edges at the endpoints.

If you omit both the *-from_edge* and *-to_edge* options, the command creates *rise-to-rise* and *fall-to-fall* delay arcs.

`-path_type` *`path_type`*

Specifies the path type you want to use to set the delay.

`-path_factor` *`multiplication_factor`*

Specifies the multiplication factor for the path type.

`-value` *`delay_value`*

Specifies the delay value in terms of the time units you use for the model.

`-total_value` *`total_value`*

Specifies the total delay value in terms of the time units used for the design. The drive arc delay and load are not considered when determining the total delay value for the arc.

Description

This command allows you to create a delay arc in a QTM from a QTM port or collection of QTM ports to a port or collection of QTM ports. If you specify a list of ports for the *-from* and *-to* ports, a delay arc is created from each start port to each end port.

To create an edge triggering arc, use the *-edge* option. For an edge triggering arc, the *clk_to_output* delay (specified as a global parameter) is added to the delay value specified. You can use *-from_edge* and *-to_edge* to specify the triggering edge for clock start points or the signal direction for data startpoints and endpoints.

You can use the *-path_type* option to specify the delay value or you can specify the delay as a value in terms of the time units used in the design. Use either the *-path_type* or the *-value* option; you cannot use both options simultaneously.

To show the information about the current QTM model, use the *report_qtm_model* command.

For a basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following command creates a delay arc from input ports {A, B, C} to output port D with a delay value of 2.0 time units.

```
pt_shell> create_qtm_delay_arc -from {A, B, C} -to D -value 2.0
```

The following command creates an arc from clock CLK to output port OUT with a delay equivalent to 3 times that of path type 'path1'.

```
pt_shell> create_qtm_delay_arc -from CLK -to OUT -path_type path1
 -path_factor 3
```

Feedback

The following example uses wildcard to match all ports matching "CL*".

```
pt_shell> create_qtm_delay_arc -from CL* -to OUT -path_type path1
 -path_factor 3
```

The following example uses a collection for the QTM port 'CLK':

```
pt_shell> create_qtm_delay_arc -from [get_qtm_ports CLK] -to OUT
          -path_type path1 -path_factor 3
```

See Also

- create_qtm_constraint_arc

---

create_qtm_drive_type

Creates a drive type in a quick timing model (QTM) description.

Syntax

string *create_qtm_drive_type*

```
-lib_cell lib_cell_name
[-input_pin input_pin_name]
[-output_pin output_pin_name]
[-input_transition_rise rtrans]
[-input_transition_fall ftrans]
drive_type_name
```

Data Types

```
lib_cell_name    string
input_pin_name   string
output_pin_name  string
rtrans           float
ftrans           float
drive_type_name  string
```

Feedback

Arguments

`-lib_cell` *`lib_cell_name`*

Specifies the library cell name in the technology library.

`-input_pin` *`input_pin_name`*

Specifies the input pin in the *lib_cell_name* is the startpoint of the arc and ends in the output pin.

`-output_pin` *`output_pin_name`*

Specifies the output pin in the *lib_cell_name* that specifies the drive.

`-input_transition_rise` *`rtrans`*

Specifies the input rising transition time associated with the *-input_pin* option to compute the delay for the drive arc. If you do not include this option, the delay table for rising input of the drive arc are loaded from library as is.

Use the *-input_transition_rise* and *-input_transition_fall* options to capture the transition time associated with the *input_pin* option. This can obtain more accurate information on the transition time and delay time for the defined drive arc.

`-input_transition_fall` *`ftrans`*

Specifies the input falling transition time associated with the *-input_pin* option to compute the delay for the drive arc. If you do not include this option, the delay table for falling input of the drive arc are loaded from library as is.

`drive_type_name`

Specifies the name given to the defined drive type.

Description

This command can be used to create a drive type. The defined drive type can be used to set the drives on output ports. The drive type is specified by referring to a lib_cell in the technology library. The library cell is specified by using the *-lib_cell* option. This library cell must be present in the technology library.

The output pin, which drives the port, is specified by using the *-output_pin* option. In addition, you can specify the input pin by using the *-input_pin* option. This option selects an arc that drives the output pin of the library cell.

If neither the input pin nor the output pin is specified, an arbitrary arc is chosen to define the drive type. If the input pin is specified and output pin is not specified, an arbitrary arc starting from the input pin defines the drive type. If the output pin is specified and input pin is not specified, the arbitrary delay arc coming into the output pin defines the drive type.

If both input and output pins are specified, the library cell must have an combinational arc from the input pin to the output pin.

To use this command, you must read in the technology library and then specify it by using the *set_qtm_technology* command.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For a basic description quick timing models, see the *create_qtm_model* man page.

Examples

In the following examples it is assumed that you have loaded the technology library, and the quick timing model technology is set. Do this by using the following the sequence of commands as a guide, substituting the name of your technology library.

```
pt_shell>read_db my_technology_library.db
```

```
pt_shell>set_qtm_technology -library my_technology_library
```

The following command creates a drive type equivalent to the BUF1 library cell.

```
pt_shell> create_qtm_drive_type -lib_cell BUF1 drive1
```

The following command creates a drive2 drive type equivalent to BUF2 library cell and specifies the output pin to use.

```
pt_shell> create_qtm_drive_type -lib_cell BUF2 -output_pin Y drive2
```

---

create_qtm_generated_clock

Creates a QTM generated clock.

Feedback

Syntax

string *create_qtm_generated_clock*

```
-source master_clock_name
[-divide_by divide_factor | -multiply_by multiply_factor]
[-invert]
generated_clock_name
```

Data Types

```
master_clock_name       string
divide_factor           int
multiply_factor         int
generated_clock_name    string
```

Arguments

`-source master_clock_name`

Specifies the name of the clock defined as master source of the generated clock. The master source must be defined as a clock, or a generated clock, prior to the generated clock definition.

`-divide_by divide_factor`

Specifies the frequency division factor. If the *divide_factor* value is 2, the generated clock period is twice as long as the master clock period.

`-multiply_by multiply_factor`

Specifies the frequency multiplication factor. If the *multiply_factor* value is *3*, the generated clock period is one-third as long as the master clock period.

`-invert`

Inverts the generated clock signal (in the case of frequency multiplication and division).

`generated_clock_name`

Specifies the name of the generated clock. If the name has been used in defining a port or internal pin, then the generated clock is defined on the existing port or internal pin. Otherwise, a new same-named internal pin is created to be the source of the generated clock.

Description

This command creates a QTM generated clock. A generated clock can be defined on the external port of the QTM, as well as the internal pin in the QTM. After defining the generated clock, the source port/pin can be used in other QTM commands the same way as those port/pins defined by the *create_qtm_port* command, i.e. delay arcs from or to the generated clock source pin can be defined with the *create_qtm_delay_arc*

command; constraint arcs related to the generated clock can be defined with the *create_qtm_constraint_arc* command.

For a basic description about QTM, see the *create_qtm_model* man page.

Examples

The following example creates a divide-by 2 generated clock on an internal pin, assume there is no port defined with name "GCLK_int", with master clock CLK.

```
pt_shell> create_qtm_generated_clock GCLK_int -source CLK -multiply_by 2
```

The following example creates a generated clock on port GCLK, assume GCLK has already been defined as a port with command create_qtm_port.

```
pt_shell> create_qtm_generated_clock GCLK -source CLK -divide_by 2
 -invert
```

---

create_qtm_load_type

Creates a load type for a quick timing model (QTM) description.

Syntax

string *create_qtm_load_type*

```
-lib_cell lib_cell_name
[-input_pin input_pin_name]
load_type_name
```

Data Types

```
lib_cell_name       string
input_pin_name      string
load_type_name      string
```

Feedback

Arguments

`-lib_cell` *`lib_cell_name`*

Specifies the name of the library cell in the technology library.

`-input_pin` *`input_pin_name`*

Specifies the input pin in the lib_cell to specify capacitance.

`load_type_name`

Specifies the name given to the defined load type.

Description

This command is used to create a load type. A load type can be used to define the load on a QTM input port. The load type is specified by referring to the *lib_cell* option in the technology library. The library cell is specified using the *-lib_cell* option. The library cell must be present in the specified technology library.

The input pin can be specified by using the *-input_pin* option. If the input pin is not specified, an arbitrary input pin is chosen to define the load type.

To use this command you must first read in the technology library, then specify the technology library by using the *set_qtm_technology* command.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

In the following example, the technology library is loaded, and the QTM technology is set:

```
pt_shell> read_db my_technology_library.db
pt_shell> set_qtm_technology -library my_technology_library
```

The following command creates a load type load1 using cell OR1. Since the input pin name is not specified, QTM selects an arbitrary input pin.

```
pt_shell> create_qtm_load_type -lib_cell OR1 load1
```

The following command creates a load type load2 using cell OR1, input pin A.

```
pt_shell> create_qtm_load_type -lib_cell OR1 -input_pin A load2
```

---

create_qtm_model

Begins the definition of a quick timing model (QTM) description.

Syntax

string *create_qtm_model*

```
        model_name
```

Data Types

```
model_name    string
```

Arguments

model_name

Specifies the name of the generated model.

Description

Specifies the name of a new quick timing model (QTM) to be created by PrimeTime. QTMs are temporary timing models that can be created quickly for a block using PrimeTime commands. The purpose of these commands is to provide timing information without the necessity of writing a detailed timing model.

QTMs are intended to be used early in the design cycle to describe rough initial timing of a block. These models will eventually be replaced, either by some other detailed timing model or by the netlist of the block, to obtain more accurate timing.

A QTM can be saved as a Synopsys DB file, which can be instantiated in a design in the same way library cells or ITS models are instantiated. Both Design Compiler and PrimeTime accept designs with instantiated QTMs. To save a QTM model, use the *save_qtm_model* command.

Other commands in the QTM command set must be placed between a *create_qtm_model* and *save_qtm_model* command. Many QTM commands exist for specifying, configuring

Feedback

and examining QTMs. The following is not an exhaustive list, but gives examples of tasks you can perform using QTM commands:

- To create a QTM port, use the *create_qtm_port* command.
- To create constraint arcs and delay arcs, use the *create_qtm_constraint_arc* and the *create_qtm_delay_arc* commands, respectively.
- To set the drive of a QTM output port, use the *set_qtm_port_drive* command.
- To set the load of a QTM input port, use *set_qtm_port_load* command.
- To show the information about the current QTM model, use the *report_qtm_model* command.

Examples

The following command creates a new QTM model with the name adder.

```
pt_shell> create_qtm_model adder
```

---

create_qtm_path_type

Creates a path type in a quick timing model (QTM) description.

Feedback

Syntax

string *create_qtm_path_type*

```
-lib_cell name
[-input_pin pin_name]
[-output_pin pin_name]
[-fanout count]
path_type_name
```

Data Types

name	string
pin_name	string
count	integer
path_type_name	string

Arguments

`-lib_cell` *name*

Specifies the name of the library cell in the technology library.

`-input_pin` *pin_name*

Specifies the input pin in the *-lib_cell* option, which is the startpoint of the arc, to define the path type.

`-output_pin` *pin_name*

Specifies the output pin in the *-lib_cell* option, which is the endpoint of the arc, to define the path type.

`-fanout` *count*

Specifies the average fanout (number of pins) to consider while computing the delay of the path type. The fanout count can range from 1 to 1000. The default is 1.

path_type_name

Specifies the name given to the defined path type.

Description

This command is used to create a path type. A path type mimics an arc in a library cell. An arc in the QTM model is defined in terms of the delays of the path type. The path type is specified by referring to a library cell in the technology library. The library cell is specified using the *-lib_cell* option. The library cell must be present in the technology library specified.

You can specify the average fanout count the arc fans out to while defining the path type. It is assumed the arc fans out to the first input pin of the same library cell, while calculating

the delays. The input pin is specified by using the *-input_pin* option. The output pin is specified by using the *-output_pin* option.

If neither input pin nor the output pin is specified, an arbitrary delay arc from the library cell is chosen to define the path type.

If the input pin is specified and output pin is not specified, an arbitrary delay arc staring from the input pin defines the path type.

If the output pin is specified and input pin is not specified, an arbitrary delay arc coming into the output pin defines the path type.

If both input and output pins are specified, the library cell must have an arc from the input pin to the output pin.

To use this command you must read in the technology library then specify the technology library by using the *set_qtm_technology* command.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For a basic information about quick timing models, see the *create_qtm_model* man page.

Examples

In the following examples the technology library is loaded by the user and the QTM technology is set. This is done by the following sequence of commands:

```
pt_shell> read_db my_technology_library.db

pt_shell> set_qtm_technology -library my_technology_library
```

The following command creates a path type path1 by using lib_cell AN2, with an average fanout count of 2 (uses default input, output pins).

```
pt_shell> create_qtm_path_type -lib_cell AN2 -fanout 2 path1
```

The following command creates a path type path2 by using cell AN2, with an average fanout count of 2, and using pin 'A' as the starting point for the path type.

```
pt_shell> create_qtm_path_type -lib_cell AN2 -input_pin A -fanout 2 path2
```

The following command creates a path type path3 by using cell AN2, with an average fanout count of 2, using pin A as the start point of the arc, and pin Z as the endpoint of the arc.

```
pt_shell> create_qtm_path_type -lib_cell AN2 -input_pin A -output_pin Z
 -fanout 2 path3
```

---

create_qtm_port

Creates a quick timing model (QTM) port.

Syntax

string *create_qtm_port*

```
-type port_type
port_list
```

Data Types

```
port_type     string
port_list     list
```

Arguments

`-type port_type`

Specifies the type of port. The port can be one of the following types: input, output, inout, internal or clock. If you want a port to be a clock, define it as a clock port.

`port_list`

Specifies the list of QTM ports you want created.

Description

This command creates QTM port. You can create a single port or a list of ports with this command. The ports can be input, output, inout, internal or clock. Any port that constrains another port or has an edge triggered launch arc originating from it, has to be defined to be of the type 'clock'.

Feedback

Bused ports are also defined by giving the start and end index (A[0:5]). Bused ports cannot be internal.

To show the information about the current quick timing model, use the *report_qtm_model* command.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following example creates an input bused QTM port A[0:5].

```
pt_shell> create_qtm_port A[0:5] -type input
```

The following example creates a clocked QTM port CLK.

```
pt_shell> create_qtm_port CLK -type clock
```

The following example creates QTM output ports A, B, C, and D.

```
pt_shell> create_qtm_port {A B C D} -type output
```

The following example creates QTM internal pin D_int.

```
pt_shell> create_qtm_port D_int -type internal
```

---

create_rule

Creates a user-defined rule. Rules are checked to identify potential problems in constraints or in the design.

Syntax

Boolean *create_rule*

```
-name name
[-severity severity]
-message message_list
[-parameters parameter_list]
[-description description]
[-global]
-checker_proc user_defined_checker
```

Data Types

name	string
severity	string
message_list	list
parameter_list	list
description	string
user_defined_checker	string

Arguments

`-name` *name*

Specifies a unique name for the rule being created.

`-severity` *severity*

Specifies the severity of a violation of this rule. Valid values are: "fatal", "error", "warning" or "info". If not specified, the severity of the rule is "warning".

`-message` *message_list*

Specifies the predefined text fragments which, along with the parameter values, make up the message text for a violation. For example, a rule that prints a violation for one clock might have *message_list* such as {"Clock " " is created on a pin instead of a port."}. In this case, one parameter (the clock name) would be defined.

`-parameters` *parameter_list*

Specifies the names of parameters which are used in conjunction with the *message_list* to create the message text for a violation. For example, a rule that needs to print the clock name as a parameter might have *parameter_list* of {"clock"}.

`-description` *description*

The description is a string enclosed in double quotes which provides more information about the rule. It can describe why a violation is problematic, and suggest ways to address the problem.

`-global`

Indicates that this rule is intended to be checked in user-defined global checking procedures only. This means that the rule is scenario independent and is

checked only one time and not per scenario. Without *-global*, the rule is assumed to be checked in user-defined scenario checking procedure only.

`-checker_proc` *`user_defined_checker`*

Associate the user-defined rule with an existing user-defined checker procedure. The checker procedure is automatically invoked in the analyze_design command if the user-defined rule is enabled and included in the rules checked by the analyze_design command. A user-defined checker procedure can only issue violations of user-defined rules associated with the checker. If the user-defined rule is a scenario rule, the user-defined checkers is invoked during scenario checks. If the user-defined rule is a global rule, the user-defined checker is invoked during global checks. All user-defined rules associated with a user-defined checker procedure must be either scenario rules or global rules. A checker procedure cannot have both scenario rules and global rules associated with it.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Creates a rule for checking in the *analyze_design* command. A rule is used for formatting output related to potential problems in the design or in the constraints for a scenario. You can pass a user-defined rule checking procedure to the *analyze_design* command. In that procedure, you can call the *create_rule_violation* command to register a violation of a rule that you defined using the *create_rule* command.

To remove a user-defined rule, use the *remove_rule* command. To temporarily disable one or more rules, use the *disable_rule* command. You can specify properties for the rule using the *set_rule_property* command.

Examples

The following example creates a rule related to clocks with two parameters:

```
pt_shell> create_rule -name CLK_0001 -severity warning \\
    -message {"Clock " " has " " source(s) on inout ports"}  \\
    -parameters {"clock" "count"} \\
    -description "A clock defined on an inout port may become \\
        invalid when the port is used in output mode."
    -checker_proc my_checker
```

See Also

- create_rule_violation
- get_rules

Feedback

create_rule_violation

Creates a violation entry for the specified rule in user-defined checking procedures.

Syntax

string *create_rule_violation*

```
-rule rule_name
-parameter_values value_list
-details details_text
```

Data Types

```
rule_name      string
value_list     list
detail_text    string
```

Arguments

`-rule rule_name`

Specifies a unique name for the rule being violated.

`-parameter_values value_list`

Specifies a list of values which are used in conjunction with the *message_list* specified in *create_rule* to create the message text for a violation. For example, a rule that needs to print the clock name as a parameter might have parameter values of {"clock1"}.

`-details detail_text`

The details is a string enclosed in double quotes which provides more information about the rule violation. It can describe why a violation is problematic, and suggest ways to address the problem.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Creates a rule violation entry in user-defined checking procedures. It is only active within the *analyze_design* command. *create_rule_violation* should be used only in user-defined rule checking procedures.

Examples

The following example creates a rule violation of rule CAP_0001 in a user-defined checking procedure:

```
proc test_user_scenario_rule {} {
  create_rule_violation -rule CAP_0001 -parameter_values {"my_port"} \\
```

Feedback

```
    -details "some details here"
}
```

See Also

- create_rule

---

create_ruleset

Creates a set of related rules

Syntax

Boolean *create_ruleset*

```
-name name
rule_list
```

Data Types

```
name        string
rule_list   list
```

Arguments

`-name`

Specifies a unique name for the ruleset being created.

rule_list

The list of rules or rulesets to include in this ruleset. If a ruleset is specified, all rules from that ruleset are included.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Creates a named set of rules for this session. Rulesets can be passed to other commands which operate on rules.

It is an error to specify the same name as an existing ruleset. If you need to redefine an existing ruleset, first remove the old one with the *remove_ruleset* command and then create a new one containing the wanted rules.

Examples

The following example creates a ruleset named "user_clock_rules" and uses it in another command.

Feedback

```
pt_shell> create_ruleset -name user_clock_rules \\
    [get_rules "UDEF_CLK_*"]
pt_shell> enable_rule user_clock_rules
```

See Also

- create_rule
- get_rules
- remove_ruleset

---

create_scenario

Creates a scenario for multi-scenario analysis.

Syntax

```
status create_scenario
  [-name scenario_name]
  [-mode mode_name]
  [-corner corner_name]
  [-common_data file_list]
  [-common_variables variable_list]
  [-specific_data file_list]
  [-specific_variables variable_list]
  [-image image]
  [-affinity host_option_names]
  [-eco_data directory_name]
```

Data Types

```
scenario_name      string
mode_name          string
corner_name        string
file_list          list
variable_list      list
image              string
host_option_names  list
directory_name     string
```

Arguments

`-name scenario_name`

Specifies a single scenario. If you use the *-mode* and *-corner* options, PrimeTime automatically names the scenario *mode_name_corner_name*.

`-mode` *`mode_name`*

Specifies the mode comprising the scenario. You must use this option with the *-corner* option; do not use this option with the *-name* option. PrimeTime automatically names the scenario *mode_name_corner_name*.

`-corner` *`corner_name`*

Specifies the corner comprising the scenario. You must use this option with the *-mode* option; do not use this option with the *-name* option. PrimeTime automatically names the scenario *mode_name_corner_name*.

`-common_data` *`file_list`*

Lists files that contain commands and data that is common to more than one scenario. These files can be used to create a common image for all scenarios which share the same common data. Creating a common image causes a runtime and disk usage overhead, thus this option should only be used if it is required. This option cannot be used in conjunction with the *-image* option.

`-common_variables` *`variable_list`*

Lists variables that are common to more than one scenario. These variables are used in conjunction with the common data files to determine commonality between scenarios. The value of the variable currently at the manager are set on the worker before the sourcing of the common data files. This option cannot be used in conjunction with the *-image* option.

`-specific_data` *`file_list`*

Lists files that contain commands and data that is specific to this scenario. This data is not used on any other scenario or in the common image generation. This data that is specific to the scenario is sent directly to the worker and executed after the common design image is generated. This option can be used in conjunction with the *-image* option.

`-specific_variables` *`variable_list`*

Lists variables that are specific to this scenario. The value of the variable currently at the manager is set on the worker before the sourcing of the specific data files. This option can be used in conjunction with the *-image* option.

`-image` *`image`*

Allows a scenario to be created with a previously saved scenario image. The image can be an image generated within a standard PrimeTime session, an image generated with a save_session call from the DMSA manager or a current_image generated during a DMSA session. The *-specific_variables* and the *-specific_data* options can be specified in conjunction with the *-image* option. The specific variables are set after the image are loaded and then the specific data files are executed.

`-affinity` *`host_option_names`*

Lists the names of the host options from which worker processes must be selected to run the scenario. If no workers of any of the host_options specified in the affinity are online then the scenario cannot be part of the current session. If host options specified in the affinity are subsequently removed, then the affinity will also be updated to reflect the removal. If while running, all the workers of the host options specified in the affinity go offline/fatal, then un-expected tasks for the scenario will terminate due to a lack-of-resources and the scenario will be dropped from the current session.

`-eco_data` *`directory_name`*

Specifies the name of directory which is used to keep all ECO data populated by command '*write_eco_scenario_data*'.

Then, command '*report_eco_scenarios*' could use the data from this directory to dertermine *live* views based upon the number of processes specified by the '*set_host_options -num_processes*', for better timing coverage while with less memory resources.

Finally, command '*start_eco_scenarios*' could launch *live* views as *Distributed Multi Scenario Analysis (DMSA)* worker processes, and merges the timing and other data from *static* view scenarios with the *live* view scenarios.

Description

The *create_scenario* command creates a scenario based on the data specified by the arguments. A scenario can be created with a set of scripts and variables. Generally, scenarios only need to be defined with *-specific_data* and *-specific_variables*. When defined in this manner, all scenarios are independent and will each be created in parallel from the scripts and variables defined for them.

Any scenarios that have identical common data, may use the *-common_data* option to create a single baseline image. Creating a baseline image causes a runtime and disk usage overhead, thus this option should only be used if it is required, for example, if there are not enough worker processes to run all scenarios in parallel. In that case, the overhead of creating and restoring of the common image may be less than sourcing scripts for scenarios running sequentially.

Alternatively, a scenario can be created with a previously saved image.

This command does not actually start the analysis. The analysis starts when the first merged reporting or the *remote_execute* command is issued.

The *create_scenario* command is available only when you run PrimeTime in distributed multi-scenario analysis (DMSA) mode. The DMSA mode can be enabled by setting the variable *multi_scenario_enable_analysis* to *true*, or by invoking pt_shell with the *-multi_scenario* option.

You can run the *create_scenario* command any time in the DMSA flow before you run the *current_session* command.

If the *-affinity* option is specified, then when the current session is created, the scenario will only enter the session if at least one worker process launched from the host_options specified in the affinity are online.

Examples

The following example creates a scenario named scen1, which is described by the specific_s1.pt file.

```
pt_shell> create_scenario -name scen1 -specific_data {specific_s1.pt}
1
```

The following example creates a scenario named scen1, which is restored from the saved image stored in the directory *./scenarios/scen1*.

```
pt_shell> create_scenario -name scen1 -image ./scenarios/scen1
1
```

The following example creates scenarios named scen1 and scen2, which are described by the common_s1_s2.pt, specific_s1.pt and specific_s2.pt files.

```
pt_shell> create_scenario -name scen1 -common_data {common_s1_s2.pt} \\
            -specific_data  {specific_s1.pt}
1
pt_shell> create_scenario -name scen2 -common_data {common_s1_s2.pt} \\
            -specific_data  {specific_s2.pt}
1
```

In the following example, an iterative loop creates a set of scenarios. The same single.tcl script is used for all scenarios, but the corner variable distinguishes the scenarios.

```
        foreach corner {bc tc wc} {
 create_scenario \\
  -name ${corner} \\
  -specific_variables {corner} \\
  -specific_data "single.tcl"
}
```

The following example creates two host_options, one called BigHosts targeting the host called pthost1 and another called SmallHosts targeting pthost2. It then creates two scenarios, scen1 and scen2, each specifying their desired affinity.

```
        set_host_options -name BigHosts   -num_processes 1 pthost1
set_host_options -name SmallHosts -num_processes 1 pthost2
create_scenario -name scen1 -specific_data {specific_s1.pt} \\
```

Feedback

```
 -affinity {BigHosts}
create_scenario -name scen2 -specific_data {specific_s2.pt} \\
 -affinity {SmallHosts}
```

The following example creates two scenarios, along with additional ECO data directory for Hybrid timing view ECO fixing.

```
        create_scenario -name scen1 -specific_data {specific_s1.pt} \\
       -eco_data scen1/eco_data
create_scenario -name scen2 -specific_data {specific_s2.pt} \\

---

create_si_context

Generates an SI context for selected blocks of the design. A top level design and full chip binary parasitics can also be generated.

Syntax

status *create_si_context*

```
[-include include_list]
[-instances instance_list]
[-parasitics_options para_options]
[-top_inst instance_name]
[-no_design_parasitics]
```

Data Types

```
include_list      list
instance_list     list
```

```
para_options      list
instance_name     string
```

Arguments

`-include` *include_list*

If this option is not specified, the context script will be generated for cross-talk. You can use this option to specify PrimeTime SI to generate the context scripts for cross-talk, noise or both. Allowed values are *xtalk* and *noise*. The generated context will be the same, only the script will be different.

`-instances` *instance_list*

Indicates that PrimeTime SI is to extract contexts for the given list of instances or for all the top level instances of the design.

`-parasitics_options` *para_options*

Specifies that a parasitic file has to be generated to be used to annotate the (block + context) design. The allowed values for the *para_options* options are *spef_format* and *sbpf_format*.

`-top_inst` *instance_name*

Specifies that PrimeTime should generate a top level design for the given instance. By default, PrimeTime generates top level design for the given design. This option can be used in conjunction with the *-instances* option to generate contexts and top level design for an arbitrary hierarchy. Note that all the instances provided in the *-instances* option must be the child instances of the top level instance provided in this option.

`-no_design_parasitics`

By default, this command also generates full chip parasitics in SBPF format. Use this option to indicate PrimeTime not to generate the SBPF file. This option should be used if your parasitic extraction tool generated SBPF.

Description

The *create_si_context* command generates contexts for all top level instances of the design or for the list of instances given in the *-instances* option. This context can be used to perform signal integrity analysis at the block level.

The effect of context on the block is the same as that of the top level and other blocks on the block. Hence, context enables accurate signal integrity analysis for block level analysis as if the block is being analyzed in the context of the full chip.

The command also generates a top level design and a top level script that can be used to perform chip level analysis after block level analysis is complete and respective ILMs are generated for each block. User can direct PrimeTime to generate contexts and top

level design for an arbitrary level of hierarchy instance using the *-top_inst* and *-instances* options.

The command creates one directory for each block (for which a context is being extracted) and outputs the context files inside the directory. Each directory contains a verilog context design (named wrapper.v), a TCL script (named wrapper.tcl) that can be used in performing block level analysis, a text file that contains aggressor annotation points (named wrapper.txt) that can be used later for annotating arrivals/slews for accurate block level analysis. The command also generates an infinite arrival script (named wrapper.pt.gz) that can be used to perform conservative block analysis in the context. The command can generate this arrival script for cross-talk, noise or both depending on the *-include* option. In addition, if the *-parasitics_options* option is given, a parasitic file (named wrapper.sbpf or wrapper.spef.gz) gets generated. Also at the level of this new directory, a top level verilog file (named design.v), a top level TCL script (named design.tcl) are also generated. In addition, if the *-no_design_parasitics* option is not given, a full chip binary parasitic file (named design.sbpf) gets generated.

The *create_si_context* command is affected by the *pt_ilm_dir* environment variable. The top design files and directories for individual blocks are created at the location given by the *pt_ilm_dir* variable.

Examples

The following example generates contexts for all top level designs along with context parasitics in SBPF and a top level design.

```
pt_shell> create_si_context -parasitics_options {sbpf_format}
```

The following example generates contexts for instances "blockA" and "blockB" along with context parasitics in SPEF.

```
pt_shell> create_si_context -instances {blockA blockB} \\
-parasitics_options {spef_format}
```

---

create_supply_net

Creates a supply net defined for the specified power domain. The supply net is created in the logic hierarchy at the same scope as the specified power domain.

Feedback

Syntax

string *create_supply_net*

```
[-domain domain_name]
[-reuse]
[-resolve unresolved | parallel | one_hot | parallel_one_hot]
supply_net_name
```

Data Types

```
domain_name          string
supply_net_name      string
```

Arguments

`-domain domain_name`

Specify which power domain this supply_net is defined for. If specified, the power domain must exist. If used with the *-reuse* option, the *supply_net_name* must correspond to a supply net which is already domain dependent.

`-reuse`

Reuse an existing supply net instead of creating a new one. You can associate one supply net with several power domains. If this option is specified, the supply net must exist.

`-resolve unresolved | parallel | one_hot | parallel_one_hot`

Resolution mechanism that determines the state and voltage of the supply net. This is intended also for checking allowed connectivity of supply nets through switches. PrimeTime currently accepts and stores this option but does not use it.

supply_net_name

Specify the name of the supply net to be created. The name should be a simple (nonhierarchical) name.

In the scope of the specified power_domain, or in the scope of the current instance if no power_domain is specified, if there is a supply net, logical hierarchical net, or logical port with the same name, the *supply_net_name* cannot be created. One exception is that when you use the *-reuse* option, the name must be the same with another existing supply_net in the same scope, and no checking is applied in this situation.

This argument is required.

Description

The *create_supply_net* command enables you to create a supply net defined in the specified power domain. A supply net connects supply ports and pins.

Feedback

Each power domain has a primary power supply net and a primary ground supply net, and it could have several other supply nets. If the command succeeds, a supply net is created in the scope of power domain, or in the current scope, if no power domain is specified. It is currently neither primary power net nor primary ground net of the power domain. Use the *set_domain_supply_net* command to set it as the primary power/ground net.

Supply nets can be created either domain dependent, or domain independent (with or without the *-domain* option). If a supply net has been created domain independent, it cannot be changed to a domain dependent supply net by the use of the *-reuse* option in a later invocation of *create_supply_net*.

This command returns the full name of the supply net (from the current scope), if successful. It returns null string if it fails.

Examples

The following example creates a supply_net A_VDD in power_domain PD1, and also re-creates A_DD in another power_domain PD2 using the *-reuse* option:

```
prompt> create_power_domain PD1 -element INST1
PD1
prompt> create_power_domain PD2 -element INST2
PD2
prompt> create_supply_net A_VDD -domain PD1
A_VDD
prompt> create_supply_net A_VDD -domain PD2 -reuse
A_VDD
prompt> create_supply_net B
B
```

See Also

- create_power_domain
- report_supply_net
- set_domain_supply_net

---

create_supply_port

Creates a supply port in specified power domain, or in current scope if no power domain is specified.

Syntax

string *create_supply_port*

```
supply_port_name
[-domain domain_name]
[-direction in | out | inout]
```

Feedback

Data Types

```
supply_port_name     string
domain_name     string
```

Arguments

supply_port_name

Specifies the name of the supply port to be created. The name should be a simple (non-hierarchical) name. This argument can be used with the *-domain* option to help avoid hierarchical names.

In the scope of the specified *power_domain*, if there is a *supply_port*, logical port, or logical hierarchical net with the same name, the *supply_port* cannot be created.

This argument is required.

-domain *domain_name*

Specifies the *power_domain* in which this port defines a supply net connection point. The power domain must exist in the current scope.

-direction in | out | inout

Defines how state information is propagated through the supply network as it is connected to the port. If the port is an input port, the state information of the external supply net connected to the port is propagated into the domain. Likewise, for an output port, the state information of the internal supply net connected to the port is propagated out of the domain.

The default value is *in*.

Description

The *create_supply_port* command creates a supply port at the scope of the specified power domain, or at the current scope if no domain is specified. A supply port provides a connection point for the supply net.

This command returns the *supply_port* object upon success. It returns a null string if it failed.

Examples

The following example creates a supply port VN1 at the scope of the PD1 power domain:

```
prompt> create_power_domain PD1 -element INST1
PD1
prompt> create_supply_port VN1 -domain PD1
VN1
```

Feedback

---

create_supply_set

Creates a set of supplies that can be used to define the power network. A supply set is created in the current logic hierarchy.

Syntax

string *create_supply_set*

```
supply_set_name
[-function {function_name net_name}]
[-update]
```

Data Types

```
supply_set_name        string
function_name          string
net_name               string
```

Arguments

supply_set_name

Specifies the name of the supply set to be created. The name should be a simple (non-hierarchical) name.

If a supply set with the same name exists in the current scope, the supply set is not created.

An exception to this rule is when you use the *-update* option. In this case, the supply set name must be the same as an existing supply set in the same scope.

This argument is required.

-function {function_name net_name}

Specifies the functional capability to which an actual supply net should be associated.

This argument takes two parameters. The first parameter is the name of the function, which is either *power* , *ground*, *pwell* or *nwell*. The second parameter is the name of the supply net that is in the same hierarchical scope of the supply set.

pwell and *nwell* are bias functions, and they are only accessible when design_attribute enable_bias is true. This attribute could be set using set_design_attribute.

This argument is required when the *-update* argument is used. Otherwise, it is optional.

`-update`

Instructs the tool to associate an actual supply net to the *power*, *ground*, *pwell* and *nwell* function of an existing supply set. It is an error if the supply set specified does not exist. Only one update is allowed for each functional of the supply set. If your update is not successful, the tool issues an error message. You can continue to update the functionality, until your update is successful.

This argument is optional. When the *-update* argument is used, the *-function* argument must also be used.

Description

The *create_supply_set* command creates a supply set in the current scope. A supply set eliminates the requirement of a supply net and supply ports in the design in the frontend tool. However, actual supply nets must be associated with the supply sets later on in the flow before physical synthesis is done.

A supply set supports the use of the following functions in the design:

- Power
- Ground
- Pwell
- Nwell

These functions, when unassociated with any supply net, can be used as supply nets for any purpose. They can be accessed by referencing them through the name of the supply set. To access the *power* function, you must specify *supply_set_name.power* and to access the *ground* function, you must specify *supply_set_name.ground*. Similarly, to access the *pwell* function, you must specify *supply_set_name.pwell* and to access the *nwell* function, you must specify *supply_set_name.nwell*.

The functions of a supply set can be used just as any other supply net in the UPF design, with no domain restrictions. However, domain restrictions are applicable when an *-update* is called. This means that the actual supply nets, being associated with a supply set, are checked for their definitions in the domains where the supply set functions have been used.

Feedback

Calling an update on an existing supply set means replacing the supply set functions with actual supply nets. After doing an *-update*, the actual supply net can be referenced through the supply set or by its actual name.

Examples

The following example creates a supply set named primary_sset in the current logical hierarchy.

```
pt_shell> create_supply_set primary_sset
primary_sset
```

The following example illustrates how a supply set function can be used.

```
pt_shell>set_design_attribute -attribute enable_bias TRUE -elements {.}
Information: Resolving '.' to the current scope '<top design>'.
1

pt_shell> create_supply_set primary_sset
primary_sset

pt_shell> create_power_domain PD_TOP
PD_TOP

pt_shell> set_domain_supply_net PD_TOP A \\
            -primary_power_net primary_sset.power \\
            -primary_ground_net primary_sset.ground \\
            -primary_power_net primary_sset.pwell \\
            -primary_ground_net primary_sset.nwell

1
pt_shell> set_retention ret_cstr -domain PD_TOP \\
            -retention_power_net primary_sset.power \\
            -retention_ground_net primary_sset.ground
1
pt_shell> set_isolation iso_cstr -domain PD_TOP \\
             -isolation_power_net primary_sset.power \\
             -isolation_ground_net primary_sset.ground \\
1
```

The following example illustrates how a supply set can be associated with actual supply nets.

```
pt_shell> create_supply_set primary_sset
primary_sset

pt_shell> create_power_domain PD_TOP
PD_TOP

pt_shell> set_domain_supply_net PD_TOP \\
           -primary_power_net primary_sset.power \\
           -primary_ground_net primary_sset.ground
```

```
1
pt_shell> set_retention ret_cstr -domain PD_TOP \\
            -retention_power_net primary_sset.power \\
            -retention_ground_net primary_sset.ground
1
pt_shell> set_isolation iso_cstr -domain PD_TOP \\
            -isolation_power_net primary_sset.power \\
            -isolation_ground_net primary_sset.ground \\
1
pt_shell> create_supply_net TOP_VDD -domain PD_TOP
TOP_VDD
pt_shell> create_supply_net TOP_VSS -domain PD_TOP
TOP_VSS
pt_shell> create_supply_set primary_sset \\
           -function {power TOP_VDD} \\
           -function {ground TOP_VSS} \\
           -update
`
1
```

---

create_testcase

Extracts a portion of the current design as a standalone testcase.

Syntax

string *create_testcase*

```
-paths path_list
   | -ports port_list
   | -endpoints pin_port_list
   | -cells cell_list
[-directory dir_name]
[-include_libs]
[-mim]
```

Data Types

```
cell_list        list
dir_name         string
path_list        list
```

```
pin_port_list     list
port_list         list
```

Arguments

`-paths` *path_list*

Extracts all cells along the specified timing paths, including startpoints and endpoints. The resulting testcase allows these timing paths to be reproduced.

In this mode, the clock path will not be included in the testcase unless the path is obtained with *-path full_clock_expanded*.

`-ports` *port_list*

Extracts fanout logic from input ports (including endpoints) and fanin logic to output ports (including startpoints).

In this mode, clock paths to sequential cells are always included.

`-endpoints` *pin_port_list*

Extracts fanin logic to endpoint pins/ports, including startpoints. The resulting testcase allows paths to these endpoints to be reproduced.

In this mode, clock paths to endpoints and their associated startpoints are always included.

`-cells` *cell_list*

Extracts the specified leaf cells, the nets driven by the cells, and the leaf cells and ports connected to the driven nets.

In this mode, clock paths are not included unless manually included in the cell list.

`-directory` *dir_name*

Specifies the output directory name. By default, the directory is named after the current design.

By default, the output directory is named after the current design.

`-include_libs`

Includes the required library files in the testcase directory, and modifies the script file to use them. This allows the testcase to be run in other design environments.

By default, the testcase references the required logic libraries in their current location. This is suitable for testcases that are used in the current design environment.

`-mim`

Keeps the same endpoint-fanout logic across multiple-instance module (MIM) instances.

When the *-endpoint* option specifies an endpoint inside an MIM instance, this option ensures that the logic is extracted consistently across the MIM instances. If this option is not used, the timing results of the testcase can differ from the original design.

This option requires that the *-endpoints* option be used to extract the testcase.

Description

The *create_testcase* command extracts a portion of the current design as a standalone testcase.

It creates a directory with the specified portion of the design, a constraints file that applies to that portion of the design, any detailed parasitics or SDF annotations used, and a run script for the testcase. Net fanout and cross-coupling are modeled so that the extracted testcase closely replicates the timing behaviors of the full design.

In a PrimeTime SI analysis, the aggressor stages with annotated aggressor timing windows are included.

The logic to be extracted must be specified by using one (and only one) of the following options: *-paths*, *-ports*, *-endpoints*, or *-cells*.

A timing-updated design is not required when using the *-ports* or *-endpoints* option. In this case, the aggressors use zero input pin slews and infinite windows. This is useful for reproducing crashes in the initial timing update.

Libraries are not copied to the test case directory by default, as they can require a lot of disk space. However, you can include them by specifying the *-include_libs* option.

Examples

The following script reads a full-chip design, then creates a small standalone testcase for a particular set of endpoints. The libraries are included in the testcase.

```
################################################
# FILE: run_full_design.tcl
#
#   Represents a typical script for STA and ECO in PrimeTime
#   Full design requires a 100 GB machine.
################################################

# STA
read_verilog ...
link_design CHIP
read_parasitics ...
read_sdf ...
```

Feedback

```
update_timing ...
report_timing ...

# Create smaller testcase design
set endpoints [get_pins ...]
create_testcase \
  -endpoints $endpoints \
  -directory my_testcase \
  -include_libs
exit
```

---

create_voltage_area

Creates a voltage area at the specified region for providing placement constraints of cells associated with the region.

Syntax

```
status create_voltage_area
   [-name voltage_area_name]
   [-coordinate coordinate_list]
   [-polygons polygon_coordinate_list]
   [-power_domains power_domain_list]
   [-guard_band_x guard_band_width]
   [-guard_band_y guard_band_width]
   cell_list
```

Data Types

```
voltage_area_name           string
coordinate_list             list
polygon_coordinate_list     list
power_domain_list           list
guard_band_width            double
cell_list                   list
```

Arguments

`-name voltage_area_name`

Specifies the name of the voltage area to be created. If there is a voltage area with the same name already, the voltage area cannot be created. The name *DEFAULT_VA* is reserved and cannot be used for a user-defined voltage area. The *-name* and *-power_domains* options are mutually exclusive, unless multiple power domains are specified.

`-coordinate coordinate_list`

Specifies a list of lower-left and upper-right coordinates of a voltage area. Specify the *coordinate_list* in the format of {llx1 lly1 urx1 ury1 ...}, where each set of {llx lly urx ury} defines a target rectangular placement area. The voltage

area geometry can be a rectangle or a rectilinear polygon. The unit is micron. The *-coordinate* and *-polygons* options are mutually exclusive.

`-polygons` *`polygon_coordinate_list`*

Specifies a list of polygons of a voltage area. Specify the *polygon_coordinate_list* in the format of {{{x1 y1} ... {xN yN} {x1 y1}} ...}, where each set of {x1 y1 ... xN yN x1 y1} defines the list of points of one polygon. The voltage area geometry can be a rectangle (five points) or a rectilinear polygon. The unit is micron. The *-coordinate* and *-polygons* options are mutually exclusive.

`-power_domains` *`power_domain_list`*

Creates a voltage area from one or more existing power domains. Unless mutliple power domains are specified, the name of the voltage area is identical to the name of the power domain. All hierarchical cells associated with the power domains are included in the voltage area. If multiple power domains are specified, the *-name* option is required.

`-guard_band_x` *`guard_band_width`*

Specifies the guard width in the horizontal direction. The guardband is the spacing along the boundary of the voltage area where cells cannot be placed because of the lack of power supply rails.

The value specified with this option must be a positive number.

`-guard_band_y` *`guard_band_width`*

Specifies the guard width in the vertical direction. The guardband is the spacing along the boundary of the voltage area where cells cannot be placed because of the lack of power supply rails.

The value specified with this option must be a positive number.

`cell_list`

Specifies a list of hierarchical cells that are contained in the voltage area. Multiple hierarchies are permitted, and one cell cannot be in two voltage areas. Leaf cells (or standard cells) cannot be specified in this option.

You must specify cell_list option when you specify the *-name* option, unless you use the *-power_domains* option to specify a single power domain.

Description

The *create_voltage_area* command creates a voltage area of specific geometry on the core area of the chip. The voltage area is associated with hierarchical cells. PrimeTime uses the voltage area information to insert ECO cells in correct locations if you use the *fix_eco_drc* or *fix_eco_timing* command with the *-physical_mode* option.

You can create a voltage area only after PrimeTime loads the physical database. To specify a file that contains *create_voltage_area* commands, use the *set_eco_options* command with the *-physical_constraint_file* option. This enables PrimeTime to load physical database, read the constraint file, and create voltage areas before starting to fix violations. The *create_voltage_area* commands in *read_sdc* are ignored.

Voltage areas can physically be completely nested; that is, one voltage area can lie completely inside another voltage area.

Voltage areas can also be logically nested; that is, one hierarchical cell can belongs to one voltage area, while one of its descendants belongs to another voltage area.

Voltage areas cannot be partially overlapped. The creation fails if you try to create a voltage area partially overlapping with an existing voltage area.

Examples

The following example creates a voltage area named V_AREA1 for hierarchical cell INST_1.

```
pt_shell> create_voltage_area -name V_AREA1 \\
          -coordinate {100 100 200 200} INST_1
```

The following example creates a voltage area from an existing power INST. domain:

```
pt_shell> create_voltage_area -power_domains INST \\
          -coordinate { 215 215 350 350 }
```

The following example creates a voltage area by using the *-polygons* option:

```
pt_shell> create_voltage_area -power_domains INST \\
          -polygons {{100 100} {300 100} {300 200} {200 200} {200 300} \\
          {100 300} {100 100}}
```

The following example creates a voltage area with disjoint polygons by using the *-polygons* option:

```
pt_shell> create_voltage_area -power_domains INST \\
          -polygons {{{100 100} {300 100} {300 200} {200 200} {200 300}
 \\
          {100 300} {100 100}} {{400 400} {500 400} {500 500} {400 500}
 \\
          {400 400}}}
```

The following example creates a voltage area named V_AREA2 from two existing power domains INST and MULT:

```
pt_shell> create_voltage_area -power_domains "INST MULT" \\
          -coordinate { 200 200 450 450 }
```

---

create_waiver

Creates a violation waiver. Waivers can conditionally suppress violations of an enabled rule.

Syntax

Boolean *create_waiver*

```
[-name name]
[-design design]
[-scenario scenario]
-rule rule_name
[-condition condition]
[-not_condition condition]
[-cells cell_list]
[-all_scenarios]
[-comment comment]
```

Data Types

```
name          string
design        string
scenario      string
rule_name     string
condition     list
cells         list
comment       string
```

Arguments

`-name name`

Specifies a name for the waiver being created. If there is an existing waiver with this name, it is overwritten. If no name is given, a unique name is automatically generated for the waiver.

`-design` *design*

Specifies the design to which the waiver is applied. If no design is given, the waiver is created for the current design. Expects linked design to be passed.

`-scenario` *scenario*

Specifies the scenario to which the waiver is applied. If no scenario is given, the waiver is created for the current scenario.

`-rule` *rule_name*

Specifies the rule. The waiver conditionally suppresses violations of the given rule.

`-condition` *condition*

There can be multiple *-condition* options. Each *-condition* specifies one requirement for the violation to be suppressed. *condition* is a list, where the first element is the name of a rule parameter, and all remaining elements are collections of netlist/constraint objects or strings. A *-condition* option is satisfied if the value of the violation parameter falls in one of the collections or strings. A violation is suppressed only if all the *-condition* and *-not_condition* options are satisfied.

`-not_condition` *condition*

There can be multiple *-not_condition* options. Each *-not_condition* specifies one requirement for the violation to be suppressed. *condition* is a list, where the first element is the name of a rule parameter, and all remaining elements are collections of netlist/constraint objects or strings. A *-not_condition* option is satisfied if the value of the violation parameter does not fall in any of the collections or strings. A violation is suppressed only if all the *-condition* and *-not_condition* options are satisfied.

`-cells` *cell_list*

List of cells for instance based waivers. The list can contain hierarchical or leaf cells. For leaf cells, the violations that affect only such instances are waived. For hierarchical cells, the violations that affect only objects inside or on the hierarchical instance are waived.

`-all_scenarios`

Use this option in conjunction with *-cells* option to indicate that the instance based waiver should apply to all the scenarios and not just the scenario specified by the "-scenario" option.

`-comment` *comment*

A comment on the waiver (up to 1024 characters).

Feedback

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Creates a violation waiver for the given rule. A violation waiver suppresses a violation if the violation satisfies all *-condition* and *-not_condition* conditions. Multiple waivers can be created on one rule. A violation is suppressed if it meets the requirements of at least one waiver.

If the rule is scenario-dependent, the waiver is active when checks are performed in the scenario specified by the "-scenario" option, or the current scenario if no scenario is specified; if the rule is scenario-independent, the waiver is active in scenario-independent checks only.

To remove a violation waiver use the *remove_waiver* command.

Examples

The following example creates a waiver for CLK_0003 violations if the *clock* parameter is CLK1 or CLK2, and if the *pin* parameter is not U1/A or U1/B:

```
pt_shell> create_waiver -name my_waiver1 -rule CLK_0003 \\
    -condition [list "clock" [get_clocks {CLK1 CLK2}]] \\
    -not_condition [list "pin" [get_pins U1/A] [get_pins U1/B]] \\
    -comment "waiver example"
```

The following example creates a waiver for all objects inside block instance hier_inst. Also, it specifies that the waiver should be applied to all scenarios.

```
pt_shell> create_waiver -name my_waiver1 -cells [get_cell hier_inst] \\
    -all_scenarios \\
    -comment "waiver example2"
```

When creating a waivers for block-to-top and SDC-to-SDC rules, *current_design* and *current_scenario* can be used to switch the context under which the object is to be retrieved. The following example shows how to create a waiver for B2T_CLK_0012 rule.

```
pt_shell> create_waiver -rule B2T_CLK_0012 \\
    -condition [list "blk_object" [current_design BLOCK; get_pins
 zGate/A]] \\
    -condition [list "blk_object_type" "pin"] \\
    -condition [list "top_object" [current_design TOP; get_pins
 b1/zGate/A]] \\
    -condition [list "top_object_type" "pin"]
```

The following example shows how to create a waiver for the S2S_CLK_0001 rule.

```
pt_shell> create_waiver -rule S2S_DIS_0001 \\
    -condition [list "object" [current_design S2S_CLK_0001; get_pins
 ck2_i2]] \\
    -condition [list "object_type" "pin"] \\
```

Feedback

```
    -condition [list "scenario1" "set2"] \\
    -condition [list "scenario2" "set1"]
```

---

current_design

Sets or returns the current design.

Syntax

string *current_design*

`[design_name]`

Data Types

design_name string

Arguments

design_name

Specifies the working or focal design for many PrimeTime commands. If you omit the *design_name* option, the *current_design* command returns a collection containing the current design. If the *design_name* option specifies a design that cannot be found, an error is issued and the working design remains unchanged.

Description

This command sets or returns the working design, which is the focus of many PrimeTime commands. Before *link_design current_design* won't return anything. Without arguments, the *current_design* command returns a collection containing the current working design. Together, the *current_design* and *current_instance* commands define the focus for many PrimeTime commands.

To display designs currently available in PrimeTime, use the *list_designs* command.

Examples

The following example uses the *current_design* command to show the current context and to change the context from one design to another.

```
pt_shell> current_design
{"TOP"}

pt_shell> list_designs
```

```
Design Registry:
    ADDER              /designs/dbs/my_design.db:ADDER
    FULL_ADDER         /designs/dbs/my_design.db:FULL_ADDER
    FULL_SUBTRACTOR    /designs/dbs/my_design.db:FULL_SUBTRACTOR
    HALF_ADDER         /designs/dbs/my_design.db:HALF_ADDER
    HALF_SUBTRACTOR    /designs/dbs/my_design.db:HALF_SUBTRACTOR
    SUBTRACTOR         /designs/dbs/my_design.db:SUBTRACTOR
 *  TOP                /designs/dbs/my_design.db:TOP

pt_shell> current_design ADDER
{"ADDER"}

pt_shell> current_design
{"ADDER"}
```

The *current_design* command can be used as a parameter to other *pt_shell* commands. In the following example, the *remove_design* command is used to delete the working design from *pt_shell*.

```
pt_shell> current_design
{"TOP"}
pt_shell> remove_design [current_design]
Removing design 'TOP'...
1
pt_shell> current_design
Error: Current design is not defined. (DES-001)
pt_shell>
```

See Also

- current_instance
- list_designs

---

current_instance

Sets the current working cell instance, which enables subsequent commands to be used relative to that instance.

Syntax

string *current_instance*

```
[instance]
```

Data Types

```
instance     string
```

Feedback

Arguments

instance

Specifies the current working cell instance to be used as the focus for subsequent commands.

Description

The *current_instance* command specifies the working cell instance. This command differs from the *current_design* command, which specifies the working design and then sets the current instance to the top level of the current design. The combination of the current design and current instance defines the focus for many PrimeTime commands.

The *current_instance* command allows you to traverse the design hierarchy similar to the way the shell *cd* command traverses the file system hierarchy. The *current_instance* command operates with a variety of *instance* arguments:

- If you do not specify an *instance* argument, the command focus returns to the top level of the hierarchy.
- If *instance* is one period (.), the command returns the current instance, and no change is made.
- If *instance* is two periods (..), the current instance moves up one level in the design hierarchy.
- If *instance* is a valid cell (or cell name) at the current level of hierarchy, the command focus moves down to that level of the design hierarchy.

Most commands that return port and pin objects consider the current instance. By default the *get_ports* command always returns ports of the top-level design. To enable the *get_ports* command to return pins of the current instance when applicable, set the *port_search_in_current_instance* variable to *true*. See EXAMPLES for details.

Examples

The following example uses *current_instance* to move up and down the design hierarchy.

```
pt_shell> current_design TOP
{"TOP"}

pt_shell> current_instance U1
U1

pt_shell> current_instance .
U1

pt_shell> current_instance U3
U1/U3
```

```
pt_shell> current_instance ../U2
U1/U2

pt_shell> current_instance
Current instance is the top-level of design 'TOP'.
```

The following example shows the use of more complex instance paths with multiple hierarchy levels separated by a slash:

```
pt_shell> current_instance U1/U3/U5
U1/U3/U5

pt_shell> current_instance ../../U2/U4
U1/U2/U4
```

The following example shows how the *get_ports* command operates within a current instance:

```
pt_shell> current_instance
Current instance is the top-level of design 'TOP'.

pt_shell> get_ports *
{"CLK", "DIN[0]", "DIN[1]", "DOUT[0]", "DOUT[1]"}

pt_shell> current_instance reg0
reg0

pt_shell> get_ports *
{"CLK", "DIN[0]", "DIN[1]", "DOUT[0]", "DOUT[1]"}

pt_shell> get_attribute [get_ports *] object_class
{"port", "port", "port", "port", "port"}

pt_shell> set_app_var port_search_in_current_instance true
true

pt_shell> get_ports *
{"reg0/clk", "reg/d", "reg/q"}

pt_shell> get_attribute [get_ports *] object_class
{"pin", "pin", "pin"}
```

---

current_power_rail

Sets or gets the power rails in a multi-rail design to be included in power analysis. As the default (if not specified), all the power rails in the design are included in power analysis. This command has no effect on single rail design.

When the variable power_enable_multi_rail_analysis is true, specifes the power rails that will be included in reporting. When false, sets the specific power rails to be included in the power analysis.

Syntax

int *current_power_rail*

`[rail_names]`

Data Types

rail_names	string

Arguments

rail_names

Specifies the names of the power rails in the design to be included in power analysis or reporting. If the *rail_names* option is not specified, the *current_power_rail* command returns a collection of power rails being included in power analysis. If the *rail_names* option refers to a power rail that is not defined in the design, an error is issued and the current rail settings remains unchanged.

Description

Sets or gets the power rails in a multirail design to be included in power analysis or in reporting. Without arguments, the *current_power_rail* command returns a collection of power rails being included in power analysis.

The command behavior depends on the power_enable_multi_rail_analysis variable. When false, (the default); concurrent multi-rail analysis is disabled; and power for all the power rails in the design are calculated. This command controls which power rails are to be included in the power analysis. When specified, only the power dissipation on the listed power rails is calculated and reported. To report power consumption per power rail, the command must be applied for each power rail, and the power reanalyzed per power rail.

When the power_enable_multi_rail_analysis variable is true, power per power rail is calculated, and the command controls the power reporting and attribute values. When specified, the power dissipation on the listed power rails is accessible via the get_attribute

and report_attribute commands, as well as the report_power command. To access the power attribute values per power rail, the command must be applied for each power rail, before issueing the get_attribute or report_attribute commands.

Before using this command, you define the design power rails by using the *create_power_rail_mapping* command. The *report_power_rail_mapping* command can be used to show the defined design power rails, library power rails, and rail mapping information.

The following power analysis results will be affected by this command in a multi-rail design:

```
- average power report
- time-based power report
- power related attributes: total_power
                            dynamic_power
                            internal_power
                            switching_power
                            leakage_power
                            x_transition_power
                            glitch_power
                            peak_power
```

Use the *current_power_rail all* command to resume the default behavior, which includes all the power rails in the design.

Peak_power and peak_time per rail are only accessible when power_enable_multi_rail_analysis is false. When concurrent multi-rail analysis is performed, only the peak power and peak time for the all the supply nets is accessible. Per rail the peak power attributes are available only when concurrent multi-rail analysis is disabled.

Examples

The following example shows generating rail-based power analysis results. The first *report_power* command will generate the power analysis results for the part of design with supply voltage of VDD1 and VDD2. The second *report_power* command will generate the results for the part of design which is supplied by VDD1.

```
pt_shell> create_power_rail_mapping VDD1 -cells block1
pt_shell> create_power_rail_mapping VDD2 -cells block2
pt_shell> current_power_rail {VDD1 VDD2}
pt_shell> report_power
pt_shell> current_power_rail VDD1
pt_shell> report_power
```

---

current_scenario

Selects a subset of the scenarios in the current session for analysis.

Syntax

status *current_scenario*

```
scenario_list
[-all]
```

Data Types

```
scenario_list        list
```

Arguments

scenario_list

Specifies a list of scenarios to analyze in the current session . If you specify a scenario that exists but is not in the current session, the command issues an error and does not change the command focus. The list can also contain patterns with the asterisk (*) and question mark (?) wildcard symbols to specify multiple scenarios. If you use wildcards symbols, the scenarios selected are automatically restricted to come from the scenarios in the current session.

-all

Selects all scenarios in the current session for analysis.

Description

The *current_scenario* command returns a collection containing all the scenarios in command focus. This command is only available if you invoke the *pt_shell* command with the *-multi_scenario* option.

Before you run the *current_scenario* command, you need to create scenarios by running the *create_scenario* command.

In multi-scenario analysis, after you create scenarios, use the *current_session* command to focus on a set of scenarios for analysis. Next, focus the analysis on a specific subset of the scenarios in the current session by running the *current_scenario* command; subsequent commands will apply only to the specified scenarios.

To determine which scenarios are in command focus, run the *report_multi_scenario_design* command with the *-session* option. If you run the command at remote workers by *remote_execute* command, it returns the name of the scenario executing the command. In this mode, the options of the command are disabled.

Examples

In the following example, three scenarios named scen1, scen2, and scen3 are created.

- scen1 is created using common_s1.pt and specific_s1.pt
- scen2 is created using common_s2.pt and specific_s2.pt
- scen3 is created using common_s3.pt and specific_s3.pt

The scenarios scen1, scen2 and scen3 are selected for the current session, which is then displayed. Notice that all three scenarios are in command focus.

The analysis is focused on only scen2 and scen3 using the *current_scenario* command and the session is displayed again. Notice that scen1 is now only in session focus but scen2 and scen3 are in command focus. That is, only scen2 and scen3 will be considered for analysis.

```
1
pt_shell> create_scenario -name scen1 -common_data {common_s1.pt} \\
-specific_data  {specific_s1.pt}
1
pt_shell> create_scenario -name scen2 -common_data {common_s2.pt} \\
-specific_data  {specific_s2.pt}
1
pt_shell> create_scenario -name scen3 -common_data {common_s3.pt} \\
-specific_data  {specific_s3.pt}
1
pt_shell> current_session {scen1 scen2 scen3}
{"scen1", "scen2", "scen3"}
pt_shell> report_multi_scenario_design -session

****************************************
Report : multi_scenario_design
 ...
****************************************

Session details
-------------------------------------------------------

Number of scenarios in current session: 3
```

```
        Focus           Scenario  (Image provider)

        Command         scen1   (scen1)
        Command         scen2   (scen2)
        Command         scen3   (scen3)

1
pt_shell> current_scenario {scen2 scen3}
{"scen2", "scen3"}
pt_shell> report_multi_scenario_design -session

****************************************
Report : multi_scenario_design
 ...
****************************************

Session details
-------------------------------------------------------

Number of scenarios in current session: 3

        Focus           Scenario  (Image provider)

        Session         scen1   (scen1)
        Command         scen2   (scen2)
        Command         scen3   (scen3)

1
```

In the following example, two scenarios named scen1 and scen2 are in focus. The *remote_execute* command is used to save PrimeTime sessions for scenarios scen1 and scen2 in directories named /u/ptms/sessions/sess_scen1 and /u/ptms/sessions/sess_scen2, respectively.

```
pt_shell> sh mkdir /u/ptms/sessions
pt_shell> remote_execute
 {save_session /u/ptms/sessions/sess_[current_scenario]}

Start of Manager/Worker Task Processing
-----------------------------------
Started    : Command execution in scenario 'scen2'
Started    : Command execution in scenario 'scen1'
Succeeded  : Command execution in scenario 'scen2'
Succeeded  : Command execution in scenario 'scen1'
-----------------------------------
End of Manager/Worker Task Processing

1
pt_shell> ls /u/ptms/sessions
pt_shell>
```

Feedback

---

current_session

Selects a set of scenarios for analysis.

Syntax

string *current_session*

```
[scenario_list]
[-all]
```

Data Types

```
scenario_list     list
```

Arguments

scenario_list

Brings the specified scenarios into focus for analysis. To specify multiple scenarios, you can use the * and *?* wildcard symbols.

`-all`

Brings all defined scenarios into focus for analysis.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

To set the current session, you need the following resources:

- At least one PrimeTime license is available for usage; since the manager can share its license with workers this criterion is always met; to query additional license that are currently checked out and can be shared with use the *report_multi_scenario_design* commadn passing *-license* option.
- At least one host option has been defined using the *set_host_options* command; to query the host options that have been created use the *report_host_usage* command.
- At least one worker process has been brought online using the *start_hosts* command; to query the workers that have come online, use the *report_host_usage* command.

Feedback

After all required resources are available, and the scenarios are created, you must select a set of scenarios to analyze by using the *current_session* command. Calling this command with a list of scenarios brings those scenarios into focus for the current session (session focus) and into focus for receiving commands (command focus) from the manager. The current session can be set with all or a subset of the created scenarios. If a scenario selected has an affinity specification, then the scenario will only be allowed enter the session if at least one worker process is online from the host options in its affinity specification.

The *current_session* command returns a collection containing all the scenarios in the current session.

Calling the *current_session* command resets all scenarios to the way they were when created by the *create_scenario* command. As part of executing the subsequent distributed command, the scenarios in command focus in the session will be rebuilt from the scripts or images used to originally define them.

If the *multi_scenario_license_mode* variable is set to '*core*' then there is a requirement that all the scenarios in the session are using the same design. When each scenario loads its design, if it detects its design is different to any other scenario in the session, then the scenario will error out, the command executing at the manager will error out and the current session will terminate with an error.

Examples

In the following example, a configuration and three scenarios named scen1, scen2 and scen3 are created. The current session is set such that scen2 and scen3 are in session and command focus.

- scen1 is created using common_s1.pt and specific_s1.pt
- scen2 is created using common_s2.pt and specific_s2.pt
- scen3 is created using common_s3.pt and specific_s3.pt

The scen2 and scen3 scenarios are brought into focus.

```
pt_shell> create_scenario -name scen1 -common_data {common_s1.pt} \\
            -specific_data  {specific_s1.pt}
1
pt_shell> create_scenario -name scen2 -common_data {common_s2.pt} \\
            -specific_data  {specific_s2.pt}
1
pt_shell> create_scenario -name scen3 -common_data {common_s3.pt} \\
            -specific_data  {specific_s3.pt}
1
pt_shell> current_session {scen2 scen3}
{"scen2", "scen3"}
```

d

date

Returns a string containing the current date and time.

Syntax

string *date*

Description

The *date* command generates a string containing the current date and time, and returns that string as the result of the command. The format is fixed as follows:

```
ddd mmm nn hh:mm:ss yyyy
```

Where:

```
ddd is an abbreviation for the day
mmm is an abbreviation for the month
nn is the day number
hh is the hour number (24 hour system)
mm is the minute number
ss is the second number
yyyy is the year
```

The *date* command is useful because it is native. It does not fork a process. On some operating systems, when the process becomes large, no further processes can be forked from it. With it, there is no need to call the operating system with *exec* to ask for the date and time.

Examples

The following command prints the date.

```
prompt> echo "Date and time: [date]"
Date and time: Thu Dec  9 17:29:51 1999
```

Feedback

debug_script

Debug a script using the TclDevKit Tcl debugger.

Syntax

string *debug_script* script [*port*] [*hostname*]

Arguments

script

This specifies the Tcl script(s) to be debugged. This script will be sourced and instrumented for debugging.

port

Specifies the port number that the debugger is listening on for a remote debugging application. By default the debugger will be launched on an available port.

hostname

Specifies the host where Prodebug is already running. This is used to connect to an existing remote Prodebug session.

::env(SNPS_TCLPRO_HOME)

This Tcl variable is used to specify the root of the TclPro installation. It is initialized from the environment variable SNPS_TCLPRO_HOME in the user's environment.

USING THE PACKAGE

The *debug_script* command is in the snpsTclPro Tcl package, and all of the commands in this package are defined in the namespace snpsTclPro. The way to use this command is to load the package, which will import the commands it exports into the global namespace. This is shown below.

```
shell> package require snpsTclPro
1.0
```

These commands can be added to the .synopsys setup file for the system, user, or current directory, or the commands can be typed when the pacakge is needed.

Description

The *debug_script* command simplifies the use of the TclDevKit Tcl debugger available from ActiveState (http://www.activestate.com). First it ensures a connection to the Prodebug debugger either by connecting to a running debug session (given a *hostname* and *port*), or by launching the debugger on *localhost* using an available port, and then connecting to it.

If there is already an active connection to the debugger then that debugger will simply be used.

Once the connection to the debugger is set up, the specified script will be sourced and debugged. The default behavior for the debugger is to stop at the first line of the source'd script.

The debugger must be run using a "remote" debugging project if you want to connect the Synopsys tools to a running prodebug session. The port number in use by the debugger can be viewed via the Application tab of the "File->Project" Settings dialog.

Examples

```
# Launch the debugger and then debug the script myscript.tcl.
shell> debug_script myscript.tcl
Selected port 2576 on host localhost
launching prodebug

# now debug another script using the same session
shell> debug_script anotherScript.tcl

# debug myscript.tcl, connecting to the specified debugger session or
# creating one if the connection fails.
shell> debug_script myscript.tcl 2576 localhost
```

CAVEATS

The debugger currently kills the process that started the debugger when you exit, despite the preferences being set differently in the debugger.

When the Synopsys tool has spawned a debugger, that debugger must be exited before the Synopsys tool can exit. If this is not the case then the Synopsys tool will hang on exit, until the debugger is exited.

The *debug_script* command waits for the debug process to start up, before it tries to connect to the debugger. If *debug_script* times out before the debugger is started due to machine or network loading, simply close the debugger that was launched, and then increase the timeout setting with the command *set_debugger_start_timeout*, and then re-run the debugger. The *set_debugger_start_timeout* command takes a single argument which is the value of the timeout in miliseconds, and the default value for the timeout is 10000.

- check_script

Feedback

define_cell_alternative_lib_mapping

Specifies which library file to use from an exact-match-only scaling library group for timing analysis of named cell instances.

Syntax

string *define_cell_alternative_lib_mapping*

```
library_file_name
-cells cell_list
[-sms_scenarios sms_scenarios_list]
```

Data Types

```
library_file_name     string
cell_list             list
sms_scenarios_list    collection
```

Arguments

library_file_name

Specifies the scaling group library file to associate with the cell. The library must be in a scaling library group previously defined by the *define_scaling_lib_group* command using the *-exact_match_only* option. For both leaf and hier cells, the list of library files supported.

-cells *cell_list*

Specifies a list of cell instances that will use the named library for timing analysis. They can be hierarchical or leaf-level cells.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios for which the command is applied. This collection is created by *get_sms_scenarios*.

Description

The *define_cell_alternative_lib_mapping* command allows you to associate cell instances with exact-match scaling libraries. Unlike the *link_path_per_instance* variable, you can apply updated cell/library associations without relinking the design.

Use this command after the *define_scaling_lib_group* command and before the *update_timing* or *report_timing* command.

Leaf cells can be associated with a single library or multiple libraries ,if its associated with multiple library then will pick the first library. Hierarchical cells can be associated with a list of libraries. For each leaf cell in the hierarchy, the first library containing the corresponding library cell is used.

Feedback

Specifications applied to leaf cells have the highest precedence. Specifications applied to lower hierarchy levels take precedence over specifications applied to higher hierarchy levels.

Make sure that the operating conditions and rail voltage set on the named cells match those of the named library file.

Examples

The following script creates an exact-match-only scaling library group containing two libraries and directs the tool to use a specific library for cells U1 and U2.

```
set link_path "* my_linked_lib.db"
read_verilog my_design.v
link_design my_design
define_scaling_lib_group -exact_match_only {my_linked_lib.db
 my_alt_lib.db}
define_cell_alternative_lib_mapping my_alt_lib.db -cells {U1 U2}
update_timing
report_timing
```

- define_scaling_lib_group
- set_operating_conditions
- set_rail_voltage

---

define_derived_user_attribute

Create an attribute defined in Tcl

Syntax

string *define_derived_user_attribute* -type *data_type*

[-user_type *type_name*] -classes *class_list* -name *attribute_name* [-info *attribute_info*] -get_command *get_cmd* [-set_command *set_cmd*] [-remove_command *remove_cmd*] [-subscript_command *sub_cmd*]

```
string data_type
string type_name
list  class_list
string attribute_name
string attribute_info
string get_cmd
```

```
string set_cmd
string remove_cmd
string sub_cmd
```

Arguments

`-type data_type`

The type of the attribute (Values: boolean, double, int, string, collection)

`-user_type type_name`

User type name. Some applications use the user_type to generate improved dialogs for setting attribute values. If this is not specified the type name is derived from the specified attribute type.

`-classes class_list`

Define attribute on these classes

`-name attribute_name`

Name of the attribute

`-info attribute_info`

Sort description of the attribute value.

`-get_command get_cmd`

Tcl command to retrieve the attribute value.

`-set_command set_cmd`

Tcl command to set the attribute value. The specified script is evaluated when the *set_attribute* command is executed.

`-remove_command remove_cmd`

Tcl command to remove the attribute value. The specified script is evaluated when the *remove_attribute* command is executed.

`-subscript_command sub_cmd`

Define a subscripted attribute. Specifying this option causes the defined attribute to be subscripted. The command should return the valid set of subscripts on this object.

Description

The *define_derived_user_attribute* command defines an attribute on a class of objects. The value of that attribute is computed by evaluating the script provided by the *-get_command* option.

Feedback

All of the commands supplied for the attribute may reference special keys. The supported keys are the following:

%object

The object to operate on. This key is supported in all commands.

%subscript

This is only valid when a subscripted attribute is created. This key is replaced by the specified subscript in the get, set and remove commands.

%value

This key is only valid in set commands. It contains the value to set the attribute to.

All of the commands supplied for the attribute define an anonymous proc context. This means any variables you refer to in these scripts are scoped locally. The anonymous proc is created in namespace used to evaluate the *define_derived_user_attribute* command. To refer to variables from that enclosing namespace use the *variable* command. You may also refer to global variables via the *global* command or by use the "$::varName" syntax.

If the value returned by the *get_command* is the empty string, then the attribute is not set on this object. This may be tested by the defined and undefined operator in the *filter_collection* command. If the value is not the empty string, the returned value is converted into the specified type. If the string cannot be converted into the type, it is considered an error.

Examples

Declare an attribute called user_tag on cells. The attribute stores attribute values into a Tcl dict keyed on the full_name of the cell. The dict is maintained in a namespace:

```
namespace eval user_tag_ns {
  # Map from name - val
  variable vals;                # Dictionary name->value

  define_derived_user_attribute -classes cell -name user_tag -type int \\
    -get_command {
      variable vals
      if {[catch {set val [dict get $vals [get_attribute %object
 full_name]]} val]} {
        return "";          # Unset.
      }
      set val
    } \\
    -set_command {
      variable vals
      set name [get_attribute %object full_name]
      dict set vals $name %value
```

Feedback

```
    } \\
     -remove_command {
       variable vals
       set name [get_attribute %object full_name]
       dict unset vals $name
    }
  }
```

---

define_design_mode_group

Defines a design mode group with a set of design modes.

Syntax

string *define_design_mode_group*

```
[-group_name name]
mode_list
```

Data Types

```
name            string
mode_list       list
```

Arguments

`-group_name name`

Specifies the name of the design mode group. By default, if no design mode group is specified, a default design mode group is created and named "default".

mode_list

Specifies a list of design modes to be created and included in the design mode group.

Description

The *define_design_mode_group* command defines a set of design modes to be placed in a design mode group for your design. You select one of the design modes to be the active mode using the *set_mode -type design* command. There are only two valid states for a design mode group. The default state of all modes enabled or the state of one mode

enabled and all others disabled. Setting one of the modes to be active automatically sets the rest of the modes in the group inactive (disabled).

You can map cell modes or paths to a design mode using the *map_design_mode* command. When you select the active design mode with the *set_mode -type design* command, the modes of the cells specified for that design mode are also active. Any paths mapped to disabled design modes automatically become false paths.

Unlike design modes, which are user-specified, cell modes are predefined, and are in the library. You can find out what cell modes are available using the *report_mode* command. For more information about cell modes, see the manual page for the *set_mode* command.

To see a report of the design modes specified for the current design, use the *report_mode -type design* command.

To remove design modes, use the *remove_design_mode* command. Removing a design mode also removes any cell mode or path specifications previously mapped to the design mode using the *map_design_mode* command.

Examples

The following example defines two design modes for the current design: SYSTEM and TEST.

```
pt_shell> define_design_mode_group {SYSTEM TEST}
```

The following example defines two independent design mode groups. The first command defines a design mode group named RW that contains design modes READ and WRITE. The second command defines a design mode group named LT that contains design modes LATCH and TRANSPARENT.

```
pt_shell> define_design_mode_group -group RW {READ WRITE}
pt_shell> define_design_mode_group -group LT {LATCH TRANSPARENT}
```

The following command enables the design mode READ and disables the design mode WRITE, because READ and WRITE belong to the same design mode group RW.

```
pt_shell> set_mode -type design READ
```

Feedback

define_flow_summary_segment

Define a custom event in flow summary report which is not a PrimeTime command.

Syntax

status *define_flow_summary_segment* [-start] [-end] [-name *event_name*]

Data Types

event_name string

Arguments

-start

To start the scope of a custom user defined event.

-end

To end the scope of a custom user defined event.

-name

User defined name of the event which encapsulates the segment.

Description

The *define_flow_summary_segment* command is used to create an artificial scope in PrimeTime's flow summary report encapsulating a set of commands and/or scripts within it. This command can be used to create an indented scope containing the set of commands and/or scripts which are invoked within the *define_flow_summary_segment -start* and *define_flow_summary_segment -end* commands.

This could be used to separate and identify a set of user scripts or PrimeTime commands within a flow summary report.

Examples

The following gives an example of define_flow_summary_segment.

```
pt_shell>set sh_flow_summary_file stdout
pt_shell> define_flow_summary_segment -start -name new_marker
pt_shell> ....   # Usual PT script
pt_shell> define_flow_summary_segment -start -name new_marker
| CUSTOM_SEGMENT_new_marker {
| | report_timing: 10.0s
| | uncaptured: 0.7s
| } 10.7s
```

Feedback

---

define_name_maps

Defines object name mapping for an application and design.

Syntax

status *define_name_maps*

```
-application application_name
-design_name design_name
-columns column_list
entries
```

Data Types

```
application_name    string
column_list         list
design_name         string
entries             list
```

Arguments

`-application application_name`

Specifies the targeting application name. Currently, only *golden_upf* is supported. The *-application* and *-design_name* options jointly specify a unique in-memory name map instance for the current session.

`-design_name design_name`

Specifies the name of the design. The *-application* and *-design_name* options jointly specify a unique in-memory name map instance for the current session.

`-columns column_list`

Specifies the column names of the name map for the *application_name*.

`entries`

Specifies name mapping entries conforming to the definition of *column_list*.

Description

The *define_name_maps* command specifies a list of object name mapping entries for a specified application. Usually, a name map is associated with a particular design name. *application_name* is predefined by the tool.

The object name map could help in certain constraint applications where the default object query or even the rule-based query algorithms could not succeed in finding the correct

objects. The typical case is when trying to apply RTL constraints onto the postoptimization netlist.

Note: It is the specific application that defines the content format and the usage model of its name map. For details about the functionality of a name map, see the documentation for the specific application.

APPLICATION golden_upf

golden_upf is the application_name assigned to golden UPF flow. The *define_name_maps* command for the *golden_upf* application typically appear in a golden UPF name mapping file, although other command such as *set_query_rules* could also exist in the golden UPF name mapping file. A *golden_upf* name map has four columns: *class*, *pattern*, *options* and *names*.

The *class*, *pattern* and *options* columns are used jointly to locate the entry in the map; the *names* column is the mapping result.

The following example illustrates the map contents and columns.

```
prompt> define_name_maps                          \\
    -application golden_upf                       \\
    -design TOP                                   \\
    -columns {class pattern options names}        \\
    {cell mid/inst/U3     {} {mid_inst/U4 mid_inst/U5}} \\
    {cell mid/inst/bot+U5 {} {mid_inst/bot/U9}}
```

The preceding name map is for the *golden_upf* application and the TOP design. The following four columns are predefined for the application:

- *class* specifies an object class name such as cell or port. The supported class names are: *cell*, *port*, *pin*, *net*, *power_domain*, *power_switch*, *supply_net*, *supply_port*, and *supply_set*.
- *pattern* specifies object matching pattern string. This is one of the object name patterns from the golden UPF file. The optional delimiter character '+' is used to indicate that a pattern is composed of a matching string (for example, "U5") and a scope (for example, scope "mid/inst/bot") for that matching string.
- *options* specifies a list of matching options for the map entry. It is derived from the golden UPF file. The supported *options* is a list of the following elements {*nocase transitive leaf*|*noleaf in*|*out*|*inout*}. *nocase* option specifies that the string in the *pattern* column should be treated case-insensitively during name lookups. For the meanings of other options, see the man page of the *find_objects* command. *leaf* and *noleaf* are mutually exclusive. *in*, *out*, and *inout* are mutually exclusive. In the preceding example, no option is used.
- *names* is a list object names where every name element is a full-path name relative to the top scope of the specified design. The *names* column is the name mapping target.

Feedback

The preceding name map would result in the following query behavior under the *golden_upf* application, although in real golden UPF flow, the queries are executed through *load_upf* command:

```
prompt> find_objects . -pattern mid/inst/U3 -object_type inst
{mid_inst/U4 mid_inst/U5}

prompt> find_objects mid/inst/bot -pattern U5 -object_type inst
{mid_inst/bot/U9}
```

See Also

---

define_power_model

Defines the power model architecture.

Syntax

string *define_power_model*

```
[model_name]
[-for model_list]
```

Data Types

model_list	list
model_name	string

Arguments

`-for model_list`

PrimeTime reads and ignore this option. Complete support will be available in future releases.

`model_name string`

PrimeTime reads and ignore this option. Complete support will be available in future releases.

Description

PrimeTime reads and ignore this command. Complete support will be available in future releases.

Feedback

Examples

The following command creates ia power model named upf_model for cellA.

```
prompt> define_power_model upf_model -for cellA {
create_power_domain PD1 -elements {.} -supply {ssh1} -supply {ssh2}
#other commands ...
}
1
```

See Also

- apply_power_model

---

define_proc_attributes

Defines attributes of a Tcl procedure, including an information string for help, a command group, a set of argument descriptions for help, and so on. The command returns the empty string.

Syntax

string *define_proc_attributes*

```
proc_name
[-info info_text]
[-define_args arg_defs]
[-define_arg_groups group_defs]
[-command_group group_name]
[-return type_name]
[-hide_body]
[-hidden]
[-dont_abbrev]
[-permanent]
```

Data Types

```
proc_name       string
info_text       string
arg_defs        list
group_defs      list
group_name      string
type_name       string
```

Arguments

proc_name

Specifies the name of the existing procedure.

`-info` *`info_text`*

Provides a help string for the procedure. This is printed by the *help* command when you request help for the procedure. If you do not specify *info_text*, the default is "Procedure".

`-define_args` *`arg_defs`*

Defines each possible procedure argument for use with *help -verbose*. This is a list of lists where each list element defines one argument.

`-define_arg_groups` *`group_defs`*

Defines argument checking groups. These groups are checked for you in parse_proc_arguments. each list element defines one group

`-command_group` *`group_name`*

Defines the command group for the procedure. By default, procedures are placed in the "Procedures" command group.

`-return` *`type_name`*

Specifies the type of value returned by this proc. Any value may be specified. Some applications use this information for automatically generated dialogs etc. Please see the type_name option attribute described below.

`-hide_body`

Hides the body of the procedure from *info body*.

`-hidden`

Hides the procedure from *help* and *info proc*.

`-dont_abbrev`

Specifies that the procedure can never be abbreviated. By default, procedures can be abbreviated, subject to the value of the *sh_command_abbrev_mode* variable.

`-permanent`

Defines the procedure as permanent. You cannot modify permanent procedures in any way, so use this option carefully.

`-deprecated`

Defines the procedure as deprecated i.e. it should no longer be called but is still available.

`-obsolete`

Defines the procedure as obsolete i.e. it used to exist but can no longer be called.

Feedback

Description

The *define_proc_attributes* command associates attributes with a Tcl procedure. These attributes are used to define help for the procedure, locate it in a particular command group, and protect it.

When a procedure is created with the *proc* command, it is placed in the Procedures command group. There is no help text for its arguments. You can view the body of the procedure with *info body*, and you can modify the procedure and its attributes. The *define_proc_attributes* command allows you to change these aspects of a procedure.

Note that the arguments to Tcl procedures are all named, positional arguments. They can be programmed with default values, and there can be optional arguments by using the special argument name *args*. The *define_proc_attributes* command does not relate the information that you enter for argument definitions with *-define_args* to the actual argument names. If you are describing anything other than positional arguments, it is expected that you are also using *parse_proc_arguments* to validate and extract your arguments.

The *info_text* is displayed when you use the *help* command on the procedure.

Use *-define_args* to define help text and constraints for individual arguments. This makes the help text for the procedure look like the help for an application command. The value for *-define_args* is a list of lists. Each element has the following format:

```
arg_name option_help value_help data_type attributes
```

The elements specify the following information:

- *arg_name* is the name of the argument.
- *option_help* is a short description of the argument.
- *value_help* is the argument name for positional arguments, or a one word description for dash options. It has no meaning for a Boolean option.
- *data_type* is optional and is used for option validation. The *data_type* can be any of: string, list, boolean, int, float, or one_of_string. The default is string.
- *attributes* is optional and is used for option validation. The *attributes* is a list that can have any of the following entries:
  - "required" - This argument must be specified. This attribute is mutually exclusive with optional.
  - "optional" - Specifying this argument is optional. This attribute is mutually exclusive with "required."

- "value_help" - Indicates that the valid values for a one_of_string argument should be listed whenever argument help is shown.
- "values {<list of allowable values>}" - If the argument type is one_of_string, you must specify the "values" attribute.
- "type_name <name>" - Give a descriptive name to the type that this argument supports. Some applications may use this information to provide features for automatically generated dialogs, etc. Please see product documentation for details. This attribute is not supported on boolean options.
- "merge_duplicates" - When this option appears more than once in a command, its values are concatenated into a list of values. The default behavior is that the right-most value for the option specified is used.
- "remainder" - Specifies that any additional positional arguments should be returned in this option. This option is only valid for string option types, and by default the option is optional. You can require at least one item to be specified by also including the required option.
- "deprecated" - Specifying this option is deprecated i.e. it should no longer be used but is still available. A warning will be output if this option is specified. This attribute cannot be combined with obsolete or required.
- "obsolete" - Specifying this option is obsolete i.e. it used to exist but can no longer be used. A warning will be output if this option is specified. This attribute cannot be combined with deprecated or required.
- "min_value" <value> - Specify the minimum value for this option. This attribute is only valid for integer and float types.
- "max_value" <value> - Specify the maximum value for this option. This attribute is only valid for integer and float types.
- "default" <value> - Specify the default value for this option. This attribute is only valid for string, integer and float option types. If the user does not specify this option when invoking the command this default value will be automatically passed to the associated tcl procedure.

The default for *attributes* is "required."

Use the *-define_arg_groups* to define argument checking groups. The format of this option is a list where each element in the list defines an option group. Each element has the following format:

{<type> {<opt1> <opt2> ...} [<attributes>]}

The types of groups are

Feedback

- *"exclusive"* Only one option in an exclusive group is allowed. All the options in the group must have the same required/optional status. This group can contain any number of options.
- *"together"* If the first option in the group is specified then the second argument is also required. This type of group can contain at most two options.
- "related" These options are related to each other. An automatic dialog builder for this command may try to group these options together.

The supported attributes are:

- *{"label" <text>}* An optional label text to identify this group. The label may be used by an application to automatically build a grouping in a generated dialog.
- *"bidirectional"* This is only valid for a together group. It means that both options must be specified together.

Change the command group of the procedure using the *-command_group* command. Protect the contents of the procedure from being viewed by using *-hide_body*. Prevent further modifications to the procedure by using *-permanent*. Prevent abbreviation of the procedure by using *-dont_abbrev*.

Examples

The following procedure adds two numbers together and returns the sum. For demonstration purposes, unused arguments are defined.

```
prompt> proc plus {a b} { return [expr $a + $b]}

prompt> define_proc_attributes plus -info "Add two numbers" \\
? -define_args {
  {a "first addend" a string required}
  {b "second addend" b string required}
  {"-verbose" "issue a message" "" boolean optional}}

prompt> help -verbose plus
Usage: plus    # Add two numbers
    [-verbose]          (issue a message)
    a                   (first addend)
    b                   (second addend)

prompt> plus 5 6
11
```

In the following example, the argHandler procedure accepts an optional argument of each type supported by *define_proc_attributes*, then displays the options and values received. Note the only one of -Int, -Float, or -Bool may be specified to the command:

```
proc argHandler {args} {
  parse_proc_arguments -args $args results
```

Feedback

```
  foreach argname [array names results] {
    echo $argname = $results($argname)
  }
}

define_proc_attributes argHandler \\
  -info "Arguments processor" \\
  -define_args {
     {-Oos "oos help"       AnOos   one_of_string
        {required value_help {values {a b}}}}
     {-Int "int help"       AnInt   int     optional}
     {-Float "float help"   AFloat  float   optional}
     {-Bool "bool help"     ""      boolean optional}
     {-String "string help" AString string  optional}
     {-List "list help"     AList   list    optional}
     {-IDup "int dup help"  AIDup   int     {optional merge_duplicates}}
   } \\
  -define_arg_groups {
     {exclusive {-Int -Float -Bool}}
   }
```

See Also

- parse_proc_arguments
- sh_command_abbrev_mode

---

define_qtm_attribute

Defines a new user-defined attribute for a class of Quick Timing Model (QTM) objects.

Syntax

string *define_qtm_attribute*

```
-type data_type
-class obj_class
attr_name
```

Data Types

```
data_type           string
obj_class           string
attr_name           string
```

Feedback

Arguments

`-type` *`data_type`*

Specifies the data type of the attribute. The supported data types are string, int, float, and Boolean.

`-class` *`obj_class`*

Specifies the class of QTM objects the new attribute is defined for. The valid object classes are lib, lib_cell or lib_pin. Attribute for 'lib' class applies to the library. Attribute for 'lib_cell' class applies to the QTM cell. Attribute for 'lib_pin' class applies to the QTM ports/pins.

`attr_name`

Specifies the name of the attribute.

Description

Use *define_qtm_attribute* command to define a new user-defined attribute that is applicable to QTM objects. A user-defined attribute is any attribute which PrimeTime does not understand by default. Those attributes already understood or reserved by PrimeTime for various classes of objects are considered application attributes and should not be re-defined. If you need to set the application attributes that are applicable to the classes of QTM objects, just use *set_qtm_attribute* directly. There is no need to define the attribute before setting them. But for user attributes that are not reserved by the application, you have to define them before set them on objects. Note that the *list_attributes* command will not show any attributes defined for QTM.

After save the QTM in proper library, those user-defined QTM attributes can be imported from db files. But you must define those user attributes you want to import with the *define_user_attribute* command and the *-import* option before the library with the QTM cell is read.

For more information, see the *define_user_attribute* man page.

Examples

The following example defines QTM attributes of various types.

```
pt_shell> define_qtm_attribute my_str_attr \\
           -class lib_pin -type string
pt_shell> define_qtm_attribute my_int_attr \\
           -class lib_cell -type int
pt_shell> define_qtm_attribute my_float_attr \\
           -class lib -type float
```

Feedback

---

define_scaling_lib_group

Defines a group of libraries for voltage and temperature scaling.

Syntax

string *define_scaling_lib_group*

```
[-exact_match_only]
[-best_match]
[-excluded_rail_names rail_name_list]
[-p_abstol process_threshold]
[-v_abstol voltage_threshold]
[-t_abstol temperature_threshold]
library_list
[-config_file DBFile_name]
```

Data Types

```
library_list     list
rail_name_list   list
config_file      string
```

Arguments

`-exact_match_only`

Specifies that this scaling group is analyzed in exact-match only mode. The tool skips scaling and tries to find the exact-match library. If not found, the linked library is used, and the SLG-216 warning is issued.

`-best_match`

Specifies that this scaling group is analyzed in best-match mode. The tool uses the closest (best-match) library, considering only libraries whose P, V, and T values match within given threshold values.

When no such library is found, the fallback library behavior is determined by the *timing_use_link_library_on_best_match_failure* variable.

After best-match chooses a library for a cell (whether within the thresholds or as a fallback), that library's voltage is used as the cell voltage for delay calculation.

`-excluded_rail_names` *`rail_name_list`*

Specifies a list of library voltage rails to be ignored by voltage scaling. These rails are ignored when validating scaling group formations and when performing the scaling calculations themselves, thus reducing N-dimensional multi-rail scaling to a lower dimension.

This option can be used to remove problematic rails that prevent valid formations in true scaling flows. It can also be used to remove problematic rails that do not match in exact-match flows.

This option affects all cells in the scaling group libraries. To exclude rails or *pg_pins* for specific library cells, use the *set_disable_pg_pins* command instead.

`-p_abstol` *`process_threshold`*

Specifies the best-match process threshold, in library process units. The default is 0.1.

`-v_abstol` *`voltage_threshold`*

Specifies the best-match voltage threshold, in main library voltage units. The default is 0.1.

`-t_abstol` *`temperature_threshold`*

Specifies the best-match temperature threshold, in degrees. The default is 20.

`library_list`

Specifies a list of libraries for voltage and temperature scaling. Only one of the libraries in the *library_list* option should be in the *link_path* variable; the remaining libraries are read automatically after the design is linked to complete the group.

A minimum of two libraries is required for one-dimensional scaling (voltage or temperature), and a minimum of four libraries is required for two-dimensional scaling (voltage and temperature).

`-config_file` *`DBFile_name`*

Specifies reading data from DBFile, mutually exclusive with *library_list*.

Description

The *define_scaling_lib_group* command defines a group of libraries that PrimeTime interpolates between for voltage and temperature scaling. Scaling with library groups supports timing, noise, and power analysis using Composite Current Source (CCS) model data, nonlinear delay model (NLDM) data, or a mix of both.

Normally, the *define_scaling_lib_group* command is run after the design is linked. However, it can be run before link to account for extra timing arcs in scaling libraries. For details, see "Mismatched Timing Arcs Across Scaling Group Libraries" below.

You can have more than one group to cover different portions of a design, but the groups cannot share libraries.

When a group is in effect, you cannot use the *set_rail_voltage* or *set_operating_conditions* command outside the range of the applicable group.

To see if a group is used for delay calculation, use the *report_delay_calculation* command. The report shows the results using the link library, then the scaling library group results if applicable and valid.

To report all scaling groups defined by the *define_scaling_lib_group* command, use the *report_lib_groups* command.

Mismatched Timing Arcs Across Scaling Group Libraries

The *define_scaling_lib_group* command supports mismatched timing arcs across scaling group libraries, but only in exact-match scaling group flows.

If the link library contains timing arcs that are not in one or more scaling libraries, the *define_scaling_lib_group* command can be run before or after the design is linked.

If a scaling library contains timing arcs that are not in the link library, then the *define_scaling_lib_group* command must be run before the design is linked. For example,

```
# define link library
set_app_var link_path {* lib_1.05V.db}

# define scaling library group
define_scaling_lib_group \
  -exact_match \
  {lib_0.9V.db lib_1.05V.db lib_1.3V.db}

# read and link design
read_verilog TOP.v
link_design TOP
```

This command ordering allows the design link process to be aware of any additional arcs in the scaling libraries.

Mismatched timing arc support is limited to exact-match scaling flows (voltage conditions exactly match library conditions). True scaling flows (with interpolation between libraries) still require consistent libraries within each group.

Feedback

Examples

The following example defines a scaling library group for two voltage domains about the nominal:

```
pt_shell> set link_path "* 1.1.db"
pt_shell> link_design
pt_shell> define_scaling_lib_group { 0.9.db 1.1.db 1.3.db }
```

---

define_sensitivity_lib_mapping

Defines the mapping between base library and sensitivity augmented library.

Syntax

string *define_sensitivity_lib_mapping*

```
-side_file side_file
library
```

Data Types

```
side_file       string
library         collection
```

Arguments

`-side_file side_file`

Specifies the sensitivity augmented library as side file of base library.

library

Specifies the base library to define the side file.

Feedback

Description

The *define_sensitivity_lib_mapping* command defines mapping between base library and sensitivity augmented library.

Examples

The following script enables SPICE2Design flow, defines mapping between base library and sensitivity side-file, then report the mapping.

```
set link_path orig.db
read_verilog ...
link_design
set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]

pt_shell> report_sensitivity_lib_mapping orig
  Lib             side_file
================================================
  orig            side.db
================================================
1
```

- reset_sensitivity_lib_mapping
- ps_enable_spice2design_analysis
- ps_enable_pvt_explorer_analysis

---

define_user_attribute

Defines a new user-defined attribute.

Syntax

string *define_user_attribute*

```
-type string | int | float | double | boolean
-classes class_list
[-range_min min]
[-range_max max]
[-one_of values]
[-import]
[-export]
[-quiet]
attr_name
```

Feedback

Data Types

class_list	list
min	double
max	double
values	list
attr_name	string

Arguments

`-type string | int | float | double | boolean`

Specifies the data type of the attribute.

`-classes` *class_list*

Defines the attribute for one or more of the classes. The valid object classes are *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, *lib_pin*, *timing_path*, *clock*, or *lib_timing_arc*.

`-range_min` *min*

Specifies *min* value for numeric ranges. This is only valid when the data type is *int* or *double*. Specifying a minimum constraint without a maximum constraint creates an attribute which accepts a value >= *min*.

`-range_max` *max*

Specifies *max* value for numeric ranges. This is only valid when the data type is *int* or *double*. Specifying a maximum constraint without a minimum constraint creates an attribute which accepts a value <= *max*.

`-one_of` *values*

Provides a list of allowable strings. This is only valid when the data type is *string*.

`-import`

Imports this attribute from a design or library database.

`-export`

Exports this attribute to extract_model design or library database.

`-quiet`

Does not report any messages.

attr_name

Specifies the name of the attribute.

Feedback

Description

Use the *define_user_attribute* command to define a new user-defined attribute. A user-defined attribute is any attribute which PrimeTime does not understand by default. The *list_attributes* command shows all attributes which PrimeTime understands.

You can apply attributes to most object classes in PrimeTime. You can use these to mark interesting cells or nets, or store values you computed, and so on. PrimeTime cannot use these attributes, but you can use them in scripts, procedures, and so on. You can list the attributes you defined using the *list_attributes* command.

User-defined attributes can be imported from a design or library database after they have been defined. A design or library database is a db or ddc format file, or a Milkyway database. You must define attributes you want to import with the *-import* option. Note that imported attributes do not appear on the design objects until the design is linked. Attributes imported from a design or library database are inherited through the hierarchy. Note that attributes defined for designs are inherited onto cells, and attributes defined for ports are inherited onto pins. The *define_user_attribute* command sets up these relationships for you automatically if you do not do it explicitly.

Examples

The following example defines attributes of various types. Note that more than one class can be specified. Also note that attr_i is defined as imported from a design or library database. Finally, attribute design1 is imported from a design or library database, and PrimeTime defines it for cells as well.

```
pt_shell> define_user_attribute attr_s \\
            -classes {cell net} -type string
pt_shell> define_user_attribute attr_i \\
            -classes cell -type int -import
pt_shell> define_user_attribute design1 \\
            -classes design -type int -import
Information: Inferred definition of attribute 'design1' for class 'cell'
        because it is imported for class 'design' (ATTR-7)
```

In the following example, attr_ir1 is defined as >= 0 and <= 100, attr_ir2 is defined as >= 0 with no maximum, and attr_ir3 is defined as <= 100 with no minimum.

```
pt_shell> define_user_attribute attr_ir1 \\
            -classes cell -type int \\
            -range_min 0 -range_max 100
pt_shell> define_user_attribute attr_ir2 \\
            -classes cell -type int -range_min 0
pt_shell> define_user_attribute attr_ir3 \\
            -classes cell -type int -range_max 100
```

In the following example, define attribute attr_oo for cells. The attribute is a string, but can only be set to A, B, C, or D.

Feedback

```
pt_shell> define_user_attribute attr_oo \\
            -classes cell -type string -one_of {A B C D}
```

After these attributes have been defined, you can list the attribute definitions using the *list_attribute* command. Notice how the 'attr_i' attribute is marked as importable from db, meaning a design or library database.

```
pt_shell> list_attributes

****************************************
Report : List of Attribute Definitions
 ...
****************************************

Properties:
    A - Application-defined
    U - User-defined
    I - Importable from db (for user-defined)

Attribute Name   Object  Type      Properties  Constraints
-------------------------------------------------------------
attr_i           cell    int       U,I
attr_ir1         cell    int       U           0 to 100
attr_ir2         cell    int       U           >= 0
attr_ir3         cell    int       U           <= 100
attr_oo          cell    string    U           A, B, C, D
attr_s           cell    string    U
attr_s           net     string    U
design1          design  int       U,I
design1          cell    int       U
```

In the following example, attr_xyz is defined and exported as string for design and port, and set values "abc" and "def" on designX and portX respectively.

```
pt_shell> define_user_attribute attr_xyz \\
            -classes {design port} -type string \\
            -export
pt_shell> set_user_attribute [get_design designX] attr_xyz abc
pt_shell> set_user_attribute [get_port portX] attr_xyz def
```

After extract_model, the attribute attr_xyz and its values are expected in .lib.

```
pt_shell> extract_model -output mymodel -format {db lib}
Model extraction : Clock period/min_pulse_width arcs extracted at context
 slew.
Wrote the LIB file ./ETM/mymodel/mod.lib
Wrote model to './ETM/mymodel/mod_lib.db'
 ...
pt_shell>sh cat ./ETM/mymodel/mod.lib
 ...
cell( designX ) {
  ...
```

```
  attr_xyz : abc;
  ...
 ...
pin("portX") {
        ...
        attr_xyz : def;
        ...
} /* end of pin portX */
 ...
} /* end of cell */
 ...
```

---

derive_clocks

Creates clocks on source pins in design.

Syntax

string *derive_clocks*

```
-period period_value
[-waveform edge_list]
```

Data Types

```
period_value      float
edge_list         list
```

Feedback

Arguments

`-period` *`period_value`*

Specifies the clock period of the automatically derived clocks. The clock period has a value greater than or equal to zero (value >= 0).

`-waveform` *`edge_list`*

Specifies the rise and fall edge times of the clock, in library time units, over an entire clock period. It defines the clock edge specification. The first time that is listed is a rising transition; typically the first rising transition after time zero. There must be an even number of increasing times and alternating rise and fall times. If you do not specify an *edge_list* value, the command assumes a default waveform that has a rise edge of *0.0* and a fall edge of *period_value*/2.

Description

Creates clocks on source pins in design. This command finds the clock source ports and pins that must have clocks defined so that every register clock pin has a clock. Then on each source set, the command creates a clock in the same way as the *create_clock* command does. The clocks are created with the specified waveform or period. For a description of commands that use clock objects, see the *create_clock* command man page.

Examples

The following example creates a clock on the source pin with a clock period of 20:

```
pt_shell> derive_clocks -period 20
```

- set_output_delay

Feedback

disconnect_net

Disconnects a net from specified pins or ports, or from all pins and ports.

Syntax

```
status disconnect_net
  -all
  net
  object_spec
```

Data Types

```
net           string
object_spec   list
```

Arguments

`-all`

Indicates that all pins and ports are to be disconnected from *net*. The *-all* and *object_spec* options are mutually exclusive.

net

Specifies the name of the net to be disconnected.

object_spec

Specifies a list of pins or ports to be disconnected from *net*. The *-all* and *object_spec* options are mutually exclusive.

Description

The *disconnect_net* command disconnects pins and ports from a *net* in the current design. Like all other netlist editing commands, for the *disconnect_net* command to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. the *disconnect_net* command returns a 1 if successful and a 0 if unsuccessful.

The *net* option and each pin and port specified in the *object_spec* option must be in scope; that is, at or below the current instance. There are three rules for *disconnect_net*. They are:

- You cannot disconnect an unconnected pin or a port.
- You cannot disconnect a pin or a port that is not connected to *net*.
- You cannot disconnect a hierarchical pin or a port that has the same name as *net*.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported

using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is re-linked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following example, the first command attempts to connect port in1 to net new_net1, but in1 is already connected to a net. The second command determines the net to which in1 is connected; the third command disconnects the port from its net. The fourth and final command connects in1 to new_net1.

Feedback

```
pt_shell> connect_net new_net1 [get_ports in1]
Error: Could not connect 'in1' to 'new_net1'
        Object is already connected - disconnect it first (NED-042)
Error: No changes made. (NED-040)
0
pt_shell> set pnet [get_nets -of_objects [get_ports in1]]
{"in1"}
pt_shell> disconnect_net $pnet [get_ports in1]
Information: Disconnected 'in1' from 'net1'. (NED-019)
1
pt_shell> connect_net new_net1 [get_ports in1]
Information: Connected 'in1' to 'new_net1'. (NED-018)
1
```

---

drive_of

Determines the drive resistance of the specified library cell pin. The *drive_of* command is a DC Emulation command provided for compatibility with Design Compiler.

Syntax

float *drive_of*

```
[-rise]
[-fall]
[-wire_drive]
[-piece val]
lib_cell_pin
```

Data Types

val	string
lib_cell_pin	string

Feedback

Arguments

`-rise`

Gets rise drive value.

`-fall`

Gets fall drive value.

`-wire_drive`

Not supported in PrimeTime.

`-piece` *`val`*

Not supported in PrimeTime.

`lib_cell_pin`

Specifies the name of the library cell pin whose drive value is to be returned. This value can be either the drive resistance or a collection that contains the library cell pin.

Description

The *drive_of* command returns the drive resistance of the given library cell pin. If neither the *-rise* nor *-fall* option is specified, the greater value of rise and fall is returned.

The *drive_of* command exists in PrimeTime for compatibility with Design Compiler. Complete information about the *drive_of* command can be found in the Design Compiler documentation. The supported method for getting the capacitance of a library cell pin is by using the *get_attribute* command with either the *drive_resistance_rise* or *drive_resistance_fall* attribute.

---

e

---

echo

Echos arguments to standard output.

Syntax

string *echo*

```
[-n]
[arguments]
```

Feedback

Data Types

arguments string

Arguments

-n

Suppresses the new line. By default, *echo* adds a new line.

arguments

Specifies the arguments to be printed.

Description

The *echo* command prints out the value of the given arguments. Each of the arguments are separated by a space. The line is normally terminated with a new line, but if the *-n* option is specified, multiple *echo* command outputs are printed onto the same output line.

The *echo* command is used to print out the value of variables and expressions in addition to text strings. The output from *echo* can be redirected using the > and >> operators.

Examples

The following are examples of using the *echo* command:

```
prompt> echo
"Running version" $sh_product_version
Running version v3.0a

prompt> echo -n "Printing to" [expr (3 - 2)] > foo
prompt> echo " line." >> foo
prompt> sh cat foo
Printing to 1 line.
```

- sh

---

enable_primetime_icc_consistency_settings

Sets all recommended variables with values for consistency with IC Compiler.

Syntax

string *enable_primetime_icc_consistency_settings*

[-all]

Feedback

Arguments

`-all`

Applies the recommended values to all variables, including flow-specific variables. If you do not use this option, flow-specific variables are not adjusted or reported.

Description

The *enable_primetime_icc_consistency_settings* command sets all common variables to have values that are recommended for consistency. By default, the flow-specific and feature gap variables are ignored.

Examples

```
pt_shell> enable_primetime_icc_consistency_settings
set rc_degrade_min_slew_when_rd_less_than_rnet false
# rc_degrade_min_slew_when_rd_less_than_rnet changed to true
set timing_clock_gating_propagate_enable true
# timing_clock_gating_propagate_enable changed to false
```

---

error_info

Prints extended information on errors from the last command.

Syntax

```
string error_info
```

Arguments

This *error_info* command has no arguments.

Description

The *error_info* command is used to display information after an error has occurred. Tcl collects information showing the call stack of commands and procedures. When an error occurs, the *error_info* command can help you to focus on the exact line in a block that caused the error.

Examples

This example shows how *error_info* can be used to trace an error. The error is that the iterator variable "s" is not dereferenced in the 'if' statement. It should be '$s == "a" '.

```
prompt> foreach s $my_list {
?         if { s == "a" } {
?           echo "Found 'a'!"
?         }
?       }
```

Feedback

```
Error: syntax error in expression " s == "a" "
       Use error_info for more info. (CMD-013)
shell> error_info
Extended error info:
syntax error in expression " s == "a" "
    while executing
"if { s == a } {
     echo "Found 'a'"
}"
    ("foreach" body line 2)
    invoked from within
"foreach s [list a b c] {
   if { s == a } {
     echo "Found 'a'"
}
}"
 -- End Extended Error Info
```

---

estimate_clock_gate_max_power

Find the worst-case internal energy when-condition in the liberty model for memory cells and set those for each of instances

Syntax

```
int estimate_clock_gate_max_power
[-target_ts]
```

Data Types

instance_list	list

Arguments

`-target_ts`

To set the target average toggle savings given by the user.

Description

Find the worst-case internal energy when-condition in the liberty model and set those for each of instances Ignore all propagated TR and SP values to the nets which are part of the when-condition If there is logic conflict with setting it will be ignored. For all other pins which are not part of the selected when-condition use the propagated TR and SP.

- PrimePower will use user defined conditions for power calculation for specific instances • Power calculation – Maximum of weighted sum of states that match the condition specified by user. – No change to toggle rate propagation • User constraint form (UI preliminary subject to change) – Set inst_power_condition <inst_name> {Pin_name bool_value derate_value,…} <related_pin> – inst_name and related_pin is mandatory – Ex: Set inst_power_condition top/blockA/mem1 {RCS 1 0.5, WCS 1 0.5} CLK – User

does not need to specify conditions on all the other pins that are not included in the inst_power_condition command – Sum of derate values in an inst_power_condition cannot exceed 1.0 – If multiple inst_power_conditions defined for an instance, then tool will pick last statement one for power analysis for the same inst_name and related_pin

Example1: Single port memory – estimate_clock_gate_max_power top/A/InstSp1 {“CS & !WE & !PD & SLEEPB” 1 0.5, “CS & WE & !PD & SLEEPB” 1 0.0} CK – Matching states – S2 = “CS & !WE & !PD & SLEEPB” 1 0.5 with CK S2_derate = 0.5 – S1 = “CS & WE & !PD & SLEEPB” 1 0.0 with CK S1_derate = 0.0 – total_derate_matching_states = 0.5 + 0.0 = 0.5 – Non_matching states – S3 = !CS & !PD & SLEEPB – total_derate_non_matching_states = 1.0 – total_derate_matching_states = 1-0.5=0.5 – Power calculation for supply VCC – matching_state_pwr – S2_pwr*S2_derate + S1_pwr*S1_derate = 40.0*0.5 + 50.0*0.0 = 20 – Non_matching_state_pwr – S3_pwr * total_derate_non_matching_states = 3.0*0.5 = 1.5 – Total_pwr_vcc = matching_state_pwr + non_matching_state_pwr = 20 + 1.5 = 21.5 – Similar calculation will be performed for cvcc – total_power = total_pwr_vcc + total_power_cvcc

This command should only be run in average mode. update_power should be used to calculate power and report_power shows the maximum power values used for memory cells.

The *state_condition* option can be used to change the when condition of the state used for derating.

The *target_ts* option can be used to set the derate value to be used for a given state condition.

The *pin* option can be used to specify the input pin which needs to be used for derating and power calculation.

Examples

The following example shows how to set maximum memory power on a single cell in the design. The command dumps out the output in the report_power command.

```
pwr_shell> estimate_clock_gate_max_power I_SINGLE_PORT -target_ts 0.5
estimate_clock_gate_max_power I_SINGLE_PORT -target_ts 0.5

1
```

The following example sets the derate value of 0.5 for cell "I_TCAM" and creates an output file "debug_s1_report.rpt"

```
pwr_shell> estimate_clock_gate_max_power I_TCAM -target_ts 0.5

estimate_clock_gate_max_power I_TCAM -target_ts 0.5
1
```

Feedback

---

estimate_clock_network_power

Virtually generate a clock tree and estimate its power.

Syntax

string *estimate_clock_network_power*

```
lib_cell
[-max_fanout fanout]
[-wire_load_model wire_load_name]
[-library lib_name]
[-input_transition transition]
[-clocks clock_list]
[-include_registers]
[-ignore_clock_gating]
```

Data Types

```
lib_cell              string
fanout                int
wire_load_name        string
lib_name              string
transition            float
clock_list            list
```

Arguments

lib_cell

Specifies the buffer or inverter to be used to build the clock tree.

-max_fanout *fanout*

Specifies the maximum fanout number that the specified buffer can drive. The default number is 32.

-wire_load_model *wire_load_name*

Specifies the wire load model to be used to compute the wire capacitance for the nets in the clock tree. The default is the wire load model set to the design.

-library *lib_name*

Specifies the library where the specified wire load model is defined.

`-input_transition` *`transition`*

Specifies the clock input transition. If not specified, use the clock transition annotated to the clock by the *set_clock_transition* command. If there is no annotation either, the default to 0.

`-clocks` *`clock_list`*

Specifies the clocks to be estimated for clock tree power. The default is all the clocks in the design.

`-include_registers`

Indicates the power of registers driven by the clock is also included in the power report.

`-ignore_clock_gating`

Indicates that existing clock tree cells like the clock gating cells are ignored when building the clock tree.

Description

The *estimate_clock_network_power* command virtually creates a clock tree for each clock and calculates power for the generated clock tree. The clock trees are built on the fly and the original design is not touched or modified. The following describes how the clock tree is built:

Find all the nets in the clock network. For each net in the clock network, insert buffers to build a clock tree, so that the fanout of each buffer in the clock tree is no bigger than the max fanout. The command tries to build a tree as balanced as possible such that the delays from the root to the leafs do not vary a lot. All the driven registers are put at the same and lowest level of the tree. The deviation of buffer fanouts at the same tree level is kept as small as possible.

The output load of each buffer is calculated using wire load model. The input transition of each buffer propagates from the root of the tree. The switching activity for each inserted buffer is equal to clock frequency or from annotation (SAIF or set_switching_activity).

If there are clock gating cells in the original clock network, the command builds a separate tree based on the fanout of the clock gating cell using the same rule for the clock tree, and this separate tree is considered as a branch of the whole clock tree, and also balances with other branches. Then the clock gating effect is accounted for by the annotated or, if not annotated, propagated switching activity. In order for you to investigate savings from clock gating, the command has the *-ignore_clock_gating* option to estimate the clock tree power by ignoring the clock gating cells and compare with the power that considers the clock gating effect. The power consumed by the registers driven by the clock is also included in the report if the *-include_registers* option is specified.

Feedback

Examples

In the following example, clock tree power is estimated for clock CLK by building the clock tree using the buffer buf1a1 of library ssc_core_typ and wire load model in the design is used to calculate the wire capacitance. The clock input transition is 0.2.

```
pt_shell> create_clock -name CLK -period 10 clk
pt_shell> set_clock_transition 0.2 CLK
pt_shell> estimate_clock_network_power ssc_core_typ/buf1a1
```

- report_power

---

estimate_eco

Estimates delay changes for the *size_cell* and *insert_buffer* commands.

Syntax

string *estimate_eco*

```
[-lib_cells lib_cell]
[-verbose]
[-max]
[-min]
[-rise]
[-fall]
[-from from_pin]
[-rise_from from_pin]
[-fall_from from_pin]
[-through_arc timing_arc]
[-to   to_pin]
[-rise_to   to_pin]
[-fall_to   to_pin]
[-data_pin]
[-inverter_pair]
[-current_library]
[-libraries lib_spec]
[-significant_digits digits]
[-nosplit]
[-type size_cell | insert_buffer]
[-power]
[-output_format_in_list]
[-sort_by sort_type]
object_list
```

Data Types

```
lib_cell        list
from_pin        string
```

```
to_pin          string
lib_spec        string
digits          integer
sort_type       string
object_list     list
```

Arguments

`-lib_cells` *lib_cell*

Specifies the list of library cells that can be used for ECO estimation. Specifying this list is mandatory for buffer insertion and optional for cell sizing.

`-verbose`

Generates a very detailed estimation report for each candidate library cell.

`-max`

Specifies only maximum delay calculation reporting. This is the default.

`-min`

Specifies only minimum delay calculation reporting.

`-rise`

Restricts reporting to rising transitions at the stage driver output pin. The default is to consider both rising and falling transitions.

`-fall`

Restricts reporting to falling transitions at the stage driver output pin.

`-from` *from_pin*

Specifies the *from_pin* of the path from which to get the estimated timing. The *from_pin* must be one of the inputs of the cell being estimated. It cannot be a hierarchical pin. No more than one of *-from*, *-rise_from*, or *-fall_from* can be used in the command.

This option can't be used together with *-rise_to*, *-fall_to*.

`-rise_from` *from_pin*

Like the *-from* option, but only rising transitions at the pin are considered.

`-fall_from` *from_pin*

Like the *-from* option, but only falling transitions at the pin are considered.

`-through_arc` *timing_arc*

Specifies a dedicated timing arc from the input to the output of the "from" cell in the path specified by the *-from* and *-to* options.

The argument of the *-through_arc* option is a cell timing arc gathered by the *get_timing_arcs* command. Use this option to restrict the timing analysis to only specific types of timing arcs through the cell. See the EXAMPLES section for details.

-through_arc should be used for cell-arcs only.

`-to` *`to_pin`*

Specifies the *to_pin* of the path from which to get the estimated timing. The *to_pin* must be an input pin of a cell in the direct fanout of the cell being estimated. It cannot be a hierarchical pin. No more than one of *-to*, *-rise_to*, or *-fall_to* can be used in the command.

This option can't be used together with *-rise_from*, *-fall_from*.

`-rise_to` *`to_pin`*

Like the *-to* option, but only rising transitions at the pin are considered.

`-fall_to` *`to_pin`*

Like the *-to* option, but only falling transitions at the pin are considered.

`-data_pin`

Estimates the slack of the related data-pin of a sequential cell. The related data-pin can be the D-pin of a sequential cell, a reset/clear pin of a sequential cell, a clock-gating enable pin, or the D-pin of a nonsequential cell.

To use the *-data_pin* option, you must first add *data_pin_slack* to the *eco_estimation_output_columns* variable.

`-inverter_pair`

Specifies that an inverter pair is to be inserted when the ECO type is *insert_buffer*.

`-current_library`

Searches only the cell's current library to resolve the *lib_cell* name.

`-libraries` *`lib_spec`*

Resolves *lib_cell* using only cells from the listed libraries.

`-significant_digits` *`digits`*

Specifies the number of digits after the decimal point displayed for time values in the generated report. Allowed values are 0-13; the default is determined by the *report_default_significant_digits* variable, which is 2 by default. This option controls only the number of digits displayed, not the precision used internally for analysis.

`-nosplit`

Prevents line-splitting and facilitates writing software to extract information from the report output.

`-type size_cell | insert_buffer`

Specifies either *size_cell* or *insert_buffer* ECO estimation. If you do not use this option, the default is *size_cell*.

`-output_format_in_list`

By default, estimate_eco output will be flush to console. When specified, estimation_eco results will be kept inside list.

For example, originally we have estimation report like this,

```
pt_shell> estimate_eco u0 -from u1/A -to u2/Z -nosplit;
delay type : max_rise
lib cell        arrival   slack
--------------------------------
*lib1/BUFX1     1.5263    5.0714
 lib1/BUFX2     1.5305    5.0669
 lib1/BUFX3     1.5284    5.0690
```

Then, we can use option '-output_format_in_list' to keep estimation into list.

```
pt_shell> set results [estimate_eco u1 -nosplit
 -output_format_in_list];
pt_shell> set line_result [lindex $results 0];
*lib1/BUFX1 1.5263 5.0714
pt_shell> echo [lindex $line_result 1];
1.5263
pt_shell> echo [lindex $line_result 2];
5.0714
```

`-sort_by` *`sort_type`*

Specifies the method of sorting library cells reported. The following types are allowed: *area*, *stage_delay*, *arrival*, *slack*, *transition*, *max_transition*, *min_transition*, *max_capacitance*, or *min_capacitance*. If you do not use this option, the default is *area*.

`-power`

Estimates changes in power in addition to timing.

`object_list`

Specifies the name of object to analyze. For *size_cell*, the object is a cell to be sized. For *insert_buffer*, the object is a pin where the buffer is to be inserted.

Feedback

Description

The *estimate_eco* command provides a method to estimate the timing effects of certain ECO commands, without actually incurring a timing update to compute the slack. As its name implies, the results of this command are estimates only, and are expected to reasonably predict, but not necessarily match, the actual slack resulting from the ECO command.

ECO estimation is supported for two ECO commands: *size_cell* and *insert_buffer*. This is specified with the *-type* argument, which takes a value of *size_cell* or *insert_buffer*, which matches the corresponding command name. Both buffer insertion and double-inverter insertion are supported for *insert_buffer* estimation.

When performing *insert_buffer* estimation, the *-lib_cell* option is required and must supply a list of one or more buffer library cells as buffer insertion candidates. The buffer cells can be specified in the form of *lib_cell* collection objects, a list of library_name/base_name names, or simply a list of base_name library cell names. The library cell specifications follow the same rules as the *insert_buffer* command. For more information, see the *insert_buffer* man page.

When performing *size_cell* estimation, the *-lib_cell* option is optional; the default is the list of alternative library cells for the specified instance cell as obtained by the *get_alternative_lib_cells* command. When the *-lib_cell* option is specified, the candidate library cells can be specified in the form of lib_cell collection objects, a list of library_name/base_name names, or simply a list of base_name library cell names. The library cell specifications follow the same rules as the *size_cell* command. To improve runtime, manually specified candidate cells are not validated for functional equivalence before estimation is performed. For more information, see the *size_cell* man page.

For both buffer insertion and cell sizing, to limit the candidate cells to a specific library, you can use the *-current_library* and *-libraries* options of the *get_alternative_lib_cells* command, and pass the resulting lib_cell collection to the *estimate_eco* command.

The *estimate_eco* command generates a report that predicts the timing and slack effects of one or more potential library cell candidates for the *size_cell* or *insert_buffer* command. By default, the estimates are shown in a compact form that lists one candidate library cell per line, with stage delay, arrival, and slack information columns. A verbose mode is also available with the *-verbose* option, which shows a separate detailed estimation report for each candidate library cell.

For example, in the verbose mode, a stage delay is divided into a cell delay, an output net delay, a buffer delay, and a delta delay. The cell delay indicates the cell arc delay of the driver cell of the net. The output net delay is the net arc delay from the driver pin of the net to the slack-critical load pin. The buffer delay is displayed only for buffer insertion estimate and indicates the cell arc delay of the buffer cell. The delta delay indicates the crosstalk delta delay of the net.

The *-min* and *-max* options are available to specify whether minimum-delay hold timing, maximum-delay setup timing, or both should be shown. By default, the maximum-delay timing is shown. The *-rise* and *-fall* options are available to specifically request rise/fall timing. By default, both rise and fall information is shown. If only the *-rise* or *-fall* option is specified, only that information is shown.

The estimate computation takes into account the incoming transition times, the output loading, the fanout loading, the detailed parasitics (if present), and the driver characteristics of the candidate cells. The rise/fall timing shown in the report represents the worst timing through the cell output pins in the corresponding direction. In the verbose report, the arrival is the arrival time at the input pin of the load cell driven by the resized or inserted cell, and the stage delay is the delay of the inserted/resized cell and the driven net.

In the compact report without the verbose option, the reported arrival time, slack, and transition time are the estimated values at the input pin of the slack-critical load cell. Maximum transition, minimum transition, maximum capacitance, and minimum capacitance values are the worst values of the pins along the path to the slack-critical load pin. Individual values are shown in verbose reporting.

To perform slack and arrival estimation, the *timing_save_pin_arrival_and_slack* variable should be set to *true* ahead of time. If this variable is not already set to *true*, the *estimate_eco* command automatically sets it to *true* and updates the design timing before it proceeds with ECO estimation.

Estimated data can be selectively reported if the content of the *eco_estimation_output_columns* variable is changed. By default, only *area*, *stage_delay*, *arrival*, and *slack* are reported. Others, such as *max_transition* and *max_capacitance*, can be reported by changing the variable. For more information, see the *eco_estimation_output_columns* man page.

The *-power* option works only for estimation using *size_cell*. By default, the total power of a cell is reported. The verbose option shows detailed power information like dynamic and leakage power. To use this option, power analysis should be enabled ahead of time by setting the *power_enable_analysis* variable to *true*. The *-power* option triggers a power update if the design power is not already up-to-date. The power numbers displayed are in Watts.

Examples

The following example shows a minimum and maximum delay summary estimation of four potential buffer cell insertions at an instance pin:

```
pt_shell> estimate_eco -type insert_buffer -min -max \\
            -lib_cells {BUFX2 BUFX4 DLY1X1 DLY2X1} \\
            wishbone/TxDone_wb_reg/D

  delay type : max_rise
```

```
 lib cell                  area  stage_delay      arrival         slack
 ---------------------------------------------------------------------
 slow/DLY1X1              19.96        0.857        2.076        14.859
 slow/DLY2X1              19.96        1.218        2.437        14.498
 slow/BUFX4               16.63        0.639        1.858        15.077
 slow/BUFX2               13.31        0.647        1.867        15.069
*No buffer                 0.00        0.491        1.711        15.225

 delay type : max_fall
 lib cell                  area  stage_delay      arrival         slack
 ---------------------------------------------------------------------
 slow/DLY1X1              19.96        0.746        1.966        14.767
 slow/DLY2X1              19.96        1.088        2.308        14.425
 slow/BUFX4               16.63        0.514        1.734        14.999
 slow/BUFX2               13.31        0.534        1.754        14.979
*No buffer                 0.00        0.354        1.573        15.160

 delay type : min_rise
 lib cell                  area  stage_delay      arrival         slack
 ---------------------------------------------------------------------
 slow/DLY1X1              19.96        0.366        2.076         0.296
 slow/DLY2X1              19.96        0.727        2.437         0.657
 slow/BUFX4               16.63        0.148        1.858         0.077
 slow/BUFX2               13.31        0.156        1.867         0.086
*No buffer                 0.00        0.000        1.711        -0.070

 delay type : min_fall
 lib cell                  area  stage_delay      arrival         slack
 ---------------------------------------------------------------------
 slow/DLY1X1              19.96        0.679        1.966         0.098
 slow/DLY2X1              19.96        1.021        2.308         0.440
 slow/BUFX4               16.63        0.447        1.734        -0.134
 slow/BUFX2               13.31        0.467        1.754        -0.114
*No buffer                 0.00        0.286        1.573        -0.294
```

The following example shows a minimum delay verbose estimation of a single potential buffer cell insertion at an instance pin:

```
pt_shell> estimate_eco -type insert_buffer \\
            -min -verbose -lib_cells {DLY1X1} \\
            wishbone/TxDone_wb_reg/D

  cell name       : wishbone/TxDoneSync1_reg
  current lib cell: slow/DFFRHQX1

  buffer lib cell: slow/DLY1X1
  min_rise                                 current          estimate
  ---------------------------------------------------------------
  input net delay                            0.012             0.012
  stage delay                                0.000             0.366
    cell delay                               0.000             0.000
    output net delay                         0.000             0.000
```

```
    buffer delay                          0.000            0.366
    delta delay                           0.000            0.000
  arrival time                            1.711            2.076
  slack                                  -0.070            0.296

  buffer lib cell: slow/DLY1X1
  min_fall                              current          estimate
  ------------------------------------------------------------------
  input net delay                         0.011            0.011
  stage delay                             0.286            0.679
    cell delay                            0.286            0.286
    output net delay                      0.000            0.000
    buffer delay                          0.000            0.392
    delta delay                           0.000            0.000

 *slow/HSBULT16_BUF_U_1       0.2074      0.0053      2.1942
```

In the following example, the *estimate_eco* command analyzes the timing of the path that starts from register clock pin reg8/CP and ends at pin U3/A, considering only the rising_to_rise arc sense from the register clock pin to the register output by means of the -through_arc option.

```
pt_shell> set my_arc [get_timing_arcs -from reg8/CP -to reg8/Q \\
  -filter "sense == rising_to_rise"]
  ...
pt_shell> estimate_eco reg8 -from reg8/CP -to U3/A -through_arc $my_arc
```

The following example shows how to evaluate the data_pin_slack for clock-gating enable pin.

```
pt_shell> set eco_estimation_output_columns "arrival slack
 data_pin_slack";
pt_shell> estimate_eco cg1/EN -data_pin -max -rise ;

  delay type : max_rise
  lib cell                          arrival     slack     data_pin_slack
  ------------------------------------------------------------------------
  slow/HSBULT16_CKGTPLT_V7_16       0.0339      9.9598      2.1871
  slow/HSBULT16_CKGTPLT_V7_12       0.0308      9.9629      2.1885

  slow/HSBULT16_CKGTPLT_V5_8        0.0346      9.9587      2.1967
  slow/HSBULT16_CKGTPLT_V7_4        0.0246      9.9692      2.1946
  slow/HSBULT16_CKGTPLT_V5_6        0.0367      9.9564      2.1965
  slow/HSBULT16_CKGTPLT_V5_4        0.0333      9.9601      2.1967
  slow/HSBULT16_CKGTPLT_V5_2        0.0303      9.9633      2.1975
```

```
  slow/HSBULT16_CKGTPLT_V7_1      0.0242      9.9690      2.1949
  slow/HSBULT16_CKGTPLT_V5_1      0.0326      9.9606      2.1975
  slow/HSBULT16_CKGTPLT_V7_2      0.0229      9.9706      2.1952
```

The following example shows how the slack value can be parsed from any *estimate_eco* verbose report for a given min/max rise/fall condition:

```
# specify lib_cell and design instance
set lib_cell INVX20
set instance wishbone/bd_ram/U9/U6200

# obtain all min/max rise/fall estimation info for a single ECO
redirect -variable rpt {estimate_eco -type size_cell -min -max \\
  -rise -fall -verbose -lib_cells $cell $instance}

# specify min/max rise/fall conditions of interest
set mm max
set rf rise

# obtain min/max rise/fall subreport
regexp "(${mm}_${rf}.+?)\\n\\n" $rpt dummy subrpt

# obtain slack from subreport
regexp {slack +[^ ]+ +([^ ]+)} $subrpt dummy slack
echo $slack
```

This report parsing example can be used with both *size_cell* and *insert_buffer* estimation.

---

estimate_memory_max_power

Find the worst-case internal energy when-condition in the liberty model for memory cells and set those for each of instances.

Syntax

```
int estimate_memory_max_power
[-pin pin_name_list]
[-dual_port]
[-state_derate_pairs]
```

instance_list
state_derate_pairs_list

Data Types

```
pin_name_list           list
instance_list           list
state_derate_pairs_list list
```

Arguments

`-pin` *pin_name_list*

To specify the input pin (or pins for -dual_port) which needs to be used for derating and power calculation.

`-dual_port`

To specify if memory cell is of dual port. Both the input pins must be passed in -pin option for this case.

instance_list

To specify the objects for which the maximum power estimation is to be done.

state_derate_pairs_list

To specify the list of when condition/regular expression and corresponding derate values.

-state_derate_pairs

To specify the list of mode for read or write states and corresponding derate values. The mode for read or write states comes from memory config file.

Description

Find the worst-case internal energy when-condition in the liberty model and set those for each of instances. Ignore all the propagated TR and SP values to the nets which are part of the when-condition, if there is a logic conflict with the setting, it is ignored. For all other pins which are not part of the selected when-condition use the propagated TR and SP.

This command should only be run in the average mode. update_power should be used to calculate power and report_power shows the maximum power values used for memory cells.

The *pin* option can be used to specify the input pin(or pins for -dual_port) which needs to be used for derating and power calculation.

Examples

The following examples shows how to provide when condition/regular expression and corresponding derate values on a single cell in the design for power estimation.

Feedback

---

exit

Terminates the application.

Syntax

```
integer exit
[exit_code]
```

Data Types

```
exit_code      integer
```

Arguments

exit_code

Specifies the return code to the operating system. The default value is 0.

Description

This command exits from the application. You have the option to specify a code to return to the operating system.

Examples

The following example exits the current session and returns the code 5 to the operating system. At a UNIX operating system prompt, verify (*echo*) the return code as shown.

Feedback

```
prompt> exit 5

% echo $status
5
```

---

extract_model

Generates an abstract timing model from the gate-level netlist of the current design.

Syntax

status *extract_model*

```
[-context_borrow]
[-latch_level levels]
-output file_name
[-format format_list]
[-script_format ptsh | dcsh]
[-library_cell]
[-ignore_boundary_parasitics]
[-test_design]
[-validate valid_list]
[-noise]
[-power]
[-sms_scenarios sms_scenarios_list]
```

Data Types

levels	int
file_name	string
format_list	list
valid_list	list
arc_list	list
sms_scenarios_list	collection

Arguments

`-context_borrow`

By default, model extraction considers the borrowing behavior of transparent latches on the design boundary based on the current timing context. Using the *-context_borrow* option is not required and has no effect.

`-latch_level` *levels*

Specifies the maximum number of levels of latches considered for extraction at the interface of the design, either 0, 1, or 2. During model extraction, the tool traces through a transparent latch and stops at a latch/register, up to the number

of levels specified by this option. If you specify a number larger than 2, that number is accepted as valid syntax, but the extraction internally considers no more than 2 levels. If the *extract_model_include_transparent_latch_constraints* variable has been set to *false*, the extraction internally considers no more than 1 level.

`-output` *`file_name`*

Specifies the root name to generate output file names. The generated model name is *file_name*_lib.db (compiled library format) or *file_name*.lib (Liberty format). The generated constraint script file name is *file_name*_constr.pt.

`-format` *`format_list`*

Specifies the output formats for the generated model. Multiple items must be enclosed in braces. The allowed values are:

- *db* (the default) - Generates the output file in compiled library format with the _lib.db extension.
- *lib* - Generates the output file in Liberty (Library Compiler) format with the .lib extension.

`-script_format ptsh | dcsh`

Specifies the output format for the constraint script. Allowed values are *ptsh* for pt_shell (the default) or *dcsh* for dc_shell.

`-library_cell`

Generates a library cell. The option specifies the default behavior, so it is not needed and has no effect.

`-ignore_boundary_parasitics`

Excludes the effects of detailed parasitics on boundary (port-connected) nets from the extracted timing model.

`-test_design`

Generates a test design containing an instance of the extracted timing model as well at the extracted model itself. The extracted timing model name is *file_name*_lib.db and the test design name is *file_name*_test.db, where *file_name* is specified by the *-output* option.

`-validate` *`valid_list`*

Specifies the type of data automatically validated after the model is created, *timing*. The validation process is performed automatically only when you use this option. Before you use this option, set the *hier_modeling_version* variable to *2.0*. The validation process uses the *write_interface_timing* and *compare_interface_timing* commands.

`-noise`

Adds noise features to the extracted model. If no noise information is available, only the estimated steady-state resistance is written to the model. This option performs an implicit *update_noise* if needed.

`-power`

Adds power features to the extracted model. This option performs an implicit *update_noise* if needed. The *power_enable_analysis* variable must be set to *true*, and you must have a PrimePower license.

`-sms_scenarios` *sms_scenarios_list*

Restricts extraction to the specified SMVA/SMS scenarios. This collection is created by the *get_sms_scenarios* command. The default is to create a model for all SMS scenarios relevant to the design.

In an SMVA/SMS analysis, the *extract_model* command creates a separate model for each SMS scenario, augmenting the file name with a description of the voltage configuration as follows:

```
<name>_<supply_group1>_<ref_name1>[..._<supply_groupN>_<ref_nam
eN>]
```

where *supply_group1,.,supply_groupN* are the supply groups included in the voltage configuration, and *ref_name1,..ref_nameN* are their corresponding voltage reference names specified with the *set_voltage_levels* command.

Description

The *extract_model* command generates a static timing model for the current design from its gate-level netlist. The generated model exhibits the same timing characteristics as the original design and therefore is used instead of the gate-level netlist for timing analysis at a higher level of the design hierarchy. To also generate noise or power information in the model, use the *-noise* or *-power* option.

By default, the *extract_model* command generates a context-independent model, in which the timing changes as the actual context varies at the top level. The timing model tracks the original block interface timing. However, the extracted model can become context-dependent. Especially when borrowing latches exist at the block interface, the generated model is valid only for the clock waveforms, latencies, input delays, and output delays specified for the extraction. When the context changes sufficiently to cause different borrowing on the interface, the timing model does not represent the new borrowing.

To generate a timing model for a design, you need the design netlist, the logic library, and the timing environment (clocks, constraints, and operating conditions). There should be

no timing violations reported by the *check_timing* and *report_constraint* commands. The generated model is captured as a library cell in .db or .lib format, or both.

The following variables are often used to control various aspects of the model extraction process:

```
extract_model_capacitance_limit
extract_model_clock_transition_limit
extract_model_data_transition_limit
extract_model_enable_report_delay_calculation
extract_model_gating_as_nochange
extract_model_num_capacitance_points
extract_model_num_clock_transition_points
extract_model_num_data_transition_points
extract_model_status_level
extract_model_with_ccs_timing
extract_model_with_clock_latency_arcs
timing_clock_gating_propagate_enable
timing_disable_clock_gating_checks
timing_enable_preset_clear_arcs
```

For a complete list:

```
pt_shell> printvar extract_model*
```

Examples

The following script reads in a design, links it, prepares it for model extraction, and extracts a model for the design, producing a .db library file.

```
set_app_var search_path ". /abc/libraries/mylib"
set_app_var link_path "* 1.3V_0C.db"
read_verilog mydesign.v
link_design mydesign
read_parasitics mydesign.spef
source myconstraints.sdc
report_constraint
check_timing
report_timing
set_app_var extract_model_capacitance_limit 5.0
extract_model -output mymodel
```

The *extract_model* command responds with the following messages:

```
pt_shell> extract_model -output mymodel
Model extraction : Clock period/min_pulse_width arcs extracted at context
 slew.
Wrote model to './ETM/mymodel/mod_lib.db'
Wrote the propagated generated clocks in ./ETM/mymodel/mod_inst.pt.gz.
Wrote generated clock uncertainty in ./ETM/mymodel/mod_inst.pt.gz.
1
```

Feedback

The following command generates an extracted timing model in .lib format, in addition to .db format. You can read the .lib file to examine the extracted timing arcs.

```
pt_shell> extract_model -output mymodel -format {db lib}
Model extraction : Clock period/min_pulse_width arcs extracted at context
 slew.
Wrote the LIB file ./ETM/mymodel/mod.lib
Wrote model to './ETM/mymodel/mod_lib.db'
 ...
```

The following command generates a test design containing an instance of the generated timing model.

```
pt_shell> extract_model -output mymodel -test_design
Model extraction : Clock period/min_pulse_width arcs extracted at context
 slew.
Wrote model to './ETM/mymodel/mod_lib.db'
Wrote test design to './ETM/mymodel/mod_test.db'
 ...
```

The following example generates a timing model and also performs timing validation of the generated model.

```
pt_shell> set_app_var hier_modeling_version 2.0
2.0
pt_shell> extract_model -output mymodel -validate timing
Model extraction : Clock period/min_pulse_width arcs extracted at context
 slew.
Wrote model to './ETM/mymodel/mod_lib.db'
Wrote the propagated generated clocks in ./ETM/mymodel/mod_inst.pt.gz.
Wrote generated clock uncertainty in ./ETM/mymodel/mod_inst.pt.gz.
 ( Worker2 )

extract_scaling_data_config

Extract scripts to generate scaling data file setup.

Syntax

string *extract_scaling_data_config*

Feedback

```
[-creation]
[-consumption]
```

Arguments

`-creation`

Script to create scaling data files.

`-consumption`

Script to replace define_scaling_library_group commands in original script.

Description

The *extract_scaling_data_config* command can be used to extract commands to use the scaling_data file flow from an exiting design setup. Run your existing script up until update_timing then 1.) Call *extract_scaling_data_config -creation*. This will generate all commands needed to generate the scaling data files needed for the new flow. 2.) Call *extract_scaling_data_config -consumption*. This will generate a sccript with define_library_scaling_group_commands to use the scaling data files created. Replace the define_library_scaling_group_commands commands in the original script with these newly created ones and the original script will now run the scaling data file flow.

Examples

The following snippet would typically be used after update timing to extract commands scripts for creating scaling data files setup.

```
pt_shell> extract_scaling_data_config -creation
```

f

filter

The *filter* command, a synonym for the *filter_collection* command, is a Design Compiler emulation command provided for compatibility between PrimeTime and Design Compiler. You use the *filter_collection* command to filter an existing collection, resulting in a new collection. The base collection remains unchanged.

See Also

- filter_collection

Feedback

filter_collection

Filters an existing collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *filter_collection*

```
[-regexp]
[-nocase]
collection1
expression
```

Data Types

collection1	collection
expression	string

Arguments

`-regexp`

Specifies that the =~ and !~ filter operators will use real regular expressions. By default, the =~ and !~ filter operators use simple wildcard pattern matching with the * and ? wildcards.

`-nocase`

Makes the pattern match case-insensitive.

collection1

Specifies the base collection to be filtered. This collection is copied to the result collection. Objects are removed from the result collection if they are evaluated as *false* by the conditional *expression* value. Substitute the collection you want for *collection1*.

expression

Specifies an expression with which to filter *collection1*. Substitute the string you want for *expression*.

Description

Filters an existing collection, resulting in a new collection. The base collection remains unchanged. In many cases, application commands that create collections support a *-filter* option that filters as part of the collection process, rather than after the collection has been made.

Feedback

This type of filtering is almost always more efficient than using the *filter_collection* command after a collection has been formed. The *filter_collection* command is most useful if you plan to filter the same large collection many times using different criteria.

The *filter_collection* command results in either a new collection or an empty string. A resulting new collection contains the subset of the objects in the input *collection1*. A resulting empty string (the empty collection) indicates that the *expression* filtered out all elements of the input *collection1*.

The basic form of the conditional expression is a series of relations joined together with AND and OR operators. Parentheses () are also supported. The basic relation compares an attribute name with a value through a relational operator.

For example,

```
is_hierarchical == true and area <= 6
```

If an attribute is a collection attribute, then you can query an attribute value from that object using "." to name the attribute on the other object. The "." operator can be chained. If the collection attribute refers to more than one object, then the expression is true if it is true for one of the objects referenced. While "." is preferred, using "->" is also supported.

For example:

```
owner.is_hierarchical == true and owner.area <= 6
shape.net.name==reset
```

The value side of a relation can be a simple string, quoted string, or an attribute name prefixed with "@". For example:

```
input_delay<=@output_delay
input_delay<=0.24
name=="@literal_name"
```

The relational operators are

```
==   Equal
!=   Not equal
>    Greater than
<    Less than
>=   Greater than or equal to
<=   Less than or equal to
=~   Matches pattern
!~   Does not match pattern
```

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only either *true* or *false*.

Existence relations determine if an attribute is defined or not defined for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
!defined
```

These operators apply to any attribute as long as it is valid for the object class.

Collection attributes support a special sizeof(attrName) operator that returns the number of objects in the attribute. If the attribute is not set then 0 is returned.

The *filter_collection* command has a *-regexp* option that uses regular expressions when matching for string attributes. Regular expression matching is done in the same way as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended.

Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed. You can make the regular expression search case-insensitive by using the *-nocase* option.

Mathematical expressions are supported. All function names must be prefixed with the '#' in order to disambiguate the function names from subscripted attribue names (i.e. "#sin(attr)"). In order to use a math expression on the right hand side of a comparison, the expression must be contained in parenthesis. This is required for backward compatibility with the legacy expression syntax as strings on the right do not require quoting.

Subscripted attributes can match against glob style subscript patterns (i.e. "input_delay(*)<1.0"). In that case the term evaluates to true if any subscript satisfies the condition.

Filters may also refer to chained attributes that may imply multiple objects in a collection (i.e. "pins.capacitance==0.2"). In that case the term returns true if any of the objects referred to in the have an attribute value satisfying the condition.

Feedback

Examples

The following example from PrimeTime creates a collection of only hierarchical cells.

```
pt_shell> set a [filter_collection [get_cells *] \\
"is_hierarchical == true"]
{"Adder1" "Adder2"}
```

The following example from PrimeTime uses existence operators to create a collection of all nonmoded cell timing_arc objects in the current design.

```
pt_shell> set b [filter_collection \\
            [get_timing_arcs -of_objects [get_cells *]] \\
            "undefined(mode)"]
```

```
The following example finds all cells from {U0(1) U1(1) U0(0) U1(0)}
with the index (0). Notice the round brackets used for the index.

pt_shell> filter_collection -regexp [get_cells] {full_name =~
 "U.*\\[0\]\)"}
{U0(0) U1(0)}
```

The following example finds all ports from in[18] to in[23]. The placement of double quotes and backslashes is necessary to avoid syntax errors.

```
pt_shell> filter_collection [get_ports] -regexp {name=~
 "in\\[(1[8-9]|2[0-3])\\]"}
{in[23] in[22] in[21] in[20] in[19] in[18]}
```

The following example finds the U2 and U4 cells, using the -nocase option:

```
pt_shell> filter_collection [get_cells] -regexp -nocase {name =~ u[24]}
{U2 U4}
```

find

The *find* command, used to create a collection of design objects, is a DC Emulation command provided for compatibility with Design Compiler.

Syntax

string *find*

```
type
[-hierarchy]
[-flat]
[object_list]
```

Feedback

Data Types

type	string
object_list	list

Arguments

type

Specifies the object class to find. The type value can be *design*, *port*, *net*, *cell*, *pin*, *clock*, *library*, *lib_cell*, or *lib_pin*.

-hierarchy

Find objects throughout the hierarchy.

-flat

Not supported by PrimeTime.

object_list

Specifies the patterns to match.

Description

The *find* command creates a collection of objects. The command exists in PrimeTime for compatibility with Design Compiler. Complete information about the *find* command can be found in the Design Compiler documentation. The supported method for creating collections of objects is to use *get** commands (for example, the *get_cells* command or the *get_pins* command).

Examples

The following example finds the N1 net in the current design:

```
pt_shell> find net N1
{N1}
```

The following example uses the * (asterisk) wildcard character to find all cells in the current design that begin with U:

```
pt_shell> find cell U*
{U0, U1, U2, U3, U4, U5, U6, U7}
```

For more examples, see the *find* command in Design Compiler.

find_objects

Finds logical hierarchy objects within a scope. This is a UPF query command.

Syntax

```
[-collection find_objects]
[-pattern pattern_string]
[-object_type inst | port | net | model]
[-direction in | out | inout]
[-transitive true | false]
[-non_leaf]
[-leaf_only]
[-regexp]
[-exact]
scope
```

Data Types

```
pattern_string      string
scope               string
```

Arguments

`-pattern pattern_string`

Specifies a search pattern. By default, the pattern is treated as an Tcl glob expression.

`-object_type inst | port | net | model`

Searches for only the specified object type:

- *inst* - Cell instance • *port* - Design port • *net* - Net • *model* - Model or library cell

`-direction in | out | inout`

Specifies the direction of the searched ports if the *-object_type port* option is used.

`-transitive true | false`

Controls whether the descendants of the elements are included in the search:

- *false* (default) - Does not search descendants. • *true* - Searches descendants.

`-non_leaf`

Searches only nonleaf design elements (elements that have child elements).

`-leaf_only`

Searches only leaf-level design elements (elements without child elements). By default, both leaf and nonleaf design elements are searched.

`-regexp`

Views the patterns argument as real regular expressions rather than simple wildcard patterns.You can widen the search by adding ".*" to the beginning or end of the expressions as needed. The -regexp and -exact options are mutually exclusive.

`-exact`

Searches for an exact match of the *pattern_string* argument; disallows wildcard expansion on the *pattern_string*.

scope

Specifies the scope in which to search for logical hierarchy objects.

Description

The *find_objects* command finds logical hierarchy objects within a scope.

Multicorner-Multimode Support

This command has no dependency on scenario specific information.

Examples

The following examples show the usage of the command with different options.

```
prompt> find_objects a -pattern * -object_type inst \\
         -transitive TRUE -non_leaf
a/b1 a/b2

prompt> find_objects a/b2 -pattern b_? -object_type net
a/b2/b_i a/b2/b_o

prompt> find_objects a/b1 -pattern * -object_type port \\
        -transitive TRUE -direction out
a/b1/c1/Z a/b1/c2/Z a/b1/b_o
```

Feedback

```
prompt> find_objects . -object_type model -pattern b* -non_leaf \\
        -transitive TRUE
a/b1 a/b2 b1

prompt> find_objects . -object_type model -pattern b* -non_leaf \\
        -transitive TRUE -exact
Warning: Can't find module or lib cell 'b*' in design 'top'. (UID-95)

prompt> find_objects . -object_type model -pattern bot -non_leaf \\
        -transitive TRUE -exact
a/b1 a/b2 b1

For black box bus port
prompt> find_objects . -pattern A* -object_type port
A[0] A[1] A[2]
```

---

fix_eco_drc

Fixes or improves design rule constraint (DRC) violations (noise violations, large delta delays, or cell electromigration violations) by sizing cells or inserting buffers or inverter pairs.

Syntax

```
status fix_eco_drc
   -type max_transition | max_capacitance | max_fanout | noise |
 delta_delay | cell_em
   [-methods method_list]
   [-buffer_list list]
   [-verbose]
   [-current_library]
   [-physical_mode none | open_site | occupied_site | freeze_silicon]
   [-hold_margin margin]
   [-setup_margin margin]
   [-cell_type combinational | clock_network]
   [-slack_lesser_than slack_limit]
   [-unfixable_reasons_format text | csv]
   [-unfixable_reasons_prefix string]
   [-delta_delay_threshold threshold]
   [-timeout seconds]
   [object_list]
```

Feedback

Data Types

list	list
margin	float
method_list	list
object_list	list
seconds	integer
slack_limit	float
string	string
threshold	float

Arguments

`-type max_transition | max_capacitance | max_fanout | noise | delta_delay | cell_em`

Specifies the type of violation to fix: maximum transition time, maximum total net capacitance, or maximum fanout DRC violations, as reported by the *report_constraint* command; or noise violations, as reported by the *report_noise* command; or large delta delays, as reported by the *report_si_bottleneck -cost_type delta_delay* command; or cell electromigration violations, as reported by the *report_cell_em_violation* command. Use multiple *fix_eco_drc* commands to fix multiple types of violations.

Note: The *cell_em* value requires PrimePower and PrimeTime-ADV-PLUS licenses. The *delta_delay* value requires a PrimeTime-ADV-PLUS license.

`-methods` *method_list*

Specifies one or more fixing methods from the following list:

- *size_cell* - Replaces cells in the timing path with logically identical cells that have a different drive strength.
- *insert_buffer* - Inserts buffers in the timing path, using the library cells specified by the *-buffer_list* option. By default, the *insert_buffer* method inserts buffers at both driver and load pins and on-route.
- *insert_buffer_at_load_pins* - Inserts buffers only at load pins, not at driver pins and the middle of timing path.
- *insert_buffer_at_driver_pins* - Inserts buffers only at driver pins, not at load pins and the middle of the timing path.
- *insert_inverter_pair* - Inserts inverter cell pairs instead of buffer cells; cannot be used together with the *insert_buffer* method.

The default is *-methods {size_cell insert_buffer}.*

`-buffer_list` *list*

Specifies the list of library cell buffers that can be used for fixing with the *insert_buffer* method, or inverters that can be used with the *insert_inverter_pair* method. To use the *insert_buffer* or *insert_inverter_pair* method, you must also use the *-buffer_list* option to specify the library cells to be used; there is no default list.

Specify the list of buffers using simple library cell base names, without the library name. The command gets the buffer cells from the libraries listed in the *link_path* variable. It searches the libraries in order and uses the first library cell found with a matching name.

The command can use a listed library cell for buffer insertion even if its *dont_use* attribute is set to *true*. The *dont_use* attribute applies only to cell sizing.

If both the *size_cell* and *insert_buffer* methods are being used, the command can insert a buffer from the list and then size it to a different buffer, even if the sized library cell is not explicitly included in the *-buffer_list* list.

`-verbose`

Shows additional information during the fixing process. In distributed multi-scenario analysis, violation information from each scenario is displayed.

The verbose mode also generates an "Unfixable Violations" report upon completion of fixing. The report shows a list of pins where fixing was considered and the reasons that the fix was not performed at the pin. This option is recommended for interactive ECO because it can help you decide what to do next. For details, see "Unfixable Violation Report" in the DESCRIPTION section of this man page.

`-current_library`

Specifies the usage of library cells from the same library when performing cell sizing. With this option, the replacement cell must come from the same library as the original cell. This option can improve runtime because fewer cells are considered as potential replacements. However, it might degrade quality of results because the variety of available alternative library cells could be reduced.

`-physical_mode none | open_site | occupied_site | freeze_silicon`

Specifies the usage of physical data to size cells or place buffers:

- *none* (the default) - DRC fixing does not use physical data.
- *open_site* - DRC fixing sizes a cell only if there is enough room available around the cell and inserts a buffer only if there is an empty site with enough room to accept the new cell without moving nearby cells. This mode retains the placement of existing cells.

- *occupied_site* - DRC fixing can size a cell and insert a buffer that overlaps existing neighbor cells, as long as the cell density (area utilization) is low enough that the nearby cells can be moved to make the required space. After the change is made, you need to use a physical implementation tool such as IC Compiler II to move the existing cells and create room for the sized or inserted cell.
- *freeze_silicon* - DRC fixing uses spare cells defined in the physical data files and identified by the *-programmable_spare_cell_names* option of the *set_eco_options* command; it does not insert new cells or size existing cells. This mode works with the IC Compiler II tool.

`-hold_margin` *margin*

Specifies a margin applied to hold timing slack during DRC fixing, in library time units. DRC fixing tries (but does not guarantee) to preserve the specified amount of hold timing slack. For example, a margin of zero seeks to prevent hold timing violations while allowing all positive hold slack to be given up for DRC fixing. By default, without this option, DRC fixing proceeds no matter how much hold timing is degraded, which is equivalent to a hold margin of minus infinity.

`-setup_margin` *margin*

Specifies a margin applied to setup timing slack during DRC fixing. DRC fixing tries to preserve the specified amount of setup timing slack. By default, DRC fixing proceeds no matter how much setup timing is degraded.

In the absence of explicit setup and hold values provided by the user, the tool tries to preserve DRC and timing by default, however, the results may not match explicit settings of *-setup_margin 0.0* and *-hold_margin 0.0*.

`-cell_type combinational | clock_network`

Specifies the types of cells modified during fixing, either *combinational* (the default) or *clock_network*. For the *combinational* setting, fixing is performed by sizing or inserting cells in data paths. For the *clock_network* setting, fixing is performed by sizing or inserting cells in the clock network. Changing clock network cells can affect clock tree timing, so use this option only when absolutely necessary.

`-slack_lesser_than` *slack_limit*

Specifies fixing of only the paths with a slack worse than the specified slack limit. The default is zero, which attempts to fix all DRC violations. The limit can be set to a positive number only if the *-type* option is set to *delta_delay*. In that case, the command works like the *report_si_bottleneck* command to select delta delay victim nets on noncritical paths.

`-unfixable_reasons_format text | csv`

Specifies the file format, either *text* or *csv* (comma-separated values), for the unfixable reasons report generated by the *-unfixable_reasons_prefix* option. The CSV report format is compatible with the PrimeTime GUI and spreadsheet programs. By default, both types of files are generated when the *-unfixable_reasons_prefix* option is used.

`-unfixable_reasons_prefix` *`string`*

Specifies a prefix used for naming the file generated by the *-unfixable_reasons_format* option. For example, specifying the prefix "abc" and using the CSV format writes out a file named abc_eco_drc.csv. If you omit this option, no files are generated.

`-delta_delay_threshold` *`threshold`*

Specifies the delta delay threshold for delta delay fixing. Fixing applies only the victim nets that belong to one or more paths with negative timing slack, and whose delta delay cost exceeds the specified threshold. The threshold must be greater than zero; it applies to delta delays in both directions (positive for max delays and negative for min delays). Using this option is mandatory when the *-type* option is set to *delta_delay*.

`-timeout` *`seconds`*

Specifies a timeout limit, in seconds, for the maximum total runtime of the command. At the end of each fixing iteration, the tool checks the total elapsed wall clock time. If the time limit is reached, the command stops running and ends with the current iteration. If you do not use this option, the command does not directly consider the total elapsed time. Instead, it considers quality of results, fix rate, and expected benefits of running more iterations.

`object_list`

Specifies a list of pin or port objects in the current design for DRC fixing, noise fixing, or delta delay reduction. If you do not specify an object list, the tool tries to fix all DRC or noise violations in the current design, or reduce delta delay on victim nets according to *-delta_delay_threshold* option.

Description

The *fix_eco_drc* command fixes or improves design rule constraint (DRC) violations, noise violations, large delta delays, or cell electromigation violations by sizing cells and inserting buffers or inverter pairs.

You can report existing violations by using the *report_constraint*, *report_noise*, *report_si_bottleneck -cost_type delta_delay*, or *report_cell_em_violation* command. The *fix_eco_drc* command attempts to fix the violations while minimizing the impact on area. By default, the command performs fixing without considering the effects on timing.

After the violations are fixed, you can write out the design changes as a script by using the *write_changes* command. You can use the script to implement the same changes in another PrimeTime session or another tool (Design Compiler, IC Compiler, or IC Compiler II). A list of design changes created in this flow is called an engineering change order (ECO).

The *fix_eco_drc* command has options to specify the following fixing parameters:

- The type of violation to fix (maximum transition time, maximum total net capacitance, maximum fanout, noise, delta delays, or cell electromigration that exceed a specified threshold and contribute to negative slack)
- The scope of the design to be fixed (a list of pins or ports, or the whole design)
- The fixing methods (cell sizing, buffer insertion, or inverter pair insertion)
- The list of library cells that can be used for buffer or inverter pair insertion
- The types of cells to be modified (cells in data paths or cells in clock networks)
- Whether to consider timing constraints during fixing, and if so, the required setup and hold timing margins
- The physical placement and sizing mode (none, open site, occupied site, or freeze silicon)

You must specify the type of violation to fix by setting the *-type* option to *max_transition*, *max_capacitance*, *max_fanout*, *noise*, *delta_delay*, or *cell_em*. By default, the command fixes violations of the specified type throughout the design. You can restrict fixing to a specified list of pins and ports.

Note: The *cell_em* fixing type requires that the *power_enable_analysis* and *power_enable_em_analysis* variables be set to *true*.

The command performs fixing using multiple iterations. It repeats these iterations until all violations are fixed or it determines that further fixing is not worth the runtime cost, based on the current quality of results and fixing option settings. You can generate a report on unfixable violations by using the *-verbose* option. To write out the unfixable violation report to a file, use the *-unfixable_reasons_prefix* option.

Note: The *cell_em* fixing type supports only a single iteration. To fix additional violations, run the *update_power* command, then rerun the *fix_eco_drc -type cell_em* command again.

By default, the command fixes the violations without considering the effects on timing. To prevent new timing violations during fixing, use the options *-setup_margin 0.0* and *-hold_margin 0.0*; or specify positive margin values to maintain positive timing slack values, or specify negative margin values to allow timing violations with the specified amount of negative slack.

The *fix_eco_drc* command is compatible with single-core analysis, distributed multi-scenario analysis (DMSA), and multicore analysis. To ensure consistent results during DMSA fixing, apply any *dont_touch* and *dont_use* attributes identically to all scenarios.

The *fix_eco_drc* command is intended for the signoff flow using delay and slew calculation in the PrimeTime tool, based on extracted parasitic data. The *timing_save_pin_arrival_and_required* variable must be set to *true* to perform fixing. If delays and slews are annotated directly (for example, in SDF format), the quality of results cannot be guaranteed.

Fixing Methods

You can use the *-methods* option to specify the fixing methods, one or more of *size_cell*, *insert_buffer*, and *insert_inverter_pair*. The default is *-methods {size_cell insert_buffer}*.

If you specify only *size_cell* as the fixing method, the command resizes the driver cell of the stage with a violation. If a violation is at a cell input pin, a driver cell to this pin is resized. If a violation is at a cell output pin, the cell itself is resized. The selection of larger cells is restricted by the *eco_alternative_area_ratio_threshold* variable. By default, this variable is set to 2.0, which restricts the new cell to no more than twice the size of the original cell.

Only combinational logic cells are resized. Sequential cells are not resized because doing so could potentially unbalance clock trees and create unexpected new violations.

If you specify only *insert_buffer* or *insert_inverter_pair* as the fixing method, the command inserts buffers or inverter pairs to fix violations, breaking physically large nets into smaller nets.

If cell sizing and buffer insertion are both enabled (the default behavior), the command chooses the best fixing method to remove each violation and minimize the impact on area. In this case, cell sizing ignores the *eco_alternative_area_ratio_threshold* variable and uses cells of any size because more layout perturbation is allowed.

Restricting the Library Cells Used for Sizing

To prevent the tool from using specific library cells for sizing, apply the *dont_use* attribute to these library cells with the *set_dont_use* command. Note that this usage restriction applies only to cell sizing, not buffer insertion. The tool uses buffers specified by the *-buffer_list* option, irrespective of the *dont_use* attribute.

Usage of library cells can also be restricted by applying the *pt_dont_use* user-defined attribute on the restricted lib_cell objects, which is a legacy feature. For an example of how to apply this attribute, see the EXAMPLES section.

Feedback

Preserving Specific Cells and Nets During Fixing

To prevent the *fix_eco_drc* command from performing fixing on specific cells or nets, apply a *dont_touch* attribute to the cell or net. For example,

```
pt_shell> set_dont_touch [get_nets n123] true
```

The *fix_eco_drc* command does not size any cell with a *dont_touch* setting and does not insert a buffer or inverter pair on any net with a *dont_touch* setting.

If you apply a *dont_touch* setting to a hierarchical cell, that setting propagates downward to the child cells and nets of the hierarchical cell. You can override the *dont_touch* setting for specific lower-level cells and nets by setting the *dont_touch* attribute to *false* for those objects.

UPF Cells

By default, UPF cells are not considered for sizing. UPF cells are cells that have one or more of the following attributes set to *true*: *always_on*, *is_isolation*, *is_retention*, or *is_level_shifter*.

To allow UPF cells to be sized, set the *eco_allow_sizing_with_lib_cell_attributes* variable. For example,

```
pt_shell> set_app_var eco_allow_sizing_with_lib_cell_attributes \\
  {always_on is_isolation is_retention is_level_shifter}
```

A buffer inserted into a net must be placed in the same power domain as the driver and all loads of the net. Buffer insertion is not performed on the following nets:

- Nets connected to any pins of an always_on cell
- Nets connected to control and clock pins of a retention cell
- A net between a port and an isolation cell
- A net between a port and a level shifter cell

Note that the *fix_eco_drc* command allows always_on buffer insertion on nets connected with an always_on cell if *eco_allow_insert_buffer_always_on_cells* variable is set to *true* (false by default).

Timing Margins

By default, the *fix_eco_drc* command fixes DRC or noise violations even if the fixing creates new timing violations or worsens existing timing violations.

To prevent new timing violations, use the *-setup_margin 0.0* and *-hold_margin 0.0* options, or specify nonzero margins to trade off DRC or noise fixing against timing. A negative margin relaxes the timing constraints and allows DRC or noise fixing to proceed and

cause timing violations up to the specified negative slack. A positive margin reserves the specified amount of positive slack, allowing less freedom to fix DRC or noise violations.

Unfixable Violation Report

The *fix_eco_drc* command, upon completion of fixing, generates a report on unfixable violations when you use the *-verbose* option. Here is a report example:

```
pt_shell> fix_eco_drc -type max_transition -verbose \\
           -methods size_cell
 ...
Unfixable violations:
  A - There are available lib cells outside area limit
  C - The violation is in clock network
  I - Buffer insertion with given lib cells cannot fix the violation
  P - Driver cell of the violation is a port
  Q - Driver cell of the violation is a sequential cell
  S - Cell sizing with alternative lib cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  V - Net or cell is invalid or has dont_touch attribute
  U - UPF restricts fixing the violation

  Violation                                  Reasons
  -----------------------------------------------
  U1/I                                           P
  U6/I                                           S

Remaining Violations:
  Violation Type                               Count
  -----------------------------------------------
  Total remaining violations                       2
  Unfixable violations                             2
```

The "Violation" column shows the cell pins where unfixable violations are located.

The "Reasons" column shows the reason or reasons that a violation could not be fixed at the cell pin, using the single-letter codes from the key shown at the beginning of the report. Here are detailed descriptions of the reasons:

- *A - There are available library cells outside area limit*

  Library cells that might have been used to fix the violation exceeded the area limit specified by the *eco_alternative_area_ratio_threshold* variable. You might be able to fix the violation by increasing the area limit.

- *C - The violation is in clock network*

  The violation is in a clock network. By default, the command does not attempt to fix violations in clock networks because doing so can change the clock tree timing and possibly create new violations. If data path fixing is not successful (*-cell_type combinational*, the default), you can try clock network fixing (*-cell_type clock_network*).

- *D - Cell or net is located in high density area*

  There is not enough room physically available in the vicinity of the violation. In the physical implementation tool (such as IC Compiler II), check the area utilization in that location. Note that when the *eco_allow_filler_cells_as_open_sites* variable is set to *true* (the default), physically aware ECO commands treat filler cells as open sites.

- *E - Physical information is incomplete or unavailable*

  The physical information is incomplete or unavailable for the specific net or cell, or the net is marked as "+USE CLOCK" in the DEF file specified by the *set_eco_options* command. See if the DEF and LEF files are consistent with your current design.

- *H - Logical and physical hierarchy is inconsistent*

  The netlist and physical layout are not consistent, and a buffer cannot be inserted. Use the physical implementation tool to resolve the inconsistency.

- *I - Buffer insertion with given library cells cannot fix the violation*

  The violation cannot be fixed using the library cells listed by the *-buffer_list* option. Specifying a wider range of buffer cells might allow the command to fix the violation.

- *O - No open free site is available*

  There is no empty free site available on the route or in the vicinity of the violation. Inspect the LEF/DEF file for filler cells and see whether they are treated as empty free sites. When the *eco_allow_filler_cells_as_open_sites* variable is set to *true* (the default), physically aware ECO commands treat all filler cells as empty free sites. Also, you can use the physical implementation tool (such as IC Compiler II) to create empty free sites.

  If the *-physical_lib_constraint_file* option of the *set_eco_options* command has been used to specify intercell or advanced-node spacing rule constraints, some empty sites might not be wide enough to be used. In that case, you can use the physical implementation tool to examine the spacing rule constraints and the cells in the vicinity of such free sites.

- *Q - Driver cell of the violation is a sequential cell*

  The driver of the stage where the violation exists is a sequential cell, so resizing cannot be applied. The *fix_eco_drc* command does not resize sequential cells.

- *S - Cell sizing with alternative library cells cannot fix the violation*

  All alternative library cells have been considered for sizing to fix the violation, but the violation cannot be fixed by cell sizing. Use a buffer insertion method to fix the violation, if needed.

- *T - Timing margin is too tight to fix the violation*

The violation is on a critical or near-critical setup or hold timing path and there is not enough timing slack to allow fixing of the targeted violation. To allow fixing to proceed, you can relax the fixing constraints by specifying more negative values for the *-setup_margin* and *-hold_margin* options or by dropping those options entirely.

- *U - UPF restricts fixing the violation*

  Certain UPF cells cannot be sized or buffered. For details, see the "UPF Cells" section of this man page.

- *V - Net or cell is invalid or has dont_touch attribute*

  One or more leaf cells or nets under the cell have the *dont_touch* attribute set to *true*. Check to see if the reason is justified.

Upon completion of fixing, the command reports a summary of the remaining violations:

```
Remaining Violations:
  Violation Type                              Count
  ------------------------------------------------
  Total remaining violations                     10
  Unfixable violations                            8
```

This summary report shows 10 remaining violations, 8 of which are unfixable. You might be able to fix two more violations by running the *fix_eco_drc* command again. You can also try other options, such as relaxing the timing margins or increasing the alternative cell area limit.

To write out the unfixable violation report as a separate file, use the *-unfixable_reasons_prefix* option and specify a prefix for the file name. By default, it writes out two report files, one in text format and the other in CSV format.

The CSV report file is compatible with the PrimeTime GUI and spreadsheet programs. To read the report into the PrimeTime GUI, choose the Report > ECO Unfixed Violation menu command. You can use the PrimeTime GUI to investigate and fix the remaining violations. The entries in the violation table are cross-referenced to the timing reports, path inspector, and layout view shown in the GUI.

Writing Changes

After you fix violations using the *fix_eco_drc* command and other ECO commands, you can write out the design changes as a script by using the *write_changes* command. You can use the script to implement the same changes in another PrimeTime session or another tool (Design Compiler, IC Compiler, or IC Compiler II). Use the *-format* option of the *write_changes* command to specify the format of the script.

Multiple Fixing Scenarios With Fewer Hosts with Hybrid Timing View

In the hybrid timing view ECO flow, the tool uses a combination of live views for accuracy-critical ECO scenarios and static views of less critical scenarios. The static-view timing and violation information is merged into the live-view scenarios at intervals determined by the tool.

Suppose you have 50 scenarios for your fixing. In a regular DMSA analysis, you would need 50 worker processes simultaneously running on one or more machines.

In the hybrid timing view ECO flow, if you have 15 live-view scenarios that cover 90 percent of the violations, the tool can merge the remaining 35 scenarios with the 15 live-view scenarios as static views. Then, you can run fixing with only 15 DMSA worker processes instead of 50. Note that if the live views have a relatively low coverage of violations (for example, 80 percent), you might not be able to achieve the desired fixing coverage.

For more information, see the man page for the *fBwrite_eco_scenario_data* and the *fBstart_eco_scenarios* commands.

Physically Aware DRC Fixing

Before you run the *fix_eco_drc* command, use the *set_eco_options* command to specify the paths to the physical data, either IC Compiler II database files or LEF/DEF library and design data exchange files:

```
set_eco_options \\
  -physical_tech_lib_path LEF_tech_file_list \\
  -physical_lib_path LEF_lib_file_list \\
  -physical_design_path DEF_design_file_list

set_eco_options \\
  -physical_icc2_lib icc2_lib_directory_path \\
  -physical_icc2_blocks icc2_block_name_list
```

The *fix_eco_drc* command reads in the physical data files as specified by the *set_eco_options* command if they are not already read in and checked by the *check_eco* command. To view the chip layout in the GUI, open the GUI with the *gui_start* command and then choose Window > Layout Window.

For more information, see the man page for the *fix_eco_timing* command.

Fixing in Multiply Instantiated Modules (MIMs)

When you set the *eco_enable_mim* variable to *true* (the default is *false*), the tool performs the same ECO changes across each set of MIMs. In physically aware fixing, the tool recognizes a set of MIM instances when they share the same DEF file; in logic-only fixing, it recognizes them when they share the same parasitics file according to the *-path* option in the *read_parasitics* command.

For more information, see the man page for the *fix_eco_timing* command.

Per-Scenario ECO Margins

In distributed multi-scenario analysis, you can use different setup and hold margins for different scenarios by specifying their values in the *-drc_setup_margin* and *-drc_hold_margin* options of the *set_eco_options* command in the worker scripts.

Note that the *-setup_margin* and *-hold_margin* options of the *fix_eco_drc* command have priority over the corresponding options of the *set_eco_options* command.

Clock Network Fixing

When the *-cell_type* option is set to *clock_network*, the command makes changes in clock networks to fix violations. Both cell sizing and buffer insertion can be used.

In physically aware fixing, you must use the *set_eco_options* command with the *-physical_enable_clock_data* option before you use the *fix_eco_drc* command. You must specify valid buffer library cells that are available to the physical implementation tool, meeting any special rules such as nondefault routing (NDR) rules. The PrimeTime tool does not perform any extra rule checking for the provided buffers.

The PrimeTime tool uses all available alternative library cells to size cells in the clock network. If your design uses specialized library cells in the clock network, use a Tcl script similar to the following example to limit the sizing candidates to selected library cells. This example limits the library cells to those that have prefix "CLK" in their library cell base names.

```
define_user_attribute -type boolean -class lib_cell is_clk_cell
set clk_lcells [get_lib_cell */CLK*]
set_user_attribute $clk_lcells is_clk_cell true
set eco_alternative_cell_attribute_restrictions is_clk_cell
```

Examples

The following example fixes maximum transition violations using only the *size_cell* method.

```
pt_shell> fix_eco_drc -type max_transition -verbose \\
          -methods size_cell
 ...
Unfixable violations:
  A - There are available lib cells outside area limit
  C - The violation is in clock network
  I - Buffer insertion with given lib cells cannot fix the violation
  P - Driver cell of the violation is a port
  Q - Driver cell of the violation is a sequential cell
  S - Cell sizing with alternative lib cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  V - Driver cell of the violation is dont_touched
  U - UPF restricts fixing the violation
```

```
  Violation                                  Reasons
  -------------------------------------------------
  U1/I                                           P
  U6/I                                           S

Remaining Violations:
  Violation Type                               Count
  -------------------------------------------------
  Total remaining violations                       2
  Unfixable violations                             2
```

After fixing, two unfixable violations remain. The unfixable reason "S" shows that U6/I was not fixed because none of the alternative library cells can fix the maximum transition violation. The reason "P" shows that U1/I was not fixed because its driver is a port, which cannot be resized.

In the next run, you try the buffer insertion method to fix the violation using the three buffer library cells BUFX1, BUFX2, and BUFX3.

```
pt_shell> fix_eco_drc -type max_transition -verbose \\
          -methods insert_buffer -buffer_list { BUFX1 BUFX2 BUFX3 }

Unfixable violations:
  A - There are available lib cells outside area limit
  C - The violation is in clock network
  I - Buffer insertion with given lib cells cannot fix the violation
  P - Driver cell of the violation is a port
  Q - Driver cell of the violation is a sequential cell
  S - Cell sizing with alternative lib cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  V - Driver cell of the violation is dont_touched
  U - UPF restricts fixing the violation

  Violation                                  Reasons
  -------------------------------------------------
  U6/I                                           I

Remaining Violations:
  Violation Type                               Count
  -------------------------------------------------
  Total remaining violations                       1
  Unfixable violations                             1
```

The command fixed the first violation but could not fix the second one because the provided buffer library cells were not strong enough.

In the next run, you could try specifying a larger list of library buffer cells, and you could try using both the *size_cell* and *insert_buffer* methods for maximum flexibility.

The following example performs physically aware fixing.

```
pt_shell> fix_eco_drc -type max_transition -verbose \\
          -methods insert_buffer -buffer_list {BUFX1 BUFX2 BUFX3} \\
          -physical_mode open_site
 ...
Unfixable violations:
  A - There are available lib cells outside area limit
  C - The violation is in clock network
  D - Cell or net is located in high density area
  E - Physical information is incomplete or unavailable
  H - Logical and physical hierarchies are inconsistent
  I - Buffer insertion with given lib cells cannot fix the violation
  O - No open free site is available
  P - Driver cell of the violation is a port
  Q - Driver cell of the violation is a sequential cell
  R - No locations are available in parasitics or location transformation
 failed
  S - Cell sizing with alternative lib cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  V - Driver cell of the violation is dont_touched
  U - UPF restricts fixing the violation

  Violation                                  Reasons
  -------------------------------------------------
  U1/I                                             O

Remaining Violations:
  Violation Type                               Count
  -------------------------------------------------
  Total remaining violations                       1
  Unfixable violations                             1
```

The unfixable violation report lists some possible unfixable violation reasons (codes D, E, H, and O) related to physically aware fixing that are not shown in the logic-only unfixable reason report. The unfixable reason "O" shows that U1/I was not fixed because there is no empty free site available.

The following example shows a report of remaining violations when the *fix_eco_drc* command is run in distributed multi-scenario analysis (DMSA) mode. There are two scenarios, scen1 and scen2. There is one remaining violation in scen1 that is unfixable, but the remaining violation in scen2 could be fixed in the next run.

```
Remaining Violations:
  Scenario                   Total  Unfixable
  -----------------------------------------
  scen1                          1          1
  scen2                          1          0
```

The following example fixes noise violations using both the *size_cell* and *insert_buffer* methods.

```
pt_shell> fix_eco_drc -type noise -verbose \\
           -methods {size_cell insert_buffer} \\
```

```
            -buffer_list { BUFX1 BUFX2 BUFX3 } \\
            -physical_mode open_site
 ...
Unfixable violations:
  A - There are available lib cells outside area limit
  C - The violation is in clock network
  D - Cell or net is located in high density area
  E - Physical information is incomplete or unavailable
  H - Logical and physical hierarchies are inconsistent
  I - Buffer insertion with given lib cells cannot fix the violation
  O - No open free site is available
  P - Driver cell of the violation is a port
  Q - Driver cell of the violation is a sequential cell
  R - No locations are available in parasitics or location transformation
 failed
  S - Cell sizing with alternative lib cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  V - Driver cell of the violation is dont_touched
  U - UPF restricts fixing the violation

  Violation                                  Reasons
  ------------------------------------------------
  U1/I                                             O

Remaining Violations:
  Violation Type                               Count
  ------------------------------------------------
  Total remaining violations                       1
  Unfixable violations                             1
```

One unfixable violation remains. The unfixable reason "O" shows that U1/I was not fixed because there is no empty free site available.

The following example uses the *-insert_inverter_pair* method to perform maximum transition fixing in a clock network.

```
pt_shell> fix_eco_drc -type max_transition -cell_type clock_network \\
            -buffer_list {INVX1 INVX2 INVX4} \\
            -methods insert_inverter_pair
```

The following example uses the *-insert_inverter_pair* method to perform maximum transition fixing in data paths.

```
pt_shell> fix_eco_drc -type max_transition -cell_type combinational \\
            -buffer_list {INVX1 INVX2 INVX4} \\
            -methods insert_inverter_pair
```

The following example uses only the pin buffering method to perform maximum transition fixing.

Feedback

```
pt_shell> fix_eco_drc -max_transition \\
           -methods {insert_buffer_at_load_pins
 insert_buffer_at_driver_pins} \\
           -buffer_list {BUFX1 BUFX2 BUFX3}
```

The following example shows usage of the *-slack_lesser_than* option to fix large noise violations with slack worse than -0.05, thereby ignoring violations with slack range between -0.05 and 0.0.

```
pt_shell> fix_eco_drc -type noise -slack_lesser_than -0.05 \\
           -buffer_list {BUFX1 BUFX2 BUFX4}
```

The following example optimizes victim nets with delta delay cost of more than 0.05 time units and that belong to a path with negative timing slack, using both the *size_cell* and *insert_buffer* fixing methods.

```
pt_shell> fix_eco_drc -type delta_delay -verbose \\
  -delta_delay_threshold 0.05 \\
  -methods {size_cell insert_buffer} \\
  -buffer_list { BUFX1 BUFX2 BUFX3 } \\
  -physical_mode open_site
```

---

fix_eco_leakage

Performs leakage recovery driven by signoff timing by replacing lower priority cells with higher priority cells.

Syntax

```
status fix_eco_leakage
   -pattern_priority pattern_list
   [-cell_type cell_types]
   [-attribute attribute_name]
   [-verbose]
   [-setup_margin margin]
```

Data Types

```
pattern_list       list
cell_types         list
attribute_name     string
margin             float
```

Arguments

`-pattern_priority` *pattern_list*

Specifies a list of library cell patterns in the order of highest to lowest priority.

`-cell_type` *cell_types*

Specifies a cell type for leakage recovery. Allowed values are *combinational* and *sequential*. The default is *{sequential combinational}*, which specifies that both sequential and combinational cells are swapped for leakage recovery.

`-attribute` *attribute_name*

Specifies an attribute name that can be used to match patterns specified by the *-pattern_priority* option. When you specify this option, PrimeTime uses the value of the attribute, instead of library cell names, for pattern matching.

`-verbose`

Shows additional information during leakage recovery process. During distributed multi-scenario analysis, the report includes setup violation information from each scenario.

`-setup_margin` *margin*

Specifies an additional timing margin to be applied to setup slacks during leakage recovery. By default, the setup margin is zero. If you specify a positive value, PrimeTime preserves the specified amount of slack during leakage recovery. If you specify a negative value, PrimeTime uses the specified amount of slack to swap more cells during leakage recovery.

Description

This command seeks to recover leakage (reduce leakage current) as much as possible by swapping cells that have positive setup slacks, which can be reduced, without creating new timing violations. You can use the *fix_eco_leakage* command in the multicore analysis and distributed multi-scenario analysis flows within PrimeTime.

Run the *fix_eco_leakage* command in distributed multi-scenario analysis flow to consider signoff timings from all scenarios. PrimeTime analyzes timing across all scenarios during the leakage recovery process and maintains signoff-state timing in all scenarios.

You must specify the required *-pattern_priority* option with a *pattern_list*. This option determines the priority order that PrimeTime follows when replacing lower priority cells with higher priority cells. Therefore, the first pattern indicates the cells with the lowest leakage (highest priority for swapping), and the last pattern indicates the cells with the highest leakage (lowest priority for swapping).

PrimeTime swaps cells if the following conditions are met:

- The original library cell has enough positive setup slack.
- The new library cell is compatible with the original library cell and satisfies the pattern matching criteria (see "Pattern Matching and Priority Order").
- The new library cell has higher priority than the original library cell.
- The new library cell does not create new setup, max_transition, or max_capacitance violations.

Pattern Matching and Priority Order

To determine the priority of cell swapping, the *fix_eco_leakage* command can perform pattern matching if the library cell names have a changing pattern and a fixed pattern. A changing pattern is a text string that represents different leakage values, such as HVT, NVT, and LVT. A fixed pattern is a text string that does not change with different leakage values, such as BUF1X.

To apply the pattern matching algorithm and identify the candidates for cell swapping, use *-pattern_priority* option; specify the cells in the *pattern_list* in the order of highest to lowest priority (most to least preferred).

For example, suppose you have three library cells: HVT_BUF1X, NVT_BUF1X, and LVT_BUF1X. They are the same buffers except with different leakage values. The HVT_BUF1X library cell has the lowest leakage, which is most preferred; the LVT_BUF1X library cell has the highest leakage, which is least preferred.

In this example, you would specify the *-pattern_priority* option with the following *pattern_list*: {HVT NVT LVT}. PrimeTime swaps cells in the following order:

- LVT_BUF1X can be replaced by HVT_BUF1X or NVT_BUF1X.
- NVT_BUF1X can be replaced by HVT_BUF1X.
- HVT_BUF1X cannot be replaced; it has the highest priority.

In this case, HVT_BUF1X has highest priority as the most preferred cell. When the tool finds an LVT_BUF1X cell, it tries to replace it with HVT_BUF1X, if doing so would not create any new timing violations. If not, then the tool tries to replace LVT_BUF1X with NVT_BUF1X. The tools also tries to replace any NVT_BUF1X cell with HVT_BUF1X. However, the tool does not change HVT_BUF1X because it is the most preferred cell.

Specifying the Pattern List

Pattern matching supports prefix, mid-fix, and postfix. For example, you can specify {HVT NVT LVT} for the following library cell names.

```
Prefix : HVT_BUF1X,  LVT_BUF1X,  NVT_BUF1X
  Mid-fix: BUF_HVT_1X, BUF_NVT_1X, BUF_LVT_1X
  Postfix: BUF1X_HVT,  BUF1X_NVT , BUF1X_LVT
```

If multiple patterns overlap each other, the largest pattern is chosen. For example, if you specify {LVT LLVT} for the pattern, PrimeTime replaces BUF1X_LLVT (with matching LLVT pattern) by BUF1X_LVT (with matching LVT pattern), even though the LVT pattern also matches BUF1X_LLVT.

Swapping Cells By Attributes Instead of Cell Names

Even if your libraries do not have the naming convention described previously, you can still recover leakage by using a user-defined attribute and the *fix_eco_leakage -attribute* command. This also gives you great flexibility to customize your own flow and apply different techniques in different stages of your design.

For example, suppose that there are six library cells: BUF_A, B_BUF, BF1X, INV_A, B_INV, and IV2X. Although the pattern matching cannot be used with these cell names, you can still recover leakage by using user-defined attributes. In this example, BUF_A and INV_A are the most preferred cells, and BF1X and IV2X are the least preferred cells. To perform cell swapping with attributes, use the following commands:

```
# Define a user-defined attribute 'eco_pattern" for lib cell.
# Assign different value to each library cell with "good ok bad"
#
```

```
define_user_attribute eco_pattern -type string -class lib_cell
set_user_attribute -class lib_cell [get_lib_cell BUF_A] eco_pattern
 "buf_good"
set_user_attribute -class lib_cell [get_lib_cell B_BUF] eco_pattern
 "buf_ok"
set_user_attribute -class lib_cell [get_lib_cell BF1X ] eco_pattern
 "buf_bad"
set_user_attribute -class lib_cell [get_lib_cell INV_A] eco_pattern
 "inv_good"
set_user_attribute -class lib_cell [get_lib_cell B_INV] eco_pattern
 "inv_ok"
set_user_attribute -class lib_cell [get_lib_cell IV2X ] eco_pattern
 "inv_bad"
#
# Specify pattern priority using an attribute
#
fix_eco_leakage -pattern_priority {good ok bad} -attribute eco_pattern
```

Note that the name of user-defined attribute for each library cell must be unique. The name of user-defined attribute for a group of library cells that can be swapped to one another must have a common base name (for example, buf or inv) along with a name to specify priority (for example, good, ok, or bad). This is required for PrimeTime to know which cells can be swapped relative to one another.

Cells That Are Not Swapped

The recovery process does not swap the following cells:

- Cells with *dont_touch*, *dont_use*, or *pt_dont_use* attributes

  As in Design Compiler and IC Compiler, a *dont_touch* attribute applied to an upper-level hierarchical cell propagates downward into the hierarchy. If a different *dont_touch* value is applied deeper in the hierarchy, it takes precedence over any higher-level *dont_touch* attributes.

  To prevent the use of specific library cells for leakage recovery, apply the *dont_use* attribute by using the *set_dont_use* command. Alternatively, you can also apply the *pt_dont_use* user-defined attribute.

  In distributed multi-scenario analysis (DMSA) fixing, a restriction in one scenario also should be applied to other scenarios. You should apply the *dont_touch* and *dont_use* attributes to all scenarios to prevent design changes across all scenarios for the affected cells and nets.

- Cells in the clock network
- Cells in the fanin cone of transparent latches

  By default, the cells in the fanin cone of transparent latches are not swapped because it is difficult to recover timing violations created from swapping. The default latch

analysis always sees zero slack at borrowing latches due to the single-segment nature of timing paths.

To allow swapping cell in the fanin cone of transparent latches, enable advanced latch analysis by setting the *timing_enable_through_paths* variable to *true*. Advanced latch analysis has global visibility of timing paths through latches and can see whether a timing violation found at the downstream of the latch is caused by swapping cells in the upstream.

Unconstrained Cells

In distributed multi-scenario analysis, a cell is unconstrained if the cell is not constrained in all scenarios. If a cell is not constrained in one scenario but constrained in another scenario, the cell is constrained in distributed multi-scenario analysis.

You can control swapping unconstrained cells by specifying the *eco_leakage_exclude_unconstrained_cells* variable. If the variable is set to *false*, PrimeTime swaps unconstrained cells. If the variable is set to *true*, PrimeTime does not swap unconstrained cells.

UPF

If a cell has the *always_on*, *is_isolation*, *is_retention*, or *is_level_shifter* low-power control attribute set to *true*, it is not considered for cell swapping.

Honoring Footprint Attributes in the Library

If you want PrimeTime to honor a footprint attribute from libraries, you need to import the attribute and specify the attribute name in the *eco_alternative_cell_attribute_restrictions* variable. Suppose your library has the *cell_footprint* attribute to indicate cell footprint. Then, the following commands restrict the *fix_eco_leakage* command to swap only footprint-compatible cells.

```
# Import 'cell_footprint' attribute to PrimeTime
define_user_attribute cell_footprint -class lib_cell -import -type string

# Restrict compatible cells only to the same cell_footprint
set eco_alternative_cell_attribute_restrictions {cell_footprint}

# Swappable cells should satisfy both the pattern priority and
# the cell_footprint attribute value
fix_eco_leakage -pattern_priority {HVT NVT LVT}
```

Examples

The following example shows how to recover leakage with the library cells having prefix HVT, NVT, and LVT for their names. Both sequential and combinational cells are swapped.

```
pt_shell> fix_eco_leakage -pattern_priority {HVT NVT LVT}
```

The following example shows how to swap only combinational cells.

Feedback

```
pt_shell> fix_eco_leakage -cell_type combinational -pattern_priority {HVT
 NVT LVT}
```

Here is typical script example for leakage recovery in distributed multi-scenario analysis.

```
#-------------------------------------------------------------------------
# Update timing & global reporting in manager process
#-------------------------------------------------------------------------
remote_execute {
  set timing_save_pin_arrival_and_slack true; update_timing -full
}
set pattern "HVT NVT LVT"
report_global_timing
report_constraint -all -max_capacitance -max_transition

#-------------------------------------------------------------------------
# Before leakage recovery:
#   Report timing, power, cell usages for each worker
#-------------------------------------------------------------------------
remote_execute {
  set pattern "HVT NVT LVT"
  report_global_timing
  report_constraint -all -max_capacitance -max_transition
  set power_enable_analysis true
  report_power -group {...} -threshold_voltage_group -pattern $pattern
}

#-------------------------------------------------------------------------
# Before leakage recovery:
#   Check cell swap compatibility. Detect any misuse of patterns
#   by using the -alternative_lib_cells and -show_others
#   options.
#-------------------------------------------------------------------------
remote_exec {
  report_cell_usage -pattern $pattern -alternative_lib_cells -show_others
}

#-------------------------------------------------------------------------
# Execute signoff-driven leakage recovery.
#-------------------------------------------------------------------------
fix_eco_leakage -pattern $pattern -verbose

#-------------------------------------------------------------------------
# Reporting after leakage recovery
#-------------------------------------------------------------------------
report_global_timing
report_constraint -all -max_capacitance -max_transition
remote_execute {
  report_global_timing
  report_constraint -all -max_capacitance -max_transition
  set power_enable_analysis true max_transition
  report_power -group {...} -threshold_voltage_group -pattern $pattern
```

```
}
exit
```

fix_eco_power

Performs power recovery by downsizing or swapping cells in paths with positive setup slack or by removing buffers.

Syntax

```
status fix_eco_power
   [-cell_type cell_types]
   [-setup_margin margin]
   [-hold_margin margin]
   [-verbose]
   [-power_attribute power_attribute_name]
   [-pba_mode none | path | exhaustive | ml_exhaustive]
   [-pba_path_selection_options option_string]
   [-pattern_priority pattern_list]
   [-attribute attribute_name]
   [-methods method_list]
   [-current_library]
   [-power_mode total | dynamic | leakage]
   [-leakage_scenario scenario_name]
   [-dynamic_scenario scenario_name]
   [-training_data file_list]
   [-timeout seconds]
   [-start_end_type reg_to_reg]
```

Data Types

```
cell_types            list
margin                float
power_attribute_name  string
option_string         string
pattern_list          list
attribute_name        string
method_list           list
```

```
scenario_name          string
file_list              list
```

Arguments

`-cell_type` *cell_types*

Specifies the types of cells considered for downsizing or swapping, either *combinational*, *sequential*, or *clock_network*. Cell types *combinational* and *sequential* can be specified together, and the default is both, *-cell_type {combinational sequential}*; cell type *clock_network* cannot be specified together with other cell types. Only sequential cells that synchronous (flip-flops, not transparent latches) can be modified during power recovery. Note that users need to specify *-power_mode dynamic* and *-dynamic_scenario* options together with the cell type *clock_network* to use PrimePower power analysis data to drive clock dynamic power recovery.

Note: The *clock_network* value requires a PrimeECO license.

`-setup_margin` *margin*

Specifies the amount of setup timing margin to keep during power recovery, in library time units. For example, setting the margin to 0.2 requires the power recovery process to keep at least 0.2 of positive setup slack in each path. Specifying a negative margin allows timing violations up to the specified negative slack value. The default margin is zero.

During power recovery, if some path endpoints have a setup slack within the specified margin, the log file reports them as "endpoints with setup slack lesser than margin." These endpoints are not violations with negative slack (less than zero slack), but rather these endpoints fall within a slack range which power recovery will try to maintain the current setup slack relative to these endpoints.

`-hold_margin` *margin*

Specifies the amount of hold timing margin to keep during buffer removal or clock dynamic power recovery, in library time units. For example, setting the margin to 0.1 requires the buffer removal or clock dynamic power recovery process to keep at least 0.1 of positive hold slack in each path. The default margin is zero. This option can be used only when the *-methods* option is set to *remove_buffer* or when the *-cell_type* option is set to *clock_network*.

`-verbose`

Shows additional information during the power recovery process. During distributed multi-scenario analysis, the report includes setup violation information from each scenario.

The verbose mode also generates an "Unusable Cells" report upon completion of power recovery process if the *eco_power_report_max_unusable_cells*

variable is set to a positive integer. The report shows a list of cells where power recovery was considered, the reason that the power recovery was not performed at the cell. For details, see "Unusable Cell Report" in the DESCRIPTION section of this man page.

`-power_attribute` *power_attribute_name*

Specifies an attribute for prioritizing library cells used for downsizing or swapping. When you use this option, the tool uses the value of the power attribute, instead of library cell's area attribute, to prioritize usage of library cells for downsizing or swapping. Library cells with lower power attribute values are preferred over those with higher values.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Specifies one of the following path-based timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode.
- *ml_exhaustive* - Performs machine learning based exhaustive path-based analysis. This mechanism will deploy machine learning techniques to trade runtime vs accuracy during the design flow. Accuracy and runtime will match the *-pba_mode exhaustive* option as the design approaches signoff.

This option works like the *-pba_mode* option in the *report_timing* and *get_timing_paths* commands. The power recovery process uses the specified analysis mode to make sure that no new timing violations are introduced, or that existing timing violations do not become worse. Path-based analysis is more accurate (less pessimistic) than conventional graph-based analysis, so it reports more positive slack and allows more opportunities for power recovery at the cost of more runtime and memory. For more information, see "Path-Based Timing Analysis During Power Recovery" in the DESCRIPTION section.

`-pba_path_selection_options` *option_string*

Specifies the path selection options for the *-pba_mode path* option. The command uses these options to collect timing paths and determine the timing

slack available in these paths for power recovery. Only the following options are supported in the option string:

- *-nworst* - Specifies the maximum number of worst paths per endpoint considered for path-based analysis. The default is 1.
- *-max_paths* - Specifies the maximum total number of paths considered for path-based analysis. The default is to automatically choose a value large enough to cover all violating endpoints.
- *-cover_design* - Covers the entire design by including the worst path through each violating pin in the design during path-based analysis. This path selection option can be used only by itself, without the other two options.

If you use one or both of the *-nworst* and *-max_paths* options, be sure to specify values large enough to cover the violating endpoints that you want to be fixed. For more information, see "Path-Based Power Recovery" in the DESCRIPTION section.

`-timeout` *`seconds`*

Specifies a timeout limit, in seconds, that sets a maximum total runtime for the command. At the end of each iteration, the tool checks the total elapsed wall clock time. If the time limit is reached, the command stops running and ends with the current iteration. You cannot use this option with *-pattern_priority* and *-method remove_buffer*.

`-pattern_priority` *`pattern_list`*

Specifies a list of library cell patterns (either name prefixes or attribute strings) in order, from highest to lowest priority. When the command performs cell swapping, it uses a library cell with a name prefix or attribute setting that matches an earlier entry in the pattern list to replace an existing cell that matches a later entry in the list.

`-attribute` *`attribute_name`*

Specifies the library cell attribute that is considered by the *-pattern_priority* option. When you use the *-attribute* option, the command gives priority to a library cell with the specified attribute matching an earlier entry in the *-pattern_priority* list; it replaces an existing cell with the attribute matching a later entry in the list.

If you omit the *-attribute* option, the command considers the library cell name instead of a library cell attribute.

`-methods` *`method_list`*

Specifies the power recovery method, either *size_cell* or *remove_buffer*, but not both. The default is *size_cell*. The *size_cell* method downsizes or swaps cells

in paths with positive setup slack. The *remove_buffer* method removes buffers without introducing or worsening timing and DRC violations.

The *remove_buffer* method cannot be used with any of the following options: *-cell_type*, *-pattern_priority*, *-attribute*, *-power_attribute*, *-current_library*, and *-power_mode*.

`-current_library`

Specifies that during cell sizing or swapping using the *-power_attribute* or *-power_mode* option, the replacement cell must come from the same library as the original cell. By default, the command looks for replacement cells in all libraries, except for downsizing based on cell area, when the command always looks for cells only in the same library.

Using the *-current_library* option can improve runtime because fewer cells are considered as potential replacements. However, it might degrade quality of results because the variety of available alternative library cells could be reduced. You cannot use this option with the *-pattern_priority* option.

`-power_mode total | dynamic | leakage`

Specifies usage of PrimePower power analysis data, and specifies the types of power considered during power recovery: *dynamic* power only, *leakage* power only, or *total* power (both dynamic and leakage). When you use this option, PrimePower power analysis data must be available from previous usage of the *update_power* or *report_power* command. You cannot use this option with the *-power_attribute*, *-pattern_priority*, or *-methods remove_buffer* option.

If you do not use the *-power_mode* option, power recovery does not use PrimePower power analysis data. Instead, the command chooses replacement cells based on the cell area by default, or based on a cell power attribute or string pattern list if you use the *-power_attribute* or *-pattern_priority* option.

`-leakage_scenario` *`scenario_name`*

Specifies the name of the scenario from which to get the leakage power data in a DMSA flow when using the *-power_mode* option. It should be the scenario with the worst leakage power.

`-dynamic_scenario` *`scenario_name`*

Specifies the name of the scenario from which to get the dynamic power data in a DMSA flow when using the *-power_mode* option. It should be the scenario with the worst dynamic power.

The *-leakage_scenario* and *-dynamic_scenario* options can be set to the same scenario or two different scenarios.

`-training_data` *`file_list`*

Specifies a list of existing files that contain training data, used for faster power optimization in the current session. When you use this option, power optimization uses only the listed files and does not use the *training_data_directory* variable to read existing training data. (Note that the command still considers the *training_data_directory* setting for writing out training data learned in the current session for usage in future sessions.)

By default, without the *-training_data* option, if the *training_data_directory* varible is set to a directory name, the command uses all training data files in that directory for faster power optimization in the current session, and writes new training data to that directory upon completion of power optimization. Otherwise, if the *training_data_directory* variable is set to an empty string (the default variable setting), ECO power optimization does not use training data in the current session and does not learn or save training data for future sessions.

The argument of the *-training_data* option is a list of files. You can specify the files using absolute or relative paths. If you use relative paths, the command looks for the training data files in the current working directory.

Training data files are generated by earlier usage of the *fix_eco_power* command with the *training_data_directory* variable set to the name of a directory, or by usage of the *record_training_data*, *size_cell*, and *write_training_data* commands. To use training data generated by both methods, put all the training data files in a single directory and set the *training_data_directory* variable to the name of that directory.

`-start_end_type reg_to_reg`

Specifies the tool to optimize cells only on register-to-register paths without degrading interface timing. When the *start_end_type* option is specified, cells that are reachable from input ports (excluding clock input ports) and output ports are not optimized, and cells in register-to-register paths are optimized using the register-to-register timing slack. This option cannot be specified without *-pba_mode* option, and cannot be specified with *cell_type clock_network_cell*.

Description

The *fix_eco_power* command tries to recover power and area as much as possible by downsizing cells in paths with positive setup slack or by removing buffers without introducing or worsening timing and DRC violations.

After power recovery, you can write out the design changes as a script by using the *write_changes* command. You can use the script to implement the same changes in another PrimeTime session or another tool such as IC Compiler II. A list of design changes created in this flow is called an engineering change order (ECO).

By default, the *fix_eco_power* command performs power and area recovery by downsizing cells in all paths with positive setup slack. The command options let you specify any one of the following power recovery methods:

- Replace cells to minimize area (the default)
- Replace cells to minimize a library cell numeric attribute (use the *-power_attribute* option)
- Replace cells based on library cell preference, as specified by an explicit string priority list (use the *-pattern_priority* option)
- Replace cells to minimize switching, leakage, or total power using power analysis data generated by the *update_power* or *report_power* command (use the *-power_mode* option)
- Remove buffers (use the *-methods remove_buffer* option)

You can apply multiple fixing methods by running the *fix_eco_power* command repeatedly with different option settings.

For all of the cell replacement methods, replacement occurs only when the following conditions are met:

- The change does not introduce or worsen any timing violations or DRC violations (max_transition or max_capacitance).
- The replacement cell has the same logical function as the original cell and meets any usage restrictions defined by the *eco_alternative_cell_attribute_restrictions* variable.
- The replacement cell is preferred over the original cell in one of the following ways, depending on the option settings: less area, smaller power attribute value, higher-priority name or attribute string, or less power based on PrimePower power analysis data.

Power recovery is an iterative process. The *fix_eco_power* command starts by making the targeted changes and then analyzes the design for new timing and DRC violations (or worsening of existing violations) caused by the changes. It incrementally backs out of previous changes to meet the timing and DRC constraints, and also explores further changes for improved power recovery, a process called "tuning." It analyzes the design again and repeats this process until it determines that the cost of further progress exceeds the potential benefit.

You can use path-based timing analysis during power recovery to reduce analysis pessimism and give more timing slack, allowing more opportunities for power recovery, at the cost of more runtime. To invoke this option in the *fix_eco_power* command, set the *-pba_mode* option to *path* or *exhaustive*.

The *fix_eco_power* command is compatible with single-core analysis, distributed multi-scenario analysis (DMSA), and multicore analysis. To ensure consistent results during DMSA power recovery, apply any *dont_touch*, *dont_use* and *size_only* attributes identically to all scenarios.

Replacing Cells to Minimize Area (Default Method)

By default, the *fix_eco_power* command by itself (without options) performs power and area recovery by downsizing cells in all paths with positive setup slack. For each cell in these paths, the command looks for alternative cells in the same library that have the same logical function but a smaller area, and considers using them to replace the existing cell. For two library cells with the same area, the one with better timing is preferred.

A smaller cell typically uses less power and has less drive strength, so the tool considers both the area reduction and timing effects of potential replacement cells along each timing path.

You might want to specify which replacement cells are allowed be used for downsizing certain cells. For example, if a library contains both low-Vt and high-Vt cells, you might want high-Vt cells to be replaced only by other high-Vt cells, because a smaller low-Vt cell would reduce switching power but increase leakage power. To do this, assign the library cells into groups and set the *eco_alternative_cell_attribute_restrictions* variable as shown in the following example.

```
# Define a lib_cell attribute called "eco_group"
define_user_attribute eco_group -type string -class lib_cell

# Assign library cells to named groups
set_user_attribute -class lib_cell [get_lib_cell INVX1_LVT] eco_group
 "INV_L"
set_user_attribute -class lib_cell [get_lib_cell INVX2_LVT] eco_group
 "INV_L"
set_user_attribute -class lib_cell [get_lib_cell INVX1_HVT] eco_group
 "INV_H"
set_user_attribute -class lib_cell [get_lib_cell INVX2_HVT] eco_group
 "INV_H"
set_user_attribute -class lib_cell [get_lib_cell BUFX1_LVT] eco_group
 "BUF_L"
set_user_attribute -class lib_cell [get_lib_cell BUFX2_LVT] eco_group
 "BUF_L"
set_user_attribute -class lib_cell [get_lib_cell BUFX1_HVT] eco_group
 "BUF_H"
set_user_attribute -class lib_cell [get_lib_cell BUFX2_HVT] eco_group
 "BUF_H"

# Restrict compatible replacement cells to the same group
set_app_var eco_alternative_cell_attribute_restrictions {eco_group}

# Perform cell downsizing with restricted cell replacement
fix_eco_power
```

Downsizing based on cell area always uses replacement cells from the same library as the original cell, and replacement cells are further restricted to the same group when you set the *eco_alternative_cell_attribute_restrictions* variable.

The other power recovery methods use cells from all available libraries by default. To restrict the selection to only cells from the same library as the original cell when using the *-power_attribute* or *-power_mode* option, also use the *-current_library* option.

Replacing Cells Based on Name Substring Pattern Priority

To perform power recovery by replacing cells in all paths with positive setup slack, using a library cell name substring to determine the order of preference, use the *-pattern_priority* option. The tool attempts to replace each cell that has a lower-priority substring with a cell that has a higher-priority substring, without introducing timing or DRC violations.

For example, suppose that you have three buffer library cells with the same area but different threshold voltages and delays, named HVT_BUF1X, MVT_BUF1X, and LVT_BUF1X (for high-Vt, mid-Vt, and low-Vt). For power recovery, the cells are preferred in that order. To perform power recovery based on these name prefixes, use the following command:

```
fix_eco_power -pattern_priority {HVT MVT LVT}
```

For each cell that contains "LVT" in the library cell name, the command looks for another cell with a similar name, with "HVT" or "MVT" in place of "LVT", and performs the replacement using that cell if it can. In this example, it replaces instances of LVT_BUF1X with HVT_BUF1X if no violations are introduced, or with MVT_BUF1X otherwise, if that replacement does not introduce violations. Instances of HVT_BUF1X are never replaced because they already have the highest priority.

The varying substrings {HVT MVT LVT} can be anywhere in the library cell name: at the beginning (prefix), inside, or at the end (suffix). For example, the substring set {HVT MVT LVT} works with the following sets of library cell names:

```
Prefix: HVT_BUF1X, MVT_BUF1X, LVT_BUF1X
  Inside: BUF_HVT1X, BUF_MVT1X, BUF_LVT1X
  Suffix: BUF1X_HVT, BUF1X_MVT, BUF1X_LVT
```

This method considers the cells that differ by the substring part of the name but otherwise exactly match by name.

Replacing Cells Based on Library Cell Attribute Pattern Priority

To perform power recovery by replacing cells in all paths with positive setup slack, using a library cell attribute substring to determine the order of preference, use the *-pattern_priority* option to specify the string priority list, together with the *-attribute* option to specify the library cell attribute name. The tool attempts to replace each cell that has a lower-priority attribute substring with a cell that has a higher-priority attribute substring, without introducing timing or DRC violations.

When you use the *-attribute* option with the *-pattern_priority* option, the tool finds replacement cells by looking at a library cell attribute instead of the library cell name. This method gives you the flexibility to customize your own cell replacement flow and apply different techniques at different stages of the design.

For example, suppose that you have library cells named BUF_A, B_BUF, BF1X, INV_A, B_INV, and IV2X. In this fixing flow, BUF_A and INV_A are preferred the most, and BF1X and IV2X are preferred the least. To define the preference attribute and perform cell replacement optimization, use the following commands:

```
# Define a string attribute named eco_pattern for lib_cell
# Assign different value to each library cell with string "good ok bad"
define_user_attribute eco_pattern -type string -class lib_cell
set_user_attribute -class lib_cell [get_lib_cell BUF_A] eco_pattern
 "buf_good"
set_user_attribute -class lib_cell [get_lib_cell B_BUF] eco_pattern
 "buf_ok"
set_user_attribute -class lib_cell [get_lib_cell BF1X ] eco_pattern
 "buf_bad"
set_user_attribute -class lib_cell [get_lib_cell INV_A] eco_pattern
 "inv_good"
set_user_attribute -class lib_cell [get_lib_cell B_INV] eco_pattern
 "inv_ok"
set_user_attribute -class lib_cell [get_lib_cell IV2X ] eco_pattern
 "inv_bad"

# Specify pattern priority using an attribute
fix_eco_power -pattern_priority {good ok bad} -attribute eco_pattern
```

For each cell that contains "bad" in the library cell's eco_pattern attribute, the command looks for another cell with a similar eco_pattern attribute setting, with "good" or "ok" in place of "bad", and performs the replacement using that cell if it can. In this example, it replaces instances of BF1X (buf_bad) with BUF_A (buf_good) if no violations are introduced, or with B_BUF (buf_ok) otherwise, if that replacement does not introduce violations. Instances of BUF_A (buf_good) are never replaced because they already have the highest priority.

This method considers the cells that differ by the substring part of the attribute string, with the rest of the attribute string matching exactly, and the replacement cell must be functionally equivalent.

In distributed multi-scenario analysis (DMSA), you must use the same string attribute settings for the same respective library cells across all scenarios. For example,

```
remote_execute {
  define_user_attribute eco_pattern -type string -class lib_cell
  set_user_attribute -class lib_cell [get_lib_cell BUF_A] eco_pattern
 "buf_good"
  set_user_attribute -class lib_cell [get_lib_cell B_BUF] eco_pattern
 "buf_ok"
  ...
```

```
}
fix_eco_power -pattern_priority {good ok bad} -attribute eco_pattern
```

Replacing Cells to Minimize a Numeric Power Attribute

To perform power recovery by replacing cells in all paths with positive setup slack, using a library cell attribute to determine the order of preference, use the *-power_attribute* option. The tool replaces cells to minimize the value of the specified library cell attribute without increasing the cell area. It can choose cells from all libraries, not just the library of the existing cell. The attribute can represent any type of quantity that you want to minimize, such as leakage power or switching power.

For example, suppose there are inverters named INV1X_LVT, INV2X_LVT, INV1X_HVT, and INV2X_HVT, contained in two libraries named LIB_L and LIB_H. You define a numeric library cell attribute named prw_attr and set the value of this attribute for the library cells as follows:

```
define_user_attribute pwr_attr -type float -class lib_cell
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV1X_HVT] pwr_attr 1.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV1X_LVT] pwr_attr 1.5
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV2X_HVT] pwr_attr 2.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV2X_LVT] pwr_attr 3.0
```

To perform power recovery and replace cells to minimize the pwr_attr value, use the following command:

```
fix_eco_power -power_attribute pwr_attr
```

The replacement cell must have a smaller value for the specified attribute and must have the same or smaller area. Only the library cells that have the specified attribute defined on them are considered as potential replacement cells.

In distributed multi-scenario analysis (DMSA), you must use the same value of power attribute for the same respective library cells across all scenarios. For example,

```
remote_execute {
  define_user_attribute pwr_attr -type float -class lib_cell
  set_user_attr -class lib_cell [get_lib_cell LIB_H/INV1X_HVT] pwr_attr
 1.0
  set_user_attr -class lib_cell [get_lib_cell LIB_L/INV1X_LVT] pwr_attr
 1.5
  set_user_attr -class lib_cell [get_lib_cell LIB_H/INV2X_HVT] pwr_attr
 2.0
  set_user_attr -class lib_cell [get_lib_cell LIB_L/INV2X_LVT] pwr_attr
 3.0
}
fix_eco_power -power_attribute pwr_attr
```

Feedback

Power Recovery Using PrimePower Analysis Data

The PrimePower tool performs comprehensive power analysis using actual switching activity and library-defined power data such as dynamic and leakage power of each cell. The tool performs a power analysis when you use the *update_power* or *report_power* command at the pt_shell prompt.

To use PrimePower power analysis data in power recovery, use the *fix_eco_power* command with the *-power_mode* option set to *dynamic*, *leakage*, or *total*. Then the power recovery process modifies the design to minimize the dynamic (switching) power, leakage power, or total (dynamic plus leakage) power as measured by the *update_power* command.

With the *-power_mode total* option, the tool chooses actions to reduce the total power the most, which can vary with local conditions in the design. For example, where not much timing slack is available, it can choose to recover power by either downsizing the cell or by increasing the cell threshold voltage, the choice depending on the local switching activity. High switching activity favors downsizing (to reduce switching power), whereas low switching activity favors increasing the threshold voltage (to reduce leakage). Where plenty of timing slack is available, it can do both.

In distributed multi-scenario analysis (DMSA) flow, the tool gets its dynamic power data from exactly one scenario, which you specify with the *-dynamic_scenario* option. Similarly, it gets its leakage power data from exactly one scenario, which you specify with the *-leakage_scenario* option. These options are used only in a DMSA flow. In general, you should specify the scenario showing the worst dynamic power and worst leakage power, respectively, for these two options. They could be the same scenario or two different scenarios.

By default, the PrimePower tool accounts for the internal power of a register cell's clock input pin as a member of the clock network, not as part of the register cell. You can change this behavior by setting the *power_clock_network_include_register_clock_pin_power* variable to *false*, so that power recovery is better reflected as part of the data path.

The following script performs total power recovery in a single-scenario flow.

```
restore_session Session1
# Enable PrimePower and set up power analysis
set_app_var power_enable_analysis true
set_app_var power_clock_network_include_register_clock_pin_power false
read_saif activity_file.saif
# or
# read_vcd activity_file.vcd
 ...
# Perform power analysis
update_power
# Report power before power recovery
report_power
```

```
fix_eco_power -power_mode total

# Report power improvement
report_power
```

The following script performs total power recovery in a DMSA flow with four scenarios. Scenario S1 has the worst leakage power and scenario S3 has the worst dynamic power.

```
current_session {S1 S2 S3 S4}
# update_power is only needed for power scenarios S1 and S3
current_scenario {S1 S3}
remote_execcute {
  # Enable PrimePower and set up power analysis
  set_app_var power_enable_analysis true
  set_app_var power_clock_network_include_register_clock_pin_power false
  read_saif activity_file.saif
  # or
  # read_vcd activity_file.vcd
  ...
  update_power
}
# Report power in power scenarios before power recovery
remote_execute -verbose { report_power }
current_scenario -all

fix_eco_power -power_mode total \\
 -leakage_scenario S1 \\
 -dynamic_scenario S3 \\

# Report power improvement in power scenarios
current_scenario {S1 S3}
remote_execute -verbose { report_power }
```

Removing Buffers

To remove buffers to recover power or area, use the *-methods {remove_buffer}* option of the *fix_eco_power* command. Using this method, the tool considers a buffer for removal when all the following conditions are met:

- The buffer is constrained for both hold and setup timing when the *eco_power_exclude_unconstrained_cells* variable is set to *true*. In a DMSA flow, it must be constrained in at least one scenario for hold timing and in at least one scenario for setup timing. When the *eco_power_exclude_unconstrained_cells* variable is set to *false*, tool also considers unconstrained buffers for removal. In a DMSA flow, a buffer must be unconstrained in all scenarios for both hold and setup timing to be considered unconstrained. If a buffer is constrained only for hold or setup timing, it will not be considered for removal regardless of the value set to *eco_power_exclude_unconstrained_cells* variable.

- Removing the buffer does not introduce any new hold or setup timing violation, or does not worsen existing violations, or does not cause the slack to become worse than the margins set by the *-hold_margin* or *-setup_margin* options.
- Removing the buffer does not introduce any new DRC violations: max_transition, max_capacitance, or max_fanout.

The following buffers are *not* considered for removal:

- A buffer in a clock network
- A buffer with one or more timing exceptions defined on itself or its pins i.e. defined through *set_false_path, set_sense, and/or set_data_check commands.*
- A buffer with its *dont_touch* attribute set to true
- A buffer with its *size_only* attribute set to true
- A buffer with its *always_on* attribute set to true
- A buffer in the fanin cone of a transparent latch (default restriction)

To allow buffer removal in the fanin cone of a transparent latch, enable advanced latch analysis by setting the *timing_enable_through_paths* variable to *true*.

When the tool removes a buffer, it stitches the parasitics at the buffer input and output pins together to form a new combined parasitic network, which is seen by the driver of the removed buffer. This behavior is based on the assumption that the physical implementation tool will maintain the existing routing and replace the buffer with a short-circuit connection.

This *fix_eco_power -methods {remove_buffer}* command only removes buffers. To also perform cell sizing or swapping for power recovery, use a separate *fix_eco_power* command with appropriate option settings.

Cells That Are Not Modified

By default, the power recovery methods do not downsize or swap the following cells:

- Cells in clock networks when cell type is not *clock_network*; cells not in clock networks when cell type is *clock_network*
- UPF power management cells (cells with the *always_on*, *is_isolation*, *is_retention*, or *is_level_shifter* attribute set to *true*)
- Transparent latches
- Cells in the fanin cones of transparent latches

To allow UPF power management cells to be modified during power recovery, set the *eco_allow_sizing_with_lib_cell_attributes* variable. For example, to allow all four types of UPF power management cells to be modified:

```
set_app_var eco_allow_sizing_with_lib_cell_attributes \
  {always_on is_isolation is_retention is_level_shifter}
```

For distributed multi-scenario analysis (DMSA), set this variable in each worker process.

By default, cells in the fanin cones of transparent latches are not modified because of the difficulty of recovering the timing violations created. The default latch analysis method always sees zero slack at borrowing latches due to the single-segment nature of timing paths.

To allow downsizing and swapping cells in the fanin cones of transparent latches, enable advanced latch analysis by setting the *timing_enable_through_paths* variable to *true*. Advanced latch analysis has global visibility of timing paths through latches and can see whether a timing violation found downstream from the latch is caused by downsizing or swapping cells upstream from the latch.

Preventing Specific Cell Instances From Being Modified

Among the cells that could be downsized or swapped out, you might want to prevent specific instances from being modified. To do this, use the *set_dont_touch* command. For example,

```
set_dont_touch [get_cells {U28}] true
```

This command sets the *dont_touch* attribute to *true* for cell instance U28, which prevents the cell from being modified by ECO commands. If U28 is a hierarchical cell, the dont_touch property is propagated downward through the hierarchy and applies by default to all lower-level objects of the cell. If you apply a different dont_touch settings to specific lower-level objects, those settings override the higher-level setting.

Preventing Specific Cell Instances From Being Removed

Among the cells, you might want to prevent specific instances from being removed but allow other sizing operations on them. To do this, use the *set_size_only* command. For example,

```
set_size_only [get_cells {U28}] true
```

This command sets the *size_only* attribute to *true* for cell instance U28, which prevents the cell from being removed by ECO commands.

Preventing Specific Library Cells From Being Used

To prevent specific library cells from being used to replace existing cells, use the *set_dont_use* command. For example,

```
set_dont_use [get_lib_cells {lib2hvt/BUF3XZ}] true
```

Alternatively, you can create a user-defined lib_cell attribute named *pt_dont_use* and set it to *true*.

In distributed multi-scenario analysis (DMSA) fixing, a restriction in one scenario should also be applied to the other scenarios. Apply the same *dont_touch*, *dont_use* and *size_only* attributes to all scenarios to ensure consistent design changes across all scenarios for the affected cells and nets.

Unconstrained Cells

Unconstrained cells are cells that belong to paths without timing constraints, such as a path starting from an input port without a *set_input_delay* constraint. By default, the cell-swapping power recovery methods swap out unconstrained cells to reduce power, without considering the timing effects.

To prevent modification of unconstrained cells, set the *eco_power_exclude_unconstrained_cells* variable to *true*. In a DMSA flow, the variable must be set in the manager process. If a cell is constrained in at least one scenario, it is considered constrained in all scenarios for cell swapping purposes.

Using the cell_footprint Library Cell Attribute in ECO Fixing

If you want PrimeTime to honor the cell_footprint library cell attribute in the power recovery process, you need to import the attribute and specify the attribute name in the *eco_alternative_cell_attribute_restrictions* variable. For example, the following commands restrict the *fix_eco_power* command to swap only footprint-compatible cells.

```
# Import cell_footprint attribute to PrimeTime before linking
define_user_attribute cell_footprint -class lib_cell -import -type string

# Restrict compatible cells only to the same cell_footprint class
set eco_alternative_cell_attribute_restrictions {cell_footprint}
  ...
# The swapped-in cell must satisfy the pattern priority criterion and
# also have a matching cell_footprint string attribute
fix_eco_power -pattern_priority {HVT MVT LVT}
```

Power Recovery in Multiply Instantiated Modules (MIM)

To perform the same ECO changes across each set of multiply instantiated modules (MIMs), set the *eco_enable_mim* variable to *true*. The MIM configuration is derived from parasitic data files. If multiple instances share the same parasitics file using the *-path* option in the *read_parasitics* command, the tool recognizes them as MIM instances. For more information, see the man page for the *fix_eco_timing* command.

Unusable Cell Report

The *fix_eco_power* command, upon completion of the power recovery process, generates a report explaining why unusable cells were not used when you use the *-verbose* option.

To generate the report, the *eco_power_report_max_unusable_cells* variable must be set to a positive integer. For DMSA, this variable must be set in the manager.

Here is a report example:

```
pt_shell> fix_eco_power -verbose
  ...
Unusable Cells:
  B - Benefit from sizing cell is too small
  L - Physical constraints restrict sizing
  S - Cell has no alternate library cell with better power
  T - Sizing cell might degrade timing
  U - UPF restrictions prevent sizing
  V - Cell is invalid or has dont_touch attribute
  W - Sizing cell might degrade DRC
  X - Cell is unusable for ECO
  Z - Cell is sized

  Cell name                          Lib_cell name          Reasons
  ------------------------------------------------------------------
   U1                                      BUF1X              T W
   U3                                      BUF2X              T W
   U5                                      BUF2X                T
   U4                                      BUF1X                U
   U8                                      BUF4X                B
   U9                                      BUF8X              T W
   U7                                      BUF1X                W
  ...
```

The "Cell name" column shows the cell pins where unusable cells are located.

The "Lib_cell name" column shows library cell name.

The "Reasons" column shows the reason or reasons that the power recovery was not performed at the cell pin, using letter codes from the key shown at the beginning of the report.

Path-Based Timing Analysis During Power Recovery

The power recovery process performs timing analysis to make sure that no new timing violations are introduced, or that existing timing violations do not become worse. Path-based analysis is more accurate (less pessimistic) than conventional graph-based analysis, so it reports more positive slack and provides more opportunities for power recovery at the cost of more runtime and memory.

To invoke path-based timing analysis in the *fix_eco_power* command, use the *-pba_mode* option with the *path* or *exhaustive* setting. In that case, the tool performs more aggressive power recovery without creating new violations in the collected timing paths.

You can use the *-pba_path_selection_options* option to specify the paths collected for analysis. The path collection options are *-nworst*, *-max_paths*, and *-cover_design*. Use

-cover_design to analyze the whole design, or *-nworst* and *-max_paths* to limit the number of paths considered and save runtime. The following rules apply to these options:

- If you use the *-pba_mode path* option without the *-pba_path_selection_options* option, the tool sets the value of *-nworst* to 1 and the value of *-max_paths* to the number of graph-based analysis violations.
- If you specify *-nworst* without *-max_paths*, the tool automatically calculates and uses a value for *-max_paths* that is large enough to collect all violating endpoints.
- If you explicitly specify both the *-max_paths* and *-nworst* option values, be sure to specify numbers large enough to cover all endpoints with violations. The tool performs power recovery throughout the design, but it only checks the timing of paths included in the collection.

When you use exhaustive path-based timing analysis during power recovery, any existing violations found by path-based analysis are guaranteed not to become worse under subsequent path-based analysis. However, violations found by graph-based analysis can increase in number and become worse. This does not mean that the quality has been degraded; in only means that graph-based analysis is pessimistically reporting the results of the changes made during power recovery.

If you use the *-pba_mode exhaustive* option, the tool analyzes timing paths collected by exhaustive path-based analysis, which can significantly increase runtime and memory. In this situation, consider setting the *pba_derate_only_mode* variable to *true*, which adjusts the derating only according to path-based conditions, thereby saving runtime.

For better runtime and memory usage during path-based power recovery, consider setting the *-pba_mode* option to *path* (instead of *exhaustive*), which gives good power recovery results using the least possible path-based analysis runtime, without creating new violations detected by path-based analysis consistent with the applied *-pba_mode path* and *-pba_path_selection_options* options.

If exhaustive path-based analysis using the *report_timing* command detects any new violations after you run the *fix_eco_power* command with the *-pba_mode path* option, you can fix the violations by using the *fix_eco_timing* command with the *-pba_mode exhaustive* option.

Per-Scenario ECO Margins

In distributed multi-scenario analysis (DMSA), you can use different setup and hold margins for each scenario by specifying their values using the *-power_setup_margin* and *-power_hold_margin* options of the *set_eco_options* command in the worker script.

Note that the *-setup_margin* and *-hold_margin* options of the *fix_eco_power* command override (have higher precedence than) the *-power_setup_margin* and *-power_hold_margin* options of the *set_eco_options* command.

Physically Aware Power Recovery

Timing fixing (*fix_eco_timing*) and DRC fixing (*fix_eco_drc*) often upsize cells and insert buffers. In physically dense designs with not much available space, physically aware fixing ensures that there is room for each ECO change and tells the layout tool (such as IC Compiler II) exactly where to implement each change.

Power recovery using the *fix_eco_power* command typically replaces cells with new cells of equal or smaller size in paths with positive setup slack, or removes buffers. Therefore, even a crowded physical layout typically does not constrain power recovery. However, if physical layout information is available, the power recovery process still keeps track of physical changes so that any space freed up by downsizing or buffer removal becomes available to use later for timing fixing and DRC fixing.

If you first use the *fix_eco_timing* or *fix_eco_drc* command in physically aware mode (by setting the *-physical_mode* option to *open_site*, *occupied_site*, or *freeze_silicon*), and afterward you use the *fix_eco_power* command, the power recovery process automatically reuses and modifies the existing physical database to keep track of the recovered area. This is also true if you first use the *check_eco* command to check the physical design data.

If you have not already used another ECO fixing or checking command, but you have set up physically aware fixing with the *set_eco_options* command, the *fix_eco_power* command automatically loads the physical data and updates the physical database to keep track of the recovered area. The recovered area can be used later during timing fixing and DRC fixing. To view the chip layout in the GUI, open the GUI with the *gui_start* command and then choose Window > Layout Window.

If the *set_eco_options* command specifies one or more physical constraint files, the *fix_eco_power* command honors those constraints, such as placement blockages and library cell spacing rules.

Clock Dynamic Power Recovery

To recover clock dynamic power using PrimePower power analysis data, use the *-cell_type {clock_network}* option of the *fix_eco_power* command together with *-power_mode dynamic* and *-dynamic_scenario* options. In distributed multi-scenario analysis (DMSA) flow, the tool gets its clock dynamic power data from exactly one scenario, which you specify with the *-dynamic_scenario* option. Using these options, the tool consider cells on clock networks for downsizing when all the following conditions are met:

- The cell is a buffer or an inverter in clock networks. In a DMSA flow, the cell is in clock networks from at least one of the scenarios.
- Sizing the cell does not introduce any new hold or setup timing violation, or does not worsen existing violations, or does not cause the slack to become worse than the

margins set by the *-hold_margin* or *-setup_margin* options at all the sequential cells driven by the cell in its transitive fanout cone.

- Sizing the cell does not introduce any new DRC violations: max_transition, max_capacitance, or max_fanout.

The following options are *not* supported for clock dynamic power recovery: *-power_mode leakage*, *-method remove_buffer*, *-path_selection_options*, *-power_attribute*, *-attribute*, *-pattern_priority*, *-leakage_scenario*, and *-training_data*.

The following script performs clock dynamic power recovery in a DMSA flow with three scenarios. Scenario S1 has the worst clock dynamic power.

```
current_session {S1 S2 S3}
# update_power is only needed for power scenarios S1
current_scenario {S1}
remote_execcute {
  # Enable PrimePower and set up power analysis
  set_app_var power_enable_analysis true
  set_app_var power_clock_network_include_register_clock_pin_power false
  read_saif activity_file.saif
  # or
  # read_vcd activity_file.vcd
  ...
  update_power
}
# Report power in power scenarios before power recovery
remote_execute -verbose { report_power }
current_scenario -all

fix_eco_power -cell_type clock_network -power_mode dynamic \\
 -dynamic_scenario S1 \\

# Report power improvement in power scenarios
current_scenario {S1}
remote_execute -verbose { report_power }
```

Examples

The following command recovers area and power by downsizing both sequential and combinational cells, without introducing new timing violations (or worsening existing timing violations).

```
pt_shell> fix_eco_power
```

The following command recovers area and power by downsizing combinational cells only.

```
pt_shell> fix_eco_power -cell_type combinational
```

The following command recovers leakage power by swapping out cells with higher leakage and replacing them with cells that have lower leakage, using the library cell name prefixes to determine which cells are preferred.

```
pt_shell> fix_eco_power -pattern_priority {HVT MVT LVT}
```

The following command recovers area and power by downsizing cells and analyzing the timing effects using path-based analysis. Because path-based analysis is less pessimistic, it allows more opportunities for downsizing without introducing new timing violations.

```
pt_shell> fix_eco_power -pba_mode path
```

The following command recovers area and power by downsizing cells using path-based analysis, using the *-pba_path_selection_options* option to specify the maximum number of worst paths per endpoint considered for analysis (*-nworst* option).

```
pt_shell> fix_eco_power -pba_mode path -pba_path_selection_options
 "-nworst 10"
```

The following command recovers leakage power by replacing low-threshold-voltage cells with high-threshold-voltage cells, based on the library cell name prefixes "HVT" and "LVT", while using exhaustive path-based analysis to determine the timing effects of the changes.

```
pt_shell> fix_eco_power -pattern_priority {HVT LVT} -pba_mode exhaustive
```

The following command removes buffers to recover area or power.

```
pt_shell> fix_eco_power -methods {remove_buffer}
```

The following script performs area and power recovery in a distributed multi-scenario analysis (DMSA) flow.

```
#------------------------------------------------------------------
# Update timing & global reporting in manager process
#------------------------------------------------------------------
remote_execute {
  set timing_save_pin_arrival_and_slack true; update_timing -full
}
report_global_timing
report_constraint -all -max_capacitance -max_transition

#------------------------------------------------------------------
# Before area/power recovery:
#   Report timing, power, cell usage for each worker process
#------------------------------------------------------------------
remote_execute {
  report_global_timing
  report_constraint -all -max_capacitance -max_transition
  set power_enable_analysis true
  report_power -group {...}
  report_cell_usage
}

#------------------------------------------------------------------
# Before area/power recovery:
#   Check compatible library cells for ECO
```

Feedback

```
#-------------------------------------------------------------------
remote_execute {
  report_eco_library_cells
}

#-------------------------------------------------------------------
# Execute signoff-driven area/power recovery.
#-------------------------------------------------------------------
fix_eco_power -verbose

#-------------------------------------------------------------------
# Reporting after area/power recovery
#-------------------------------------------------------------------
report_global_timing
report_constraint -all -max_capacitance -max_transition
remote_execute {
  report_global_timing
  report_constraint -all -max_capacitance -max_transition
  set power_enable_analysis true
  report_power -group {...}
  report_cell_usage
}
exit
```

---

fix_eco_robustness

Performs design variation robustness ECO fixing.

Syntax

status *fix_eco_robustness*

```
-type bottleneck | variation_robustness | setup | hold
 | voltage_robustness | voltage_slack
[-attribute attribute_name]
[-buffer_list buffer_list]
[-cell_type combinational | sequential]
[-leakage_budget_ratio value]
[-leakage_scenario scenario_name]
[-legalize]
[-max_violators num_cells]
[-methods method_list]
[-object object]
[-pba_mode]
[-physical_mode none | open_site]
[-power_attribute attribute_name]
[-power_mode mode]
[-robustness_pattern_priority pattern_list]
[-sizing_pattern_regexp pattern_list]
[-start_end_type reg_to_reg]
[-voltage_shift value]
[-voltage_shift_ratio value]
```

Data Types

```
attribute_name   string
buffer_list      list
method_list      list
mode             string
object           string
pattern_list     list
scenario_name    string
value            float
```

-type bottleneck | variation_robustness | setup | hold | voltage_robustness | voltage_slack

Specifies the type of design violations to fix. Only one value can be specified.

-attribute *attribute_name*

Specifies an attribute name that can be used to match patterns specified by the *-robustness_pattern_priority* option. When you specify this option, the tool uses the value of the attribute instead of library cell names for pattern matching.

-buffer_list *buffer_list*

Specifies the list of library cell buffers that can be used with the *insert_buffer* method; there is no default list.

-cell_type combinational | sequential

Specifies the type of cells to be modified for timing fixing:

- *combinational* (the default) - Fixing is performed by sizing or inserting combinational logic cells in the data path.
- *sequential* - Fixing is performed by sizing sequential cells to fix violations at the sequential cell's input or output pin. Only the *size_cell* fixing method (*-methods size_cell*) is supported for this type of fixing.

-leakage_budget_ratio *value*

Specifies the maximum leakage impact allowance for a robustness ECO run. During the ECO, if the command detects that the design's leakage increment value is larger than or equal to the maximum allowance, the tool does not perform the remaining ECO steps. You must specify this option with the *-power_attribute* option. It does not work with the *-power_mode* option.

-leakage_scenario *scenario_name*

Specifies the name of the scenario from which to get the leakage power data in a DMSA flow when using the *-power_mode* option. It should be the scenario with the worst leakage power.

-legalize

Invokes the advanced legalizer to consider 3nm physical rules. This option requires an IC Compiler II reference library to be defined by the *set_eco_options* command prior to ECO fixing.

-max_violators *num_cells*

Specifies the maximum number of cells to be reported and fixed.

-method *method_list*

Specifies one or more fixing methods from the following list:

- *size_cell* - Replaces cells in the timing path with logically identical cells that have a better sensitivity or drive strength.
- *insert_buffer* - Inserts buffers in the timing path, using the library cells specified by the *-buffer_list* option.

For hold fixing, the default is *{size_cell insert_buffer}*. For other fixing types, the default is *size_cell*.

-object *object*

Specifies a *design_variation* object or a *timing_path* object.

For setup (*-type setup*), hold (*-type hold*), and bottleneck (*-type bottleneck*) fixing, you must provide a valid non-empty *design_variation* object to this option.

For voltage slack (*-type voltage_slack*) fixing, you must provide a recalculated path object that has gone through voltage slack analysis. A regular timing path collection will not trigger voltage slack ECO fixing. Other fixing types do not require the *-object* option.

-pba_mode none | path | exhaustive | ml_exhaustivess

Specifies one of the following path-based timing analysis modes:

- *none* - Disables path-based analysis and enables ordinary graph-based analysis for cell robustness and voltage robustness analysis and ECO. This is the fastest mode.
- *path* (default) – Perform on-demand exhaustive path-based analysis for cell robustness and voltage robustness analysis. This results in more accurate timing and better QoR.
- exhaustive – Perform on-demand exhaustive path-based analysis for cell robustness and voltage robustness analysis. This results in the best timing accuracy, but it is the slowest mode.
- ml_exhaustive - Perform on-demand exhaustive path-based analysis for cell robustness and voltage robustness analysis. The uses machine-learning exhaustive PBA to trade runtime versus accuracy during the ECO flow. Accuracy and runtime will match the *-pba_mode exhaustive* option.

For fixing types *setup*, *hold*, *bottleneck*, and *voltage_slack*, the *-pba_mode* option does not affect the PrimeShield analysis results, but it does affect how the ECO fixing engine makes design changes while considering graph-based or path-based timing.

-physical_mode none | open_site

Specifies the usage of physical data to size cells or place buffers:

- *none* (the default) - Robustness fixing does not use physical data.
- *open_site* - Robustness fixing sizes a cell only if there is enough room available around the cell and inserts a buffer only if there is an empty site with enough room to accept the new cell without moving nearby cells. This mode retains the placement of existing cells.

-power_attribute *power_attribute_name*

Specifies a user-defined attribute for library cells that defines the leakage power of the library cell at the worst operating condition corner for leakage. When you use this option, timing fixing attempts to minimize the increase in leakage by giving higher priority to library cells with less leakage. By default, without this option, timing fixing considers area instead of leakage.

For fixing types setup (*-type setup*), hold (*-type hold*), and voltage_slack (*-type voltage_slack*), you can specify the *-power_attribute* option alone to achieve power-aware robustness ECO fixing. With the *-leakage_budget_ratio* option, you can achieve even more precise control over the power impact.

For fixing types bottleneck (*-type bottleneck*), variation_robustness (*-type variation_robustness*) and voltage_robustness (*-voltage_robustness*), you must use both *-power_attribute* and *-leakage_budget_ratio* to achieve power-aware ECO fixing.

-power_mode *mode*

Specifies the use of PrimePower power analysis data and specifies the types of power to consider during timing fixing. The only supported value is *leakage*.

Power analysis data must be available from a previous *update_power* or *report_power* command. You cannot use the *-power_mode* option with the *-power_attribute* option. This option applies only to the *setup*, *hold*, and *voltage_slack* fixing types.

When you use the *-power_mode* option for *setup* fixing, the tool tries to minimize the increase in the specified type of power by giving higher priority to library cells that use less power.

Similarly, for *hold* fixing, the tool prioritizes the library cells with lower power during cell sizing and buffer insertion.

By default, without the *-power_mode* option, robustness fixing considers area instead of power.

-robustness_pattern_priority *pattern_list*

Specifies a list of library cell patterns, from highest to lowest priority. The *-robustness_pattern_priority* option is required for *bottleneck*, *variation_robustness*, and *voltage_robustness* fixing, but it is optional for *setup* and *voltage_slack* fixing. The ECO strictly follows the provided pattern to perform pattern-based cell swapping.

-sizing_pattern_regexp *pattern_list*

Specifies a regular expression pattern that can be used to match library cells with different cell drive strengths.

This option only applies to the *bottleneck*, *variation_robustness*, and *voltage_robustness* fixing types.

-start_end_type *reg_to_reg*

Restricts ECO fixing to register-to-register paths. This option is supported only for the *voltage_robustness* and *variation_robustness* ECO fixing types.

-voltage_shift *value*

Specifies the voltage drop used for the sensitivity calculation, as an absolute value in volts. The default is a 5% relative drop from each cell's nominal VDD value. You should use the same value used for the *report_cell_robustness -type voltage* option.

-voltage_shift_ratio *value*

Specifies the voltage drop used for the sensitivity calculation, as a relative ratio (such as 0.95) of each cell's nominal VDD value. The default is a 5% relative drop. You should use the same value used for the *report_cell_robustness -type voltage -voltage_shift_ratio* option.

Description

The *fix_eco_robustness* command improves design variation by performing VT-swap, sizing, and buffer insertion operations without introducing or worsening timing and DRC violations. Because timing-critical cells and endpoints also affect the robustness analysis, you should run *fix_eco_robustness* after timing, DRC, and power fixing to avoid over-fixing. However, you can perform *variation_robustness* and *voltage_robustness* fixing in the early stage to minimize the number of weak cells in the design to improve signoff quality. By default, ECO fixing uses path-based timing analysis for improved accuracy.

You can report the existing violations using the *report_variation_bottleneck*, *report_cell_robustness*, *report_design_variation*, and *report_timing -voltage_slack_lesser_than* commands. The *fix_eco_robustness* command attempts to fix the violations while minimizing the impact on the area or power.

In general, VT swapping is more effective in improving a design's variation robustness while retaining the design's area characteristics. However, swapping to a lower VT usually leads to an increase in leakage power. To address this, the *fix_eco_robustness* command has a power-aware flow to minimize the ECO impact on the power.

After robustness ECO fixing, you can write out the design changes as a script by using the *write_changes* command. You can use this script to implement the same changes in another PrimeTime session, or in another tool such as the IC Compiler II tool. The list of design changes created in this flow is called an engineering change order (ECO).

Setup Fixing

The *fix_eco_robustness* command attempts to improve the timing slack of the setup variation critical endpoints in order to achieve a 99.865% (3 sigma) joint success rate (JSR) in setup timing. You must run the *get_design_variation* and *report_design_variation* commands before performing setup robustness ECO fixing. The *fix_eco_robustness* command takes the object argument by variable reference. For example,

```
set dvar [get_design_variation -sample_size 100000 $max_path]
report_design_variation -target_success_rate 0.99865 $dvar
fix_eco_robustness -type setup -object dvar
```

The default fixing method for setup fixing is *size_cell*. ECO fixing replaces cells with lower variation cells or higher drive strength cells to improve the path's variability. You can specify VT patterns by using the *-robustness_pattern_priority* option. This ensures the ECO only performs pattern-based VT swap.

Hold Fixing

The *fix_eco_robustness* command attempts to improves the timing slack of the hold variation critical endpoints in order to achieve a 99.865% (3 sigma) joint success rate (JSR) in hold timing. You must run the *get_design_variation* and *report_design_variation* commands before hold robustness ECO fixing. The *fix_eco_robustness* command takes the object argument by variable reference. For example,

```
set dvar [get_design_variation -sample_size 100000 $min_path]
report_design_variation -target_success_rate 0.99865 $dvar
fix_eco_robustness -type hold -object dvar \\
  -buffer_list {BUFFD1 BUFFD2 BUFFD6 BUFFD8}
```

The default fixing methods for hold fixing are both *size_cell* and *insert_buffer*. Both methods aim to improve the hold timing JSR by improving the worst timing slack of the hold critical endpoints. The *-robustness_pattern_priority* option does not apply to hold fixing.

Bottleneck Fixing

The *fix_eco_robustness* command tries to reduce the design's High Sigma Failure Rate (HSFR) by VT swap and cell sizing. Variation bottleneck analysis applies only to setup

timing; it does not apply to hold timing. You must run the *get_design_variation* and *report_variation_bottleneck* commands before performing robustness bottleneck ECO fixing. The command takes the object argument by variable reference. For example,

```
set dvar [get_design_variation -sample_size 100000 $max_path]
report_variation_bottleneck -max_violators 50000 -pba
fix_eco_robustness -type bottleneck -object dvar \\
  -robustness_pattern_priority {LVT SVT HVT}
```

The default fixing method is *size_cell*. You must specify one or both of the *-robustness_pattern_priority* and *-sizing_pattern_regexp* options. If both options are provided, ECO fixing prioritizes VT swap over cell sizing.

Cell Robustness Fixing

Cell robustness analysis uses the same High Sigma Failure Rate calculation algorithm as the variation bottleneck analysis, except that it does not require the *get_timing_path* and *get_design_variation* commands. Therefore, you do not need to provide an object argument to the *fix_eco_robustness* command. For example,

```
fix_eco_robustness -type variation_robustness \\
  -robustness_pattern_priority {LVT SVT HVT}
```

The default fixing method is *size_cell*. You must specify one or both of the *-robustness_pattern_priority* and *-sizing_pattern_regexp* options. If both options are provided, ECO fixing prioritizes VT swap over cell sizing.

Voltage Robustness Fixing

Voltage robustness ECO targets the weak cells that are sensitive to voltage drop in the design that could lower a path's voltage slack. After running voltage robustness ECO fixing, an average voltage slack improvement is expected; that is, the average post-ECO voltage slack is greater than the average pre-ECO voltage slack.

```
fix_eco_robustness -type variation_robustness \\
  -robustness_pattern_priority {LVT SVT HVT}
```

The default fixing method is *size_cell*. You must specify one or both of the *-robustness_pattern_priority* and *-sizing_pattern_regexp* options. If both options are provided, ECO fixing prioritizes VT swap over cell sizing.

Voltage Slack Fixing

Voltage slack ECO prioritizes fixing paths with smaller voltage slack to improve the design's resilience to IR drops. You must first define a voltage target by setting the *eco_voltage_slack_target* variable before using the *get_timing_paths* command. You must also provide the path object to the command by reference using the *-object* option. ECO

fixing attempts to improve the voltage slack of the given path to be greater than or equal to the specified target voltage slack value. For example,

```
set eco_voltage_slack_target 0.02
set path [get_timing_path -vdd_slack_lesser_than 0.02 \\
  -pba_mode exhaustive -path full_clock_expanded]
fix_eco_robustness -type voltage_slack -object path
```

The default fixing method is *size_cell*. ECO fixing replaces cells on the critical path with lower variation or bigger drive strength cells to improve the voltage slack. You can specify a VT pattern by using the *-robustness_pattern_priority* option. This ensures that ECO fixing performs only pattern-based VT swaps.

Pattern Priority and Sizing Pattern Regular Expression

The *bottleneck*, *variation_robustness*, and *voltage_robustness* fixing types require one or both of the *-robustness_pattern_priority* and *sizing_pattern_regexp* options. The *fix_eco_robustness* command uses the provided pattern for pattern-based sizing. Setup and voltage slack can only accept the *-robustness_pattern_priority* option.

For the *-robustness_pattern_priority* option, specify the VT patterns in the order of lowest variation VT type to highest variation VT type.

Assume the following three types of library cells are available in the design:

```
*/BUFF_D1_L10_UL
*/BUFF_D1_L10_L
*/BUFF_D1_L10_S
```

The pattern "UL" represents the lowest variation whereas "S" represents the highest variation. Set the pattern as follow:

```
fix_eco_robustness -type variation_robustness \\
  -robustness_pattern_priority {_L10_UL _L10_L _L10_S}
```

The tool swaps the critical cell to an "L10_L" cell if it is an "L10_S" cell. It swaps to an "L10_UL" cell if it is an "L10_L" cell. The tool only swaps one type up in every ECO iteration, which means it never swaps from an L10_S cell to an L10_UL cell in one iteration.

Avoid specifying a non-unique pattern list such as {UL L S}. This is because the command uses a simple wildcard matching technique to match the patterns to the lib cells names. You can validate the patterns by using the command *report_eco_library_cells -robustness_pattern_priority*, which reports alternative library cells with the given pattern.

For the *-sizing_pattern_regexp* option, specify the sizing pattern in the regular expression. Assume the following three types of library cells are available in the design:

```
*/BUFF_D1_L10_UL
*/BUFF_D2_L10_UL
*/BUFF_D3_L10_UL
```

"D1" represents the lowest drive strength and "D3" represents the highest drive strength. Specify the command as follows:

```
fix_eco_robustness -type variation_robustness \\
  -sizing_pattern_regexp {_D[0-9]+_}
```

You can specify both the *-robustness_pattern_priority* and *-sizing_pattern_regexp* options concurrently. In this case, ECO fixing uses the VT swap method first, using the priority pattern, until it reaches the lowest VT pattern. Then, it performs cell sizing using the sizing pattern.

```
fix_eco_robustness -type variation_robustness \\
  -sizing_pattern_regexp {_D[0-9]+_} \\
  -robustness_pattern_priority {_L10_UL _L10_L _L10_S}
```

If needed, you can specify multiple pattern sets separated by ";":

```
fix_eco_robustness -type variation_robustness \\
  -robustness_pattern_priority {_L10_UL _L10_L _L10_S;_LL _SS}
fix_eco_robustness -type variation_robustness \\
  -sizing_pattern_regexp {_D[0-9]+_;D_[0-9]+}
```

Information messages indicate the successful configuration of the VT and sizing patterns.

```
...
Information: Found 591 sets of vt patterns.
Information: Found 449 sets of sizing patterns.
 ...
```

Power-Aware Robustness ECO

There are two power-aware options for *fix_eco_robustness*: *-power_attribute* and *-power_mode*.

The *fix_eco_robustness* command supports the *-power_attribute* for all ECO fixing types. ECO fixing optimizes power during robustness fixing based on the defined power attribute value. For example, create a user-defined attribute "leak_attr" for lib_cell object:

```
# Create a user-defined attribute "leak_attr" for lib_cell object
define_user_attribute leak_attr -type float -class lib_cell

# Assign values that reflect leakage of each lib_cell at worst corner
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV1X_HVT] leak_attr
 1.0
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV2X_HVT] leak_attr
 2.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV1X_LVT] leak_attr
 10.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV2X_LVT] leak_attr
 15.0
 ...
```

The *-power_attribute* option can be specified with the *-leakage_budget_ratio* option, which controls the maximum power impact a design can have after ECO fixing. For *variation_robustness*, *voltage_robustness*, and *bottleneck* fixing types, you must use the *-leakage_budget_ratio* option together with the *-power_attribute* option. For the *setup*, *hold*, and *voltage_slack* fixing types, the *-leakage_budget_ratio* option is optional because these fixing types use the same power optimization technique as in the *fix_eco_timing* command.

```
# Run power-aware voltage slack ECO
fix_eco_robustness -type voltage_slack \\
  -power_attribute leak_attr

# Run power-aware voltage slack ECO with maximum 2% power impact
fix_eco_robustness -type voltage_slack \\
  -power_attribute leak_attr -leakage_budget_ratio 0.02

# Run cell robustness ECO with maximum 1% power impact
fix_eco_robustness -type variation_robustness \\
  -power_attribute leak_attr -leakage_budget_ratio 0.01
```

Only the *setup*, *hold*, and *voltage_slack* fixing methods support the *-power_mode* leakage option. With the *-power_mode* leakage option, the tool fixes the violations considering leakage power without requiring user-defined power attributes. This mode requires the power data to be ready by running *update_power* or *report_power* before ECO fixing.

```
set power_enable analysis true
report_power
fix_eco_robustness -power_mode leakage -leakage_scenario tt_lkg
```

Physically-Aware Robustness ECO

Set the *-physical_mode* option to *open_site* to enable the command to load physical data into memory and use that data while fixing robustness violations. Before you run the *fix_eco_robustness* command, use the *set_eco_options* command to specify the paths to the physical data, either IC Compiler II database files or LEF/DEF library and design data exchange files.

To consider 3nm physical rules, you must enable the advanced legalization mode by using the *-legalize* option. The advanced legalizer requires IC Compiler II reference library in the seesion, and the tool errors out if the physical data is not available.

All physically-aware robustness ECOs are in-place changes, which means that the tool searches free space and upsizes the instance in the same location without moving surrounding cells.

Fixing Summary

After completing *variation_robustness*, *bottleneck*, or *voltage robustness* ECO, the command prints an ECO summary. In the summary, the pre-ECO values such as the "Total cell found" and "Total slack found" are the total violators found and total slack found in all

ECO iterations. Other values, like "Total percentage fixed" and "Total cell remaining", are estimated. These estimated numbers are generally very close compared to the golden numbers found in the post-ECO analysis. The prediction algorithm is designed to estimate the ECO trend without an extra time cost. It is highly recommended that you run a post-ECO analysis to get the golden values.

```
Fixing Summary:
-------------------------------------------------------
Total robustness cell found                        66
Total robustness cell fixed                        63
Total robustness cell remaining                    3
Total percentage of cells fixed                    95.45%

Total robustness_slack found                       -4.56
Total robustness_slack remaining                   -0.44
Total percentage of robustness_slack reduced       90.35%
```

Unfixable reasons

After running ECO fixing for the *variation_robustness*, *bottleneck*, and *voltage_robustness* fixing types, the command generates a summary to show the unfixable reasons for the remaining cells. Below are the unfixable messages and the corresponding definitions:

```
01) Not covered in patterns:        The violator is not covered in either
 VT or sizing pattern
02) Dont touch:                     The violator is a dont_touch cell
03) Clock cell:                     The violator is a clock component
06) Lowest pattern already:         Current library cell is the lowest
 pattern already
07) No available candidates:        All swappable cells have a dont_use
 attribute
08) Hold critical:                  The violator has hold timing
 violations. ECO can further degrade hold timing.
09) Physical rule:                  ECO violates physical rules
10) Hold timing degrade:            ECO can cause hold timing degradation
11) Setup timing degrade:           ECO can cause setup timing
 degradation
12) Cells attributes restriction:   ECO doesn't meet attribute
 restriction
14) Not enough space:               Not enough space for sizing
16) Sequential cell:                The violator is a sequential cell
17) Combinational cell:             The violator is a combination cell
19) Advanced legalizer:             ECO violates N3 physical rules
20) Leakage budget limit:           ECO exceeds maximum leakage impact
 allowance
21) Cannot be further improved:     Cannot further improve robustness
 slack
```

Feedback

Distributed Multi-Scenario Analysis (DMSA)

Run the *fix_eco_robustness* command in the DMSA manager only. If you have multiple scenarios, the command requires at least one scenario that has robustness violations. Other scenarios will be considers for timing impact only during ECO fixing.

Examples

The following example fixes design variation bottleneck cells using the VT swap. The "LVT" type cells have the lowest variation. The "HVT" type cells have the highest variation. The VT pattern can be expressed as {LVT SVT HVT} in the order of lowest sensitivity to highest sensitivity.

```
prompt> set path [get_timing_path -pocv_pruning -pba_mode exhaustive \\
          -path_type full_clock_expanded \\
          -nworst 10 -max_paths 10000 \\
          -slack_lesser_than 1.0]
prompt> set dvar [get_design_variation -sample_size 100000 $max_path]
prompt> report_variation_bottleneck -max_violators 10000
prompt> fix_eco_robustness -type bottleneck -object dvar \\
          -robustness_pattern_priority {LVT SVT HVT}
```

The following example fixes voltage robustness cells with 10% voltage drop using a sizing pattern. The sizing pattern can be expressed as "_D[0-9]+_" in regular expression form.

```
prompt> report_cell_robustness -type voltage \\
          -max_violators 10000 -pba \\
          -voltage_shift_ratio 0.1
prompt> fix_eco_robustness -type voltage_robustness \\
          -sizing_pattern_regexp {_D[0-9]+_} \\
          -voltage_shift_ratio 0.1
```

The following example fixes cell robustness cells found in register-to-register paths using the VT swap. The VT pattern can be expressed as {LVT SVT HVT} in the order of lowest sensitivity to highest sensitivity.

```
prompt> report_cell_robustness -type variation_robustness \\
          -max_violators 10000 -pba -start_end_type reg_to_reg
prompt> fix_eco_robustness -type variation_robustness \\
                    -robustness_pattern_priority {LVT SVT HVT} \\
                    -start_end_type reg_to_reg
```

The following example shows how to fix setup design variation violations with the power-aware flow using user-defined power attribute values

```
prompt> report_cell_usage -power_attr pwr_attr
prompt> set path [get_timing_path -pocv_pruning -pba_mode exhaustive \\
          -path_type full_clock_expanded \\
          -nworst 10 -max_paths 10000 \\
          -slack_lesser_than 1.0]]
prompt> set dvar [get_design_variation -sample_size 100000 $max_path]
```

Feedback

```
prompt> fix_eco_robustness -type setup -object dvar \\
          -power_attribute pwr_attr \\
          -robustness_pattern_priority {LVT SVT HVT}
```

The following example shows how to run physical-aware voltage slack ECO with the target slack equals 0.02V.

```
prompt> set_eco_options \\
          -physical_tech_lib_path $LEF_tech_file_list \\
          -physical_lib_path $LEF_lib_file_list \\
          -physical_design_path $DEF_design_file_list

## This variable must be set before get_timing_path, otherwise the ECO
 will error out
prompt> set eco_voltage_slack_target 0.02
prompt> set path [get_timing_path -vdd_slack_lesser_than 0.02 \\
           -pba_mode exhaustive \\
           -path_type full_clock_expanded \\
           -nworst 10 -max_paths 10000 \\
           -slack_lesser_than 1.0]
prompt> fix_eco_robustness -type voltage_slack \\
           -object path -physical_mode open_site
```

The following example shows how to run voltage slack ECO in DMSA mode.

```
prompt> set eco_voltage_slack_target 0.02
prompt> remote_execute -v { \\
          set eco_voltage_slack_target 0.02
          set path [get_timing_path -vdd_slack_lesser_than 0.02 \\
            -pba_mode exhaustive \\
            -path_type full_clock_expanded \\
            -nworst 10 \\
            -max_paths 10000 \\
            -slack_lesser_than 1.0]
           }
prompt> fix_eco_robustness -type voltage_slack \\
          -object path -physical_mode open_site
```

fix_eco_timing

Fixes or improves timing violations through engineering change orders (ECOs).

Syntax

```
status fix_eco_timing
   -type setup | hold
   [-methods method_list]
   [-slack_lesser_than slack_limit]
   [-slack_greater_than slack_limit]
   [-group group_name]
   [-pba_mode none | path | exhaustive | ml_exhaustive]
   [-from from_list]
   [-to to_list]
   [-setup_margin margin]
   [-hold_margin margin]
   [-buffer_list list]
   [-verbose]
   [-current_library]
   [-ignore_drc]
   [-cell_type combinational | sequential | clock_network]
   [-physical_mode none | open_site | occupied_site | freeze_silicon]
   [-path_selection_options option_string]
   [-timeout seconds]
   [-power_attribute power_attribute_name]
   [-clock_fixes_per_change violation_limit]
   [-clock_max_level_from_reg level_limit]
   [-estimate_unfixable_reasons]
   [-power_mode total | dynamic | leakage]
   [-leakage_scenario scenario_name]
   [-dynamic_scenario scenario_name]
   [-load_cell_list list]
   [-target_violation_type violation_type]
   [-wns_limit wns_value]
   [-unfixable_reasons_format text | csv]
   [-unfixable_reasons_prefix string]
```

Data Types

```
method_list          list
slack_limit          float
group_name           string
from_list            list
to_list              list
margin               float
list                 list
option_string        string
```

```
seconds                integer

scenario_name          string
violation_type         string
wns_value              float
string                 string
```

Arguments

`-type setup | hold`

Specifies fixing of either *setup* (maximum delay) or *hold* (minimum delay) timing violations.

`-methods method_list`

Specifies one or more fixing methods from the following list:

- *size_cell* - Replaces cells in the timing path with logically identical cells that have a different drive strength.
- *size_cell_side_load* - Same as *size_cell*, but also replaces cells in the fanout of drivers in the path with logically identical cells to reduce parasitic load capacitance along the path (used only for *-type setup* fixing).
- *insert_buffer* - Inserts buffers in the timing path, using the library cells specified by the *-buffer_list* option. By default, the *insert_buffer* method considers buffer insertion at driver pins, load pins, and on-route.
- *insert_buffer_at_load_pins* - Inserts buffers only at load pins, not at driver pins or on-route.
- *insert_buffer_at_driver_pins* - Inserts buffers only at driver pins, not at load pins or on-route.
- *insert_inverter_pair* - Inserts pairs of inverter cells instead of buffer cells; cannot be used together with the *insert_buffer* method
- *bypass_buffer* - Bypasses buffers or inverter pairs in a clock network; can be used only when the *clock_network* cell type is specified.
- *remove_buffer* - Removes buffers to improve setup timing without introducing or worsening hold timing and DRC violations.

For setup fixing (*-type setup*), you can specify either *size_cell* or *size_cell_side_load*; the default is *{size_cell_side_load}*. You can use the *insert_buffer* method alone or together with *size_cell* or *size_cell_side_load* if the *-physical_mode* option is set to either *open_site* or *occupied_site*; for the *freeze_silicon* setting, *insert_buffer* is the only method allowed. To insert buffers

only at driver pins, use the *insert_buffer_at_driver_pins* method without the *insert_buffer* method.

For hold fixing (*-type hold*), you can specify one or more of the methods *size_cell*, *insert_buffer*, *insert_buffer_at_load_pins*, and *insert_inverter_pair*; the default is *{size_cell insert_buffer}*. To insert buffers only at load pins, use the *insert_buffer_at_load_pins* option without the *insert_buffer* option.

The *insert_inverter_pair* method inserts inverter pairs both at driver and load pins, choosing from the inverter library cells specified by the *-buffer_list* option. This method works well together with *size_cell* (*-methods {size_cell insert_inverter_pair}*).

The *remove_buffer* method has the following restrictions:

- It cannot be used with any of the following options: *-cell_type*, *-power_attribute*, *-current_library*, *-load_cell_list*, *-timeout*, *-unfixable_reasons_format*, *-unfixable_reasons_prefix*, and *-power_mode*.
- In setup fixing, it cannot be combined with other methods; it must be used by itself.
- It cannot be used in hold fixing.

`-slack_lesser_than` *`slack_limit`*

Specifies fixing of only the paths with a slack worse than the specified slack limit. The default is zero, which attempts to fix all timing violations.

`-slack_greater_than` *`slack_limit`*

Specifies fixing of only the paths with a slack better than the specified slack limit. By default, the command tries to fix all timing violations. You can use this option to avoid consideration of paths with very negative slacks caused by known design problems or constraints, while still considering less extreme violations.

You can combine the *-slack_lesser_than* and *-slack_greater_than* options to fix paths that have a slack within a specified range.

`-group` *`group_name`*

Restricts fixing to paths that belong to the specified path groups. By default, paths are divided into groups according to the clock that captures data at the path endpoint; a path group is created by each *create_clock* command. You can also create path groups explicitly by using the *group_path* command. You can specify multiple path groups by using a list of group names (wildcards allowed) or a collection created by the *get_path_groups* command.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Specifies one of the following timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode.
- *ml_exhaustive* - Performs machine learning based exhaustive path-based analysis. This mechanism will deploy machine learning techniques to trade runtime vs accuracy during the design flow. Accuracy and runtime will match the *-pba_mode exhaustive* option as the design approaches signoff.

This option works like the *-pba_mode* option in the *report_timing* and *get_timing_paths* commands. The fixing process uses the specified analysis mode to find the timing violations that need to be fixed.

`-from` *`from_list`*

Specifies a list of "from" pins or ports. Only the timing paths that start from the specified objects are considered for fixing.

`-to` *`to_list`*

Specifies a list of "to" pins or ports. Only the timing paths that end at the specified objects are considered for fixing.

The *-from* and *-to* options are like the options of the same name in the *report_timing* and *get_timing_paths* commands, except that you can only specify pins or ports, not nets or cells, as the objects. The default behavior is to consider all pins and ports, and to select the path with the worst slack within each path group.

`-setup_margin` *`margin`*

Specifies an additional margin for setup fixing, in library time units. The default margin is zero. This option affects the target amount of timing slack to achieve during setup fixing, or the minimum amount of setup margin to maintain during hold fixing. Use this option together with the *-slack_lesser_than* option, specifying a positive slack value, to target fixing of paths with positive slack and obtain the desired margin.

During setup fixing, a positive margin specifies overfixing, which attempts to achieve the specified positive slack value. A negative margin specifies

underfixing, which attempts to improve the timing and achieve the specified negative slack value. For paths not already selected for setup fixing (by default, paths with zero or better slack), there is no attempt to change the path to meet the margin requirement; only paths already targeted for setup fixing are modified.

During hold fixing, the tool attempts to preserve the specified setup margin while making changes to fix hold violations.

`-hold_margin` *`margin`*

Specifies an additional margin for hold fixing, in library time units. The default margin is zero. This option affects the target amount of timing slack to achieve during hold fixing, or the minimum amount of hold margin to maintain during setup fixing. Use this option together with the *-slack_lesser_than* option, specifying a positive slack value, to target fixing of paths with positive slack and obtain the desired margin.

During hold fixing, a positive hold margin specifies overfixing, which attempts to achieve the specified positive slack value. A negative margin specifies underfixing, which attempts to improve the timing and achieve the specified negative slack value. For paths not already selected for hold fixing (by default, paths with zero or better slack), there is no attempt to change the path to meet the margin requirement; only paths already targeted for hold fixing are modified.

During setup fixing, the tool attempts to preserve the specified hold margin while making changes to fix setup violations.

In the absence of explicit setup and hold values provided by the user, the tool tries to preserve DRC and timing by default, however, the results might not match explicit settings of *-setup_margin 0.0* and *-hold_margin 0.0*.

`-buffer_list` *`buffer_list`*

Specifies the list of library cell buffers that can be used with the *insert_buffer* method or inverters that can be used with the *insert_inverter_pair* method. To use the *insert_buffer* or *insert_inverter_pair* method, you must also use the *-buffer_list* option to specify the allowed library cells; there is no default list.

Specify the list of buffers using simple library cell base names, without the library name. The command gets the buffer cells from the libraries listed in the *link_path* variable. It searches the libraries in order and uses the first library cell found with a matching name.

The command can use a listed library cell for buffer insertion even if its *dont_use* attribute is set to *true*. The *dont_use* attribute applies only to cell sizing.

In hold fixing, if you use *-methods {size_cell insert_buffer}*, the command can insert a buffer from the list and then size it to a different buffer, even if the sized library cell is not explicitly included in the *-buffer_list* list.

`-verbose`

Shows additional information during the fixing process. In distributed multi-scenario analysis, violation information from each scenario is displayed.

The verbose mode also generates an "Unfixable Violations" report upon completion of fixing if the *eco_report_unfixed_reason_max_endpoints* variable is set to a positive integer. The report shows a list of pins where fixing was considered, the reason that the fix was not performed at the pin, and the fixing priority for the pin. For details, see "Unfixable Violation Report" in the DESCRIPTION section of this man page. To generate the report without actually performing any fixing, use the *-estimate_unfixable_reasons* option.

`-current_library`

Specifies the usage of library cells from the same library when performing cell sizing. With this option, the replacement cell must come from the same library as the original cell. This option can improve runtime because fewer cells are considered as potential replacements. However, it might degrade quality of results because the variety of available alternative library cells could be reduced.

`-ignore_drc`

Causes timing fixing to ignore DRC violations. By default, timing fixing is not performed when there are any existing DRC violations on the path (max_transition, max_capacitance, and max_fanout violations). With this option, the command proceeds with timing fixing without considering DRC violations, possibly worsening those violations.

`-cell_type combinational | sequential | clock_network`

Specifies the type of cells to be modified for timing fixing:

- *combinational* (the default) - Fixing is performed by sizing or inserting combinational logic cells in the data path.
- *sequential* - Fixing is performed by sizing sequential cells to fix violations at the sequential cell's input or output pin. Only the *size_cell* fixing method (*-methods size_cell*) is supported for this type of fixing.
- *clock_network* - Fixing is performed by sizing, inserting combinational cells, or bypassing combinational cells in the clock network, thereby changing clock arrival times.

You can specify just one of these options, or both *combinational* and *sequential* together to fix both cell types simultaneously.

The *sequential* and *clock_network* type modifications can adversely affect clock tree timing, so you should try *combinational* type fixing first and only apply the other types afterward if needed.

`-physical_mode none | open_site | occupied_site | freeze_silicon`

Specifies the usage of physical data to size cells or place buffers:

- *none* (the default) - Timing fixing does not use physical data. For setup fixing using buffer insertion (*-type setup -methods {insert_buffer ...}*), you must use physical data by choosing one of the other physical mode options.
- *open_site* - Timing fixing sizes a cell only if there is enough room available around the cell and inserts a buffer only if there is an empty site with enough room to accept the new cell without moving nearby cells. This mode retains the placement of existing cells.
- *occupied_site* - Timing fixing can size a cell and insert a buffer that overlaps existing neighbor cells, as long as the cell density (area utilization) is low enough that the nearby cells can be moved to make the required space. After the change is made, you need to use a physical implementation tool such as IC Compiler II to move the existing cells and create room for the sized or inserted cell.
- *freeze_silicon* - Timing fixing uses spare cells defined in the physical data files and identified by the *-programmable_spare_cell_names* option of the *set_eco_options* command; it does not insert new cells or size existing cells. This mode works with the IC Compiler II physical implementation tool. For details, see "Physically Aware Freeze Silicon Flow" in the DESCRIPTION section.

`-path_selection_options` *`option_string`*

Specifies the path selection options for the *get_timing_paths* command, which the *fix_eco_timing* command uses to collect timing paths for fixing. Because fixing is performed only on these paths, to check the quality of results after fixing, use the *get_timing_paths* or *report_timing* command with the same options.

The *-path_selection_options* option cannot be used together with the *-from*, *-to*, *-group*, *-pba_mode*, *-slack_lesser_than*, or *-slack_greater_than* options.

The *-path_selection_options* option

- Supports only the options of the *get_timing_paths* command that are relevant to ECO timing fixing.
- Must be enclosed with curly braces { } when it contains any collection.
- Must explicitly use the *-max_paths* and *-nworst* options with values that are suitable for timing fixing unless either the *-start_end_pair* or *-cover_design* option is used.

`-timeout` *`seconds`*

Specifies a timeout limit, in seconds, that sets a maximum total runtime for the command. At the end of each fixing iteration, the tool checks the total elapsed wall clock time. If the time limit is reached, the command stops running and ends with the current iteration. If you do not use this option, the command does not directly consider the total elapsed time. Instead, it considers quality of results, fix rate, and expected benefits of running more iterations.

`-power_attribute` *`power_attribute_name`*

Specifies a user-defined attribute for library cells that defines the leakage power of the library cell at the worst operating condition corner for leakage. When you use this option, timing fixing attempts to minimize the increase in leakage by giving higher priority to library cells with less leakage. By default, without this option, timing fixing considers area instead of leakage.

`-clock_fixes_per_change` *`violation_limit`*

Specifies the minimum number of violations to be fixed per cell sizing, buffer insertion, or inverter pair insertion in the clock network. This setting has an effect only if the *-cell_type* option is set to *clock_network*. The default is 1. Set this option to a value larger than 1 to reduce the number of changes made to the clock network.

For example, if you set this option to 4, the command makes a change in the clock network only if the change fixes at least 4 violating endpoints at leaf sequential cells in the transitive fanout of the change. Setting a larger value reduces the number of changes and also forces them to occur at higher levels of the clock network, closer to the clock source and farther from the sequential cells.

`-clock_max_level_from_reg` *`level_limit`*

Specifies the highest level of a clock network tree in which timing fixes can occur. The higher the level is, the closer the fix is performed to the clock source. This option has an effect only if the *-cell_type* option is set to *clock_network*. The default is 0, which disables the limit and allows changes anywhere in the clock network.

Setting this option to 1 allows changes to be made only at the immediate driver cell to a clock pin of a sequential cell. In this case, the command can size the immediate driver or insert a buffer between this driver and the clock pin of the sequential cell. Setting this option to 2 allows the command to make these changes at both the immediate driver and one buffer level above the immediate driver; and so on for larger settings.

`-estimate_unfixable_reasons`

Performs a fixing analysis (without actually making any changes) and generates a report on violations that are unlikely to be fixed and the reasons that they are unfixable. This option is similar to the *-verbose* option, except that no actual fixing is performed; only the report is generated. To use this option, the *eco_report_unfixed_reason_max_endpoints* variable must be set to a positive integer (the default is 0). For details, see "Unfixable Violation Report" in the DESCRIPTION section.

`-power_mode total | dynamic | leakage`

Specifies usage of PrimePower power analysis data, and specifies the types of power considered during timing fixing: *dynamic* power only, *leakage* power only, or *total* power (both dynamic and leakage). Power analysis data must be available from previous usage of the *update_power* or *report_power* command. You cannot use the *-power_mode* option with the *-power_attribute* or *-cell_type clock_network* option.

When you use the *-power_mode* option for setup fixing, the tool tries to minimize the increase in the specified type of power by giving higher priority to library cells that use less power. This includes side-load sizing by the *-methods size_cell_side_load* option.

Similarly, for hold fixing, the tool prioritizes the library cells with lower power during cell sizing and buffer insertion.

By default, without the *-power_mode* option, timing fixing considers area instead of power.

`-leakage_scenario` *`scenario_name`*

Specifies the name of the scenario from which to get the leakage power data in a DMSA flow when using the *-power_mode* option. It should be the scenario with the worst leakage power.

`-dynamic_scenario` *`scenario_name`*

Specifies the name of the scenario from which to get the dynamic power data in a DMSA flow when using the *-power_mode* option. It should be the scenario with the worst dynamic power.

The *-leakage_scenario* and *-dynamic_scenario* options can be set to the same scenario or two different scenarios.

`-load_cell_list` *`list`*

Specifies a list of library load capacitance cells, buffer cells, or inverter cells that can be used along the data path for hold fixing with the *insert_buffer* method. You can specify usage of these special single-pin cells to fix hold violations on the order of picoseconds, either alone or together with the *-buffer_list* option.

`-target_violation_type endpoint | tns`

Specifies the target violation type for clock network fixing. This option can be used only when *clock_network* is specified for the *-cell_type* option.

- *endpoint* (the default) - Timing fixing targets improvement of endpoint slack for each endpoint without degrading any existing endpoint violation.
- *tns* - Timing fixing targets improvement of overall Total Negative Slack (TNS). It might degrade existing endpoint violations even further, up to the current Worst Negative Slack (WNS) as long as TNS improves. If the *-wns_limit* option is used, it allows degradation of existing endpoint violations to the specified WNS limit.

Note: The *tns* value requires a PrimeTime-ADV license.

`-wns_limit limit_value`

Specifies the limit of Worst Negative Slack (WNS) for the *-target_violation_type tns* option. The default is the existing WNS.

`-unfixable_reasons_format text | csv`

Generates an unfixable reasons report file in the specified format, either *text* or *csv* (comma-separated values). The CSV report format is compatible with the PrimeTime GUI and spreadsheet programs. By default, without this option, both *text* and *csv* files are generated.

`-unfixable_reasons_prefix string`

Specifies a prefix used for naming the file generated by the *-unfixable_reasons_format* option. For example, specifying the prefix "abc" and using the CSV format writes out a file named abc_eco_tim.csv. If you omit this option, no files are generated.

Description

The *fix_eco_timing* command fixes or improves timing violations by sizing cells and inserting buffers or inverter pairs. It attempts to fix the specified types of violations while minimizing the impact on area and power.

After the violations are fixed, you can write out the design changes as a script by using the *write_changes* command. You can use the script to implement the same changes in another PrimeTime session or another tool (Design Compiler, IC Compiler, or IC Compiler II). A list of design changes created in this flow is called an engineering change order (ECO).

The *fix_eco_timing* command has options to specify the following fixing parameters:

- The type of timing violations to fix (setup or hold)
- The scope of the design to be fixed (from/to startpoints/endpoints, path groups, a path collection, or the whole design)
- The fixing methods (cell sizing, buffer insertion, or inverter pair insertion)
- The list of library cells that can be used for buffer or inverter pair insertion
- The types of cells to be modified (data paths, sequential cells, or clock networks)
- The targeted amount of timing margin (slack) to achieve
- The graph-based analysis mode (graph-based, path-based, or path-based exhaustive)
- The physical placement and sizing mode (none, open site, occupied site, or freeze silicon)

You must specify the fixing type, either *setup* or *hold*, using the *-type* option because of the different nature of these violations. By default, setup fixing uses cell sizing alone to reduce data path delays, whereas hold fixing uses both cell sizing and buffer insertion to increase data path delays. By default, fixing occurs only in data paths, not in clock networks.

The command performs fixing using multiple iterations, starting with the worst violations. It repeats fixing iterations until all violations are fixed or it determines that further fixing is not worth the runtime cost, based on the current quality of results and fixing option settings. You can generate a report on unfixable violations by using the *-verbose* or *-estimate_unfixable_reasons* option. Based on the report, you can target the unfixed violations using another *fix_eco_timing* command with different option settings.

Setup fixing seeks to avoid introducing design rule checking (DRC) violations, but it is allowed to introduce hold violations because setup violations are harder to fix. Hold fixing seeks to avoid introducing both setup and DRC violations. To fix both setup and hold violations, fix setup violations first, then hold violations, using separate *fix_eco_timing* commands.

The *fix_eco_timing* command is compatible with single-core analysis, distributed multi-scenario analysis (DMSA), and multicore analysis. To ensure consistent results during DMSA fixing, apply any *dont_touch*, *dont_use* and *size_only* attributes identically to all scenarios.

The *-from*, *-to*, *-path_selection_options*, and *-group* options allow targeted fixing of the design. The *-from* and *-to* options restrict fixing to paths with specific startpoints and endpoints. The *-path_selection_options* restricts fixing to a path collection created in a manner similar to the *get_timing_paths* command. The *-group* option restricts fixing to named path groups.

The *fix_eco_timing* command requires pin slack information. If the *timing_save_pin_arrival_and_slack* variable is not already set to *true*, the *fix_eco_timing* command automatically sets it to *true* and updates the design with arrival and slack information.

The *fix_eco_timing* command is intended for the signoff flow using delay and slew calculation in the PrimeTime tool, based on extracted parasitic data. If delays and slews are annotated directly (for example, in SDF format), the quality of results cannot be guaranteed.

Setup Fixing

By default, setup fixing uses cell sizing alone to reduce data path delays. You can specify the maximum area increase by setting the *eco_alternative_area_ratio_threshold* variable. By default, the variable is set to 2, which limits the area increase to twice the area of the cell before fixing. Note that this limit applies to *each iteration* of setup fixing, so in multiple fixing iterations, the final size can be more than twice the original size. If you set the variable to 0, there is no size limit on upsizing.

Limiting the area increase can result in better timing predictability after physical implementation of the ECO changes, as the changes are less likely to disturb the existing layout during incremental placement and routing. However, more changes (and more runtime) might be required to achieve the needed slack improvement.

In addition to cell sizing, you can use buffer insertion (*-methods {insert_buffer}*) to reduce path delays to critical loads. It is recommended that you perform cell sizing first, using a separate *fix_eco_timing* command, to reduce the number of buffers required and minimize the layout disturbance.

For setup fixing using buffer insertion, the *-physical_mode* option must be set to *open_site*, *occupied_site*, or *freeze_silicon*. The fixing rate depends very much on having empty sites available in the layout. Using the *-buffer_list* option, specify a good representative set of buffers that cover the necessary delay and area range. Be sure to specify buffers with good drive strength and short delays, and omit buffers with long delays.

Buffers and delay cells placed by the hold fixing tool might hurt setup paths. To remove the redundant buffers that cause the setup violation, use the *-methods {remove_buffer}* otion. A buffer in a setup violation path is removed if the following conditions are met:

- It does not worsen existing violations or does not cause the slack to become worse than the margins set by the *-hold_margin* or *-setup_margin* options.
- Removing the buffer does not introduce any new DRC violations: *max_transition*, *max_capacitance*, or *max_fanout*.

The *fix_eco_timing -methods {remove_buffer}* command only removes buffer cells. To also perform cell sizing for setup fixing, use a separate *fix_eco_timing* command with appropriate option settings.

Hold Fixing

By default, hold fixing uses both cell sizing and buffer insertion to increase delays in the data path (*-methods {size_cell insert_buffer}*). You can choose to use these methods separately or together. When used together, the command performs cell sizing first, then buffer insertion, to reduce the number of buffers required and minimize the layout disturbance. Cell sizing includes downsizing, upsizing, and same-size cell replacement of buffer and delay cells to fix hold violations.

When using the *-buffer_list* option, specify a representative set of buffers that cover the necessary delay range. However, avoid specifying an excessive number of similar buffers, which can lead to longer runtimes with no fixing benefit.

To fix small hold violations (on the order of 5 ps or less), you can insert load capacitance cells in the data path instead of buffers. To insert load cells, use the *fix_eco_timing -type hold* with the *-load_cell_list* option with a list of load cells. If you use both the *-load_cell_list* and *-buffer_list* options in the same *fix_eco_timing* command, the tool automatically fixes small hold violations by inserting load cells and larger hold violations by inserting buffers.

Restricting the Library Cells Used for Sizing

To prevent the tool from using specific library cells for sizing, apply the *dont_use* attribute to these library cells with the *set_dont_use* command. Note that this usage restriction applies only to cell sizing, not buffer insertion. The tool uses buffers specified by the *-buffer_list* option, irrespective of the *dont_use* attribute.

Usage of library cells can also be restricted by applying the *pt_dont_use* user-defined attribute on the restricted lib_cell objects, which is a legacy feature. For an example of how to apply this attribute, see the EXAMPLES section.

Preserving Specific Cells and Nets During Fixing

To prevent the *fix_eco_timing* command from performing fixing on specific cells or nets, apply a *dont_touch* attribute to the cell or net. For example,

```
pt_shell> set_dont_touch [get_nets n123] true
```

The *fix_eco_timing* command does not size any cell with a *dont_touch* setting and does not insert a buffer or inverter pair on any net with a *dont_touch* setting.

If you apply a *dont_touch* setting to a hierarchical cell, that setting propagates downward to the child cells and nets of the hierarchical cell. You can override the *dont_touch* setting for specific lower-level cells and nets by setting the *dont_touch* attribute to *false* for those objects.

Preventing Specific Cell Instances From Being Removed

Among the cells, you might want to prevent specific instances from being removed but allow other sizing operations on them. To do this, use the *set_size_only* command. For example,

```
set_size_only [get_cells {U28}] true
```

This command sets the *size_only* attribute to *true* for cell instance U28, which prevents the cell from being removed by ECO commands.

Fixing Margin

The *-setup_margin* and *-hold_margin* options let you specify overfixing or underfixing of timing violations. By default, when the command finds a violation, it tries to fix the violation to attain a slack of zero. Setting a positive margin changes the target to the specified positive slack value (overfixing); this results in safer timing but requires more fixing effort. Conversely, specifying a negative margin changes the target to the specified negative slack value (underfixing); this does not completely fix the violation but is more likely to be successful.

Note that the margin setting affects only the target slack for violations being fixed; it has no effect on the choice of paths to be fixed. To choose violations for fixing based on existing slack values, use the *-slack_lesser_than* and *-slack_greater_than* options.

You can specify both a setup margin and a hold margin for a fixing operation. This can be useful during hold fixing because downsizing cells or inserting buffers in a data path to fix a hold violation can worsen setup timing for the same path. By specifying a setup margin of zero or more during hold fixing, the tool checks for setup timing effects and ensures that no new setup violations are introduced.

When you use path-based analysis (*-pba_mode* option set to *path* or *exhaustive*), the margin setting applies to path-based calculated slack only for the matching fixing type, either setup or hold. For example, during hold fixing (*-type hold*), the *-hold_margin* setting applies to the path-based slack being recalculated, whereas setup checking performed in the background uses graph-based analysis, so the *-setup_margin* setting applies to the graph-based slack.

Total Percentage of Violations Fixed (Fix Rate)

Upon completion of fixing, the *fix_eco_timing* command reports the total percentage of violations fixed, sometimes called the "fix rate." For example,

```
Fixing Summary:
-----------------------------------------------
Total violating endpoints found              25
Total violating endpoints fixed              23
Total violating endpoints remaining           2
Total percentage of violations fixed      92.0%
```

This report is based on the number of violating endpoints fixed, which can be less than the number of fixed violations of various types. For example, when the command fixes rise and fall violations from multiple startpoints that end at a single endpoint, all of the fixed violations count as a single fixed violating endpoint.

In distributed multi-scenario analysis, the fix rate is based on the sum of all detected and fixed violating endpoints across all scenarios, even if some endpoints overlap between the scenarios. For example, suppose that scenario S1 has 100 violating endpoints and scenario S2 has and 200 violating endpoints. If the *fix_eco_timing* command fixes 99 violations in scenario S1 and 198 in scenario S2, the fix rate is (99+198)/(100+200) = 99.0%.

Remaining Violations

The *fix_eco_timing* command applies an intelligent adaptive algorithm to optimize runtime, memory, fix rate, and number of changes. It typically runs multiple fixing iterations in an attempt to address all violations. However, some violations can remain unfixed due to the high cost of fixing.

For example, if a path has a huge hold violation that would require 15 buffers to be inserted in one stage, the *fix_eco_timing* command stops fixing the path because this large number of buffers might cause a large timing difference in the physical implementation tool. In this case, it is recommended to fix such violations in the implementation tool or adjust the constraints so that violations are more realistic.

However, if you still want to fix these violations, you can run the *fix_eco_timing* command multiple times, perhaps using different fixing options, until they are all fixed.

Unfixable Violation Report

The *fix_eco_timing* command, upon completion of violation fixing, generates a report on unfixable violations when you use the *-verbose* option. You can get the same type of report without performing any actual fixing by using the *-estimate_unfixable_reasons* option.

To generate the report, the *eco_report_unfixed_reason_max_endpoints* variable must be set to a positive integer. For DMSA, this variable must be set in the manager.

Here is a report example:

```
pt_shell> fix_eco_timing -type hold -buffer_list {BUFX1 BUFX2 BUFX3} \\
          -physical_mode open_site -verbose
  ...
Unfixable violations:
  A - There are available library cells outside area limit
  B - Delay improvement is too small to fix the violation
  C - The violation is in clock network
  D - Cell or net is located in high density area
  E - Physical information is incomplete or unavailable
  H - Logical and physical hierarchies are inconsistent
  I - Buffer insertion with given library cells cannot fix the violation
  L - Available physical area limits the use of one or more library cells
  O - No open free site is available
  R - No locations are available in parasitics or location transformation
 failed
  S - Cell sizing with alternative library cells cannot fix the violation
  T - Timing margin is too tight to fix the violation
  U - UPF restricts fixing the violation
  V - Net or cell is invalid or has dont_touch attribute
  W - Fixing the violation might degrade DRC violations

  Violation                                              Reasons  Prio/slk
  ------------------------------------------------------------------------
  S:U2/Z                                                   T         P7
    U3/Z                                                 I W         P6
    U4/Z                                                   U         P9
    U6/Z                                                   U         P6
  E:U8/I                                                           -2.105
  C:U3/Z                                                 I W         P6
    U5/Z                                                   S         P3
    U7/Z                                                   U         P0
  E:U9/A                                                           -0.307
  ...
```

The "Violation" column shows the cell pins where unfixable violations are located. The letter codes S and E indicate the start and end of a sequence of pins in a violating path. The letter code C indicates continuation of a path segment from a point in a timing path with a shared segment already reported earlier in the table.

The "Reasons" column shows the reason or reasons that a violation could not be fixed at the cell pin, using letter codes from the key shown at the beginning of the report.

The "Prio/slk" column shows the fixing priority or endpoint slack. For each pin in a timing path, the fixing priority is ranked from P0 to P9 (lowest to highest priority), with the fixing of higher-priority pins potentially more effective in reducing violations than lower-priority pins. For each path endpoint ("E" in the Violation column), the total path slack is shown.

In the foregoing example, the first entry in the table is pin U2/Z, at the start (S) of the timing path having the worst slack. The unfixable reason "T" means that U2/Z was not

fixed because the timing margin was too tight, and fixing the timing at this point has a relatively high priority (P7).

The entries in the table are organized in order from path startpoint (S) to path endpoint (E), and the timing paths are shown in order of slack, worst-slack paths first. The first path sequence shows the full path from U2/Z through U8/I. At the path endpoint, the path slack is reported in the "Prio/slk" column, -2.105.

The second path sequence is reported as starting from U3/Z and ending at U9/A, omitting the segment of the path from U2/Z and U3/Z already reported for the first path. The letter C at the begriming of this sequence indicates the continuation of a path segment partially shared with an earlier path, starting with the last shared point, which helps to avoid duplicate entries in the table.

You can interpret the reported priority P0 through P9 as a fixing bottleneck ranking. If you are able to fix only some of a large number of violations, to get the best possible gain from each fix, you can collect stages with higher priorities and try to fix them first.

These are the unfixable reason codes reported in the "Reasons" column:

- *A - There are available library cells outside area limit*

  Library cells that might have been used to fix the violation exceeded the area limit specified by the *eco_alternative_area_ratio_threshold* variable. You might be able to fix the violation by increasing the area limit.

- *B - Delay improvement is too small to fix the violation*

  The violating slack was too negative to be fixed by improving the delay in this stage. You can improve (but not completely fix) the violation by setting a negative margin for the target slack using the *-setup_margin* or *-hold_margin* option.

- *C - The violation is in clock network*

  The violation is in a clock network. By default, the command does not attempt to fix timing violations in clock networks because doing so can change the clock tree timing and possibly create new timing violations. If data path fixing and sequential cell fixing are not successful (*-cell_type combinational*, *-cell_type sequential*), you can try clock network fixing (*-cell_type clock_network*).

- *D - Cell or net is located in high density area*

  There is not enough room physically available in the vicinity of the violation. In the physical implementation tool (such as IC Compiler II), check the area utilization in that location. Note that when the *eco_allow_filler_cells_as_open_sites* variable is set to *true* (the default), physically aware ECO commands treat filler cells as open sites.

- *E - Physical information is incomplete or unavailable*

The physical information is incomplete or unavailable for the specific net or cell, or the net is marked as "+USE CLOCK" in the DEF file specified by the *set_eco_options* command. See if the DEF and LEF files are consistent with your current design.

- *H - Logical and physical hierarchy is inconsistent*

  The netlist and physical layout are not consistent, and a buffer cannot be inserted. Use the physical implementation tool to resolve the inconsistency.

- *I - Buffer insertion with given library cells cannot fix the violation*

  The violation cannot be fixed using the library cells listed by the *-buffer_list* option. Specifying a wider range of buffer cells might allow the command to fix the violation.

- *L - Available physical area limits the use of one or more library cells*

  The area of a library cell that could be used for fixing exceeds the available area in the physical layout. Use the physical implementation tool to increase the available area.

- *M - Violations in leaf cells are less than the threshold*

  The tool did not perform a fix at this clock network location because the number of violations that could be fixed in the leaf cells of the transitive fanout of this location is less than the threshold specified by the *-clock_fixes_per_change violation_limit* option. The fix might be performed if you set a lower limit.

- *N - Cell level higher than the threshold*

  The tool did not perform a fix at this clock network location because the clock tree level of this location is higher than the threshold specified by the *-clock_max_level_from_reg* option. The fix might be performed if you set a higher limit or disable the limit.

- *O - No open free site is available*

  There is no empty free site available on the route or in the vicinity of the violation. Inspect the LEF/DEF file for filler cells and see whether they are treated as empty free sites. When the *eco_allow_filler_cells_as_open_sites* variable is set to *true* (the default), physically aware ECO commands treat all filler cells as empty free sites. Also, you can use the physical implementation tool (such as IC Compiler II) to create empty free sites.

  If the *-physical_lib_constraint_file* option of the *set_eco_options* command has been used to specify intercell or advanced-node spacing rule constraints, some empty sites might not be wide enough to be used. In that case, you can use the physical implementation tool to examine the spacing rule constraints and the cells in the vicinity of such free sites.

- *Q - Capture and launch timing conflict with each other*

Both the capture and launch sides of a flip-flop have timing violations, and the *-cell_type* option is set to *clock_network*. For example, suppose that a flip-flop has a setup slack of -2.0 on the D pin and a hold slack of -1.0 on the Q pin. Changing the clock arrival time to fix one violation would worsen the other violation, so the two violations cannot be fixed by this method. If a branch cell in a clock network shows this unfixed violation reason, it means that a leaf sequential cell in its clock tree has violations on both the capture and launch sides.

- *R - No locations are available in parasitics or location transformation failed*

  Either the parasitics files do not contain location coordinates, which are required to use the buffer insertion method for setup fixing, or location transformation has failed.

- *S - Cell sizing with alternative library cells cannot fix the violation*

  All alternative library cells have been considered for sizing to fix the violation, but the violation cannot be fixed by cell sizing. Use a buffer insertion method to fix the violation, if needed.

- *T - Timing margin is too tight to fix the violation*

  The violation is on a critical or near-critical setup or hold timing path and the opposite constraint does not have enough timing slack to allow fixing of the targeted violation. To allow fixing to proceed, you can relax the fixing constraints by specifying negative values for the *-setup_margin* and *-hold_margin* options.

- *U - UPF restricts fixing the violation*

  Certain UPF cells cannot be sized or buffered. For details, see the "UPF Cells" section of this man page.

- *V - Net or cell is invalid or has dont_touch attribute*

  One or more leaf cells or nets under the cell have the *dont_touch* attribute set to *true*. Check to see if the reason is justified.

- *W - Fixing the violations might degrade DRC violations*

  Timing fixing would create new DRC violations or worsen existing DRC violations. To fix timing violations at the expense of DRC violations, use the *-ignore_drc* option.

To write out the unfixable violation report as a separate file, use the *-unfixable_reasons_format* option and specify either *text* or *csv* as the format. To specify a prefix for the file name, use the *-unfixable_reasons_prefix* option.

The CSV report file is compatible with the PrimeTime GUI and spreadsheet programs. To read the report into the PrimeTime GUI, choose the Report > ECO Unfixed Violation menu command. You can use the PrimeTime GUI to investigate and fix the remaining violations.

The entries in the violation table are cross-referenced to the timing reports, path inspector, and layout view shown in the GUI.

UPF Cells

By default, UPF cells are not considered for sizing. UPF cells are cells that have one or more of the following attributes set to true: *always_on*, *is_isolation*, *is_retention*, or *is_level_shifter*.

To allow UPF cells to be sized, set the *eco_allow_sizing_with_lib_cell_attributes* variable. For example,

```
pt_shell> set_app_var eco_allow_sizing_with_lib_cell_attributes \
  {always_on is_isolation is_retention is_level_shifter}
```

For distributed multi-scenario analysis (DMSA), set this variable in each worker process.

A buffer inserted into a net must be placed in the same power domain as the driver and all loads of the net. Buffer insertion is not performed on the following nets:

- Nets connected to any pins of an always_on cell
- Nets connected to control and clock pins of a retention cell
- A net between a port and an isolation cell
- A net between a port and a level shifter cell

Note that the *fix_eco_drc* command allows always_on buffer insertion on nets connected with an always_on cell if the *eco_allow_insert_buffer_always_on_cells* variable is set to *true* (false by default).

Writing Changes

After you fix violations using the *fix_eco_timing* command and other ECO commands, you can write out the design changes as a script by using the *write_changes* command. You can use the script to implement the same changes in another PrimeTime session or another tool (Design Compiler, IC Compiler, or IC Compiler II). Use the *-format* option of the *write_changes* command to specify the format of the script.

The number of changes in the *write_changes* script can be different from the number of sized cells and inserted buffers reported by the *fix_eco_timing* command. For example, if the *fix_eco_timing* command inserts a buffer in the first iteration and then sizes the buffer in the next iteration, it reports two changes, one buffer insertion and one sizing. The *write_changes* command combines these two actions into a single change, insertion of the final sized buffer.

After you implement the changes in a physical implementation tool such as IC Compiler II, extract new parasitic data, write a new Verilog file, and check the final design timing again in the PrimeTime tool.

Multiple Fixing Scenarios With Fewer Hosts with Hybrid Timing View

In the hybrid timing view ECO flow, the tool uses a combination of live views for accuracy-critical ECO scenarios and static views of less critical scenarios. The static-view timing and violation information is merged into the live-view scenarios at intervals determined by the tool.

Suppose you have 50 scenarios for your fixing. If you run ordinary DMSA, you need to have 50 worker processes simultaneously running in one or multiple machines.

In the hybrid timing view ECO flow, if you have 15 live-view scenarios that cover 90 percent of the violations, the tool can merge the remaining 35 scenarios with the 15 live-view scenarios as static views. Then can run fixing with only 15 DMSA worker processes instead of 50. Note that when the live views have a relatively low coverage of violations (for example, 80 percent), you might not be able to achieve the desired fixing coverage. For more information, see the man page for the *fBwrite_eco_scenario_data* and the *fBstart_eco_scenarios* commands.

Ignoring DRC Violations

If you use the *-ignore_drc* option, the command ignores DRC violations as it tries to fix timing violations. This option is recommended only for later stages of an ECO cycle, after you have fixed all violations possible without causing or worsening DRC violations. When no more timing violations can be fixed due to DRC constraints, you can use this option to trade off DRC violations to fix more timing violations.

Physically Aware Timing Fixing

Set the *-physical_mode* option to *open_site* or *occupied_site* to enable the command to load physical data into memory and use that data while fixing timing violations. Before you run the *fix_eco_timing* command, use the *set_eco_options* command to specify the paths to the physical data, either IC Compiler II database files or LEF/DEF library and design data exchange files:

```
set_eco_options \\
  -physical_tech_lib_path LEF_tech_file_list \\
  -physical_lib_path LEF_lib_file_list \\
  -physical_design_path DEF_design_file_list

set_eco_options \\
  -physical_icc2_lib icc2_lib_directory_path \\
  -physical_icc2_blocks icc2_block_name_list
```

The *fix_eco_timing* command reads in the physical data files as specified by the *set_eco_options* command if they are not already read in and checked by the *check_eco* command. To view the chip layout in the GUI, open the GUI with the *gui_start* command and then choose Window > Layout Window.

With the physical data loaded into memory, the tool considers physical constraints such as available free space, cell density, and net topology when it sizes cells and inserts buffers. For cell sizing, the tool selects a library cell that meets both the timing and physical constraints. For buffer insertion, the tool searches for the best placement location to maximize timing improvement while minimizing disturbance of existing cells in the layout.

Early in the ECO cycle, to maximize the fix rate, you can set the *-physical_mode* option to *occupied_site*, which allows sized cells and inserted buffers to overlap existing cells, as long as those cells to be moved to make space for the changes. Late in the ECO cycle, to minimize layout disturbance, set the option to *open_site* mode, which preserves the placement of existing cells.

After you finish running the *fix_eco_timing* command, you can write a changelist file that can be used by the physical implementation tool to implement the ECO changes. With the physical mode enabled, the commands in the changelist file might contain placement information.

The following *add_buffer_on_route* command written by the *write_changes* command specifies the layout coordinates for the new buffer in the IC Compiler or IC Compiler II tool.

```
add_buffer_on_route net1 BUF1X -location {100.0 200.0 0}
```

The following *size_cell* command written by the *write_changes* command specifies the instance to be sized and the new library cell to be used, which fits in the available space. It does not specify any location because the cell is upsized in its current location.

```
size_cell U16 AND2X
```

The following *insert_buffer* command written by the *write_changes* command places a new buffer in an available free site at a specified location.

```
insert_buffer U2/Z BUF2X -location {200.0 300.0 0}
```

After physical data is loaded into memory, the PrimeTime tool keeps track of ECO changes and updates the physical database appropriately. Therefore, it is recommended that you perform only physically aware fixing in the whole PrimeTime session. For example, after you have performed fixing with the *-physical_mode* option set to *open_site* or *occupied_site*, do not run the *fix_eco_timing* command again with the option set to *none*. Otherwise, the logic-only fixing changes can corrupt the physical database, resulting in significant layout disturbance when the changes are made in the physical implementation tool. For the same reason, you should avoid what-if commands such as the *size_cell* and *insert_buffer* commands.

Physically Aware Freeze Silicon Flow

In the freeze silicon flow, fixing is performed only by buffer insertion using spare cells already implemented in silicon. Only the interconnect mask layers are modified, which saves the high cost of modifying the silicon layer masks. Thus, when the *-physical_mode*

option is set to *freeze_silicon*, the *-methods* option can be set only to *insert_buffer*. The freeze silicon mode works with the IC Compiler II physical implementation tool.

In this flow, timing fixing uses spare cells defined in the DEF file or IC Compiler II database. You must identify the spare cells by using the *set_eco_options* command with the *-programmable_spare_cell_names* option. You can query the current ECO option settings by using the *report_eco_options* command.

An ECO change in the freeze silicon mode inserts a buffer directly on top of a matching programmable spare cell. The *write_changes* command writes out the change in the changelist file as an *insert_buffer* or *add_buffer_on_route* command output with location. The exact location of the buffer in the programmable spare cell is guided by the layout and the net topology.

The *write_changes* command also writes out a *map_freeze_silicon* command corresponding to each buffer. The IC Compiler II tool uses this command to program the mapped buffer into the spare cell. If the mapped buffer uses only a portion of a programmable spare cell, the *map_freeze_silicon* command backfills the leftover space with one or more smaller matching programmable spare cells, so that the leftover space can be used later for implementing further ECO changes.

Fixing in Multiply Instantiated Modules (MIMs)

When you set the *eco_enable_mim* variable to *true* (the default is *false*), the tool performs the same ECO changes across each set of MIMs. In physically aware fixing, the tool recognizes a set of MIM instances when they share the same DEF file; in logic-only fixing, it recognizes them when they share the same parasitics file according to the *-path* option in the *read_parasitics* command.

Suppose a CPU module is instantiated four times in the TOP module as CPU1, CPU2, CPU3 and CPU4, and the files CPU.def and CPU.SPEF are associated with the CPU module. The tool derives the MIM configuration when the following settings are used.

In physically-aware fixing,

```
set_eco_options -physical_design_path {TOP.def CPU.def}
```

In logic-only fixing,

```
read_parasitics -path {CPU1 CPU2 CPU3 CPU4} CPU.SPEF
```

or

```
read_parasitics -path [all_instance CPU] CPU.SPEF
```

If MIMs are detected, the *fix_eco_timing* command shows the current MIM configuration before it starts fixing. Verify that the MIM configuration matches your expectations. If not, check the DEF file or parasitics file configuration in your setup script.

When fixing violations, a change in one MIM instances is replicated in all instances of the MIM set. For example, a buffer insertion in CPU1 is replicated in CPU2, CPU3, and CPU4. Whenever the tool fixes a violation, it analyzes all MIM instances and makes sure that it does not cause timing violations in other instances. Thus, it is possible to get a lower fix rate with MIM ECO enabled because timing might be more constrained by multiple instances.

After fixing is completed, use the *write_changes* command to generate the changelist file for the associated MIM instances. In the preceding example, one changelist file is written for the CPU1 through CPU4 instances. For more information, see the man page of the *write_changes* command.

Per-Scenario ECO Margins

In distributed multi-scenario analysis, you can use different setup and hold margins for different scenarios by specifying their values in the *-timing_setup_margin* and *-timing_hold_margin* options of the *set_eco_options* command in the worker scripts.

Note that the *-setup_margin* and *-hold_margin* options of the *fix_eco_timing* command have priority over the corresponding options of the *set_eco_options* command.

Clock Network Fixing

When the *-cell_type* option is set to *clock_network*, the command makes changes in clock networks to fix timing violations. Clock network fixing methods include cell upsizing, cell downsizing, buffer or inverter pair insertion and bypass.

If the *bypass_buffer* method is applied, new timing is annotated on the changed nets based on net topology, capacitance and net delay change estimates. For signoff accurate timing, it is recommended to run the *implement_eco* command to implement the changes and get new timing after extracting new parasitics from the changed nets.

The *fix_eco_timing* command has options to control the scope of the changes in the clock network:

- Use the *-clock_max_level_from_reg* option to limit the changes to lower levels of the clock trees. For example, setting the option to 1 limits changes to the leaf level of the clock tree.
- Use the *-clock_fixes_per_change* option to reduce the number of changes in the clock network by setting a minimum number of violations to fix per change. For example, setting the option to 4 requires at least four violations to be fixed per change.

In physically aware timing fixing, you must use the *set_eco_options* command with the *-physical_enable_clock_data* option before you use the *fix_eco_timing* command. You must specify valid buffer library cells that are available to the physical implementation tool, meeting any special rules such as nondefault routing (NDR) rules. The PrimeTime tool does not perform any extra rule checking for the provided buffers.

The PrimeTime tool uses all available alternative library cells to size cells in the clock network. If your design uses specialized library cells in the clock network, use a Tcl script similar to the following example to limit the sizing candidates to selected library cells. This example limits the library cells to those that have prefix "CLK" in their library cell base names.

```
define_user_attribute -type boolean -class lib_cell is_clk_cell
set clk_lcells [get_lib_cell */CLK*]
set_user_attribute $clk_lcells is_clk_cell true
set eco_alternative_cell_attribute_restrictions is_clk_cell
```

In an unfixable violation report generated by using the *-verbose* or *-estimate_unfixable_reasons* option, the unfixable reason codes *M*, *N*, and *Q* apply to clock network fixing, as described in the "Unfixable Violation Report" section of this man page.

The tool does not perform fixing on a clock mesh, where multiple drivers drive the same net. However, if the clock mesh is connected to a normal clock tree, the tool can perform ECO changes in the normal clock tree portion of the clock network.

TNS Driven Timing Fixing With Clock Network ECO

If you specify *tns* for the *-target_violation_type* option, the command attempts to improve overall Total Negative Slack (TNS) even if it degrades existing endpoint violations. However, the tool limits existing violation degradation to the current Worst Negative Slack (WNS). If you want to improve TNS further by allowing WNS degradation, use the *-wns_limit* option to specify the allowed limit.

Suppose a design has WNS of -100, and a specific flip-flop has slack -60 at D pin and -40 at Q pin. The command may degrade slack from -60 to -100 at D pin if TNS improves. If -80 is specified for the *-wns_limit* option, however, the command only degrades slack from -60 to -80 to meet the limit requirement. If -200 is specified for the *-wns_limit* option, the command can degrade slack from -60 to -200 as long as TNS improves.

Leakage Power

Leakage power can increase during timing fixing. By default, timing fixing performs optimization to meet timing requirements while minimizing the increase in area, without considering leakage.

If leakage power is more important than area, you can use the *-power_attribute* option to optimize power during timing fixing, based on a library cell attribute that defines the leakage power value for the cell. For example,

```
# Create a user-defined attribute "leak_attr" for lib_cell object
define_user_attribute leak_attr -type float -class lib_cell

# Assign values that reflect leakage of each lib_cell at worst corner
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV1X_HVT] leak_attr
 1.0
```

```
set_user_attr -class lib_cell [get_lib_cell LIB_H/INV2X_HVT] leak_attr
 2.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV1X_LVT] leak_attr
 10.0
set_user_attr -class lib_cell [get_lib_cell LIB_L/INV2X_LVT] leak_attr
 15.0
 ...

# Perform setup timing fixing with leakage power consideration
fix_eco_timing -type setup -power_attribute leak_attr

# Perform hold timing fixing with leakage power consideration
fix_eco_timing -type hold -power_attribute leak_attr
```

While fixing timing violations, the tool chooses library cells to minimize the increase in leakage power, and does not consider area. It replaces only the existing cells that have the leak_attr attribute, and replaces them only with other cells that also have the leak_attr attribute.

Instead of assigning the leakage values explicitly, you can import the attribute values from the cell library database. For details, see SolvNet 2371111, "Extracting Leakage Power for Library Cells"; and SolvNet 2040404, "PrimeTime J-2014.12 Update Training," Module 8: ECO - Power Recovery.

In distributed multi-scenario analysis, the respective library cells in different libraries must be assigned matching leakage power values.

PrimePower Dynamic, Leakage, and Total Power

The PrimePower tool performs comprehensive power analysis using actual switching activity and library-defined power data such as dynamic and leakage power of each cell. The tool performs a power analysis when you use the *update_power* or *report_power* command at the pt_shell prompt.

Total power (both dynamic and leakage) can increase when cells are upsized to improve timing. By default, the command performs optimization to fix timing violations while minimizing the increase in area, without considering power.

To better manage the total power overhead, you can use PrimePower power analysis data in timing fixing by using the *-power_mode* option set to *dynamic*, *leakage*, or *total*. Then timing fixing tries to reduce the overhead of the dynamic (switching) power, leakage power, or total (dynamic plus leakage) power as measured by the *report_power* command while fixing similar timing violations. For hold fixing, only the *leakage* setting is supported.

With the *-power_mode total* option, the tool chooses actions to fix setup or hold timing violations while reducing the total power overhead. The action chosen can vary depending on the local conditions in the design. For example, it can choose to fix setup timing violations by either upsizing the cell or by lowering the cell threshold voltage, the choice depending on the local switching activity. High switching activity favors lowering the

threshold voltage (to reduce switching power overhead), whereas low switching activity favors upsizing the cell (to reduce leakage power overhead). A similar strategy applies to buffer insertion. Among the buffers that give similar fix, the ones with lower total power overhead are favored.

With the *-power_mode leakage* option, the tool fixes setup or hold timing violations considering leakage power without requiring user-defined power attributes.

In the distributed multi-scenario analysis (DMSA) flow, the tool gets its dynamic power data from exactly one scenario, which you specify with the *-dynamic_scenario* option. Similarly, it gets its leakage power data from exactly one scenario, which you specify with the *-leakage_scenario* option. These options are used only in a DMSA flow. In general, you should specify the scenario showing the worst dynamic power and worst leakage power, respectively, for these two options. They could be the same scenario or two different scenarios.

Load Capacitance Cells for Hold Fixing

Hold fixing can use load capacitance (dummy load) cells along the data path to target violations on order of picoseconds using the *insert_buffer* method. You can use the *-load_cell_list* option separately from or together with the *-buffer_list* option.

When the fixing method is specified as {*size_cell insert_buffer*} with both the *-load_cell_list* and *-buffer_list* options, the command performs cell sizing first, then load capacitance cell insertion, followed by buffer insertion. This sequence minimizes the layoutdisturbance. With the *-physical_mode open_site* option, to control the search area for inserting load capacitance cells, set the *eco_insert_buffer_search_distance_in_site_rows* variable.

The *-load_cell_list* option can use buffer cells, inverter cells, and dedicated load cells for load cell insertion. Buffer and inverter cells inserted as load cells have unconnected outputs. Dedicated load cells are smaller single-pin cells that are easier to place. They have the following attributes:

```
Attribute Name      Type          Value
-----------------------------------------
function_id         string        unknown
is_black_box        boolean       true
is_combinational    boolean       true
number_of_pins      int           1
```

The file written by the *write_changes -format icctcl* command contains commands like the following to set the location and orientation of each new load cell:

```
create_cell U_LOAD_CAP_CELL_1 CLOAD1
connect_net $existing_target_net [get_pins {U_LOAD_CAP_CELL_1/A}]
set_cell_location -coordinates {150.00 30.60} -orientation N
```

Feedback

Examples

The following example overfixes setup violations with a slack worse than -0.1 to achieve a positive setup slack of 0.1 (while ignoring paths with a setup slack better than -0.1):

```
pt_shell> fix_eco_timing -type setup -slack_lesser_than -0.1
 -setup_margin 0.1
```

The following example overfixes setup violations with a slack worse than 0.2 to achieve a positive setup slack of 0.2. Note that this overfixes some positive-slack paths, for example, by increasing the slack from 0.1 to 0.2.

```
pt_shell> fix_eco_timing -type setup -slack_lesser_than 0.2 -setup_margin
 0.2
```

The following example overfixes all setup violations to achieve a positive setup slack of 0.2, while preserving a hold slack of at least 0.1:

```
pt_shell> fix_eco_timing -type setup -setup_margin 0.2 -hold_margin 0.1
```

The following example fixes setup violations with slack between -2.0 and 0.0 (while ignoring paths with violations worse than -2.0):

```
pt_shell> fix_eco_timing -type setup -slack_greater_than -2.0
```

The following example fixes hold violations using only cell sizing.

```
pt_shell> fix_eco_timing -type hold -methods size_cell
```

The following example fixes hold violations using only pin buffering.

```
pt_shell> fix_eco_timing -type hold \\
            -methods {insert_buffer_at_load_pins
 insert_buffer_at_driver_pins} \\
            -buffer_list {BUFX1 BUFX2 BUFX3}
```

The following example fixes a small set of hold violations that have an exhaustive path-based slack of less than zero:

```
pt_shell> fix_eco_timing -type hold -pba_mode exhaustive \\
           -buffer_list {BUFX2 DLY1X2 DLY2X2}
```

The following example fixes setup violations only in a selected set of path groups, with verbose reporting of unfixable violations:

```
pt_shell> fix_eco_timing -type setup -group {SYSCLK* IOCLK} -verbose
```

The following example fixes setup violations only by sizing sequential cells:

```
pt_shell> fix_eco_timing -type setup -cell_type sequential
```

The following example fixes setup violations by sizing both sequential and combinational cells:

```
pt_shell> fix_eco_timing -type setup -cell_type {sequential
 combinational} \\
 -methods size_cell
```

The following example applies the *pt_dont_use* user-defined attribute to a set of library cells. You must define the user-defined attribute first.

```
pt_shell> define_user_attribute pt_dont_use \\
          -quiet -type boolean -class lib_cell
```

You can use the attribute directly with the *set_user_attribute* command, or for convenience, you can define the following procedure:

```
proc set_pt_dont_use {lib_cell} {
  set_user_attribute \\
    -class lib_cell \\
    [get_lib_cell -quiet $lib_cell] \\
    pt_dont_use true
  }
```

Now you can use this procedure to apply the attribute:

```
set_pt_dont_use {lib/CLKBUF* lib/CLKMUX*}
```

In the distributed multi-scenario analysis (DMSA) flow, you must define and apply the attribute at the scenarios using the *remote_execute* command.

The following example uses the *-physical_mode* option to specify the *open_site* mode.

```
pt_shell> fix_eco_timing -type hold -physical_mode open_site \\
           -buffer_list {BUFX2 DLY1X2 DLY2X2}
```

The following example uses the *-path_selection_options* option to target specific paths for fixing setup violations.

```
pt_shell> fix_eco_timing -type setup -path_selection_options \\
           {-through u01/A -to ff0/D -max_paths 10 -nworst 5}
```

The following example uses the *-path_selection_options* option to target specific paths for fixing hold violations.

```
pt_shell> fix_eco_timing -type hold -buffer_list {BUFX2 DLY1X2 DLY2X2}
 \\
           -path_selection_options {-delay_type min -from ff0/Q \\
           -max_paths 100 -nworst 10}
```

In the distributed multi-scenario analysis flow, you must define variables in the worker processes if you want to use them in the *-path_selection_options* option. The following

example uses the *-path_selection_options* option in distributed multi-scenario analysis with a variable.

```
pt_shell> remote_exec {set startpoints [get_pins {ff0/Q ff1/Q}] }
pt_shell> fix_eco_timing -type hold -buffer_list {BUFX2 DLY1X2 DLY2X2}
 \\
           -path_selection_options {-delay_type min -from $startpoints
 \\
           -max_paths 100 -nworst 5}
```

Alternatively, you can define the variable as a list instead of a collection:

```
pt_shell> remote_exec {set startpoints "{ff0/Q ff1/Q}"}
pt_shell> fix_eco_timing -type hold -buffer_list {BUFX2 DLY1X2 DLY2X2}
 \\
           -path_selection_options {-delay_type min -from $startpoints
 \\
           -max_paths 100 -nworst 5}
```

The following example performs setup fixing by modifying the clock network.

```
pt_shell> fix_eco_timing -type setup -cell_type clock_network
```

The following example uses the *insert_inverter_pair* method to perform setup fixing in a clock network.

```
pt_shell> fix_eco_timing -type setup -methods insert_inverter_pair \\
           -cell_type clock_network -buffer_list {INVX1 INVX2 INVX4}
```

The following example uses the *insert_inverter_pair* method to perform hold fixing in data paths.

```
pt_shell> fix_eco_timing -type hold -methods insert_inverter_pair \\
           -buffer_list {INVX1 INVX2 INVX4}
```

The following example uses the *-estimate_unfixable_reasons* option to generate a report of unfixable reasons without actually fixing the design. The variable *eco_report_unfixed_reason_max_endpoints* must be set to a positive integer.

In this example, if the command reports unfixable reason code "I: buffer list with given lib cells cannot fix violation," you can modify the buffer list to include a larger range of buffer library cells and get a quick estimate of the results before you start actual fixing.

```
pt_shell> set_app_var eco_report_unfixed_reason_max_endpoints 50
pt_shell> fix_eco_timing -type hold -buffer_list {BUFFX1 BUFFX2} \\
           -estimate_unfixable_reasons
```

The following example uses the *load_cell_list* option to perform hold fixing for violations in order of picoseconds along data path.

Feedback

```
pt_shell> fix_eco_timing -type hold -methods insert_buffer \\
           -load_cell_list {CLOAD1 CLOAD2} -slack_greater_than -0.005
```

The following example uses the *-load_cell_list* option in single operation along with the *-buffer_list* option to fix hold violations.

```
pt_shell> fix_eco_timing -type hold -methods insert_buffer \\
           -load_cell_list {CLOAD1 CLOAD2} -buffer_list {BUFX1 BUFX2}
```

The following example uses the *remove_buffer* method to fix setup violations.

```
pt_shell> fix_eco_timing -type setup -methods remove_buffer
```

---

fix_eco_wire

Performs ECO wire optimization by spacing, widening, rerouting wires, or changing layers.

Syntax

status *fix_eco_wire*

```
[-methods method_list]
[-path_selection_options option_string]
[-nets net_list]
[-min_routing_layer layer_name]
[-max_routing_layer layer_name]
```

Data Types

```
method_list       list
option_string     string
net_list          list
layer_name        string
```

Arguments

`-methods method_list`

Specifies the fixing methods, one or more of *space_wire*, *widen_wire*, *reroute_wire*, or *change_layer*. The default is *-methods {space_wire widen_wire change_layer}*.

`-path_selection_options option_string`

Specifies the path selection options for the *get_timing_paths* command, which the *fix_eco_wire* command uses to collect timing paths for fixing. Based on the specified methods, *fix_eco_wire* identifies fixable target nets under collected timing paths automatically. Because fixing is performed only on these paths, to check the quality of results after fixing, use the *get_timing_paths* or *report_timing* commands with the same options.

The -path_selection_options and -nets options are mutually exclusive; you can specify only one.

`-nets` *net_list*

Specifies the list of target nets for ECO wire optimization. To check the quality of results after fixing, use the *get_timing_paths* or *report_timing* commands with -nets options.

The -nets and -path_selection_options options are mutually exclusive; you can specify only one.

`-min_routing_layer` *layer_name*

Specifies the minimum routing layer for the nets. Only one layer can be specified. The *-methods {change_layer}* fixing method is required for the -min_routing_layer option. If -min_routing_layer is not specified, the tool automatically assigns it to the lowest low resistance layer when it is available. If low resistance layers are not available in the design, -methods {change_layer} will be ignored.

`-max_routing_layer` *layer_name*

Specifies the maximum routing layer for the nets. Only one layer can be specified. The *-methods {change_layer}* fixing method is required for the -max_routing_layer option. If -max_routing_layer is not specified, the tool automatically assigns it to the highest low resistance layer when it is available. If low resistance layers are not available in the design, -methods {change_layer} will be ignored.

Description

The *fix_eco_wire* command performs ECO wire optimization for automatically or manually specified nets. This command is available for PrimeECO where it performs timing and routing co-optimization for better QoR with less routing disturbance.

ECO wire optimization includes spacing, widening, rerouting wires, and changing layers, which are enabled by space_wire, widen_wire, reroute_wire, and change_layer methods, respectively. For specified methods, *fix_eco_wire* applies relevant non-default routing to the target nets and reflects the timing effect of wire fixing for users to check the quality of results after fixing. Note that *set_routing_rule* applies the specified non-default routing to the target nets but does not change the timing. ECO wire optimization changes performed by *set_routing_rule* are classified as "manual" method.

After you finish running the *fix_eco_wire* command, you can implement the ECO changes with *implement_eco* command.

Requirements

The minimum requirements to run the *fix_eco_wire* command is identical to those for *implement_eco* command.

Feedback

Examples

The following example uses the *-path_selection_options* option to target specific paths for spacing and rerouting wire fixing.

```
prompt> fix_eco_wire -methods {space_wire reroute_wire} \\
           -path_selection_options {-max_paths 20 -nworst 1}
```

The following example uses the *-nets* option to target specific nets for widening and layer-changing wire fixing.

```
prompt> fix_eco_wire -nets {widen_wire change_layer} \\
           -nets {n43, n134} -min_routing_layer M5 -max_routing_layer M6
```

---

foreach_in_collection

Iterates over the elements of a collection.

Syntax

string *foreach_in_collection*

```
itr_var
collections
body
```

Data Types

```
itr_var             string
collections         list
body                string
```

Arguments

itr_var

Specifies the name of the iterator variable.

collections

Specifies a list of collections over which to iterate.

body

Specifies a script to execute per iteration.

Description

The *foreach_in_collection* command is used to iterate over each element in a collection. You cannot use the Tcl-supplied *foreach* command to iterate over collections because the *foreach* command requires a list, and a collection is not a list. Also, using the *foreach* command on a collection causes the collection to be deleted.

The arguments for the *foreach_in_collection* command parallel those of the *foreach* command: an iterator variable, the collections over which to iterate, and the script to apply at each iteration. All arguments are required.

Note: The *foreach_in_collection* command does not allow a list of iterator variables.

During each iteration, the *itr_var* option is set to a collection of exactly one object. Any command that accepts *collections* as an argument also accepts *itr_var* because they are of the same data type (collection).

You can nest the *foreach_in_collection* command within other control structures, including another *foreach_in_collection* command.

Note that if the body of the iteration is modifying the netlist, it is possible that all or part of the collection involved in the iteration will be deleted. The *foreach_in_collection* command is safe for such operations. If a command in the body causes the collection to be removed, at the next iteration, the iteration ends with a message indicating that the iteration ended prematurely.

An alternative to collection iteration is to use complex filtering to create a collection that includes only the desired elements, then apply one or more commands to that collection. If the order of operations does not matter, the following are equivalent. The first is an example without iterators.

```
set s [get_cells {U1/*}]
command1 $s
command2 $s
unset s
```

The following is a similar approach using the *foreach_in_collection* command:

```
foreach_in_collection itr [get_cells {U1/*}] {
  command1 $itr
  command2 $itr
}
```

For collections with large numbers of objects, the non-iterator version is more efficient, though both produce the same results if the commands are order-independent.

Feedback

Examples

The following example from PrimeTime removes the wire load model from all hierarchical cells in the current instance.

```
pt_shell> foreach_in_collection itr [get_cells *] {
?             if {[get_attribute $itr is_hierarchical] == "true"} {
?               remove_wire_load_model $itr
?             }
?          }
Removing wire load model from cell 'i1'.
Removing wire load model from cell 'i2'.
```

gen_ctpm

Generate the CTPM for a library with different target spice model.

Syntax

string *gen_ctpm*

```
-base_lib base_lib
-side_file side_file
-header header_file
-subckt subckt_folder
-simulator sim_exec
[-max_cores number]
[-temperature temperature]
[-sub_ext extention]
[-sub_prefix prefix]
[-lib_cells lib_cell_name_list]
[-output output_name]
[-verbose]
```

Data Types

```
base_lib            string
side_file           string
header_file         string
subckt              string
sim_exec            string
number              int
temperature         float
extention           string
```

```
prefix              sting
lib_cell_name_list  list
output_name         string
```

Arguments

`-base_lib` *base_lib*

Specifies the base library, which is characterized using original spice model.

`-side_file` *side_file*

Specifies the sensitivity augmented library which is the side-file of base library, as used in *define_sensitivity_lib_mapping base_lib -side_file side_file*.

`-header eader_file`

Specifies the target spice header file, all needed spice options needs to be included.

`-subckt` *subckt_folder*

Specifies the target spice subckt folder contains all lib_cells' subckt files with name as {prefix}{lib_cell_name}{extention}. You can use a single subckt file without -sub_ext and -sub_prefix, but runtime will be significantly slower.

`-simulator` *sim_exec*

Specifies the HSPICE simulator path used for simulation.

`-max_cores` *number*

Specifies the upper bound of number of cores used for the command on local machine. Default value is 16.

`-temperature` *temperature*

Specifies the retargeting temperature, if it's different from base library.

`-sub_ext` *extention*

Specifies the subckt file extention for per lib_cell subckt in *subckt_folder*. Default is ".spi".

`-sub_prefix` *prefix*

Specifies the subckt file prefix for per lib_cell subckt in *subckt_folder*. Default is "".

`-lib_cells` *lib_cell_name_list*

Specifies the list of lib_cells to run gen_ctpm. By default, all lib_cells in library will be included. This option is used for flow pipe-clean purpose to generate CTPM for only a single lib_cell or specific lib_cells in the library.

`-output` *output_name*

Specifies the output name of CTPM. By default, the generated CTPM name is base_lib db file name and replace ".db" with ".ctpm". Example, base_lib file is "mylib1.db", default generated CTPM name is "mylib1.ctpm".

`-verbose`

Generates the lib_timinig_arc based correlation details for each arc. The correlation data is printed for rise and fall seperately and contains following details: 1) Relative and absolute error for pre- and post-CTPM, for both delay and slew 2) The pass/fail column indicates whether the post-CTPM error crosses the threshold defined by *set_check_ctpm_tolerance* command. By default it's 3%/3ps.

Description

The *gen_ctpm* command can be used to generate the compact timing power model (CTPM) of any target spice model. By generating the CTPMs, the PrimeShield tool enables the timing and power impact assessment of a given target. You can define the target using a SPICE model representing the next process design kit (PDK), the spot model, or a different SPICE corner. The CTPM generation in the PrimeShield tool uses an advanced machine learning algorithm. The aim is to bridge the gap between the base and the target by capturing the gap through the SPICE process parameters placed in a CTPM database. The generated CTPMs are used in a base STA session. When a CTPM is used in a base STA session, the quality of results (QoR) of the session improves to match the QoR of the target. You can perform this targeting analysis without the characterized libraries for that target, thereby saving time on cycles waiting for official characterization libraries. This targeting analysis only requires the augmented libraries representing the timing behavior of each arc, for a given physical SPICE parameter perturbation range.

Examples

The following script is generating CTPM with target_header, where subckt per lib_cell in subckt_dir are named as "{lib_cell_name}{.spi}".

ps_shell> gen_ctpm \\ -base_lib base.db \\ -side_file augmented_sensitivity.db \\ -header target_header.spi \\ -subckt subckt_dir/ \\ -simulator /global/apps/hspice_2022.06-1/hspice/bin/hspice \\ -max_cores 16

---

generate_power_profile

Generate power profile.

Syntax

status *generate_power_profile*

file_name]

Data Types

file_name	string

Arguments

ile_name

Specifies the name of the file for power profile generation.

Description

This command is used to generate power profile. The power profile can be either static or time based. Static power profile uses csv format, while time based profile uses xlsx format.

For power profile generation, user need to provide LEF/DEF files through the command *set_eco_options* with options *-physical_tech_lib_path -physical_lib_path -physical_design_path*.

For static power profile generation, static power analysis has be run first before invoking the command *generate_power_profile*. For time based power profile generation, user has to invoke *update_power* first for time based power analysis. Since the power profile generation is based on the waveform data in FSDB file from *update_power* command, the following options have to be specified before *update_power*: *set_power_analysis_option -include all_with_leaf -separate_power_waveform all*. This is to store leaf cell based waveform data including all power components in the FSDB file. The FSDB file name is

obtained from the command *set_power_analysis_option -waveform_output*. The default FSDB file name is primetime_px.fsdb.

Examples

The following example generates static power profile.

```
pt_shell> update_power
pt_shell> set_eco_options -physical_tech_lib_path tech.lef
pt_shell> set_eco_options -physical_lib_path design.lef
pt_shell> set_eco_options -physical_design_path design.def
pt_shell> generate_power_profile power.csv
```

The following example sets power analysis option to include power waveform data on all leaf cells for all power components. Then it invokes time based power analysis, and generates time based power profile.

```
pt_shell> set_app_var power_analysis_mode time_based
pt_shell> read_vcd test.vcd
pt_shell> set_power_analysis_option -include all_with_leaf
 -separate_power_waveform all
pt_shell> update_power
pt_shell> set_eco_options -physical_tech_lib_path tech.lef
pt_shell> set_eco_options -physical_lib_path design.lef
pt_shell> set_eco_options -physical_design_path design.def
pt_shell> set_power_profile_options -row 100 -column 100
 -enable_time_based true
pt_shell> generate_power_profile power.xlsx
```

See Also

- set_power_profile_options

---

get_alternative_lib_cells

Creates a collection of library cells that can be used to replace a cell instance in the current design using the *size_cell* command.

Syntax

```
collection get_alternative_lib_cells
  [-current_library]
  [-libraries lib_spec]
  [-base_names]
  cell
```

Data Types

```
lib_spec      list
cell          string
```

Feedback

Arguments

`-current_library`

Restricts selection of the new library cells to only the same library as that of the cell being considered for replacement. You can use the this option only if the *lib_cell* argument specifies a cell instance or a base cell name without a library name.

`-libraries` *`lib_spec`*

Specifies a list of libraries from which to select alternative library cells. You can specify either a list of library names or a collection created by the *get_libs* command. The default is to select from all libraries specified in the *link_path* variable.

`-base_names`

Returns a list of library cell base names, without library names. If library cells from different libraries share the same base name, the duplicate names are removed from the result. This option is enabled by default if you invoke pt_shell with the *-multi_scenario* option.

`cell`

Specifies a single cell instance in the design or full library cell name. The command creates a collection of alternative library cells that are functionally equivalent to the specified cell instance or library cell.

Description

The *get_alternative_lib_cells* command creates a collection of library cells that are functionally equivalent to a specified cell or library cell, but can have different properties such as size and drive strength. You can relink an instance of the cell to an alternative library cell by using the *size_cell* command.

A library cell is included in the collection only if it satisfies the same criteria used by the *size_cell* command to determine whether a library cell is equivalent. Cells are equivalent if they have the same:

- Number of input pins
- Number of output pins
- Logical functionality
- Number, type, and sense of enabled cell timing arcs

By default, the I/O pins do *not* need to have the same names or ordering. Furthermore, a 2-input NAND gate and a 2-input OR gate, each cell with one negated input, are functionally equivalent, by DeMorgan's theorem.

To enforce identical pin naming, set the *eco_strict_pin_name_equivalence* variable to true. In that case, the command considers matching pin names and their respective functions as an additional requirement for equivalence.

To disable the requirement that timing arcs must match between the alternative library cell and the original library cell, set the *eco_strict_lib_arc_equivalence* variable to *false*.

To see a comparison of the slack and design cost within a set of alternative library cells, use the *report_alternative_lib_cells* command.

Examples

The following example shows how to find alternative library cells for a cell instance in the design. Here, U1_max is an instance of the library cell lib_max/OR3 and U2_min is an instance of lib_min/OR3.

```
pt_shell> set link_path [list * lib_max.db]
* lib_max.db
pt_shell> set_min_library lib_max.db -min_version lib_min.db
Loading db file '/u/libs/lib_max.db'
Loading db file '/u/libs/lib_min.db'
Created max/min library relationship:
  Max: /u/libs/lib_max.db:lib_max
  Min: /u/libs/lib_min.db:lib_min
 ...
pt_shell> get_alternative_lib_cells -libraries lib_min U1_max
{"lib_min/OR3", "lib_min/OR3P"}
pt_shell> get_alternative_lib_cells -libraries lib_max U2_min
{"lib_max/OR3", "lib_max/OR3P"}
pt_shell> get_alternative_lib_cells U1_max
{"lib_max/OR3P", "lib_min/OR3", "lib_min/OR3P"}
pt_shell> get_alternative_lib_cells U2_min
{"lib_max/OR3", "lib_max/OR3P", "lib_min/OR3P"}
pt_shell> get_alternative_lib_cells U2_min -current_library
{"lib_min/OR3P"}
pt_shell> get_alternative_lib_cells -base_names U2_min
{"OR3", "OR3P"}
```

The following example shows how to find alternative library cells for a lib_cell object.

```
pt_shell> get_alternative_lib_cells lib_max/OR3
{"lib_max/OR3P", "lib_min/OR3", "lib_min/OR3P"}
pt_shell> get_alternative_lib_cells lib_max/OR3 -current_library
{"lib_max/OR3P"}
```

---

get_app_var

Gets the value of an application variable.

Syntax

string *get_app_var*

```
[-default | -details | -list]
[-only_changed_vars]
var
```

Data Types

```
var     string
```

Arguments

`-default`

Gets the default value.

`-details`

Gets additional variable information.

`-list`

Returns a list of variables matching the pattern. When this option is used, then the *var* argument is interpreted as a pattern instead of a variable name.

`-only_changed_vars`

Returns only the variables matching the pattern that are not set to their default values, when specified with *-list*.

var

Specifies the application variable to get.

Description

The *get_app_var* command returns the value of an application variable.

There are four legal forms for this command:

- `get_app_var <var>`

Returns the current value of the variable.

- `get_app_var <var> -default`

Returns the default value of the variable.

- `get_app_var <var> -details`

Returns more detailed information about the variable. See below for details.

- `get_app_var -list [-only_changed_vars] <pattern>`

Returns a list of variables matching the pattern. If *-only_changed_vars* is specified, then only variables that are changed from their default values are returned.

In all cases, if the specified variable is not an application variable, then a Tcl error is returned, unless the application variable *sh_allow_tcl_with_set_app_var* is set to true. See the *sh_allow_tcl_with_set_app_var* man page for details.

When *-details* is specified, the return value is a Tcl list that is suitable as input to the Tcl *array set* command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key, and each even-numbered element in the list is the value of the previous key.

The supported keys are as follows:

name

This key contains the name of the variable. This key is always present.

value

This key contains the current value of the variable. This key is always present.

default

This key contains the default value of the variable. This key is always present.

help

This key contains the help string for the variable. This key is always present, but sometimes the value is empty.

type

This key contains the type of the application variable. Legal values of for this key are: string, bool, int, real. This key is always present.

constraint

This key describes additional constraints placed on this variable. Legal values for this key are: none, list, range. This key is always present.

min

This key contains the min value of the application variable. This key is present if the constraint is range. The value of this key may be the empty string, in which case the variable only has a max value constraint.

max

This key contains the max value of the application variable. This key is present if the constraint is "range". The value of this key may be the empty string, in which case the variable only has a min value constraint.

list

This key contains the list of legal values for the application variable. This key is present if the constraint is "list".

Examples

The following are examples of the *get_app_var* command:

```
prompt> get_app_var sh_enable_page_mode
1

prompt> get_app_var sh_enable_page_mode -default
false

foreach {key val} [get_app_var sh_enable_page_mode -details] {   echo
 "$key: $val"
}
=>  name: sh_enable_page_mode
    value: 1
    default: false
    help: Displays long reports one page at a time
    type: bool
    constraint: none

prompt> get_app_var -list sh_*message
sh_new_variable_message
```

- write_app_var

Feedback

get_attribute

Retrieves the value of an attribute on an object or on a collection of objects.

Syntax

string *get_attribute*

```
[-class class_name]
[-quiet]
[-value_list]
-objects object_list
-name attribute_name
object_spec
attr_name
```

Data Types

```
class_name        string
object_spec       collection
attr_name         string
```

Arguments

`-class class_name`

Specifies the class name of the *object_spec* argument, provided the *object_spec* option is a name. The valid values for the *object_spec* option are *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, *lib_pin*, and *clock*.

`-quiet`

Prevents the reporting of messages related to the nonexistence of an object, the nonexistence of an attribute on an object, or the unavailabilty of an attribute on the specified object class. However, more serious usage issues are reported, even when this option is specified.

`-value_list`

Indicates that the return value should be a list, even if there is only a single object specified to retrieve the attribute. Normally, the return value of the *get_attribute* command is a string if there is only a single object, and a list if multiple objects are specified.

`-objects object_list`

Specifies a list of objects from which to get the attribute values. Each element in the list is a collection of objects. This option is mutually exclusive with *object_spec*. Either one (and only one) of *-objects* or *object_spec* must be specified.

`-name attribute_name`

Specifies the name of the attribute whose value is returned. This option is mutually exclusive with *attr_name*. Either one (and only one) of *-name* or *attr_name* must be specified.

object_spec

Specifies an object from which to retrieve the attribute value. The *object_spec* argument must be either a collection of one or more objects, or a name which is combined with the *-class* option to find the object. If the *object_spec* option is a name, you must also use the *-class* option. This positional option is provided for compatibility with other tools.

attr_name

Specifies the name of the attribute where the value is retrieved. This positional option is provided for compatibility with other tools.

Description

This command retrieves the value of an attribute on an object or on a collection of objects. The object is either a string name of exactly one object, or a collection of one or more objects. The return value is a string or a list of strings if multiple objects are specified to retrieve an attribute.

Examples

In the following example, the first command defines the X attribute for cells. The second command sets the attribute to a value on all cells in this level of the hierarchy. The third command retrieves the value from one cell, combines it with the *full_name* application attribute, and creates a simple report.

```
pt_shell> define_user_attribute -type int -class cell X
pt_shell> set_user_attribute [get_cells *] X 30
Set attribute 'X' on 'i1'
Set attribute 'X' on 'i2'
pt_shell> foreach_in_collection sel [get_cells *] {
            echo -n "On '[get_attribute $sel full_name]', "
            echo "X =  [get_attribute $sel X]"
          }
On 'i1', X =  30
On 'i2', X =  30
```

In the next example, the *get_attribute* command is used to retrieve a list of attribute values for a collection of cells.

```
pt_shell> set flipflops [get_cells ff*]
{"ffa", "ffb", "ffc", "ffd"}
pt_shell> get_attribute $flipflops is_sequential
true true true true
```

---

get_cell

Creates a collection of cells from the current design relative to the current instance. You can assign these cells to a variable or pass them into another command.

Syntax

collection *get_cells*

```
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-filter expression]
[-of_objects objects]
patterns
```

Data Types

expression	string
objects	list
patterns	list

Arguments

`-hierarchical`

Searches for cells level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a cell block1/adder, a hierarchical search finds it using "adder".

`-filter` *`expression`*

Filters the collection with the *expression* value. For any cells that match *patterns* or *objects*, the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive; you can specify only one.

`-of_objects` *`objects`*

Creates a collection of cells connected to the specified objects. In this case, each object is either a named pin, a pin collection, a named net, a net collection, a named library cell, or a collection of library cells. Note that library cells can not be combined with other types of objects. The *-of_objects* and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

`patterns`

Matches cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type cell. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

This command creates a collection of cells in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any cells match the *patterns* or *objects* option and passes the filter (if specified). If no objects match the criteria, an empty string is returned.

If any *patterns* or *objects* option fails to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_cells* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_cells* result to a variable.

When issued from the command prompt, the *get_cells* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_cells* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command (for example, if you want to display the object class), use the *get_cells* command as an argument to the *query_objects* command.

For information about collections and querying of objects, see the *collections* man page.

Examples

The following example queries the cells that begin with "o" and reference an FD2 library cell. Although the output looks like a list, it is not. The output is just a display.

```
pt_shell> get_cells "o*" -filter "ref_name == FD2"
{"o_reg1", "o_reg2", "o_reg3", "o_reg4"}
```

The following example shows that, given a collection of pins, you can query the cells connected to those pins.

```
pt_shell> set pinsel [get_pins o*/CP]
{"o_reg1/CP", "o_reg2/CP"}

pt_shell> query_objects [get_cells -of_objects $pinsel]
{"o_reg1", "o_reg2"}
```

The following example removes the wire load model from cells i1 and i2.

```
pt_shell> remove_wire_load_model [get_cells {i1 i2}]
Removing wire load model from cell 'i1'.
Removing wire load model from cell 'i2'.
1
```

get_cells

Creates a collection of cells from the current design relative to the current instance. You can assign these cells to a variable or pass them into another command.

Syntax

collection *get_cells*

```
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-filter expression]
[-of_objects objects]
patterns
```

Data Types

expression	string
objects	list
patterns	list

Arguments

`-hierarchical`

Searches for cells level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a cell block1/adder, a hierarchical search finds it using "adder".

`-filter expression`

Filters the collection with the *expression* value. For any cells that match *patterns* or *objects*, the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

Feedback

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive; you can specify only one.

`-of_objects` *`objects`*

Creates a collection of cells connected to the specified objects. In this case, each object is either a named pin, a pin collection, a named net, a net collection, a named library cell, or a collection of library cells. Note that library cells can not be combined with other types of objects. The *-of_objects* and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

`patterns`

Matches cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type cell. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

This command creates a collection of cells in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any cells match the *patterns* or *objects* option and passes the filter (if specified). If no objects match the criteria, an empty string is returned.

If any *patterns* or *objects* option fails to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always

anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_cells* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_cells* result to a variable.

When issued from the command prompt, the *get_cells* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_cells* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command (for example, if you want to display the object class), use the *get_cells* command as an argument to the *query_objects* command.

For information about collections and querying of objects, see the *collections* man page.

Examples

The following example queries the cells that begin with "o" and reference an FD2 library cell. Although the output looks like a list, it is not. The output is just a display.

```
pt_shell> get_cells "o*" -filter "ref_name == FD2"
{"o_reg1", "o_reg2", "o_reg3", "o_reg4"}
```

The following example shows that, given a collection of pins, you can query the cells connected to those pins.

```
pt_shell> set pinsel [get_pins o*/CP]
{"o_reg1/CP", "o_reg2/CP"}

pt_shell> query_objects [get_cells -of_objects $pinsel]
{"o_reg1", "o_reg2"}
```

The following example removes the wire load model from cells i1 and i2.

```
pt_shell> remove_wire_load_model [get_cells {i1 i2}]
Removing wire load model from cell 'i1'.
Removing wire load model from cell 'i2'.

---

get_clock_crossing_points

Gets a collection of clock-crossing endpoints between the given launch and the capture clocks.

Syntax

string *get_clock_crossing_points*

```
[-from from_clock]
[-to to_clock]
[-valid]
[-quiet]
```

Data Types

```
from_clock    collection of one object
to_clock      collection of one object
valid         Boolean
quiet         Boolean
```

Arguments

`-from from_clock`

Launch clock for getting endpoints.

`-to to_clock`

Capture clock for getting endpoints.

`-valid`

Does not include endpoints that only have false paths reaching them.

`-quiet`

Does not issue an error if no endpoints are found.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Gets a collection of endpoints where the launch clock is the *from_clock* and the capture clock is *to_clock*. By default, all such endpoints are included, even though the paths between launch clock and capture clock are all *false*, or if there is a clock groups relationship between the clocks.

Feedback

To obtain only non-false path endpoints, use the *-valid* option. To not report any error if no such endpoints could be found, use the *-quiet* option.

Examples

The following example shows a simple usage:

```
pt_shell> get_clock_crossing_points -from CLK1 -to CLK2
{"ffa/D", "ffb/D"}
```

See Also

- report_clock_crossing

---

get_clock_network_objects

Returns a collection of objects that belong or relate to the direct clock network.

Syntax

collection *get_clock_network_objects*

```
-type cell | register | net | pin | clock_gating_output
[-include_clock_gating_network]
[clock_list]
```

Data Types

```
clock_list     list
```

Arguments

```
-type cell | register | net | pin | clock_gating_output
```

Specifies one of the following types of clock network objects to return:

- *cell* - Cells that belong to the clock network, including non-inverting or inverting buffers, combinational cells, library defined clock gating cells, etc.
- *register* - Latches, flip-flops or black-box IPs, such as memory cells, that are driven by the clock network.
- *net* - Nets that connect the clock network cells to other clock network cells, to the driven registers, or to the I/O ports of design.
- *pin* - Pins and ports that are connected with the clock network nets. Note that the clock pins of the driven registers are included.
- *clock_gating_output* - Output pins of clock gating cells, either defined by the library, inserted by Power Compiler, automatically inferred by PrimeTime,

or manually set by the user. The results are consistent with those of *report_clock_gating_checks*, and can be affected by other clock gating check related commands or variables.

`-include_clock_gating_network`

Indicates that clock gating networks are included in the clock network.

`clock_list`

Specifies the clock domains of which the clock network objects are returned. By default, the command returns all clock network objects.

Description

This command returns a collection of clock network objects of certain type (specified by the *object_type* option) that belong or relate to one or several clock domains (specified by the *clock_list* option), or all clock domains if the *clock_list* option is not specified.

A clock network is a special logic part of the design that propagates the clocks from the clock sources to the clock pins of latches, flip-flops (that function as anything but propagating clocks) or black-box IPs. The propagation also stops at design output ports, dangling pins or nets, or the sources of other clocks. The *get_clock_network_objects* command retrieves certain types of objects from the direct clock network (including the latches, flip-flops and black-box IPs driven by the clock network). If the specified clock is a generated clock, the propagation does not go backward to the clock network of its master clock. If the specified clock is a master clock, the propagation does not go forward to the clock network of its generated clocks either.

The *-include_clock_gating_network* option indicates that discrete logic structure functioning as clock gating is taken as belonging to the clock network. Only the typical clock gating logic is considered as qualified clock gating network to be included in the clock network. The typical clock gating logic starts from the output of a level sensitive latch driven by the specified clock, possibly goes through a couple of buffers, and comes back to the specified clock network through one of the input pins of an AND or OR gate. The input pin must be a PrimeTime clock check enable pin, either inferred or manually set. Therefore, similarly, the results can be affected by clock gating check related commands or variables. When the clock gating network is included in the clock network, all objects in the clock gating network is considered as clock network objects. The latch is regarded as a clock network *cell*, but not a clock network *register*. The *clock_gating_output* object type is not affected by this option.

Examples

The following command returns a collection of clock network pins of all clock domains in the design, not including pins of the clock gating networks.

```
pt_shell> get_clock_network_objects -type pin
```

get_clock_relationship

Shows the relationship between two clocks.

Syntax

string *get_clock_relationship*

```
[-type logically_exclusive | physically_exclusive | asynchronous |
 allow_paths]
clock_list
```

Data Types

clock_list	list

Feedback

Arguments

`-type logically_exclusive | physically_exclusive | asynchronous | allow_paths`

Checks one of the following types of clock relationship:

- *logically_exclusive* - Returns true if two given clocks are logically exclusive.
- *physically_exclusive* - Returns true if two given clocks are physically exclusive.
- *asynchronous* - Returns true if two given clocks are asynchronous to each other.
- *allow_paths* - Returns true if two given clocks are asynchronous and the timing analysis is allowed between these two clocks.

clock_list

This required argument specifies a list of clocks, which must contain two entries.

Description

Shows the relationship between two given clocks. If the option *-type* is not specified, the command returns a list of all relationships that exist between the two given clocks.

If the option *-type* is specified, the command returns either *true* or *false* depending on the existence of the relationship of given type between the two clocks.

Examples

The following example defines two asynchronous clock domains. The relationship between two clocks is then shown:

```
pt_shell> set_clock_groups -asynchronous -name g1 -group CLK33 -group
 CLK50
1
pt_shell> get_clock_relationship {CLK33 CLK50}
{asynchronous}
pt_shell> get_clock_relationship {CLK33 CLK50} -type logically_exclusive
false
pt_shell> get_clock_relationship {CLK33 CLK50} -type asynchronous
true
```

See Also

- create_clock
- remove_clock_groups

Feedback

- report_clock
- set_clock_groups

---

get_clocks

Creates a collection of clocks from the current design. You can assign these clocks to a variable or pass them into another command.

Syntax

collection *get_clocks*

```
[-quiet]
[-regexp]
[-nocase]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-filter expression`

Filters the collection with the *expression* option. For any clocks that match the *patterns* argument, the expression is evaluated based on the clock's attributes. If the expression evaluates to true, the clock is included in the result.

patterns

Matches clock names against patterns. Patterns can include the wildcard characters "*" and "?".

Feedback

Description

The *get_clocks* command creates a collection of clocks in the current design that match certain criteria. The command returns a collection if any clocks match the *patterns* argument and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

You can use the *get_clocks* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_clocks* command result to a variable.

When issued from the command prompt, the *get_clocks* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_clocks* command provides a fast, simple way to display clocks in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use the *get_clocks* command as an argument to the *query_objects* option.

For information about collections and the querying of objects, see the *collections* man page. In addition, see the man page for the *all_clocks* command, which also creates a collection of clocks.

Examples

The following example applies the *set_max_time_borrow* command to all clocks in the design matching "PHI*".

```
pt_shell> set_max_time_borrow 0 [get_clocks "PHI*"]
```

The following example sets the variable clock_list to a collection of clocks that have period of 15.

```
pt_shell> set clock_list [get_clocks * -filter "period==15"]
```

Feedback

get_command_hooks

Get registered hooks for this command

Syntax

string *get_command_hooks commandName*

```
string commandName
```

Arguments

commandName

Command to query

Description

The *get_command_hooks* command returns information about any hooks registered on the specified command. The data returned is in Tcl dict format and may be queried using that command.

Examples

When a command has both before and after hooks registered the data will look like this

```
prompt> get_command_hooks place_opt
before {before0 report_timing}
after {after0 {echo "Done with placement"}}
```

See Also

- add_command_hook
- remove_command_hook
- get_current_hook_command

get_command_option_values

Queries current or default option values.

Syntax

get_command_option_values

[-default | -current]

-command *command_name*

Feedback

Data Types

command_name string

Arguments

-default

Gets the default option values, if available.

-current

Gets the current option values, if available.

-command *command_name*

Gets the option values for this command.

Description

This command attempts to query a default or current value for each option (of the command) that has default and/or current-value-tracking enabled. Details of how the option value is queried depend on whether one of the *-current* or *-default* options is specified (see below).

A "Tcl array set compatible" (possibly empty) list of option names and values is returned as the Tcl result. The even-numbered entries in the list are the names of options that were enabled for default-value-tracking or current-value-tracking and had at least one of these values set to a not-undefined value). Each odd-numbered entry in the list is the default or current value of the option name preceding it in the list.

Any options that were not enabled for either default-value-tracking nor current-value-tracking are omitted from the output list. Similarly, options that were enabled for default-value-tracking or current-value-tracking, but for which no (not-undefined) default or current value is set, are omitted from the result list.

If neither *-current* nor *-default* is specified, then for each command option that has either default-value-tracking or current-value-tracking (or both) enabled, the value returned is as follows:

- The current value is returned if current-value-tracking is enabled and a (not-undefined) current value has been set;
- Otherwise the default value is returned if default-value-tracking is enabled and a (not-undefined) default value has been set;
- Otherwise the name and value pair for the option is not included in the result list.

If *-current* is specified, the value returned for an option is the current value if current-value-tracking is enabled, and a (not-undefined) current value has been set; otherwise the name and value pair for the option is omitted from the result list.

Feedback

If *-default* is specified, the value returned for an option is the default value if default-value-tracking is enabled, and a (not-undefined) default value has been set; otherwise the name and value pair for the option is omitted from the result list.

The result list from *get_command_option_values* includes option values of both dash options and positional options (assuming that both kinds of options of a command have been enabled for value-tracking).

The command issues a Tcl error in a variety of situations, such as if an invalid command name was passed in with *-command*.

Examples

The following example shows the use of *get_command_option_values*:

```
prompt> test -opt1 10 -opt2 20
1

prompt> get_command_option_values -command test
-bar1 10 -bar2 20
```

---

get_coupling_capacitors

Creates a collection of parasitic coupling capacitors from the specified net. You can assign these coupling capacitors to a variable or pass them into another command.

Syntax

collection *get_coupling_capacitors*

```
[-filter expression]
[-quiet]
[-parasitic_corners corner_list]
[-all_parasitic_corners]
[-of_objects objects]
[-from node_name]
[-to node_name]
[-unit]
[-info]
```

Data Types

```
expression          string
corner_list         list
```

```
objects             list
node_name           string
```

Arguments

`-filter` *expression*

Filters the collection with the *expression* value. For any coupling capacitors that match *patterns* or *objects*, the expression is evaluated based on the coupling capacitor's attributes. If the expression evaluates to true, the coupling capacitor is included in the result.

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-parasitic_corners` *corner_list*

Indicates the parasitic corner ordering for coupling capacitance values. This option is only applicable for parasitics information obtained using *read_parasitics* with the GPD parasitic format. If the *-parasitic_corners* option is not specified, then the single parasitic corner specified by *set parasitic_corner_name* is returned.

`-all_parasitic_corners`

Specifies that all parasitic corners are to be returned. The parasitics ordering is determined according to the corner definitions of the GPD parasitics.

`-of_objects` *objects*

Creates a collection of coupling capacitors associated with the specified objects. Each object must be a named net or net collection.

You must use either the *-of_objects* option or the *-from* and *-to* options.

`-from` *node_name*

Constrains the selected coupling_capacitors to be part of a path starting from the specified node. The node name can be either a pin, port, or an internal node, where the internal node name syntax is *net_name*:*node_id*, where the legal *node_id* range is from 1 to the number of nodes in the net. This option is used only with the *-to* option.

`-to` *node_name*

Constrains the selected coupling_capacitors to be part of a path ending with the specified node, using the same node name syntax as the *-from* option.

`-unit`

Show unit of coupling_capacitors

Feedback

`-info`

Get unit info of coupling_capacitors

Description

This command creates a collection of coupling capacitors for the specified nets that match certain criteria. You must use either the *-of_objects* option and specify a net collection or the *-from* and *-to* options to specify a path from which to get the coupling capacitors. If no objects match the criteria, an empty string is returned.

When issued from the command prompt, the *get_coupling_capacitors* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

For information about collections and querying of objects, see the *collections* man page.

Examples

The following example queries the parasitic coupling capacitors of net n22, subject to those objects whose max corner capacitance is greater than 0.5e-3.

```
pt_shell> get_coupling_capacitors -of_objects n22 \\
  -filter "capacitance_max > 0.5e-3"
{"coupling_capacitor"}
```

---

get_current_hook_command

Get the currently running command string

Syntax

string *get_current_hook_command*

Feedback

Description

The *get_current_hook_command* command may only be run from within a command hook. The command returns the command string used to invoke the command.

Note that option values may have been abbreviated when the hooked command was executed. In that case the information returned will also include abbreviated option values.

See Also

- add_command_hook
- remove_command_hook

---

get_current_power_domain

Gets the power domains that are included in the power analysis.

This command works only in UPF mode.

Syntax

string *get_current_power_domain*

Arguments

None.

Description

The *set_current_power_domain* command provides the control of calculating power consumption for the domains of interest. Domain-based power consumption data can be generated for a multipower domain design. Only the power dissipated in the blocks covered by the current power domain list is calculated and reported. The *get_current_power_domain* command returns the power domains included in the power analysis.

Examples

The following example shows generating domain-based power analysis results. The design has two subblocks, InstA and InstB, which are covered by power domains PD1 and PD2, respectively. The first *report_power* command generates the power analysis results for the whole design, which is the default behavior. The second *report_power* command generates the power analysis results for the power consumed in power domain PD1. The third *report_power* command generates the results for the power consumed in power domain PD2.

```
pt_shell> ...
pt_shell> create_power_domain PD1 -elements {InstA}
pt_shell> create_power_domain PD2 -elements {InstB}
pt_shell> ...
pt_shell> report_power
pt_shell> set_current_power_domain PD1
pt_shell> report_power
pt_shell> get_current_power_domain
pt_shell> set_current_power_domain PD2
pt_shell> report_power
pt_shell> get_current_power_domain
```

See Also

- set_current_power_domain

---

get_current_power_net

Gets the power nets that are included in the power analysis.

This command works in UPF mode only.

Syntax

string *get_current_power_net*

Arguments

None.

Description

The *set_current_power_net* command provides control of calculating power consumption for the power nets of interest. Power net-based power consumption data can be generated for a multi-supply design. Only the power dissipated on the cell or part of cell that is supplied by the current power netlist is calculated and reported. The *get_current_power_net* command returns the power nets being included in the power analysis.

Examples

The following example shows generating power net-based power analysis results. The design has two subblocks "InstA" and "InstB", which is covered by power domain PD1 and PD2, respectively. There are a total of six supply nets defined. Among them, four are power nets and two are ground nets. The primary power net for power domain "PD1" is "VDDIS", and the primary power net for power domain "PD2" is "VDDGS". The first *report_power* command generates the power analysis results for the whole design, which is the default behavior. The second *report_power* command generates the power consumption associated with power net "VDDI". The third *report_power* command

generates the power consumption associated with power net "VDDIS", which is the output of power switch "top_header". The fourth and fifth reports are for "VDDG" and "VDDGS", respectively.

```
pt_shell> ...
pt_shell> create_power_domain PD1 -elements {InstA}
pt_shell> create_power_domain PD2 -elements {InstB}
pt_shell> create_supply_net VDDI  -domain PD1
pt_shell> create_supply_net VDDIS -domain PD1
pt_shell> create_supply_net VSS   -domain PD1
pt_shell> set_domain_supply_net PD1 -primary_power_net VDDIS
 -primary_ground_net VSS
pt_shell> connect_supply_net -ports InstA/LS_u1/VDDL VDDI
pt_shell> connect_supply_net -ports InstA/LS_u1/VDD VDDIS
pt_shell> connect_supply_net -ports InstA/LS_u1/VSS VSS
pt_shell> create_power_switch top_header \\
                     -domain PD1 \\
                     -output_supply_port {NSLEEPOUT VDDIS} \\
                     -input_supply_port {NSLEEPIN VDDI} \\
                     -on_state {state1 NSLEEPIN {CNTL}} \\
                     -control_port { CNTL ctrl }
pt_shell> ...

Feedback

get_current_sms_scenario

Queries the SMS scenarios pushed by the closest/most recent *push_sms_scenario* command.

Syntax

string *get_current_sms_scenario*

Description

The *get_current_sms_scenario* command can be used to query the SMS scenarios pushed by the closest/most recent *push_sms_scenario* command. These are the SMS scenarios applicable in the current context. This command is only available with SMVA/SMC analysis.

Examples

The following example specifies 3 voltage reference names {high,low,typ} for each one of the supply groups SN1 and SN2. PrimeTime automatically considers all the relevant combinations of voltage levels, in this case up to nine prior to the use of the *push_sms_scenario* command. The example shows a sequence of a *push_sms_scenario* command followed by a *pop_sms_scenario* command and their expected effect on subsequent *get_current_sms_scenario* commands. For more examples, please look at the *push_sms_scenario* command manual.

```
pt_shell> set_voltage_levels SN1 -reference_names { high low typ }
pt_shell> set_voltage -o SN1 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN1 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN1 -reference_name typ 0.9 -min 1.0
pt_shell> set_voltage_levels SN2 -reference_names { high low typ }
pt_shell> set_voltage -o SN2 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN2 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN2 -reference_name typ 0.9 -min 1.0
```

The following command shows no outstanding SMS scenarios are pushed by any previous *push_sms_scenario* command.

```
pt_shell> get_current_sms_scenario
0
```

The following command pushes the SN1:low SMS scenario collection. A subsequent command *get_current_sms_scenario* shows the SN1:low SMS scenario collection is now applicable to commands in the current context.

```
pt_shell> push_sms_scenario -sms_scenarios [get_sms_scenario
 -supply_group SN1 -reference_name low]

pt_shell> get_attribute [get_current_sms_scenario] description
{SN1:low}
```

Feedback

The following command pops the SN1:low SMS scenario collection, ending its corresponding scope. There are no outstanding pushed SMS scenario collections after this command, as shown using the *get_current_sms_scenario* command.

```
pt_shell> pop_sms_scenario

pt_shell> get_current_sms_scenario
0
```

---

get_defined_attributes

Returns attribute names defined for the specified class.

Syntax

string *get_defined_attributes*

```
-class class_name
-return_classes
[-details]
[-application]
[-user]
[attr_pattern]
```

Data Types

attr_pattern	string
class_name	string

Arguments

`-class class_name`

Specifies the class for which to get the attributes. Valid classes are application-defined. This option cannot be used with the *-return_classes* option.

`-return_classes`

Returns the set of application-defined classes. This option cannot be used with the *-class* option.

`-details`

Returns additional information on a single attribute.

Feedback

`-application`

Returns application-defined attributes only. This option is mutually exclusive with the *-user* option.

`-user`

Returns user-defined attributes only. This option is mutually exclusive with the *-application* option.

`attr_pattern`

Specifies a list of attribute names or glob-style patterns to check on the existences of.

Description

This command returns a list of attribute names that are defined for the specified class.

There are three legals forms for this command:

- *get_defined_attributess -return_classes*

  Returns the application defined object classes.

- *get_defined_attributes -class cell [<pattern>]*

  Returns all the attributes, optionally those matching a pattern.

- *get_defined_attributes -class cell -details <attrName>*

  Returns more detailed information about the attribute. See below for details.

When *-details* is specified, the return value is a Tcl list that is suitable as input to the Tcl *array set* command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key, and each even-numbered element in the list is the value of the previous key.

The supported keys are as follows:

name

This key contains the name of the attribute

info

The short help defined for the attribute

type

The type of value the attribute stores.

settable

Indicates that the value is settable with the *set_attribute* command.

application

The value is 1 if the attribute is application defined, else 0.

subscripted

The value is 1 if the attribute is subscripted, else 0.

min_value

Not always present. If present, the value is the minimum allowed value.

max_value

Not always present. If present, the value is the maximum allowed value.

allowed_values

Not always present. If present, the value is the set of allowed values.

allowed_subscripts

Present if the attribute is subscripted. Contains the list of legal subcripts for the attribute if the attribute uses global subscripts. If empty, then the subscripts vary per object.

smart_subscripts

Present if the attribute is subscripted. Contains the list of supported smart subscripts if the attribute supports smart subscripts.

collection_types

Present if the attribute is a collection type. Specifies the class names of objects that may be present.

default_subscript

Present on subscripted attributes if specification of the subscript value is optional.

user_derived

The value is 1 if the attribute was created by the *define_derived_user_attribute* command, else 0.

tcl_get_command

Present if the attribute is user_derived. Contains the command used to retrieve the attribute value.

tcl_set_command

Present if the attribute is user_derived. Contains the command used to set the attribute value

Feedback

tcl_remove_command

Present if the attribute is user_derived. Contains the command used to remove the attribute value.

tcl_subscript_command

Present if the attribute is user_derived and subscripted. Contains the command used to retrieve the valid subscripts for an object.

Examples

The following are examples of the *get_defined_attributes* command:

```
prompt> get_defined_attributes -class cell
name full_name object_class ....

prompt> get_defined_attributes -class cell *name*
name full_name reference_name ...

prompt> get_defined_attributes -class cell full_name -details
name full_name info {} type string application 1 settable 0
subscripted 0 user_derived 0
```

- get_attribute
- help_attributes

---

get_defined_commands

Get information on defined commands and groups.

Syntax

string *get_defined_commands* [-details]

[-groups] [*pattern*]

```
string pattern
```

Arguments

`-details`

Get detailed information on specific command or group.

`-groups`

Search groups rather than commands

Feedback

pattern

Return commands or groups matching pattern. The default value of this argument is "*".

Description

The *get_defined_commands* gets information about defined commands and command groups. By default the command returns a list of commands that match the specified pattern.

When *-details* is specified, the return value is a list that is suitable as input to the *array set* command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key name, and each even-numbered element in the list os the value of the previous key. The *-details* option is only legal if the pattern matches exactly one command or group.

When *-group* is specified with *-details*, the supported keys are as follows:

name

This key contains the name of the group.

info

This key contains the short help for the group.

commands

This key contains the commands in the group

When *-details* is used with a command, the supported keys are as follows:

name

This key contains the name of the command.

info

This key contains the short help for the command.

groups

This key contains the group names that this command belongs to.

options

This key contains the options defined for the command. The value is a list.

return

This key contains the return type for the command.

Feedback

Each element in the *options* list also follows the key value pattern. The set of available keys for options are as follows:

name

This key contains the name of the option.

info

This key contains the short help for the option.

value_info

This key contains the short help string for the value

type

The type of the option.

required

The value will be 0 or 1 depending if the option is optional or required.

is_list

Will be 1 if the option requires a list.

list_length

If a list contains the list length constraint. One of any, even, odd, non_empty or a number of elements.

allowed_values

The allowed values if the option has specified allowed values.

min_value

The minimum allowed value if the option has specified one.

max_value

The maximum allowed value if the option has specified one.

Examples

```
prompt> get_defined_commands *collection
add_to_collection append_to_collection copy_collection filter_collection
foreach_in_collection index_collection sort_collection
prompt> get_defined_commands -details sort_collection
name sort_collection info {Create a sorted copy of the collection}
groups {} options {{name -descending info {Sort in descending order}
value_info {} type boolean required 1 is_list 0} {name -dictionary info
{Sort strings dictionary order.} value_info {} type boolean required 1
is_list 0} {name collection info {Collection to sort} value_info
collection type string required 0 is_list 0} {name criteria info {Sort
```

Feedback

```
criteria - list of attributes} value_info criteria type list required 0
is_list 1 list_length non_empty}}
```

See Also

- help
- man

---

get_design

Creates a collection of one or more designs loaded into PrimeTime. You can assign these designs to a variable or pass them into another command.

Syntax

collection *get_designs*

```
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-hierarchical`

Searches for designs inferred by the design hierarchy relative to the current instance. The full name of the object at a particular level must match the patterns. Using this option does not force an autolink.

`-filter expression`

Filters the collection with the *expression* value. For any designs that match *patterns*, the expression is evaluated based on the design's attributes. If the expression evaluates to true, the design is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive; you can specify only one.

`patterns`

Matches design names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type design.

Description

This command creates a collection of designs from those currently loaded into PrimeTime that match certain criteria. The command returns a collection if any designs match the *patterns* option and pass the filter, if specified. If no objects matched your criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_designs* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_designs* result to a variable.

When issued from the command prompt, the *get_designs* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable .

The "implicit query" property of the *get_designs* command provides a fast, simple way to display designs in a collection. However, if you want the flexibility provided by the

query_objects command (for example, if you want to display the object class), use the *get_designs* command as an argument to the *query_objects* command.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the designs that begin with 'mpu.' Although the output looks like a list, it is just a display. A complete listing of designs is available using the *list_designs* command.

```
pt_shell> get_designs mpu*
{"mpu_0_0", "mpu_0_1", "mpu_1_0", "mpu_1_1"}
```

The following example shows that, given a collection of designs, you can remove those designs.

```
pt_shell> remove_design [get_designs mpu*]
Removing design mpu_0_0...
Removing design mpu_0_1...
Removing design mpu_1_0...
Removing design mpu_1_1...
```

See Also

- collections
- filter_collection
- list_designs
- query_objects
- remove_design
- collection_result_display_limit

---

get_design_variation

Performs design variation analysis based on Monte Carlo (MC) statistical simulation for the given path collection and generates a *design_variation* object collection.

Syntax

collection *get_design_variation*

```
path_collection
[-sample_size number]
```

Feedback

Data Types

path_collection	collection
number	int

Arguments

path_collection

Specifies the timing path collection for design variation analysis, as generated by the *get_timing_paths* command.

-sample_size *number*

Specifies the number of samples in the Monte Carlo (MC) run. The default is 10000. The range is from 5000 to 1000000000 (1 billion). Larger sample counts require more runtime and memory for simulation.

Description

This command performs design variation analysis based on Monte Carlo (MC) statistical simulation for the given path collection. The command returns a *design_variation* object. You can then use the *report_design_variation* and *report_variation_bottleneck* commands to generate design variation-related reports on the *design_variation* object.

To generate a path collection for design variation analysis, use the *get_timing_paths* command with the *-pba_mode path* or *-pba_mode exhaustive* option, and use the *-pocv_pruning* option to save runtime. The *-pocv_pruning* option prunes away subcritical paths not contributing to a high sigma failure rate.

You can specify the number of samples used in Monte Carlo simulation. The default is 10,000 samples, resulting in a *get_design_variation* runtime of about 10 minutes or less for a collection of 1 million paths. Using more samples or a larger path collection results in more runtime and memory usage. To reduce the turnaround time, it is recommended to specify 16 cores in the *set_host_options* command.

Design variation analysis requires that the *ps_enable_analysis* variable be set to *true*.

Examples

The following example shows a typical usage of the *get_design_variation* command.

```
prompt> set mypaths \\
          [get_timing_paths \\
            -pba_mode exhaustive \\
            -path_type full_clock_expanded -nworst 10 \\
            -max_paths 2000000 -pocv_pruning -slack_lesser_than 1.0]

prompt> set mydvar [get_design_variation -sample_size 100000 $mydvar]

prompt> report_design_variation -num_sigma 3.0 -nworst 10 $mydvar \\
           -significant_digits 5 -nosplit
```

get_designs

Creates a collection of one or more designs loaded into PrimeTime. You can assign these designs to a variable or pass them into another command.

Syntax

collection *get_designs*

```
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-hierarchical`

Searches for designs inferred by the design hierarchy relative to the current instance. The full name of the object at a particular level must match the patterns. Using this option does not force an autolink.

`-filter expression`

Filters the collection with the *expression* value. For any designs that match *patterns*, the expression is evaluated based on the design's attributes. If the expression evaluates to true, the design is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive; you can specify only one.

`patterns`

Matches design names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type design.

Description

This command creates a collection of designs from those currently loaded into PrimeTime that match certain criteria. The command returns a collection if any designs match the *patterns* option and pass the filter, if specified. If no objects matched your criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_designs* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_designs* result to a variable.

When issued from the command prompt, the *get_designs* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable .

Feedback

The "implicit query" property of the *get_designs* command provides a fast, simple way to display designs in a collection. However, if you want the flexibility provided by the *query_objects* command (for example, if you want to display the object class), use the *get_designs* command as an argument to the *query_objects* command.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the designs that begin with 'mpu.' Although the output looks like a list, it is just a display. A complete listing of designs is available using the *list_designs* command.

```
pt_shell> get_designs mpu*
{"mpu_0_0", "mpu_0_1", "mpu_1_0", "mpu_1_1"}
```

The following example shows that, given a collection of designs, you can remove those designs.

```
pt_shell> remove_design [get_designs mpu*]
Removing design mpu_0_0...
Removing design mpu_0_1...
Removing design mpu_1_0...
Removing design mpu_1_1...
```

---

get_distributed_variables

From the DMSA manager, gets the values of Tcl variables from workers and creates either an array of values, indexed by the scenario name, or a list of merged values.

Syntax

status *get_distributed_variables*

```
[-pre_commands pre_command_string]
[-post_commands post_command_string]
```

Feedback

```
[-attributes attribute_list]
[-merge_type min | max | average | sum | list | unique_list | none]
[-null_merge_method ignore | error | override]
variable_list
```

Data Types

```
pre_command_string          string
post_command_string         string
attribute_list              list
variable_list               list
```

Arguments

`-pre_commands pre_command_string`

Specifies a string of commands to be executed in the worker context before the retrieval of variables. Group commands with the semicolon character (;). The maximum length of the command string is 1,000 characters.

`-post_commands post_command_string`

Specifies a string of commands to be executed in the worker context after the retrieval of variables. Group commands with the semicolon character (;). The maximum length of the command string is 1,000 characters.

`-attributes attribute_list`

Specifies a list of attributes to be retrieved from a worker collection. If you do not use this option, only the *full_name*, *scenario_name*, and *object_class* attributes are retrieved. Use this option together with the *set_distributed_parameter -collection_levels* command to control the number of collection levels to traverse when retrieving attributes from each worker.

`-merge_type min | max | average | sum | list | unique_list | none`

Merges variable values that come from the scenarios as they are retrieved, producing a single value or list. You can specify any one of the following arguments:

- *min* - Gets the minimum variable value.
- *max* - Gets the maximum variable value.
- *average* - Gets the average of all variable values.
- *sum* - Gets the sum of all variable values.
- *list* - Gets a single list of all variable values. If the inputs are list variables, then a combined list is created. If the inputs are arrays, then merging is performed element by element and a single array is created. In the result, the members of the list can be in any order.

- *unique_list* - Same as the *list* option except that duplicate elements are removed from the list or array created.
- *none* (default)- Brings back the scenario variable values as an array, indexed by the scenario name.

Scalar variables, lists, and arrays of one or more dimensions can be merged, but not collection objects.

`-null_merge_method ignore | error | override`

Specifies the tool behavior when a null (empty) value of {} is encountered during the merging operations. You can specify one of the following arguments:

- *ignore* (default) - Ignores the null value.
- *error* - Issues an error message if a null value is found.
- *override* - Allows a null value to override other values.

`variable_list`

Specifies a list of variables to retrieve from the workers.

Description

The *get_distributed_variables* command retrieves variable values from the workers and makes them available for further processing at the manager. The variables specified in the *variable_list* option must be worker variables. Each worker variable can have a different value depending on the scenario context. This command can be used only in the manager process of a distributed multi-scenario analysis (DMSA) run.

By default, the command creates an array at the manager for each variable. The array has the same name as the variable and is indexed by the scenario name. Each value in the array for a given scenario index has the same value as the worker variable in that scenario's context. The variable can be a Tcl array, Tcl list, or collection.

By default, the *get_distributed_variables* command brings back a scenario variable as an array. By using the *-merge_type* option, you can merge the values back into a variable during retrieval. Merging can be especially useful when you are writing customized DMSA scripts.

When the number of scenarios is greater than the number of processors, variables can be destroyed during the save and restore process. In that situation, use the *-pre_commands* option to generate the variables to be transmitted. When retrieving a collection, use the *-attributes* option to specify what attributes are to be retrieved from the workers for the given collection.

Examples

In the following example, the number of scenarios is less than the number of processors.

```
pt_shell> remote_execute {set my_paths [get_timing_paths -nworst 10]}
pt_shell> get_distributed_variables my_paths -attributes {slack}
pt_shell> foreach_in_collection path $my_paths(scen1) {
             echo [get_attribute $path slack]
             }
pt_shell> remote_execute {set pslack [get_attribute get_pins U1/A] slack}
pt_shell> get_distributed_variables pslack
pt_shell> echo [array get pslack]
{scen1 0.1231 scen2 0.1232}
```

In the following example, the number of scenarios is greater than the number of processors.

```
pt_shell> get_distributed_variables my_paths \\
  -pre_commands {set my_paths [get_timing_paths -nworst 10]} -attributes
 slack
```

The following example shows how to access an attribute that is a collection.

```
pt_shell> remote_execute {set my_pins [get_pins *]}
pt_shell> get_distributed_variable my_pins -attributes {direction clocks}
pt_shell> foreach_in_collection pin $my_pins(scen1) {
               echo "direction:[get_attribute $pin direction]"
               set my_clocks [get_attribute $pin clocks]
               foreach_in_collection my_clock $my_clocks {
               echo "full clock name : get_attribute $my_clock
 full_name" }
          }
```

In the following example, the slack variable is set at each scenario, and the *get_distributed_variables* command returns the minimum value of the variable.

```
scenario best_case:
set slack 0.3084

scenario typical_case:
set slack 0.0901

scenario worst_case:
set slack -0.7081

pt_shell> get_distributed_variables {slack} -merge_type min
1
pt_shell> echo $slack
-0.7081
```

The following example generates a list of all clocks at all scenarios:

```
pt_shell> remote_execute {set clock_names \\
             [get_object_name [all_clocks]]}
pt_shell> get_distributed_variables clock_names -merge_type list
```

```
1
pt_shell> echo $clock_names
CLK33 CLK66 CLK50 CLK100 ATPGCLOCK JTAGCLK
```

The following example merges the my_cells variable from three scenarios with the *unique_list* mode:

```
scenario best_case:
set cells {{U1 U2} {U4 U5} {U7 U8}}
scenario type_case:
set cells {{U2 U3} {U6 U7}}
scenario worst_case:
set cells {{U1} {U5 U6}}

pt_shell> get_distributed_variables my_cells -merge_type unique_list
1
pt_shell> echo $my_cells
U4 U7 U3 U1 U5 U8 U6 U2
```

---

get_drc_error_data

Creates a collection of DRC error data objects.

Syntax

```
collection get_drc_error_data
[-all]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects objects]
[patterns]
```

Data Types

```
expression          string
exact_count         int
minimum_count       int
objects             list
patterns            list
```

Feedback

Arguments

`-all`

Includes unopened DRC error data objects, if matched. The default is to return only DRC error data objects that are currently open.

`-filter` *`expression`*

Filters the collection with *expression*.

For any DRC error data objects that match the *patterns* or *objects* argument, the expression is evaluated based on the DRC error data object's attributes. If the expression evaluates to true, the DRC error data object is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* argument and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters.

The *-regexp* and *-exact* options are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find.

If the command finds a different number of objects, it raises a Tcl error and stops processing.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find.

If the command finds fewer objects, it raises a Tcl error and stops processing.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object.

If one or more patterns does not match, the command raises a Tcl error and stops processing.

`-of_objects` *`objects`*

Creates a collection of DRC error data objects connected to the specified objects. You can specify the following types of objects: DRC error types (drc_error_type), DRC errors (drc_error), and blocks.

The *-of_objects* option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

`patterns`

Matches DRC error data object names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of DRC error data objects.

The *-of_objects* option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

Description

The *get_drc_error_data* command creates a collection of DRC error data objects that match certain criteria. The command returns a collection if any DRC error data objects match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the command returns the empty string.

To include DRC error data objects that are not open, use the *-all* option. The *get_drc_error_data* command creates a collection that contains the DRC error data object, but does not open the DRC error data object. To query or modify the error type objects and error objects in the DRC error data object, you must open the DRC error data object with the *open_drc_error_data* command.

You can use the *get_drc_error_data* command at the command prompt or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_drc_error_data* result to a variable.

When issued from the command prompt, *get_drc_error_data* behaves as though *query_objects* had been called to display the objects in the collection. By default, a

Feedback

maximum of 100 objects is displayed; you can change this maximum by using the *shell.common.collection_result_display_limit* application option.

The "implicit query" property of the *get_drc_error_data* command provides a fast, simple way to display the DRC error data objects in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use the *get_drc_error_data* command as an argument to the *query_objects* command.

For information about collections and the querying of objects, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example creates a collection that contains the DRC error data object named "dppinassgn.err", and then opens it.

```
prompt> set data [get_drc_error_data -all dppinassgn.err]
{"dppinassgn.err"}
prompt> open_drc_error_data $data
{"dppinassgn.err"}
```

---

get_drc_error_types

Creates a collection of physical DRC error types from the given error data. You can assign these physical DRC error types to a variable or pass them into another command.

Syntax

```
collection get_drc_error_types
-error_data drc_error_data
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
```

Feedback

```
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
[-of_objects objects]
```

Data Types

```
drc_error_data  collection
expression      string
exact_count     int
minimum_count   int
patterns        list
objects         list
```

Arguments

`-error_data drc_error_data`

Specifies the error data in which to find objects.

`-filter expression`

Filters the collection with *expression*. For any physical DRC error types that match *patterns* (or *objects*) the expression is evaluated based on the physical DRC error type's attributes. If the expression evaluates to true, the physical DRC error type is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as a true regular expression rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with true regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Creates a collection of physical DRC error types connected to the specified objects. In this case, each object is either a named drc_error or a drc_error collection. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

`patterns`

Matches physical DRC error type names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of drc_error_type. *patterns* and *-of_objects* are mutually exclusive; you must specify one, but not both. If both the *patterns* and *-of_objects* are omitted, then the wildcard "*" is used as the *pattern*

Description

The *get_drc_error_types* command creates a collection of physical DRC error types in the given error data that match certain criteria. The command returns a collection if any physical DRC errors match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_drc_error_types* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_drc_error_types* result to a variable.

Feedback

When issued from the command prompt, *get_drc_error_types* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the *shell.commmon.collection_result_display_limit* application option.

The "implicit query" property of *get_drc_error_types* provides a fast, simple way to display physical DRC error types in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_drc_error_types* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the physical DRC error type that is named "route short". Although the output looks like a list, it is not. The output is just a display. The quotation marks around (route short) are required because the type name contains a space.

```
prompt> set data [open_drc_error_data -file_name my_design.err]
prompt> get_drc_error_types -error_data $data {"route short"}
{"route short"}
```

The following example shows that, given a collection of physical DRC errors, you can query the physical DRC error types connected to those errors.

```
prompt> set error [get_drc_errors -error_data $data 9]
{"9"}
prompt> query_objects [get_drc_error_types -error_data $data -of_objects
 $error]
{"route short"}
```

The following example gets the physical DRC errors associated with an error type.

```
prompt> get_drc_errors -error_data $data -of_objects \\
        [get_drc_error_types -error_data $data {"route short"}]
{"9", "10", "11"}
1
```

See Also

- collections
- filter_collection
- query_objects

Feedback

get_drc_errors

Creates a collection of physical DRC errors from the given error data. You can assign these physical DRC errors to a variable or pass them into another command.

Syntax

```
collection get_drc_errors
-error_data drc_error_data
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
[-of_objects objects]
[-boundary region]
```

Data Types

drc_error_data	collection
expression	string
exact_count	int
minimum_count	int
objects	list
region	region
patterns	list

Arguments

`-error_data` *drc_error_data*

Specifies the error data for finding objects.

`-filter` *expression*

Filters the collection with *expression*. For any physical DRC errors that match *patterns* (or *objects*) the expression is evaluated based on the physical DRC error's attributes. If the expression evaluates to true, the physical DRC error is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators

to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Creates a collection of physical DRC errors connected to the specified objects. In this case, each object is either a named drc_error_type, net, pin, port, cell, pin guide, voltage area, or a collection of these objects. *-of_objects* and *patterns* are mutually exclusive; you may specify one, but not both.

`-boundary` *`region`*

Creates a collection of physical DRC errors with shapes within or touching the specified boundary shape. The region may be entered as a bounding box or as a list of coordinates. *-boundary* and *patterns* are mutually exclusive; you may specify one, but not both.

`patterns`

Matches physical DRC error names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type drc_error. *patterns* and *-of_objects* are mutually exclusive; you may specify one, but not both. *patterns* is also mutually exclusive with *-of_objects*; you may specify one, but not both. If both the *patterns* and *-of_objects* are ommitted, then the wildcard "*" is used as the *pattern*

Feedback

Description

The *get_drc_errors* command creates a collection of physical DRC errors in the given error data that match certain criteria. The command returns a collection if any physical DRC errors match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_drc_errors* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_drc_errors* result to a variable.

When issued from the command prompt, *get_drc_errors* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the *shell.common.collection_result_display_limit* application option.

The "implicit query" property of *get_drc_errors* provides a fast, simple way to display physical DRC errors in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_drc_errors* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the physical DRC errors that is associated with an error type named "route short". Although the output looks like a list, it is not. The output is just a display. Note the required quotes because the type name contains a space.

```
prompt> set data [open_drc_error_data -file_name my_design.err]
prompt> get_drc_errors -error_data $data -filter {type_name == "route
 short"}
{"9", "10", "11"}
```

The following example shows that, given a collection of error types, you can query the physical DRC errors connected to those error types.

```
prompt> set type [get_drc_error_types -error_data $data {{route short}}]
{"route short"}
prompt> query_objects [get_drc_errors -error_data $data -of_objects
 $type]
{"9", "10", "11"}
```

Feedback

The following example gets the *objects* attribute for physical DRC error 9, which in this case are two nets associated with the error.

```
prompt> get_attribute [get_drc_errors -error_data $data 9] objects
{"F_12_", "F_11_"}
1
```

---

get_em_max_capacitance

Reports electromigration (EM) maximum capacitance data from the library for a specified instance pin or library pin.

Syntax

status *get_em_max_capacitance*

```
[-related_pin pin]
[-transition_time transition_time]
[-toggle_rate toggle_rate]
[-current_type type]
object_name
```

Data Types

transition_time float *toggle_rate* float *load* float *object_name* string

Arguments

`-related_pin pin`

Reports max EM toggle rate for the specified arc.

`-transition_time float`

Specifies the transition time at the input.

`-toggle_rate float`

Specifies the toggle rate at the output pin.

`-current_type type`

Specifies the table to use for getting the maximum capacitance values. Valid values are *ave*, *rms*, and *peak*. If this option is not used, the command checks all three current types and gets the worst one.

Feedback

Description

This command reports the EM maximum capacitance from the library for a specific cell pin.

Examples

The following command reports the maximum capacitance for the pin 'U1/Z'.

```
pt_shell> get_em_max_capacitance U1/Z
```

The following command reports the maximum capacitance for the pin 'U2/Z' with the rms current type.

```
pt_shell> get_em_max_capacitance  -current_type rms U2/Z
```

---

get_em_max_toggle_rate

Reports electromigration (EM) maximum toggle rate data from the library for a specified instance pin or library cell pin.

Syntax

status *get_em_max_toggle_rate*

```
[-related_pin pin]
[-transition_time transition_time]
[-transition_type transition_type]
[-output_load load]
[-current_type type]
[-verbose]
object_name
```

Data Types

pin	pin
transition_time	float
transition_type	max|min
load	float
type	string
object_name	string

Feedback

Arguments

`-related_pin` *pin*

Reports max EM toggle rate for the specified arc.

`-transition_time` *float*

Specifies the transition time at the input.

`-transition_type` *max|min*

Specifies the transition type at input. Valid values are *max* and *min*.

`-output_load` *float*

Specifies the load at the output pin.

`-current_type` *type*

Specifies the table to use for toggle rate calculations. Valid values are *average*, *rms*, and *peak*. If this option is not used, the command checks only the RMS table.

`-verbose`

Shows the slew rate and capacitance values used for max toggle rate violation calculations; also reports errors for missing EM data for pins.

object_name

Specifies an instance pin from the current design or a library cell pin.

Description

This command reports the EM maximum toggle rate from the library for a specific cell pin or library cell pin.

Examples

The following command reports the max toggle rate for the pin 'cell_em/test_em_cell_2/Z' with a load of 5.4.

```
pt_shell> get_em_max_toggle_rate -output_load 5.4
 cell_em/test_em_cell_2/Z
```

The following command reports the max toggle rate for the pin 'cell_em/test_em_cell_2/A' with a transition time of 0.5.

```
pt_shell> get_em_max_toggle_rate  -transition_time 0.5
 cell_em/test_em_cell_2/A
```

```
The following command reports the EM max toggle rate arc for a specified
 arc.
```

Feedback

```
pt_shell> get_em_max_toggle_rate -transition_time 2.053 -output_load
 2.053  \\
  -related_pin cell_em/test_em_cell_3/A cell_em/test_em_cell_3/Z
```

The following command reports the max toggle for the specified pin from the average type table.

```
pt_shell> get_em_max_toggle_rate -current_type ave cell_em/test_em_cell/Z
```

---

get_generated_clock

Creates a collection of generated clocks.

Syntax

collection *get_generated_clocks*

```
[-quiet]
[-regexp]
[-nocase]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-filter` *`expression`*

Filters the collection with the *expression* option. For any generated clocks that match the *patterns* option, the expression is evaluated based on the generated clock's attributes. If the expression evaluates to true, the generated clock is included in the result.

`patterns`

Matches generated clock names against patterns. Patterns can include the wildcard characters "*" and "?".

Description

The *get_generated_clocks* command creates a collection of generated clocks from the current design that match certain criteria. The command returns a collection if any generated clocks match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

To create a generated clock in the design, use the *create_generated_clock* command. To remove a generated clock from the design, use the *remove_generated_clock* command. To show information about clocks and generated clocks in the design, use the *report_clock* command.

You can use the *get_generated_clocks* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_generated_clocks* command result to a variable.

When issued from the command prompt, the *get_generated_clocks* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_generated_clocks* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_generated_clocks* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following command applies the *set_clock_latency* command on all generated clocks in the design matching the "GEN*".

```
pt_shell> set_clock_latency 2.0 [get_generated_clocks "GEN*"]
```

The following command removes all the generated clocks in the design matching "GEN1*".

Feedback

```
pt_shell> remove_generated_clock [get_generated_clocks "GEN1*"]
```

---

get_generated_clocks

Creates a collection of generated clocks.

Syntax

collection *get_generated_clocks*

```
[-quiet]
[-regexp]
[-nocase]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-filter` *`expression`*

Filters the collection with the *expression* option. For any generated clocks that match the *patterns* option, the expression is evaluated based on the generated clock's attributes. If the expression evaluates to true, the generated clock is included in the result.

`patterns`

Matches generated clock names against patterns. Patterns can include the wildcard characters "*" and "?".

Description

The *get_generated_clocks* command creates a collection of generated clocks from the current design that match certain criteria. The command returns a collection if any generated clocks match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

To create a generated clock in the design, use the *create_generated_clock* command. To remove a generated clock from the design, use the *remove_generated_clock* command. To show information about clocks and generated clocks in the design, use the *report_clock* command.

You can use the *get_generated_clocks* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_generated_clocks* command result to a variable.

When issued from the command prompt, the *get_generated_clocks* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_generated_clocks* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_generated_clocks* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following command applies the *set_clock_latency* command on all generated clocks in the design matching the "GEN*".

```
pt_shell> set_clock_latency 2.0 [get_generated_clocks "GEN*"]
```

The following command removes all the generated clocks in the design matching "GEN1*".

```
pt_shell> remove_generated_clock [get_generated_clocks "GEN1*"]
```

---

get_gpd_corners

Returns a string containing a space-separated list of the operating condition corners defined in a specified GPD directory.

Syntax

string *get_gpd_corners*

`-gpd` *gpd_directory*

Data Types

gpd_directory	string

Arguments

`-gpd` *gpd_directory*

Specifies the absolute or relative path to the GPD directory.

Description

This command reports the operating condition corners stored in a Galaxy Parasitics Database (GPD) directory. You can query the database without reading it into the PrimeTime tool.

Examples

The following command reports the operating corners of the GPD directory named mypara.gpd.

```
pt_shell> get_gpd_corners -gpd /mydata/mydesign/mypara.gpd
CMINW125 CMINB40 CMINN25 CMAXW125 CMAXB40 CMAXN25
```

Feedback

See Also

---

get_gpd_layers

Returns a string containing a space-separated list of the layer names defined in a specified GPD directory.

Syntax

string *get_gpd_layers*

```
-gpd gpd_directory
[-type routing | via | all]
[-dblayer_name]
[-layer_name]
```

Data Types

```
gpd_directory       string
```

Arguments

`-gpd gpd_directory`

Specifies the absolute or relative path to the GPD directory.

`-type routing | via | all`

Specifies the type of layers to report: *routing* layers only, *via* layers only, or *all* layers. The default is *all*.

`-dblayer_name`

Outputs layers in terms of design layer name.

`-layer_name`

Outputs layers in terms of ITF mask name.

Description

This command reports the names of the layers stored in a Galaxy Parasitics Database (GPD) directory. You can query the database without reading it into the PrimeTime tool.

Feedback

Examples

The following command reports all layers of the GPD directory named mypara.gpd.

```
pt_shell> get_gpd_layers -gpd /mydata/mydesign/mypara.gpd
SUBSTRATE poly M1 M2 M3 M4 M5 polyCont V1 V2 V3 V4
```

The following command reports the routing layers of the GPD directory named mypara.gpd.

```
pt_shell> get_gpd_layers -type routing -gpd /mydata/mydesign/mypara.gpd
SUBSTRATE poly M1 M2 M3 M4 M5
```

See Also

- get_coupling_capacitors
- get_gpd_corners

---

get_ground_capacitors

Creates a collection of parasitic ground capacitors from the specified net. You can assign these ground capacitors to a variable or pass them into another command.

Syntax

collection *get_ground_capacitors*

```
[-filter expression]
[-quiet]
[-parasitic_corners corner_list]
[-all_parasitic_corners]
[-of_objects objects]
[-from node_name]
[-to node_name]
[-unit]
[-info]
```

Data Types

expression	string
corner_list	list
objects	list
node_name	string

Feedback

Arguments

`-filter` *`expression`*

Filters the collection with the *expression* value. For any ground capacitors that match *patterns* or *objects*, the expression is evaluated based on the ground capacitor's attributes. If the expression evaluates to true, the ground capacitor is included in the result.

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-parasitic_corners` *`corner_list`*

Indicates the parasitic corner ordering for ground capacitance values. This option is only applicable for parasitics information obtained using *read_parasitics* with the GPD parasitic format. If the *-parasitic_corners* option is not specified, then the single parasitic corner specified by *set parasitic_corner_name* is returned.

`-all_parasitic_corners`

Specifies that all parasitic corners are to be returned. The parasitics ordering is determined according to the corner definitions of the GPD parasitics.

`-of_objects` *`objects`*

Creates a collection of ground capacitors associated with the specified objects. Each object must be a named net or net collection.

You must use either the *-of_objects* option or the *-from* and *-to* options.

`-from` *`node_name`*

Constrains the selected ground capacitors to be part of a path starting from the specified node. The node name can be either a pin, port, or an internal node, where the internal node name syntax is *net_name*:*node_id*, where the legal *node_id* range is from 1 to the number of nodes in the net. This option is used only with the *-to* option.

`-to` *`node_name`*

Constrains the selected ground capacitors to be part of a path ending with the specified node, using the same node name syntax as the *-from* option.

`-unit`

Show unit of ground_capacitors

`-info`

Get unit info of ground_capacitors

Feedback

Description

This command creates a collection of ground capacitors for the specified nets that match certain criteria. You must use either the *-of_objects* option and specify a net collection or the *-from* and *-to* options to specify a path from which to get the ground capacitors. If no objects match the criteria, an empty string is returned.

When issued from the command prompt, the *get_ground_capacitors* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

For information about collections and querying of objects, see the *collections* man page.

Examples

The following example queries the parasitic ground capacitors of net n22, subject to those objects whose max corner capacitance is greater than 0.5e-3.

```
pt_shell> get_ground_capacitors -of_objects n22 \\
  -filter "capacitance_max > 0.5e-3"
{"ground_capacitor"}
```

See Also

---

get_gui_stroke_bindings

Queries the data for stroke bindings.

Syntax

get_gui_stroke_bindings

```
[-dictionary dict_name]
[-builtin]
```

Feedback

Arguments

`-dictionary` *`dictionary_name`*

Report only the bindings for the specified dictionary.

`-builtin`

Return information on the built-in commands that are available for use in bindings.

Description

This command queries the current state of stroke bindings for the application. If no options are specified, the application returns data for all dictionaries. The *-dictionary* option limits the data returned to only that for a given dictionary. The *-builtin* option queries for the built-in commands that are available for use with bindings.

A user does not typically use this command. The tool provides built-in reporting commands that produce human-readable reports from the information returned by this command. You can use the *report_gui_stroke_bindings* and *report_gui_stroke_builtins* commands for report generation.

This command returns its data as a Tcl list, suitable for further processing into reports or command streams by Tcl procedures.

DATA FORMAT

The command returns data differently depending on the options that are provided.

The data for a dictionary is a list of entries where each entry contains the stroke sequence and the data for the command invoked by that sequence. If the command queries more than one dictionary, another level of lists is added with dictionary name followed by dictionary data.

Built-in command data is formatted as a list of commands. Each command has the name of the built-in command followed by the data for the command.

Examples

The following example returns all binding information for all dictionaries.

```
psyn_gui-t> get_gui_stroke_bindings
```

The following example returns the bindings for the Graphics dictionary.

```
psyn_gui-t> get_gui_stroke_bindings -dictionary Graphics
```

The following example returns the built-in commands available for use in bindings.

```
psyn_gui-t> get_gui_stroke_bindings -builtin
```

Feedback

---

get_hier_clocks

Creates a collection of clocks captured in binary block models or top-level context data written in the HyperScale flow.

Syntax

string *get_hier_clocks*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-of_objects objects]
[patterns]
```

Data Types

expression	string
objects	list
patterns	list

Arguments

`-filter expression`

Filters the collection with *expression*. For any *hier_clock* objects that match *patterns*, the expression is evaluated based on the *hier_clock*'s attributes. If the expression evaluates to *true*, the *hier_clock* is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

patterns

Matches hier clocks names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

The *patterns* and *-of_objects* options are mutually exclusive.

-of_objects *cells*

Specifies a list of objects to obtain associated hierarchical clock objects from.

In a top-level analysis, this can be a list of hierarchical subblock instances from which to query how top-level clocks propagate into those blocks.

In a block-level analysis, this can be a list of clock input ports from which to query top-level clock information from the currently applied block context data.

The *patterns* and *-of_objects* options are mutually exclusive.

Description

The *get_hier_clocks* command creates a collection of clocks that are captured in the binary block model or top context data written for HyperScale flow. The command returns a collection if any clocks match the *patterns* argument and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Unlike the *get_clocks* command, this command returns *hier_clock* objects instead of *clock* objects. *hier_clock* objects are similar in that they contain attributes with clock information (such as name, period, and source), but they cannot be used in place of *clock* objects in commands that support *clock* objects.

hier_clock objects are not user-defined by *create_clock* or *create_generated_clock* commands in the constraints for the current session; but rather, they are automatically loaded as part of the binary subblock model or top-level context, which represents the clocks originally captured from user-defined *create_clock* or *create_generated_clock* commands when the block model or top-level context was generated. These *hier_clock* objects are meant to provide visibility into what clocks are expected in the binary model and context; or what clocks were defined by the model or context data provider.

You can use the *report_attribute -application* command to list all attributes defined on *hier_clock* objects.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the *hier_clock* objects and creates a collection of them.

```
pt_shell> get_hier_clocks SUB*
{"SUB_CLK1", "SUB_CLK2"}
```

See Also

- set_clock_map

---

get_ilm_objects

Returns a collection of nets, cells, or pins that are part of the interface logic for the current design.

Syntax

collection *get_ilm_objects*

```
[-type net | pin | cell]
```

Arguments

`-type net | pin | cell`

Specifies the type of object to be returned as a collection of objects. Allowed values are *net*, *pin*, or *cell*. A collection is returned of objects of the specified type that belong to the interface logic on the current design.

Description

Returns a collection of nets, cells, or pins that have been identified as belonging to interface logic by using the *identify_interface_logic* command. The *is_interface_logic_pin* attribute identifies pins that are part of the interface logic, The command takes into account that the design corresponding to the interface logic model (ILM) is flattened, hierarchical nets are reduced to a single flattened net, and hierarchical pins and cells on the original design are not contained in the ILM. The objects returned are those that will be referred to in the interface logic netlist, script, and back-annotation files written using the *write_ilm_** commands. Use the *get_ilm_objects* command to review the objects that have been identified as belonging to the interface logic on the current design.

For a discussion of ILM creation and the associated commands, see the *identify_interface_logic* man page.

Examples

The following example returns a collection of all interface logic cells.

```
pt_shell> get_ilm_objects -type cell
```

The following command returns a collection of all nets in the flattened ILM netlist.

```
pt_shell> get_ilm_objects -type net
```

Feedback

---

get_latch_loop_groups

Returns a list of collections of pins, each collection containing the transparent latch data pins contained within one latch loop group.

Syntax

list *get_latch_loop_groups*

```
[-of_objects pin_list]
[-loop_breakers_only]
```

Data Types

pin_list list

Arguments

`-of_objects pin_list`

Specifies a collection of data pins of transparent latches. This option returns only pins of loop groups containing the specified pins. By default, the command returns one collection for each loop group in the design.

`-loop_breakers_only`

Specifies that the returned collection contains only pins that are loop breaker latch data pins (that have a *true* value for the *is_latch_loop_breaker* pin attribute). By default, all transparent latch data pins within the loop group are returned in the collections.

Description

When sequential loops of transparent latches exist in a design, a loop group containing all latch data pins of intersecting loops is formed. The *get_latch_loop_groups* command analyzes the design and returns a collection for each loop group formed. The collection contains the latch data pins of the loop group. Combinational pins are not included in the results.

Feedback

You can use the results of the *get_latch_loop_groups* command to find paths within loops that violate timing. For an example, see the EXAMPLES section.

Before using the *get_latch_loop_groups* command, you must set the *timing_enable_through_paths* variable to *true*.

Examples

The following example reports violating paths within latch loops by using the *get_latch_loop_groups* command. No paths outside the loops are reported.

```
pt_shell> foreach a_loop_group [get_latch_loop_groups
 -loop_breakers_only] {
            report_timing -from $a_loop_group -to $a_loop_group
 -slack_lesser_than 0.0
          }
```

See Also

- report_latch_loop_groups
- timing_enable_through_paths

---

get_lib

Creates a collection of libraries loaded into PrimeTime. You can assign these libraries to a variable or pass them into another command.

Syntax

collection *get_libs*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-of_objects objects]
[patterns]
```

Data Types

expression	string
objects	list
patterns	list

Feedback

Arguments

`-filter` *`expression`*

Filters the collection with the *expression* option. For any libraries that match *patterns* (or *objects*), the expression is evaluated based on the library's attributes. If the expression evaluates to true, the library is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-of_objects` *`objects`*

Creates a collection of libraries that contain the specified objects. In this case, each object is either a named library cell or a library cell collection. the *-of_objects* and *patterns* options are mutually exclusive; you can specify only one.

`patterns`

Matches library names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type lib. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

The *get_libs* command creates a collection of libraries from those currently loaded into PrimeTime that match certain criteria. The command returns a collection if any libraries match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Feedback

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* option and filter the *expression* option. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_libs* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_libs* command result to a variable.

When issued from the command prompt, the *get_libs* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_libs* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_libs* command as an argument to the *query_objects* command. For example, use this if you want to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries all loaded libraries. Although the output looks like a list, it is just a display. Note that a complete listing of libraries is available using the *list_libs* command.

```
pt_shell> get_libs *
{"misc_cmos", "misc_cmos_io"}
```

The following example shows that given a library collection, you can remove those libraries. Note that you cannot remove libraries if they are referenced by a design.

```
pt_shell> remove_lib [get_libs misc*]
Removing library misc_cmos...
Removing library misc_cmos_io...
```

---

get_lib_cell

Creates a collection of library cells from libraries loaded into PrimeTime. You can assign these library cells to a variable or pass them into another command.

Syntax

collection *get_lib_cells*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-of_objects objects]
patterns
```

Data Types

expression	string
objects	list
patterns	list

Arguments

`-filter expression`

Filters the collection with the *expression* value. For any library cells that match the *patterns* or *objects* argument, the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-of_objects` *objects*

Creates a collection of library cells that are referenced by the specified cells or own the specified library pins. In this case, each object is either a named library pin or netlist cell, or a library pin collection or a netlist cell collection. The *-of_objects* and *patterns* options are mutually exclusive; you must specify one, but not both.

patterns

Matches library cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type lib_cell. The *patterns* and *-of_objects* options are mutually exclusive; you must specify one, but not both.

Description

This command creates a collection of library cells from libraries currently loaded into PrimeTime that match certain criteria. The command returns a collection if any library cells match the *patterns* or *objects* option and pass the filter, if specified. If no objects match the criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_lib_cells* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_lib_cells* command result to a variable.

When issued from the command prompt, the *get_lib_cells* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_lib_cells* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command (for example, if you want to display the object class), use the *get_lib_cells* command as an argument to the *query_objects* command.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries all library cells that are in the misc_cmos library and begin with AN2. Although the output looks like a list, it is just a display.

```
pt_shell> get_lib_cells misc_cmos/AN2*
{"misc_cmos/AN2", "misc_cmos/AN2P"}
```

The following example shows one way to find out the library cell used by a particular cell.

```
pt_shell> get_lib_cells -of_objects [get_cells o_reg1]
{"misc_cmos/FD2"}
```

get_lib_cells

Creates a collection of library cells from libraries loaded into PrimeTime. You can assign these library cells to a variable or pass them into another command.

Syntax

collection *get_lib_cells*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-of_objects objects]
patterns
```

Data Types

expression	string
objects	list
patterns	list

Feedback

Arguments

`-filter` *`expression`*

Filters the collection with the *expression* value. For any library cells that match the *patterns* or *objects* argument, the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-of_objects` *`objects`*

Creates a collection of library cells that are referenced by the specified cells or own the specified library pins. In this case, each object is either a named library pin or netlist cell, or a library pin collection or a netlist cell collection. The *-of_objects* and *patterns* options are mutually exclusive; you must specify one, but not both.

`patterns`

Matches library cell names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type lib_cell. The *patterns* and *-of_objects* options are mutually exclusive; you must specify one, but not both.

Description

This command creates a collection of library cells from libraries currently loaded into PrimeTime that match certain criteria. The command returns a collection if any library cells

match the *patterns* or *objects* option and pass the filter, if specified. If no objects match the criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_lib_cells* command at the command prompt, or you can nest it as an argument to another command. For example, you can use it in the *query_objects* command. In addition, you can assign the *get_lib_cells* command result to a variable.

When issued from the command prompt, the *get_lib_cells* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_lib_cells* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command (for example, if you want to display the object class), use the *get_lib_cells* command as an argument to the *query_objects* command.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries all library cells that are in the misc_cmos library and begin with AN2. Although the output looks like a list, it is just a display.

```
pt_shell> get_lib_cells misc_cmos/AN2*
{"misc_cmos/AN2", "misc_cmos/AN2P"}
```

The following example shows one way to find out the library cell used by a particular cell.

```
pt_shell> get_lib_cells -of_objects [get_cells o_reg1]
{"misc_cmos/FD2"}
```

---

get_lib_pin

Creates a collection of library cell pins from libraries loaded into PrimeTime. You can assign these library cell pins to a variable or pass them into another command.

Syntax

collection *get_lib_pins*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[patterns | -of_objects objects]
```

Data Types

expression	string
patterns	list
objects	list

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any library cell pins that match the *patterns* option (or the *objects* option), the expression is evaluated based on the library cell pin's attributes. If the expression evaluates to true, the library pin is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* option and the *-exact* option are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`patterns`

Matches library cell pin names against patterns. The *patterns* option can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. The *patterns* option can also include collections of type *lib_pin*. The *patterns* and *-of_objects* options are mutually exclusive; you must specify one, but not both.

`-of_objects` *`objects`*

Creates a collection of library cell pins referenced by the specified netlist pins or owned by the specified library cells. In this case, each object is either a named library cell or netlist pin, or a library cell collection or netlist pin collection. The *-of_objects* and *patterns* options are mutually exclusive; you must specify one, but not both.

Description

The *get_lib_pins* command creates a collection of library cell pins from libraries currently loaded into PrimeTime that match certain criteria. The command returns a collection if any library cell pins match the *patterns* or *objects* options and pass the filter (if specified). If no objects matched the criteria, the empty string is returned.

---

get_lib_timing_arcs

Creates a collection of library arcs for custom reporting and other processing. You can assign these library arcs to a variable and get the desired attribute for further processing.

Syntax

string *get_lib_timing_arcs*

```
[-to to_list]
[-from from_list]
[-of_objects object_list]
[-filter expression]
[-quiet]
```

Data Types

to_list	list
from_list	list
object_list	list
expression	string

Arguments

`-to` *to_list*

Specifies the "to" library pins, or ports. All backward library arcs from the specified library pins or ports are considered.

`-from` *from_list*

Specifies the "from" library pins, or ports. All forward library arcs from the specified library pins or ports are considered.

`-of_objects` *object_list*

Specifies library cells or timing arcs. If a library cell is specified, all library cell arcs of that cell are considered. If a timing arc collection is given in the object list, the corresponding library timing arc is considered.

`-filter` *`expression`*

Specifies the filter expression. A filter expression is a string that comprises a series of logical expressions describing a set of constraints you want to place on the collection of library arcs. Each subexpression of a filter expression is a relation contrasting an attribute name with a value, by means of an operator.

`-quiet`

Specifies that all messages are to be suppressed.

Description

Creates a collection of library arcs for custom reporting and other processing. You can assign these library arcs to a variable and get the desired attribute for further processing. Use the *foreach_in_collection* command to iterate among the library arcs in the collection. You can use the *get_attribute* command to obtain information about the paths. You can also use the filter expression to filter the library arcs that satisfy the specified conditions.

The following attributes are supported on library timing arcs:

```
from_lib_pin
is_disabled
is_user_disabled
mode
object_class
sdf_cond
sense
to_lib_pin
```

One attribute of a library timing arc is the *from_lib_pin*, which is the library pin from which the timing arc begins. In the same way, *to_lib_pin* is the library pin to which the timing arc ends. To get more information on *from_lib_pin* and *to_lib_pin*, use the *get_attributes* command. The *object_class* attribute holds the class name of library timing arcs: *lib_timing_arc*.

See the *collections* and *foreach_in_collection* man pages for more information.

Examples

The following procedure is an example you can use of how the collection returned from an invocation of *get_lib_timing_arcs* can be used to provide useful and readable cell level arc information.

```
proc show_lib_arcs {args} {
  set lib_arcs [eval [concat get_lib_timing_arcs $args]]
  echo [format "%15s    %-15s  %18s" "from_lib_pin" "to_lib_pin" \\
            "sense"]
  echo [format "%15s    %-15s  %18s" "------------" "----------" \\
            "-----"]

  foreach_in_collection lib_arc $lib_arcs {
```

```
    set fpin [get_attribute $lib_arc from_lib_pin]
    set tpin [get_attribute $lib_arc to_lib_pin]
    set sense [get_attribute $lib_arc sense]
    set from_lib_pin_name [get_attribute $fpin base_name]
    set to_lib_pin_name [get_attribute $tpin base_name]
    echo [format "%15s -> %-15s  %18s" \\
        $from_lib_pin_name $to_lib_pin_name \\
        $sense]
  }
}
```

```
pt_shell> show_lib_arc -of_objects [get_timing_arcs -of_objects ffa]

   from_lib_pin    to_lib_pin                    sense
   ------------    ----------                    -----
             CP -> D                    setup_clk_rise
             CP -> D                     hold_clk_rise
             CP -> Q                       rising_edge
             CP -> QN                      rising_edge
             CD -> Q                         clear_low
             CD -> QN                       preset_low
```

```
pt_shell> show_lib_arc -of_objects mylib/AN2

   from_lib_pin    to_lib_pin                    sense
   ------------    ----------                    -----
              A -> Z                    positive_unate
              B -> Z                    positive_unate
```

```
pt_shell> show_lib_arc -from mylib/AN2/A

   from_lib_pin    to_lib_pin                    sense
   ------------    ----------                    -----
              A -> Z                    positive_unate
```

Feedback

get_libs

Creates a collection of libraries loaded into PrimeTime. You can assign these libraries to a variable or pass them into another command.

Syntax

collection *get_libs*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-of_objects objects]
[patterns]
```

Data Types

```
expression       string
objects          list
patterns         list
```

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any libraries that match *patterns* (or *objects*), the expression is evaluated based on the library's attributes. If the expression evaluates to true, the library is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-of_objects` *objects*

Creates a collection of libraries that contain the specified objects. In this case, each object is either a named library cell or a library cell collection. the *-of_objects* and *patterns* options are mutually exclusive; you can specify only one.

patterns

Matches library names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type lib. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

The *get_libs* command creates a collection of libraries from those currently loaded into PrimeTime that match certain criteria. The command returns a collection if any libraries match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* option and filter the *expression* option. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_libs* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_libs* command result to a variable.

When issued from the command prompt, the *get_libs* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_libs* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_libs* command as an argument to the *query_objects* command. For example, use this if you want to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Examples

The following example queries all loaded libraries. Although the output looks like a list, it is just a display. Note that a complete listing of libraries is available using the *list_libs* command.

```
pt_shell> get_libs *
{"misc_cmos", "misc_cmos_io"}
```

The following example shows that given a library collection, you can remove those libraries. Note that you cannot remove libraries if they are referenced by a design.

```
pt_shell> remove_lib [get_libs misc*]
Removing library misc_cmos...
Removing library misc_cmos_io...
```

get_license

Obtains a license for a feature.

Syntax

```
status get_license
   [-quantity num_licenses]
   feature_list
```

Data Types

```
num_licenses      integer
feature_list      list
```

Arguments

`-quantity num_licenses`

Specifies the total number of licenses to check out for each feature. If a license is already checked out, the command acquires only the additional licenses

Feedback

needed to bring the total to the specified quantity. If you do not use this option, the command checks out one license per feature.

This option is useful if you need to reserve multiple licenses for a multicore run. You can reserve the required number of licenses early in the session, rather than risking a failure or a performance degradation later in the session if the licenses are not available.

feature_list

Specifies a list of features to obtain. To specify more than one feature, enclose the list enclosed in curly braces ({ }).

Description

This command obtains licenses for the specified features. These features remain checked out by you until you run the *remove_license* command or until you exit the program.

To list the features that you currently have checked out, run the *list_licenses* command.

Examples

This example obtains two licenses of the PrimePower feature:

```
pt_shell> get_license PrimePower -quantity 2
Information: Checked out license 'PrimePower' (PT-019)
Information: Checked out license 'PrimePower' (PT-019)
1
```

See Also

---

get_message_ids

Get application message ids

Syntax

string *get_message_ids* [-type *severity*] [*pattern*]

```
string severity
string pattern
```

Feedback

Arguments

`-type severity`

Filter ids based on type (Values: Info, Warning, Error, Severe, Fatal)

pattern

Get IDs matching pattern (default: *)

Description

The *get_message_ids* command retrieves the error, warning and informational messages used by the application. The result of this command is a Tcl formatted list of all message ids. Information about the id can be queried with the *get_message_info* command.

Examples

The following code finds all error messages and makes the application stop script execution when one of these messages is encountered.

```
foreach id [get_message_ids -type Error] {
  set_message_info -stop_on -id $id
}
```

See Also

- print_message_info
- set_message_info
- suppress_message

---

get_message_info

Returns information about tool error, warning, and information messages.

Syntax

integer *get_message_info*

```
-error_count | -warning_count | -info_count
   | -limit message_id | -save_limit message_id
   | -occurrences message_id | -suppressed message_id
   | -id message_id
```

Data Types

message_id string

Feedback

Arguments

`-error_count`

Returns the number of error messages issued so far.

`-warning_count`

Returns the number of warning messages issued so far.

`-info_count`

Returns the number of information messages issued so far.

`-limit` *`message_id`*

Returns the current user-specified limit for a given message ID, as previously set with the *set_message_info -limit* command.

`-save_limit` *`message_id`*

Returns the current *save_limit* value for a given message ID, as previously set with the *set_message_info -save_limit* command.

`-occurrences` *`message_id`*

Returns the number of occurrences of a given message ID.

`-suppressed` *`message_id`*

Returns the number of times a message was suppressed either due to a *suppress_message* specification (complete exclusion) or due to exceeding a numerical limit.

`-id` *`message_id`*

Returns information about the specified message. The information is returned as a pairwise Tcl list compatible with the *array set* command.

Description

The *get_message_info* command retrieves information about error, warning, and information messages.

For example, if the following message is issued by the tool, information about its issuance is recorded:

Error: unknown command 'wrong_command' (CMD-005)

It can be useful to be able to retrieve recorded information about issued tool messages. For example, you can stop a script if a certain type of error has occurred, or if a more than a certain number of that error has occurred, or monitor the number of messages issued by a single command.

Feedback

You can also find out how many times a specific message has occurred, or how many times it has been suppressed, or whether an issuance or save limit has been specified for it.

This command has multiple mutually-exclusive options. One option must be specified; multiple options cannot be specified.

Examples

The following example uses the *get_message_info* command to count the number of errors that occurred during execution of a specific command, and to return from the procedure if the error count exceeds a given amount:

```
prompt> proc do_command {limit} {
    set current_errors [get_message_info -error_count]
    command
    set new_errors [get_message_info -error_count]
    if {[expr $new_errors - $current_errors] > $limit} {
      return -code error "Too many errors"
    }
    ...
  }
```

The following example uses the *get_message_info* command to retrieve information on the CMD-014 message:

```
prompt> get_message_info -id CMD-014
id CMD-014 severity Error limit 10000 save_limit -1 occurrences 0
 suppressed 0 message
{Invalid %s value '%s' in list.}
```

See Also

- print_message_info
- set_message_info
- suppress_message
- get_message_ids

---

get_message_instances

Returns a collection of recorded message instances of the specified message id.

Syntax

collection *get_message_instances*

```
[message_id]
```

Feedback

Data Types

message_id string

Arguments

message_id

Returns instances of the specified message_id as collection.

Description

This command creates a collection of saved message instances of the specified message id. This command returns a collection if the specified *message_id* has any saved instances. If no saved instances of this *message_id* exist, a empty string is returned.

The number of instances of a message to be saved has to be specified using the *save_limit* option of the *set_message_info* command.

The attributes of message instances can be queried by iterating through the objects of the message instance collection. For example, the attributes arguments, message_id and message_body can be queried on each message instance. The *arguments* attribute of the *message_instance* object class returns comma separated list of arguments of the specific message instance.

Examples

The following example uses the *get_message_instances* command to get a collection of message instances of DES-121 message, iterates through the message instances and queries attributes.

```
pt_shell> set coll  [get_message_instances DES-121]
pt_shell> foreach_in_collection itr $coll {
    echo [get_attribute -class message_instance $itr message_id]
    echo [get_attribute -class message_instance $itr arguments]
    echo [get_attribute -class message_instance $itr message_body]
}
```

See Also

- print_message_info
- set_message_info
- suppress_message
- get_message_ids

Feedback

get_net

Creates a collection of nets from the netlist. You can assign these nets to a variable or pass them into another command.

Syntax

collection *get_nets*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-top_net_of_hierarchical_group]
[-segments]
[-boundary_type btype]
[-of_objects objects]
patterns
```

Data Types

expression	string
btype	string
objects	list
patterns	list

Arguments

`-hierarchical`

Searches for nets level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a net block1/muxsel, a hierarchical search would find it using "muxsel." You cannot use the *-hierarchical* option with the *-of_objects* option.

`-filter expression`

Filters the collection with *expression*. For any nets that match *patterns* (or *objects*), the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the net is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to

compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-exact* option, makes matches case-insensitive. You can use *-nocase* only when you also use the *-exact* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-top_net_of_hierarchical_group`

Keep only the top net of a hierarchical group. When more than one hierarchical net of the same group is specified (local nets at various hierarchical levels of the same physical net), only the net closest to the top of the hierarchy is saved with the collection. In the case of multiple nets at the same level, the first net specified is kept. Although this option can be used when there are multiple nets specified, it is best used in combination with the *-segments* option and with a single net.

`-segments`

Return all global segments for given nets. This modifies the initial search which matches *patterns* or *objects*. It is applied after filtering, but before the *-top_net_of_hierarchical_group* option is determined. For each net, all global segments which are part of that net will be added to the result collection. Global net segments are all those physically connected across all hierarchical boundaries. Although this option can be used with other options and when there are multiple nets specified, it is best used with a single net. When combined with the *-top_net_of_hierarchical_group* option, you can isolate the highest net segment of a physical net.

`-boundary_type` *`btype`*

Specifies what to do when getting nets of boundary pins. This option requires the *-of_objects* option. Allowed values are lower, upper, and both, meaning the net inside the hierarchical block, outside the hierarchical block, or both nets, respectively. The option has no meaning for non-hierarchical pins. Note that The "upper" value is less useful, as getting pins of a hierarchical net will return the pin outside the hierarchical block, and a subsequent get_nets would find the upper hierarchical net. Using upper on a hierarchical pin is the same as omitting the option.

`-of_objects` *`objects`*

Creates a collection of nets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell or cell collection. The

-of_objects and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

patterns

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type net. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

The *get_nets* command creates a collection of nets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any nets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_nets* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_nets* result to a variable.

When issued from the command prompt, the *get_nets* command behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of *get_nets* provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_nets* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the nets that begin with 'NET' in block 'block1'. Although the output looks like a list, it is just a display.

Feedback

```
pt_shell> get_nets block1/NET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example shows that with a collection of pins, you can query the nets connected to those pins.

```
pt_shell> current_instance block1
block1
pt_shell> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
pt_shell> query_objects [get_nets -of_objects $pinsel]
{"NET1QNX", "NET2QNX"}
```

This example shows how to use the *-top_net_of_hierarchical_group* and *-boundary_type* options. Given the following circuit:

```
u1                                    u2

-----------------+              +-------------------

                 |              |

 u1/Z -- net5 ---+--- topnet ---+--- net7 -- u1/A

                 |              |

-----------------+              +-------------------
```

there are hierarchical cells u1 and u2 at this level, connected by a net *topnet*. Within u1 is a pin u1/Z driving *net5*, and withing u2 is a pin u1/A being driven by *net7*. These three nets are physically the same net. Assume these are the only nets in the design. Notice the difference in the results of the following two *get_nets* commands:

```
pt_shell> get_nets * -hierarchical
{"topnet", "u1/net5", "u2/net7"}
pt_shell> get_nets * -hierarchical -top_net_of_hierarchical_group
{"topnet"}
```

Assume that at the top level, topnet is connected to pins u2/in and u1/out. Here are some examples of the *-boundary_type* option. Notice now in this case, the "upper" type does not add value.

```
pt_shell> get_nets -of_objects u2/in
{"topnet"}
pt_shell> get_nets -of_objects u2/in -boundary_type upper
{"topnet"}
pt_shell> get_nets -of_objects u2/in -boundary_type lower
{"u2/net7"}
pt_shell> get_nets -of_objects u2/in -boundary_type both
{"u2/net7", "topnet"}
pt_shell> get_nets -boundary lower -of_objects \\
```

Feedback

```
                [get_pins -of_objects [get_nets topnet]]
{"u1/net5", "u2/net7"}
```

---

get_nets

Creates a collection of nets from the netlist. You can assign these nets to a variable or pass them into another command.

Syntax

collection *get_nets*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-top_net_of_hierarchical_group]
[-segments]
[-boundary_type btype]
[-of_objects objects]
patterns
```

Data Types

expression	string
btype	string
objects	list
patterns	list

Arguments

`-hierarchical`

Searches for nets level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a net block1/muxsel, a

hierarchical search would find it using "muxsel." You cannot use the *-hierarchical* option with the *-of_objects* option.

`-filter` *`expression`*

Filters the collection with *expression*. For any nets that match *patterns* (or *objects*), the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the net is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-exact* option, makes matches case-insensitive. You can use *-nocase* only when you also use the *-exact* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-top_net_of_hierarchical_group`

Keep only the top net of a hierarchical group. When more than one hierarchical net of the same group is specified (local nets at various hierarchical levels of the same physical net), only the net closest to the top of the hierarchy is saved with the collection. In the case of multiple nets at the same level, the first net specified is kept. Although this option can be used when there are multiple nets specified, it is best used in combination with the *-segments* option and with a single net.

`-segments`

Return all global segments for given nets. This modifies the initial search which matches *patterns* or *objects*. It is applied after filtering, but before the *-top_net_of_hierarchical_group* option is determined. For each net, all global segments which are part of that net will be added to the result collection. Global net segments are all those physically connected across all hierarchical boundaries. Although this option can be used with other options and when there are multiple nets specified, it is best used with a single net. When combined

with the *-top_net_of_hierarchical_group* option, you can isolate the highest net segment of a physical net.

`-boundary_type` *`btype`*

Specifies what to do when getting nets of boundary pins. This option requires the *-of_objects* option. Allowed values are lower, upper, and both, meaning the net inside the hierarchical block, outside the hierarchical block, or both nets, respectively. The option has no meaning for non-hierarchical pins. Note that The "upper" value is less useful, as getting pins of a hierarchical net will return the pin outside the hierarchical block, and a subsequent get_nets would find the upper hierarchical net. Using upper on a hierarchical pin is the same as omitting the option.

`-of_objects` *`objects`*

Creates a collection of nets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell or cell collection. The *-of_objects* and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

`patterns`

Matches net names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type net. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

Description

The *get_nets* command creates a collection of nets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any nets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl *regexp* command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_nets* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_nets* result to a variable.

When issued from the command prompt, the *get_nets* command behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of *get_nets* provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_nets* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the nets that begin with 'NET' in block 'block1'. Although the output looks like a list, it is just a display.

```
pt_shell> get_nets block1/NET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example shows that with a collection of pins, you can query the nets connected to those pins.

```
pt_shell> current_instance block1
block1
pt_shell> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
pt_shell> query_objects [get_nets -of_objects $pinsel]
{"NET1QNX", "NET2QNX"}
```

This example shows how to use the *-top_net_of_hierarchical_group* and *-boundary_type* options. Given the following circuit:

```
u1                                      u2

-----------------+              +-------------------

                 |              |

 u1/Z -- net5 ---+--- topnet ---+--- net7 -- u1/A

                 |              |

-----------------+              +-------------------
```

there are hierarchical cells u1 and u2 at this level, connected by a net *topnet*. Within u1 is a pin u1/Z driving *net5*, and withing u2 is a pin u1/A being driven by *net7*. These three

Feedback

nets are physically the same net. Assume these are the only nets in the design. Notice the difference in the results of the following two *get_nets* commands:

```
pt_shell> get_nets * -hierarchical
{"topnet", "u1/net5", "u2/net7"}
pt_shell> get_nets * -hierarchical -top_net_of_hierarchical_group
{"topnet"}
```

Assume that at the top level, topnet is connected to pins u2/in and u1/out. Here are some examples of the *-boundary_type* option. Notice now in this case, the "upper" type does not add value.

```
pt_shell> get_nets -of_objects u2/in
{"topnet"}
pt_shell> get_nets -of_objects u2/in -boundary_type upper
{"topnet"}
pt_shell> get_nets -of_objects u2/in -boundary_type lower
{"u2/net7"}
pt_shell> get_nets -of_objects u2/in -boundary_type both
{"u2/net7", "topnet"}
pt_shell> get_nets -boundary lower -of_objects \\
             [get_pins -of_objects [get_nets topnet]]
{"u1/net5", "u2/net7"}
```

---

get_noise_violation_sources

Creates a collection of noise violation sources for custom reporting and other processing. You can assign these pins to a variable and get the desired attribute for further processing.

Syntax

integer *get_noise_violation_sources*

```
[-above]
[-below]
[-low]
[-high]
```

Feedback

```
[-nworst_endpoints pin_count]
[-max_sources_per_endpoint pin_count]
[-slack_type area | height | area_percent]
[object_list]
```

Data Types

```
pin_count       integer
object_list     list
```

Arguments

`-above`

Performs the reporting only above the rails. If this option is combined with the *-low* option, it reports the noise bumps above the low rail. If it is combined with the *-high* option, it reports the noise bumps above the high rail. Otherwise, it reports the noise bumps above the high rail and above the low rail.

`-below`

Performs the reporting only below the rails. If this option is combined with the*-low* option, it reports the noise bumps below the low rail. If this option is combined with the*-high* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps below the high rail and below the low rail.

`-low`

Performs the reporting only for the low rail. If this option is combined with the *-above* option, it reports the noise bumps above the low rail. If it is combined with the*-below* option, it reports the noise bumps below the low rail. Otherwise, it reports the noise bumps for both below and above the low rail.

`-high`

Performs the reporting only for the high rail. If this option is combined with the *-above* option, it reports the noise bumps above the high rail. If it is combined with the *-below* option, it reports the noise bumps below the high rail. Otherwise, it reports the noise bumps for both below and above the high rail.

`-nworst_endpoints` *`pin_count`*

Specifies the number of endpoint pins to be reported. The default is 1.

`-max_sources_per_endpoint` *`pin_count`*

Specifies the number of violation source pins per endpoint to be reported. The default is 1.

`-slack_type area | height | area_percent`

Specifies the type of slack to be used. The voltage margin is defined by the noise bump height and noise immunity curves or DC noise margin.

Feedback

- *height* (default) - Reports noise slack as the voltage margin.
- *area* - Reports noise slack as the voltage margin multiplied by the noise bump width.
- *area_percent* - Reports noise slack as the percentage of the noise constraint area. The noise constraint area is computed by multiplying the noise height constraint by the noise bump width.

object_list

Specifies the load pins for which the noise reporting is performed. If no pin is specified, reporting is performed on the entire design.

Description

Provides a collection of noise violation source pins for failing noise endpoints in the current design.

Examples

The following example creates a collection of the worst violation source for the worst endpoint in the current design and assigns it to the viol_pins variable.

```
pt_shell> set viol_pins [get_noise_violation_sources]
```

The following example creates a collection of maximum 10 violation sources for the endpoint ffa/Q above the low rail.

```
pt_shell> get_noise_violation_sources -above -low \\
           -max_sources_per_endpoint 10 [get_pin ffa/Q]
```

The following example creates a collection of maximum 10 violation source for the worst two endpoints.

```
pt_shell> get_noise_violation_sources -max_sources_per_endpoint 10 \\
           -nworst_endpoints 2
```

---

get_object_name

Gets the name of objects in the given collection.

Feedback

Syntax

string *get_object_name*

```
        collection
```

Data Types

```
collection       string
```

Arguments

collection

Specifies the collection.

Description

The *get_object_name* command is a convenient way to get the *full_name* attribute of objects. When multiple objects are passed to the *get_attribute* command, the values are returned as a Tcl list, containing one entry for each object.

Examples

The following example shows how to use the *get_object_name* command:

```
pt_shell> get_object_name [get_cells i1]
i1
pt_shell> get_attribute [get_cells {i1 i2}] full_name
i1 i2
pt_shell> get_object_name [get_cells i*]
i1 i2 i3
```

See Also

- collections
- get_attribute

---

get_path_count_for_tag

Gets the number of paths for a given path tag set or multiple path tag sets.

Syntax

integer *get_path_count_for_tag*

```
[-name tag_names]
```

Feedback

Data Types

tag_names list

Arguments

-name *tag_names*

Specifies a list of path tag set names. The command returns the total number of paths in the listed path tag sets. Without this option, the command returns the total number of paths in all defined path tag sets.

Description

This command returns number of paths for a given path tag set or list of path tag sets, or all tag sets if you omit the *-name* option.

The command returns an integer, the sum of the numbers of paths in all the specified path tag sets. If a path belongs to multiple path tag sets, that path counts multiple times toward the reported total.

To report the number of paths separately for multiple path tag sets, use the *report_path_tag_set* command.

Examples

The following example tags a collection of timing paths and then reports the number of tagged paths in the path tag set.

```
pt_shell> set_app_var enable_path_tagging true
true
pt_shell> set mypaths [get_timing_paths ...]
pt_shell> create_path_tag_set $mypaths -name tag1
1
pt_shell> echo "Tagged [get_path_count_for_tag -name tag1] paths in tag1"
Tagged 100 paths in tag1
```

See Also

- get_timing_paths
- create_path_tag_set
- report_path_tag_set
- enable_path_tagging

---

get_path_group

Creates a collection of path groups from the current design. You can assign these path groups to a variable or pass them into another command.

Feedback

Syntax

collection *get_path_groups*

```
[-quiet]
[-regexp]
[-nocase]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, it modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

When combined with the *-regexp* option, it makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-filter expression`

Filters the collection with the *expression* value. For any path groups that match the *patterns* values, the expression is evaluated based on the path group's attributes. If the expression evaluates to true, the path group is included in the result.

patterns

Matches path group names against patterns. Patterns can include the wildcard characters "*" and "?".

Description

The *get_path_groups* command creates a collection of path groups from the current design that match certain criteria. The command returns a collection if any path groups match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Path groups control the optimization cost function and also affect timing reports.

Feedback

You can use the *get_path_groups* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_path_groups* result to a variable.

When issued from the command prompt, the *get_path_groups* command behaves as though the *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_path_groups* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_path_groups* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following generates a timing report for each path group matching "Z*".

```
pt_shell> foreach_in_collection grp [get_path_groups Z*] { \\
?                report_timing -group $grp \\
?          }
```

See Also

---

get_path_groups

Creates a collection of path groups from the current design. You can assign these path groups to a variable or pass them into another command.

Syntax

collection *get_path_groups*

```
[-quiet]
[-regexp]
```

Feedback

```
[-nocase]
[-filter expression]
patterns
```

Data Types

expression	string
patterns	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, it modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

When combined with the *-regexp* option, it makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-filter expression`

Filters the collection with the *expression* value. For any path groups that match the *patterns* values, the expression is evaluated based on the path group's attributes. If the expression evaluates to true, the path group is included in the result.

patterns

Matches path group names against patterns. Patterns can include the wildcard characters "*" and "?".

Description

The *get_path_groups* command creates a collection of path groups from the current design that match certain criteria. The command returns a collection if any path groups match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Path groups control the optimization cost function and also affect timing reports.

You can use the *get_path_groups* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_path_groups* result to a variable.

Feedback

When issued from the command prompt, the *get_path_groups* command behaves as though the *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_path_groups* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_path_groups* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following generates a timing report for each path group matching "Z*".

```
pt_shell> foreach_in_collection grp [get_path_groups Z*] { \\
?                 report_timing -group $grp \\
?          }
```

---

get_pg_pins

Create a collection of upf_pg_pin_info objects in the current design.

Syntax

string *get_pg_pins*

```
[-of_objects ell ]
```

Arguments

-of_objects

Gets the upf_pg_pin_info ojects of the object list. Of_objects takes cell list as value .

Feedback

Description

The *get_pg_pins* command creates a collection of upf_pg_pin_info objects in the current design. The command returns a collection handle (identifier) of upf_pg_pin_info objects oif *-of_objects* arguments. If no objects match the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a supply net and creates collection of it.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_supply_net SN1 -domain TOP_DOMAIN
1
pt_shell> get_pg_pins -of_objects [get_cell FF1]
{"FF1/PWR FF1/GND"}
```

See Also

- create_supply_net
- report_supply_net

---

get_pin

Creates a collection of pins from the netlist. You can assign these pins to a variable or pass them into another command.

Syntax

collection *get_pins*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-leaf]
[patterns | -of_objects objects]
```

Data Types

```
expression      string
patterns        list
objects         list
```

Feedback

Arguments

`-hierarchical`

Searches for pins level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the *find* UNIX command. For example, if there is a pin block1/adder/D[0], a hierarchical search finds it using "adder/D[0]". You cannot use the *-hierarchical* option with the *-of_objects* option.

`-filter` *`expression`*

Filters the collection with the *expression*. For any pins that match *patterns* (or *objects*), the expression is evaluated based on the pin's attributes. If the expression evaluates to true, the pin is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, this makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The*-exact* and *-regexp* options are mutually exclusive.

`-leaf`

Returns only leaf (non-hierarchical) pins. If you use the *-leaf* and *-of_objects* options together, and *-of_objects* specifies a collection of nets, the command returns pins on the leaf cells connected to the specified nets; in this case, hierarchical boundaries can be crossed to find these pins.

`patterns`

Matches pin names against patterns. The *patterns* option can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. The *patterns* option can also include collections of type pin. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

`-of_objects` *objects*

Creates a collection of pins connected to the specified objects. Each object is a named cell or net, cell collection or pin collection, a named library pin, or a collection of library pins. Note that library pins can not be combined with other types of objects. The*-of_objects* and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

Description

The *get_pins* command creates a collection of pins in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any pins match the *patterns* or *objects* options and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

When used with the *-of_objects* option, the *get_pins* command searches for pins connected to any cells or nets specified in the *objects*. For net objects, there are two variations of pins that will be considered. By default, only pins connected to the net at the same hierarchical level are considered. When combined with the *-leaf* option, only pins connected to the net that are on leaf cells are considered. In this case, hierarchical boundaries are crossed in order to find pins on leaf cells.

If no *patterns* (or *objects*) match any objects, and the current design is not linked, the design automatically links.

When a cell has bus pins, the *get_pins* command can find them in several ways. For example, if cell u1 has a bus "A" with indecies 2 to 0, and the bus_naming_style for your design is "%s[%d]", then to find these pins, you can use "u1/A[*]" as the pattern. You can also find the same three pins with "u1/A" as the pattern.

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_pins* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_pins* command result to a variable.

When issued from the command prompt, the *get_pins* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_pins* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the

Feedback

query_objects command, use the *get_pins* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the 'CP' pins of cells that begin with 'o'. Although the output looks like a list, it is just a display.

```
pt_shell> get_pins o*/CP
{"o_reg1/CP", "o_reg2/CP", "o_reg3/CP", "o_reg4/CP"}
```

The following example shows that given a collection of cells, you can query the pins connected to those cells.

```
pt_shell> set csel [get_cells o_reg1]
{"o_reg1"}
pt_shell> query_objects [get_pins -of_objects $csel]
{"o_reg1/D", "o_reg1/CP", "o_reg1/CD", "o_reg1/Q", "o_reg1/QN"}
```

The following example shows the difference between getting local pins of a net and leaf pins of net. In this example, NET1 is connected to i2/a and reg1/QN. Cell i2 is hierarchical. Within i2, port a is connected to the U1/A and U2/A.

```
pt_shell> get_pins -of_objects [get_nets NET1]
{"i2/a", "reg1/QN"}
pt_shell> get_pins -leaf -of_objects [get_nets NET1]
{"i2/U1/A", "i2/U2/A", "reg1/QN"}
```

The following example shows how to create a clock using a collection of pins.

```
pt_shell> create_clock -period 8 -name CLK [get_pins o_reg*/CP]
1
```

Feedback

get_pins

Creates a collection of pins from the netlist. You can assign these pins to a variable or pass them into another command.

Syntax

collection *get_pins*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-leaf]
[patterns | -of_objects objects]
```

Data Types

```
expression      string
patterns        list
objects         list
```

Arguments

`-hierarchical`

Searches for pins level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the *find* UNIX command. For example, if there is a pin block1/adder/D[0], a hierarchical search finds it using "adder/D[0]". You cannot use the *-hierarchical* option with the *-of_objects* option.

`-filter expression`

Filters the collection with the *expression*. For any pins that match *patterns* (or *objects*), the expression is evaluated based on the pin's attributes. If the expression evaluates to true, the pin is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, this makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The*-exact* and *-regexp* options are mutually exclusive.

`-leaf`

Returns only leaf (non-hierarchical) pins. If you use the *-leaf* and *-of_objects* options together, and *-of_objects* specifies a collection of nets, the command returns pins on the leaf cells connected to the specified nets; in this case, hierarchical boundaries can be crossed to find these pins.

`patterns`

Matches pin names against patterns. The *patterns* option can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. The *patterns* option can also include collections of type pin. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

`-of_objects` *`objects`*

Creates a collection of pins connected to the specified objects. Each object is a named cell or net, cell collection or pin collection, a named library pin, or a collection of library pins. Note that library pins can not be combined with other types of objects. The*-of_objects* and *patterns* options are mutually exclusive; you can specify only one. In addition, you cannot use the *-hierarchical* option with the *-of_objects* option.

Description

The *get_pins* command creates a collection of pins in the current design, relative to the current instance, that match certain criteria. The command returns a collection if any pins match the *patterns* or *objects* options and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

When used with the *-of_objects* option, the *get_pins* command searches for pins connected to any cells or nets specified in the *objects*. For net objects, there are two variations of pins that will be considered. By default, only pins connected to the net at the same hierarchical level are considered. When combined with the *-leaf* option, only pins connected to the net that are on leaf cells are considered. In this case, hierarchical boundaries are crossed in order to find pins on leaf cells.

If no *patterns* (or *objects*) match any objects, and the current design is not linked, the design automatically links.

When a cell has bus pins, the *get_pins* command can find them in several ways. For example, if cell u1 has a bus "A" with indecies 2 to 0, and the bus_naming_style for your design is "%s[%d]", then to find these pins, you can use "u1/A[*]" as the pattern. You can also find the same three pins with "u1/A" as the pattern.

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_pins* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_pins* command result to a variable.

When issued from the command prompt, the *get_pins* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_pins* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_pins* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the 'CP' pins of cells that begin with 'o'. Although the output looks like a list, it is just a display.

```
pt_shell> get_pins o*/CP
{"o_reg1/CP", "o_reg2/CP", "o_reg3/CP", "o_reg4/CP"}
```

The following example shows that given a collection of cells, you can query the pins connected to those cells.

```
pt_shell> set csel [get_cells o_reg1]
{"o_reg1"}
pt_shell> query_objects [get_pins -of_objects $csel]
{"o_reg1/D", "o_reg1/CP", "o_reg1/CD", "o_reg1/Q", "o_reg1/QN"}
```

The following example shows the difference between getting local pins of a net and leaf pins of net. In this example, NET1 is connected to i2/a and reg1/QN. Cell i2 is hierarchical. Within i2, port a is connected to the U1/A and U2/A.

Feedback

```
pt_shell> get_pins -of_objects [get_nets NET1]
{"i2/a", "reg1/QN"}
pt_shell> get_pins -leaf -of_objects [get_nets NET1]
{"i2/U1/A", "i2/U2/A", "reg1/QN"}
```

The following example shows how to create a clock using a collection of pins.

```
pt_shell> create_clock -period 8 -name CLK [get_pins o_reg*/CP]
1
```

---

get_placement_blockages

Creates a collection of placement blockages from the current design.

Syntax

```
collection get_placement_blockages
[-all]
[-name expression]
```

Data Types

```
name          string
```

Arguments

`-all`

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-name`

Specifies the name of the placement blockage. It can be a wildcard expression

Feedback

- * (asterisk) indicates all placement blockages
- *xx** indicates any placement blockage whose name begins with *xx*
- PB_77 indicates one placement blockage that does not yet have a name and its object_id is 77
- PB_* indicates any placement blockage that does not yet have a name.

Description

This command creates a collection of placement blockages that meet the selection criteria. It returns a collection of placement blockages if one or more blockages meet the selection criteria. If no blockages match the selection criteria, it returns an empty string. You can use the *get_placement_blockages* command as an argument to another command or assign its result to a variable. Refer to the example below for details.

You can use the *get_placement_blockages* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* man page for information about working with collections.

Examples

The following examples show some uses of this command to create placement blockages:

```
prompt> get_placement_blockages *
{"PB_1", "PB_2", "PB_3"}
```

See Also

- collections
- create_placement_blockage

---

get_point_to_point_resistance

Return the equivalent resistance of a set of parasitic resistors from a given node to a given node in a net. The command returns a single value for a single corner case or a set of values for multi-corner case. Each value corresponds to the equivalent resistance for the corresponding corner.

Syntax

float *get_point_to_point_resistance*

Feedback

```
[-from node_name]
[-to   node_name]
[-quiet]
[-parasitic_corners corner_list]
[-all_parasitic_corners]
[-unit]
[-info]
[-ignore_layers]
```

Data Types

```
corner_list         list
node_name           string
node_name           string
```

Arguments

`-from node_name`

Constrains the selected resistors to be part of a path starting from the specified node. The node name can be either a pin, port, or an internal node, where the internal node name syntax is net_name:node_id, where the legal node_id range is from 1 to the number of nodes in the net. This option is used only with the -to option.

`-to node_name`

Constrains the selected resistors to be part of a path ending with the specified node, using the same node name syntax as the *-from* option.

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-parasitic_corners corner_list`

Indicates the parasitic corner ordering for resistance values. This option is only applicable for parasitics information obtained using *read_parasitics* with the GPD parasitic format. If the *-parasitic_corners* option is not specified, then the sin- gle parasitic corner specified by *set parasitic_corner_name* is returned.

`-all_parasitic_corners`

Specifies that all parasitic corners are to be returned. The parasitics ordering is determined according to the corner definitions of the GPD parasitics.

`-unit`

Show unit of get_point_to_point_resistance

`-info`

Get unit info of get_point_to_point_resistance

`-ignore_layers`

Specify layer to mark a certain connections to become ideal for calculations

Description

This command returns the equivalent point-to-point resistance (P2P) resistance between two points, which can be nodes/pins/ports. You must specify the *-from* and *-to* options to specify a path from which to get the equivalent resistance.

Examples

The following example queries the point to point resistance from internal node n22:1 to internal node n22:5

```
<_shell>get_point_to_point_resistance -from n22:1 -to n22:5
0.45
```

---

get_port

Creates a collection of ports from the current design or instance. You can assign these ports to a variable or pass them into another command.

Syntax

collection *get_ports*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[patterns]
[-of_objects objects]
```

Data Types

expression	string
patterns	list
objects	list

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any ports that match the *patterns* option, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`patterns`

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type port. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

`-of_objects` *`objects`*

Creates a collection of ports connected to the specified objects. Each object is a named net collection. The *-of_objects* and *patterns* options are mutually exclusive; you can specify only one.

Description

The *get_ports* command creates a collection of ports in the current design or instance that match certain criteria. The command returns a collection if any ports match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If the *port_search_in_current_instance* variable is true, then the *get_ports* command gets the ports of current instance. If the *port_search_in_current_instance* variable is *false* (the default), the *get_ports* command gets the ports of the current design.

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter the *expression* option; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You

can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_ports* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_ports* command result to a variable.

When issued from the command prompt, the *get_ports* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_ports* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* command, use the *get_ports* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page. In addition, refer to the *all_inputs* and *all_outputs* man pages, which also create collections of ports.

Examples

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
pt_shell> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

The following example sets the driving cell for ports beginning with "in" to an FD2.

```
pt_shell> set_driving_cell -cell FD2 -library my_lib [get_ports in*]
```

The following example reports ports connected to nets matching the pattern "bidir*".

```
pt_shell> report_port [get_ports -of_objects [get_nets "bidir*"]]
```

---

get_ports

Creates a collection of ports from the current design or instance. You can assign these ports to a variable or pass them into another command.

Syntax

collection *get_ports*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[patterns]
[-of_objects objects]
```

Data Types

expression	string
patterns	list
objects	list

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any ports that match the *patterns* option, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

When combined with the *-regexp* option, makes matches case-insensitive. You can use the *-nocase* option only when you also use the *-regexp* option.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the "*" and "?" wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`patterns`

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type port. The *patterns* and *-of_objects* options are mutually exclusive; you can specify only one.

`-of_objects` *`objects`*

Creates a collection of ports connected to the specified objects. Each object is a named net collection. The *-of_objects* and *patterns* options are mutually exclusive; you can specify only one.

Description

The *get_ports* command creates a collection of ports in the current design or instance that match certain criteria. The command returns a collection if any ports match the *patterns* option and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

If the *port_search_in_current_instance* variable is true, then the *get_ports* command gets the ports of current instance. If the *port_search_in_current_instance* variable is *false* (the default), the *get_ports* command gets the ports of the current design.

Regular expression matching is the same as in the *regexp* Tcl command. When using the *-regexp* option, take care in the way you quote the *patterns* and filter the *expression* option; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_ports* command at the command prompt, or you can nest it as an argument to another command (for example, the *query_objects* command). In addition, you can assign the *get_ports* command result to a variable.

When issued from the command prompt, the *get_ports* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

The "implicit query" property of the *get_ports* command provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by

Feedback

the *query_objects* command, use the *get_ports* command as an argument to the *query_objects* command. For example, use this to display the object class.

For information about collections and the querying of objects, see the *collections* man page. In addition, refer to the *all_inputs* and *all_outputs* man pages, which also create collections of ports.

Examples

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
pt_shell> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

get_power_domains

Create a collection of power domains in the current design.

Syntax

string *get_power_domains*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
```

Feedback

```
[patterns]
[-of_objects cells]
```

Data Types

```
expression              string
patterns                list
cells                   string
```

Arguments

`-filter expression`

Filters the collection with *expression*. For any power domains that match *patterns*, the expression is evaluated based on the power domain's attributes. If the expression evaluates to true, the power domain is included in the result. This option works the same as the *filter* command in dc_shell.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`patterns`

Matches power domain names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page. The *patterns* and *-of_objects* options are mutually exclusive.

`-of_objects cells`

Returns a collection of power domain that owns the cells. The *patterns* and *-of_objects* options are mutually exclusive.

Description

The *get_power_domains* command creates a collection of power domains in the current design, that match certain criteria. The command returns a collection handle (identifier) if any power domains match the *patterns* or *-of_objects* value and pass the filter, if specified. If no objects match the criteria, the empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Examples

The following example queries the power domain and creates collection of it.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_power_domain SUB_DOMAIN -power_down \\
           -power_down_ctrl [get_nets pd_ctrl] \\
           -object_list [get_cells mid1]
1
pt_shell> get_power_domain {TOP_DOMAIN SUB_DOMAIN}
{"", ""}

prompt> get_power_domain TOP*
{""}
```

See Also

- report_power_domain

---

get_power_group_objects

Returns a collection of cells in a power group.

Syntax

collection *get_power_group_objects*

group_names

Data Types

group_names list

Arguments

group_names

Specifies the power groups of which the collection of cells will be returned.

Description

The *get_power_group_objects* command returns a collection of cells contained by the specified power groups.

Examples

In the following example, the cells included in the newly created power group are displayed.

Feedback

```
pt_shell> create_power_group -name my_group [get_cells "u1 u2"]
1
pt_shell> get_power_group_objects my_group
{"u1", "u2"}
```

See Also

- create_power_group
- remove_power_groups
- report_power_groups

---

get_power_per_pgpin

Reports power on every power pin of the cell

Syntax

```
collection get_power_per_pgpin
  [-power_type switching | internal | leakage | total]
  [-return_supply_level leaf | top | through_switch]
  object_list
```

Data Types

```
object_list      list
```

Arguments

`-power_type switching | internal | leakage | total`

Specifies the power type to be reported.

`-return_supply_level leaf | top | through_switch`

Specifies the power net to be reported:

- *leaf* - Reports the hierarchical net connected to the leaf cell.
- *top* - Report the flat net connecting the leaf cell from the top most context.
- *through_switch* - Reports the supply_net after getting propagated through the switches.

object_list

Specifies a list of leaf cells.

Feedback

Description

The *get_power_per_pgpin* command reports the power on the power pins of the leaf cell. The command output is in the form of a list of lists where every power pin list consists of the power pin name, supply_net or rail name and the power associated with the power pin.

The variable power_enable_multi_rail_analysis must be set to true for *get_power_per_pgpin* command to function properly.

Examples

In the following example, the *get_power_per_pgpin* command is specified after *update_power*.

```
pt_shell> get_power_per_pgpin U76
{U76 {VDD 'VDD' 4.044e-07} {VNW '' 6.795e-10} {VPW '' 0}}
```

See Also

- get_power_per_rail
- report_power
- report_power_pin_info

---

get_power_per_rail

Reports power on given rails or supply_nets of the design for a given list of hierarchical cells.

Syntax

```
collection get_power_per_rail
  [-rails rail_list]
  [-power_type switching | internal | leakage | total]
  [-return_supply_level leaf | top | through_switch]
  object_list
```

Data Types

```
rail_list        list
object_list      list
```

Arguments

`-rails rail_list`

Specifies the power nets/rails to be reported.

`-power_type switching | internal | leakage | total`

Specifies the power type to be reported.

Feedback

`-return_supply_level leaf | top | through_switch`

Specifies the power net to be reported:

- *leaf* - Reports the hierarchical net connected to the leaf cell.
- *top* - Report the flat net connecting the leaf cell from the top most context.
- *through_switch* - Reports the supply_net after getting propagated through the switches.

object_list

Specifies a list of hierarchical/leaf cells.

Description

The *get_power_per_rail* command reports the power on the rails for each of the cells specified. The command output is in the form of a list of lists where every list consists of the supply_net or rail name , hierarchy or cell name and the associated power with the rail for the given cell. Supports when multi-rail analysis is enabled. Please set variable "power_enable_multi_rail_analysis true".

Examples

In the following example, the *get_power_per_rail* command is specified after *update_power*.

```
pt_shell> get_power_per_rail "four_mini_inst/two_mini_1" -rails
 four_mini_inst/VDD_MINI_1
{ four_mini_inst/VDD_MINI_1 four_mini_inst/two_mini_1 9.354e-05 }
  { unconnected four_mini_inst/two_mini_1 1.031e-05 }

pt_shell> get_power_per_rail "four_mini_inst" -power_type total \\
          -return_supply_level through_switch
{ unconnected four_mini_inst 3.063e-05 } { VDD four_mini_inst 0.0001921 }
```

---

get_power_switches

Create a collection of UPF power switches in the current design.

Syntax

string *get_power_switches*

Feedback

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-of_objects upf_power_domain|upf_supply_net]
[patterns]
```

Data Types

```
expression      string
patterns        list
```

Arguments

`-filter expression`

Filters the collection with the *expression* argument. For any UPF power switches that match the *patterns* argument, the expression is evaluated based on the power switch's attributes. If the expression evaluates to true, the power switch is included in the result. This option works the same as the *filter* command in pt_shell.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

patterns

Matches supply net names against patterns. Patterns can include the wildcard characters "*" (asterisk) and "?" (question mark). For more details about using and escaping wildcards, see the *wildcards* man page. The *patterns* and *-of_objects* arguments are mutually exclusive.

-of_objects

Gets the power switches of the object list. Objects could be combination of upf_power_domain or upf_supply_net. The *patterns* and *-of_objects* arguments are mutually exclusive.

Description

The *get_power_switches* command creates a collection of UPF power switch objects in the current design, that match certain criteria. The command returns a collection handle

Feedback

(identifier) if any supply nets match the *patterns* or *-of_objects* arguments and pass the filter (if specified). If no objects match the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a power switch and creates collection of it.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_supply_net SN1 -domain TOP_DOMAIN
1
pt_shell> create_supply_net SN2 -domain TOP_DOMAIN
1
pt_shell> create_power_switch my_switch -domain TOP_DOMAIN \\
          -output_supply_port {OUT SN2} \\
          -input_supply_port {IN SN2} \\
          -on_state {state1 IN {CNTL} } \\
          -control_port {ctrl CNTL}

pt_shell> get_power_switches *
{"my_switch"}
```

See Also

- create_power_switch
- report_power_switch

---

get_qtm_ports

Creates a collection of quick timing model (QTM) ports. You can assign these QTM ports to a variable or pass them into another command.

Syntax

collection *get_qtm_ports*

```
        patterns
```

Data Types

patterns	list

Feedback

Arguments

patterns

Matches QTM port names against patterns. Patterns can include the wildcard characters "*" and "?".

Description

The *get_qtm_ports* command creates a collection of QTM ports from the current QTM model that match certain criteria. The command returns a collection if any QTM ports match the *patterns* option. If no objects match the criteria, an empty string is returned.

To create a QTM port, use the *create_qtm_port* command.

See the *collections* man page for information about collections and the querying of objects.

For basic information about quick timing models, see the *create_qtm_model* man page.

Examples

The following command applies the *set_qtm_port_load* command to all QTM ports in the model matching "IN*".

```
pt_shell> set_qtm_port_load -value 2.0 [get_qtm_ports "IN*"]
```

The following command creates a delay arc from QTM port A to all QTM ports in the model matching "OUT*".

```
pt_shell> create_qtm_delay_arc -from A -to [get_qtm_ports "OUT*"] -value
 3.0
```

See Also

- create_qtm_constraint_arc
- create_qtm_delay_arc

- save_qtm_model
- set_qtm_port_drive
- set_qtm_port_load

Feedback

get_random_numbers

Generates a list of random numbers for a specified variation.

Syntax

```
list get_random_numbers
  -sample_size size_value
  -seed seed_value
  variation_object
```

Data Types

size_value	integer
seed_value	integer
variation_object	collection

Arguments

`-sample_size` *size_value*

Specifies the sample size.

`-seed` *seed_value*

Specifies the seed for this particular stream. This number must be a positive integer. A different number generates a different sample.

variation_object

Specifies the variation from which to generate random samples. There can only be one object.

Description

This command generates random numbers in a list.

Examples

In the following example, the returned list contains a sample of size 500 of random numbers generated from a variation with a normal distribution with mean 15.0 and standard deviation 2.0. The seed for this random number stream is 17777.

```
pt_shell> create_variation -name test -type normal -values { 15.0 2.0 }
_sel21

pt_shell> set rnd_list [get_random_numbers -sample_size 500 \\
          -seed 17777 [get_variations test]]
10.613445  14.553537  13.051448  16.382267 ...
```

Feedback

get_related_supply_net

Returns a collection of UPF related supply nets for given pins.

Syntax

```
collection get_related_supply_net
  [-ground]
  [pins]
```

Data Types

```
pins        list
```

Arguments

`-ground`

Includes ground supply in the collection.

pins

Specifies a list of pins to be queried.

Description

The *get_related_supply_net* command returns a collection of UPF supply nets for the given pins. Power supply net is returned by default. If the ground options is specified, ground supply net is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns the related supply net of all the pins of instance LS.

```
prompt> get_related_supply_nets [get_pin Mod1/LS/*]
{"SS1.pwr" "SS1.pwr"}
```

See Also

- report_supply_net

get_resistors

Creates a collection of parasitic resistors from the specified net. You can assign these resistors to a variable or pass them into another command.

Syntax

collection *get_resistors*

Feedback

```
[-filter expression]
[-quiet]
[-parasitic_corners corner_list]
[-all_parasitic_corners]
[-of_objects objects]
[-from node_name]
[-to node_name]
[-unit]
[-shortest]
[-info]
```

Data Types

```
expression          string
corner_list         list
node_name           string
objects             list
node_name           string
```

Arguments

`-filter expression`

Filters the collection with the *expression* value. For any resistors that match *patterns* or *objects*, the expression is evaluated based on the resistor's attributes. If the expression evaluates to true, the resistor is included in the result.

`-quiet`

Suppresses warning and error messages if there are no objects that match. Syntax error messages are not suppressed.

`-parasitic_corners corner_list`

Indicates the parasitic corner ordering for resistance values. This option is only applicable for parasitics information obtained using *read_parasitics* with the GPD parasitic format. If the *-parasitic_corners* option is not specified, then the single parasitic corner specified by *set parasitic_corner_name* is returned.

`-all_parasitic_corners`

Specifies that all parasitic corners are to be returned. The parasitics ordering is determined according to the corner definitions of the GPD parasitics.

`-of_objects objects`

Creates a collection of resistors associated with the specified objects. Each object must be a named net or net collection.

You must use either the *-of_objects* option or the *-from* and *-to* options.

`-from` *`node_name`*

Constrains the selected resistors to be part of a path starting from the specified node. The node name can be either a pin, port, or an internal node, where the internal node name syntax is *net_name*:*node_id*, where the legal *node_id* range is from 1 to the number of nodes in the net. This option is used only with the *-to* option.

`-to` *`node_name`*

Constrains the selected resistors to be part of a path ending with the specified node, using the same node name syntax as the *-from* option.

`-unit`

Show unit of get_resistors

`-shortest`

Get the shortest path of the selected resistors with the specified starting node and the specified ending node. This option is used only the *-from* and *-to* options.

`-info`

Get unit info of get_resistors

Description

This command creates a collection of resistors for the specified nets that match certain criteria. You must use either the *-of_objects* option and specify a net collection or the *-from* and *-to* options to specify a path from which to get the coupling capacitors. If no objects match the criteria, an empty string is returned.

When issued from the command prompt, the *get_resistors* command behaves as though the *query_objects* command had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *collection_result_display_limit* variable.

For information about collections and querying of objects, see the *collections* man page.

Examples

The following example queries the parasitic resistors of net n22, subject to those objects whose max corner resistance is greater than 0.5e-3.

```
pt_shell> get_resistors -of_objects n22 -filter "resistance_max > 0.5e-3"
{"resistor"}
```

---

get_rule_property

Gets a property value on a rule. Properties affect how a specific rule check is performed, or how the output of a rule violation is presented.

Syntax

string *get_rule_property*

```
property_name
rule
```

Data Types

```
property_name     string
rule              string
```

Arguments

property_name

The name of a valid property on the specified rule.

rule

Specifies the name of an existing rule.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Obtains a property value for one rule. Properties can control rule checking; for example, the limit of some comparison. Properties can also control the output; for example, the maximum number of pins shown in the more info section of a violation.

Feedback

Examples

The following example gets the *max_percent* property for rule *EXD_0009* and assigns it to a variable.

```
pt_shell> set maxPercentVar [get_rule_property max_percent EXD_0009]
```

See Also

- create_rule

---

get_rules

Creates a collection of rules. You can assign the resulting collection to a variable or pass it into another command.

Syntax

collection *get_rules*

```
[-filter expression]
[-quiet]
patterns | -of_objects objects
```

Data Types

```
expression        string
patterns          list
objects           list
```

Arguments

`-filter expression`

Filters the collection with *expression*. For any rules that match *patterns* (or *objects*) the expression is evaluated based on the rule's attributes. If the expression evaluates to true, the rule is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-of_objects objects`

Creates a collection of rules contained in the specified rulesets. In this case, each entry is either a named ruleset or a collection of rulesets. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches rule names against patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type rule. *patterns* and *-of_objects* are mutually exclusive; you must specify one, but not both.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

The *get_rules* command creates a collection of rules defined in the session that match certain criteria. The command returns a collection if any rules match the *patterns* or *objects* and pass the filter (if specified). If no rules match the criteria, the empty string is returned.

Examples

The following example performs the *disable_rule* command on the collection of rules matching pattern "CSL_*".

```
pt_shell> disable_rule [get_rules CSL_*]
```

See Also

- create_rule
- create_ruleset
- get_rulesets

---

get_rulesets

Creates a collection of rulesets. You can assign the resulting collection to a variable or pass it into another command.

Syntax

collection *get_rulesets*

```
[-filter expression]
[-quiet]
patterns | -of_objects objects
```

Data Types

```
expression      string
patterns        list
objects         list
```

Feedback

Arguments

`-filter` *expression*

Filters the collection with *expression*. For any rulesets that match *patterns* (or *objects*) the expression is evaluated based on the ruleset's attributes. If the expression evaluates to true, the ruleset is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-of_objects` *objects*

Creates a collection of rulesets containing the specified rules. In this case, each entry is either a named rule or a collection of rules. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

patterns

Matches ruleset names against patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type ruleset. *patterns* and *-of_objects* are mutually exclusive; you must specify one, but not both.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

The *get_rulesets* command creates a collection of rulesets defined in the session that match certain criteria. The command returns a collection if any rulesets match the *patterns* or *objects* and pass the filter (if specified). If no rulesets match the criteria, the empty string is returned.

Examples

The following example performs the *disable_rule* command on the rules in ruleset "my_set1"

```
pt_shell> disable_rule [get_rulesets my_set1]
```

See Also

- create_rule
- create_ruleset
- get_rules

Feedback

get_selection

Returns a collection containing the current selection in the GUI.

Syntax

```
collection get_selection
[-slct_targets target_selection_bus
  [-slct_targets_operation operation]]
-create_slct_buses
[-name selection_bus]
[-type object_type]
[-design design]
[-more_than more]
[-fewer_than fewer]
[-count]
[-num num]
[-type_list]
```

Data Types

target_selection_bus	string
operation	string
selection_bus	string
object_type	string
design	string
more	integer
fewer	integer
num	integer

Arguments

`-slct_targets` *target_selection_bus*

Specifies the name of a selection bus in which to store the result. When you use this option, the *target_selection_bus* value is also returned as result of the command. By default, the result is returned in a collection.

`-slct_targets_operation` *operation*

Specifies which operation should be used when storing the result in the selection bus specified by the *target_selection_bus* argument. The valid values for the *operation* argument are *clear*, *add*, and *remove*. You can use the *-slct_targets_operation* option only if you also use the *-slct_targets* option.

`-create_slct_buses`

Specifies to create a new selection bus in which to store the result. Using this option is equivalent to using the *create_selection_bus* command to create a selection bus and then providing the created selection bus to the *-slct_targets* option.

Feedback

`-name selection_bus`

Specifies the selection bus from which the selection is taken.

`-type object_type`

Specifies the type of selected object with which to filter the selection. The valid values for *object_type* and their descriptions are as follows:

```
design -design object
port -port object
net -net object
cell -cell object
pin -pin object
path -timing path object
```

`-design design`

Returns only objects in the filter specified by the value of *design*.

`-more_than more`

Returns true if the selection bus contains more than the number of objects specified by *more*.

`-fewer_than fewer`

Returns true if the selection bus contains more than the number of objects specified by *fewer*.

`-count`

Returns the number of elements contained in the selection bus.

`-num num`

Returns only the number of objects specified by *num* or fewer.

`-type_list`

Returns a Tcl list of the types of elements contained in the selection bus.

Description

This command returns the current selection in the tool as a collection. It returns a collection handle (identifier) if any objects are selected. If no objects are selected, the command returns an empty string. If you do not use the *-type* option, the command returnS a heterogeneous collection of all objects currently selected. If you use *-type*, the collection is filtered to a homogeneous one containing only objects of the type you specify.

You can use the *get_selection* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*), or assign the *get_selection* result to a variable.

Feedback

When issued from the command prompt, *get_selection* behaves as if you had called *query_objects* to display the objects in the collection. By default, the command displays a maximum of 100 objects. You can change this maximum by using the *collection_result_display_limit* variable.

The "implicit query" property of *get_selection* provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the options of the *query_objects* command (for example, if you want to display the object class), use *get_selection* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns the collection of the selected cell objects.

```
prompt> get_selection -type cell
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

The following example assigns the collection to a variable named *collect_a* that is passed to the *query_objects* command.

```
prompt> set collect_a [get_selection -type cell]
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
prompt> query_objects $collect_a
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

See Also

- change_selection
- collections
- filter_collection
- query_objects

---

get_shapes

Creates a collection by selecting shapes from the design.

Syntax

```
collection get_shapes
[-of_objects objects]
```

Data Types

```
objects        collection
```

Feedback

Arguments

`-of_objects` *of_objects*

Creates a collection containing the shapes connected to the specified net. Each object in the list is a collection.

This command creates a collection of shapes by selecting shapes from the current design that meet the selection criteria. It returns a collection handle if one or more shapes meet the selection criteria. If no shapes match the selection criteria, it returns an empty string.

Use the *get_shapes* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following example gets all shapes connected to the specified net.

```
prompt> get_shapes * -of_objects [get_nets net1]
{PATH_31_0 PATH_31_1}
```

See Also

- collections
- get_attribute
- query_objects

---

get_si_bottleneck_nets

Creates a collection of nets that have the largest crosstalk effects that contribute to timing violations.

Syntax

status *get_si_bottleneck_nets*

```
[-cost_type type]
[-slack_lesser_than slack_limit]
[-minimum_active_aggressors active_aggressor_count]
[-delta_delay_threshold threshold]
[-min]
[-max]
[-all_nets]
[-nets net_list]
```

```
[-max_nets number]
[-include_clock_nets]
```

Data Types

type	list
slack_limit	float
number	integer
digits	integer
active_aggressor_count	integer
net_list	list

Arguments

`-cost_type` *type*

Sorts the nets based on the cost. The *delta_delay*, *delta_delay_ratio*, *total_victim_delay_bump* options are the costs of the victim nets. The *delay_bump_per_aggressor* option for aggressor nets of the selected victim nets.

`-slack_lesser_than` *slack_limit*

Applies the cost function only to victim nets with slack less than the specified limit. The default is zero. Specify a positive value to find more bottleneck nets, and vice versa.

`-minimum_active_aggressors` *active_aggressor_count*

Sets the minimum number of active aggressors for the net to be selected. The default is 1.

`-delta_delay_threshold` *threshold*

Restricts to only the victim nets whose delta delay cost exceeds the specified threshold. The threshold must be at least zero. The default is zero. This option applies only if the *-cost_type* option is set to *delta_delay*.

`-min`

Considers only minimum-delay (hold) constraints.

`-max`

Considers only maximum-delay (setup) constraints.

`-all_nets`

Considers all nets with SI cost that contribute to negative path slacks. By default, the command reports the 20 nets with the worst bottleneck cost.

`-nets` *list*

Restricts the bottleneck analysis to only the nets specified in a list or collection of nets. By default, the command considers all nets in the design.

Feedback

`-max_nets` *number*

Sets the maximum number of nets to be collected. The default is 20.

`-include_clock_nets`

Includes the clock nets for bottleneck analysis. By default, clock nets are excluded.

Description

This command has the same behavior as the *report_si_bottleneck* command, but returns nets as a collection instead of reporting on them. For more information, see the man page for the *report_si_bottleneck* command.

Examples

The following command creates a collection of nets belonging to paths with setup or hold violations that have the largest delta delays.

```
pt_shell> set my_nets [get_si_bottleneck_nets]
{"DX23[17]", "REG_ADDR[2]", "REG_DATA[5]", "RE_RDY", "REG_DATA[6]",
"REG_ADDR[4]", "DX23[22]", "DX23[11]", "REG_ADDR[7]", "DX23[1]"}

pt_shell> foreach_in_collection n $my_nets \\
  {echo [get_attribute [get_nets $n] si_xtalk_bumps]}
{ n24331 0.025178  0.025697 }
{ n26710 0.021577  0.022355 } { RE_RDY screened_by_macro_model
 screened_by_macro_model }
{ _CG_RDY_IN 0.022645  0.023179 }
{ REG_ADDR[2] 0.018784  0.018983 }
{ REG_ADDR[8] 0.014359  0.014527 }
 ...
```

---

get_sms_scenarios

Gets a voltage/corner scenario collection for use with SMS features.

Syntax

```
status get_sms_scenarios
  [-supply_group supply_group_list]
  [-reference_names levels]
  [-propagated]
```

Feedback

Data Types

```
supply_group_list     list
levels                list
```

Arguments

`-supply_group` *supply_group_list*

Specifies a supply group. The reference voltage names for the supply group should be previously specified using the *set_voltage_levels* command. Multiple *-supply_group* options can be applied to the command. For every *-supply_group* option, there must be a corresponding *-reference_names* option. The reference voltage names of the *supply_group* will be part of the scenario being specified.

`-reference_names` *levels*

Specifies one or more reference voltage names of the corresponding *supply_group* that was specified using the *-supply_group* option. Multiple *-reference_names* options can be applied to the command. For every *-reference_names* option, there must be a corresponding *-supply_ggroup* option. The reference voltage names of the *supply_group* will be part of the scenario being specified.

`-propagated`

With this option the command returns a collection including all SMS scenarios used for comprehensive Multi Voltage timing analysis of the design. The collection includes only the scenarios relevant to all the analyzed timing paths. Voltage configurations which are not relevant to any timing path are not included in this collection. This option is only available with SMVA analysis and after update_timing. This option is mutually exclusive with command options *-supply_group* and *-reference_names*.

`-disabled`

With this option the command returns a collection including all SMS scenarios disabled using *configure_sms_scenarios -disable*. The same collection can be reported using *report_sms_scenarios -disabled*.

Description

The command specifies a voltage scenario or a set of voltage scenarios. For each *-supply_group* specified, there should be corresponding *-reference_names* specified. The reference voltage names for the *supply_group* become part of the scenario. If any *supply_group* is not referenced, it is assumed that all reference voltage names for the *supply_group* are part of the scenario.

In order to reference a supply group, the command *set_voltage_levels* must previously have been run. *set_voltage_levels* is used to specify the names of the reference voltage names.

After you run the *get_sms_scenarios* command and reference a particular supply group, it is not possible to reset the reference voltage names of the supply group using *set_voltage_levels*, unless the design is reset using *reset_design*.

When specifying multiple supply groups, be sure to specify the options in the correct order. The tool determines correspondence of the *-supply_group* and *-reference_names* options by order. The first *-supply_group* option is matched with the first *-reference_names* option, and so on.

Examples

The following example specifies reference voltage names for three supply groups using the *set_voltage_levels* command, then creates several scenarios.

Scenario *$sc1* includes level *sleep* of supply group *A* and levels *1.0V,1.1V* of supply group *B*, and all levels of supply group *C*. Scenario *$sc2* includes level *1.2V* of supply group *B*, and all levels of groups *A* and *C*. Both *$sc1* and *$sc2* represent several voltage scenarios. Scenario *$sc3* includes level *fast* of supply group *A*, level *1.2V* of supply group *B*, and level *v0.9* of supply group *C*. Scenario *$sc3* specifies a single voltage scenario, because all supply groups are specified, and only one level is in the scenario for each supply group. Note that scenario *$sc3* is included within the *$sc2* scenarios.

```
pt_shell> set_voltage_levels -reference_names {sleep slow fast}
 [get_supply_group A]
1
pt_shell> set_voltage_levels -reference_names {1.0V 1.1V 1.2V}
 [get_supply_group B]
1
pt_shell> set_voltage_levels -reference_names {v0.9 v1.0}
 [get_supply_group C]
1
pt_shell> set sc1 [get_sms_scenarios -supply_group A -reference_names
 {sleep} \\
          -supply_group B -reference_names {1.0V 1.1V}]
__sel22
pt_shell> set sc2 [get_sms_scenarios -supply_group B -reference_names
 {1.2V}]
__sel22
pt_shell> set sc3 [get_sms_scenarios -supply_group A -reference_names
 {fast} \\
          -supply_group B -reference_names {1.2V} \\
          -supply_group C -reference_names {v0.9}]
__sel22
```

Feedback

get_supply_groups

Creates a collection of supply groups in the current design.

Syntax

string *get_supply_groups*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[patterns]
```

Data Types

expression	string
patterns	list

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any supply groups that match the *patterns* option, the expression is evaluated based on the supply group's attributes. If the expression evaluates to true, the supply group is included in the result. This option works the same as the *filter* command in dc_shell.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

patterns

Matches supply group names against patterns. Patterns can include the wildcard characters "*" (asterisk) and "?" (question mark). For details about using and escaping wildcards, refer to the *wildcards* man page. The *patterns* and *-of_objects* arguments are mutually exclusive.

Feedback

Description

The *get_supply_groups* command creates a collection of supply groups in the current design that match certain criteria. The command returns a collection handle (identifier) if any supply groups match the *patterns* or *-of_objects* arguments and pass the filter (if specified). If no objects match the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a collection of supply_groups.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_supply_net SN1 -domain TOP_DOMAIN
1
pt_shell> get_supply_nets {SN1}
{"SN1"}

prompt> get_supply_groups SN*
{"SN1"}
```

- report_supply_group

---

get_supply_nets

Create a collection of UPF supply nets in the current design.

Syntax

string *get_supply_nets*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-hierarchy]
[-pg_types power|ground|pwell|nwell]
[-segments ]
[-of_objects Cell|upf_pg_pin_info|upf_power_domain]
[patterns]
```

Data Types

```
expression      string
patterns        list
```

Feedback

Arguments

`-filter` *`expression`*

Filters the collection with the *expression* option. For any UPF supply nets that match the *patterns* option, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result. This option works the same as the *filter* command in dc_shell.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-hierarchy`

Searches for supply nets in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the patterns argument; the name cannot contain hierarchy delim- iter characters. If you do not specify this option, the tool searches for supply nets only in the current scope. You can use hierarchy delimiter characters in the patterns argument to specify hierarchical sup- ply nets relative to the current scope.

`-pg_types`

Filters supply net based on pg_types. pg_types could be list of following values: power, ground, pwell, nwell.

`-segments`

Gets all the net segments connected to the list of nets. The search will stop at power switches.

`-of_objects`

Gets the supply net of the object list. Objects could be combination of cell, upf_power_domain or upf_pg_pin_info. get_pg_pins returns a collection of upf_pg_pin_info objects which could be used as of_objects. The *patterns* and *-of_objects* arguments are mutually exclusive.

`patterns`

Matches supply net names against patterns. Patterns can include the wildcard characters "*" (asterisk) and "?" (question mark). For details about using

Feedback

and escaping wildcards, refer to the *wildcards* man page. The *patterns* and *-of_objects* arguments are mutually exclusive.

Description

The *get_supply_nets* command creates a collection of UPF supply nets in the current design that match certain criteria. The command returns a collection handle (identifier) if any supply nets match the *patterns* or *-of_objects* arguments and pass the filter (if specified). If no objects match the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a supply net and creates collection of it.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_supply_net SN1 -domain TOP_DOMAIN
1
pt_shell> get_supply_nets {SN1}
{"SN1"}

prompt> get_supply_nets SN*
{"SN1"}
```

See Also

- create_supply_net
- report_supply_net

---

get_supply_ports

Create a collection of UPF supply ports in the current design.

Syntax

string *get_supply_ports*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-of_objects objects]
[patterns]
```

Feedback

Data Types

expression	string
patterns	list

Arguments

`-filter` *expression*

Filters the collection with the *expression* option. For any UPF supply ports that match the *patterns* option, the expression is evaluated based on the supply port's attributes. If the expression evaluates to true, the supply port is included in the result. This option works the same as the *filter* command in dc_shell.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* option as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-of_objects objects`

Creates a collection of supply ports connected to the specified objects. The -of_objects and patterns options are mutually exclusive; you can specify only one. In addition, you cannot use the -hierarchical option with the -of_objects option.

patterns

Matches supply port names against patterns. Patterns can include the wildcard characters "*" (asterisk) and "?" (question mark). For details about using and escaping wildcards, refer to the *wildcards* man page. The *patterns* and *-of_objects* options are mutually exclusive.

Description

The *get_supply_ports* command creates a collection of UPF supply ports in the current design that match certain criteria. The command returns a collection handle (identifier) if any supply ports match the *patterns* or *-of_objects* options and pass the filter (if specified). If no objects match the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Examples

The following example creates a supply port and creates a collection of it.

```
pt_shell> create_power_domain TOP_DOMAIN
1
pt_shell> create_supply_port SN1 -domain TOP_DOMAIN
1
pt_shell> get_supply_ports {SN1}
{"SN1"}

prompt> get_supply_ports SN*
{"SN1"}
```

See Also

- create_supply_port

---

get_supply_sets

Creates a collection of UPF supply sets in the current design.

Syntax

collection *get_supply_sets*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[patterns]
```

Data Types

expression	string
patterns	list

Arguments

`-filter expression`

Filters the collection with the *expression* option. For any UPF supply set that matches the *patterns* option, the expression is evaluated based on the supply set's attributes. If the expression evaluates to true, the supply set is included in the result.

This option works the same as the *filter* command in dc_shell.

`-quiet`

Suppresses warning and error messages if no object matches. Syntax error messages are not suppressed.

Feedback

`-regexp`

Uses the *patterns* option as real regular expressions rather than simple wildcard patterns.

`-nocase`

Performs case-insensitive matching.

`patterns`

Matches supply set names against patterns. Patterns can include the asterisk (*) and question mark (?) wildcard characters. For information about using and escaping wildcards, see the *wildcards* man page.

Description

The *get_supply_sets* command creates a collection of UPF supply sets in the current design that match certain criteria. The command returns a collection handle (identifier) if any supply set matches the *patterns* options and pass the filter (if specified). If no object matches the criteria, an empty string is returned.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a supply set and creates a collection of it.

```
prompt> create_supply_set SS1
1
prompt> get_supply_sets {SS1}
{"SS1"}
prompt> get_supply_sets SS*
{"SS1"}
```

---

get_switching_activity

Gets switching activity annotation on nets, pins, ports, and cells of the current design.

Syntax

integer *get_switching_activity*

```
[-state_condition state]
[-path_sources name_list]
[-toggle_rate]
[-glitch_rate]
```

```
[-static_probability]
[-rise | -fall]
[-only_related_clock clock_name]
[-toggle_limit limit]
[-exclude exclusion_group]
[-include_only inclusion_group]
[-average_activity]
[-relative_toggle_rate]
object_list
```

Data Types

state	string
name_list	string
clock_name	string
limit	integer
exclusion_group	string
inclusion_group	string
object_list	list

Arguments

`-state_condition` *state*

Specifies the state condition when getting state-dependent toggle rate and glitch rate on pins or state-dependent static probabilities on cells. State dependent toggle rate and glitch rate can be retrieved for a pin when the internal power of the library cell pin is characterized with state-dependent power tables. State-dependent static probabilities for a cell is annotated when the cell leakage power is characterized with state-dependent power tables. The state condition specified with this argument must be logically equivalent to a state condition in the internal/leakage power characterization. The state condition should be enclosed between " ". Moreover, if you want to get switching activity information for the default state condition, then the *state* argument should be "default". If the *-state_condition* option is applied to a cell, then only static probability is reported. Only leakage power is associated with cells. If the *state* argument is applied to a pin, then the tool looks for the condition in the internal power tables and report the toggle rate/glitch rate/static probability for that pin.

Given a design object, the command returns the list comprised of object name, the *state* argument, static probability for the *state* argument and the annotation source indicator. If the *state* argument does not represent a valid state for the cell, then the value of -2 is returned. If the cell has no state-dependent static probability annotation for the *state* argument, then the value of -1 is returned.

`-path_sources` *name_list*

Specifies the path sources when getting path-dependent toggle rate and glitch rate on pins. This is used when the library cell pin has path-dependent internal power. The path source or sources specified with this argument must be the

same as those in the internal power characterization. The *-path* option takes a path condition (a list of input pins). Again, the path condition after the *-path* option should be enclosed between " ". If there are multiple input pins in the path condition, then each input pin should be separated by a space, for example "A B".

Note that if the *name_list* argument is given using the *-path_sources* option, then the *state* argument should also be provided using the *-state_condition* option.

Given a design object, the command returns a list comprised of object name, the *-state_condition* option, source pin name, toggle rate value, toggle rate annotation source indicator, glitch rate value, and glitch rate annotation source indicator. If the combination of the *state* and *name_list* arguments does not represent a valid state-dependent-path-dependent (SDPD) condition for the design object, then the value of -2 is returned. If the design object does not have toggle rate or glitch rate annotation for the given SDPD conditions, then the value of -1 is returned.

`-toggle_rate`

Specifies the toggle rate (rise and fall, if applicable) which is reported for the given design object. Given a design object, the command returns the list comprised of object name, simple toggle rate value (without glitches), and annotation source indicator. The unit of returned toggle rate value is the number of toggle counts per target technology library time unit. If the object has no toggle rate value annotation, then this command returns the value -1. If the given object is not found in the design, then the value of -2 is returned.

An annotation source indicator can have the following possible values:

- file: implies that the *-toggle_rate* value was annotated through a SAIF or vcd file
- propagated: implies that the *-toggle_rate* value is propagated using random vectors from annotated design points
- default: implies that the *-toggle_rate* value is default
- UNINITIALIZED: implies that the *-toggle_rate* value is uninitialized
- create_clock: implies that the *-toggle_rate* value was annotated by a *create_clock* command
- set_switching_activity: implies that the *-toggle_rate* value was annotated by a *set_switching_activity* command

- set_case_analysis: implies that the *-toggle_rate* value was annotated by a *set_case_analysis* command
- implied: implies that the activity was implied without random vector propagation from annotated design points

The object name is the full name relative to the current instance.

`-glitch_rate`

Specifies the glitch rate (rise and fall, if applicable) which is reported for the given design object. Given a design object, the command returns the list comprised of object name, glitch rate value, and an annotation source indicator. The unit of the returned glitch rate value is the number of glitch counts per target technology library times unit. If the object has no glitch rate value annotation, then this command returns the value -1. If the given object is not found in the design, then the value of -2 is returned.

`-static_probability`

Specifies the static probability value which is reported for the given design object. Given a design object, the command returns the list comprised of object name, simple static probability and an annotation source indicator. The static probability is defined as the percentage of time the signal is at logic state 1. If the object has no static probability value annotation, then this command returns the value -1. If the given object is not found in the design, then the value of -2 is returned.

If none of the *-toggle_rate*, *-glitch_rate* and *-static_probability* options are set, then the command assumes all three options to be true, and returns the *-toggle_rate*, *-glitch_rate*, and *-static_probability* values.

`-rise`

Use with the *-state_condition* option. This option reports either rise or fall transitions. If the *-state_condition* option and *state* argument are given and neither the *-rise* nor *-fall* option is given, then by default the command assumes both to be true. If the *-rise* or *-fall* option is given along with the *-static_probability* option, then the *-rise* and *-fall* options are ignored as static probability does not depend on rise or fall transitions type.

`-fall`

Use with the *-state_condition* option. This option reports either rise or fall transitions. If the *-state_condition* option and *state* argument are given and neither the *-rise* nor *-fall* option is given, then by default the command assumes both to be true. If the *-rise* or *-fall* option is given along with the *-static_probability* option, then the *-rise* and *-fall* options are ignored as static probability does not depend on rise or fall transitions type.

`-only_related_clock` *`clock_name`*

Only nets and objects that are in the clock domain, *clock_name* argument are included. Objects not in the domain are filtered out. When the *-average_activity* option is used, objects are filtered out before averaging takes place.

`-toggle_limit` *`limit`*

Changes the definition of what is considered to be low activity. This definition is used by the *-exclude* and *-include_only* options, depending on the criteria given to those options. The value of the argument represents the maximum number of toggles considered to be low activity. The default is 1. The number of toggles on a net is defined as the toggle rate times the simulation duration. For vector free power analysis (where no SAIF file or VCD is used) the default simulation duration is 10000 ns. If a SAIF is used, the duration is taken from the SAIF file. If a VCD file is used to annotate activity, then the duration is the duration of the VCD simulation.

The *-toggle_limit* option has no effect unless the *-exclude* or *-include_only* options are used. The *-toggle_limit* option only affects the behavior of these other options.

`-exclude` *`exclusion_group`*

This option filters out objects in the *object_list* argument, so that switching activity is not reported for objects that meet the specified criteria.

When the *-average_activity* option is used, the *-exclude* option serves to filter out nets before the average is taken.

For more information about how to use the *-exclude* and *-include_only* options, read the appropriate section in the man page for the *report_switching_activity* command.

`-include_only` *`inclusion_group`*

This option filters out objects in the *object_list* argument, so that switching activity is reported only on objects that meet the specified criteria.

When the *-average_activity* option is used, the *-include_only* option serves to filter out nets before the average is taken.

For more information about how to use the *-exclude* and *-include_only* options, read the appropriate section in the man page for the *report_switching_activity* command.

`-average_activity`

When this option is used, the *-static_probability*, *-rise*, *-fall*, and *-path_sources* options cannot be used.

When the *-average_activity* option is used, the *object_list* argument should consist only of hierarchical cells. For each hierarchical cell given, the average toggle rate and glitch rate of nets within the hierarchical cell is computed and reported.

In this case, the *-include_only* and *-exclude* options play the role of filtering out nets in the hierarchical cell before the average toggle rate is computed.

Static probabilities are never averaged. If the *-average_activity* option is used, only average toggle rate and average glitch rate is reported. Since the nets in the hierarchical cell might have different sources for the activity information, the activity source for the toggle and glitch rate reports as "averaged".

`object_list`

Specifies a list of nets, pins, ports, or cells in the current design for which the *-static_probability*, *-toggle_rate*, and *-glitch_rate* options switching activity values are reported.

When the *-average_activity* option is used, the *object_list* argument should consist of hierarchical cells whose average switching activity on nets in the cell is computed.

`-relative_toggle_rate`

When this option is used, the toggle rate specifies the relative toggle rate with respect to the related clock for the given design object.

Description

This command is used to report different kinds of switching activity information on design nets, ports, pins, and cells. These include simple toggle rate, glitch rate, and static probability on nets, ports, and pins; state and path dependent toggle rate and glitch rate on cell pins, and state dependent static probabilities on cells.

Toggle rates, glitch rates, and static probabilities are reported using the *-toggle_rate*, *-glitch_rate* and *-static_probability* options, respectively. The toggle rate, glitch rate, and static probability can be made state dependent by specifying the state condition with the *-state_condition* option. The toggle rate and glitch rate can be made path dependent by specifying the path source or sources with the *-path_sources* option.

The design objects that are annotated with switching activity can only be specified explicitly as a list of objects. Note that the *object_list* argument should always be provided to the command.

Average activity statistics for a hierarchical block, or portions of a hierarchical block is obtained using the *-average_activity* option.

For more statistics on the switching activity annotation on the current design, use the *report_switching_activity* command.

If the *power_analysis_mode* variable is set to *averaged* or *leakage_variation*, and if a VCD file is read with the *read_vcd* command (without the *-pipe* option), then the tool annotates the activity from the VCD before reporting the switching activity. In addition, unannotated objects where the activity can be derived accurately without random vector simulation (for example, clock nets, Qbar pins where the Q pin is annotated, constant nets) is reported by the *report_switching_activity* command as having the *implied* argument activity. Activity propagation for other unannotated nodes does not happen until the *update_power* command runs.

If the *power_analysis_mode* variable is set to *time_based*, then the *get_switching_activity* command does not have access to toggle rate information before running the *update_power* command. The command reports whether a net is uninitialized or whether it annotates from the VCD file. But since the VCD file has not been read yet, the toggle rate (and other values) is reported as -1.

Use of the *-exclude* and *-include_only* filtering options allow you to filter out objects before reporting switching activity. This is useful, for instance, to report only nets with no switching activity. In this case, the *object_list* argument could be all nets in the design (obtained by the *[get_net * -hierarchical -top]* argument), while the *-include_only {no_switching_activity}* option filters the large set to return a list of only those nets with no switching activity.

Examples

The following *get_switching_activity* command reports simple toggle rate value, glitch rate value, and static probability value on all design input ports.

```
pt_shell> get_switching_activity -toggle_rate -glitch_rate \\
         -static_probability [all_inputs]
pt_shell> get_switching_activity [all_inputs]
```

The following example reports different switching activity values on design output ports.

```
pt_shell> get_switching_activity -toggle_rate \\
          [all_outputs]

pt_shell> get_switching_activity -glitch_rate \\
          [all_outputs]

pt_shell> get_switching_activity -static_probability \\
          [all_outputs]

pt_shell> get_switching_activity -toggle_rate \\
          -static_probability [all_outputs]

pt_shell> get_switching_activity -glitch_rate \\
          -static_probability [all_outputs]

pt_shell> get_switching_activity -glitch_rate \\
          -toggle_rate [all_outputs]
```

```
pt_shell> get_switching_activity -glitch_rate \\
          -toggle_rate -static_probability [all_outputs]
```

The following example reports state dependent static probabilities on the cell or1:

```
pt_shell> get_switching_activity -static_probability \\
          -state_condition "A & B" [get_cell or1]

pt_shell> get_switching_activity -state_condition "A & B" \\
          [get_cell or1]

pt_shell> get_switching_activity -static_probability \\
          -state_condition "A & ! B" [get_cell or1]

pt_shell> get_switching_activity -static_probability \\
          -state_condition "! A & B" [get_cell or1]

pt_shell> get_switching_activity -static_probability \\
          -state_condition "! A & ! B" [get_cell or1]

pt_shell> get_switching_activity -static_probability \\
          -state_condition "default" [get_cell or1]
```

The following example reports simple and path dependent toggle rates and glitch rates on the output pin Y of the cell xor1:

```
pt_shell> get_switching_activity -toggle_rate -glitch_rate \\
          [get_pin xor1/Y]

pt_shell> get_switching_activity -toggle_rate -glitch_rate \\
          -path_sources "A" -state_condition "B" [get_pin xor1/Y]

pt_shell> get_switching_activity -rise -fall -toggle_rate \\
          -glitch_rate -path_sources "A" -state_condition "B" [get_pin
 xor1/Y]

pt_shell> get_switching_activity -rise -toggle_rate \\
          -glitch_rate -path_sources "A" -state_condition "B" [get_pin
 xor1/Y]

pt_shell> get_switching_activity -fall -toggle_rate \\
          -glitch_rate -path_sources "A" -state_condition "B" [get_pin
 xor1/Y]

pt_shell> get_switching_activity -toggle_rate -glitch_rate \\
          -path_sources "B" -state_condition "A" [get_pin xor1/Y]

pt_shell> get_switching_activity -toggle_rate -glitch_rate \\
          -path_sources "A B" -state_condition "default" [get_pin xor1/Y]
```

The following example reports the average switching activity on certain nets within the hierarchical cell "state_machine1". The nets used are those that are driven by sequential cells and have annotated switching activity.

```
pt_shell> get_switching_activity -toggle_rate -average_activity \\
          -include_only {sequential & annotated} [get_cell
 state_machine1]
```

The following example reports the switching activity on every pin that is an output of a sequential cell. This might be useful for checking to see that switching activity annotation to sequential cells happened properly when you invoke a command, such as the *read_saif* command.

```
pt_shell> get_switching_activity  \\
          -include_only {sequential} [get_pin * -hierarchical]
```

The following example reports the switching activity on every pin that is an output of a sequential cell or a black box and does not have annotated activity. This could be useful for generating a list of pins that you might want to annotate before propagation of switching activity.

```
pt_shell> get_switching_activity  \\
          -include_only {sequential,black_box & !annotated} [get_pin *
 -hierarchical]
```

The following example reports the switching activity on every net that has fewer than 10 toggles during simulation. Note that the *get_switching_activity* command reports toggle rates, not toggle counts. To obtain the toggle count of a net, multiply the rate by the simulation time.

```
pt_shell> get_switching_activity  -toggle_limit 10 \\
          -include_only {low_activity} [get_net * -hierarchical -top]
```

The following example reports on a net in the *averaged* power analysis mode. The net is in the VCD file, and the *read_vcd* command had previously been given. This example runs the *get_switching_activity* command before and after the *update_power* argument. The example shows that before power analysis, on the first invocation of an activity reporting command, the VCD activity is applied, then the toggle rate and source are reported. After power analysis, the toggle rate is also reported.

```
pt_shell> get_switching_activity "z[31]"
Information: Reading file vcd.dump.gz to annotate toggle rates on the
 design...

****************************************************************
Summary:
Total number of nets = 1629
Number of annotated nets = 1629 (100.00%)
Total number of leaf cells = 1339
Number of fully annotated leaf cells = 1339 (100.00%)
```

pt_shell> update_power
Information: Running average power analysis...
1
pt_shell> get_switching_activity "z[31]"
 {"z[31]" 0.00330065 file 0 file 0.525616 file}
```

The following example reports on a net in the *time_based* power analysis mode. The net is in the VCD file. This example runs the *get_switching_activity* command before and after the *update_power* argument. The example shows that before power analysis, the activity source is known (file), but the toggle rate is unknown and is reported as -1. After the *update_power* argument, the toggle rate is known and is reported.

```
pt_shell> get_switching_activity  "z[31]"
 {"z[31]" -1 file -1 file -1 file}
pt_shell> update_power
Information: The waveform options are:
               File name:      primetime_px.fsdb
               File format:    fsdb
               Time interval:  0.01ns
               Hierarchical level:     1

Information: Power analysis is running, please wait ...

Information: analysis is done for time window (0ns - 9998.03ns)

---

get_timing_arcs

Creates a collection of timing arcs for custom reporting and other processing. You can assign these timing arcs to a variable and get the desired attribute for further processing.

Feedback

Syntax

string *get_timing_arcs*

```
[-to to_list]
[-from from_list]
[-of_objects object_list]
[-filter expression]
[-quiet]
```

Data Types

to_list	list
from_list	list
object_list	list
expression	string

Arguments

`-to to_list`

Specifies a list of to pins or to ports to get timing arcs for. All backward arcs from the specified pins or ports are considered.

`-from from_list`

Specifies a list of from pins or from ports to get timing arcs for. All forward arcs from the specified pins or ports are considered.

`-of_objects object_list`

Specifies cells or nets to get timing arcs for. If a cell is specified, all cell_arcs of that cell are considered. If a net is specified, all net_arcs of that net are considered.

`-filter expression`

Specifies a string that comprises a series of logical expressions describing a set of constraints you want to place on the collection of arcs. Each subexpression of a filter expression is a relation contrasting an attribute name with a value by means of an operator.

`-quiet`

Specifies that all messages are to be suppressed.

Description

The *get_timing_arcs* command creates a collection of arcs for custom reporting or other operations. Use the *foreach_in_collection* command to iterate among the arcs in the collection. You can use the *get_attribute* command to obtain information about the arcs.

Feedback

You can also use the filter expression to filter the arcs that satisfy the specified conditions. The following attributes are supported on timing arcs:

```
delay_max_fall
delay_max_rise
delay_min_fall
delay_min_rise
from_pin
is_annotated_fall_max
is_annotated_fall_min
is_annotated_rise_max
is_annotated_rise_min
is_cellarc
is_disabled
is_user_disabled
mode
object_class
sdf_cond
sense
to_pin
```

One attribute of a timing arc is from_pin which is the pin or port from which the timing arc begins. In the same way, the to_pin is the pin or port at which the timing arc ends. In order to get more information about the from_pin and the to_pin, use the *get_attributes* command. The *object_class* attribute holds the name of the timing arc class *timing_arc*.

Examples

The following procedure gets the same arguments as the *get_timing_arcs* command and prints out some of the attributes of the timing arcs.

```
proc format_float {number {format_str "%.2f"}} {

  switch -exact -- $number {
    UNINIT { }
    INFINITY { }
    default {set number [format $format_str $number]}
  }
  return $number;
}

proc show_arcs {args} {

  set arcs [eval [concat get_timing_arcs $args]]
  echo [format "%15s    %-15s  %8s %8s  %s" "from_pin" "to_pin" \\
            "rise" "fall" "is_cellarc"]
  echo [format "%15s    %-15s  %8s %8s  %s" "--------" "------" \\
            "----" "----" "----------"]

  foreach_in_collection arc $arcs {
```

Feedback

```
    set is_cellarc [get_attribute $arc is_cellarc]
    set fpin [get_attribute $arc from_pin]
    set tpin [get_attribute $arc to_pin]
    set rise [get_attribute $arc delay_max_rise]
    set fall [get_attribute $arc delay_max_fall]

    set from_pin_name [get_attribute $fpin full_name]

    set to_pin_name [get_attribute $tpin full_name]
    echo [format "%15s -> %-15s  %8s %8s  %s" \\
        $from_pin_name $to_pin_name \\
        [format_float $rise] [format_float $fall] \\
        $is_cellarc]
  }
}
```

```
pt_shell> show_arcs -of_objects ffa

       from_pin    to_pin              rise     fall  is_cellarc

Arguments

`-from` *from_list*

Collects only paths that start from the specified list of pins, ports, nets, or cell instances; or from startpoints clocked by the named clocks. Valid startpoints are clock pins of sequential devices and input ports of the design.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must start with a rising transition. If you specify a clock object, the option selects startpoints clocked by the named clock and launched by a rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *`fall_from_list`*

Same as the *-rise_from* option, except that the path must start with a falling transition.

`-to` *`to_list`*

Collects only paths that end at the specified list of pins, ports, nets, or cell instances; or at endpoints clocked by the named clocks. Valid endpoints are data input pins of sequential devices and output ports of the design.

Due to the infrastructure of the timing analyzer, the *-to* option runs more efficiently than the *-from* option. As a result, endpoint-oriented path gathering (based on using the *-to* option) outperforms equivalent startpoint-oriented path gathering (based on using the *-from* option).

`-rise_to` *`rise_to_list`*

Same as the *-to* option, except that the path data must end with a rising transition. If you specify a clock object, the option selects endpoints clocked by the named clock and captured by a rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Same as the *-rise_to* option, except that the path data must end with a falling transition.

`-through` *`through_list`*

Collects only paths in which the data goes through the named pins, ports, cell instances, or nets. You can use this option multiple times in a command.

When a single *-through* list contains multiple objects, the data path can go through any one of the listed objects. When you use multiple *-through* options, the data path must meet each of the *-through* options in sequence.

For example, the following command gets a path that starts at A1, then passes through either B1 or B2, then passes through C1, and ends at D1.

```
pt_shell> report_timing -from A1 -through {B1 B2} -through C1 -to
 D1
```

If advanced analysis through transparent latches is enabled (*timing_enable_through_paths* set to *true*), and the pins specified in the last

-through option are latch loop breakers, then the timing paths collected are constrained by the worst of the closing edges at the latch or by a required value computed using logic downstream of the latch loop breaker.

`-rise_through` *`rise_through_list`*

Same as the *-through* option, except that it applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

Same as the *-through* option, except that it applies only to paths with a falling transition at the specified objects.

`-exclude` *`exclude_list`*

Excludes all paths in which the data goes from, through, or to the specified list of pins, ports, nets, or cell instances; or excludes all paths belonging to the specified list of path tag sets. This option checks only data paths (not clock paths) for excluded objects.

Using the *-exclude* option can result in significantly longer runtimes. To reduce the runtime impact, use this option together with other topological restriction options, such as *-from* and *-through*.

The *-exclude* option does not check borrowing paths considered by the *-trace_latch_borrow* option.

`-rise_exclude` *`rise_exclude_list`*

Same as the *-exclude* option, but applies only to rising transitions at the named pins, ports, nets, or cell instances.

`-fall_exclude` *`fall_exclude_list`*

Same as the *-exclude* option, but applies only to falling transitions at the named pins, ports, nets, or cell instances.

You can use no more than one of the *-exclude*, *-rise_exclude*, or *-fall_exclude* options in a command.

`-delay_type` *`delay_type`*

Specifies the type of path delay constraint to consider for finding and sorting paths with the worst slack:

- *max* (default) -- max delay (setup constraint)
- *min* -- min delay (hold constraint)
- *min_max* -- both min and max delay (stores min path first, max second)
- *max_rise* -- max delay, rising at data path endpoint

- *max_fall* -- max delay, falling at data path endpoint
- *min_rise* -- min delay, rising at data path endpoint
- *min_fall* -- min delay, falling at data path endpoint

`-nworst` *`paths_per_endpoint`*

Collects up to the specified number of worst paths per endpoint. The default is 1. A larger value results in a larger collection and more runtime. Allowed values are 1 to 2000000.

If you set *-nworst* to a value greater than 1, the command automatically does the following:

- Implicitly sets *-max_paths* equal to the *-nworst* setting if the *-max_paths* option is not used in the command, so that at least one set of multiple paths to an endpoint can be collected.
- Implicitly sets *-slack_lesser_than 0.0* if the *-slack_lesser_than* and *-slack_greater_than* options are not specified, so that only violators are collected.

`-max_paths` *`max_path_count`*

Collects up to the specified maximum total number of paths.

If the *-group* option is specified, the total number of paths collected is at most the specified number of paths per path group.

If the *-group* option is not specified, the total number of paths collected is at most the specified number of paths among all path groups.

The *max_path_count* must be greater than zero. The default *max_path_count* is equal to the *-nworst* setting, or 1 if the *-nworst* option is not specified.

If you set *-max_paths* to a value greater than 1, the command implicitly sets *-slack_lesser_than 0.0* if the *-slack_lesser_than* and *-slack_greater_than* options are not specified, so that only violators are collected.

The *-nworst* option controls the maximum number of paths collected *per endpoint*, whereas the *-max_paths* option controls the *overall total maximum number* of paths collected. The *-max_paths* setting should be at least as large as the *-nworst* setting, so by default the tool implicitly sets *-max_paths* to the same value as *-nworst* if the *-max_paths* option is not specified.

`-group` *`path_group_list`*

Collects only paths that belong to the specified path groups.

Path groups are created by the *create_clock* and *group_path* commands. Without the *-group* option, the *get_timing_paths* command collects paths without

considering path groups. For example, the *get_timing_paths* command alone creates a collection containing the single worst path in the design, whereas *get_timing_paths -group [get_path_groups]* creates a collection containing multiple paths, consisting of the single worst path *in each path group*.

`-unique_pins`

Collects only the single worst timing path through any given sequence of pins. No other paths are collected for the same sequence of pins from startpoint to endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin sequence, then paths starting with a falling edge are not collected for that sequence of pins.

For non-unate logic such as XOR gates, using this option greatly reduces the number of paths collected because of the large number of possible rising/falling edge combinations through each sequence of pins.

Using this option can require longer runtimes when used with the *-nworst* option because many paths must be analyzed to find the worst path through each pin sequence, but only the worst path is collected and counted toward the total number of requested paths.

`-slack_greater_than` *`minimum_slack`*

Collects only paths with slack greater than the specified *minimum_slack* value; these paths have a negative slack better than the specified *minimum_slack* value (or a positive slack that is farther from causing a violation). This option is intended to be used with the *-slack_lesser_than* option to collect paths within a specific range of slack.

Unlike the *-slack_lesser_than* option, the *-slack_greater_than* option acts in a post-processing way as a filter to restrict the paths that are collected. As a result, the number of paths collected might be less than the number specified with the *-nworst* and *-max_paths* options.

`-slack_lesser_than` *`maximum_slack`*

Collects only paths with slack less than the specified *maximum_slack* value; these paths have a negative slack worse than the specified *maximum_slack* value (or a positive slack that is closer to causing a violation).

If this option is not specified, the default is computed as follows, highest precedence first:

- If exhaustive PBA is used (*-pba_mode* set to *exhaustive* or *ml_exhaustive*), then the default is 0.0, so that only violators are collected.
- Otherwise, if either *-max_paths* or *-nworst* is set to a value greater than 1, then the default is 0.0, so that only violators are collected.

- Otherwise, the default is "infinity", so that the worst path is collected.

The *-slack_lesser_than* and *-slack_greater_than* options act as filters to restrict the paths that are collected, so the number of paths collected can be fewer than the number specified with the *-nworst* and *-max_paths* options. If no paths meet the slack criteria, no paths are collected.

`-ignore_register_feedback` *`feedback_slack_cutoff`*

Ignores noninverting timing loops that start and end at the same register pin that holds a value. To be ignored, the data-to-output arc and the output-to-data path must be either both inverting or both noninverting. This option applies to minimum delay as well as maximum delay constraints. Paths are ignored only if they have a slack less than the specified *feedback_slack_cutoff* value.

This option acts as a filter to restrict the paths that are collected, so the number of paths collected might be less than the number specified with the *-nworst* and *-max_paths* options.

`-include_hierarchical_pins`

Causes the collected paths to include points for the hierarchical pins as well as leaf pins. The hierarchical pins are included for informational purposes only; the *report_timing* command reports them as having zero incremental delay and they do not affect the timing results.

`-trace_latch_borrow`

Controls the type of data collected for a path that starts at a transparent latch.

If the path startpoint borrows from the previous path segment, using this option causes the path data to include the set of borrowing paths that lead up to the borrowing latch, starting with a nonborrowing path or a noninverting sequential loop. Each path segment is maintained separately, including the time borrowed and lent and the endpoints of the path segment.

Without the *-trace_latch_borrow* option, the command does not include upstream borrowing latches when in default latch analysis mode or borrowing latch loop breakers when in advanced latch analysis mode (*timing_enable_through_paths* set to *true*) as path segments in the timing report.

`-trace_latch_forward`

Controls the type of data collected for a path that ends at a transparent latch D pin.

If advanced analysis through transparent latches is enabled (*timing_enable_through_paths* set to *true*) and this transparent latch D pin is constrained by a downstream required time, this option causes the data to include the paths in the fanout of this D pin that led to the downstream required

constraint. These paths can include multiple path segments whereby the constraint is the result of propagating through more than one latch constrained by the downstream required time. In this case, each path segment is maintained separately, showing the downstream required time for that path segment.

Without the *-trace_latch_forward* option, the command does not trace the path beyond the specified endpoint.

`-pba_mode none | path | exhaustive | ml_exhaustive`

Specifies one of the following path-based timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths. To control the ordering of the paths (either by original graph-based slack or recalculated path-based slack), set the *pba_path_mode_sort_by_gba_slack* variable.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode. You cannot use the *exhaustive* mode together with the *-start_end_pair*, *-cover_design*, or *path_collection* options.
- *ml_exhaustive* - Performs Machine Learning based exhaustive path-based analysis. This mechanism deploys machine learning techniques to trade runtime versus accuracy during the analysis. Accuracy and runtime will approach *-pba_mode exhaustive* as the design approaches zero-slack signoff.

In ordinary graph-based (default) timing analysis, the tool considers both the worst arrival time and worst slew among all signals feeding into a path, even when the worst arrival and worst slew come from different signals.

In path-based timing analysis, the tool considers each path in isolation from other paths, which eliminates impossible combinations of worst slew and worst arrival, and similar combinations of effects such as crosstalk and CRPR. As a result, path-based analysis reduces pessimism and increases accuracy at the cost of more runtime.

`-start_end_type` *`from_to_type`*

Restricts the collection to one of four classes of paths based on the type of startpoint and endpoint:

- *reg_to_reg* - from register to register
- *reg_to_out* - from register to output port

- *in_to_reg* - from input port to register
- *in_to_out* - from input port to output port

In this description, "register" means any valid startpoint or endpoint that is not an input port, output port, or bidirectional port, even if not a sequential register. For example, a clock-gating check endpoint qualifies as a "register" in the *in_to_reg* from-to type. A bidirectional port qualifies as both an input port and an output port.

`-normalized_slack`

Collects and sorts paths using normalized slack instead of absolute slack. Normalized slack is the absolute slack divided by an idealized maximum allowable propagation delay (typically the clock period). To use this option, the *timing_enable_normalized_slack* variable must be set to *true* for the current timing update.

`-start_end_pair`

Collects the worst path for each startpoint-endpoint pair in the design.

If *-slack_lesser_than* is not specified, all violating startpoint-endpoint pairs are collected (an implicit *-slack_lesser_than* value of 0.0). If *-slack_lesser_than* is specified, the violating startpoint-endpoint pairs meeting that requirement are collected. The number of paths collected is limited to 2000000 unless *-max_paths* is used to exceed this.

The following options can be used to control the *-start_end_pair* behavior:

```
-max_paths
-nworst
-slack_lesser_than
-from / -rise_from / -fall_from
-through / -rise_through / -fall_through
-to / -rise_to / -fall_to
-exclude / -rise_exclude / -fall_exclude
```

The *-start_end_pair* option can result in very large collections and long runtimes. Use the preceding options thoughtfully to generate the collection. For example, you could use the *-slack_lesser_than* option to specify a slack limit that is only slightly greater than the worst slack in the design.

The following options cannot be used with the *-start_end_pair* option:

```
-cover_design
-slack_greater_than
-unique_pins
-ignore_register_feedback / -report_ignored_register_feedback
-pba_mode exhaustive | ml_exhaustive
path_collection
```

The *-start_end_pair* option sorts the paths first by endpoint and then by slack, with the paths sharing the same endpoint collected together in order of increasing slack.

`-cover_design`

Collects the worst path through each violating pin in the design, so that the collected paths cover every violating pin in the design. A pin is deemed to be violating if its slack is less than zero, or less than the value specified with the *-slack_lesser_than* option if that option is used. The slack of a pin is the worst slack among all paths that start at, pass through, or end at that pin. There is no limit on the number of returned paths.

The following options can be used to control the *-cover_design* behavior:

-slack_lesser_than
-from / -rise_from / -fall_from
-through / -rise_through / -fall_through
-to / -rise_to / -fall_to
-exclude / -rise_exclude / -fall_exclude

The following options cannot be used with the *-cover_design* option:

-nworst
-max_paths
-start_end_pair
-unique_pins
-ignore_register_feedback
-pba_mode exhaustive | ml_exhaustive
path_collection

`-cover_through` *through_list*

Collects the single worst violating path through each of the named pins, ports, cell instances, and nets. Only paths with negative slack are collected (or with slack less than the value specified by the *-slack_lesser_than* option, if used).

The number of paths collected is less than or equal to the number of objects in the *through_list*. Fewer paths are collected if there are no violating paths through the objects, or if the worst path through one object is the same as the worst path through another object; duplicate paths are combined into a single path.

The following options cannot be used with the *-cover_through* option:

-nworst
-max_paths
-start_end_pair
-unique_pins
-through / -rise_through / -fall_through
-exclude / -rise_exclude / -fall_exclude
-ignore_register_feedback

-pba_mode exhaustive | ml_exhaustive
path_collection

-dont_merge_duplicates

Prevents the merging of duplicate paths across multiple scenarios in distributed multi-scenario analysis (DMSA).

By default, when the same path is collected in more than one scenario, the tool keeps only the single most critical instance of that path in the merged report and shows its associated scenario.

If you use this option, the tool does not merge duplicate instances of the same path, but instead collects all critical instances of the path from all scenarios. Because the number of paths collected might be limited by *-nworst*, *-max_paths*, or other command options, the resulting merged collection might be more focused on a portion of the design that is critical in multiple scenarios, and less evenly spread out across different portions of design.

-pre_commands *pre_command_string*

Specifies a list of commands, separated by semicolons, to be executed in the worker context before execution of the *get_timing_paths* command. This option is available only if you invoke the PrimeTime tool with the *-multi_scenario* option. The maximum size of a command is 1000 characters.

-post_commands *post_command_string*

This option is like the *-pre_commands* option, except that the commands are executed after (instead of before) the *get_timing_paths* command.

-path_type *format*

Specifies whether propagated clock path information should be included in the collected timing path objects.

Use the *-path_type full_clock_expanded* option to include clock path information, stored in *launch_clock_paths* and *capture_clock_paths* attributes of each timing path object. These attributes include one or more *timing_path* objects representing the propagated clock path segments, including segments for the source latency paths of any generated clocks.

You can query these clock path attributes to obtain information about them. If the path object is later reported with the *report_timing* command, the clock paths are included in the timing report.

By default (when this option is omitted), propagated clock path information is not included in the timing path objects.

Note that while the *report_timing* command supports several *-path_type* values, the *get_timing_paths* command supports only *full_clock_expanded*. If you

specify a value of *full* or *full_clock*, the *get_timing_paths* command interprets it as *full_clock_expanded*.

`-attributes` *`attribute_list`*

Specifies the attributes to be returned to the distributed manager from a worker path collection.

By default, a worker collection returns only the *full_name*, *scenario_name*, and *object_class* attributes. To control how much data is retrieved from the worker, use this option together with the *set_distributed_parameters -collection_levels* command.

This option is available only in distributed multi-scenario analysis (DMSA).

`-tag_paths_filtered_by_pba` *`tag_name`*

When used with the *-pba_mode path* option, the *-tag_paths_filtered_by_pba* option causes tagging of all paths originally found by path-based analysis and later discarded by path-based analysis, using the specified tag name. In future *get_timing_paths* and *report_timing* commands, you can exclude the tagged paths from further analysis by specifying the tag name as an argument to the *-exclude* option.

`path_collection`

Performs path-based analysis on the specified paths and returns a new path collection. You can use this argument only with the *-pba_mode path* option. This option is mutually exclusive with options that control the selection of paths to collect.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios to analyze. Only paths compatible to the specified SMS scenarios collection will be returned. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

`-domain_crossing` *`domain_crossing_mode`*

Specifies the domain crossing report mode. Allowed values include *all, only_crossing, exclude_crossing*. The default mode is *all*. This option is applied as a reporting filter, ensuring that only paths which satisfy the specified mode are reported. With the default setting of *all*, all paths are considered for reporting, including cross-domain and intra-domain. With the *only_crossing* mode, reports include only cross-domain paths. Using the *exclude_crossing* mode only reports intra-domain paths.

This option is only available with SMVA/SMC analysis.

`-pocv_pruning`

Restricts the path collection to only those paths that contribute to joint success rate. This option prunes away all subcritical paths that have no impact on the high-sigma failure rate.

This option should always be used when obtaining paths to perform design variation analysis with the *get_design_variation* command.

This option works only with the *-pba_mode exhaustive* option. It can significantly reduce runtime and memory in both the *get_timing_paths* and *get_design_variation* commands.

`-vdd_slack_lesser_than` *`maximum_vdd_slack`*

Performs Vmin analysis on the paths and assigns voltage slack in the path if the value is less than the specified *maximum_vdd_slack value.*

The *-vdd_slack_lesser_than* option must be used with *-pba_mode path*| *exhaustive*.

`-vdd_slack_greater_than` *`minimum_vdd_slack`*

Performs Vmin analysis on the paths and assigns voltage slack in the path if the value is greater than the specified *minimum_vdd_slack value.*

The *-vdd_slack_greater_than* option must be used with *-pba_mode path*| *exhaustive*.

Description

The *get_timing_paths* command creates a collection of paths for custom reporting or other operations. Most of the *get_timing_paths* command options are shared by the *report_timing* command, and the behavior of these shared options is identical. The order in which paths are returned from *get_timing_paths* matches the reported timing path order of *report_timing*.

You can pass the generated collection directly to another command, or you can set a variable to the collection for later reporting. For example,

```
pt_shell> sizeof_collection [get_timing_paths -nworst 4 -max_paths 20]
Warning: report_timing has satisfied the max_paths criteria. ...
20

pt_shell> set mypaths [get_timing_paths -nworst 4 -max_paths 20]
Warning: report_timing has satisfied the max_paths criteria. ...
Information: Defining new variable 'mypaths'. (CMD-041)
 ...
pt_shell> sizeof_collection $mypaths
20
pt_shell> get_attribute $mypaths slack
-1.157432 -0.987188 -0.984205 -0.971914 -0.968931 -0.873521 ...
```

```
pt_shell> report_timing $mypaths
(20 path timing reports displayed)
```

To iterate over the paths in a collection, use the *foreach_in_collection* command. To obtain information about paths, use the *get_attribute* and *report_attribute* commands. To get a list of timing path attributes, use the following command:

```
pt_shell> list_attributes -application -class timing_path
 ...
Attribute Name             Object        Type       Properties
 Constraints
------------------------------------------------------------------------
---
arrival                    timing_path   float      A
capture_clock_paths        timing_path   collection A
clock_uncertainty          timing_path   float      A
close_edge_adjustment      timing_path   float      A
common_path_pessimism      timing_path   float      A
 ...
```

For more information on these *timing_path* attributes, see the *timing_path_attributes* man page.

User-defined attributes can be created for timing paths and set on specific timing paths with the *define_user_attribute* and *set_user_attribute* commands. To be queried, the attribute must be set on a timing path collection that has been stored in a variable. For example,

```
pt_shell> define_user_attribute -classes timing_path -type boolean
 is_special
pt_shell> set mypath [get_timing_paths ...]
pt_shell> set_user_attribute -class timing_path $mypath is_special true
pt_shell> get_attribute $mypath is_special
true
```

This behavior differs from user attributes set on other objects, such as pins, which allow user attributes to be set and queried directly in the design (not stored in a collection variable).

The *get_timing_paths* command constructs a new timing path at every invocation. Timing paths derived from two identical *get_timing_paths* commands and stored in two different collection variables do not share the same user attributes. For example,

```
pt_shell> define_user_attribute comment -type string -class timing_path
pt_shell> set p1 [get_timing_paths]
pt_shell> set p2 [get_timing_paths]
pt_shell> set_user_attribute $p1 comment "Hello world"
pt_shell> get_attribute $p1 comment
Hello world
pt_shell> get_attribute $p2 comment
```

```
Warning: Attribute 'comment' does not exist on timing_path
 'path' (ATTR-3)
```

Each *timing_path* object contains a collection of *timing_point* objects (stored in the *points* attribute of the path). A "point" corresponds to a pin or port along the path. You can iterate through these points with the *foreach_in_collection* command and query their attributes by using the *get_attribute* command. To get a list of timing point attributes, use the following command:

```
pt_shell> list_attributes -application -class timing_point
 ...
Attribute Name              Object         Type     Properties
 Constraints
------------------------------------------------------------------------
---
annotated_delay_delta       timing_point   float    A
annotated_delta_transition  timing_point   float    A
aocvm_coefficient           timing_point   float    A
applied_derate              timing_point   float    A
arrival                     timing_point   float    A
 ...
```

For more information on these *timing_point* attributes, see the *timing_point_attributes* man page.

For information about creating collections and iterating over the elements of a collection, see the examples in the EXAMPLES section and the man pages of the *collections* and *foreach_in_collection* commands.

To report the dominant and overridden timing exceptions related to a timing path, use the *report_timing* command with the *-exceptions* option. To get more information about the exceptions that apply to the path, you can create a path collection with the *get_timing_paths* command and query the following timing path attributes:

```
Attribute                          Possible Reason
-------------------------------------------------------------------
dominant_exception                 false_path / min_max_delay /
                                   multicycle_path / path_margin
startpoint_unconstrained_reason    no_launch_clock /
 dangling_start_point /
                                   fanout_of_disabled
endpoint_unconstrained_reason      no_capture_clock / dangling_end_point /
                                   fanin_of_disabled
```

Examples

You can find some detailed examples of custom timing reports in:

```
$SYNOPSYS_ROOT/auxx/pt/examples/tcl
```

where $SYNOPSYS_ROOT is the installation directory for PrimeTime.

The following procedure reports the startpoint name, endpoint name, and the slack of the worst path in each path group.

```
proc custom_report_worst_path_per_group {} {
  echo [format "%-20s %-20s %7s" "From" "To" "Slack"]
  echo "-------------------------------------------------------------"
  foreach_in_collection path [get_timing_paths] {
    set slack [get_attribute $path slack]
    set startpoint [get_attribute $path startpoint]
    set endpoint [get_attribute $path endpoint]
    echo [format "%-20s %-20s %s" [get_attribute $startpoint full_name]
 \\
      [get_attribute $endpoint full_name] $slack]
  }
}

pt_shell> custom_report_worst_path_per_group

>From                 To                     Slack
-------------------------------------------------------
ffa/CP               QA                   0.1977
ffb/CP               ffd/D                3.8834
```

The following example shows Total Negative Slack, Total Positive Slack, and Worst Negative Slack for the current design.

```
proc report_design_slack_information {} {
  set design_tns 0
  set design_wns 100000
  set design_tps 0
  foreach_in_collection group [get_path_groups *] {
    set group_tns 0
    set group_wns 100000
    set group_tps 0
    foreach_in_collection path [get_timing_paths -nworst 10000 -group
 $group] {
      set slack [get_attribute $path slack]
      if {$slack < $group_wns} {
        set group_wns $slack
        if {$slack < $design_wns} {
           set design_wns $slack
        }
      }
      if {$slack < 0.0} {
        set group_tns [expr $group_tns + $slack]
      } else {
        set group_tps [expr $group_tps + $slack]
      }
    }
    set design_tns [expr $design_tns + $group_tns]
    set design_tps [expr $design_tps + $group_tps]
    set group_name [get_attribute $group full_name]
```

```
    echo [format "Group '%s' Worst Negative Slack : %g" $group_name
 $group_wns]
    echo [format "Group '%s' Total Negative Slack : %g" $group_name
 $group_tns]
    echo [format "Group '%s' Total Positive Slack : %g" $group_name
 $group_tps]
    echo ""
  }
  echo "-----------------------------------------"
  echo [format "Design Worst Negative Slack : %g" $design_wns]
  echo [format "Design Total Negative Slack : %g" $design_tns]
  echo [format "Design Total Positive Slack : %g" $design_tps]
}

pt_shell> report_design_slack_information

Group 'CLK' Worst Negative Slack : -3.1166
Group 'CLK' Total Negative Slack : -232.986
Group 'CLK' Total Positive Slack : 4.5656

Group 'vclk' Worst Negative Slack : -4.0213
Group 'vclk' Total Negative Slack : -46.1982
Group 'vclk' Total Positive Slack : 0

-----------------------------------------
Design Worst Negative Slack : -4.0213
Design Total Negative Slack : -279.184
Design Total Positive Slack : 4.5656
```

If you use the *-pba_mode* option, path recalculation (path-based analysis) is used during the path search, and the worst recalculated paths meeting your criteria are returned. This option requires that a path search to be performed to ensure that the paths being returned truly are the worst paths. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing improvement from path-based analysis increases, the runtime for the path search increases. Large *-nworst* values can significantly increase the time needed for the search.

To see the worst path in the design with path-based analysis applied:

```
pt_shell> report_timing [get_timing_paths -pba_mode exhaustive]
```

To report all endpoints in the design which fail after considering path-based analysis:

```
pt_shell> set mypaths [get_timing_paths -pba_mode exhaustive \\
            -slack_lesser_than 0 -max_paths 1000]
pt_shell> report_timing $mypaths
```

Feedback

get_trace_option

Get the current option value controlling behavior of command tracing and output annotation..

Syntax

get_trace_option [-command name |-profile |-memory_threshold |-cpu_threshold |-time_treshold] [-annotate | -is_traced]

string *name*

Arguments

`-command` *name*

This option is mutually exclusive with -profile, -memory_threshold, -cpu_threshold, and -time_threshold. The option identifies the command for which tracing or annotation option is returned.

`-annotate`

If this option is given, then the *annotate* setting for the given command is returned. This option is mutually exclusive with -is_traced and is meaningful only in combination with the -command option.

`-is_traced`

If this option is given, then returns 1 if the given command is traced and logged, 0 otherwise. This option is mutually exclusive with -annotate and is meaningful only in combination with the -command option.

`-profile`

This option is mutually exclusive with all others. The option returns a list of the currently enabled profile metrics, or "all" if all metrics are enabled.

`-memory_threshold`

This option is mutually exclusive with all others. The option returns the currently set memory profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

`-cpu_threshold`

This option is mutually exclusive with all others. The option returns the currently set cpu profile threshold, if any, in seconds. If no threshold is set, then it returns the string "unset".

Feedback

`-time_threshold`

This option is mutually exclusive with all others. The option returns the currently set wall clock time profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

Description

The command is used to query the current setting for the command annotation option that is set with the set_trace_option command, or profile metric settings.

Examples

The following example sets the annoation type of the *get_attribute* command.

```
prompt> get_trace_option -command get_attribute -annotate
annotate
```

The following example sets, then gets, the currently enabled profile metrics.

```
prompt> set_trace_topion -profile {cpu time}
prompt> get_trace_topion -profile
cpu time
```

The following example gets the threshold for memory profile metric before one has been set.

```
prompt> get_trace_option -memory_threshold
unset
```

The following example will list the commands in the Builtins command group that are not traced and logged.

```
prompt> foreach cmd [dict get [get_defined_commands -details -groups
 Builtins] commands] {
?  if {![get_trace_option -command $cmd -is_traced]}
?    {echo $cmd}
?  }
```

See Also

- set_trace_option

---

get_unix_variable

This is a synonym for the *getenv* command.

Feedback

See Also

- printenv
- printvar
- setenv
- sh

---

get_vias

Creates a collection by selecting vias from the design.

Syntax

```
collection get_vias
[-of_objects objects]
```

Data Types

```
objects        collection
```

Arguments

`-of_objects` *of_objects*

Creates a collection containing the vias connected to the specified net. Each object in the list is a collection.

Description

This command creates a collection of vias by selecting vias from the current design that meet the selection criteria. It returns a collection handle if one or more vias meet the selection criteria. If no vias match the selection criteria, it returns an empty string.

Use the *get_vias* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following examples create via collections of net n300:

```
prompt> get_vias -of_objects [get_nets n300]
{"VIA_C_67"}
```

Feedback

See Also

- get_attribute
- query_objects

---

get_voltage_areas

Creates a collection of voltage_areas from the current design.

Syntax

```
collection get_voltage_areas
```

Data Types

```
name          string
```

Arguments

```
name design
```

Specifies the net name for finding objects. The net and the voltage areas will be found in the top design

Description

This command creates a collection of voltage_areas from the current design that match certain criteria. The command returns a collection handle (identifier) if any voltage_areas match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the *get_voltage_areas* command at the command prompt or nest it as an argument to another command.

You can also assign the *get_voltage_areas* result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following returns voltage_area from its shapes

```
prompt> get_voltage_areas net321
{VA_1}
```

Feedback

See Also

- create_voltage_area
- get_placement_blockages
- get_attribute

---

getenv

Returns the value of a system environment variable.

Syntax

string *getenv*

```
        variable_name
```

Data Types

```
variable_name      string
```

Arguments

variable_name

Specifies the name of the environment variable to be retrieved.

Description

The *getenv* command searches the system environment for the specified *variable_name* and sets the result of the command to the value of the environment variable. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the *env* Tcl array variable. The *getenv*, *setenv*, and *printenv* environment commands are convenience functions to interact with this array.

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you set the variable to a new value using the *setenv* command, you see the new value within the application and within any new child processes you initiate from the application using the *exec* command. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the *exec* command, that value is not reflected in the current application.

See the *set*, *unset*, and *printvar* commands for information about working with non-environment variables.

Feedback

Examples

In the following example, *getenv* returns you to your home directory:

```
prompt> set home [getenv "HOME"]
/users/disk1/bill

prompt> cd $home

prompt> pwd
/users/disk1/bill
```

In the following example, *setenv* changes the value of an environment variable:

```
prompt> getenv PRINTER
laser1

prompt> setenv PRINTER "laser3"
laser3

prompt> getenv PRINTER
laser3
```

In the following example, the requested environment variable is not defined. The error message shows that the Tcl variable *env* was indexed with the value UNDEFINED, which resulted in an error. In the second command, *catch* is used to suppress the message.

```
prompt> getenv "UNDEFINED"
Error: can't read "env(UNDEFINED)": no such element in array
        Use error_info for more info. (CMD-013)

prompt> if {[catch {getenv "UNDEFINED"} msg]} {
         setenv UNDEFINED 1
       }
```

See Also

- printenv
- printvar
- setenv
- unsetenv

---

group_path

Groups paths for reporting.

Feedback

Syntax

status *group_path*

```
-name group_name
-default
[-weight weight_value]
[-from from_list]
[-rise_from rise_from_list]
[-fall_from fall_from_list]
[-to to_list]
[-rise_to rise_to_list]
[-fall_to fall_to_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-comment comment_string]
```

Data Types

group_name	string
weight_value	float
from_list	list
rise_from_list	list
fall_from_list	list
to_list	list
rise_to_list	list
fall_to_list	list
through_list	list
rise_through_list	list
fall_through_list	list
comment_string	string

Arguments

`-name` *group_name*

Specifies a name for the group. If a group with this name already exists, the command adds the paths or endpoints to that group. If a group with this name does not exist, the command creates a new group.

You must use either the *-name* option or the *-default* option.

`-default`

Specifies that endpoints or paths are moved to the default group and removed from the current group.

`-weight` *weight_value*

Specifies a cost function weight for this group, which is used by the Design Compiler tool to prioritize optimization. The *weight_value* value must be a number between 0.0 and 100.0, the default is 1.0. A weight of 0.0 eliminates the

paths in this group from cost function calculations. Do not use very small values (for example, 0.0001).

`-from` *`from_list`*

Specifies a list of timing path startpoint objects. A valid timing startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected.

When the timing path has interior transparent latches, the *-from*, *-rise_from*, and *-fall_from* options refer to the clock, clock pin, or data pin of the last interior latch on the path, not to the initial startpoint of the timing path.

You can use only one of the *-from*, *-rise_from*, and *-fall_from* options.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *`fall_from_list`*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-to` *`to_list`*

Specifies a list of timing path endpoint objects. A valid timing endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If you specify a cell, one path endpoint on that cell is affected.

You can use only one of the *-to*, *-rise_to*, and *-fall_to* options.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Same as the *-to* option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-through` *`through_list`*

Specifies a list of path throughpoints (ports, pins, cells, or nets).

You can use multiple *-through*, *-rise_through*, and *-fall_through* options in a single command to specify paths that traverse through multiple points in the design. The tool respects the order in which you specify these options.

The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```
-from A1 -through B1 -through C1 -to D1
```

If you specify more than one object with one *-through*, *-rise_through*, or *-fall_through* option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```
-from A1 -through {B1 B2} -through {C1 C2} -to D1
```

`-rise_through` *`rise_through_list`*

It is similar to the *-through* option, but applies only to paths with a rising transition at the specified objects.

`-fall_through` *`fall_through_list`*

It is similar to the *-through* option, but applies only to paths with a falling transition at the specified objects.

`-comment` *`comment_string`*

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

Description

The *group_path* command groups a set of paths for reporting by the *report_timing* and *report_constraint* commands.

By default, the PrimeTime tool creates a single clock group for each clock created by the *create_clock* command, using the same name for the group as the clock name. By using the *group_path* command to assign paths to specific clock groups, you control the scope of path reporting from different groups.

By default, the *report_timing* command reports the worst setup path in each clock group (or only the clock groups specified by the *-group* option). For example, if you combine all the paths clocked by CLK1 and CLK2 into a new group called CLKN, then the *report_timing* command reports only the single worst path from the combined group CLKN. On the other hand, if you put all paths that end at output OUT1 into a new group called END-OUT1, the *report_timing* command reports the worst path that ends at OUT1, even if other paths clocked by the same clock have worse timing.

If you specify a clock as the "from" object, all paths with startpoint clocked by that clock are included in the group.

If you specify a clock as the "to" object, all paths with an endpoint clocked by that clock are included in the group.

When multiple path group definitions apply to a path, the more specific definition overrides the more general. They apply with the following precedence (more specific to more general):

```
1. group_path -from pin -to pin
2. group_path -from pin -to clock
3. group_path -from pin
4. group_path -from clock -to pin
5. group_path -to pin
6. group_path -from clock -to clock
7. group_path -from clock
8. group_path -to clock
```

If multiple path groups definitions with the same object specification precedence apply to the same path, the path group whose name comes first in alphanumeric order is applied.

The PrimeTime tool creates default groups for clock gating checks and asynchronous preset/clear checks named *"**clock_gating_default**"* and *"**async_default**"* respectively. You can move the paths belonging to these groups into user-defined groups by using the *group_path* command.

Note that the *group_path* command is not compatible with hierarchical model extraction.

To undo the *group_path* command, use the *remove_path_group* command. To report path group information for a design, use the *report_path_group* command.

When a path has transparent latches in the interior of the path, *group_path* is only applied when all the path specifiers are satisfied at or after the last interior latch on the path. The *-from* parameter refers to the clock, clock pin, or data pin of the last interior latch. The *-through* pins must be after the last interior latch.

Examples

The following example groups all endpoints clocked by CLK1A or CLK1B into a new group 'group1'.

Feedback

```
pt_shell> group_path -name group1 -to {CLK1A CLK1B}
```

The following example adds paths that end at OUT1 and ff34/D to the existing path group named 'ADDR'.

```
pt_shell> group_path -name ADDR -to {OUT1 ff34/D}
```

The following example removes the paths that end at OUT1 and CLK2 from existing groups and places them in the default group.

```
pt_shell> group_path -default -to {OUT1 CLK2}
```

The following example groups all paths from inputs I1 and I2 to outputs O5 and O7 into a group named 'serious'.

```
pt_shell> group_path -name serious -from {I1 I2} -to {O5 O7}
```

---

gui_add_annotation

Adds an annotation to the layout window.

Syntax

```
status gui_add_annotation
[-window window_name]
[-group group_type]
[-type shape_type]
[-symbol_type symbol_type]
[-symbol_size symbol_size]
[-text text]
[-color color]
[-pattern pattern]
```

Feedback

```
[-width line_width]
[-line_style line_style]
[-visible visible]
[-info_tip info_tip]
[-query_text query_text]
[-query_command query_command]
[-radius radius]
points
```

Data Types

window_name	string
group_type	string
shape_type	string
symbol_type	string
symbol_size	string
text	string
color	string
pattern	string
line_width	string
line_style	string
visible	boolean
info_tip	string
query_text	string
query_command	string
radius	float
points	list

Arguments

`-window` *window_name*

Specifies the instance name of the layout window. If window name is omitted, the annotation will apply to all layout windows.

`-group` *group_type*

Specifies the annotation group. If group name is omitted, the *global* name is used.

`-type` *shape_type*

Specifies the type of annotation. The supported values for this option are

rect
line
arrow
polygon
polyline
text
symbol
ruler
manhattan_ruler

circle
circular_ruler

The default is symbol, rect, or polygon if the number of points is 1, 2, or larger than 2 respectively.

`-symbol_type` *symbol_type*

Specifies the type of symbol annotation. This option is only valid when annotation type is symbol. The supported values for this option are

square
x
triangle
diamond

The default is x.

`-symbol_size` *symbol_size*

Specifies the size of symbol annotation. An even symbol size will grow one automatically to find the appropriate center point. The default symbol size is 25.

`-text` *text*

Specifies the annotation text.

`-color` *color*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes may be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette.

`-pattern` *pattern*

Specifies the annotation fill pattern. The default fill pattern is none. An empty value forces the tool to use the window default value, which is usually set to solid fill.

`-width` *line_width*

Specifies the annotation line width. The default line width is 1.

`-line_style` *line_style*

Specifies the annotation line style. The default line style is none. An empty value forces the tool to use the window default value, which is usually set to solid line.

Feedback

`-visible` *visible*

Specifies the visibility of the annotation. The default visible is true.

`-info_tip` *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_text` *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_command` *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
%x       the x position clicked in design coordinates
%y       the y position clicked in design coordinates
```

Feedback

`-radius` *radius*

Specifies the radius of circle annotation. This option is only valid when annotation type is circle.

points

Specifies the points for the specified annotation type. The points are specified by a tool command language (Tcl) list in which each list element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.
- bbox_ul : the annotation is placed at the upper left of the bounding box of the object.
- bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

Feedback

Description

This command defines a new annotation and returns a collection containing that annotation if it is successful.

Examples

```
Create a green rectangle annotation.

prompt> gui_add_annotation -window Layout.1 \\
   -type rect -color green {{200 200} {777 777}}

Create a light_green rectangle annotation using light_green from the
 highcontrast palette.

prompt> gui_add_annotation -window Layout.1 \\
   -type rect -color light_green:highcontrast {{200 200} {777 777}}

Create a light_green x annotation of size 100 using light_green from the
 highcontrast palette.

prompt> gui_add_annotation -window Layout.1 \\
   -type x -symbol_size 100 -color light_green:highcontrast [list
 {1835.0010 119.2950}]

Create a red polyline annotation in the group Test1.

prompt> gui_add_annotation -window Layout.2 \\
   -group Test1 -type polyline -color red \\
   -width 2 {{123 456} {789 12} {200 200}}

Create a line between two cells A and B.

prompt> gui_add_annotation -window Layout.1 \\
   -type line [list [get_cells A] [get_cells B]]

Create a line between the center of largest rectangle of cell A and the
 center of
the largest rectangle of cell B.

prompt> gui_add_annotation -window Layout.1 \\
   -type line [list [list [get_cells A] center] [list [get_cells B]
 center]]

Create a line between the bottom left of cell A's bounding box and the
 middle of
the top of cell B's bounding box.

prompt> gui_add_annotation -window Layout.1 -type line \
   [list [list [get_cells A] bbox_ll] [list [get_cells B] bbox_center 0.0
 0.5]]
```

Feedback

```
Create a blue rectangle which displays the annotation points using the
 annotation_query
tcl procedure.

prompt> proc annotation_query { object window view } { \\
  return [get_attribute $object points] \\
  }

prompt> gui_add_annotation -window Layout.1 -type rect -color blue \\
  -query_text {=annotation_query %object %window %view} -info_tip
 {annotation points} \\
  {{110 110} {160 160}}

Create a circle annotation whose center is {100 100} and radius is 10.

prompt> gui_add_annotation -type circle -radius 10 {{100 100}}

Create a circle annotation whose center is {100 100} and boundary is at
 point {120 120}

prompt> gui_add_annotation -type circle {{100 100} {120 120}}

Create a circular ruler annotation with 3 circles (radius 20, 40, 100) at
 100, 100.

prompt> gui_add_annotation -type circular_ruler {{100 100} {120 100} {140
 100} {200 100}}
```

---

gui_append_utable

Append data rows to an existing UserTable.

Syntax

string *gui_append_utable*

```
-name                  Name
-rows                  TCL_Data_List

-import                File_Name [-val_map ...] [-col_map ...] [-tsv_mode]
 [-ssv_mode]
-val_map               Column_Value_Map
-col_map               Column_Value_Map
```

```
[-tsv_mode]
[-ssv_mode]

-column                Name
[-expr]                Value

Name             String
File_Name        String
Column_Value_Map    TCL List of column value pairs
TCL_DataList     TCL List of String List
Value            Value String
```

Arguments

`-name` *Name*

The name of an existing UserTable that the new data rows should be added to.

`-rows` *TCL_Data_List*

A TCL list of string lists that match the number of columns.

`-import` *File_Name*

A value file that is imported and appended to the given UserTable.

`-val_map` *Column_Value_Map*

A list of column-value pairs that are used to fill empty data values for a given column when importing a file.

`-col_map` *Column_Value_Map*

A list of column-value pairs that are used to map a table column name to the imported table column name. The default is to map to the same name. But if the name of a column in the imported file is different then use this option.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

Description

```
This command appends new data to and existing table. This can be done by
 either
appending a TCL list of lists as new rows, or by importing CSV files and
 appending
them. Also you have the ability to add a new column that can also be
 filled
```

Feedback

with a math expression that can use +,-,* and / on referenced column values in
the same row.

When appending a TCL list of lists as new rows, row columns are filled left to right,
first to last, in a given list of lists. Extra data values in a row list are ignored
and if the row list is too short on values it will fill the extra columns with
empty fields. If the **-rows** argument is just a single list of values, it is
assumed to be only one row of values that will be added. Again extra row values
are ignored and missing row values are filled with empty fields.

Another way to add new rows to an existing table is to import another table and
append its content to this table. Use the -import option along with related options
-val_map and **-col_map**. Only columns that match the target table are imported
unless you use the -col_map option to map column names that have a different
name in the import table. Columns that don't match are filled with null or a default
value if it is listed in the **-val_map** option.

Finally one can add a whole new column to an exsisting table that optionally can be
filled with a math expression that references data in other columns of the current row.
Expressions that reference other columns must surround the column with @{...} see
example below.

Examples

The following example appends two rows of static data given as a TCL list of lists
to the given UserTable that has three columns of data.

```
shell> gui_append_utable -name my_table -rows {
 ...      { /top/ModA  0.01  1000 }
 ...      { /top/ModB  0.03  5000 }
 ...   }
```

The following example first creates a TCL list of lists and then appends it to the
given UserTable.

```
shell> set rows {}
shell> ... loop through collection and set vars and append to list...
```

Feedback

```
shell> lappend rows [list $cellname $delay $area]
shell> ...
shell> gui_append_utable -name MyTable -rows $rows
```

The following example appends a given CSV file to an existing table MyTable.
It also uses a column map to map the target column name like (edge) to the column
that matches that data in the CSV file (rise_fall). The columns in the target table ("Extra Col" and sum) would be filled with null but by defining
a value map that maps the target column with a default value it then fills that
column with a default value if it is empty.

```
        set column_map {
  edge  rise_fall
  cap   capacitance
}

set empty_value_map {
  {Extra Col} {not used}
  sum         0
}

gui_append_utable -name MyTable -import values.csv \\
  -val_map $empty_value_map -col_map $column_map
```

Finally below is an example of adding a new expression column to a table.

```
        # Create a table with 3 columns with data type double (postfix)
gui_create_utable -name MyTable -col {Label A:double B:double}

# Add some rows:
gui_append_utable -name MyTable -rows {
  {LabelA 0 1}
  {LabelB 2 3}
  {LabelC 4 5}
}

# Now lets add a new expression column:
# NOTE: referenced column names are surrounded by @{...}
gui_append_utable -name MyTable -column Expr:double -expr { 100 * (@{A} +
 @{B}) }

# Now add a new row (Note: Requires an empty value for the expr column
 added in the previous step!):
```

Feedback

```
gui_append_utable -name MyTable -rows {LabelD 11 22 {}}
```

---

gui_change_charts_model

Change data in model used in chart's plots

Syntax

```
status gui_change_charts_model
-model model_id
[ -column string ]
{ -add | -delete | -modify | -calc | -query }
[ -header string ]
[ -type string ]
[ -expr string ]
```

Data Types

model_id int

Arguments

-model *model_id*

Model to change (previously created by *gui_create_charts_model* command).

`-column string`

The column name or number to delete, modify, calculate or query.

`-add`

Add column to model. The *expr* option specifies the expression to use to calculate the values in the new column.

`-delete`

Delete column from model. Use the *column* option to specify the column to delete.

Note: the original columns of the model cannot be deleted, only newly added columns can be removed after they are created.

`-modify`

Modifies the values in an existing column. Use the *column* option to specify the column to modify and the *expr* option to specify the expression to use to calculate the new values in the column.

Note: the original columns of the model cannot be modified, only newly added columns can be modified are created.

`-calc`

Calculate values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the expression to use to calculate the values.

The calculated values are returned by the command. The model is not modified.

`-query`

Query values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the expression to use to query the values.

The expression should return true or false and the returned values are those where the expression evaluates to true.

The queried values are returned by the command. The model is not modified.

`-header string`

Specifies the name of the header when adding or modifying a column.

`-type string`

Specify the type of the new column for *add*, *modify* options.

Feedback

`-expr` *string*

Specifies the expression to use when adding, modifying, calculating or querying values of a column of the model.

The expression can use tcl variable names that match the column name (as long as the column name is a legal tcl variable name). A few extra variables are also allowed:

- column : current column
- row : current row
- pi : value of pi (3.141592653...)
- NaN : Special 'not a number' real value that can be used to indicate absence of data.

A number of extra functions are allowed as well as the normal tcl expression functions:

- column : get column value for row
- row : get row value for column
- cell : get cell value for row and column
- setColumn : set column value for row
- setRow : set row value for column
- setCell : set cell value for row and column
- header : get header value for column
- setHeader : set header value for column
- type : get type for column
- setType : set type for column
- map : map row number to range
- bucket : get bucket for column value
- norm : normalize column value
- rand : get random number
- rnorm : get normaized random number
- color : get color from name

Feedback

- remap : map column value to range
- timeval : get time value from column with time format

Some special character sequences in the expression are replaced with model values before the expression is evaluated.

- @<n> : value for specified column number (<n>) for current row.
- @c : column number.
- @r : row number.
- @nc : number of columns.
- @nr : number of rows.
- @v : value for current row and column.
- @{<name>} : value for specified column name (<name>) for current row.
- #{<name>} : column number for specified column name (<name>)

Normally the '@' symbols return data in the value format but this can be forced to be a string by using '@#' instead of '@'.

Description

Change data in existing model to add, delete or modify columns for use in charts.

Examples

The following example adds a new column to the model where the value is the sum of the first two columns.

```
shell> gui_change_charts_model -model $model -add -expr {column(0) +
 column(1)} -header Sum
```

See Also

- gui_create_charts_plot
- gui_define_charts_proc

---

gui_change_error_highlight

Manipulates error objects highlight sets.

Syntax

string *gui_change_error_highlight*

-add | -remove [-color *color_id*] [-selected | -all | -all_visible] [-type *error_type_list*] [-layer *layer_strings*] [-include_net *nets* | -exclude_net *nets*]

```
color_name        A color name
error_type_list   A Tcl list of error type names
layer_strings     A Tcl list of layer strings
nets              A Tcl list of net names or a collection of nets
```

Arguments

`-add | -remove`

Required mutually exclusive option which specifies that the errors are added or removed from the error highlight set. If -add, the specified errors become drawn in the given highlight color. If -remove, the specified errors become drawn in the default violation color.

`-color <color_id>`

This option specifies the color for the operation. If a color is given with the -color option, it must be one of the supported color names: blue, green, light_blue, light_green, light_orange, light_purple, light_red, orange, purple, red, yellow. If -color option is provided with the -add option, the specified color will be used to color the specified errors in the given color. If -color option is provided with the -remove option, errors in the specified color highlight set will be removed from the highlight set and will become drawn in the default violation color. When given with the -remove option, this option is mutually exclusive with -selected, -all, -all_visible, -type, -layer, -include_net, and exclude net options.

`-selected`

This option is mutually exclusive with -all, -all_visible, -type, -layer, -include_net and -exclude_net. If this option is present, currently selected errors in the current tab error list become highlighted in the specified color.

`-all`

This option is only meaningful with the -remove and is mutually exclusive with -color, -all_visible, and -selected. When given with the -remove option, removes highlight colors from all errors in all open error views.

`-all_visible`

This option is mutually exclusive with -selected, -type, -layer, -include_net and -exclude_net. If this option is given with the -add option, currently visible errors in the current tab error list become highlighted in the specified color. If this option is given with the -remove option, all error highlight colors are removed from currently visible errors in the current tab error list. They become drawn in the default violation color.

`-type <error_type_list>`

This option is mutually exclusive with -selected and -all_visible. It may be combined with -layer, and -include_net or -exclude_net. Errors that are of one of the given types become highlighted in the specified color. If combined with layer and/or net specifications, errors must match all given specifications to be selected for highlighting.

`-layer <layer_string_list>`

This option is mutually exclusive with -selected and -all_visible. It may be combined with -type, and -include_net or -exclude_net. Errors that are of one of the given layers become highlighted in the specified color. If combined with error type and/or net specifications, errors must match all given specifications to be selected for highlighting.

`-include_net <nets>`

This option is mutually exclusive with -selected, -all_visible and with -exclude_net. It may be combined with -type and -layer. Errors that are associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

`-exclude_net <nets>`

This option is mutually exclusive with -selected, -all_visible and with -include_net. It may be combined with -type and -layer. Errors that are not associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

Description

The command specifies the color to use in drawing the specified errors. Errors can be drawn in a highlight color by adding them to the error highlight color set. Errors can be removed from the error highlight color set and revert to being drawn in the default violation color. The command behavior is determined by combinations of the options as follows:

Adding errors to a highlight set:

If -color is given with the -add option, the specified errors are added to the error highlight color set and become draw in the specified color. The specified color becomes the current error highlight color.

If -color is omitted with the -add option, the specified errors are added to the current error highlight color set and become draw in the current error highlight color.

If -selected is given with the -add option, selected errors are added to the error highlight color set and become draw in the specified color.

If -all_visible is given with the -add option, all visible errors in the current tab error list are added to the error highlight color set and become draw in the specified color.

If -type, -layer -include_net or -exclude_net is given with the -add option, visible errors in the current tab error list matching the given criteria are added to the error highlight color set and become drawn in the specified color.

Removing errors from a highlight set:

If -color is given with the -remove option, all errors in the specified error highlight color set are removed and become drawn in the default violation color.

If -selected is given with the -remove option, selected errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all is given with the -remove option, all errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all_visible is given with the -remove option, all visible errors in the current tab error list are removed from respective error highlight color sets and become drawn in the default violation color.

If -type, -layer -include_net or -exclude_net is given with the -remove option, visible errors in the current tab error list matching the given criteria are removed from the respective error highlight color set and become drawn in the default violation color.

Examples

The following example puts the currently selected errors in the blue error highlight set:

```
gui_change_error_highlight -add -color blue -selected
```

The following example puts "Short" type errors associated with a net named "C0_9_" in the red error highlight set:

```
gui_change_error_highlight -add -color red -type {Short} -include_net {C0_9_}
```

The following example puts "Floating Port" type errors not associated with NULL net in the green error highlight set. Please note the use of parentheses as delimiters. Since the expected argument for -type and -exclude_net options is a list of strings, multi-word strings or empty string signifying NULL net must be delimited:

```
gui_change_error_highlight -add -color green -type {{Floating Port}} -exclude_net {{}}
```

The following example adds all visible errors in the current tab error list to the light_red highlight set:

```
gui_change_error_highlight -add -color light_red -all_visible
```

Feedback

The following example removes all errors from all error highlight sets:

gui_change_error_highlight -remove -all

The following example removes errors in the red color highlight set from the highlight set:

gui_change_error_highlight -remove -color red

The following example removes all visible errors in the current tab error list from highlight sets:

gui_change_error_highlight -remove -all_visible

See Also

- gui_set_selected_errors

---

gui_change_highlight

Manipulate the set of globally highlighted objects.

Syntax

string *gui_change_highlight*

```
[-add | -remove | -toggle]
[-color color_id | -all_colors]
[-collection clct]

string          color_id
collection      clct
```

Arguments

`-add`

Use -add to highlight a collection of objects in a color specified with color. If -color is not specified, the current color is used. You cannot use -all_colors with -add. You must specify a collection with -collection. If -remove or -toggle are not specified, then -add is implied.

`-remove`

Use -remove to remove highlighting from objects. Use -collection to remove highlighting from specific objects. Use -color to remove highlighting from objects of a specific color. Use -all_colors to remove all highlighting. If you specify a collection, you cannot specify colors.

`-toggle`

Use -toggle to toggle the highlight state of a collection of objects. You must use -collection with -toggle, and you cannot use -color or -all_colors. Toggling an

object that is highlighted will cause it to no longer be highlighted. Toggling an object that is not highlighted with cause it to be highlighted with the current color. If no operation is specified, then -add is assumed.

`-color` *`color_id`*

Specifies the color to be used for the highlight operation. This is mutually exclusive with -all_colors. The allowed colors are blue, light_blue, yellow, purple, light_purple, orange, light_orange, red, light_red, green, and light_green. If neither -color nor -all_colors is specified, then the current highlight color is assumed. You cannot use -color with -toggle.

`-all_colors`

This option is only valid with -remove. Use this option to clear all highlight colors.

Description

The gui_change_highlight command is used to operate on the set of highlighted objects. Objects can be added or removed from the set, or their presence can be toggled as described above. The set has a current color that can be modified with gui_set_highlight_options(2). The current color is used as needed when no color is specified.

The tool provides eleven built in highlight colors with the names yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

The gui_change_highlight command uses colors from the highlight color palette.

Examples

Highlight in green all cells with names matching foo*.

shell> gui_change_highlight -color green -collection [get_cells foo* -hier -all]

Remove highlights from all objects in the collection returned by the get_cells command.

shell> gui_change_highlight -remove -collection [get_cells foo* -hier -all]

Clear all objects with blue highlights.

shell> gui_change_highlight -remove -color blue

Clear objects with the current highlight color.

shell> gui_change_highlight -remove

Clear all highlights.

shell> gui_change_highlight -remove -all_colors

Toggle the highlight state of all objects in a collection returned by the get_cells command.

Feedback

```
shell> gui_change_highlight -toggle -collection [get_cells foo*]
```

See Also

- gui_get_highlight
- gui_get_highlight_options

---

gui_change_schematic

Performs abstraction on the current or specified schematic view.

Syntax

string *gui_change_schematic*

```
-type abstraction_name
-operation operation_name
-clct objects
[-window window_name]
```

Data Types

```
abstraction_name    string
operation_name      string
objects             collection
window_name         string
```

Arguments

`-type abstraction_name`

Name of abstraction type. Currently supported types: "Hierarchy".

`-operation operation_name`

Name of operation to be applied for the specified abstraction type. Currently supported operations: "Expand", "Collapse".

`-clct objects`

The collection of objects in the target schematic to which the specified abstraction operation will be applied.

`-window window_name`

Optionally specifies the target schematic to which the abstraction is applied. If not specified, the current application schematic will be the target.

Feedback

Description

The command applies the specified abstraction operation to the specified objects within the target schematic view.

Examples

The following example collapses currently selected modules within the current schematic view.

```
prompt> gui_change_schematic -type Hierarchy -operation Collapse -clct
 [get_current_selection]
```

---

gui_change_selection_utable

Change Current Selection by adding objects named in the given table.

Syntax

string *gui_change_selection_utable*

```
-name         Table_Name
[-obj_col     Col_Name]
[-filter      Filter]

Table_Name    String
Col_Name      String
Filter        Table Filter String
```

Arguments

`-name` *Table_Name*

The name of the user table to use for finding object names to add to the current selection.

`-obj_col` *Col_Name*

The column name containing object names with a data type set. By default it uses the full_name and object_class type or named columns.

`-filter` *Filter*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

Description

```
This command takes a table name and if a filter is given, reduces the
 rows
to those that match the filter and then tries to add to the current
 selection
```

Feedback

any object names found in those table rows. The object names are searched for
in the column given by the *-obj_col* command argument. By default it uses the full_name and object_class type or named columns to determine object names
to add to the current selection.

Examples

The following example adds all object with the object names found in the column 'pins' that match the filter '*ALU*'.

```
shell> gui_change_selection_utable -name my_table -obj_col pins -filter
 {pins =~ *ALU*}
```

---

gui_clear_error_data_filter

Remove the filter from error data.

Syntax

string *gui_clear_error_data_filter*

Description

Remove the filter and restore visibility of errors. Errors may remain hidden based on null net association or fixed status state if the "Hide Null-Net Errors" option or the "Hide Fixed Errors" option has been set.

Examples

The following example removes the error data filter

gui_clear_error_data_filter

Feedback

See Also

- gui_error_browser
- gui_set_error_data_filter
- gui_set_error_browser_option

---

gui_clear_parasitics

Clears parasitics annotated on a net.

Syntax

status *gui_clear_parasitics*

```
[-all]
[nets]
```

Data Types

```
nets            string
```

Arguments

`-all`

Clears parasitic annotation for all nets. This is the default if no nets are specified.

nets

A list of one or more nets for which to clear parasitics. Glob-style wildcards (*) are supported.

The default is to clear all nets.

---

gui_clear_selected_errors

Clears selection in the Error Browser.

Syntax

string *gui_clear_selected_errors*

Description

Clears selected errors in the Error Browser.

Feedback

Examples

The following example clears selected errors:

gui_clear_selected_errors

See Also

- gui_error_browser
- gui_get_errors
- gui_set_current_errors
- gui_set_selected_errors

---

gui_close_error_data

Removes an error data file from the error browser.

Syntax

```
status gui_close_error_data
[error_data]
```

Data Types

```
error_data        collection
```

Arguments

error_data

A collection of physical DRC error data objects to remove from the error browser. A collection of the error data or the error data name can be used to remove it from the error browser.

Description

The *gui_close_error_data* command removes the given error data from the GUI error browser. If no error data is given, then the command removes all error data from the error browser and hides the error browser.

When a command opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The *gui_open_error_data* command opens an error data if necessary. It does not increment the open_count if the error data is already open and in memory. If the *gui_open_error_data* command increments the open_count, then a subsequent call to *gui_close_error_data* for the same error data decrements the open_count. Otherwise,

Feedback

a subsequent call to *gui_close_error_data* simply removes the error_data from the error browser without decrementing the open_count.

Examples

The following example removes the physical DRC error data file that is named "my_design_dppinassgn.err" from the error browser.

```
prompt> gui_close_error_data "my_design_dppinassgn.err"
1
```

The following example removes all physical DRC error data file from the error browser and hides the error browser.

```
prompt> gui_close_error_data
1
```

---

gui_close_utable

Close and free the given list of UserTables in memory.

Syntax

string *gui_close_utable*

```
-names   Table_Names

Table_Names     String List
```

Feedback

Arguments

`-names Table_Names`

The list of table names to close and free in memory.

Description

```
This command closes and frees all the table names given by the user. If
 the
table was in read only mode (streaming), then the connection to the table
file is closed.
```

Examples

The following example closes a list of user tables.

```
shell> gui_close_utable -names {my_table1 my_table2}
```

See Also

- gui_append_utable

---

gui_close_window

Close the specified window

Syntax

```
status gui_close_window
{ -window window_id | -type window_type | -all }
[ -exact_type_match ]
```

Data Types

```
window_id       string
window_type     string
```

Feedback

Arguments

`-window window_id`

Specifies the window name id.

Any matching window of this name will be closed.

This option precludes the *-type* and *-all* options.

`-type window_type`

Specifies the window type id. Any matching window of this type will be closed.

If the *-exact_type_match* options is not specified then types derived from this window type will also be closed. Derived types are created with the *gui_create_window_type* command.

This option precludes the *-window* and *-all* options.

`-all`

Specifies that we want to close all the windows.

This option precludes the *-window* and *-type* options.

`-exact_type_match`

Specifies that types derived from the specified type are excluded when the *-type* option is specified.

Note: this option should only be used with the *-type* option.

Description

This command closes the specified window(s).

Windows can be specified by name, type or as all windows.

Examples

The following examples will create a toplevel window and a child layout view window, then close the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> gui_close_window -window $x
```

See Also

- gui_create_window

---

gui_connect_charts_signal

Connect to charts signal

Syntax

```
status gui_connect_charts_signal
{ -view view_name | -plot plot_name }
-from signal_name
-to tcl_proc
```

Data Types

```
view_name    string
plot_name    string
signal_name  string
tcl_proc     string
```

Arguments

`-view view_name`

Charts view to connect to.

`-plot plot_name`

Plot to connect to.

`-from signal_name`

Signal name to connect to.

Supported names are:

objIdPressed (id proc) plot object clicked on with mouse

annotationIdPressed (id proc) plot or view annotation clicked on with mouse

chartObjsAdded (non-id proc) objects added to chart

`-to tcl_proc`

Tcl procedure to call when the signal is emitted.

Feedback

For plot an id procedure is called with three arguments (view, plot and object_id) and a non-id procedure is called with two arguments (view, chart).

For view an id procedure is called with two arguments (view, object_id) and a non-id procedure is called with one arguments (view).

Description

Connects signals emitted from charts events to tcl callbacks.

Examples

The following example calls chartObjPressed proc when object in plot pressed.

```
shell> gui_connect_charts_signal -plot $plot -from objIdPressed -to
 chartObjPressed
```

See Also

- gui_create_charts_plot

---

gui_create_attrgroup

Creates a group of attributes for an object type.

Syntax

```
status gui_create_attrgroup
-class design_object
-name name
[-attr_list {{attr_1}...{attr_n}}]
```

Data Types

```
design_object      string
name               string
attr_1             string
attr_n             string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the name of the attribute group to be created for the specified object type.

`-attr_list {{attr_1}...{attr_n}}`

Lists and orders the attributes to be included in the group.

Feedback

Description

The *gui_create_attrgroup* command creates a new attribute group for a specific type of design object. The command adds the attribute group to the display in GUI tools, such as the Properties dialog box, List views, layout view InfoTips, and other graphic windows.

An attribute can be assigned to more than one attribute group at the same time.

The order of the attributes in an attribute group is important and is set by the *-attr_list* option when you create the group. Use the *gui_update_attrgroup* command if you need to change or reorder the attribute list for an attribute group.

Examples

```
prompt> gui_create_attrgroup -class Cell -name "Hierarchy" \\
   -attr_list { "Name" "Hierarchical" "Owning Cell"
   "isPhysConstraint" "Hard Macro" "Num Children" "Num Nets"
   "Num Pins" "Utilization" "Area" "Aspect Ratio" "Min Aspect"
   "Max Aspect" "Min Area" "Max Area" "Area / 1M" "Hier Req Area / 1M"
   "Reference" "Logical Name" "FullName" }

prompt> gui_create_attrgroup -class Cell -name "Edit" \\
   -attr_list { "Name" "isPhysConstraint" "Orientation"
   "Location" "Bounding Box" "Fixed Location" "Is Resizable"
   "Hard Macro" "Placed" "Is IO" "Off Litho Grid" "FullName" }

prompt> gui_create_attrgroup -class Pin -name "Timing" \\
   -attr_list { "Name" "Is Clock" "Slew"  "slack_max" }

prompt> gui_create_attrgroup -class Net -name "Timing" \\
   -attr_list { "Name" "Lumped C" "Total Lumped C"
   "Lumped Resistance" }
```

See Also

- gui_delete_attrgroup
- gui_list_attrgroups
- gui_update_attrgroup

---

gui_create_category_rule

Creates a category rule for automatic generation of one or more object categories.

Syntax

string *gui_create_category_rule*

```
[-name rule_name]
[-filter filter_spec]
```

Feedback

```
-category category_spec
[-builtin]
```

Data Types

```
rule_name           string
filter_spec         string
category_spec       string
```

Arguments

`-name rule_name`

Specifies the name of the category rule to be created. If this option is omitted, a unique new rule name is automatically generated.

`-filter filter_spec`

Specifies the filter. The basic form of a filter conditional expression is a series of relations joined together with && (and), || (or), and ! (not) operators. Parentheses are used to override precedence. The basic relation is either a Boolean attribute or a comparison of one non-Boolean attribute with another or with a constant value using relational operators.

For example, a filter expression can have any of the following forms:

- *-filter {endpoint_clock_is_propagated}* (Boolean attributes)
- *-filter {(slack < 0)}* (Comparison with a literal number)
- *-filter {(path_group.full_name == "inputs")}* (Comparison with a literal string)
- *-filter {(startpoint_clock.full_name == endpoint_clock.full_name)}* (Comparison of attributes)

Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection. The following relational operators are supported:

- == (Equal)
- *!*= (Not equal)
- =~ (Matches pattern)
- *!*~ (Does not match pattern)
- &~ (Contains all elements)
- |~ (Contains some elements)
- > (Greater than)

- < (Less than)
- >= (Greater than or equal to)
- <= (Less than or equal to)

The matching operators are used to match wildcard regular expressions. The containment operators are used to compare space-separated set or list attributes.

`-category` *`category_spec`*

Specifies the category. The category specification can be fixed literal text, or it can include an optional object attribute name enclosed in angle brackets; for example, *-category <path_type>*. Additional literal text is optionally allowed to the left and to the right of the angle brackets; for example *-category {Path Type: <path_type>}*. Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection; for example, *-category <startpoint_clock.full_name>*.

When a category rule is "executed" later in the GUI, a separate category (bin of objects) is generated for each unique value of the attribute specified by the *-category* option. (The GUI "category-rule-execution engine" examines attribute values for an input set of objects.)

`-builtin`

Indicates that the rule being created belongs to the built-in group of category rules. If this option is omitted, the rule being created does not belong to the built-in group.

The built-in group of category rules is a group of category rules that are created before any non-built-in rules. This group of rules includes both built-in rules created by the tool (at tool startup time) and built-in rules that you create before creating any non-built-in rules.

Description

This command creates a category rule. If rule creation is successful, the command returns the name of the newly-created category rule; otherwise, it returns an empty string. After a category rule has been created, it can be used later (at "category-rule execution time" in the GUI) with other rules to generate one or more object categories.

Examples

This example creates a simple category rule:

```
prompt> gui_create_category_rule -name pathgroups \\
        -category <path_group.full_name>
pathgroups
```

Feedback

This example creates a simple filtering rule:

```
prompt> gui_create_category_rule -name {Negative Slack} \\
        -category {Failing Paths} -filter {slack < 0}
Negative Slack
```

This example creates a regular expression filtering rule:

```
prompt> gui_create_category_rule -name {ATPG Sessions} \\
        -category {ATPG Sessions} -filter {session_name =~ "atpg*"}
Negative Slack
```

This example creates a set or list containment filtering rule:

```
prompt> gui_create_category_rule -name {Through CPU and CTRL} \\
        -category {Through CPU and CTRL} -filter { blocks &~ "CPU CTRL"}
Negative Slack
```

See Also

- gui_list_category_rules
- gui_remove_category_rules

---

gui_create_charts_arrow_annotation

Create arrow annotation in view or plot

Syntax

```
arrow_id gui_create_charts_arrow_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-start position
-end position
[ -line_width length ]
[ -fhead string ]
[ -thead string ]
[ -angle angles ]
[ -length lengths ]
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
length           string
angles           string
lengths          string
```

Feedback

```
name_value_list  string
arrow_id         annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-start position`

Start point of the arrow line.

`-end position`

End point of the arrow line.

`-line_width length`

Width of the connecting line.

`-fhead string`

Front arrow head type.

One of triangle, stealth, diamond, line or none.

`-thead string`

Tail arrow head type.

One of triangle, stealth, diamond, line or none.

`-angle angles`

Angle of arrow heads.

Use single value for same angle for both front and tail heads. Use two values for different angle for front and tail heads.

`-length lengths`

Length of arrow heads.

Use single value for same length for both front and tail heads. Use two values for different length for front and tail heads.

Feedback

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

arrow_id

Returns id of created annotation.

Description

Add an arrow annotation to plot or view.

The arrow annotation is a line with optional arrow heads draw at each end.

The line and arrow heads can be customized.

Examples

The following example creates an arrow annotation on a plot from (0 0) to (100 100) with arrows at both ends. The front head uses a line and the tail head a triangle.

```
shell> gui_create_charts_arrow_annotation -plot $plot -start {0 0} -end
 {100 100} \
  -fhead line -thead triangle
```

- gui_get_charts_property

gui_create_charts_ellipse_annotation

Create ellipse annotation in view or plot

Feedback

Syntax

```
ellipse_id gui_create_charts_ellipse_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-center position
-rx length
-ry length
[ -properties name_value_list ]
```

Data Types

```
view_name         string
plot_name         string
position          string
length            float
name_value_list   string
ellipse_id          annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-center position`

Center of the ellipse.

`-rx length`

X Radius of the ellipse.

`-ry length`

Y Radius of the ellipse.

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Feedback

Returns

ellipse_id

Returns id of created annotation.

Description

Add an ellipse annotation to plot or view.

The background and border of the ellipse can be customized.

Examples

The following example creates an ellipse annotation on a plot centered at (0 0) with a radius of 60 in x direction and 40 in y direction.

```
shell> gui_create_charts_ellipse_annotation -plot $plot -center {0 0} -rx
 60 -ry 40
```

---

gui_create_charts_model

Create a model from data for use in charts

Syntax

```
model_id gui_create_charts_model
{ -csv filename | -clct collection |
-tcl tcl_list }
[ { -comment_header | -first_line_header } ]
[ -first_column_header ]
```

Feedback

```
[ -transpose ]
[ -columns column_names ]
[ -column_type column_type ]
[ -name string ]
```

Data Types

```
filename      string
collection    string
tcl_list      string
column_names  string
column_type   string
```

Arguments

`-csv filename`

Create model from contents of specified csv filename.

A CSV file has comma separated fields.

The *comment_header*, *first_line_header* and *first_column_header* options can be used to determine which (if any) lines are used for horizontal and vertical headers.

`-clct collection`

Create model from contents of a collection. Each row consists of a list of attribute values from the collection object.

The *columns* option can be used to specified which attributes are used to populate the table from the collection. If the *columns* option is not specified then the attributes from the ALL attribute group are used.

`-tcl tcl_list`

Create model from the values in a tcl variable.

The tcl variable must be a list of lists. The data is a list of rows where each row is a list of column values.

The *transpose* option can be used to transpose the value array so lists of columns can be specified where each column is a list of row values.

`-comment_header`

Specifies that the first comment (line starting with a #) contains the names of the horizontal column headers.

Only used by the *csv* option.

`-first_line_header`

Specifies that the first line contains the names of the horizontal column headers.

Feedback

Used by the *csv* and *tcl* options.

`-first_column_header`

Specifies that the first column (first field in each row) contains the names of the vertical row headers.

If the data also has a horizontal header then the first field of the horizontal header is ignored.

Used by the *csv* and *tcl* options.

`-transpose`

Specifies that the tcl value array from *tcl* option is transposed so lists of columns can be specified where each column is a list of row values.

`-columns` *`column_names`*

Specifies a list of names for the attributes to query from the collection to generate the columns of each row.

Used by the *clct* option.

`-column_type` *`column_type`*

Specifies the type and optional formatting of the values in the columns.

If the type of the column is not specified then the application will try to automatically determine it depending on whether the values can be all converted to real or integer values. If not the default string type is used.

The specified value is an ordered list of column type data. Each column type data is a list where the first element specifies the type and any extra elements specify extra name values to customize the type. By default, the type is associated with the column number matching the index of the item but a specific column can be specified by including the column name or number with the type value in the first element.

Syntax:

- column_type_data : { <column_type> [<name_values>]}
- column_type : { [<column>] <type> }
- column : column_name|column_index
- type : integer|real|string|...
- name_values : <name_value> <name_value> ...
- name_value : { <name> <value> }

Feedback

The supported name values are dependant on the column type.

Column types can be queried using:

```
gui_get_charts_data -global -name column_types
```

The column types named values can be queried using:

```
gui_get_charts_data -global -name column_type.names -data $type
```

`-name` *`string`*

Specifies the name of the model.

This can be used to annotate the model so the user can more easily identify what data it contains in the gui.

If the *csv* option is used then the filename is the default name.

Returns

model_id

The id of the created model.

This can be used as input to the *gui_create_charts_plot* command and other commands to do further processing on the model.

Description

This command creates a persistant model and loads data into it so it can be used as the data source for one or more plots.

The command returns a model id which can be used as input to the *gui_create_charts_plot* and other charts commands.

Examples

The following example creates a model from the csv file "test.csv" using the first line for the column headers.

```
shell> gui_create_charts_model -csv "test.csv" -first_line_header
```

The following example creates a model from a collection of all shapes with columns for the name and layer attributes.

```
shell> gui_create_charts_model -clct [get_nets] -columns [list name
 layer]
```

See Also

- gui_create_charts_plot

Feedback

gui_create_charts_plot

Create a plot of the type using the supplied data

Syntax

```
plot_name gui_create_charts_plot
-view view_name
{ -clct collection | -model model_id }
-type plot_type
[ -columns column_names ]
[ -title string ]
[ -properties name_value_list ]
[ -xmin float ]
[ -ymin float ]
[ -xmax float ]
[ -ymax float ]
```

Data Types

```
view_name        string
collection       string
model_id         int
plot_type        string
column_names     string
name_value_list  string
```

Arguments

`-view view_name`

Parent view for plot.

`-clct collection`

Collection to use for input data. Each row consists of a list of attribute values from the collection object.

The *columns* option is used to specified which attributes are read from the collection to populate the table values.

Note: the resultant model is a snapshot of the specified collection's attribute values and will not updates as the collection is changed.

`-model model_id`

The model to use for input data.

`-type plot_type`

The type of plot to display:

The plot types can be queried using the command *gui_get_charts_data -global -name plot_types*

Feedback

`-columns column_names`

Specifies the columns to use for each plot column parameter.

The columns string is a command separated list of name value pairs of the form "<parameter name>=<column name>".

The parameter names are plot type dependent.

When the *model* option is specified the column names are column indices (0 based) or column header names.

When the *clct* option is specified the column names are attributes names.

`-title string`

Specifies the title for the plot.

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created plot.

`-xmin float`

User specified minimum x value (to override the auto calculated range).

`-ymin float`

User specified minimum y value (to override the auto calculated range).

`-xmax float`

User specified maximum x value (to override the auto calculated range).

`-ymax float`

User specified maximum y value (to override the auto calculated range).

Returns

plot_name

The id of the created plot.

Description

Create plot in a view using values in data model.

The view and model data must be created before the plot can be added.

Examples

The following example creates a distribution plot from the specified model using values from the first column.

Feedback

```
shell> set window [gui_get_current_window -mru]
shell> set view [gui_create_window -parent $window -type Charts]
shell> gui_create_charts_plot -view $view -model $model -type
 distribution -columns "value=0"
```

---

gui_create_charts_point_annotation

Create point annotation in view or plot

Syntax

```
point_id gui_create_charts_point_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-position position
[ -size length ]
[ -type symbol_type ]
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
length           float
symbol_type      string
name_value_list  string
point_id           annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-position` *position*

Point position.

`-size` *length*

Point size.

`-type` *symbol_type*

Point symbol type.

One of: dot, cross, plus, y, triangle, itriangle, box, diamond, star5, star6, circle, pentagon, ipentagon, hline, vline.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

point_id

Returns id of created point.

Description

Add a point annotation to plot or view.

The background and border of the point can be customized.

Examples

The following example creates a point annotation on a plot with a circle symbol at (0 0).

```
shell> gui_create_charts_point_annotation -plot $plot -position {0 0}
 -type circle
```

---

gui_create_charts_polygon_annotation

Create polygon annotation in view or plot

Syntax

```
poly_id gui_create_charts_polygon_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-points position_list
[ -properties name_value_list ]
```

Data Types

```
view_name         string
plot_name         string
position_list     string
name_value_list   string
poly_id             annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-points position_list`

List of polygon points.

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Feedback

Returns

poly_id

Returns id of created polygon.

Description

Add a polygon annotation to plot or view.

The background and border of the polygon can be customized.

Examples

The following example creates a polygon annotation on a plot with a red background with 50% alpha.

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -background 1 -fill_color red -fill_alpha 0.5
```

---

gui_create_charts_polyline_annotation

Create polyline annotation in view or plot

Syntax

```
poly_id gui_create_charts_polyline_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
```

Feedback

```
-points position_list
[ -properties name_value_list ]
```

Data Types

```
view_name         string
plot_name         string
position_list     string
name_value_list   string
poly_id             annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-points position_list`

List of polygon points.

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

poly_id

Returns id of created poly line.

Description

Add a multi-point line annotation to plot or view.

The background and border of the line can be customized.

Examples

The following example creates a polyline annotation on a plot with a red border with 50% alpha.

Feedback

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -border 1 -stroke_color red -stroke_alpha 0.5
```

---

gui_create_charts_rectangle_annotation

Create rectangle annotation in view or plot

Syntax

```
rect_id gui_create_charts_rectangle_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
[ -rectangle string ]
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
name_value_list  string
rect_id            annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

Feedback

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-rectangle string`

Rectangle bounding box

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

rect_id

Returns id of created rectangle.

Description

Add a rectangle annotation to plot or view.

The background and border of the rectangle can be customized.

Examples

The following example creates a rectangle annotation on a plot from (0 0) to (100 100).

```
shell> gui_create_charts_rectangle_annotation -plot $plot -start {0 0}
 -end {100 100}
```

---

gui_create_charts_text_annotation

Create text annotation in view or plot

Syntax

```
text_id gui_create_charts_text_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
{ -position position | -rectangle bounding_box }
-text string
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
bounding_box     string
name_value_list  string
text_id            annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-position position`

The position of the text.

`-rectangle bounding_box`

The bounding box of the text.

Feedback

`-text` *`string`*

The text to display.

`-properties` *`name_value_list`*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

text_id

Returns id of created text.

Description

Add a text annotation to plot or view.

The background, border and font of the text can be customized.

Examples

The following example creates a text annotation on a plot at (0 0) with the text "Test text".

```
shell> gui_create_charts_text_annotation -plot $plot -position {0 0}
 -text "Test text"
```

gui_create_clock_graph

Creates a clock graph.

Feedback

Syntax

gui_create_clock_graph

```
-clct objects
[-levelized]
[-latency]
```

Arguments

`-clct`

Collection of objects to be used to generate a clock graph.

`-levelized`

Generates a levelized clock graph.

`-latency`

Generates a latency clock graph.

Description

The command generates a levelized or latency clock graph using a selected set of objects.

Examples

The following example generates a levelized clock graph using a collection of clock paths.

```
prompt> gui_create_clock_graph -clct $clock_paths -levelized
```

See Also

- change_selection

---

gui_create_menu

Create a menu item for the toplevel menubar or a context menu item. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item.

Syntax

string *gui_create_menu* -menu *HierMenuName*

```
<-tcl_cmd       TclCmd|-separator|-heading headingText>
[-enable_cmd    EnableCmd]
[-get_state_cmd GetStateCmd]
[-icon          IconFilePath]
[-hot_key       HotKey]
[-tooltip       ToolTip]
[-help_string   HelpStr]
[-anchor_item   AnchorItem]
```

```
[-anchor_offset AnchorOffset]
[-position      MenuPos]
[-window_type   WindowTypeName]
[-root          ContextMenuRoot]
[-reference     RefMenuItem]

HierMenuName    String
TclCmd          String
EnableCmd       String
GetStateCmd     String
IconFilePath    String
HotKey          String
ToolTip         String
HelpStr         String
AnchorItem      String
AnchorOffset    Integer
MenuPos         Integer
WindowTypeName  String
ContextMenuRoot String
RefMenuItem     String
```

Arguments

`-menu` *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to create. If a level of the hierarchy does not exist in the menu structure it will be created automatically by this command. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so.

`-tcl_cmd` *TclCmd*

TclCmd specifies the tcl command to execute when the menu item is selected. This option is mutually exclusive with the -separator and -heading options.

`-separator`

This option creates a menu item separator. It is mutually exclusive with the -tcl_cmd and -heading options.

`-heading` *headingText*

This option creates a text heading in the menu with the specified *headingText*. It is visually distinct from actual menu items, and it is not selectable like an actual menu item is. This is used to provide general grouping information without requiring an additional level of sub menu. This option is mutually exclusive with the -separator and -tcl_cmd options.

`-enable_cmd` *`EnableCmd`*

EnableCmd specifies the tcl command to evaluate whether the menu item should be enabled or disabled. The tcl command should return "true" or "1" to enable, and return "false" or "0" to disable. If the enable_cmd is not specified then the menu item will always be enabled.

`-get_state_cmd` *`GetStateCmd`*

GetStateCmd specifies the tcl command that will be executed to determine whether the menu item should be in an on (checked or pushed-in) or off (unchecked or normal) state. Most menu items don't have persistent state, and for those the get_state_cmd should not be specified. This tcl command returns "true" or "1" for the "on" state, and returns "false" or "0" for the "off" state.

`-icon` *`conFilePath`*

IconFilePath specifies the absolute pathname of the icon file. The file should be in *.xpm* format. Typical application-supplied icons are 16x16 pixels in size and use a transparent background (color 'None' in xpm format).

`-hot_key` *`HotKey`*

HotKey specifies the hotkey (accelerator) for the menu item.

`-tooltip` *`ToolTip`*

ToolTip specifies the tooltip for the menu item.

`-help_string` *`HelpStr`*

HelpStr specifies the help string for the menu item. The help string is displayed in the status bar.

`-anchor_item` *`AnchorItem`*

AnchorItem specifies the existing menu item that will be used as the anchor position for this new menu item. This option is used together with the -anchor_offset option to determine the location of the new menu item. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

`-anchor_offset` *`AnchorOffset`*

AnchorOffset specifies the offset from the anchor item position that will be used to determine the location of the new menu item in the menu hierarchy. The offset must be a positive or negative integer, and not zero. If positive, the new menu item will be placed below the anchor item by the specified offset. If negative, it will be placed above the anchor item position by the absolute value of the specified offset. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

`-position` *`MenuPos`*

MenuPos specifies the absolute menu position for the menu item within the parent popup menu. The -position option cannot be used with the -anchor_item and -anchor_offset options.

`-window_type` *`WindowTypeName`*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-root` *`ContextMenuRoot`*

ContextMenuRoot specifies the context menu root to which the menu item being defined will be added. A context menu root groups menu items that share the same context menu root. The context menu root is used for context menu. Context menu, is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

`-reference` *`RefMenuItem`*

RefMenuItem specifies the menu item under the toplevel window's menu bar, which will be used to define the behavior of the menu item being defined. Often used with the -root option to help associate a context menu item with an already defined menu entry under the menu bar. Used with the -window_type option to completely specify the reference menu item under the menu bar. If the -window_type option is not specified, the default toplevel window type as specified with the tcl variable "::gui_default_window_type" will be used.

Description

This command creates a menu item for the menu bar of a top level window. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item. The menu hierarchy separator is denoted by "->".

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default empty value. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_icc_gui.tcl for IC Compiler.

Feedback

Examples

The following simple example adds a new toplevel popup menu *&Favorite* in the menubar and add a submenu named *Preferences* then add an item named *My &Item* to that submenu. This menu item will be enabled if *enable_my_item* is set to 1 and disabled otherwise. A hotkey and tooltip are also provided.

```
set enable_my_item 1
proc enable_my_item {} {
    if { $::enable_my_item == 1 } {
        return 1
    }
    return 0
}
gui_create_menu -menu "&Favorite->Preferences->My &Item" \\
             -tcl_cmd "echo {executing My Item}" \\
             -enable_cmd "enable_my_item" \\
             -hot_key "Ctrl+N" \\
             -tooltip "short tooltip description for My Item" \\
             -help_string "long status bar description for My Item" \\
             -icon_file "/syn/sparc/my_item.xpm"
```

The following IC Compiler example illustrates creating a new menu item in the context menu of the layout window which will refer to the Zoom Fit Selection menu item from the Layout window main menu bar. This assumes that the tcl variable "gui_default_window_type" is set to the ICC window type "LayoutWindow" and thus it is not necessary to specify the -window_type option with the value of "LayoutWindow".

gui_create_menu -menu "Zoom Fit Selection" \\ -root layout_view_menu_root \\ -reference "View->Zoom->Zoom Fit Selection"

The following example create a new Tcl-based menu entry in the context menu which invokes a procedure # called do_my_thing.

gui_create_menu -menu "Do My Thing" \\ -root layout_view_menu_root \\ -tcl "do_my_thing"

The following IC Compiler example illustrates adding a context menu item to the path schematic context menu which refers to a menu item in the Main window. This example assumes that there is a context menu root called "path_schematic_contextmenu_root", a hierarchical menu item in the toplevel menu bar of the window type "MainWindow" with the hierarchical menu name "Schematic->Delete Selected".

gui_create_menu -menu "Remove Selected" \\ -root path_schematic_contextmenu_root \\ -reference "Schematic->Delete Selected" -window_type MainWindow

gui_create_pref_category

Create a preference category.

Syntax

string *gui_create_pref_category* -category *Category*

```
Category        String
```

Arguments

```
-category Category
```

Category specifies the category to create.

Description

This command creates a preference service category with the specified name, which can be used to store and categorize key-value pairs that are created with the *gui_create_pref_key* command. If successful, the command returns the name of the category that is created.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false.

Feedback

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
```

---

gui_create_pref_key

Create a preference key.

Syntax

string *gui_create_pref_key* -key *Key*

```
-value_type ValueType
-value Value
[-category Category]
[-keep_value_if_exist]
[-read_only]
[-description Description]
[-min Minimum_Value]
[-max Maximum_Value]
[-legal_value_list Value_List]
[-string_to_int_map Value_Map]
[-save_on_exit Boolean_Value]

Key             String
Category        String
ValueType       one of [bool|integer|double|color|string|rect|point|size]
Value           Depends on the value type
Description     String
Minimum_value   Minimum integer or double value
```

```
Maximum_value   Maximum integer or double value
Value_List      String List
Value_Map       A list of string pair lists, each mapping a string value
 to an integer value.
Boolean_Value   true | false
```

Arguments

`-key` *Key*

Key specifies the name of the key to create.

`-value_type` *ValueType*

ValueType specifies the data type of the value of the key. It must be one of [bool | integer | double | color | string].

`-value` *Value*

Value specifies the value of the key. The value should be set appropriately in accordance with its value type. The *bool* type accepts [true, false, 0, 1, on, off]. The *color* type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

`-category` *Category*

Category specifies the category that the key belongs to. If not specified, a default category will be assigned.

`-keep_value_if_exist`

This Boolean option specifies to keep current value if the key already exists. The default is that the key will be assigned the value given in the *-value* option.

`-read_only`

If given, this flag specifies that the preference key value is read-only and its value cannot be set after the key has been created.

`-description` *Description*

If given, the given description string with the meaning of the key is assigned to the preference key.

`-min` *Minimum_Value*

If given, specifies the minimum value for an integer or double type preference key.

`-max` *Maximum_Value*

If given, specifies the maximum value for an integer or double type preference key.

Feedback

`-legal_value_list` *`Value_List`*

If given, this option specifies discrete valid values for an iteger, double or string type preference key. Input the argument using Tcl list syntax: {{prefVal} ...}

`-string_to_int_map` *`Value_Map`*

If given, provides a map from a string key value to an integer value for preferences of integer type. Input the argument as a Tcl list of Tcl list where the internal list is a pair of the string value and the integer value: {{stringval intval} ...}

`-save_on_exit` *`Boolean_Value`*

If given, specifies whether the preference key value is saved to the user preference file upon existing the application. Acceptable argument is either *true* or *false*.

Description

This command creates a preference key with the specified key name. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to the default category. Returns the value of the preference key.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type
 integer -value 200
```

---

gui_create_schematic

Creates a schematic view.

Syntax

string *gui_create_schematic*

```
[-clct objects]
[-size {w h}]
[-be_specific bool]
```

Data Types

```
objects  collection
{w h}    string
```

Arguments

`-clct objects`

Generates a schematic for the specified object collection. The current selection is used if not specified.

`-size {w h}`

Generates a schematic for the specified width (w) and height (h). Application default view size is used if not specified.

`-be_specific bool`

Controls the behavior of the schematic generation as to whether additional objects beyond those specifed using -clct. If not specifed, or specifed as false, additional objects will be included in the new schematic to provide connectivity and context. If specified as true, only the objects specified will be included in the new schematic.

Description

The command generates a new schematic view from the current selection or an object collection if specified.

Examples

The following example generates a schematic view of the hierarchical cell named RAM_1.

```
prompt> gui_create_schematic -clct [find cell RAM_1]
```

Feedback

- change_selection

---

gui_create_task

Create a task.

Syntax

gui_create_task

```
-task          TaskName
-item_root     ItemRootName
[-default]

TaskName          String
ItemRootName      String
```

Arguments

`-task` *TaskName*

TaskName specifies the name of the new task. Task name must be unqiue.

`-item_root` *ItemRootName*

ItemRootName specifies the name of the task root that will be associated with the task. Item root names are unique. If the same item root is associated with multiple tasks, then the tasks share the same item root.

`-default`

This option specifies that this command will be the default task set as the current task. If another task is later created with this option, the the later setting overrides any previous settings.

Description

This command creates a task. A task defines the user task context for the whole application. Tasks may be used to configure menus and also to present a hierarchical list of task items to the user to navigate in the Task Assistant. The hierarhical list of task items is defined with the gui_create_task_item command.

Examples

The following simple example creates a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -task MyAppTask -item_root MyAppTaskRoot
```

Feedback

```
gui_create_task_page -name InputFormPage -format tk -source
 create_widget_proc
gui_create_task_page -name AppDocument -format html
 -source ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask
 -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask
 -page AppDocument
```

See Also

- gui_create_task_item
- gui_create_task_page

---

gui_create_task_item

Create an item in the task tree to access in the Task Assistant.

Syntax

gui_create_task_item

```
-name           ItemName
<-task TaskName | -item_root ItemRootName>
-page           PageName
[-search_terms  TermsList]

ItemName          String
TaskName          String
ItemRootName      String
PageName          String
TermsList         List
```

Arguments

`-name ItemName`

ItemName specifies the hierarchical name given to the task item being created. This is also the text displayed to the user in the Task Assistant.

`-task TaskName`

TaskName specifies the task in which this task item is created. If a task name is used to create the task item, the item is inserted into the task item root associated with the task in the create_task command. If other tasks use the same item root, they will also see the new task item created with this command. This option is mutually exclusive with the -item_root option. One must be specified but not both.

Feedback

`-item_root` *`ItemRootName`*

ItemRootName specifies the task item root in which this task item is created. Item root names are associated with task names with the gui_create_task command and allows multiple tasks to share a single task item root. This option is mutually exclusive with the -item_root option. One must be specified but not both.

`-page` *`PageName`*

PageName specifies the page content factory associated with this task item. When the user selects the task item, the page specified by this option will be constructed and shown in the Task Assistant.

`-search_terms` *`TermsList`*

TermsList specifies additional terms that can be matched by the command search feature to find this task item. For example, if the task page allows the user to specify values for input parameters to a command, you may want to associate the name of that command as additional search term for the task item.

Description

This command creates a task item in the given task. Task items are defined in a hierarchy with hierarchy levels delimited by the separator string "->". The hierarchy of task items are shown in the task item navigation tree in the Task Assistant.

When the user selects a leaf item in the task navigation tree, the Task Assistant will show the task page associated with the item by this command. Currently, the pages can either be constructed from an HTML document or from a Tk widget factory.

Examples

The following simple example adds a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot

gui_create_tk_task_page -name InputFormPage -create_command
 create_widget_proc
gui_create_html_task_page -name AppDocument -path ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask
 -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask
 -page AppDocument
```

See Also

- gui_create_task

Feedback

gui_create_task_page

Creates a task page with Command Form, HTML content or Tk Command Form.

Syntax

gui_create_task_page

```
-name taskPageName
-format pageType
-source contentSource
```

Data Types

taskPageName string

pageType string

contentSource string

Arguments

-name *taskPageName*

taskPageName specifies the name of a new task page.

-format *pageType*

Define this new page as a specified Type Page. *pageType* can be command, html, tk or tab. Which specifies the Command Form Page, HTML Page, Tk Command Form Page or Tabs Page.

-source *contentSource*

Define the content to be shown in this page. If this page is a Command Form Page or a Tk Command Form Page, *contentSource* is the command name. If it is a HTML Page, *contentSource* specifies the full path to the file with HTML source for the task page. If it is a Tabs Page, *contentSource* specifies a list of existing page names or page&title pairs.

Description

The *gui_create_task_page* command creates several kinds of task pages which can be shown in the task assistant. The name option value is the unique name of the page. The format option defines which kind of page to be created and the source option defines what content to be shown in the task page.

Examples

The following simple example creates three new task pages, then show them in the task assistant.

Feedback

```
prompt> gui_create_task_page -name page1 -format command -source
 gui_report_map
prompt> gui_create_task_page -name page2 -format html
 -source ./MyAppDocument.html
prompt> proc create_widget_proc {widgetName parentName} {
          p#populate $wigetName with Tk
        p}
prompt> gui_create_task_page -name page3 -format tk -source
 create_widget_proc
prompt> gui_create_task_page -name page4 -format tab -source {page1 page2
 {page3 title} }
prompt> gui_create_task -task "Testing Task" -item_root
 test_task_item_root
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 1"
 -page page1
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 2"
 -page page2
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 3"
 -page page3
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 4"
 -page page4
prompt> gui_show_task -task "Testing Task:Testing Page"
```

---

gui_create_timing_plot

Creates a plot for timing.

Syntax

status *gui_create_timing_plot*

```
[-type type]
-objects objects
-attribute attribute_name
-tcl_cmd tcl_command
[-view view_name]
[-title title_label]
[-num_bins num_bins]
[-min min_value]
[-max max_value]
[-greater_than gt_value]
[-less_than lt_value]
[-midpoint mid_value]
[-worst worst_side]
```

```
[-xlabel x_axis_label]
[-ylabel y_axis_label]
[-bin_width bin_width]
[-max_num_bins max_num_bins]
[-output_file file_path]
[-verbose]
```

Data Types

```
type                string
objects             list | collection | string
attribute_name      string
tcl_command         string
plot_name           string
view_name           string
title_label         string
num_bins            integer
min_value           float
max_value           float
gt_value            float
lt_value            float
mid_value           float
worst_side          string
x_axis_label        string
y_axis_label        string
bin_width           float
max_num_bins        integer
```

Arguments

`-type type`

Specifies the type of the timing plot. It currently supports *histogram*. The default value is *histogram*.

`-objects objects`

Specifies the objects to collect the data. It can be an object list, a collection, or a pre-defined category or objects, such as *failing_timing_paths*.

failing_timing_paths is identical to calling *get_timing_paths -delay_type min_max -pba_mode path -slack_lesser_than 0.0 -max_paths 2000000*.

`-attribute attribute_name`

Specifies the name of the attribute to construct the timing plot. The value of the named attribute will then be used. If an object does not have the attribute value, a message is issued and the object is excluded from the timing plot. The options *-attribute* and *-tcl_cmd* mutually exclusive.

If the object in *objects* is a timing path, a pre-defined word can be used as *attribute_name*, such as *slack*, *datapath_delay*, and *logic_depth*.

`-tcl_cmd` *`tcl_command`*

Specifies the Tcl command to construct the timing plot. The Tcl command is evaluated for each object in *objects*. If the Tcl command evaluation fails for any object, a message is issued and the object is excluded from the timing plot. The options *-attribute* and *-tcl_cmd* mutually exclusive.

The Tcl command should be a Tcl procedure with only one argument. The command takes an object in *objects* as the input and returns a real value as the output.

`-view` *`view_name`*

Specifies the name of a new or an existing view.

`-title` *`title_label`*

Specifies the label to use for the timing plot. If not specified, a default title is constructed by concatenating *y_axis_label* and *x_axis_label*.

`-num_bins` *`num_bins`*

Specifies the number of bins to use in creating the histogram. The value must be greater than or equal to 1.

`-min` *`min_value`*

Specifies the minimum value to use in the timing plot. The default value is negative infinity. Any object whose associated value is less than this value is to be dropped from the timing plot with an information message.

`-max` *`max_value`*

Specifies the maximum value to use in the timing plot. The default value is positive infinity Any object whose associated value is greater than this value is to be dropped from the timing plot with an information message.

`-greater_than` *`gt_value`*

Specifies the non-inclusive least value limit to use in the timing plot. The default value is negative infinity. Any object whose associated value is less than or equal to this value is to be dropped from the histogram with an information message.

`-less_than` *`lt_value`*

Specifies the non-inclusive greatest value limit to use in the timing plot.
The default value is positive infinity. Any object whose associated value is greater than or equal to this value is to be dropped from the histogram with an information message.

`-midpoint` *`mid_value`*

Specifies the midpoint value to use in interpreting histogram bins. The default value is zero if *objects* is *failing_timing_paths*. An x-axis tick mark is placed on the midpoint value and all bins to the *worst* side of the midpoint are colored red while all bins to the other side of the midpoint are colored green. The *worst* side is *none* by default but can be set to *left* or *right* using the *-worst* option.

`-worst` *`worst_side`*

Specifies whether values less than or greater than the midpoint are to be considered "worst." Allowed values are *left*, meaning that values less than midpoint are worse; *right*, meaning that values greater than the midpoint are worse. If *objects* is *failing_timing_paths*, the default value is *left*. If not the default value is *none* meaning neither side is worst.

`-xlabel` *`x_axis_label`*

Specifies the label to place along the x-axis of the timing plot. If *attribute_name* is specified, the default value is *attribute_name*. If *tcl_command* is specified, the default value is *tcl_command*.

`-ylabel` *`y_axis_label`*

Specifies the label to place along the y-axis of the timing plot. If *objects* is *failing_timing_paths*, the default value is *timing paths*. Otherwise, The default value is "Count".

`-bin_width` *`bin_width`*

Specifies the width of each bin. The value must be greater or equal to 1e-12.

`-max_num_bins` *`max_num_bins`*

Specifies the maximum number of bins allowed when the width of each bin is specified. The value must be greater than or equal to 1.

`-output_file` *`file_path`*

Specifies the file path of the output image. It supports different image format, including bmp, jpg, png, pbm, pgm, ppm, xbm, xpm, and svg.

It is useful to view the plot when the GUI is off.

`-verbose`

Outputs more information messages.

Description

The *gui_create_timing_plot* command constructs a timing plot with the values from the object in *objects* evaluated by the given attribute name or Tcl command.

Feedback

Examples

These examples show creation of custom histograms using the *gui_create_timing_plot* command.

The following example shows creating a timing histogram showing the slacks of the failing timing paths.

```
pt_shell> gui_create_timing_plot -type histogram \\
                -objects failing_timing_paths -attribute slack
1
```

If the GUI is off, the -output_file option should be specified. Otherwise, an error message will be issued.

```
pt_shell> gui_stop -close
pt_shell> gui_create_timing_plot -type histogram \\
                -objects failing_timing_paths -attribute slack
Error: The GUI is off and the -output_file option is not specified.
0
```

The following example shows creating a timing histogram using the *-attribute* flag to retrieve an attribute value for each object in a pin list. In this example, the *fanout_load* attribute value is used to bin all pins in the design. The plot is labeled with the title string "Pin Fanout" using the *-title* option. The new view is named *My View* by the *-view* option,

```
pt_shell> gui_create_timing_plot -type histogram \\
                -objects [get_pins *] -attribute fanout_load \\
                -title "Pin Fanout" -view "My View"
1
```

The following example shows creation of another histogram binning cells by area. The plot is added into the view named *My View* in the previous example.

```
pt_shell> gui_create_timing_plot -type histogram \\
                -objects [get_cells *] -attribute area \\
                -title "Cell area" -view "My View"
1
```

The following example shows creation of a histograms using the *-tcl_cmd* flag to use a user-defined Tcl procedure to retrieve a value for each object in *objects*. First, we define a Tcl procedure named "myproc" that retrieves the *fanout_load* attribute value for the object that is passed in the procedure argument.

```
proc myproc { obj } {
    set result [get_attribute $obj fanout_load]
    return $result
}
```

The procedure "myproc" can then be used in the *gui_create_timing_plot* command.

Feedback

```
pt_shell> gui_create_timing_plot -type histogram -tcl_cmd myproc \\
          -title "Pin Fanout" -objects [get_pins *]
1
```

In this example, the embedded command *[get_pins *]* is first interpreted to create a collection of all pins in the design. The Tcl procedure "myproc" is then invoked for each pin object in the collection to retrieve a value per pin to use in creating the histogram.

See Also

- collections
- get_timing_paths

---

gui_create_tk_palette_type

Create a type of Tk palette.

Syntax

```
status gui_create_tk_palette_type
-type string
-title string
[ -icon string ]
-window_types string_list
[ -dock_edge dock_edge ]
-create_command string
```

Data Types

```
dock_edge  string
```

Arguments

`-type string`

Unique palette type name for the palette.

The type name must be non-empty, must start with a letter or underscore, and must only contain letter, number or underscore characters.

`-title string`

Title string for the palette.

`-icon string`

Icon to display for the palette.

`-window_types string_list`

List of window types which the palette is to be added to.

Feedback

`-dock_edge` *dock_edge*

The default edge to add the palette

```
left   - dock on left edge
right  - dock on right edge
top    - dock on top edge
bottom - dock on bottom edge
```

`-create_command` *string*

The option specifies the tcl command to be run when the palette is created so that the palette's tk widget can be populated with tk child widgets and any other initialization can be performed.

The tcl procedure takes two arguments 'windowName' and 'parentName' where 'windowName' is the tk palette widget to populate and 'parentName' is the name of the parent window.

Description

Creates a user defined tk palette when a window of any of the specified types is created.

Examples

The following example creates a palette of type 'mypalette', with a title of 'My Palette' which calls the 'build_my_palette' tcl procedure to populate the palette with tk widgets whenever a new window of type 'LayoutWindow' is created.

The 'build_my_palette' creates a text entry filed in a frame for the palette.

```
shell> proc build_my_palette {windowName parentName} {
   set top_frame [frame $windowName.frame]
   pack $top_frame -fill both -expand 1
   set entry [entry $top_frame.entry -textvariable $::var]
   pack $entry
 }
shell> gui_create_tk_palette_type -type mypalette -title "My Palette" \\
  -create_command build_my_palette -window_types "LayoutWindow"
 -dock_edge right
```

---

gui_create_toolbar

Create a toolbar with the specified name.

Syntax

string *gui_create_toolbar* -name *ToolBarName*

```
[-title       Title]
[-dock_side   DockSide]
```

Feedback

```
[-hidden]
[-window_type WindowTypeName]

ToolBarName     String
Title           String
DockSide        String
WindowTypeName  String
```

Arguments

`-name ToolBarName`

ToolBarName is the toolbar identifier for the new toolbar.

`-title Title`

Title specifies the title or caption of the toolbar.

`-dock_side DockSide`

DockSide specifies the side of the window the tool docks to by default. The legal values are top, bottom, left, right.

`-hidden`

-hidden specifies the toolbar should be hidden by default.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command creates a toolbar with the given name and title. Returns the name of the toolbar created.

Examples

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

See Also

- gui_set_hotkey
- gui_report_hotkeys

Feedback

gui_create_toolbar_item

Create a button in the specified toolbar.

Syntax

string *gui_create_toolbar_item* -toolbar *ToolBarName*

```
<-menu MenuName|-separator SeparatorName>
[-window_type WindowTypeName]
[-dropdown_menu MenuName]
[-dropdown_icon IconName]

ToolBarName     String
MenuName        String
SeparatorName   String
WindowTypeName  String
IconName        String
```

Arguments

`-toolbar ToolBarName`

ToolBarName specifies the toolbar that the new toolbar item will be added to.

`-menu MenuName`

MenuName specifies the name of the menu item to be invoked from this toolbar button. The "name" of a menu is a string whcih specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -separator option.

Feedback

`-separator` *`SeparatorName`*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -menu option.

`-window_type` *`WindowTypeName`*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-dropdown_menu` *`MenuName`*

MenuName specifies the associated menu to add as a dropdown menu for the item.

`-dropdown_icon` *`IconName`*

IconName specifies the icon to display on the dropdown menu button.

If not specified a standard menu will be used.

Description

This command adds a toolbar button to the specified toolbar using information described in the -menu option. The -menu option specifies the hierarchical menu name for some menu item. Thus, the toolbar icon becomes another interface for a menu item. Returns the item name if successful.

Examples

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

Create a drop down menu button that has actions that run a command

```
gui_create_menu -menu "Item 1" -tcl_cmd "echo 1" -root "my_root"
gui_create_menu -menu "Item 2" -tcl_cmd "echo 2" -root "my_root"
gui_create_toolbar -name "MyToolbar" -title "My Toolbar" -dock_side top
gui_create_toolbar_item -toolbar MyToolbar -menu "Item 1" \
  -dropdown_menu "my_root" -dropdown_icon my_icon
```

- gui_report_hotkeys

Feedback

---

gui_create_utable

Create a new UserTable.

Syntax

string *gui_create_utable*

```
-name              Table_Name
-parent            Table_Name
-columns           Column_List
-timing_path       Tim_Clct
[-expr_columns     Column_Expr_List]
[-meta_obj         MetaObj_Name]
[-replace]
[-fixed_name]

Table_Name         String
Column_List        List of Strings
Column_Expr_List   A list of column-expression pairs
Tim_Clct           Timing Path Collection
MetaObj_Name       String
```

Arguments

`-name` *Table_Name*

The name of the user table to create.

`-parent` *Table_Name*

The name of the parent table that is related to this user table.

`-columns` *Column_List*

A TCL list of column names for the table with optional data type Xpostfix information.

Feedback

`-expr_columns` *`Column_Expr_List`*

This allows you to create an expression that fills a table column with the result of that expression. The option is a list of column-expr pairs. Thus the list must have an even number of elements where the odd elements are the column names and the even number elements are the associated expression.The expression can reference other column values by surounding the column name in the following syntax: @{...}. The expression itself can include operators like '+','-','/' and '*' and parentheses. See the example below and see *gui_append_utable* for more info.

`-timing_path` *`Tim_Clct`*

Create and fill a Timing Point Table with the given Timing Path Collection. This is exclusive with the -columns option.

`-meta_obj` *`MetaObj_Name`*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-replace`

If a table already exists with that name, replace it.

`-fixed_name`

Mark the table name as 'fixed' so that it can not be changed in the GUI.

Description

```
This command creates a new user table with the given list of column
 names.
In addition, column names can have postfixes that describe the data type
 of that column.
Or one can use a MetaData object to define the column data types.

Important: This command returns the actual table name created which might
be different if the given table name had bad characters or already
 exists.
So, capture the return value and use it in future calls to this table.

Supported column name postfixes are:

  :string
  :int
  :double
  :cell
  :net
  :port
  :pin
  :point
```

:endpoint
:file

Examples

```
The following example creates a new UserTable with the given list of
 columns. The last
three columns also have some data type postfixes. Also note that the
 return value of
the create is captured since the name could be altered if it contained
 illegal chars.
This captured name is then used in following commands like the append
 command.
This example also adds an empty column at the end which is then filled
 with an
expression that references other columns.

set tableName [gui_create_utable -name MyTable -replace \\
                    -columns {
                      full_name
                      arrival:double
                      delay:double
                      {Expr Col:double}
                    } \\
                    -expr_columns {
                      {Expr Col} { 100 * (@{arrival} + @{delay}) }
                    }
               ]

# Append a TCL row: (note: that expr column is empty: {} )

gui_create_vm

Creates a new visual mode container for visual mode buckets. The buckets contain coloring attributes for a collections of design objects.

Syntax

string *gui_create_vm*

```
-name identifier
[-update_cmd update_command]
[-title label]
[-help_topic subject]
[-infotip infotip]
[-discrete  true | false]
[-icon string]
[-netfilter string]
[-float bool]
[-top_exaggeration float]
[-mid_exaggeration float]
[-bot_exaggeration float]
[-show_only_pins_of_nets bool]
[-enable_bucket_delete bool]
```

Data Types

```
identifier          string
update_command      string
label               string
subject             string
infotip             string
net_filter          string
icon_spec           string
```

Arguments

`-name identifier`

Specifies the name that identifies the visual mode. Use this name when another visual mode command requires a visual mode name.

`-update_cmd update_command`

Specifies a Tcl command to execute when the visual mode is accessed. Use this option to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-title` *label*

Specifies an optional title that is used to label the visual mode in the GUI. The *label* string can contain space characters. By default, the title is the empty string, and the *-name* option value is used to provide the label.

`-help_topic` *subject*

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

`-infotip` *infotip*

Specifies the infoTip text string.

`-discrete true | false`

Specifies an optional true or false string indicating whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. By default, visual modes are discrete.

`-icon` *string*

Specifies the icon file. The file contains an icon image for the GUI menus.

`-netfilter` *string*

Specifies the net connection filtering.

`-float true | false`

Specifies whether the bucket contents have a floating point range. By default, this option is false.

`-top_exaggeration` *float*

Specifies the exaggeration for the top bucket. The value should be greater than or equal to zero. By default, the value is 0.

`-mid_exaggeration` *float*

Specifies the exaggeration for the middle bucket. The value should be greater than or equal to -1. By default, the value is -1.

`-bot_exaggeration` *float*

Specifies the exaggeration for the bottom bucket. The value should be greater than or equal to zero. By default, the value is 0.

`-show_only_pins_of_nets true | false`

Specifies whether the layout shows pins of net objects in buckets. By default, the value is false.

Feedback

`-enable_bucket_delete true | false`

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

Description

The *gui_create_vm* command creates an instance of a visual mode. The visual mode provides a container for visual mode buckets, which associate coloring attributes with collections of design objects.

If the -update_cmd that you specify needs input from the user, then you can define the arguments to your procedure with define_proc_attributes, and then use the gui_show_command_form command for your procedure as the -update_cmd. This will show a form that will prompt for the arguments to your procedure and then it will call your proc to update the visual mode using those values. See the man pages for gui_show_command_form and define_proc_attributes for additional details.

Examples

The following example creates a new visual mode named mycoloring1 with the GUI label "Cells Colored By X":

```
prompt> gui_create_vm -name mycoloring1 -title {Cells Colored By X}
```

---

gui_create_vm_objects

Create objects to hold annotations in visual modes

Feedback

Syntax

string *gui_create_vm_objects <clct>*

```
string <clct>
```

Arguments

<clct>

Objects to convert.

Description

Layout visual modes are used to color objects in the layout given certain criteria. Sometimes you want not only object coloring but some additional annotations displayed with the objects in a bucket.

In order to create this type of visual mode, you need special type of object that can hold annotations. Use this command to create these special objects.

Objects of this type support name and core_obj attribute. The core_obj attribute returns the object that was used to create this object.

Examples

shell> *set objs [gui_create_vm_objects $cells]*

- gui_update_vm_annotations

---

gui_create_vmbucket

Create new Visual Mode Bucket

Syntax

string *gui_create_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip *infotip*] [-netfilter *net_filter*] [-color *color*] [-pattern *pattern*] [-exaggeration double] [-number int] [-maxval double] [-minval double] [-visible *visibility*] [-title *label*] [-collection *handle*] [-above *bucket_identifier* | -below *bucket_identifier* -at *top*| *bottom*]

```
string mode_identifier
string bucket_identifier
string infotip
```

Feedback

```
string net_filter
string color
string pattern
string visibility
string label
string handle
string bucket_identifier
string bucket_identifier
string top|bottom
```

Arguments

`-vmname mode_identifier`

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name bucket_identifier`

Specifies the name by which the visual mode bucket will be identified. It is used as the argument when associated visual mode commands require a visual mode bucket name to be specified.

`-infotip infotip`

String for infotip.

`-netfilter net_filter`

Specifies net connection filtering.

`-color color`

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

`-pattern pattern`

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

`-exaggeration double`

Specifies bucket min pixel exaggeration value >= 0.

`-number int`

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

Feedback

`-maxval double`

Specifies bucket maximum value.

`-minval double`

Specifies bucket minimum value.

`-visible` *visibility*

Specifies initial visibility of bucket. Valid values are TRUE and FALSE.

`-title` *label*

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

`-collection` *handle*

Tcl object collection to be colored by this visual mode bucket.

`-above` *bucket_identifier*

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

`-below` *bucket_identifier*

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

`-at` *top|bottom*

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

Description

The gui_create_vmbucket command creates an instance of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The visual mode bucket can be assigned coloring styles and a collection of design objects to which the coloring will be applied when they are rendered as a part of the visual mode.

Examples

Create a visual mode with two buckets, one whose objects will be colored red, and another whose objects will be colored blue:

shell> *gui_create_vm -name foo1 -title "My Visual Mode"*

shell> *gui_create_vmbucket -vmname foo1 -name red -title "Red" -color red*

Feedback

shell> *gui_create_vmbucket -vmname foo1 -name blue -title "Blue" -color blue -below red*

---

gui_create_window

Creates a window of the specified window type.

Syntax

```
string gui_create_window
-type window_type
[ -parent parent_window_id ]
[ -show_state window_state ]
[ -title title ]
[ -rect rect | -size {width height} ]
[ -icon icon ]
```

Data Types

```
window_type          string
parent_window_id     string
window_state         string
title                string
rect                 rectangle
width                integer
height               integer
icon                 string
```

Feedback

Arguments

`-type` *`window_type`*

Specifies the type of window you are creating. The tool creates an instance of this window type.

You can display a list of the supported window types by using the *gui_get_window_types* command.

`-parent` *`parent_window_id`*

Specifies the window ID of the parent top-level window for the view window you are creating.

If you do not specify a window ID and the window type is not a top-level window type, the tool uses the current top-level window. If there is no current top-level window, the tool creates a new top-level window automatically to host the window you are creating.

`-show_state` *`create_window_state`*

Specifies the window state in which to display the window you are creating. The result varies depending on whether the window is a top-level window or a view window.

For a top-level window, you can specify one of the following states:

```
maximized -- show maximized (fill whole screen)
minimized -- show iconified
normal    -- show at preferred size
```

Note that the window manager might not fully honor the specified state. See your window manager documentation for more details.

For a view window, you can specify one of the following states:

```
maximized -- show maximized in view area and raise to top
minimized -- show iconified in view area
normal    -- show at preferred size in view area and raise to top
```

If you display a view window in its maximized state, the tool also maximizes any existing view windows. If you display a view window in its minimized or normal state, the tool changes any maximized view windows to their normal states.

The default is -show_state normal.

`-title` *`title`*

Specifies the title for the top-level or view window you are creating.

Note that the window manager might not fully honor the specified top-level window title string. See your window manager documentation for more details.

Feedback

`-rect rect`

Specifies the size and position of the window in the following format:

`{{x1 y1} {x2 y2}}`

The coordinates {*x1 y1*} specify the location of the top-left corner, and the coordinates {*x2 y2*} specify the location of the bottom-right corner. These coordinates are relative to the top-left corner of the screen, for a top-level window, or to the top-right corner of the view area in the parent top-level window, for a view window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The *-rect* option and the *-size* option are mutually exclusive.

`-size {width height}`

Specifies the width and height of the window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The *-size* option and the *-rect* option are mutually exclusive.

`-icon icon`

Specifies the image to be used for the top-level or view window icon.

For a view window, the icon appears in the top-left corner of the title bar when the window is in its normal or minimized state and at the left side of the menu bar when the window is maximized.

For a top-level window, the icon might not be displayed when the window is in its normal, minimized, or maximized state. See your window manager documentation for more details.

Description

This command creates a window of the specified type and returns the window ID. The window type that you specify controls whether the window is a top-level window or a view window.

Examples

The following example creates a top-level layout window and a minimized layout view window.

```
prompt> set top [gui_create_window -type LayoutWindow]
LayoutWindow.1
prompt> gui_create_window -type Layout -parent $top \\
```

Feedback

```
   -show_state minimized
layout.1
```

---

gui_create_window_toolbar_group

Create group in view toolbar

Syntax

```
status gui_create_window_toolbar_group
[ -window window_id ]
[ -toolbar string ]
[ -group string ]
-type string
-name string
[ -label string ]
[ -icon string ]
[ body ]
```

Data Types

window_id string

Arguments

-window *window_id*

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

-toolbar *string*

Specifies the toolbar id.

Feedback

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-group` *string*

Specifies the parent group name.

`-type` *string*

Specifies the group type.

If the string '?' is specified for the type, the command will return a list of allowed types.

`-name` *string*

Specifies the unique name for the group.

Note: The command will fail if the name has already been used in a toolbar.

`-label` *string*

Specifies the optional label for the group.

`-icon` *string*

Specifies the optional icon for the group.

body

Tcl commands to add items or sub groups to the group.

Description

This command adds a new control group to the specified view's toolbar.

Examples

The following example will create buttons in a stamp group in the toolbar of the specified Charts View and attach a callback when any button is pressed.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   gui_create_window_toolbar_group -name buttons -type stamp -label
 Controls {
shell>     set button1 [gui_create_window_toolbar_item -name button1
 -type button]
shell>     set button2 [gui_create_window_toolbar_item -name button2
 -type button]
shell>     set_attribute $button1 label "Button 1"
shell>     set_attribute $button2 label "Button 2"
shell>     set_attribute $button1 activated_proc buttonPressed
shell>     set_attribute $button2 activated_proc buttonPressed
shell>   }
shell> }
```

Feedback

```
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
shell> gui_show_window_toolbar -window $charts
```

See Also

---

gui_create_window_toolbar_item

Create item in view toolbar

Syntax

```
status gui_create_window_toolbar_item
[ -window window_id ]
[ -toolbar string ]
[ -group string ]
-type string
-name string
[ -label string ]
[ -icon string ]
```

Data Types

```
window_id  string
```

Arguments

`-window window_id`

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-toolbar string`

Specifies the toolbar id.

Feedback

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-group` *string*

Specifies the optional name of the group to add the item to.

Note: Only allowed when no active group.

`-type` *string*

Specifies the item type.

If the string '?' is specified for the type, the command will return a list of allowed types.

`-name` *string*

Specifies the unique name for the item.

Note: The command will fail if the name has already been used in a toolbar.

`-label` *string*

Specifies the label for the item.

`-icon` *string*

Specifies the icon for the item.

Description

This command adds a new control item to the specified view's toolbar.

The control is added to the current active group or in it's own stamp if there is no current group

Examples

The following example will create a button in the toolbar of the specified Charts View and attach a callback when the button is pressed.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   set button [gui_create_window_toolbar_item -name button -type
 button]
shell>   set_attribute $button activated_proc buttonPressed
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
shell> gui_show_window_toolbar -window $charts
```

Feedback

gui_create_window_toolbar_type

Create new type for view toolbar

Syntax

```
status gui_create_window_toolbar_type
-type string
[ -name string ]
[ -icon string ]
-view_types string_list
-command string
[ -apply ]
```

Arguments

`-type string`

Specifies the toolbar type.

The toolbar type must be unique.

`-name string`

Specifies the user visible name for the toolbar.

If not specified then the type name is used.

`-icon string`

Specifies the optional icon for the toolbar.

`-view_types string_list`

Specifies the window view types which the toolbar can be added to.

`-command string`

Specifies the command to run to initialize the toolbar.

`-apply`

Specifies that the type will be applied to existing views.

Feedback

Description

This command defines a new toolbar type which will be populated using the user supplied tcl proc when the toolbar is created in the associated view.

Examples

The following example will create a user toolbar in the Charts view with a button.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   gui_create_window_toolbar_group -name stamp -type stamp {
shell>     set button [gui_create_window_toolbar_item -name button -type
 button]
shell>     set_attribute $button label "Button"
shell>     set_attribute $button activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

---

gui_define_charts_proc

Define tcl command to use in charts expression evaluation

Syntax

```
status gui_define_charts_proc
name
args
body
```

Arguments

name

Name of the procedure.

Feedback

The procedure name must be non-empty, start with an underscore or a letter and contain only underscore or letter characters.

args

The arguments of the procedure.

body

The body of the procedure.

Description

Define custom tcl command to use in charts expression evaluation.

The syntax and arguments are the same as the standard tcl *proc* command.

If the arguments and body strings are empty then any existing procedure of that name is deleted.

To list all the defined charts procedures you can use the command:

```
shell> gui_get_charts_data -global -name procs
```

To get the args and body for an existing procedure you can use the command:

```
shell> gui_get_charts_data -global -name proc_data -data <proc_name>
```

Examples

The following example changes a model to create a new column with the square root of values in the first column.

```
shell> gui_define_charts_proc test_proc { arg } { return [expr
 {$arg/2.0}] }
shell> gui_change_charts_model -model $model -add -expr
 "test_proc(column(0))" -type real
```

See Also

- gui_change_charts_model

---

gui_delete_attrgroup

Removes a group of attributes or all attribute groups for an object type.

Syntax

```
status gui_delete_attrgroup
-class design_object
-name name
```

Feedback

```
[-all]
[-quiet]
```

Data Types

```
design_object       string
name                string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the name of the attribute group to be removed for the specified object type.

`-all`

Removes all attribute groups defined for the specified object type.

`-quiet`

Keep quiet and don't print any messages if command was not successfull.

Description

The *gui_delete_attrgroup* command removes the specified attribute group or all attribute groups for the specified object type.

Examples

```
prompt> gui_delete_attrgroup -class Cell -name "Hierarchy"
```

```
prompt> gui_delete_attrgroup -class Cell -all
```

See Also

- gui_create_attrgroup
- gui_list_attrgroups
- gui_update_attrgroup

---

gui_delete_menu

Delete a menu item for the toplevel menubar or a context menu

Syntax

string *gui_delete_menu*

Feedback

```
[-menu HierMenuName | -all]
[-window_type WindowTypeName | -root ContextMenuRoot]

HierMenuName    String
WindowTypeName  String
ContextMenuRoot String
```

Arguments

`-menu HierMenuName`

HierMenuName specifies the hierarchical menu name of the menu item to be deleted. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -all option.

`-all`

This option flag specifies all menu items in a menu root to be deleted. The option cannot be given with the -window_type option.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-root ContextMenuRoot`

ContextMenuRoot specifies the context menu root to from which the menu item will be added. A context menu root name groups menu items to be included in a pop-up context menu. A context menu is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

Description

This command deletes a menu item for the menu bar of a top level window. The menu hierarchy separator is denoted by "->". If there is a toolbar button or hotkeys defined for the menu being deleted they will also be deleted. If the path to the menu is a submenu that menu item and all its sub-items will be deleted.

The option -all may be used with a menu root name to remove all menu items from a menu. This is useful if a user wishes to customize or modify an entire context menu.

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default value of $::synopsys/admin/setup/.synopsys_galileo_gui.tcl. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_galileo_gui.tcl.

Examples

The following example deletes the Quit item from the File menu.

```
gui_delete_menu -menu "File->Quit"
```

---

gui_delete_toolbar

Delete a toolbar with the specified name.

Syntax

string *gui_delete_toolbar* -name *ToolBarName*

```
[-window_type WindowTypeName]

ToolBarName      String
WindowTypeName   String
```

Feedback

Arguments

`-name` *`ToolBarName`*

ToolBarName is the toolbar identifier for the toolbar to be deleted.

`-window_type` *`WindowTypeName`*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command deletes a toolbar and all of its toolbar items.

Examples

Delete a toolbar called mytoolbar.

```
gui_delete_toolbar -name mytoolbar
```

See Also

---

gui_delete_toolbar_item

Remove a toolbar button specified by the menu name from the specified toolbar.

Feedback

Syntax

string *gui_delete_toolbar_item* -toolbar *ToolBarName*

```
<-menu MenuName|-separator SeparatorName>
[-window_type WindowTypeName]

ToolBarName      String
MenuName         String
SeparatorName    String
WindowTypeName   String
```

Arguments

`-toolbar ToolBarName`

ToolBarName specifies the toolbar to be modified.

`-menu MenuName`

ItemName specifies the hierarchical menu name for some menu item, that this toolbar item is associated with. This option is mutually exclusive with the -separator option.

`-separator SeparatorName`

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -item option.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command deletes a toolbar item specified by *MenuName* or *SeparatorName* from the specified toolbar. Returns the name of the deleted toolbar item if successful.

Examples

Delete the button bound to File->Quit from the toolbar mytoolbar.

```
gui_delete_toolbar_item -name mytoolbar -menu "File->Quit"
```

See Also

- gui_set_hotkey
- gui_report_hotkeys

Feedback

---

gui_delete_window_toolbar_item

Delete view toolbar items

Syntax

```
status gui_delete_window_toolbar_item
[ -window window_id ]
[ -toolbar string ]
{ -item string | -all }
```

Data Types

```
window_id  string
```

Arguments

`-window window_id`

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-toolbar string`

Specifies the name of the toolbar to delete from.

`-item string`

Specifies the item name to delete.

`-all`

If set option is *not* specified then all items in the toolbar are deleted.

If set option is specified then all items in the set are deleted.

Feedback

Description

This command deletes one or more control items from the specified view's toolbar.

Examples

The following example will create a button in the toolbar of the specified Charts View and delete it.

```
shell> proc init_my_toolbar { args } {
shell>   set button [gui_create_window_toolbar_item -name button -type
 button]
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
shell> gui_delete_window_toolbar_item -window $charts -toolbar my_toolbar
 -item button
```

See Also

- gui_show_window_toolbar

---

gui_edit_vmbucket_contents

Edit the collection contents of a Visual Mode Bucket

Syntax

string *gui_edit_vmbucket_contents* -vmname *mode_identifier*

-name *bucket_identifier* [-add | -remove | -replace] [-collection *handle*]

```
string  mode_identifier
string  bucket_identifier
string  handle
```

Feedback

Arguments

`-vmname` *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name` *bucket_identifier*

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-add`

Add the collection to the collection already in the bucket

`-remove`

Remove the collection from the collection already in the bucket

`-replace`

Replace the collection already in the bucket

`-collection` *handle*

Tcl object collection to be colored by this visual mode bucket.

Description

The gui_edit_vmbucket_contents command modifies the collection stored in a visual mode bucket. The collection can either be appended to, removed, or replaced. The flags to control this are mutually exclusive.

Examples

Add the current selection to the collection in the bucket 0 of the SNAPSHOT visual mode:

shell> *gui_edit_vmbucket_contents -vmname SNAPSHOT -name 0 -add -collection [get_selection]*

See Also

Feedback

- gui_remove_vm
- gui_remove_vmbucket
- gui_set_vm
- gui_update_vm

gui_error_browser

Show or hide the Error Browser Dialog

Syntax

string *gui_error_browser*

[-hide | -show | -toggle]

Arguments

`-hide`

Hides the Error Browser Dialog.

`-show`

Shows the Error Browser Dialog. If no option flag is provided, this is the default.

`-toggle`

Show the Error Browser Dialog if it is currently hidden, else hide it.

Description

The *gui_error_browser* command controls the visibility of the Error Browser Dialog. The Error Browser Dialog displays violations with physical shapes recorded by a checker, for example a DRC engine. This command is valid only when there is a design open. If the Error Browser Dialog is shown and it was not previously shown. If the Error Browser Dialog is shown and it was previously shown, it will show the error data last loaded.

Examples

The following example creates and shows the Error Browser Dialog:

gui_error_browser -show

gui_eval_command

Executes and optionally logs a tool command language (Tcl) command.

Feedback

Syntax

string *gui_eval_command*

```
-command command
[-echo]
[-history]
[-honor_preview | -preview]
```

Data Types

command string

Arguments

`-command` *command*

Specifies the Tcl command to execute and to record in the command replay log.

`-echo`

Echoes the command and displays the command result in the console log view. By default, the tool does not echo the command or display the result in the log view.

`-history`

Appends the command to the command history list in the console history view. By default, the tool does not append the command to the command history list.

`-honor_preview`

This option is mutually exclusive with the -preview option. Honors the Preview Command Only settting in the dialog. By default, the tool does not honor the Preview Command Only settting.

`-preview`

This option is mutually exclusive with the -honor_preview option. Runs the given command in preview mode, irregardless of the current preview mode set from a command dialog. When -preview is given, -echo is turned on since the previewed command cannot be seen in the xterm if -echo is turned off. As with all commands issued from command dialogs when in preview mode, if a script editor is present, then the previewed command is redirected to the scripte editor. Using this option does not set or clear the global preview mode in the application.

Description

This command executes a Tcl command and records it in the command replay log. Use the *-echo* option to echo the command and its result in the console log view Use the *-history* option to append the command to the command history list. Use the

Feedback

-honor_preview option to honor the Preview Command Only settting. Use the *-preview* option to preview the command only without executing it.

The result of a nested command is passed back as the result of *gui_eval_command*.

Examples

The following example evaluates the command "echo abc".

```
prompt> gui_eval_command -command {echo abc}
abc
```

The following example previews the command "echo abc".

```
prompt> gui_eval_command -command {echo abc} -preview
abc
```

---

gui_eval_task_command

Executes a command from a task assistant page

Syntax

string *gui_eval_task_command*

```
-command command
[-task taskName | -script]
```

Data Types

```
command    string
command    taskName
```

Arguments

`-command command`

Specifies the Tcl command to execute and to add to the favorites and most-recently-used (MRU) palettes. The executed command is logged in the command log.

`-task taskName`

If this option is present, then the given task name is used when the command is added to the favorites and MRU palettes. If not present, then the current task name is used.

`-script`

This option is mutually exclusive with the -task option. If this option is present, the command is not run but is appended in the script editor.

Feedback

Description

This command executes the given Tcl command and records it in the command replay log. Use the *-script* option to append the command to the script editor only without executing it.

The result of a nested command is passed back as the result of *gui_eval_task_command*.

Examples

The following example evaluates the command "echo abc".

```
prompt> gui_eval_task_command -command {echo abc}
abc
```

The following example adds the command "echo abc" to the script editor.

```
prompt> gui_eval_task_command -command {echo abc} -script
abc
```

---

gui_execute_menu_item

Execute a menu item in the currently active window.

Syntax

```
status gui_execute_menu_item
{ -menu menu_item_id }
```

Data Types

```
menu_item_id      string
```

Arguments

`-menu menu_item_id`

menu_item_id specifies the hierarchical name of the menu item to execute. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item in the File menu. These names are allowed to also specify the keyboard accelerator for the menu text which is specified with an embedded '&', but they are not required to do so.

Description

This command checks for the existence and enabled state of the given menu item in the currently active window. If it exists and is enabled, the menu item is executed.

The command returns and result value string from the executed menu item, if any.

Feedback

Examples

The following example activates the main window named Toplevel.2, then executes the *Hierarchy Browser* menu item in the *View* menu in Tolevel.2.

```
shell> gui_set_active_window -window Toplevel.2
shell> gui_execute_menu_item -menu "View->Hierarchy Browser"
```

See Also

---

gui_exist_pref_category

Check the existence of a preference category.

Syntax

bool *gui_exist_pref_category* -category *Category*

```
Category        String
```

Arguments

`-category Category`

Category specifies the category.

Description

This command checks the existence of a preference category. Return "1" if the specified category exists, otherwise return "0".

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_get_pref_keys

Feedback

- gui_exist_pref_key
- gui_update_pref_file

---

gui_exist_pref_key

Check the existence of a preference key.

Syntax

bool *gui_exist_pref_key* -key *Key*

[-category *Category*]

```
Key             String
Category        String
```

Arguments

`-key Key`

Key specifies the preference key of interest.

`-category Category`

Category specifies the category. Default category will be used if missing.

Description

This command checks the existence of a preference key given the key name and the preference category. Return "1" if the specified key exists, otherwise return "0".

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value

- gui_get_pref_keys
- gui_exist_pref_category
- gui_update_pref_file

Feedback

gui_exist_window

Check for the existence of specified window or window type

Syntax

```
status gui_exist_window
{ -window window_id | -type window_type }
[ -parent window_id ]
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-window window_id`

Specifies the window id to test existence for.

This option is mutually exclusive with the *-type* option.

`-type window_type`

Specifies that the existence of a window of this window type is tested for.

If the *-parent* option is specified then the existence of a window of this window type is tested for in the specified toplevel window.

If the *-parent* option is *not* specified then the existence of a window of this window type is tested for in any toplevel window.

This option is mutually exclusive with the *-window* option.

`-parent window_id`

Specifies the toplevel window to check for existence in.

Note: This option is only relevant if the *-type* option is specified.

Description

This command checks the existence of the specified window, or window type across toplevel windows or within a specified toplevel window.

The command returns "1" or "0" for success or failure respectively.

Examples

The following example will create a toplevel window and a child layout view window, then check the existence of the command layout window.

Feedback

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> set layout_exist [gui_exist_window $x]
shell> if { $layout_exist == 1} {echo "layout exist" }
```

See Also

---

gui_export_utable

Export the UserTable to a value file.

Syntax

string *gui_export_utable*

```
-name         Table_Name
[-file        File_Name [-tsv_mode] [-ssv_mode]]
[-filter      Filter]
[-tsv_mode]
[-ssv_mode]
[-add_col_type]
[-add_metadata]
[-overwrite]

Table_Name    String
File_Name     String
```

Arguments

`-name Table_Name`

The name of the user table to export to a CSV value file.

`-file File_Name`

The name of the file to write the table to, by default the name of the table is used with the '.csv' extension.

Feedback

`-filter Filter`

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-add_col_type`

This flag will add column type information to be added as a postfix to the header column names. This allows type information to be available if imported again by this tool at a later time.

`-add_metadata`

Add metadata to the top of the exported table. See the command gui_set_utable_meta for more information.

`-overwrite`

This flag will force the destination file to be overwritten.

Description

```
This command exports the contents of the given UserTable into a CSV value
 file.
The first line contains all the column names and if the -add_col_type
 flag is
given, it also appends column data type information to the column names.
```

Examples

```
The following example just exports the given UserTable to a file with the
 same name
as the table plus a '.csv' extension.

shell> gui_export_utable -name my_table

The following example exports the UserTable 'my_table' to the filename
 'results' and
uses the Tab char as a delimiter. The resultant file will be called
 'results.tsv'.

shell> gui_export_utable -name my_table -file results -tsv_mode
```

Feedback

- gui_open_utable
- gui_show_utable
- gui_write_utable

---

gui_fill_utable

Fill generated data rows to an existing UserTable.

Syntax

string *gui_fill_utable*

```
-name              Name

-file_column       Name
-file_suffix       Suffix
-file_dir          Directory
-label_column      Name
-label_value       Value
-date_column       Name
-tag_column        Name
-title_column      Name

Name               String
File_Name          String
Suffix             File Suffix String
Directory          Directory Path String
Value              Value String
```

Arguments

`-name Name`

The name of an existing UserTable that the new data rows should be added to.

Feedback

`-file_column` *Directory*

The column name that is filled with the filenames found in the directory.

`-file_dir` *Directory*

The directory path to search for files matching the file suffix option.

`-label_column` *Name*

The column name that is filled with a label for each entry added.

`-label_value` *Value*

The label value used to fill the -label_column argument as each entry is added.

`-date_column` *Name*

The column name used to fill in the date of the file that was added.

`-tag_column` *Name*

The column name used to fill in the metadata tag of the file if it exists.

`-title_column` *Name*

The column name used to fill in the metadata title of the file if it exists.

Description

Using the various options one can generate rows of data that include columns for file names, file dates, labels and if available in the file the tag and title meta data for all files found according to the specified file suffix and directory. For more information on Meta Data please see the command *gui_set_utable_meta*.

Examples

The following example creates a table of data where each row contains information about a CSV file that was found in the given directory. The filename is actual a link that when clicked will load that CSV file and make it a child of this table. Thus this basically creates a table of links to other tables represented by CSV files.

```
shell> gui_create_utable -name csv_toc \\
         -columns {status:boolean comment report file date tag title} \\

shell> gui_fill_utable -name csv_toc \\
         -file_column file \\
         -file_suffix ".csv" \\
         -file_dir "./csv_files/" \\
         -label_column report \\
```

Feedback

```
        -label_value value_files \\
        -date_column date \\
        -tag_column tag \\
        -title_column title
```

---

gui_foreach_utable_row

Iterate/visit the given table row column values for the given filter and call a TCL proc.

Syntax

string *gui_foreach_utable_row*

```
-name             Table_Name
-action           Action
-columns          Column_List
[-filter          Filter_Expr]
[-data            Data]

Table_Name       String
Action           TCL Procedure Name
Column_List      StringList
Filter_Expr      String
Data             String
```

Feedback

Arguments

`-name` *`Table_Name`*

The table name on which to visit all the rows filtered by the filter.

`-action` *`Action`*

The user TCL procedure that will be called on every row that matches the filter.

`-columns` *`Column_List`*

Provides a list of one or more column names whose data will be passed to the action procedure.

`-filter` *`Filter_Expr`*

To only visit a certain set of rows in the table you must ether first filter the table in the view or use this filter expression to only target the rows of interest.

`-data String`

Provides an optional data string that is passed to the user TCl proc.

Description

```
This command allows you iterate/visit each row in a table filtered
by the filter value and call a user given TCL procedure.
The procedure must accept two fixed arguments, the 'table_name'
and a 'user_data' argument which may be filled with the '-data' option.
This is then followed by an argument for every column name given which
will have the current row value for that column.
If no filter option is given the all rows will be visited unless the
table is currently viewed, then all rows will be visited that match
the current view filter setting.
```

Examples

```
The following example calls a print TCL procedure for every row that
matches the filter.

shell>
  proc printVal { table data pin direction } {
    puts "table: $table, data: $data, pin: $pin, direction: $direction"
  }

  gui_foreach_utable_row -name $table \\
    -columns {{full_name} {direction}} \\
    -action printVal -filter {slack > 0.0}

The following example uses the gui_set_utable_values command to update
the table values. This is not as efficient as calling the
 gui_set_utable_values
command for all filtered values but it gives you more control for each
row update action.
```

Feedback

```
shell>
  proc setVal { table data pin direction } {
    # Do some arbritary functions with the received data...
    # Update the table row itself:
    gui_set_utable_values -name $table -column direction \\
      -value $data -filter "{full_name} == $pin"
  }
  gui_foreach_utable_row -name $table \\
      -data out \\
      -columns {{full_name} {direction}} \\
      -action setVal -filter {slack > 0.0}
```

- gui_get_utable
- gui_set_utable
- gui_set_utable_values

---

gui_get_annotations

Return a collection of layout annotations

Syntax

string *gui_get_annotations*

[-window *window_name*] [-group *group_id*] [-within *region*] [-intersect] [-at *location*] [-filter *filter*] [-nocase] [-regexp]

```
string window_name
string group_name
string filter
rectangle region
location point
```

Arguments

`-window window_name`

Specifies the instance name of the layout window. If not specified implies all windows.

`-group group_name`

Specifies the annotation group name. If not specified implies all groups.

`-within region`

Search for annotations contained within the specified rectangle.

Feedback

`-intersect`

Use this option with the -within option. When -intersect is specified, all annotations that touch the search rectangle are also returned.

`-at` *`location`*

Search for annotations that are close to the specified point.

`-filter` *`filter`*

Only return annotations that satisfy the filter expression.

`-nocase`

Ignore case in the filter expression. Option requires -filter.

`-regexp`

Use regular expressions in the filter expression. Option requires -filter.

Description

Returns a collection of gui_annotation objects that satisfy the requirements. You can use get_attribute to query properties of the annotations. Also some attributes may be modified with set_attribute.

Examples

The following example retrieves all the annotations in the Layout.1 window.

```
shell> gui_get_annotations -window Layout.1
```

This example shows how to use the client_data attribute to find annotations with that setting.

```
shell> gui_get_annotations -filter client_data==MyData
```

This example shows how to find annotations that are within a specified rectangle

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}}
```

To also find the annotations that touch the search rectangle:

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}} -intersect
```

gui_get_bucket_option

Returns the value of a bucket option of a given visual or map mode.

Syntax

```
string gui_get_bucket_option
-map map_name
```

Feedback

```
-bucket bucket_name
-option option_name
[-default]
```

Data Types

```
map_name          string
bucket_name       string
option_name       string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-bucket bucket_name`

Specifies the name of the bucket.

`-option option_name`

Specifies the name of the option to be set.

`[-default]`

Specifies that command has to return default option value.

Description

This command returns an option value that are available for the bucket in the specified visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. The command can return either current or default value.

Examples

The following example returns the value of 'visible' option of 'light blue' bucket of 'Highlight' visual mode:

```
prompt> gui_get_bucket_option -map {Highlight} -bucket {light blue}
 -option {visible}
```

See Also

- gui_set_bucket_option
- gui_get_bucket_option_list
- gui_get_map_list
- gui_get_map_option

Feedback

- gui_get_map_option_list
- gui_set_map_option

---

gui_get_bucket_option_list

Lists the available options for buckets in the specified visual mode or map mode.

Syntax

```
string gui_get_bucket_option_list
-map map_name
```

Data Types

map_name	string

Arguments

`-map` *map_name*

Specifies the name of the visual mode or map mode.

Description

This command displays a list of all options that are available for the buckets in the specified visual mode or map mode.

Examples

The following example displays a list of the available options for buckets in the global route congestion map:

```
prompt> gui_get_bucket_option_list -map AREAPARTITION
```

See Also

- gui_get_bucket_option
- gui_get_map_list

- gui_get_map_option_list
- gui_set_bucket_option
- gui_set_map_option

Feedback

gui_get_category

Returns the contents of the specified category as a collection, including the contents of any offspring categories.

Syntax

collection *gui_get_category*

```
-category category_hierarchical_name
[-tree tree_id]
```

Data Types

category_hierarchical_name	list
tree_id	string

Arguments

`-category` *category_hierarchical_name*

Specifies the hierarchical name of the category whose contents are returned as a collection. The *category_hierarchical_name* value is a unique hierarchical name of a category in Tool Command Language (Tcl) list format.

`-tree` *tree_id*

Specifies the string ID of the category tree in which the get-category operation occurs. The current category tree is used if the *-tree* option is not specified.

Description

This command returns the contents of the specified category as a collection, including the contents of any direct or indirect offspring categories.

You should use this command only if at least one category tree is available. The command acts on the specified category tree.

Examples

The following example gets the contents of the ALL root category as a collection, including the contents of all direct or indirect offspring categories of the ALL root category, and captures the collection returned by the *gui_get_category* command in a Tcl variable:

```
prompt> set category_collection [gui_get_category -category {ALL}]
```

The following example gets the contents of the {Launch Clock: CLK1} category. This category is a child of the {Pathgroup: CLK1} category, which in turn is a child of the ALL root category.

```
prompt> set clct [gui_get_category \\
        -category {ALL {Pathgroup: CLK1} {Launch Clock: CLK1}}]
```

Feedback

See Also

- gui_create_category_rule
- gui_list_category_rules
- gui_remove_category_rules

---

gui_get_cell_block_marks

Gets a list of the block mark string values on one or more cells.

Syntax

list *gui_get_cell_block_marks*

```
        cells
```

Data Types

```
cells       list
```

Arguments

cells

Lists one or more cell name patterns or cell collections.

Description

This command gets the block mark string values from one or more hierarchical or leaf-level cell instances.

Examples

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_get_cell_block_marks I_TOP/I_ALU
ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the *get_cells* command, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
prompt> gui_get_cell_block_marks [get_cells I_TOP/I_ALU]
ALU
```

Feedback

The following example shows how using the *get_attribute* command to query the *block_mark* attribute is an alternative to using the *gui_get_cell_block_marks* command:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_get_cell_block_marks I_TOP/I_ALU
ALU
prompt> get_attribute -class cell I_TOP/I_ALU block_mark
ALU
```

---

gui_get_charts_data

Get charts data

Syntax

```
value gui_get_charts_data
{ -global | -model model_id | -view view_name |
-plot plot_name | -annotation annotation_name }
[ -column column_name ]
[ { -header | -row int } ]
-name string
[ -data string ]
```

Data Types

```
model_id          int
view_name         string
plot_name         string
annotation_name   string
column_name       int
value               string
```

Arguments

`-global`

Get global data.

`-model model_id`

Model to get data from.

`-view view_name`

View to get data from.

`-plot` *`plot_name`*

Plot to get data from.

`-annotation` *`annotation_name`*

Annotation to get data from.

`-column` *`column_name`*

Column to get model data from.

Only used by the *model* option.

`-header`

get model data from header.

Only used by the *model* option.

`-row` *`int`*

Row to get model data from.

Only used by the *model* option.

`-name` *`string`*

Name of data to return.

The supported names depend on which object the data is extracted from:

For model the following names are supported:

value Get value of model horizontal header (using the *header* option) value or row value (using the *row* option). The column is specified using the *column* option.

num_rows Get number of rows in model.

num_columns Get number of columns in model.

header Get model header names. If column is specified using the *column* option then only the header for that column is returned.

row Get model row values for the row specified using *row* option.

column Get model column values for the column specified using *column* option.

duplicates Get rows with duplicate values (same value in all columns).

column_index Get model column index from name specified in *data* option.

name Get the model name.

title Get the model title.

Feedback

The following data names are queried on the specifed column (single value) or, if the column is not specified, then on all columns (list of values):

type Get model column type.

min or minimum Get model minimum column value.

max or maximum Get model maximum column value.

mean or avg or average Get model average column value.

monotonic Get if model column monotonic (increasing or descreasing)

increasing Get if model column increasing

num_unique Get number of unique model values in column.

unique_values Get unique model values in column.

unique_counts Get counts of each unique model value in column.

num_null Get number of null values in column.

median Get model median column value.

lower_median Get model lower median column value.

upper_median Get model upper median column value.

stddev or std_dev Get model standard deviation value.

outliers Get model outlier values.

For view the following names are supported:

plots return a list of all plots in the view.

annotations return a list of all annotations in the view.

selected_objects return a list of all selected objects in the view.

For plot the following names are supported:

model Model index.

view Parent view name.

annotations Get plot's annotation object ids.

objects Get plot's object ids.

selected_objects Get plot's selected object ids.

errors Get plot's error messages.

Feedback

For annotation the following names are supported:

view Parent view name.

plot Parent plot name.

The following global data the following names are supported:

models Get model indices

views Get view names.

plot_types Get plot type names.

plots Get all plots names.

column_types Get all column type names.

column_type.names Get names of parameters for specified column type (in *data* option).

annotation_types Get all annotation type names.

symbol_names Get all symbol names.

procs Get all user defined procedure names.

You can also use the special name "?" which will return a list of the supported names for the specified object.

`-data` *`string`*

Extra data needed to query some data values.

Returns

value

Returned value.

Description

Get data from model, view, plot type, plot objects or from global object.

If model is specified then the *column* and *header* or *row* should be specified.

Examples

The following example gets all the view names.

```
shell> set views [gui_get_charts_data -global -name views]
```

The following example gets all the plots of the first view.

Feedback

```
shell> set plots [gui_get_charts_data -view [lindex $views 0] -name
 plots]
```

The following example gets all the annotations of the first plot.

```
shell> gui_get_charts_data -plot [lindex $plots 0] -name annotations
```

The following example gets all the model names.

```
shell> set models [gui_get_charts_data -global -name models]
```

The following example gets the value at row 2, column 1 in the first mode.

```
shell> gui_get_charts_data -model [lindex $models 0] -name value -row 2
 -column 1
```

See Also

- gui_set_charts_data

---

gui_get_charts_property

Get charts property

Syntax

```
value gui_get_charts_property
{ -view view_name | -plot plot_name |
-annotation annotation_id }
-name string
```

Data Types

```
view_name       string
plot_name       string
annotation_id   string
value             string
```

Arguments

`-view view_name`

View to get property from.

`-plot plot_name`

Plot to get property from.

`-annotation annotation_id`

Plot or view annotation to get property from.

Feedback

`-name string`

Name of property to return.

The supported names depend on which object the property is extracted from but can be listed by using the special property name "?".

Returns

value

Returned value.

Description

Get property from view, plot, view annotation, plot annotation or plot objects.

Examples

The following example gets the position of an annotation in a plot.

```
shell> gui_get_charts_property -plot $plot -annotation $annotation -name
 position
```

See Also

- gui_set_charts_property

---

gui_get_color_value

Get the RGB color value for given color index or name, else return all color information for the palette.

Syntax

string *gui_get_color_value [index]*

```
[-palette string]
[-color_name string]
```

Arguments

index

Use given color index number. An error message is posted if the given index is greater than the maximum index allowed for the current or given Palette. This argument is exclusive with option -color_name.

-palette

User given palette name, the default is 'highcontrast'. Valid values are: highcontrast, highlight, default_tech, qt, style. An error message is printed if an invalid palette name is given.

-color_name

Use given color name. Must be valid for the current/given palette. If an invalid color name is given an error message is posted. This option is exclusive with the 'index' argument.

Description

Get the RGB color value string for the given color name or index value.

If no argument is given the command will return a TCL list of lists. One list for every color in the current/given palette. The list for each color contains the index number, the RGB color value and, if available, a color name.

Examples

```
shell> gui_get_color_value 10
#005000

shell> gui_get_color_value -color_name magenta
#ff00ff

shell> gui_get_color_value
{0 #000000 }
{1 #464646 }
{2 #00ff64 }
{3 #78bec8 }
{4 #ff00ff magenta}
{5 #00af96 }
{6 #0000be }
{7 #00ffff cyan}
{8 #b1f476 light_green}
{...}
```

---

gui_get_current_task

Get the name of the current task.

Syntax

string *gui_get_current_task*

Description

The gui_get_current_task command queries the name of the current task.

Feedback

See Also

- gui_create_task

- gui_get_task_list

---

gui_get_current_task_page

Get the name of the current task page.

Syntax

string *gui_get_current_task page*

Description

The gui_get_current_task_page command queries the name of the current task page.

See Also

- gui_create_task
- gui_get_current_task

Feedback

- gui_get_current_task_item
- gui_set_current_task
- gui_get_task_list

---

gui_get_current_window

Retrieves the window ID of the active top-level or view window.

Syntax

```
string gui_get_current_window
[ -toplevel | -view | -parent parent_window_id ]
[ -hier_name ]
[ -types window_type_list ]
[ -mru ]
```

Data Types

```
parent_window_id    string
window_type_list    list
```

Arguments

`-toplevel`

Retrieves the active top-level window unless you also specify the *-types* option.

If you also specify the *-types* option, the *-toplevel* option retrieves the most recently active top-level window that has one of the specified window types.

The *-toplevel*, *-view*, and *-parent* options are all mutually exclusive.

`-view`

Retrieves the active view window in the active top-level window unless you also specify the *-types* option, the *-mru* option, or both.

if you also specify the *-types* option but not the *-mru* option, the *-view* option retrieves the most recently active view window with one of the specified window types in the active top-level window.

if you also specify the *-mru* option but not the *-types* option, the *-view* option retrieves the most recently active view window in any of the open top-level windows.

If you also specify both the *-types* option and the *-mru* option, the *-view* option retrieves the most recently active view window that has one of the specified window types and is in an open top-level window.

The *-view*, *-toplevel*, and *-parent* options are all mutually exclusive.

`-parent` *`parent_window_id`*

Retrieves the active view window in the specified top-level window unless you also specify the *-types* option.

If you also specify the *-types* option, the *-parent* option retrieves the most recently active view window that has any of the specified window types and is in the specified top-level window.

The *-parent*, *-toplevel*, and *-view* options are all mutually exclusive.

`-hier_name`

Returns the window ID in Qtcl format, which is similar to a full path name for the window, for use with the qtcl_* commands.

Note that a value returned in this format is not usable by gui_* commands.

`-types` *`window_type_list`*

Forces the tool to retrieve a window with one of the specified window types.

Use this option to restrict the search to certain types of windows. If you specify multiple types, they should be consistent (all toplevel window types or all view window types), but nonconsistency is not considered an error. The first type in the list determines whether the tool retrieves a top-level window or a view window when the *-toplevel* and *-view* options are not specified.

When you use the *-types* option, you should not use the *-toplevel* option or the *-view* option because the tool can determine from the list whether the window should be a top-level window or a view window. If you specify one of these options, any types that do not correspond to the option are silently ignored. For example, if you specify *-view*, then all top-level types are ignored.

`-mru`

Forces the tool to retrieve the most recently active view window from among all the open top-level and view windows. This option is effective only when you specify the *-view* option or when all the window types you specify with the *-types* option are view window types.

Description

This command retrieves the window ID of the active top-level or view window based on the options that you specify, or returns an empty string if no match is found.

A view window is a child window of a top-level window and is created with the *gui_create_window* command.

If you do not specify the *-toplevel*, *-view*, and *-parent* options, the tool uses the *-types* option to determine the window type. If you also do not specify the *-types* option, the tool uses the *-toplevel* option by default.

Feedback

Examples

The following example retrieves the active top-level window:

```
prompt> gui_get_current_window -toplevel
```

The following example retrieves the active view window:

```
prompt> gui_get_current_window -view
```

The following example retrieves the most recently active layout view:

```
prompt> gui_get_current_window -types "Layout" -mru
```

The following example return $cons:

```
prompt> set top1 [gui_create_window -type LayoutWindow]
prompt> set top2 [gui_create_window -type LayoutWindow]
prompt> set cons [gui_create_window -type Layout -parent $top]
prompt> gui_get_current_window -parent $top
```

---

gui_get_eco_context

Gets the context for manual ECO in the GUI for a given type if specified or for all the types.

Syntax

```
status gui_get_eco_context
[-type ype of context]
```

Data Types

type	string

Feedback

Arguments

type

Gets the context for the given type. Supported types are 'insert_buffer' or 'size_cell'. If no type is specified, it will get you both the types.

Description

The *gui_get_eco_context* command sets the context of manual ECO in the GUI.

The *gui_reset_eco_context* command can be used to reset the context and *gui_set_eco_context* can be used to set the context in the GUI for manual ECO

Examples

The following example shows how to get a given context.

```
prompt> gui_get_eco_context -type insert_buffer
1
prompt> gui_get_eco_context
1
```

See Also

- gui_set_eco_context
- gui_reset_eco_context

---

gui_get_error_browser_option

Get Error Browser Dialog option values

Syntax

string *gui_get_error_browser_option*

-grouping | -show_mode | -view_mode | -zoom_factor | -hide_fixed | -hide_ignored | -advance_to_next_unfixed_error | -dim | -show_open_locator_nodes | -show_tooltip | -show_command_buttons | -highlight_objects | -auto_set_object_visible | -auto_set_object_visible_type

Arguments

```
-grouping | -show_mode | -view_mode | -zoom_factor | -hide_fixed
| -hide_ignored | -advance_to_next_unfixed_error | -dim |
-show_open_locator_nodes | -show_tooltip -show_command_buttons
```

Feedback

```
| -highlight_objects | -auto_set_object_visible |
-auto_set_object_visible_type
```

Mutually exclusive required option to specify the Error Browser option value to query.

Description

This command gets the value of the requested option setting for the Error Browser. One option value can be queried at a time.

The *-grouping* option returns *type* or *layer* which indicates whether errors are grouped by types or layers.

The *-show_mode* option returns *all*, *selected*, or *none* which indicates whether all errors, selected errors, are no errors are shown in layout views.

The *-view_mode* option returns *zoom*, *pan*, of *off* which indicates whether the layout view zooms to, pans to, or does not change to the currently selected errors in the Error Browser.

The *-zoom_factor* option returns a float value between *0.1* and *10.0* and indicates the zoom factor used when the view_mode is zoom.

The *-hide_fixed* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether fixed errors are hidden from display in the Error Browser and layout views.

The *-hide_ignored* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether ignored errors are hidden from display in the Error Browser and layout views.

The *-advance_to_next_unfixed* option returns *true* to mean advance to next unfixed error when an error is fixed or *false* to mean advanced to next fixed/unfixed error.

The *-dim* option returns *true* to mean "dimmed" or *false* to mean "not dimmed" and indicates whether layout views are dimmed when errors are displayed.

The *-show_open_locator_nodes* returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether net nodes are highlighted along with the open locator flylines for selected open locator errors.

The *-show_tooltip* returns *true* to mean show tooltips or *false* to mean don't show tooltips in the error browser list and details panes.

The *-show_command_buttons* returns *true* to mean show the commannd buttons or *false* to mean don't show the command buttons in the error browser.

The *-highlight_objects* returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether associated design objects are highlighted in the layout view for selected errors.

Feedback

The *-auto_set_object_visible* returns whether auto set layout/object visibility is turned on or not.

The *-auto_set_object_visible_type* returns whether auto set layout/object visibility turns on layers/objects incrementally (the default) or exclusively.

Examples

The following example gets the grouping option

gui_get_error_browser_option -grouping

The following example gets whether layout views are dimmed when errors are displayed

gui_get_error_browser_option -dim

See Also

- gui_error_browser
- gui_set_error_browser_option

---

gui_get_error_data

Creates a collection of physical DRC error data that are currently shown in the error browser.

Syntax

```
collection gui_get_error_data
```

Description

The *gui_get_error_data* command creates a collection of physical DRC error data that are currently shown in the error browser.

You can use the *get_drc_error_data* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *gui_get_error_data* result to a variable.

When issued from the command prompt, *gui_get_error_data* behaves as though *query_objects* had been called to display the objects in the collection.

Examples

The following example queries the physical DRC error data that are currently shown in the error browser. Although the output looks like a list, it is not. The output is just a display.

```
prompt> gui_get_drc_error_data
{"my_design_dppinassgn.err"}
```

Feedback

See Also

- gui_open_error_data
- gui_close_error_data

---

gui_get_errors

Creates a collection of violation objects or errors in the Error Browser.

Syntax

collection *gui_get_errors*

[-visible] [-current] [-selected] [-fixed 0 | 1 | true | false] [-ignored 0 | 1 | true | false] [-id *ErrorObjectIDList*] [-data_name *ErrorDataName*]

```
ErrorObjectIDList   list
ErrorDataName       string
```

Arguments

`-visible`

Return errors that are currently visible in the Error Browser. This option will be exclusive to *-data_name* and *-id*.

`-current`

Return errors in the current error set, visible and hidden in the Error Browser. This option will be exclusive to *-data_name* and *-id*.

`-selected`

Return selected errors. This option will be exclusive to *-data_name* and *-id*.

`-fixed`

If this option is present, will only get errors that match the specified fixed state.

`-ignored`

If this option is present, will only get errors that match the specified ignored state.

`-id`

Return errors specified by error object ids. It will only work with *-data_name* and exclusive to *-visible*, *-current* and *-selected*.

`-data_name` *`ErrorDataName`*

ErrorDataName specifies the error data to get error objects. It will only work with *-id* and exclusive to *-visible*, *-current* and *-selected*.

Feedback

The error data name may be omitted. If omitted, selects the design, the parent of all open error data.

Description

This command creates a collection of violation objects or errors in the Error Browser.

If *-visible* option specified, return all visible errors in the Error Browser. If *-current* option specified, return all errors in the current error set. If *-selected* option specified, return all selected errors. *-visible*, *-current* and *-selected* will be exclusive to *-id* and *-data_name*. If specified together, an error message will be issued.

If *-fixed* option specified, if true then return all fixed errors, else return all non-fixed errors. If *-ignored* option specified, if true then return all ignored errors, else return all non-ignored errors. If *-fixed* and *-ignored* are specified together, return a combination of each result.

If *-id* option specified, return all errors based on the id list from specified error data. If *-data_name* option specified, return errors from the specified data. If the *-data_name* option is omitted, selects the design, the parent of all open error data. *-id* and *-data_name* have to be specified together. They will be exclusive to *-visible*, *-current* and *-selected*.

Examples

The following example gets errors from current error set and with fixed status 1.

```
gui_get_errors -current -fixed 1
```

The following example gets errors from zroute.err with id 1 and 2.

```
gui_get_errors -data_name zroute.err -id {1, 2}
```

- gui_zoom_to_selected_errors

---

gui_get_hierview_data

Get various state about the Hierarchy View and its sub-views. [Default return last used Hierarchy View name]

Syntax

string *gui_get_hierview_data*

Feedback

```
[-view              View_Name]
[-tree_type]
[-tree_attr_group]
[-tree_filter]
[-map_area]
[-map_color]
[-childlist_name]
[-childlist_attr_group]
[-childlist_filter]
[-sub_view]
[-columns]
[-values            Column_Name]
[-elide]
[-attr]

View_Name      String
Column_Name    String
```

Arguments

`-view View_Name`

Use the given HierView window name (ex: Hier.1). Default is to get the most recent used HierView window name.

`-tree_type`

Get the current Hier Tree type (logical | rtl). Note: RTL is only available in RTLA.

`-tree_attr_group`

Get and return the current Hier Tree attribute group name.

`-tree_filter`

Get and return the current Hier Tree filter expression.

`-map_area`

Get and return the Hier Map Area attribute group name.

`-map_color`

Get and return the Hier Map Color attribute group name.

`-childlist_name`

Get and return the current ChildList sub-view name.

`-childlist_attr_group`

Get and return the current ChildList attribute group name.

`-childlist_filter`

Get and return the current ChildList filter expression.

Feedback

`-sub_view`

Get and return the current active sub-view type. The sub-view types are 'hier_tree', 'hier_map' and 'child_list'.

`-columns`

Get and return a list of all column name(s) of all selected table cells.

`-values` *`Column_Name`*

Get and return a list of all selected table cell value(s) in the given column name. *Note*: Any of the column value(s) in the row of the selected cell(s) can be retrieved.

`-elide`

Get and return the current text elide for the view.

`-attr`

Get the attribute name for the given column short name (display label).

Description

```
This command allows you to get various current Hierarchy View related
 view settings
and selected table cell data.
```

See Also

- gui_set_hierview_data

---

gui_get_highlight

Get a collection of highlighted objects.

Syntax

string *gui_get_highlight*

```
[-color color_id | -all_colors]
[-return_select_bus | -more_than ]

string          color_id
collection      clct
```

Arguments

`-color` *`color_id`*

Specifies the color of objects to be returned. If neither -color nor -all_colors is used, the current color is assumed. The allowed colors are yellow, orange,

Feedback

red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

`-all_colors`

Specifies that all highlighted objects are to be returned.

`-return_select_bus`

Create a new selection bus in which to store the result instead of returning a collection of objects.

`-more_than`

Return 1 if more than the specified number of objects would be returned, otherwise 0.

Description

The gui_get_highlight command returns a collection of objects highlighted with the specified colors.

Examples

Get a collection of green highlighted objects.

shell> gui_get_highlight -color green

Get a collection of all highlighted objects.

shell> gui_get_highlight -all_colors

Query if any objects are highlighted

shell> gui_get_highlight -all_colors -more_than 0

See Also

- gui_change_highlight
- gui_get_highlight_options
- gui_set_highlight_options

---

gui_get_highlight_options

Query the options that control highlighting.

Syntax

string *gui_get_highlight_options*

`[-current_color | -all_colors | -auto_cycle_color]`

Feedback

Arguments

`-current_color`

This option returns a string which is the current highlight color, or the default color for highlighting operations.

`-all_colors`

This option returns Tcl list of all of the colors which are allowed to be used for highlighting.

`-auto_cycle_color`

This option returns the current value of the auto cycle setting ("true" or "false").

Description

The gui_get_highlight_options command queries the settings which control highlighting. Exactly one option must be provided.

Examples

Get the current highlight color.

shell> gui_get_highlight_options -current_color

Get all highlight colors.

shell> gui_get_highlight_options -all_colors

See Also

- gui_change_highlight
- gui_get_highlight
- gui_set_highlight_options

---

gui_get_map

Retrieves attributes for a specified map mode.

Syntax

string *gui_get_map*

```
-name identifier
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
```

```
[-icon_file]
[-update_cmd]
[-float]
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]
```

Data Types

identifier string

Arguments

-name *identifier*

Specifies the name of the map mode to be queried.

-buckets

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

-title

Returns the title string.

-help_topic

Returns the help topic string.

-infotip

Returns the InfoTip string.

-discrete

Returns a true or false value that indicates whether the buckets of this map mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this map mode was created, and cannot be changed.

-icon_file

Returns the gui menu icon file.

-update_cmd

Returns the Tcl command that is executed when the map mode is accessed. A typical use for this option is to update the state of the map mode if its contents are likely to change under certain circumstances.

-float

Returns a true or false value indicating whether the map mode buckets have a floating point range.

Feedback

`-top_exaggeration`

Returns the top bucket exaggeration.

`-mid_exaggeration`

Returns the middle bucket exaggeration.

`-bot_exaggeration`

Returns the bottom bucket exaggeration.

Description

The *gui_get_map* command queries the option values of an existing map mode.

Examples

To retrieve names of the buckets in the map mode named "densityMap", use the following command:

```
prompt>gui_get_map -name densityMap -buckets
```

See Also

- gui_get_mapbucket

---

gui_get_map_list

Lists the current visual and map modes.

Syntax

```
string gui_get_map_list
```

Arguments

The *gui_get_map_list* command has no arguments.

Description

The *gui_get_map_list* command returns a list of existing visual and map modes.

Examples

The following example gets the names of all available visual and map modes:

```
prompt> gui_get_map_list
```

Feedback

gui_get_map_option

Gets the value for an option in the specified visual mode or map mode.

Syntax

```
string gui_get_map_option
-map map_name
-option option_name
[-default]
```

Data Types

```
map_name        string
option_name     string
```

Feedback

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-option option_name`

Specifies the name of the option to be set.

`[-default]`

Gets the option default value.

Description

This command gets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You can get set option specific value or its default value.

Examples

The following example gets the number of bins in the global route congestion map:

```
prompt> gui_get_map_option -map AREAPARTITION \\
        -option num_bins -value 9
```

See Also

- gui_get_bucket_option

- gui_get_map_list
- gui_set_map_option
- gui_get_map_option_list
- gui_set_bucket_option

---

gui_get_map_option_list

Lists the available options for the specified visual mode or map mode.

Syntax

```
string gui_get_map_option_list
-map map_name
```

Data Types

```
map_name        string
```

Feedback

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

Description

This command displays a list of all options that are available for the specified visual mode or map mode.

Examples

The following example displays a list of the available options for the global route congestion map:

```
prompt> gui_get_map_option_list -map AREAPARTITION
```

See Also

- gui_get_map_option
- gui_set_bucket_option
- gui_set_map_option

---

gui_get_mapbucket

Gets attributes for Map Mode Bucket

Syntax

string *gui_get_mapbucket*

```
-map mode_identifier
-name bucket_identifier
[-infotip]
[-color]
[-pattern]
[-exaggeration]
[-number]
[-maxval]
[-minval]
[-visible]
[-special]
```

Feedback

```
[-title]
[-objcount]
```

Data Types

```
mode_identifier   string
bucket_identifier string
```

Arguments

`-map` *mode_identifier*

Specifies the map mode to which the bucket is a member. The map mode must already exist.

`-name` *bucket_identifier*

Specifies the name of the map mode bucket to be queried. To see the list of buckets associated with a specific map mode use the gui_get_map command with the -buckets option.

`-infotip`

Return infotip string.

`-color`

Return bucket rendering color.

`-pattern`

Return bucket rendering fill pattern.

`-exaggeration`

Return bucket min pixel exaggeration value.

`-number`

Return bucket display number.

`-maxval`

Return bucket maximum value.

`-minval`

Return bucket minimum value.

`-visible`

Return visibility.

`-special`

Return whether bucket is special.

Feedback

`-title`

Return bucket title.

`-objcount`

Return the number of objects in the bucket.

Description

The gui_get_mapbucket command queries an instance of a map mode bucket for the specified option values. The values are returned in a list of option-value pairs.

Examples

Query the current color for the bucket named "Bucket10" in the map mode "densityMap":

```
prompt> gui_get_mapbucket -map densityMap -name Bucket10 -color
```

Query the current color and pattern for the bucket named "Bucket10" in the map mode "densityMap":

```
prompt> gui_get_mapbucket -map densityMap -name Bucket10 -color -pattern
```

See Also

- gui_get_map

---

gui_get_menu_roots

Return a sorted list of all menu roots used by the application.

Description

This command returns a list of all the menu roots used by the application. The menu roots include menu roots used by toplevel menu bars and menu roots used by context menus. A menu root is used to group menu items that share the same menu root together. All items under each toplevel window's menu bar shares the same menu root; similarly, all items in a context menu (menu brought up with right mouse click in a window) shares the same context menu root.

See Also

- gui_create_menu

---

gui_get_mouse_tool_option

Get the value of a mouse tool option

Feedback

Syntax

string *gui_get_mouse_tool_option* -tool *string*

-option *string*

```
string string
string string
```

Arguments

`-tool string`

Tool to get option for.

`-option string`

Option to get.

Description

This command returns value of a mouse tool option .

Examples

```
> gui_get_mouse_tool_option -tool SELECT -option InputMode
Smart
```

See Also

- gui_mouse_tool
- gui_set_mouse_tool_option

---

gui_get_performance_log_option

Gets the current option value controlling performance log behavior.

Syntax

`string` **`gui_get_performance_log_option`**

Description

This command is used to query the current setting for the performance log which is set by gui_set_performance_log_option.

Examples

```
The following example sets, then gets the current setting.

prompt> gui_set_performance_log_option -commands {gui_zoom
 win_select_objects}
```

Feedback

```
prompt> gui_get_performance_log_option
commands: gui_zoom win_select_objects
```

See Also

- gui_log_performance
- gui_set_performance_log_option

---

gui_get_pref_categories

Return a list of the current preference categories.

Syntax

string *gui_get_pref_categories*

Description

This command returns a tcl list of the current preference categories.

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_pref_keys

Return a list of preference keys under the specified category.

Syntax

string *gui_get_pref_keys* -category *Category*

Feedback

```
Category        String
```

Arguments

```
-category Category
```

Category specifies the category to use.

Description

Return a list of preference keys under the specified category.

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_pref_value

Get the value of a preference key.

Syntax

string *gui_get_pref_value* -key *Key* [-category *Category*]

```
Key             String
Category        String
```

Arguments

```
-key Key
```

Key specifies the key to retrieve the value from.

Feedback

`-category Category`

Category specifies the category to search for the key. If not specified, a default category will be used.

Description

This command retrieves the value of a preference key from the specified key name and category.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command *gui_get_pref_value* is then used to retrieve the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
set x [gui_get_pref_value -category my_category -key some_key]
```

See Also

- gui_create_pref_category
- gui_create_pref_key

- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_pref_value_type

Get the data type of the value of a preference key.

Syntax

string *gui_get_pref_value_type* -key *Key* [-category *Category*]

Feedback

```
Key             String
Category        String
```

Arguments

`-key Key`

Key specifies the key to retrieve the value type from.

`-category Category`

Category specifies the category to search for the key. If not specified, a default category will be used for searching the key.

Description

This command retrieves the data type of the value of a preference key from the specified key name and category.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200. The command *gui_get_pref_value_type* is then used to retrieve the data type of the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type
 integer -value 200
set x [gui_get_pref_value_type -category my_category -key some_key]
{comment: x should be equal to "integer" }
```

- gui_exist_pref_key
- gui_update_pref_file

Feedback

gui_get_presets

Gets list of preset name for object specified by category

Syntax

```
string gui_get_presets
-category category
[-system]
[-shared]
```

Data Types

```
category    string
```

Arguments

`-category category`

Specifies the name of the category that the presets be retrieved from.

`-system`

Return system presets. This option is mutually exclusive with the -shared option.

`-shared`

Return shared presets. This option is mutually exclusive with the -system option.

Description

This command retrieves the list of presets for a category.

Examples

The following example gets the system presets for the Layout.

```
prompt> gui_get_presets -category Layout -system
```

See Also

- gui_set_preset

gui_get_region

Returns the coordinates of the current region rectangle or rectilinear polygon.

Syntax

```
list gui_get_region
```

Feedback

Description

This command returns the coordinates of the rectangle or rectilinear polygon that defines the current region in layout region mode.

Note that the preferred command for typical extension writing is usually *gui_set_layout_user_command* instead of *gui_get_region* because *gui_set_layout_user_command* has snapping, mouse up drag, cancel, and user prompt capabilities.

Examples

```
prompt> gui_get_region
{{-1743.945 18.357} {42.833 1523.657}}
```

See Also

- gui_set_region
- gui_set_layout_user_command

---

gui_get_setting

Gets a setting on the specified window.

Syntax

string *gui_get_setting*

```
-window WindowID
{ -setting Setting | -list }

WindowID         String
Setting         String
```

Arguments

`-window WindowID`

WindowID specifies the window to get the setting

`-setting Setting`

Setting specifies the setting to get

`-list`

Specifies that the list of available settings needs to be returned

Feedback

Description

Gets the list of available settings on the specified window. Windows are views or top level windows. The setting is a property of the window. The returned value is a string which has the type of the setting being read. Some windows might not have this function implemented.

Examples

```
shell> gui_get_setting -window Layout.1 -setting showCell
1

shell> gui_get_setting -window Layout.1 -setting viewLevel
2
```

See Also

- gui_set_setting

---

gui_get_task_list

Lists all the available task names.

Syntax

string *gui_get_task_list*

Description

The gui_get_task_list command queries the names of all available tasks.

Description

prompt> *gui_get_task_list* all {Block Implementation} {Design Planning}

See Also

- gui_create_task
- gui_set_task_list
- gui_set_current_task
- gui_get_current_task

---

gui_get_task_page

Return the name of the task page for the given task item.

Feedback

Syntax

string *gui_get_task_page*

Syntax

gui_get_task_page

```
-task           TaskName
-item           ItemName

TaskName          String
ItemName          String
```

Arguments

`-task` *TaskName*

TaskName specifies the name of the task.

`-item` *ItemName*

ItemName specifies the hierarchical name of the task item for which to get the page name",

Description

This command returns the name of the task page for the task item identified by the option values. This is useful when you want to create a new task item re-using a task page that is invoked by an existing task item.

Examples

To reuse the task page from the built-in task item "Pin Assignment->Pin Placement" in the task "Hierarchical Design" in your own task flow, you can do the following:

```
prompt> set pageName [gui_get_task_page -task "Hierarchical Design" \
                        -item "Pin Assignment->Pin Placement"]
prompt> gui_create_task_item -task myTask -name myItemName \
                        -page $pageName
```

See Also

- gui_create_task_item
- gui_set_current_task
- gui_get_task_list

Feedback

gui_get_toolbar_names

Return a Tcl list of the names of all the toolbars that have been created with the *gui_create_toolbar* command.

Syntax

void *gui_get_toolbar_names* [-window *WindowId*]

```
WindowId        String
```

Arguments

`-window WindowId`

Return toolbars defined in this window. If omitted, return toolbars defined in the active window.

Description

Return a Tcl list of the names of all the toolbars that have been created with gui_create_toolbar command for the specified window.

See Also

- gui_create_toolbar
- gui_create_toolbar_item
- gui_delete_toolbar
- gui_delete_toolbar_item
- gui_hide_toolbar
- gui_show_toolbar

gui_get_user_units

Gets the units for GUI.

Syntax

```
status gui_get_user_units
-type unit_type
[-numeric]
```

Data Types

```
unit_type          string
```

Feedback

Arguments

`-type unit_type`

Specifies the type of unit to get. The valid value is: "power".

`-numeric`

If the -numeric option is specified, the command returns a number representing the unit value in terms of the base unit for that quantity type. The base unit for power is W (watt).

Description

This command returns a string representing the GUI unit for a quantity type.

Examples

The following examples get the unit of power.

```
prompt> gui_get_user_units -type power
1kW
prompt> gui_get_user_units -type power -numeric
1000
```

See Also

- gui_set_user_units

---

gui_get_utable

Get various state about User Table(s) [default: return list of all table names].

Syntax

string *gui_get_utable*

```
-name           Table_Name
-has_name
-headers
-tag
-window         Window_name
-values         Column_Name
-bus_values     Column_Name
-rows
-parent
-filter
-columns

Table_Name      String
Window_Name     String
Column_Name     String
```

Feedback

Arguments

`-name Table_Name`

A table name argument used with other argument switches below.

`-has_name`

Check if given table name given by the '-name' argument switch exist and return '1', else return '0'.

`-headers`

Get the table column headers for given table argument.

`-tag`

Get the table MetaData tag string for given table argument.

`-window Window_Name`

A UserTable window name argument used with other arguments below. If used alone it will return the current table name of the given window name.

`-values Column_Name`

Get the selected table cell value(s) in the given column for the given window argument. *Note*: Any column value(s) in the row of the selected cell(s) can be retrieved.

`-bus_values Column_Name`

Just like the '-values' option, except if the columns contain compressed bus values like 'bus*[*]*', then a list of values will be returned that match the glob expression.

`-bus_values Column_Name`

Get the selected table cell bus values in the given column for the given window argument. If the table cell value is a compressed bussed value then all values are returned for that compressed value.

`-columns`

Get the selected table column name(s) for the given window argument.

`-rows`

Get the selected table row number(s) for the given window argument.

`-parent`

Get the parent table name for the given table name argument if it exists.

`-filter`

Get the filter expression for the current table shown in the given window name.

Feedback

Description

This command allows you to get all current loaded UserTable names.
Other options allow you to get various other table state.

Examples

The following example check to see if the UserTable 'my_table' is currently loaded.

```
shell> if { [gui_get_utable -name my_table -has_name] } {
          echo "yes my_table is loaded"
       }
```

The following example looks for the 'full_name' column in the current active UserTable
and prints all the selected values in that column.
Note: If the table was a compressed table then using the option '-bus_values'
will return all the values for the compressed value.

```
shell> # Get the current active UserTable window:
       set win [gui_get_current_window -mru -type UserTable]
       # Get the table name in that window:
       set table [gui_get_utable -window $win]

       if { $table != {} } {
         # Get the selected column names in that table:
         set columns [gui_get_utable -window $win -columns]
         # If the column name 'full_name' is selected then list the values:
         if { [lsearch -exact $columns full_name] != -1} {
           set values [gui_get_utable -window $win -values full_name]
           foreach v $values {
             echo "value: $v"
           }
         }
       }
```

---

gui_get_vm

Retrieves attributes for a specified visual mode.

Syntax

string *gui_get_vm*

```
-name identifier
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
[-icon_file]
[-update_cmd]
[-netfilter]
[-float]
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]
[-show_only_pins_of_nets]
[-enable_bucket_delete]
```

Data Types

```
identifier     string
```

Arguments

`-name` *identifier*

Specifies the name of the visual mode to be queried.

`-buckets`

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

`-title`

Returns the title string.

`-help_topic`

Returns the help topic string.

`-infotip`

Returns the InfoTip string.

`-discrete`

Returns a true or false value that indicates whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this visual mode was created, and cannot be changed.

`-icon_file`

Returns the gui menu icon file.

`-update_cmd`

Returns the Tcl command that is executed when the visual mode is accessed. A typical use for this option is to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-netfilter`

Returns net connection filtering.

`-float`

Returns a true or false value indicating whether the visual mode buckets have a floating point range.

`-top_exaggeration`

Returns the top bucket exaggeration.

`-mid_exaggeration`

Returns the middle bucket exaggeration.

`-bot_exaggeration`

Returns the bottom bucket exaggeration.

`-show_only_pins_of_nets`

Returns a true or false value that indicates whether the layout shows only pins of net objects in buckets.

Feedback

`-enable_bucket_delete`

Returns a true or false value indicating whether the visual mode buckets can be deleted from context menu.

Description

The *gui_set_vm* command queries the option values of an existing visual mode.

Examples

To retrieve names of the buckets in the visual mode named "mycoloring1", use the following command:

```
prompt>gui_get_vm -name mycoloring1 -buckets
```

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_get_vmbucket
- gui_remove_vm
- gui_remove_vmbucket
- gui_set_vm
- gui_set_vmbucket
- gui_update_vm

---

gui_get_vmbucket

Get attributes for Visual Mode Bucket

Syntax

string *gui_get_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip] [-netfilter] [-color] [-pattern] [-exaggeration] [-number] [-maxval] [-minval] [-visible] [-title] [-collection] [-objcount] [-gui_object]

```
string mode_identifier
string bucket_identifier
```

Feedback

Arguments

`-vmname` *mode_idnetifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name` *bucket_identifier*

Specifies the name of the visual mode bucket to be queried. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-infotip`

Return infotip string.

`-netfilter` *net_filter*

Return net connection filtering.

`-color`

Return bucket rendering color.

`-pattern`

Return bucket rendering fill pattern.

`-exaggeration`

Return bucket min pixel exaggeration value.

`-number`

Return bucket display number.

`-maxval`

Return bucket maximum value.

`-minval`

Return bucket minimum value.

`-visible`

Return visibility.

`-title`

Return bucket title.

`-collection`

Return object collection.

Feedback

`-objcount`

Return the number of objects in the bucket.

`-gui_object`

Return gui object collection.

You can use this option only if you also use the *-collection* option.

Description

The gui_get_vmbucket command queries an instance of a visual mode bucket for the specified option values. The values are returned in a list of option-value pairs.

Examples

Query the current color for the bucket named "cat1" in the visual mode "foo":

shell> *gui_get_vmbucket -vmname foo -name cat1 -color*

Query the current color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> *gui_get_vmbucket -vmname foo -name cat1 -color -pattern*

See Also

---

gui_get_window_ids

Get a list of window ids

Feedback

Syntax

```
ids gui_get_window_ids
[ -parent window_id ]
[ -type window_type ]
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-parent window_id`

Specifies the toplevel window id to get child view window ids from.

`-type window_type`

Specifies that the windows id returned should be restricted to those of the specified type.

Note: as a type can be only be associated with either a toplevel window or a child view window (not both) the type implies whether toplevel or child view window ids are returned.

If this option is not specified then either all toplevel window ids are returned (*-parent* option not specified) or all child view window ids of a specified toplevel window id are returned (*-parent* option specified).

Returns

ids

Returned list of window ids.

Description

This command gets a list of the ids of all toplevel windows, all toplevel windows of a specified type, all child view windows of a specified type, or all child view windows of a specified type in a specified toplevel window.

Examples

The following example will create a toplevel window and a child layout window. Then this command will be used to retrieve the ids of the existing windows.

```
shell> set top [gui_create_window -type TopLevel]
shell> set cons [gui_create_window -type Layout -parent $top]
shell> set ids [gui_get_window_ids]   # return list containing values of
 $top and value of $cons.
shell> set childs [gui_get_window_ids -parent $top]   # return value of
 $cons.
```

Feedback

```
shell> set layout_instances [gui_get_window_ids -type Layout] # return
 value of $cons.
```

---

gui_get_window_pref_categories

Get list of preference categories for object specified by window

Syntax

```
categories gui_get_window_pref_categories
{ -window window_id | -window_type window_type }
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

Returns

categories

The returned preference categories.

Feedback

Description

This command retrieves the list of preference categories for a window or window type.

Examples

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_categories -window TopLevel.1]
```

---

gui_get_window_pref_keys

Get list of preference categories for object specified by window

Syntax

```
categories gui_get_window_pref_keys
{ -window window_id | -window_type window_type }
[ -category category ]
```

Data Types

```
window_id       string
window_type     string
category        string
```

Feedback

Arguments

`-window window_id`

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

`-category category`

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

Returns

categories

The returned preference categories.

Description

This command retrieves the list of preference categories for a window or window type.

Examples

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_keys -window TopLevel.1]
```

See Also

---

gui_get_window_pref_value

Get preference value for object specified by window or window type

Syntax

```
value gui_get_window_pref_value
{ -window window_id | -window_type window_type }
[ -category category ]
-key key
```

Data Types

```
window_id       string
window_type     string
category        string
key             string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference will be retrieved from. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference be retrieved from. This option is mutually exclusive with the -window option.

`-category category`

Specifies the category to search for the key. If not specified, a default category will be used.

`-key key`

Specifies the key to retrieve the value from.

Returns

value

The value of the key.

Feedback

Description

This command retrieves the value of a preference key from the specified key name and category of the specified window or window type. If a preference is set on a window type, then all instances of that type will inherits the preference, so the value can be set on a type and retrieved from any instance of that type (or derived from that type).

Examples

The following example creates a preference for a window and then uses the *gui_get_window_pref_value* command to retrieve the value for the preference.

```
shell> gui_set_window_pref_key -window Console.1 -key test -value_type
 integer -value 201
shell> set x [gui_get_window_pref_value -window Console.1 -key test]
shell> if {$x == 201} { echo "success" }
```

- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_window_presets

Gets list of preset name for object specified by window_type

Feedback

Syntax

```
string gui_get_window_presets
-window_type window_type
[-system]
[-shared]
```

Data Types

window_type	string

Arguments

`-window_type` *window_type*

Specifies the name of the window type that the presets be retrieved from.

`-system`

Return system presets. This option is mutually exclusive with the -shared option.

`-shared`

Return shared presets. This option is mutually exclusive with the -system option.

Description

This command retrieves the list of presets for a window type. This command has been deprecated, please use gui_get_presets instead.

Examples

The following example gets the system presets for the Layout.

```
prompt> gui_get_window_presets -window_type Layout -system
```

See Also

- gui_get_presets
- gui_set_preset
- gui_set_window_preset

---

gui_get_window_toolbar_items

Get window toolbar items

Syntax

```
status gui_get_window_toolbar_items
[ -window window_id ]
```

Feedback

```
[ -toolbar string ]
[ { -group string | -item string } ]
```

Data Types

window_id string

Arguments

-window *window_id*

Specifies the window name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

-toolbar *string*

Specifies the name of the toolbar to return items for.

If the string '?' is specified for the type, the command will return a list of allowed set names.

-group *string*

Specifies the name of the group to return.

If the string '?' is specified for the type, the command will return a list of allowed item groups.

-item *string*

Specifies the name of the item to return.

If the string '?' is specified for the type, the command will return a list of allowed item names.

Description

This command returns a collection of existing window toolbar items.

If no options are specified then all items are returned, if a set is specified then all items in the set are returned, if an item is specified then just that item (if it exists) is returned.

Examples

The following example will creates a button in a window toolbar and gets a collection for it.

```
shell> proc init_my_toolbar { args } {
shell>   set button [gui_create_window_toolbar_item -name button -type
 button]
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
```

Feedback

```
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
shell> set button [gui_get_window_toolbar_items -window $charts -toolbar
 my_toolbar -item button]
```

See Also

- gui_create_window_toolbar_type
- gui_create_window_toolbar_item
- gui_create_window_toolbar_group
- gui_create_window

---

gui_get_window_types

Get a list of window types

Syntax

```
types gui_get_window_types
[ -type token ]
```

Data Types

```
token    string
```

Arguments

`-type window_types`

Specifies whether to return toplevel windows ('toplevel') or child view windows ('child').

If toplevel window types are specified then the first type is guaranteed to be the default toplevel window type.

Returns

types

Returned list of window types.

Description

This command returns a list of existing window types. Instances of these types can be instantiated with the *gui_create_window* command. The returned list can be restricted to just toplevel windows or child view windows by specifying the *-type* option.

Feedback

Examples

The following examples illustrate some usages of the command.

```
shell> gui_get_window_types
shell> gui_get_window_types -type toplevel
shell> gui_get_window_types -type child
```

See Also

- gui_create_window
- gui_get_window_ids
- gui_set_active_window
- gui_get_current_window

---

gui_group_charts_plots

Group plots in charts view

Syntax

```
status gui_group_charts_plots
-view view_name
[ -x1x2 ]
[ -y1y2 ]
[ -overlay ]
[ plots ]
```

Data Types

```
view_name     string
plot_id_list  list
```

Arguments

`-view view_name`

Charts View to group.

`-x1x2`

This option specifies that two plots are connected such that they have a shared y axis range but two independent x axes ranges.

If the *-overlay* option is used then the two plots are overlaid and the X axis of the first plot is placed on the bottom and the X axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results horizontal stacking is recommended so the shared y axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-y1y2* option.

`-y1y2`

This option specifies that two plots are connected such that they have a shared x axis range but two independent y axes ranges.

If the *-overlay* option is used then the two plots are overlaid and the Y axis of the first plot is placed on the bottom and the Y axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results vertical stacking is recommended so the shared x axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-x1x2* option.

`-overlay`

This option specifies that the plots have shared x and/or y ranges and are drawn on top of each other so they can share a single key and title.

If the *-x1x2* or *-y1y2* option are specified then only the x or y axis range is shared (See descriptions of these options above).

If neither of the *-x1x2* or *-y1y2* options are specified then both the x and y axis ranges are shared. In this case two or more plots can be specified.

`plots`

List of plots to group.

For *x1x2* or *y1y2* options this must be two plots. For *-overlay* option, without the *x1x2* and *y1y2* options, this must be two or more plots.

Description

Group related plots in a view.

Feedback

Grouped plots can share x or y axis ranges and can be overlaid.

Sharing x and/or y axis is useful when you want to compare data across two plots. Overlay is useful when you want to display multiple plot types with the same data e.g. a combined barchart and xy plot (line plot).

Examples

The following example groups two plots so they are overlaid and share a common x axes.

```
shell> gui_group_charts_plots -view $view -y1y2 -overlay -plots [list
 $plot1 $plot2]
```

See Also

- gui_create_charts_plot

---

gui_hide_palette

Hides the specified palette.

Syntax

```
status gui_hide_palette
{ -name palette_id | -type palette_type | -all }
[ -parent window_id ]
```

Data Types

```
palette_id    string
palette_type  string
window_id     string
```

Arguments

`-name palette_id`

Specifies the palette name id or title.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this name in all toplevel windows are hidden.

This option precludes the *-type* and *-all* options.

`-type palette_type`

Specifies the palette type id. Any matching palette of this type will be hidden.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this type in all toplevel windows are hidden.

Feedback

This option precludes the *-name* and *-all* options.

`-all`

Hides all palettes.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes in all toplevel windows are hidden.

This option precludes the *-name* and *-type* options.

`-parent window_id`

Specifies the parent toplevel window to hide the palette type in.

Note: this option is only applicable if the *-type* option is specified.

Description

This command hides the specified palettes.

Examples

The following example hides all Layer palettes:

```
shell> gui_hide_palette -type Layout
```

See Also

- gui_show_palette

---

gui_hide_toolbar

Hides the specified toolbar or all the toolbars in the specified window or for a window type.

Syntax

void *gui_hide_toolbar*

```
-toolbar tool_bar_name | -all
[-window window_id]
[-window_type window_type]
```

Data Types

```
tool_bar_name     string
window_id         string
window_type       string list
```

Feedback

Arguments

`-toolbar` *`tool_bar_name`*

Specifies the toolbar you want to hide. The *-toolbar* option and the *-all* option are mutually exclusive.

`-all`

Hides all the toolbars in the specified window. The *-all* option and the *-toolbar* option are mutually exclusive.

`-window` *`window_id`*

Specifies the window in which you want to hide the specified toolbar or all toolbars. This option is mutually exclusive with the *-window_type* option. If both *-window* and *-window_type* options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

`-window_type` *`window_type`*

Specifies the window types in which you want to hide the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the *-window* option. If both *-window* and *-window_type* options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

Description

This command hides either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or in all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by *gui_show_toolbar* will be saved and restored on next invocation of the tool if save and restore has not been disabled.

Examples

The following example hides the File toolbar in the active window:

```
prompt> gui_hide_toolbar -toolbar File
```

The following example hides all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_hide_toolbar -all -window LayoutWindow.1
```

The following example hides the File toolbar in all TimingWindow type windows:

```
prompt> gui_hide_toolbar -all -window_type TimingWindow
```

Feedback

The following example hides all the toolbars in all window types:

```
prompt> gui_hide_toolbar -all -window_type [gui_get_window_types -type
 toplevel]
```

See Also

---

gui_hide_window_toolbar

Hide toolbar in view

Syntax

```
status gui_hide_window_toolbar
-window window_id
```

Data Types

```
window_id  string
```

Arguments

```
-window window_id
```

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

Description

This command hides the specified view's toolbar.

Examples

The following example will show a Charts View, show and hide the toolbar.

```
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
```

Feedback

```
shell> gui_show_window_toolbar -window $charts
shell> gui_hide_window_toolbar -window $charts
```

See Also

- gui_create_window
- gui_show_window_toolbar

---

gui_import_utable

Create a UserTable and import records from a value file or a report.

Syntax

string *gui_import_utable*

```
-file            File_Name [-tsv_mode] [-ssv_mode]
[-name           Table_Name]
[-tsv_mode]
[-ssv_mode]
[-fold]
[-report_type    Report_Type_Name]
[-meta_obj       MetaObj_Name]
[-replace]

Table_Name            String
File_Name             String
Report_Type_Name      String
MetaObj_Name          String
```

Arguments

`-file File_Name`

The name of the CSV value file from which to import and fill the user table with.

`-name Table_Name`

The name for the user table created. By default, the name takes the name of the file minus the extension.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-fold`

This flag causes extra row data past the number of columns specified to fold into the last column. The default is to discard extra data.

`-report_type`

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

`-meta_obj` *`MetaObj_Name`*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-replace`

Optional flag that will replace the given table name, if it already exists, with the imported table data.

Description

```
This command creates a new UserTable in memory and imports the data from
 a CSV/TSV/SSV
value file. The name of the table will take the base name of the file
 unless a name is
provided.

The first line of the file is assumed to be a header line that defines
 the column names.
In addition, column names can have postfixes that describe the data
 format of that column.

Supported column name postfixes are:

  :string
  :int
  :double
  :cell
  :net
  :port
  :pin
  :point
  :endpoint
  :file
```

Examples

```
The following example creates a new UserTable called 'data' and imports
 the values from
the CSV file 'data.csv'.
```

Feedback

```
shell> gui_import_utable -file data.csv

The following example creates a new UserTable, names it 'my_table' called
 'data' and
imports the values from the CSV file 'data.csv'. It also instructs the
 import to fold
any extra data found in the row into the last column defined.

shell> gui_import_utable -file data.csv -name my_table -fold
```

---

gui_list_attrgroups

Lists attribute group information for a specified object type or all object types.

Syntax

```
status gui_list_attrgroups
-class design_object
-name name
[-all]
[-tcl]
[-full]
[-attr_list]
```

Data Types

```
design_object      string
name               string
```

Feedback

Arguments

`-class` *design_object*

Specifies the type of design object.

`-name` *name*

Specifies the name of the attribute group to be listed for the specified object type or for all object types.

`-all`

Lists the attribute groups for all object types. This option and the -class option are mutually exclusive.

`-tcl`

Lists the attribute group information in a tool command language (Tcl) format that is suitable for Tcl processing.

`-full`

Specifies the full Tcl output format, which reports all possible group information.

`-attr_list`

Lists attributes only.

Description

The *gui_list_attrgroups* command lists attribute group information for the specified object type or for all object types. Use the *-tcl* option to get results that are suitable for Tcl processing.

Examples

```
prompt> gui_list_attrgroups -class Cell -tcl
"Hierarchy" "Edit"

prompt> gui_list_attrgroups -class Cell -name "Hierarchy" -tcl -attr_list
{Name} {Hierarchical} {Owning Cell} {isPhysConstraint} {Hard Macro} ...
 {FullName}

prompt> gui_list_attrgroups -all -tcl
Cell {  "Hierarchy" "Edit" }  Net {  "Timing" }  Pin {  "Timing" }

prompt> gui_list_attrgroups -class Cell -tcl -attr_list
{ "Hierarchy" { {Name} {Hierarchical} {Owning Cell} ...{FullName} } }
{ "Edit" { {Name} {isPhysConstraint} {Orientation} ... {FullName} } }

prompt> gui_list_attrgroups -class Cell
Cell, "Hierarchy", { {Name} {Hierarchical} {Owning Cell}
 {isPhysConstraint} ... }  ;
```

Feedback

```
Cell, "Edit", { {Name} {isPhysConstraint} {Orientation} {Location} ... }
  ;
The fields displayed above are in the following order:
Class, Group Name, Attributes list;
```

See Also

- gui_delete_attrgroup
- gui_list_attrgroups
- gui_update_attrgroup

---

gui_list_category_rules

Lists all category rules except built-in rules by default.

Syntax

list *gui_list_category_rules*

```
[-all | -names rule_names_list]
[-format script | tcl_list]
```

Data Types

rule_names_list list

Arguments

`-all`

Lists all category rules, including built-in rules.

This option and the *-names* option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

`-names` *rule_names_list*

Specifies the names of the category rules to be listed.

This option and the *-all* option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

`-format script | tcl_list`

Specifies the output format in which the category rules are listed. The default output format is *script*.

When the *script* format is used, the category rules are listed as a Tool Command Language (Tcl) script of *gui_create_category_rule* commands that you can

replay. In this case, the rules are streamed to the output stream. You can redirect the output by using the *redirect* command, for example, if you want to capture the script output in a file to use again later. When the *script* format is used, the command result is an empty string.

If the *tcl_list* format is specified, the category rules are listed in an "array set compatible" Tcl list format. In this case, the command result is a Tcl list.

Description

This command lists category rules that have already been created by the *gui_create_category_rule* command during the current run of the tool.

When you run this command without specifying either the *-all* option or the *-names* option, the command lists all category rules except built-in rules. Specify the *-all* option to list all category rules, including the built-in rules. Specify the *-names* option to list individual rules by name.

Examples

The following example lists all category rules, including the built-in rules:

```
prompt> gui_list_category_rules -all
gui_create_category_rule  -name Pathgroups  -builtin \\
  -category <path_group.full_name>
gui_create_category_rule  -name Session  -builtin \\
  -category <session_name>
gui_create_category_rule  -name {Path Type}  -builtin \\
  -category <path_type>
  ...
  ...
```

The following example lists all category rules except the built-in rules:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> gui_list_category_rules
gui_create_category_rule  -name rule1 \\
  -category <session_name>
gui_create_category_rule  -name rule2 \\
  -category <path_group.full_name>
```

The following example redirects the script output to a file that you can source during a subsequent run of the tool:

```
prompt> redirect -file /remote/dir1/rules.tcl {gui_list_category_rules}
prompt>
```

The following example uses the *-names* option to list only the rules named rule1 and rule3:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> gui_create_category_rule  -name rule3 -category
 <startpoint.full_name>
rule3
prompt> gui_list_category_rules -names {rule1 rule3}
gui_create_category_rule  -name rule1 \\
  -category <session_name>
gui_create_category_rule  -name rule3 \\
  -category <startpoint.full_name>
```

The following example uses the *tcl_list* output format to query the category specification of the rule named rule1:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> array set rules [gui_list_category_rules -format tcl_list]
Information: Defining new variable 'rules'. (CMD-041)
prompt> array set rule1_options $rules(rule1)
Information: Defining new variable 'rule1_options'. (CMD-041)
prompt> set rule1_cat_spec $rule1_options(category)
Information: Defining new variable 'rule1_cat_spec'. (CMD-041)
<session_name>
```

---

gui_list_cell_block_marks

Lists the cell names and block mark values for cells that are marked in the design.

Syntax

list *gui_list_cell_block_marks*

Arguments

This command has no arguments

Feedback

Description

This command lists the cell names and block mark values for all cells that are marked in the design. The listing is sorted by the full names of the marked cells.

Examples

The following example sets block marks on two hierarchical cell instances, and then lists the names of all the marked cells and their block marks:

```
prompt> gui_remove_cell_block_marks -all
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_set_cell_block_marks I_TOP/I_REG_FILE  REG_FILE
prompt> gui_list_cell_block_marks
I_TOP/I_ALU    ALU
I_TOP/I_REG_FILE    REG_FILE
```

---

gui_list_vm

List Current Visual Modes

Syntax

string *gui_list_vm*

Description

The gui_list_vm command will return a list of existing visual modes.

Examples

To get the names of all available visual modes, use the following command:

shell> *gui_list_vm*

See Also

gui_load_cell_density_mm

Loads the data for cell density map mode.

Syntax

```
status  gui_load_cell_density_mm
[-area area]
```

Data Types

area	list

Arguments

`-area` *area*

Analyzes area for cell density. If area is not given, the default area is whole design area.

Description

The command generates the map mode view of cell density in a given area. Each grid is colored based on the percentage of occupied area of cells in the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows cell density in the specified area.

```
prompt> gui_load_cell_density_mm -area \\
{284.820 390.670 1202.790 954.120}
```

gui_load_cell_power_density_mm

Loads the data for cell power density map mode.

Feedback

Syntax

```
gui_load_cell_power_density_mm
[-update_power]
```

Arguments

`-update_power`

Enables power analysis and updates the power data if it is not up-to-date.

Description

The *gui_load_cell_power_density_mm* command generates map mode view of cell power density. The grids are colored based on the total power generated from cells within the grid.

To generate the power data for cells, 1. Power analysis must be enabled ahead of time by setting the *power_enable_analysis* variable to *true*. 2. You have to use the *update_power* command to calculate the latest power information. Alternatively, you can also use *-update_power* option to set the variable and perform the fBgui_load_cell_power_density_mm *command.*

Examples

The following example shows cell power density map.

```
prompt> gui_load_cell_power_density_mm -update_power
```

See Also

- update_power
- power_enable_analysis

---

gui_load_pin_density_mm

Loads the data for pin density map mode.

Syntax

status *gui_load_pin_density_mm*

`[-area area]`

Data Types

area list

Feedback

Arguments

`-area area`

Area to be analyzed for pin density. By default, the command uses the entire design area.

Description

The command generates map mode view of pin density in a given area. The grids are colored based on the number of pins within the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows pin density in the specified area.

```
prompt> gui_load_pin_density_mm -area \\
  {284.820 390.670 1202.790 954.120}
```

---

gui_log_performance

Controls the start and stop of a performance data logging process and outputs into a file.

Syntax

```
string gui_log_performance
[-start file_name|-stop]
[-compress]
[-quiet]
```

Data Types

file_name	string

Arguments

`-start file_name`

This option is mutually exclusive with -stop. The argument is the path name of the file to which the log is output. The option begins logging performance data. If the file already exists, the command overwrites the existing file.

`-stop`

This option is mutually exclusive with -start. This option stops logging performance data. After stopped, the log cannot be reopened for appending.

Feedback

`-compress`

If given, the log is saved as a compressed file. This option must be combined with -start.

`-quiet`

If given, this option causes the command to ignore error conditions.

Description

This command controls the start and stop of a performance data logging process. The performance data is logged before and after executing the commands which are required. The data includes cpu, memory and time. After successfully start a log, the command returns the path name with extension .log or .log.gz if not given in *file_name*.

Examples

```
Start logging and save the log to a file without compressing.

prompt> gui_log_performance -start ./test
/an/absolute/path/.test.log

Start logging and save the log to a compressed file.

prompt> gui_log_performance -start ./test -compress
/an/absolute/path/.test.log.gz

Stop logging

prompt> gui_log_performance -stop
```

---

gui_merge_utable

Merge 2 (loaded) tables via the given join column(s).

Syntax

string *gui_merge_utable*

```
-name             Table_Name
-merge_table      Table_Name
-join_columns     Column_Names
[-output_table    Table_Name]
[-columns         Column_Names]

Table_Name       String
Column_Names     List of Strings
```

Feedback

Arguments

`-name` *`Table_Name`*

A primary table name to merge into unless an output table name is also given.

`-merge_table` *`Table_Name`*

The merge table name. This table must have the same 'join columns' as the primary table.

`-join_columns` *`Column_Names`*

The join columns can be one or more columns that provide a unique key that only matches one row at a time. This usually is a full object name like a net,port or cell name, but can also be a 'key set' like a full_name plus object_class.

`-output_table` *`Table_Name`*

An *optional* output table name where the resultant merged table is stored, default is the primary table.

`-columns` *`Column_Names`*

An *optional* merge column list of columns that specify the columns to merge from the merge table, default is all.

Description

This command allows you to merge two loaded tables with a common set of (key/join) columns and produces a resultant merged table that can be saved under a new table name or by default, will be saved in the original primary table. Both tables have to be loaded in memory, see links for gui_import_utable and gui_open_utable below to read in tables.

Examples

The following example merges two tables (tableA & tableB) joining them via the common key columns (full_name & object_class) and then outputs the result into tableC. It also only merges the column 'power' from tableB with all of tableA, by default all columns in tableB would be merged.

```
shell> # Import tableA:
       gui_import_utable -file tableA.csv
       # Import tableB:
       gui_import_utable -file tableB.csv

       # Merge them into a new tableC
       gui_merge_utable -name tableA -merge tableB -output tableC \\
            -join_columns {full_name object_class} -columns {power}

       # View merged tableC:
       gui_show_utable -name tableC
```

---

gui_mouse_tool

Operate mouse tools of a given view

Syntax

gui_mouse_tool

-window *window* [-start *tool* | -current | -list | -add_point *{x y}* | -drag *{{x1 y1} {x2 y2}}* | -delete_point | -apply | -reset | -cancel | -cycle | -cycle_back]

```
window          String
tool            String
```

Arguments

`-window window`

window specifies the window of which this command should operate the mouse tool.

`-start tool`

Starts the given mouse tool.

`-current`

Return the name of current active tool.

`-list`

Return the names of all available tools.

`-add_point {x y}`

Add an input point

`-drag {{x1 y1} {x2 y2}}`

Perform drag operation between two points.

Feedback

`-delete_point`

Removes last input point

`-apply`

Performs tool action

`-reset`

Clears all pending input or ends the tool if no pending

`-cancel`

Cancels mouse tool unconditionally

`-cycle`

Cycles through choices for a given operation

`-cycle_back`

Cycles back through choices for a given operation

Description

The *gui_mouse_tool* controls the mouse tool of a view that supports mouse actions log and replay capabilities. Not all views need to support all of the functionality provided by the interface of this command. User can use the command to script varios mouse action.

Examples

The following example has the layout view start the zoom in tool and perform a zoom to particular area.

```
> gui_mouse_tool -window Layout.1 -start ZOOM_IN_TOOL
> gui_mouse_tool -window Layout.1 -add_point {27.461 433.400}
> gui_mouse_tool -window Layout.1 -add_point {51.261 393.123}
> gui_mouse_tool -window Layout.1 -cancel
```

---

gui_open_error_data

Opens an error data file in the error browser.

Syntax

```
gui_open_error_data
[-file_name file_name]
[error_data]
```

Data Types

```
file_name        string
error_data       list
```

Feedback

Arguments

`-file_name` *file_name*

Specifies the name of the exported error file to open in the error browser. The name of the error data file to be opened and shown in the error browser. If other error data was already loaded into the error browser, the specified data is added to the existing data. This option is mutually exclusive with the *-name* and *error_data* options.

error_data

Specifies the data name or list of data names to open in the error browser. If the error data is already open, then a collection of the error data or the error data name can be used to show it in the error browser.

Description

The *gui_open_error_data* command displays the given error data in the GUI error browser. If the error browser is not already visible, it is first made visible.

If you specify a file name with the *-file_name* option, the command first opens an error data file with the given file name.

Note that if the command first opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The *gui_open_error_data* command opens an error data only when necessary. It does not increment the open_count if the error data is already open and in memory. If the *gui_open_error_data* command increments the open_count, then a subsequent call to *gui_close_error_data* for the same error data decrements the open_count. Otherwise, a subsequent call to *gui_close_error_data* simply removes the error_data from the error browser without decrementing the open_count.

Examples

The following example opens the physical DRC error data file that is named "my_design_dppinassgn.err" and shows it in the error browser.

```
prompt> gui_open_error_data -file_name my_design_dppinassgn.err]
```

The following example first opens the physical DRC error data file that is named "my_design_dppinassgn.err", then shows it in the error browser.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> gui_open_error_data $data
```

Feedback

- remove_drc_error_data

---

gui_open_utable

Open the given UserTable file.

Syntax

string *gui_open_utable*

```
-file         File_Name
[-name        Table_Name]
[-read_only]

File_Name     String
Table_Name    String
```

Arguments

`-file File_Name`

The name of the file to open and copy the UserTable into memory.

`-name Table_Name`

The name of the user table located in the file. By default the name of the file minus the extension is used.

`-read_only`

This flag stops the table from being copied into memory and instead the table contents are streamed which can save a lot of system memory if the table is huge.

Feedback

Description

This command opens the given UserTable file and copies the table contents into memory unless the **-read_only** flag is given which causes the contents to be streamed in as needed. This can save system memory if the table is huge.

Examples

The following example opens the UserTable file 'my_table.utable' and copies the
table 'my_table' into memory.

```
shell> gui_open_utable -file my_table.utable
```

The following example opens the given UserTable file but instead of copying it
into memory it connects in read-only mode, steaming the contents as needed.

```
shell> gui_open_utable -file my_table.utable -read_only
```

---

gui_overlay_layout

Add/Remove/Adjust a design overlay to a layout window

Syntax

gui_overlay_layout

```
-window windowID
-design design
-add
```

Feedback

```
-remove
-brightness value

windowID        String
design          String
add             Boolean flag
remove          Boolean flag
brightness      Integer
```

Arguments

`-window windowID`

windowID specifies the layout window to add the overlay

`-design design`

design specifies the design to overlay

`-add`

add the design as an overlay

`-remove`

remove the design as an overlay

`-brightness value`

adjust the brightness of the overlay design

Description

Use this command to add, remove, or adjust an overlay on a layout view. The design to overlay must already be an opened design. You cannot overlay the same design twice nor can you overlay a design on itself. The -add and -remove flags are mutually exclusive. The brightness of an overlay can be varied from 0 (not visible at all) and 100 (fully bright). The -remove flag is mutually exclusive with the -brightness flags.

Examples

```
shell> gui_overlay_layout -window Layout.1 -design fill_view -add
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness
 Off
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness
 33%
shell> gui_overlay_layout -window Layout.1 -design fill_view -remove
```

---

gui_place_charts_plots

Place plots in charts view

Feedback

Syntax

```
status gui_place_charts_plots
-view view_name
[ -vertical ]
[ -horizontal ]
[ -rows int ]
[ -columns int ]
[ plots ]
```

Data Types

```
view_name     string
plot_id_list  list
```

Arguments

`-view view_name`

Charts View to place plots in.

`-vertical`

Stack plots vertically.

`-horizontal`

Stack plots horizontally.

`-rows int`

Stack plots in grid using the specified number of rows.

`-columns int`

Stack plots in grid using the specified number of columns.

plots

List of plots to place. If not specified then all plots are placed

Description

Place plots in a view.

Examples

The following example stacks all plots horizontally.

```
shell> gui_place_charts_plots -view $view -horizontal
```

See Also

- gui_create_charts_plot

Feedback

gui_query_objects

Get the value of a query text for a collection of object.

Syntax

string *gui_query_objects*

object_collection

Data Types

`string object_collection`

Arguments

object_collection

Specifies the collection of objects to use to get the query text.

Description

The *object_collection* command returns and displays the query text. Same text will be shown in Query toolbar for a particular object query.

A *object_collection* is collection of objects for which the query text will be generated. The collection of objects might be returned as the result of another command such as the *get_cells* command.

For information about collections, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example displays query text for the all plan groups in the design.

```
prompt> gui_query_objects [get_plan_groups]
*********************************
Object summary:
plan_group : 5
*********************************

plan_group : RES_I109

plan_group : RES_I110

plan_group : RES_I111
```

```
plan_group : RES_I112

plan_group : RES_I113
```

The following example displays a query text for cell named RES_I112/nr02d0_B3_1.

```
prompt> gui_query_objects [get_cells RES_I112/nr02d0_B3_1]
*********************************
cell : RES_I112/nr02d0_B3_1

gui_read_user_map

Reads map mode data of file and display in layout, using user map mode(userMap). The command will show a dialog for user to complete the option values. If user executes the command with options, the option values will sync up to the dialog.

Syntax

string *gui_read_user_map*

```
[-file inputFile]

[-title mapTitle]

[-replace Replace current map if it exists.]

[-preview Preview data in dialogue.]
```

Data Types

```
inputFile     string
mapTitle      string
```

Arguments

`-file` *inputFile*

Specifies the name of the input file. It can be a single file name(generated in previous working directory) or have an absolute path.

For displaying the output data as a user-map, including the meta data is recommanded.

`-title` *`mapTitle`*

Specifies the title of the user map to display.

`-replace`

To replace the current user map.

`-preview`

To preview data in dialogue.

Description

Read map mode data from csv file. User map is a general feature and will not have all of the features of the map that was written only the basic data presentation and bucket settings.

Here's an example of the input file of cell density map with Meta data and header:

```
#META_DATA
#type,name,property,value
#table,,tag,gui_write_user_map
#table,,app_name,icc2

---

gui_remove_all_annotations

Removes specified group of annotations or all annotations from the specified layout window or from all windows.

Syntax

```
status gui_remove_all_annotations
[-window window_name]
[-group group_name]
```

Data Types

```
window_name      string
group_name      string
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-group group_name`

Specifies the annotation group name.

Description

This command removes specified group of annotations from the specified layout window. If group name is omitted, it will remove all annotations groups. If window name is omitted, it will remove annotations from all windows. The command returns 1 if it is successful.

Examples

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \\
   -type rect -text Test1 -color green -width 2 \\
   -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_all_annotations -window Layout.1
1
```

Feedback

See Also

- gui_remove_annotations

---

gui_remove_all_rulers

Removes rulers from the specified layout window or from all windows.

Syntax

```
status gui_remove_all_rulers
[-window window_name]
```

Data Types

```
window_name      string
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

Description

This command removes rulers form specified layout window, or from all windows if the *-window* option is omitted, and returns 1 if it is successful.

Examples

```
prompt> gui_remove_all_rulers -window Layout.1
1
```

See Also

- gui_remove_ruler

---

gui_remove_annotations

Removes specified group of annotations from the specified layout window.

Syntax

```
status gui_remove_annotations
[-window window_name]
[-group group_name]
[anno]
```

Feedback

Data Types

```
window_name      string
group_name      string
anno      collection
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-group group_name`

Specifies the annotation group name.

`anno`

Specifies a collection of annotations to remove. Get a collection of annotations with the gui_get_annotations command. This option cannot be specified with any other option.

Description

This command removes specified group of annotations from the specified layout window. If group name is omitted, global group name is used. If window name is omitted, global window name is used. The command returns 1 if it is successful.

Examples

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \\
   -type rect -text Test1 -color green -width 2 \\
   -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_annotations -window Layout.1
1
prompt> gui_remove_annotations [gui_get_annotations -filter
 client_data==MyData]
1
```

---

gui_remove_category_rules

Removes all category rules except built-in rules by default.

Feedback

Syntax

string *gui_remove_category_rules*

```
[-all | -names rule_names_list]
```

Data Types

rule_names_list	list

Arguments

`-all`

Removes all category rules, including built-in rules.

This option and the *-names* option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

`-names` *rule_names_list*

Specifies the names of the category rules to be removed.

This option and the *-all* option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

Description

This command removes category rules that have already been created by the *gui_create_category_rule* command during the current run of the tool.

When you use this command without specifying any options, it removes all category rules except built-in rules. Specify the *-all* option to remove all category rules, including the built-in rules. Specify the *-names* option to remove individual rules by name.

The command returns an empty string as its result.

Examples

The following example removes all category rules, including the built-in rules:

```
prompt> gui_remove_category_rules -all
```

The following example removes all category rules except the built-in rules:

```
prompt> gui_remove_category_rules
```

The following example removes the rules named Rule1 and Rule2:

```
prompt> gui_remove_category_rules -names {Rule1 Rule2}
```

Feedback

The following example removes non-built-in rules at the top of a user-defined category rule creation script, which is being developed interactively. You can repeatedly change and refine this script by using a text editor, and you can source the script multiple times in a single run of the tool.

```
        # first remove all existing user-defined non-built-in rules
gui_remove_category_rules
# now create the user-defined category rules
gui_create_category_rule ...
gui_create_category_rule ...
and so forth
```

---

gui_remove_cell_block_marks

Removes the block mark string values from one or more cells.

Syntax

status *gui_remove_cell_block_marks*

`-all | cells`

Data Types

cells list

Arguments

`-all`

Removes all block marks on all cells that are marked.

This option and the *cells* option are mutually exclusive, and one of them must be specified.

cells

Removes block marks from one or more cells specified in a list of cell name patterns or cell collections.

This option and the *-all* option are mutually exclusive, and one of them must be specified.

Feedback

Description

This command removes the block mark string values from one or more hierarchical or leaf-level cell instances. If the *-all* option is specified, then all the block marks are removed from all the cell instances that are marked. If the *cells* option is specified, then block marks are removed only from the specified cell instances.

Examples

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then removes the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
prompt> gui_remove_cell_block_marks I_TOP/I_ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the *get_cells* command, and then removes the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
prompt> gui_remove_cell_block_marks [get_cells I_TOP/I_ALU]
```

The following example removes all the block marks from all the cell instances that are marked:

```
prompt> gui_remove_cell_block_marks -all
```

See Also

- gui_set_cell_block_marks
- gui_get_cell_block_marks

---

gui_remove_charts_annotation

Remove annotation object from view or plot

Syntax

```
status gui_remove_charts_annotation
{ -view view_name | -plot chart_id }
{ -id string | -all }
```

Data Types

```
view_name  string
chart_id   string
```

Feedback

Arguments

`-view view_name`

View to remove annotations from.

`-plot chart_id`

Plot to remove annotations from.

`-id string`

Id of annotation to remove.

`-all`

Remove all remove annotations.

Description

Removes one or all annotations from a chart or a view.

Examples

The following example removes all annotations from a view.

```
shell> gui_remove_charts_annotation -view $view -all
```

See Also

- gui_create_charts_text_annotation

---

gui_remove_charts_model

Remove model from charts

Syntax

```
status gui_remove_charts_model
-model model_id
```

Feedback

Data Types

model_id int

Arguments

-model *model_id*

Charts model to remove.

Description

Remove model data from charts.

Note: It is recommended that existing plots using the model should also be removed as they may lose access to some or all of the original data.

Examples

The following example removes a model.

```
shell> gui_remove_charts_model -model $model
```

See Also

- gui_create_charts_model

---

gui_remove_charts_plot

Remove one or all plots from a charts view

Syntax

```
status gui_remove_charts_plot
-view view_name
{ -plot chart_id | -all }
```

Data Types

view_name string
chart_id string

Arguments

-view *view_name*

View to remove chart from.

-plot *chart_id*

Chart to remove.

Feedback

`-all`

Remove all changes.

Description

Removes one or all charts from a view.

Examples

The following example removes all charts from a view.

```
shell> gui_remove_charts_plot -view $view -all
```

---

gui_remove_pref_key

Remove a preference key.

Syntax

string *gui_remove_pref_key* -key *Key*

`[-category Category]`

```
Key             String
Category        String
```

Arguments

`-key Key`

Key specifies the key which will be used together with the specified category to uniquely identify the key to be removed.

`-category Category`

Category specifies the category that owns the specified key. If not specified, a default category will be used.

Description

This command removes the preference key specified by the key name.

- gui_exist_pref_key
- gui_update_pref_file

---

gui_remove_ruler

Removes the specified rulers.

Syntax

```
status gui_remove_ruler
[-window window_name]
-point point | -all
```

Data Types

```
window_name      string
point            point
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-point point`

Specifies the coordinates of the point near the ruler to be removed, in following format:

```
{x y}
```

`-all`

Removes all rulers.

Description

This command removes rulers from the specified layout window, or from all windows if the *-window* option is omitted, and returns 1 if it is successful.

Examples

```
prompt> gui_remove_ruler -window Layout.1 -point {400 400}
1
```

Feedback

```
prompt> gui_remove_ruler -window Layout.1 -all
1
```

See Also

- gui_remove_all_rulers

---

gui_remove_user_map

Remove current/all user map mode.

Syntax

string *gui_write_user_map*

```
[-all]
```

Arguments

`-all`

Remove all user map mode.

Description

Remove current/all user map mode.

Examples

```
Remove current user map in layout:

prompt>gui_remove_user_map
```

See Also

- gui_read_user_map
- gui_write_user_map

---

gui_remove_vm

Remove Visual Mode

Syntax

string *gui_remove_vm* -name *identifier*

```
string identfier
```

Feedback

Arguments

`-name identifier`

Specifies the name of the visual mode to be removed.

Description

Removes the specified visual mode and all the associated buckets.

Examples

To remove visual mode named "mycoloring1", use the following command:

shell> *gui_remove_vm -name mycoloring1*

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_get_vm
- gui_get_vmbucket
- gui_list_vm
- gui_remove_vmbucket
- gui_set_vmbucket
- gui_update_vm

---

gui_remove_vmbucket

Removes the specified bucket or all buckets from the specified visual mode

Syntax

string *gui_remove_vmbucket*

-vmname *mode_identifier* [-name *bucket_identifier*] [-all]

Data Types

mode_identifier	string
bucket_identifier	string

Feedback

Arguments

`-vmname` *mode_identifier*

Specifies the visual mode of which the bucket is a member. The visual mode must already exist.

`-name` *bucket_identifier*

Specifies the name of the bucket to be removed from the specified visual mode.

`-all`

Removes all buckets associated with the specified visual mode.

Description

Removes the specified bucket or all buckets from the specified visual mode.

Examples

To remove the visual mode bucket named red from the visual mode named vm1, enter the following command:

```
prompt> gui_remove_vmbucket -vmname vm1 -name red
```

To remove all the visual mode buckets from the visual mode named vm1, enter the following command:

```
prompt> gui_remove_vmbucket -vmname vm1 -all
```

See Also

- gui_create_vm

---

gui_report_errors

Output a textual report of errors.

Feedback

Syntax

string *gui_report_errors*

[-errors *Errors*] [-file *FileName*] [-include_hidden]

```
Errors          String
FileName        String
```

Arguments

`-errors Errors`

The *-errors* specifies the handle for a collection of errors to report on. This argument is optional. If omitted, a report is output for the errors currently loaded in the Error Browser error list.

`[-file FileName]`

FileName specifies the name of the file to write the report to. This argument is optional. If omitted, the report is output to stdout.

`[-include_hidden]`

-include_hidden specifies that errors that are currently hidden from the errors list due to filters or fixed errors being hidden should be included in the report. This option is ignored if errors are given with the *-errors* option.

Description

This command outputs a tabular textual representation of errors. If the -errors argument is omitted and an output file is specified, performs the same operation as the Error Browser option menu command to save to file.

Examples

The following example saves a textual report of current errors to a file named myErrors.txt:

gui_report_errors -file "myErrors.txt"

See Also

- gui_error_browser
- gui_set_current_errors

---

gui_report_hotkeys

Report on the current hotkey bindings

Feedback

Syntax

string *gui_report_hotkeys*

```
[-window_type WindowTypeName]

WindowTypeName  String
```

Arguments

`-window_type` *WindowTypeName*

WindowTypeName specifies the type of top level window that the hotkey should apply to. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command prints a report on the current key bindings. The list of bindings printed in the report are sorted by hotkey.

Examples

The following example creates a menu item and add an additional hotkey to it.

```
gui> gui_report_hotkeys

*************************************
Report : hotkeys
Window : LayoutWindow
Version: V-2004.06-GALILEO-BETA1-1
Date   : Tue Aug 31 10:37:17 2004
*************************************

Hot Key    Type  Function
-----------------------------------------------------
Ctrl+O     Menu  File->Open Design...
Ctrl+S     Menu  File->Save Design
Ctrl+R     Menu  Edit->Properties
M          Menu  Edit->Move...
C          Menu  Edit->Copy...
Ctrl+F     Menu  View->Zoom->Zoom Full
F          Menu  View->Zoom->Zoom Full
P          Tcl   query_objects [get_selection]
 ...
```

---

gui_report_map

Report information for a specified map mode.

Syntax

string *gui_report_map*

```
-name identifier
-report_type outputType
```

Data Types

```
identifier      string

outputType      string (Values: histogram, count)
```

Arguments

`-name` *identifier*

Specifies the name of the map mode to be queried.

`-report_type outputType`

Specifies the mode of report. Value of *outputType* can be *histogram* or *count*.

Description

The *gui_report_map* command queries the option values of an existing map mode name and a report mode. Histogram mode will print '###' as a graph bar for each bucket. Count mode will generate only count numbers of blocks in each bucket.

Feedback

Examples

To generate a histogram data for the map mode named "cellDensityMap". Use the following command:

```
prompt>gui_report_map -name cellDensityMap -report_type histogram
**************************************
Report : map
Design : ORCA
Mode   : histogram
Version: P-2019.03-DEV
Date   : Tue Nov  6 22:01:35 2018

---

gui_report_performance

Generates a performance report.

Syntax

```
status gui_report_performance
[-type report_type]
[-file file_name]
[-compress compress_method]
```

Data Types

```
report_type       string
file_name          string
compress_method   string
```

Feedback

Arguments

`-type` *report_type*

Specifies the report type. If report type is omitted or the value of this option is simple, output a simple version report. If the value of this option is detail, output a detail version report which includes additional information of x11 performance, region searching, attribute querying and render time.

The supported values for this option are

simple
detail

`-file` *file_name*

Outputs the report as a file and specifies the file name. If file name is omitted, output the report to console.

`-compress` *compress_method*

Specifies the compress method. The supported values for this option are

none
gzip

Description

This command report the performance data of machine state, design information, GUI configurations and current GUI views state.

Examples

```
Generate a simple version report and output to console.

prompt> gui_report_performance

Generate a detail version report and output to a file.

prompt> gui_report_performance -type detail -file file_name

Generate a detail version report and output to a compressed file

prompt> gui_report_performance -type detail -file file_name -compress
 gzip
```

---

gui_report_proc_arg_type_names

Report on the available type_name attribute values.

Feedback

Syntax

string *gui_report_proc_arg_type_names*

Description

This command prints a report on the available values for the type_name attribute for the *-define_args* argument to the *define_proc_attributes* command.

When a tcl proc has been defined using the *define_proc_attribute* command, a GUI form for the command will be auto-generated and shown from the application command search feature or using the command *gui_show_command_form*. The kinds of proc argument input fields used in the generated GUI form depend on the *type_name* attribute values provided for command options. The *type_name* attribute value for an option is given as a part of the *-define_args* argument. The *-define_args* option accepts a list of the following values, in this order:

```
* option name
* option decription
* option value type description
* data_type
* list of option attribute name-value pairs
```

Here is the usage for the *type_name* attribute within argument value for the *define_proc_attributes* command option *-define_args*:

```
define_proc_attributes <procedure name> \\
  -define_args { \\
    {<option name> <option description> <value type description>
 <data_type> \\
      {[required | optional] {type_name <type_name_value>}} \\
  } \\
}
```

where <type_name_value> can be substituted with any of the type names reported by *gui_report_proc_arg_type_names*.

For the *type_name* attribute value to have effect on the input field used in a GUI form, the <data_type> value must be *string*, for a single value, or *list* for multiple values. The value *list* is not supported for all *type_name* values as shown in the report's *data_type* column.

The following is an example of a *define_proc_attribute* command invocation with options accepting a collection or names of nets:

```
define_proc_attributes myProc \\
  -define_args { \\
    {-net "select a net" "net name or a collection of a net" string \\
          {optional {type_name net}}} \\
    {-nets "select nets" "net names or a collection of nets" list   \\
          {optional {type_name net}} \\
```

```
  } \\
}
```

In the above example, the *-net* option has *data_type* value *string* and *type_name* value *net*. This option accepts a single net as input. The *-nets* option has *data_type* value *list* and *type_name* value *net*. This option accepts multiple nets as input.

The report produced by this command lists the available *type_name* values. When one of these supported *type_name* values is used, the GUI form for the proc will use an input field that is appropriate for user input of that kind of value. For example, for a *net* type input, as shown in the example above, the form will use an object selector field which is configured to accept net input.

A proc argument with any combination of unspecified or unsupported *data_type* and *type_name* values is represented with a simple text input field in the generated GUI form.

Some *type_name* values use input editors that allow further configuration. For example, an editor for a file name can be configured to allow input of only existing files. Or an editor for a layer name can be configured to allow input of only certain types of layers.

Available configuration options are shown in the options column, then described in more detail at the end of the report output in a separate table keyed by associate type_name values. When providing optional configuration, list the configuration name-value pairs after the type_name value as a part of the the type_name attribute value. The following is an example of a "file" type_name attribute with multiple optional configuration settings:

```
define_proc_attributes myProc \\
  -define_args { \\
    {-file_option "Select an existing file name" "file name"  string \\
      {required
        {type_name {file {subtype exist} \\
                         {operation "Save As"} \\
                         {filter {"Text files (*.txt)" "All files (*)"}}
 \\
                   } \\
        } \\
      } \\
    } \\
  }
```

Examples

The following example outputs a report of available type_name attribute values.

```
gui> gui_report_proc_arg_type_names
****************************************************************************
*****
Report : Supported Values for "type_name" Option Attribute
Version: L-2016.03-SP5-BETA
Date   : Fri Sep 16 08:09:34 2016
```

Feedback

```

Feedback

gui_report_task

task.

Syntax

string *gui_report_task*

```
-task | -item_root          TaskName | ItemRootName
[-file]                     FileName

TaskName          String
ItemRootName      String
FileName          String
```

Arguments

`-task TaskName`

TaskName specifies the name of a task on which to report. This option is mutually exclusive with the -item_root option.

`-item_root ItemRootName`

ItemRootName specifies the name of a task item root name on which to report. This option is mutually exclusive with the -task option.

`-file FileName`

FileName optionally specfies the output file into which the report is written.

Description

This command outputs a textual report of the given task to the xterm console. If -file is given, then the report is also output to the given file. The report will have the following approximate format. The strings bracketed with the angle brackets will be replaced with the actual attribute value.

Attributes are omitted if they are not defined. Item are shown one to a line with the hierarchy structure indicated by indentations and bars. The leaf-leveltask item names are followed by the associated task page name:

```
Task: <task name>
 Default: <true | false>
 Items: <items>
```

See Also

- gui_create_task
- gui_get_task_list

Feedback

gui_reset_eco_context

Resets the context for manual ECO in the GUI for a given type if specified or for all the types.

Syntax

```
status gui_reset_eco_context
[-type ype of context]
```

Data Types

```
type        string
```

Arguments

type

Resets the context for the given type. Supported types are 'insert_buffer' or 'size_cell'. If no type is specified, it will reset both the types.

Description

The *gui_reset_eco_context* command resets the context of manual ECO in the GUI.

The *gui_reset_eco_context* command can be used to reset the context and *gui_set_eco_context* can be used to set the context in the GUI for manual ECO. *gui_get_eco_context* can be used to get the context set for a given 'type'.

Examples

The following example shows how to reset a given context.

```
prompt> gui_reset_eco_context -type "insert_buffer"
1
prompt> gui_reset_eco_context
1
```

See Also

- gui_set_eco_context
- gui_get_eco_context

gui_schematic_add_logic

Adds logic to a schematic

Syntax

string *gui_schematic_add_logic* [-window <*win*>]

Feedback

[-new] [-schematic <*schem*>] *objs*

```
string <win>
string <schem>
string objs
```

Arguments

`-window <win>`

Top level window name to place new schematic (default: current window). This option is ignored unless -new is specified.

`-new`

Create new schematic.

`-schematic <schem>`

Schematic view to update (default: most recently active schematic).

objs

Objects to add to the schematic.

Description

This command adds logic into a Path Schematic view. The command either creates a new view containing the specified objects or updates an existing view. The command always returns the name of the schematic that was updated or created.

Examples

The following example creates a new path schematic containing all the cells in the current design:

```
gui_schematic_add_logic -new [get_cells *]
```

See Also

- gui_get_current_window
- gui_schematic_remove_logic

---

gui_schematic_remove_logic

Removes logic from a schematic

Syntax

string *gui_schematic_remove_logic* [-schematic <*schem*>] *objs*

Feedback

```
string <schem>
string objs
```

Arguments

`-schematic <schem>`

Schematic view to update (default: most recently active schematic).

objs

Objects to remove from the schematic.

Description

This command removes logic into a Path Schematic view. The command returns the name of the schematic that was updated

Examples

The following example removes the cell "U1" from the most recently active schematic view:

```
gui_schematic_remove_logic [get_cells U1]
```

See Also

- gui_get_current_window
- gui_schematic_add_logic

---

gui_scroll

Scroll a window's viewport.

Syntax

gui_scroll

-window *window* [-selection | -clct *clct* | [-habs *absX* | -hrel *relX*] [-vabs *absY* | -vrel *relY*]]

```
window String
absX  Float
relX  Float
absY  Float
relY  Float
```

Arguments

`-window window`

window specifies the window to be scrolled.

Feedback

`-selection`

Determine the bounding box for all selected objects present in the view, and scroll such that the center of that box is visible.

`-clct` *`clct`*

Determine the bounding box for the collection objects present in the view, and scroll such that the center of that box is visible.

`-habs` *`absX`*

Scroll such that the specified X model position is centered in the viewport.

`-hrel` *`relX`*

Scroll horizontally by the specified number of pages. A page is the width of the viewport. Negative values scroll left and positive values scroll right.

`-vabs` *`absY`*

Scroll such that the specified Y model position is centered in the viewport.

`-vrel` *`relY`*

Scroll vertically by the specified number of pages. A page is the height of the viewport. Negative values scroll up and positive values scroll down.

Description

The *gui_scroll* command adjusts the position of views that support zooming. The viewport can be adjusted in the X and/or Y direction. Absolute values are expressed in model coordinates. Relative values allow paging. For example, *-hrel 1.0* means page to the right by the width of the viewport.

Examples

Scroll such that model coordinates (287.0, 1422.0) are centered in the viewport.

```
gui_scroll -window Layout.1 -habs 287.0 -vabs 1422.0
```

Scroll to the right by one viewport width.

```
gui_scroll -window Layout.1 -hrel 1.0
```

See Also

- gui_zoom

---

gui_select_by_name

Select or highlight objects by name

Feedback

Syntax

```
status gui_select_by_name
[ { -select | -highlight } ]
-object_type string
[ -pattern string ]
[ -filter string ]
[ { -replace | -add | -remove } ]
[ -regexp ]
[ -nocase ]
[ -exact ]
[ -all ]
```

Arguments

`-select`

Specifies that the matching objects are to be selected.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

`-highlight`

Specifies that the matching objects are to be highlighted.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

`-object_type string`

Specifies the type of objects to be selected.

The available types are dependant on the individual product. Please see your product's documentation for details.

`-pattern string`

Specifies the pattern to be used for a match.

By default matching is case-sensitive and uses wildcard patterns. If non case-sensitive matching is required use the *-nocase* option. If regular expression matching is required use the *-regexp* option. If no pattern matching is required use the *-exact* option.

`-filter string`

Specifies the expression to use when filtering the results.

`-replace`

Specifies that matching objects should replace the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

Feedback

`-add`

Specifies that matching objects should be added to the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

`-remove`

Specifies that matching objects should be removed from the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

`-regexp`

Specifies the pattern matching should use regular expressions.

`-nocase`

Specifies the pattern matching should be case-insensitive.

`-exact`

Specifies that no pattern matching should be used so wildcards and regular expressions are ignored.

`-all`

Specifies that physical only objects be include in the search.

Description

This command allows objects of a specified type to be selected or highlighted.

It is used by the Select By Name Toolbar and Select By Name Dialog for correct log and replay of the resultant selection or highlight.

The command returns whether the search was successful or not.

Examples

The following example will add all nets matching the pattern 'A*' to the current selection.

```
shell> gui_select_by_name -select -object_type {Nets} -pattern {A*} -add
```

The following example will only highlight the Port '*Logic0*'.

```
shell> gui_select_by_name -highlight -object_type {Ports} -pattern
 {*Logic0*} -exact
```

Feedback

See Also

- change_selection
- gui_change_highlight

---

gui_select_vmbucket

Select the Contents of a Visual Mode Bucket

Syntax

string *gui_select_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-replace | -add | -remove]

```
string  mode_identifier
string  bucket_identifier
```

Arguments

`-vmname mode_identifier`

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes, use the *gui_list_vm* command.

`-name bucket_identifier`

Specifies the name of the visual mode bucket.

`-replace`

Optional argument that indicates that the contents of the visual mode bucket will replace the selection list.

`-add`

Optional string that indicates that the contents of the visual mode bucket will be added to the selection list.

`-remove`

Optional string that indicates the contents of the visual mode bucket will be removed from the selection list.

Description

The *gui_select_vmbucket* command selects the contents of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The contents of the visual mode bucket can replace, be added to, or be removed from the selection list.

Feedback

Examples

Select the 2nd bucket of SNAPSHOT visual mode.

shell> *gui_select_vmbucket -vmname SNAPSHOT -name 1 -replace*

---

gui_selection_stack

Command to manipulate selection stack

Syntax

```
status gui_selection_stack
{ -push | -pop | -clear | -get n | -remove n | -list }
```

Arguments

`-push`

Push the global selection onto the top of the selection stack

`-pop`

Pop the selection from the top of the selection stack and make it the global selection.

`-clear`

Clear the selection stack.

`-get n`

Get the nth element of the selection stack.

Feedback

`-remove n`

Remove the nth element of the selection stack.

`-list`

List the selection stack.

Description

Allows the user to push the global selection onto a stack to be popped off later.

Note: The selection stack has a maximum depth (default 10) to prevent the stack getting too large. Any selection pushed onto the stack when it is full will remove the oldest (bottommost) entry in the stack.

The 'gui_selection_stack_depth' variable can be set to change the depth.

Examples

The following example pushes the global selection to the stack, clears the global selection, and restores the pushed selection.

```
shell> gui_selection_stack -push
shell> change_selection
shell> gui_selection_stack -pop
```

See Also

- gui_selection_stack
- gui_selection_stack_depth

---

gui_set_active_window

Make the specified window the active window

Syntax

```
status gui_set_active_window
-window window_id
```

Data Types

```
window_id    string
```

Arguments

`-window window_id`

Specifies the window name id.

The matching window of this id will be made the active window.

Feedback

Note: both toplevel windows and child windows of a particular toplevel window have a currently active window. If the window is a toplevel window then the currently active toplevel window is changed, of the window is a child window the currently active child window in the specified window's parent is changed.

Description

This command makes the specified window the active window.

Examples

The following example will make the toplevel window Toplevel.2 active.

```
shell> gui_set_active_window -window Toplevel.2
```

See Also

- gui_close_window
- gui_exist_window

- gui_get_window_ids
- gui_create_window
- gui_get_current_window

---

gui_set_bucket_option

Sets the value for an option on a bucket in the specified visual mode or map mode.

Syntax

```
string gui_set_bucket_option
-map map_name
-bucket bucket_name
-option option_name
-value value | -default
```

Data Types

```
map_name          string
bucket_name       string
option_name       string
value             string
```

Feedback

Arguments

`-map` *`map_name`*

Specifies the name of the visual mode or map mode.

`-bucket` *`bucket_name`*

Specifies the name of the bucket.

`-option` *`option_name`*

Specifies the name of the option to be set.

`-value` *`value`*

Specifies the value for the option.

The *-value* option is mutually exclusive with the *-default* option. You must use one, but not both.

`-default`

Sets the option to its default value.

The *-default* option is mutually exclusive with the *-value* option. You must use one, but not both.

Description

This command sets the value for an option on a bucket in a visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. You must set the option to either a specific value or its default value. Use the *-value* option to set a specific value or use the *-default* option to set the option to its default value.

Examples

The following example sets the color of *bucket1* to yellow in the global route congestion map:

```
prompt> gui_set_bucket_option -map AREAPARTITION \\
        -bucket bucket1 -option color -value yellow
```

See Also

---

gui_set_cell_block_marks

Sets a block mark on one or more cells.

Syntax

status *gui_set_cell_block_marks*

```
cells
block_mark
```

Data Types

```
cells          list
block_mark     string
```

Arguments

cells

Lists one or more cells to mark with a block mark, in a list of cell name patterns or cell collections.

block_mark

Specifies the block mark string value to be set for the listed cells.

Description

This command sets a block mark for one or more hierarchical or leaf-level cell instances. Typically, a short symbolic string name is used as the block mark. Ultimately, a block mark can appear in the GUI as the text label for a timing path category generated from a dynamic category rule. Such block marks should be kept short to avoid using up too much screen space in the GUI.

A common application involves marking certain interesting intellectual property (IP) blocks within a design. These block marks affect the calculation of the following timing path shell attributes, which are defined only when the GUI is running:

- *blocks* - An ordered block level path; includes start, through, and end blocks
- *through_blocks* - Includes through blocks, but not the start and end blocks
- *start_block* - The start block
- *end_block* - The end block

- *start_end_blocks* - A pair consisting of the start block and the end block, in that order
- *start_end_blocks_sorted* - A pair consisting of the start block and the end block, sorted alphabetically

These block marks also affect the calculation of the following cell shell attribute, which is defined only when the GUI is running:

- *block_mark* - String value of a cell instance's (explicit) block mark, or an empty string if there is no explicit block mark

In calculating the timing path shell attributes listed previously, a block is calculated for each timing point of a timing path. If the leaf cell instance on which a timing point resides is explicitly marked with a block mark, by using the *gui_set_cell_block_marks* command, the block for the timing point is the block mark for the leaf cell. If the leaf cell instance on which a timing point resides is not explicitly marked, the block for the timing point is the block mark on the first explicitly marked hierarchical cell located by traversing up the logical hierarchy from that leaf cell instance.

If no direct or indirect hierarchical parent cell is found to be explicitly marked, the block for the timing point has a default implicit string value of "_Top_". For a timing point that is a startpoint or endpoint of a timing path, where the startpoint or endpoint is an external design port, the block has a default implicit string value of "_Port_".

Note: Each timing point of a timing path always has a defined block, which can be an explicit block mark, "_Top_", or "_Port_".

The *through_blocks* attribute value can be an empty set of blocks, which is represented by the string value "_Empty_".

Examples

The following example sets the block mark to ALU for a hierarchical cell instance identified by a cell name:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU  ALU
```

The following example sets the block mark to ALU for a hierarchical cell instance identified by a nested run of the *get_cells* command:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU]  ALU
```

The following example sets the block mark for a list of cell instances where the first item is identified by a cell name and the second item is identified by a nested run of the *get_cells* command:

```
prompt> gui_set_cell_block_marks [list I_ALU  [get_cells
 I_STACK_TOP/I1_STACK_MEM]]  \\
       my_mark
```

Feedback

See Also

- gui_get_cell_block_marks
- gui_remove_cell_block_marks

---

gui_set_charts_data

Set charts data

Syntax

```
status gui_set_charts_data
{ -global | -model model_id | -view view_name |
-plot plot_name | -annotation string }
[ -column int ]
[ { -header | -row int } ]
-name string
-value string
[ -data string ]
```

Data Types

```
model_id   int
view_name  string
plot_name  string
```

Arguments

`-global`

Set global data.

`-model model_id`

Model to set data in.

`-view view_name`

View to set data in.

`-plot plot_name`

Plot to set data in.

`-annotation string`

Set annotation data

`-column int`

Column to set model data in.

Only used by the *model* option.

Feedback

`-header`

Set model header data.

Only used by the *model* option.

`-row` *int*

Row to set model data in.

Only used by the *model* option.

`-name` *string*

Name of data to set.

The supported names depend on which object the data is being set in:

For model the following names are supported:

value Set value of model horizontal header or row value.

column_type Set specific column type or all model column types. If the column is specified then this is the type for the specified column, if no column is specified this is a list of types for the model's columns. See *gui_create_charts_model column_type* for details of the syntax.

name Set model name.

For view the following names are supported:

fit fit plots in the view.

For plot no names are currently supported:

For global no names are currently supported:

`-value` *string*

The value to set.

`-data` *string*

Extra data value

Description

Set data in model, view, plot or globally.

If model is specified then the *column* and *header* or *row* should be specified.

Examples

The following example sets the name of a model.

```
shell> gui_set_charts_data -model $model -name "Test Model"
```

Feedback

See Also

- gui_get_charts_data

---

gui_set_charts_property

Set charts property

Syntax

```
status gui_set_charts_property
{ -view view_name | -plot plot_name |
-annotation annotation_id }
-name string
-value string
```

Data Types

```
view_name       string
plot_name       string
annotation_id   string
```

Arguments

`-view view_name`

View to set property in.

`-plot plot_name`

Plot to set property in.

`-annotation annotation_id`

Plot annotation to set property in.

`-name string`

Name of property to set.

The supported names depend on which object the data is being set in:

`-value string`

The value to set.

Description

Set property of view, plot or plot annotation.

Examples

The following example sets the line stroke color of a plot to red.

Feedback

```
shell> gui_set_charts_property -plot $plot -name "stroke.color" -value
 red
```

See Also

- gui_get_charts_property

---

gui_set_current_errors

Sets the current error data and the current error group in the Error Browser.

Syntax

string *gui_set_current_errors*

[-data_name *ErrorDataName*] [-group *Group*]

```
ErrorDataName       String
Group         String
```

Arguments

`-data_name ErrorDataName`

ErrorDataName specifies the error data to make current. The error data name may be omitted. If omitted, makes all open error data current.

`-group Group`

Group specifies the group name, either a layer name or error type name, to make current. The group name may be omitted. If omitted, an entire error data file is made current.

Description

Sets the current error data and the current error group in the Error Browser. This is analogous to selecting error data and group in the Error Browser tree view. By default, there is are no current errors. The current errors determine the errors that are displayed in the error list and in the layout view by default.

If the error data option is omitted, selects the design, the parent of all open error data. The group option is valid only when there is a single error data specified, and raises an error if no error data was specified. The group string is interpreted as error type if error grouping has been set to *type*, else the group string is interpreted as layer. If the group option is omitted, all groups in the specified error data are made current.

Feedback

Examples

The following example sets error grouping by error type, and sets the "Open Locator" type errors for LVS error data as the current errors:

gui_set_error_browser_option -grouping type gui_set_current_errors -data_name LVS -group "Open Locator"

The following example sets the design as current, displaying all errors in all open error data in the error list and layout view.

gui_set_current_errors

See Also

- gui_error_browser
- gui_set_selected_errors

---

gui_set_current_task

Set current task to the given task.

Syntax

string *gui_set_current_task* -name *task_name*

-task *task_name*

`string task_name`

Arguments

`-task task_name`

Specifies the name of the task to make current.

Description

The gui_set_current_task command sets the current application task to the given task.

See Also

- gui_create_task
- gui_get_current_task
- gui_get_task_list

Feedback

gui_set_eco_context

Sets context for manual ECO in the GUI

Syntax

```
status gui_set_eco_context
[-type Type of context]
[-lib_cells Set library cell]
[-filter_using_attributes Use the following attributes to filter on
 library cells]
```

Data Types

```
type        string
lib_cells   list
filter_using_attributes   string
```

Arguments

type

Set the type of context. Supported types are 'insert_buffer' or 'size_cell'.

lib_cells

Set the library cells for the given context.

filter_using_attributes

Uses the attributes from this list to filter on the library cells. Supported types are 'dont_touch' and 'dont_use'

Description

The *gui_set_eco_context* command sets the context of manual ECO in the GUI.

When GUI ECO dialogs are up and running the library cell is controlled using these set of commands. The *gui_reset_eco_context* command can be used to reset the context and *gui_reset_eco_context* can be used to get the current context given a 'type'.

Examples

The following example shows how a context can be set for a given type.

```
prompt> gui_set_eco_context -type insert_buffer -lib_cells {INV* BUFF*}
 -filter_using_attributes {dont_touch}
1
prompt> gui_set_eco_context -type size_cell -lib_cells $lib_cell_clct
 -filter_using_attributes {dont_use}
1
```

Feedback

See Also

- gui_get_eco_context
- gui_reset_eco_context

---

gui_set_error_browser_option

Sets options for the Error Browser dialog box.

Syntax

string *gui_set_error_browser_option*

[-grouping *Group*] [-show_mode *ShowMode*] [-view_mode *ViewMode*] [-zoom_factor *ZoomFactor*] [-hide_fixed *DoHide*] [-hide_ignored *DoHide*] [-advance_to_next_unfixed *DoNext*] [-dim *DoDim*] [-show_open_locator_nodes *DoShow*] [-show_tooltip *DoShow*] [-show_command_buttons *DoShow*] [-highlight_objects *DoHighlight*] [-auto_set_object_visible *SetVisible*] [-auto_set_object_visible_type *SetVisibleType*]

```
Group              String
ShowMode           String
ViewMode           String
ZoomFactor         float
DoHide             Boolean
DoNext             Boolean
DoDim              Boolean
DoShow             Boolean
DoHighlight        Boolean
SetVisible         Boolean
SetVisibleType     String
```

Arguments

`-grouping Group`

The *-grouping* option accepts argument values *type* or *layer* and sets whether errors are grouped by types or layers. This is similar to selecting or deselecting *Show by Layer* option in the Error Browser *Options* menu. By default, errors are grouped by type by default.

`-show_mode ShowMode`

The *-show_mode* option accepts argument values *all*, *selected*, or *none* and sets whether all errors, selected errors, are no errors are shown in layout views. This is similar to making a selection from the *Show* field in the Error Browser. The default is that all errors are shown.

Feedback

`-view_mode` *`ViewMode`*

The *-view_mode* option accepts argument values *zoom*, *pan*, or *off* and sets the layout view to zoom to, pan to, or not change to the currently selected errors in the Error Browser. This is similar to making a selection from the *Follow* field in the Error Browser. The default is to zoom to the selected error.

`-zoom_factor` *`ZoomFactor`*

The *-zoom_factor* option accepts float values between *0.1* and *10.0* and sets the zoom factor used when the view_mode is *zoom*. The zoom factor rounds to 1/10 precision. The default value is *1.0*.

`-hide_fixed` *`DoHide`*

The *-hide_fixed* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether fixed errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Fixed Errors* option in the Error Browser *Options* menu. By default, fixed errors are shown.

`-hide_ignored` *`DoHide`*

The *-hide_ignored* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether ignored errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Ignored Errors* option in the Error Browser *Options* menu. By default, ignored errors are shown.

`-advance_to_next_unfixed` *`DoNext`*

The *-advance_to_next_unfixed* option accepts Boolean values *1* or *true* to mean advance to next unfixed error when an error is fixed and *0* or *false* to advance to next fixed/unfixed error. This is similar to checking or unchecking the *Advance To Next Unfixed When Error is Fixed* option in the Error Browser. By default, unfixed errors are not advanced to.

`-dim` *`DoDim`*

The *-dim* option accepts Boolean values *1* or *true* to mean "dim" and *0* or *false* to mean "do not dim". The option governs whether layout views are dimmed when errors are displayed. This is similar to checking or unchecking the *Dim* option in the Error Browser. By default, layout views are not dimmed.

`-show_open_locator_nodes` *`DoShow`*

The *-show_open_locator_nodes* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether net nodes are highlighted together with the open locator flylines for selected open locator errors. This is similar to selecting or deselecting the *Display Net Nodes*

for Selected Open Locators option in the Error Browser *Options* menu. By default, the tool does not show the net node highlights.

`-show_tooltip` *`DoShow`*

The *-show_tooltip* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether tool tips are shown on the error browser list view and details pane. By default, the tool shows the tool tips.

`-show_command_buttons` *`DoShow`*

The *-show_command_buttons* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether the command buttons at the bottom of the error browser are shown. By default, the tool shows the command buttons.

`-highlight_objects` *`DoHighlight`*

The *-highlight_objects* option accepts Boolean values *1* or *true* to mean "highlight", and *0* or *false* to mean "do not highlight". This setting controls whether design objects associated with the selected error are highlighted in the layout view using design object highlighting. When the error object selection changes, the highlight is automatically removed from the associated design objects. By default, the tool does not highlights associated design objects.

`-auto_set_object_visible` *`SetVisible`*

The *-auto_set_object_visible* option accepts Boolean values *1* or *true* to mean "turn on" and *0* or *false* to mean "do not turn on". The option governs whether relevant object visibility of layout view are turned on when errors are displayed. This is similar to checking or unchecking the *Auto Set Object Visible* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on for related error object display.

`-auto_set_object_visible_type` *`SetVisibleType`*

The *-auto_set_object_visible_type* option accepts argument values *incremental*, or *exclusive* to mean turn on layers/objects incrementally or exclusively when a different error is selected. This is similar to selecting the *Auto Set Object Visible Incremental/Exclusive* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on incrementally for related error object display.

Description

This command sets option setting for the Error Browser. Multiple option values can be set using one command.

Feedback

Examples

The following example sets the grouping of errors by layers, to show all errors, and to pan to selected errors.

```
prompt> gui_set_error_browser_option -grouping layer -show_mode all
 -view_mode pan
```

The following example sets the option to dim layout views when errors are displayed and to hide fixed errors:

```
prompt> gui_set_error_browser_option -dim true -hide_fixed true
```

- gui_error_browser
- gui_get_error_browser_option

---

gui_set_error_data_filter

Set a filter on open error data.

Syntax

string *gui_set_error_data_filter*

-show | -hide [-types *TypeList*] [-layers *LayerList*] [-objects *ObjectCollection*] [-typed_object_names *ObjectSpecification*] [-object_types *ObjectTypeSpecification*]

```
TypeList         String List
LayerList        String List
ObjectSpec       String List or collection
ObjectCollection collection
ObjectTypeList   String List
```

Arguments

`-show | -hide`

Mutually exclusive required option to specify whether the filtering should hide the records matching the filter criteria (-hide) or prune to the records matching the filter criteria (-show).

`-types` *`TypeList`*

Optional argument to specify a list of type names as filter criteria. An error record would match this criteria if its type attribute value matches any type name in the list.

`-layers` *`LayerList`*

Optional argument to specify a list of layer strings as filter criteria. An error record would match this criteria if its layer string matches any layer string in the list. The layer strings is the layer_names string attribute value for the error. It is is also displayed in the error browser.

`-objects` *`ObjectCollection`*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects,such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any object in the collection. Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects".

`-typed_object_names` *`ObjectSpecification`*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects, such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any objects in the specification. Specify objects with type-name, object-name-list pairs, for example

{ net { NetName1 NetName2 NetName3 {} } }.

Multilple such pairs may be listed to specify objects of multiple types as filter criteria, for example

{ { net { Net1 Net2 Net3 {} } } { pin { PinA PinB } } }.

Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects". A null object association can be specified using an empty string as the object name.

`-object_types` *`ObjectTypeList`*

Optional argument to specify a list of object type names as filter criteria. An error record would match this criteria if the type attribute value of any of its associated objects matches any type name in the list.

Specify object types with type-name, type-name-list pairs, for example

{ net_type { Signal Power } }.

Multilple such pairs may be listed to specify lists for multiple object types as filter criteria, for example

{ { net_type { Signal Power } } { route_type { Detail User } } }.

Description

Set the given filter on open error data. Filter state is set and is applied on currently open error data and subsequently opened error data until cleared. When a new filter is set, the new filter overrides any previously set filter. There is no accumulation of filters.

In order to show errors that have been hidden by a previously set filter, clear the filter with gui_clear_error_data_filter.

You can either filter out errors matching the filter specification (use -hide) or prune the current errors to errors matching the filter specification (use -show).

If multiple kinds of criteria are used in a filter, then an error must satisfy each kind of criteria to be a match. For example, if a filter with both an error type list (the -types option) AND an object type list (the -object_types option) is set, then for an error to be a match for the filter, its type must be one of the types set in the filter AND its associated object type must be one of the object types set in the filter.

Examples

The following example illustrates how to show only errors of type "Short":

gui_set_error_data_filter -show -types "Short"

The following example illustrates how to show only errors of type "Short" that are also associated with the "Signal" net type:

gui_set_error_data_filter -show -types "Short" -object_types {{net_type "Signal"}}

The following example illustrates how to hide errors associated with the "Global" route type:

gui_set_error_data_filter -hide -object_types {{route_type {Global}}}

The following example shows how to clear the error data filter:

gui_clear_error_data_filter

Feedback

gui_set_error_status

Set the error status value of one or more error records.

Syntax

string *gui_set_error_status*

-errors *Errors* -status *Status*

```
Errors            String
Status            Status
```

Arguments

`-errors` *Errors*

Errors specifies the handle for a collection of errors on which to set the fixed state.

`-status` *Status*

The *-status* argument specifies the status value. The supported status values are tool dependent. All tools with physical error data for the error browser support values "error" and "fixed". Some tools also support "ignored".

Description

This command sets the status of the given error objects to the given status value.

The status of an error is displayed in the Error Browser and an error can be hidden or shown based on its status value. The status is a part of the textual report written to a file by gui_report_errors.

See Also

- gui_error_browser
- gui_set_error_browser_option

gui_set_hierview_data

Set various state in the current or named Hierarchy View and its sub-views.

Syntax

string *gui_set_hierview_data*

Feedback

```
[-view                  View_Name]
[-tree_type             Tree_Type]
[-tree_attr_group       Attr_Name]
[-tree_filter           String]
[-map_area              Attr_Name]
[-map_color             Attr_Name]
[-childlist_name        String]
[-childlist_attr_group Attr_Name]
[-childlist_filter      String]
[-elide                 Elide_Type]
View_Name      String
Attr_Name      String
Tree_Type      String (logical|rtl)
```

Arguments

`-view View_Name`

Use the given HierView window name (ex: Hier.1) for the following actions. Default is to get the most recent used HierView window name.

`-tree_type Tree_Type`

Set the current Hier Tree type to Logical or RTL hierarchy. RTL hierarchy is only available in RTLA. The default is logical.

`-tree_attr_group Attr_Name`

Set the current Hier Tree attribute group name.

`-tree_filter String`

Set the current Hier Tree filter expression.

`-map_area Attr_Name`

Set the Hier Map Area attribute group name.

`-map_color Attr_Name`

Set the Hier Map Color attribute group name.

`-childlist_name String`

Set the current ChildList sub-view name.

`-childlist_attr_group Attr_Name`

Set the current ChildList attribute group name.

`-childlist_filter String`

Set the current ChildList filter expression.

`-elide Elide_Type`

Set the text elide for the view. Supported types are 'middle', 'left', 'right'.

Feedback

Description

This command allows you to set various current Hierarchy View related view settings.

See Also

- gui_get_hierview_data

---

gui_set_highlight_options

Change the options that control highlighting.

Syntax

string *gui_set_highlight_options*

```
[-current_color color_id | -next_color | -auto_cycle_color enable]

string          color_id
bool            enable
```

Arguments

`-current_color color_id`

Changes the current highlight color to the specified value. The current highlight color is used as a default when no color is specified for some operations.

`-next_color`

Changes the current highlight color to the next color in the set of available colors. This will wrap around so that it can be used to cycle through the color set. The provided colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

`-auto_cycle_color enable`

Specify if the current color should automatically be incremented after each gui_change_highlight -add operation. The color is not advanced if an explicit color is specified with the -color option of gui_change_highlight.

Description

The gui_set_highlight_options command can be used to modify highlighting behavior.

Examples

Set the current highlight color to blue.

shell> gui_set_highlight_options -current_color blue

Feedback

Enable auto cycling.

shell> gui_set_highlight_options -auto_cycle_color true

Advance to the next color.

shell> gui_set_highlight_options -next_color

See Also

- gui_change_highlight
- gui_get_highlight
- gui_get_highlight_options

---

gui_set_hotkey

Sets a key binding to a Tcl command or a menu command in a GUI window.

Syntax

string *gui_set_hotkey*

```
-hot_key key_name
-tcl_cmd command_name | -menu menu_name
[-replace]
[-delete]
[-replay_log_only]
[-window_type window_type_name | -all_window_types]

key_name              string
command_name          string
menu_name             string
window_type_name      string
```

Arguments

`-hot_key key_name`

Specifies the key that you are associating with the specified command. The *key_name* is a string that contains the key name can also contain one or more modifiers. The valid modifier keys are *SHIFT*, *ALT*, and *CTRL*. You specify the modifier names by prepending them to the key name and connecting them with a plus sign (+).

If you bind an unmodified key and the shift-modified key is not bound, the binding works for both the shifted and nonshifted keys. If you set separate bindings for the shift-modified key and the unmodified key, the bindings are unique. Note that shift modifiers work only with letter keys and function keys.

Feedback

Menus display the first key binding defined for a menu item. The key binding always appears in uppercase with its modifiers. For example, an unmodified accelerator for the letter "a" is shown as "A' and a shift-modified "a" (an uppercase A) is shown as "SHIFT+A."

`-tcl_cmd` *`command_name`*

Specifies the tool command language (Tcl) code that the tool executes when you press the key and its modifiers, if any.

The *-tcl_cmd* option and the *-menu* option are mutually exclusive.

`-menu` *`menu_name`*

Specifies the menu command that the tool invokes if you press the key and its modifiers, if any, when the menu command is enabled.

The *menu_name* is a string that specifies the hierarchy of the menu labels, with the labels connected by arrows formed from a hyphen and a greater than sign (->). For example, "File->Exit" specifies the Exit command on the File menu. The *menu_name* can also include the mnemonic for the menu text, which is specified with an embedded ampersand (&), but they are not required to do so.

The *-menu* option and the *-tcl_cmd* option are mutually exclusive.

`-replace`

Replaces an existing key binding for the specified menu command or Tcl command with the specified key.

`-delete`

Removes the key binding from the specified menu command or Tcl command.

`-replay_log_only`

Limits logging of the Tcl command associated with the key to the command replay log file. The tool suppresses the command echo and result display to the xterm and console, and the command does not appear in the output log or the Tcl history log.

The tool ignores this option if you do not specify the *-tcl_cmd* option.

`-window_type` *`window_type_name`*

Specifies the type of top-level window that the key should apply to. (A top-level window is a window with a menu bar.) If you do not specify this option, the tool uses the application default window type.

The read-only variable *gui_default_window_type(3)* specifies the application default window type.

Feedback

`-all_window_types`

Sets the key binding in every type of window for which it is applicable.

For menu command key bindings, the tool searches all of the top-level windows for the specified menu command and adds the key binding in any window where it exists. If the tool does not find any applicable windows, it issues a warning.

For Tcl command key bindings, the tool adds the binding in every type of top-level window.

Description

This command binds a given key to a function in the graphical user interface (GUI). The function might be available on a menu or specified by Tcl code. A menu command can have multiple key bindings. Key bindings can be specified for built-in or user-defined menu commands.

Key bindings for menu commands have several additional features that Tcl command key binding do not have. The function for a menu command key binding is invoked only when the menu command is enabled. This ensures that the function is invoked only when it is valid to invoke the function. In addition, the primary key bindings for menu commands appear with the menu text to make it easier for you to remember the bindings.

Examples

The following example creates a menu item and adds an additional key binding to it.

```
prompt> gui_create_menu -menu "&Test->Sub&Menu->Echo Hi" \
   -tcl_cmd "echo hi" -hot_key "Ctrl+5"
prompt> gui_set_hotkey -menu "Test->SubMenu->Echo Hi" \
   -hot_key "Ctrl+Y"
```

The following example creates a key binding, P, that invokes a Tcl command to print a query on the currently selected objects.

```
prompt> gui_set_hotkey -tcl_cmd {query_objects [get_selection]} \
   -key P
```

---

gui_set_layout_layer_visibility

Set the visibility of layers in a layout window

Syntax

```
status gui_set_layout_layer_visibility
collection_of_layers
[-window windowID]
-toggle | -only
```

Data Types

```
string windowID
```

Arguments

collection_of_layers

The collection of layers or list of layer names provided in technology file.

-window *windowID*

This specifies the window to have its mode changed. If not specified then the currently active window will be used.

-toggle

Toggle the visibility of the specified layers. The option is mutually exclusive with -only.

-only

Turn off all layers and then turn on only the specified layers. The option is mutually exclusive with -toggle.

Description

This command is used to set visibility of layers in a layout view.

Examples

To turn on visibility of METAL2, METAL3 layers only:

```
shell-t> gui_set_layout_layer_visibility {METAL2 METAL3} -only -window
 Layout.1
1
```

Feedback

To toggle visibility of layer METAL3:

```
shell-t> gui_set_layout_layer_visibility {METAL3} -toggle -window
 Layout.1
1
```

See Also

- gui_set_setting

---

gui_set_layout_user_command

Set user defined command for layout input.

Syntax

status *gui_set_layout_user_command*

```
-apply_cmd TclCmd | -clear
[-input_type InputType]
[-snap_type SnapType]
[-status_text string]
[-cancel_cmd TclCmd]
```

Data Types

```
TclCmd    string
InputType one of [rectangle | line | polygon | point]
SnapType  one of [litho | site | midsite | wiretrack | midwiretrack |
 user]
```

Arguments

`-apply_cmd` *TclCmd*

The user procedure to be called when input completed. The coordinates will be passed as an argument to this procedure. The options is mutually exclusive with -clear.

`-clear`

Cancel all pending input and return layout to default mouse mode. The options is mutually exclusive with -apply_cmd.

`-input_type` *InputType*

The desired input type: rectangle | line | polygon | point. Default is rectangle

`-snap_type` *SnapType*

The desired snap type: litho | site | midsite | wiretrack | midwiretrack | user Default is litho

Feedback

`-status_text` *string*

The help string to be shown in layout window status bar.

`-cancel_cmd` *TclCmd*

The user procedure to be called when input is canceled.

Description

This command is used to facilitate creation of user defined tools to extend the layout view standard capabilities. The command sets layout view to given input mode and executes user callback procedure on input complete. The input points are passed as an argument to user callback.

Examples

Cut the object shape with user specified rectangle

```
proc my_cut_object_shape_proc { rect } {
  change_selection [cut_objects [get_selection] -bbox {$rect}]
}

gui_set_layout_user_command -apply_cmd {my_cut_object_shape_proc}
 -status_text "Drag the rectangle to cut selected objects" -input_type
 rectangle
1
```

See Also

- change_selection
- get_selection

---

gui_set_map_option

Sets the value for an option in the specified visual mode or map mode.

Syntax

```
string gui_set_map_option
-map map_name
-option option_name
-value value | -default
```

Data Types

```
map_name        string
option_name     string
value           string
```

Feedback

Arguments

`-map` *`map_name`*

Specifies the name of the visual mode or map mode.

`-option` *`option_name`*

Specifies the name of the option to be set.

`-value` *`value`*

Specifies the value for the option.

The *-value* option is mutually exclusive with the *-default* option. You must specify one, but not both.

`-default`

Sets the option to its default value.

The *-default* option is mutually exclusive with the *-value* option. You must specify one, but not both.

Description

This command sets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You must set the option to a specific value or its default value. Use the *-value* option to set a specific value or the *-default* option to set the option to its default value.

Examples

The following example sets the number of bins to 9 in the global route congestion map:

```
prompt> gui_set_map_option -map AREAPARTITION \\
        -option num_bins -value 9
```

See Also

- gui_get_bucket_option

Feedback

gui_set_mouse_tool_option

Set an option on a mouse tool

Syntax

string *gui_set_mouse_tool_option* -tool *string*

-option *string* -value *string*

```
string string
string string
string string
```

Arguments

`-tool string`

Tool to set option for.

`-option string`

Option to set.

`-value string`

New option value.

Description

This command sets a mouse tool option. Mouse tool options influence the operation of the mouse tool when that tool is active

Examples

```
> gui_set_mouse_tool_option -tool SELECT -option InputMode -value
 Rectangle
```

See Also

- gui_mouse_tool
- gui_get_mouse_tool_option

gui_set_performance_log_option

Configures performance log behavior of logging specific commands or all default commands

Feedback

Syntax

```
status gui_set_performance_log_option
[-commands command_names | -log_all]
[-add | -remove]
```

Data Types

command_names	list

Arguments

`-commands` *command_names*

This option is mutually exclusive -log_all. If -add or -remove are not given, the argument sets or refreshes the commands to be logged. If a logging process has not been started, this argument sets the specific commands to be logged for the upcoming logging process. If already been started, this argument refreshes the commands to be logged from now on.

If -add or -remove are given, the argument set the commands to be added to or removed from already existing commands list.

`-add`

This option is mutually exclusive with -remove and must be used with -commands. Use -add to add commands to the already existing commands list which is set by this command. If there is no existing commands list, this argument generates a commands list to be logged.

`-remove`

This option is mutually exclusive with -add and must be used with -commands. Use -remove to remove commands from the already existing commands list which is set by this command.

`-log_all`

This option is mutually exclusive with -commands. This option resets the commands to be logged as default.

Description

This command controls the performance log behavior of logging specific commands or all default commands. After execute option -commands, the default commands list is not effective until execute option -log_all. The commands to be logged can be reset as default by option -log_all. This command can be used before and during a logging process and change the commands to be logged. After successfully execute this command, the logging behavior changes.

Feedback

Examples

```
Configure log behavior which logs performance data before and after
 executing
commands of gui_zoom and win_select_object.

prompt> gui_set_performance_log_option -commands {gui_zoom
 win_select_objects}

Add command gui_get_current_window to the already existing commands list.

prompt> gui_set_performance_log_option -commands {gui_get_current_window}
 -add

Remove command gui_get_current_window from the already existing commands
 list.

prompt> gui_set_performance_log_option -commands {gui_get_current_window}
 -remove

Reset the log behavior which logs performance data of all default
 commands.

prompt> gui_set_performance_log_option -log_all
```

See Also

- gui_log_performance
- gui_get_performance_log_option

---

gui_set_pref_value

Set the value of a preference key.

Syntax

string *gui_set_pref_value* -key *Key* -value *Value*

```
[-category Category]

Key             String
Value           Depends on the data type of the value of the specified
 key
Category        String
```

Arguments

```
-key Key
```

Key specifies the key to set the new value.

Feedback

`-value Value`

Value specifies the new value of the key. The new value should be of the same data type, one of (integer,bool,double,color,string) as the data type of the value of the key.

`-category Category`

Category specifies the category that owns the specified key. If not specified, a default category will be used.

Description

This command set the value of a preference key. Returns the value of the preference key.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command *gui_set_pref_value* is then used to change the value of the preference key to true.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
gui_set_pref_value -category my_category -key some_key -value true
```

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_set_preset

Sets the specified preset for object specified by category

Feedback

Syntax

```
status gui_set_preset
-category category
[-system]
[-shared]
-default
-name name
```

Data Types

```
category    string
name         string
```

Arguments

`-category category`

Specifies the name of the category that the presets be applied to.

`-system`

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

`-shared`

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

`-default`

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

`-preset preset`

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

Description

This command applies the default or specified preset to a category.

Examples

The following example applies the system presets 'floorplan' to the Layout.

```
prompt> gui_set_preset -category Layout -name floorplan -system
```

See Also

- gui_get_presets

Feedback

gui_set_region

Sets the coordinates of the current region rectangle or rectilinear polygon.

Syntax

```
status gui_set_region
shape
```

Data Types

```
shape            list
```

Arguments

shape

Specifies the region coordinates.

For a rectangle, the values should be given in the following format:

```
{{x1 y1} {x2 y2}}
```

For a rectilinear polygon, the values should be given in the following format:

```
{{x1 y1} {x2 y2} ... {xN yN}}
```

Description

This command sets the region shape to be used in layout region mode and returns 1 if it is successful.

Examples

```
prompt> gui_set_region {{-1743.945 18.357} {42.833 1523.657}}
1
```

See Also

- gui_get_region

gui_set_selected_errors

Changes the selection in the Error Browser to add or replace errors.

Syntax

int *gui_set_selected_errors*

```
-add | -replace errors
```

Feedback

Data Types

errors string

Arguments

-add *errors*

Adds the specified errors to the current selection. This option is mutually exclusive with the *-replace* option.

-replace *errors*

Replaces the specified errors in the current selection. This options is mutually exclusive with the *-add* option.

Description

Sets new selected errors or adds new selected errors in the Error Browser. Errors are identified as a collection of error objects. If the *-add* option is given, the command adds the given errors to the currently selected errors. If the *-replace* option is given, the command replaces the current selection with the given errors. The command fails if the given errors are not in the current set specified by the *gui_set_current_errors* command, or with a click in the Error Browser tree view. The command returns 1 if successful, 0 otherwise.

See Also

- gui_clear_selected_errors
- gui_error_browser
- gui_set_current_errors

---

gui_set_setting

Sets a setting on the specified window.

Syntax

gui_set_setting

```
-window WindowID
-setting Setting
-value Value

WindowID        String
Setting        String
Value        String | Bool | Int | Double
```

Feedback

Arguments

`-window WindowID`

WindowID specifies the window to set the setting

`-setting Setting`

Setting specifies the setting to set

`-value Value`

Value specifies the value of the setting

Description

Sets a setting on the specified window. Windows are views or top level windows. The setting is a property of the window and the value's type is specific to the given setting.

Examples

```
shell> gui_set_setting -window Layout.1 -setting showCell -value true
```

```
shell> gui_set_setting -window Layout.1 -setting viewLevel -value 1
```

See Also

- gui_get_setting

---

gui_set_task_list

Set the list of tasks that are visible in the task assistant, and set their order.

Syntax

gui_set_task_list

```
-tasks    TaskList

TaskList    List
```

Arguments

`-tasks TaskList`

TaskList specifies the list of tasks that will be visible in the task assistant and their order. Tasks which are not included in the list will still exist but will not be shown in the selection combo box of the task assistant.

Description

The gui_set_task_list command sets the list of tasks that are visible and available in the task assistant and sets their order.

Feedback

Examples

The following simple example sets the visible list of tasks to "Design Planning" followed by "Routing".

```
gui_set_task_list -tasks {{Design Planning} {Routing}}
```

See Also

- gui_get_task_list
- gui_create_task

---

gui_set_user_units

Sets the units for GUI.

Syntax

```
status gui_set_user_units
-type unit_type
-value unit_value
```

Data Types

```
unit_type          string
unit_value         string
```

Arguments

`-type unit_type`

Specifies the type of unit to set. The valid value is: "power".

`-value unit_value`

Specifies the unit value. The format of *unit_value* is "positive double number + *unit*". For power, examples include "1mW", "1e-2W", "7.1uW", and so on.

Description

This command sets the units that are used for GUI. "power" is the sole option for *unit_type* currently.

Examples

The following example sets the unit of power to 120mW.

```
prompt> gui_set_user_units -type power -value 120mW
1
```

Feedback

See Also

- gui_get_user_units

---

gui_set_utable

Set various state about User Tables.

Syntax

string *gui_set_utable*

```
[-name          Table_Name]
[-parent        Table_Name]

[-tag           Report_Tag]
[-title         Report_Title]
[-comment       Report_Comment]
[-menu          Root_Menu]

```

Feedback

Arguments

`-name` *`Table_Name`*

A table name argument used with other arguments below.

`-parent` *`Table_Name`*

Set the parent table name for the given table name argument.

`-tag` *`Report_Tag`*

Set a tag string for the given table name argument.

`-title` *`Report_Title`*

Set a report title for the given table name argument.

`-comment` *`Report_Comment`*

Set a report comment for the given table name argument.

`-menu` *`Root_Menu`*

Assign a TCL defined Context Sensitive Menu Root name to this table that is shown when the user right clicks on any table cell in the table.

`-column` *`Column_Name`*

The column name argument is used with other arguments below.

`-prefix` *`Prefix_Char`*

Formats numeric data to the given prefix char. Special prefix characters are " " space which means no formating and "A" which means automatic formating. If given a table name, then it only applies to that table. If also given a column name, then it only applies to that tables column. If given by itself then it sets the default for all table columns that are numeric. Examples: (...,n=nano,m=milli,k=killo,M=Mega...)

`-link` *`Link_String`*

The link string use with the *-action* option below.

`-action` *`TCL_Expr`*

These options allow you to define a link action for every empty table cell in a given column. A link action is basically a TCL procedure call. In addition you can pass arguments that reference other values in the same row but in different columns. This option required the use of the options *-column* which indicates the column that this action is applied to and the *-link* text that is shown in the table cell under that column. (See Example Below)

Feedback

`-create_hook` *`TCL_Proc`*

Set table create TCL hook proc name. The proc is called when a new UserTable is created.

`-close_hook` *`TCL_Proc`*

Set table close TCL hook proc name. The proc is called when a UserTable is closed.

`-enter_hook` *`TCL_Proc`*

Set a specific table name enter hook TCL proc name. The named proc is called when a UserTable with the specified *-name* option is entered/shown. The argument to the proc is the name of the table that was entered/shown. Note: The enter hook is only run if the table is changed for the current UserTable window.

`-exit_hook` *`TCL_Proc`*

Set a specific table name exit hook TCL proc name. The named proc is called when a UserTable with the specified *-name* option is exited to show another table. The argument to the proc is the name of the table that was exited. Note: The exit hook is only run if the table is changed for the current UserTable window.

`-select_hook` *`TCL_Proc`*

Set table data select TCL hook proc name. This proc is called when any Table cell in any column is sected.

`-sel_action` *`TCL_Proc`*

Set the TCL action proc name that is called when a selection is made in the *-column* option given above. The arguments to the proc are the data of the selection and the selected row number and the total number of rows selected.

`-dsel_action` *`TCL_Proc`*

Set the TCL action proc name that is called when a deselection is made in the *-column* option given above. The arguments to the proc are the data of the deselection and the deselected row number and the column name of the new selection. An empty new column argument means a selection in the same column was made.

`-window` *`Window_Name`*

This option is used with other options below.

`-filter` *`Filter_Expr`*

This allows you to set the filter value on the current table visible in the view given by the '-window' option.

Feedback

Description

This command allows you to set various state and actions on User Tables.

Examples

The following example creates a new table MyTable and assigns the various state
and action options described above.

```
        # Create MyTable with columns: cell, voltage, current and add
 some data
# Note: the last column "Show" is left empty for an action column.
gui_create_utable -name MyTable \\
  -columns {cell voltage:double current:double Show}
gui_append_utable -name MyTable -rows {
  {A 5.0 0.2 {}}
  {B 6.0 0.4 {}}
  {C 7.0 0.6 {}}
}

# Create a context menu with one item:
set menuRoot "My Custom Menu"
gui_create_menu -root $menuRoot -menu "MyItem" -tcl_cmd "echo MyItem"

# Create various hooks that are executed at create/close and selection.
proc createTableHook { table } {
  puts stdout "*New table created: $table"
}
proc closeTableHook { table } {
  puts stdout "*Closing table: $table"
}
proc selectHook { table } {
  set win [gui_get_current_window -mru -type UserTable]
  set columns [gui_get_utable -window $win -columns]
  set values  [gui_get_utable -window $win -values $columns]
  foreach v $values {
    echo "Table: $table, Selected Value: $v"
  }
  # return "1" if default selection action should be ignored
  return "0"
}
proc selAction {data row rowCount} {
  puts stdout "selAction $data $row $rowCount"
}
proc dselAction {data row newColumn} {
  puts stdout "dselAction $data $row $newColumn"
}

# Create an action proc used for a column action
```

Feedback

```
proc power { v c } {
  puts stdout [expr $v * $c]
}

# Set various state and actions on my table:
gui_set_utable -name MyTable \\
    -title "My Report" \\
    -tag   "My Tag" \\
    -comment "This is a comment..." \\
    -menu $menuRoot \\
    -create_hook createTableHook \\
    -close_hook  closeTableHook \\
    -sel_action selAction \\
    -dsel_action dselAction \\
    -select_hook selectHook \\
    -action {power @{voltage} @{current}} \\
      -column Show -link Power

# Note the action calls the TCL proc power and also references
# column values using the @{column_name} argument syntax.

gui_show_utable -name MyTable -mru
```

---

gui_set_utable_meta

Create a MetaData Object for use in creating a new UserTable.

Syntax

string *gui_set_utable_meta*

Feedback

```
-name         MetaDataObj_Name
[-remove]
[-title       Report_Title]
[-comment     Report_Comment]
[-tag         Report_Tag]
[-menu        Root_Menu]
[-col_name    Column_Name]
[-col_type    Column_Type]
[-read_only]
[-hidden]
[-user_enums Column_Type_Enums]
[-user_list  Column_Type_List]

MetaDataObj_Name   String
Report_Title       String
Report_Comment     String
Report_Tag         String
Root_Menu          String
Column_Name        String
Column_Type        String
Column_Type_Enums  List of Strings
Column_Type_List   List of Strings
```

Arguments

`-name MetaDataObj_Name`

The name of the MetaData object.

`-remove`

Remove and free the given MetaData object.

`-title Report_Title`

Report title for a table.

`-comment Report_Comment`

Report comment for a table.

`-tag Report_Tag`

A tag string assigned to the table.

`-menu Root_Menu`

User Context Sensitive Menu Root name.

`-col_name Column_Name`

A column name that has the following column type.

`-col_type Column_Type`

A column type name.

-read_only

Mark the given column name as read only which prevents editing data in that column.

-hidden

Mark the given column name as hidden.

-user_enums *Column_Type_Enums*

A list of single string values for a new user type defined by the -col_type argument.

-user_list *Column_Type_List*

A list of multi string values for a new user type defined by the -col_type argument. A table cell of this type can contain multiple unique values of this type separated by a comma.

Description

```
This command creates a new MetaData object that then can be used to add
 useful meta data to
the creation of a new UserTable. A new UserTable is created via the
 gui_create_utable
and the gui_import_utable commands. MetaData can be used to define
 certain column data/object
types instead of using column name postfixes. Users can also define new
 data types that
are made of a list of unique string values. A table cell can then be set
 to only allow
single values (enums) of that new type or a comma separated list of
 values (lists) of that
new data type. MetaData can also be exported via the gui_export_utable
 command along with
the table data.
```

Examples

```
The following example creates a new MetaData object named myMetaObj which
 contains a
report title and comment.

shell> gui_set_utable_meta -name myMetaObj -title "My Report" -comment
 "This is a comment"

The following example adds a definition of a new data type 'myData'
 assigned to
the column 'myDataColumn'. This new data type has 4 values (valA valB
 valC and valD).
Also optionally the user can add a help string after the value separated
 by a
colon ':' which is used to show tool tips.
```

Feedback

```
shell> gui_set_utable_meta -name myMetaObj -col_name myDataColumn
 -col_type myData -user_enums {
  {valA: Help string for valA...}
  {valB: Help string for valB...}
  {valC: Help string for valC...}
  {valD: Help string for valD...}
}

The following example then imports a CSV file and adds the previously
 defined MetaData to
that new table.

shell> gui_import_utable -file myTable.csv -meta_obj myMetaObj
```

---

gui_set_utable_values

Set the given UserTable values in the given column(s) and the filtered set of rows.

Syntax

string *gui_set_utable_values*

```
-name             Table_Name
-columns          Column_List
-values           Value_List
[-filter          Filter_Expr]

Table_Name      String
Column_List     StringList
Value_List      StringList
Filter_Expr     String
```

Arguments

`-name Table_Name`

The table name on which to set the new values.

Feedback

`-columns` *`Column_List`*

Provides a list of one or more column names that indicate the location of values to set.

`-values` *`Value_List`*

Provides a list of values used to set in the columns given above. *Note:* The number of values must match the number of columns.

`-filter` *`Filter_Expr`*

To only update a certain set of rows in the table with new values you must ether first filter the table in the view or use this filter expression to only target the rows of interest.

Description

```
This command allows you to update/change the values in the table rows
selected by the given columns and the given filter value.
If no filter option is given the all rows will be updated unless the
table is currently viewed, then all rows will be updated that match
the current view filter setting.
```

Examples

```
The following example updates the value of column 'direction' to 'out'
and the column 'state' to the value 'open' for all the rows that match
the filter where 'pin_module' is equal to 'my_module'.
```

```
shell> gui_set_utable_values -name $table -column {{direction} {state}}
 -value {out open} \\
     -filter {pin_module == my_module}
```

See Also

- gui_get_utable
- gui_set_utable
- gui_foreach_utable_row

---

gui_set_vm

Sets visual mode attributes.

Syntax

string *gui_set_vm*

`-name` *`identifier`*
`[-update_cmd` *`update_command`*`]`

```
[-title label]
[-help_topic subject]
[-infotip infotip]
[-buckets buckets]
[-icon string]
[-netfilter string]
[-float bool]
[-set_exaggerations]
[-top_exaggeration float]
[-mid_exaggeration float]
[-bot_exaggeration float]
[-show_only_pins_of_nets bool]
[-enable_bucket_delete bool]
```

Data Types

```
identifier          string
update_command      string
label               string
subject            string
infotip             string
buckets             string
net_filter          string
icon_spec           string
```

Arguments

`-name identifier`

Specifies the name of the visual mode to be modified. This name is used as the argument when the associated visual mode commands requires a visual mode name to be specified.

`-update_cmd update_command`

Specifies an optional Tcl command that is executed when the visual mode is accessed. A typical use for this command is to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-title label`

Specifies an optional title. The title can include embedded spaces. Use this option to provide a label for the visual mode in the GUI.

If you do not specify the *-title* option, the default title is an empty string and the tool uses the *-name* option value to provide the label.

`-help_topic subject`

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

Feedback

`-infotip infotip`

Specifies the infoTip string.

`-buckets buckets`

Specifies the rendering order of the buckets. The tool renders the specified buckets from left to right based on their order in the list. Buckets that are not included in the list are rendered before any of the buckets that are specified in the list.

`-icon string`

Specifies the icon file name. Use this option to provide an icon for GUI menus.

`-netfilter string`

Specifies the net connection filtering.

`-float true | false`

Specifies whether the bucket contents have a floating point range. By default, the value is false.

`-set_exaggerations`

Specifies the bucket exaggerations.

`-top_exaggeration float`

Specifies the exaggeration for the top bucket, the value should be greater than or equal to zero. By default, the value is 0.

`-mid_exaggeration float`

Specifies the exaggeration for the middle bucket, the value should be greater than or equal to -1. By default, the value is -1.

`-bot_exaggeration float`

Specifies the exaggeration for the bottom bucket, the value should be greater than or equal to zero. By default, the value is 0.

`-show_only_pins_of_nets true | false`

Indicates that layout only show pins of net objects in buckets.

`-enable_bucket_delete true | false`

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

Description

The *gui_set_vm* command modifies one or more attribute values of an existing visual mode.

Feedback

Examples

The following example changes the title of a visual mode from "mycoloring1" to "test":

```
prompt> gui_set_vm -name mycoloring1 -title {test}
```

See Also

- gui_create_vm
- gui_create_vmbucket

- gui_update_vm

---

gui_set_vmbucket

Set attributes for Visual Mode Bucket

Syntax

string *gui_set_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip *infotip*] [-netfilter *net_filter*] [-color *color*] [-pattern *pattern*] [-exaggeration double] [-number int] [-maxval double] [-minval double] [-visible *visibility*] [-title *label*] [-collection *handle*] [-above *bucket_identifier* | -below *bucket_identifier* | -at *top*| *bottom*]

```
string  mode_identifier
string  bucket_identifier
string  infotip
string net_filter
string  color
string  pattern
string  visibility
string  label
string  handle
string  bucket_identifier
string  bucket_identifier
string  top|bottom
```

Feedback

Arguments

`-vmname` *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name` *bucket_identifier*

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-infotip` *infotip*

String for infotip.

`-netfilter` *net_filter*

Specifies net connection filtering.

`-color` *color*

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

`-pattern` *pattern*

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

`-exaggeration double`

Specifies bucket min pixel exaggeration value >= 0.

`-number int`

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

`-maxval double`

Specifies bucket maximum value.

`-minval double`

Specifies bucket minimum value.

`-visible` *visibility*

Specifies visibility state of bucket contents. Valid values are TRUE and FALSE.

`-title label`

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

`-collection handle`

Tcl object collection to be colored by this visual mode bucket.

`-above bucket_identifier`

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

`-below bucket_identifier`

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

`-at top|bottom`

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

Description

The gui_set_vmbucket command modifies an instance of a visual mode bucket.

Examples

Change the color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> *gui_set_vmbucket -vmname foo -name cat1 -color #00FF00 -pattern FDiagPattern*

Color the objects in the current selection red by placing them in the bucket named "cat1" in the visual mode "foo" and setting its bucket color:

shell> *gui_set_vmbucket -vmname foo -name cat1 -collection [get_selection] -color red*

- gui_set_vm
- gui_update_vm

---

gui_set_window_pref_key

Create a preference key owned by a particular window or window type

Syntax

```
new_value gui_set_window_pref_key
{ -window window_id | -window_type window_type }
[ -category category ]
-key key
-value_type value_type
-value value
```

Data Types

```
window_id       string
window_type     string
category        string
key             string
value_type      string
value           string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference will be applied to. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference be applied to. This option is mutually exclusive with the -window option.

`-category category`

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

`-key key`

Specifies the name of the key to create.

Feedback

`-value_type` *value_type*

Specifies the the data type of the value of the key. It must be one of [bool | integer | double | color | string].

`-value` *value*

Specifies the value of the key. The value should be set appropriately in accordance with its value type. The bool type accepts [true, false, 0, 1, on, off]. The color type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

Returns

new_value

The new value of the key.

Description

This command creates a preference key with the specified key name or sets the value of an existing pref key. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to a default category. Returns the value of the preference key.

Examples

The following example will create a window and set a preference on that window.

```
shell> set wnd [gui_create_window -type Console]
shell> gui_set_window_pref_key -window $wnd -category {caption} -key
 {title}
 -value_type string -value {Command Console}
```

- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories

Feedback

- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_set_window_preset

Sets the specified preset for object specified by window_type

Syntax

```
status gui_set_window_preset
-window_type window_type
[-system]
[-shared]
-default
-preset preset
```

Data Types

```
window_type     string
preset          string
```

Arguments

`-window_type window_type`

Specifies the name of the window type that the presets be applied to.

`-system`

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

`-shared`

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

`-default`

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

`-preset preset`

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

Feedback

Description

This command applies the default or specified preset to a window type. This command has been deprecated, please use gui_set_preset instead.

Examples

The following example applies the system presets 'floorplan' to the Layout.

```
prompt> gui_set_window_preset -window_type Layout -preset floorplan
 -system
```

See Also

- gui_set_preset
- gui_get_presets
- gui_get_window_presets

---

gui_show_clock_network

Brings up the dialog for the PrimeTime GUI command gui_show_clock_network

Syntax

status *gui_show_clock_network*

```
[-clock_network]
[-clock_source_network]
[-all]
[-used_as_clock]
[-used_as_data]
[-both]
```

Arguments

`-clock_network`

Takes into consideration only the clock_network for the selected clocks.

`-clock_source_network`

Consideres the clock_source_latency_network for the selected clocks.

`-all`

Takes into consideration total clock_network for the selected clocks. This is same as specifying -clock_network and -clock_source_network

`-used_as_clock`

Consideres the clock pins which are only used as clocks.

Feedback

`-used_as_data`

Consideres the clock pins which are only used as data.

`-both`

Tis takes into onsideration all the pins (pins used as clocks and data).

Description

This command brings up the dialog for the command gui_show_clock_network. Make sure you have a valid clock on the selection bus before issuing this command, else the command will not process the choosen options.

Examples

The following example brings up the dialog

```
pt_shell> change_selection [get_clocks]

pt_shell> gui_show_clock_network -all -both
```

See Also

- change_selection

---

gui_show_command_form

Generate and show a form dialog for a shell command.

Syntax

string *gui_show_command_form* -command *command*

```
string command
```

Arguments

`-command` *command*

The name of the shell command to show in the form.

Description

Create a form dialog for a shell command. The form contains fields to allow entry of option arguments.

The dialog provides the following operations for the command:

```
- execute the command
- append the command to a script
- show the man page for the command.
```

Feedback

This command creates form dialogs for application defined commands. It will also create a form dialog for a public user defined tcl proc when its option value types have been defined using the *define_proc_attributes* command. The kinds of value input fields used in the form depends on the *type_name* attribute given for the option using the *-define_args* option. See man pages for *define_proc_attributes* and *gui_report_proc_arg_type_names* for more information.

This command is available only when the GUI is running.

Examples

The following example creates a form dialog for the command *gui_start*

```
shell> gui_show_command_form -command gui_start
1
```

The following is an example of a tcl proc definition followed by a *define_proc_attribute* command invocation to define its attributes. The proc is then shown in a form dialog with the *gui_show_command_form* command. The example proc accepts a net and routing layers as arguments.

```
shell> proc myProc {args} {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo $argname = $results($argname)
  }
}
shell> define_proc_attributes myProc \\
  -info "echo argument values" \\
  -define_args { \\
    {-net "select a net" "net" string \\
          {required {type_name net}}} \\
    {-layers "select routing layers" "routing layers" list \\
          {optional {type_name {layer {subtype routing}}}}} \\
  }
shell> gui_show_command_form -command myProc
```

See Also

- define_proc_attributes
- gui_report_proc_arg_type_names
- gui_start
- gui_stop

---

gui_show_file_in_editor

Show the contents of a file in an external text editor.

Feedback

Syntax

```
gui_show_file_in_editor
-filename filename
[ -line linenum ]
```

Data Types

```
filename string
linenum  integer
```

Arguments

`-filename filename`

filename specifies the name of the file to be edited.

`-line linenum`

linenum specifies the line in the file to start editing at.

Description

The gui_show_file_in_editor command opens a text editor to edit the specified file. The editor is a separate task so doen not block the current application.

By default the file is edited using the text editor from the EDITOR environment variable in a xterm. If the EDITOR environment variable is not set then the 'vi' text editor is used.

Both the editor and terminal (xterm) are searched for on the users path. If either the editor or terminal can no be found the command will fail.

Examples

The following example shows the file "test.txt" starting at line 100.

```
shell> gui_show_file_in_editor -file test.txt -line 100
```

See Also

- gui_show_url_in_browser

---

gui_show_man_page

Show a man page in the man browser

Syntax

string *gui_show_man_page* [-apropos]

[*topic*]

```
string topic
```

Feedback

Arguments

topic

Man page topic to be shown.

-apropos

Use the apropos command so search for commands that are related to the given topic.

Description

This command will launch or raise the man page browser, and display the topic specified in it. If no topic is specified, then the HOME page for man page indexes will be shown.

If the specified topic does not exactly match a given man page, then additional searching will be done for commands. If the topic matches one or more commands, then an index page will be generated showing all of the commands which match the specified topic pattern. If the topic doesn't match any commands, then we will use the topic as the initial part of a command and add a * to it and do command matching. Any completions for the command will be shown on an index page that can then be used to select a man page for viewing.

If the -apropos option is specified, then the topic will be searched via the apropos command and the topics returned will be shown with thier brief help strings, and provide links the the man pages referenced.

Examples

To show the man page for the find command:

gui_show_man_page find

To show the man page for all commands containing the word cell:

gui_show_man_page *cell*

To show the man page for the get_attribute command using command completion:

gui_show_man_page get_attr

---

gui_show_map

Displays or hides the specified visual mode or map mode.

Feedback

Syntax

```
string gui_show_map
-map map_name
-show true | false
[-window window]
```

Data Types

```
map_name        string
window          string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-show true | false`

Displays the visual mode or map mode when set to *true*, or hides the visual mode or map mode when set to *false*.

`-window window`

Specifies the name of layout window in which to display or hide the visual mode or map mode.

Description

This command displays or hides the specified visual mode or map mode. If the *-window* option is not specified, the command uses the most recently active layout window.

Examples

The following example displays the highlight visual mode in the most recently active layout window:

```
prompt> gui_show_map -map Highlight \\
        -show true
```

See Also

- gui_get_map_list

---

gui_show_palette

Shows the palette in the specified window state.

Syntax

```
status gui_show_palette
{ -name palette_id | -type palette_type }
```

Feedback

```
[ -parent parent_name ]
[ -show_state window_state ]
[ -dock_edge dock_edge ]
[ -size {width height} ]
```

Data Types

```
palette_id    string
palette_type  string
parent_name   string
window_state  string
dock_edge     string
width         float
height        float
```

Arguments

`-name palette_id`

Specifies the palette name id or title.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this name in all toplevel windows are shown.

This option precludes the *-type* option

`-type palette_type`

Specifies the palette type id. Any matching palette of this type will be shown.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this type in all toplevel windows are shown.

This option precludes the *-name* option

`-parent parent_name`

Specifies the parent toplevel window name.

`-show_state window_state`

Specifies the window state to show the palette.

Legal states are *maximized*, *minimized*, *normal*, or *docked*.

The default is *normal*.

`-dock_edge dock_edge`

Specifies the edge to dock the palette.

Legal dock edges are *left*, *top*, *right*, or *bottom*.

Feedback

Note: this option is only valid if the state is set to *docked*.

The default is *right*.

`-size {width height}`

Specifies the width and height of the palette.

Note: this option is only valid if the state is set to *normal*.

Description

This command shows the specified palette in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

Examples

The following example shows the Layer palette docked on the left of the workspace.

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_palette -type Layout -parent $top]
shell> gui_show_palette -name $layout -show_state docked -dock_edge left
```

See Also

- gui_hide_palette

---

gui_show_parasitics

Highlights parasitics for a specified set of nets.

Syntax

status *gui_show_parasitics*

```
[-parasitic_corners corner_names]
[-all_parasitic_corners]
[-aggressor_net aggr_net]
[-nores]
[-nocg]
[-nocc]
[-novia]
nets
```

Data Types

aggr_net	string
corner_names	string
nets	string

Feedback

Arguments

`-parasitic_corners` *corner_names*

A list of one or more corner names for which to display parasitic element values.

`-all_parasitic_corners`

Shows values from all corners.

`-aggressor_net` *aggr_net*

Specifies an aggressor net for which to show coupling capacitance.

`-nores`

Do not display parasitic resistors.

`-nocg`

Do not display parasitic ground capacitors.

`-nocc`

Do not display parasitic coupling capacitors.

`-novia`

Do not display via parasitics.

nets

A list of one or more nets for which to show parasitics. At least one net is required. Glob-style wildcards (*) are supported.

---

gui_show_rtl_source_file_line

Show the contents of an RTL file in the RTL Source Browser view.

Syntax

```
status gui_show_rtl_source_file_line
[ -window string ]
-filename string
[ -line int ]
```

Arguments

`-window` *string*

Window specifies the GUI window to show the view in.

This option is optional, the current window is used by default.

Feedback

`-filename` *string*

Filename specifies the name of the file to be show.

`-line` *int*

Line specifies the line in the file to move to.

This option is optional, the first line of the file is used by default.

Description

The gui_show_rtl_source_file_line command shows the contents of the specified RTL file in a RTL Source Browser view. A line can also be specified to automatically move to that line in the file.

If the format of the file is recognised then syntax highlighting will be added and folding of blocks allowed.

Currently Verilog, System Verilog and VHDL files are supported and are recognised by their file suffix (.v, .sv/.vs, .vhd/.vhdl).

Examples

The following example shows the file "test.v" starting at line 100.

```
shell> gui_show_rtl_source_file_line -filename test.v -line 100
```

See Also

- gui_create_window

---

gui_show_short_regions

Displays noncritical polygons, including metal fill polygons, in the vicinity of a short identified by the StarRC tool during extraction.

Syntax

status *gui_show_short_regions*

`[-gpd` *gpd_dir*`]`

Data Types

gpd_dir	string

Feedback

Arguments

`-gpd` *gpd_dir*

The GPD generated from the StarRC extraction. The argument is the GPD directory.

---

gui_show_source_file

Show the contents of a file in the source browser view.

Syntax

```
status gui_show_source_file
[ -window string ]
-filename string
[ -line int ]
[ -reuse ]
```

Arguments

`-window` *string*

Window specifies the GUI window to show the view in.

This option is optional, the current window is used by default.

`-filename` *string*

Filename specifies the name of the file to be show.

`-line` *int*

Line specifies the line in the file to move to.

`-reuse`

Specifies that an existing Source Browser view can be used instead of creating a new one.

Description

The gui_show_source_file command shows the contents of the specified file in a source browser view. A line can also be specified to automatically move to that line in the file.

If the format of the file is recognised then syntax highlighting will be added and folding of blocks allowed.

Currently only tcl, Verilog and VHDL files are supported and are recognised by their file suffix (.tcl, .v, .vhd/.vhdl).

Feedback

Examples

The following example shows the file "test.tcl" starting at line 100.

```
shell> gui_show_source_file -filename test.txt -line 100
```

See Also

- gui_show_file_in_editor
- gui_show_url_in_browser

---

gui_show_task_assistant

Show the task assistant.

Syntax

gui_show_task_assistant

```
-task          TaskName
-item          ItemName

TaskName         String
ItemName         String
```

Arguments

`-task` *TaskName*

TaskName specifies the name of the task to show in the task assistant.

`-item` *ItemName*

ItemName specifies the name of the task item to show in the task assistant.

Description

The gui_show_task_assistant command opens the task assistant window and displays the page for given task and task item.

See Also

- gui_create_task
- gui_set_current_task
- gui_get_current_task_item
- gui_get_current_task_page

Feedback

gui_show_timing_paths

Shows the details of a collection of timing paths in a timing path inspector.

Syntax

gui_show_timing_paths

```
-paths paths
[-new]
```

Arguments

`-paths`

Collection of timing pathss to be inspected.

`-new`

Creates a new timing path inspector window.

Description

The command shows the details of a collection of timing paths in a timing path inspector. Unless requested by the user, this command will use the most recently used timing path inspector window if it exists. Otherwise it will create a new timing path inspector window.

Examples

The following example inspects a collection of timing paths.

```
prompt> gui_show_timing_paths -paths $paths
```

See Also

- change_selection

gui_show_toolbar

Displays the specified toolbar or all the toolbars in the specified window or for a window type.

Syntax

void *gui_show_toolbar*

```
-toolbar tool_bar_name | -all
[-window window_id]
[-window_type window_type]
```

Feedback

Data Types

```
tool_bar_name      string
window_id          string
window_type        string list
```

Arguments

`-toolbar tool_bar_name`

Specifies the toolbar you want to display. The *-toolbar* option and the *-all* option are mutually exclusive.

`-all`

Displays all the toolbars in the specified window. The *-all* option and the *-toolbar* option are mutually exclusive.

`-window window_id`

Specifies the window in which you want to display the specified toolbar or all toolbars. This option is mutually exclusive with the *-window_type* option. If both *-window* and *-window_type* options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

`-window_type window_type`

Specifies the window types in which you want to display the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the *-window* option. If both *-window* and *-window_type* options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

Description

This command displays either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or in all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by *gui_hide_toolbar* will be saved and restored on next invocation of the tool if save and restore has not been disabled.

Examples

The following example displays the File toolbar in the active window:

```
prompt> gui_show_toolbar -toolbar File
```

Feedback

The following example displays all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_show_toolbar -all -window LayoutWindow.1
```

The following example displays the File toolbar in all TimingWindow type windows:

```
prompt> gui_show_toolbar -all -window_type TimingWindow
```

The following example display all the toolbars in all window types:

```
prompt> gui_show_toolbar -all -window_type [gui_get_window_types -type
 toplevel]
```

See Also

---

gui_show_url_in_browser

Show the contents of a URL in an external web browser.

Syntax

gui_show_url_in_browser

`-url` *URL*

`URL` *String*

Arguments

`-url` *Url*

Url specifies the url to be displayed.

Feedback

Description

The gui_show_url_in_browser command an external web browser to display the specified web page. The default web browser is defined by the application but is usually 'firefox' on UNIX platforms.

If the web browser supports external comminication (which 'firefox' does) then if no web browser is running the web browser is started. If the web browser is running then the URL is loaded in the browser usually as a new tab.

The default browser can be set using the 'gui_online_browser' variable but the set of valid browsers is usually restricted by the application so not all browsers may be supported. If a unsupported browser is specified the command will fail.

See Also

- gui_online_browser
- gui_show_file_in_editor

---

gui_show_utable

Show the current loaded user tables in a UserTable view.

Syntax

string *gui_show_utable*

```
[-name            Table_Name]
[-window          Window_Name]
[-filter          Filter_Expr]

[-distribution]   [-columns Column_List]
[-report]         [-columns Column]
[-compress]       [-columns Column]

[-plot            Plot_Type]        [-columns Column]

[-import          CSV_Filename      [-tsv_mode] [-ssv_mode] [-report_type]]
[-meta_obj        MetaObj_Name]
[-open            utable_Filename   [-read_only]]

[-mru]
[-top_window]

Table_Name       String
Filter_Expr      String
Column           String
Column_List      StringList
View_Name        String
CSV_Filename     String
```

Feedback

```
MetaObj_Name     String
utable_Filename  String
Plot_Type        box|distribution|scatter
```

Arguments

`-name` *Table_Name*

The name of the user table to show inside the view. If not given, the view will show the default help page. The user can then select a table via the table selector located at the top of the view.

`-window` *Window_Name*

The name of an existing UserTable window/view to activate.

`-filter` *Filter_Expr*

Apply the given filter expression to the opened table view. *Note:* This option is exclusive with the *-import* option. To use this command and filter option you must first use *gui_import_utable*.

`-distribution`

Show table in distribution mode for the column given by the '-columns' option.

`-report`

Show table in report mode for the list of columns given by the '-columns' option.

`-compress`

Show table with column given by '-columns' option, compressed by common bus notations. *Note:* If given a list of columns only the first column is used to compress bus names. Additional columns are given a postfix to indicate the reduction function used on those numeric columns, by default the function is 'MAX', other allowed functions are 'MIN', 'SUM' and 'MEAN'. See example below.

`-plot` *Plot_Type*

Show a plot of the table data for the columns given by the '-columns' option.

`-columns` *Column_List*

Provides a list of one or more column names for the previous options.

`-import` *CSV_Filename*

The name of a CSV (comma seperated values) file to import and create a UserTable from. A column configuration form is presented to allow the user to adjust the final produced UserTable.

Feedback

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-report_type`

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

`-meta_obj` *`MetaObj_Name`*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-open` *`utable_Filename`*

The name of a UserTable native filename (.utable extension) to load into memory and present to the user. *Note*, this option is exclusive with the *-import* option.

`-read_only`

This flag can only be used with the *-open* option. It opens the file in a streaming read only manner, not copying all the data into memory which can save a lot of system memory if the file is huge.

`-mru`

This flag will show the given table in the most recently used User Table view (mru). This option can not be used with the *-window* option.

`-top_window`

This flag will also open a new top level window to house the User Table view in.

Description

```
This command creates a new view (or reuse an existing view) to display
 and
interact with your User Tables. For convenience, options are given for
 you
to also import or open a new table from a file and display it.

User Tables provide a way for you to define and interact with your own
 tables of data.
The data can persist on disk separate from the design database, and is
 completely
under your control. User Tables can be generated from the attributes of a
 set of
```

Feedback

```
selected objects or they can come from external sources via an ASCII
 value file
in CSV/TSV/SSV format.

Interactively these tables can be viewed and support sorting, filtering,
 summary reporting,
value distributions, editing, etc. as well as the ability to
 select/highlight objects in
the design using the object names in columns identified as object type
 columns.

This command is available only when the GUI is running.
```

Examples

The following example just creates and opens a new UserTable view.

```
shell> gui_show_utable
```

```
The following example opens a new UserTable view and displays the
 contents of my_table.
```

```
shell> gui_show_utable -name my_table
```

```
The following example opens a new UserTable view and shows the import
 form used to configure
the table being created from the values file results.csv. If no header
 line is supplied
in the values file the configuration form will use default names that can
 be edited by the
user before committing to table creation.
```

```
shell> gui_show_utable -import results.csv
```

```
The following example opens a new UserTable view and connects to the
 UserTable file
my_table.utable in a read only streaming mode for display.
```

```
shell> gui_show_utable -open my_table.utable -read_only
```

```
The following example used the most recently used UserTable view and
 shows a compressed table
on the column {Cell Name} and assignes the 'SUM' reduction function on
 the given columns.
```

```
shell> gui_show_utable -name my_table -mru -columns { {Cell Name} {Int
 Power:SUM} {Tot Power:SUM} } -compress
```

---

gui_show_window

Show the window in the specified window state

Syntax

```
status gui_show_window
-window window_id
[ -show_state window_state ]
[ { -rect rect | -size isize } ]
```

Data Types

```
window_id       string
window_state    string
rect            {{x1 y1} {x2 y2}}
isize           {width height}
```

Arguments

`-window window_id`

Specifies the toplevel window or view id to show.

`-show_state show_window_state`

Specifies the window state to show the toplevel window or view.

For a toplevel window we have one of:

```
normal     - show at preferred size
maximized  - show maximized (fill whole screen)
minimized  - show iconized
hidden     - hide but do not destroy
```

Note: The window manager may or may not fully honor the specified state. See your window manager documentation for more details.

Feedback

For a view window we have one of:

```
normal    - show at preferred size in view area and raise to top
maximized - show maximized in view area and raise to top
minimized - show iconized in view area
hidden    - hide but do not destroy
```

Note: If displaying maximized then any existing view windows are also maximized. If displaying minimized or normal then any maximized windows are shown as normal.

The default is *SHOW_WINDOW_STATE_NORMAL*.

`-rect rect`

Specifies the size and position of the window.

It is of this format "{{x1 y1} {x2 y2}}", where {x1 y1} specifies the top left location and {x2 y2} specifies the bottom right location of the window.

Note: This option precludes the use of the *-size* option.

`-size isize`

Specifies the width and height of the window.

It is of this format "{width height}"

Note: This option precludes the use of the *-rect* option.

Description

This command shows the specified toplevel window or view in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

Examples

The following examples will create a layout window then use this command to illustrate the various options

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_window -type Layout -parent $top]
shell> gui_show_window -window $layout -show_state {maximized}
shell> gui_show_window -window $layout -show_state {normal}
```

See Also

- gui_get_window_types
- gui_get_window_ids
- gui_set_active_window
- gui_get_current_window

---

gui_show_window_toolbar

Show toolbar in view

Syntax

```
status gui_show_window_toolbar
-window window_id
[ -toolbar string ]
```

Data Types

```
window_id  string
```

Arguments

`-window window_id`

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-toolbar string`

Specifies the optional toolbar name to show.

Note: the command will fail if the set does not exist

Description

This command shows the specified view's toolbar.

Note: a view's toolbar will only be shown if it has controls in it.

Examples

The following example will show a Charts View and show the toolbar.

```
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
shell> gui_show_window_toolbar -window $charts
```

Feedback

See Also

- gui_create_window
- gui_hide_window_toolbar

---

gui_start

Starts the application GUI.

Syntax

```
status gui_start
[-file script]
[-no_windows]
[-offscreen 1|0]
[-- x_args ...]

string script
```

Arguments

`-file script`

The given script file is sourced before the GUI starts.

`-no_windows`

The GUI starts without showing the default window.

`-offscreen`

If the specified value is 1 then the GUI starts in offscreen mode.

If the specified value is 0 then the GUI starts in normal (X Display) mode.

`-- x_args`

X11-specific arguments to pass to the X connection.

Description

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. start_gui is an alias for gui_start.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful gui_start command has no effect.

Examples

The following example starts the application GUI.

shell> *gui_start*

Feedback

See Also

- gui_stop
- start_gui
- stop_gui

---

gui_stop

Stops the application GUI.

Syntax

```
status gui_stop
 [-close]
```

Arguments

-close

Close the GUI so it can be restarted on a different display.

Without this option (the default) the GUI is just disabled and hidden and can be quickly restored using gui_start.

The limitation of not using close is that the same display must be used when the GUI is started again.

Description

This command stops the application GUI and returns to the shell prompt.

It is ignored if the application GUI has not been started or has been stopped.

stop_gui is an alias for gui_stop.

Examples

The following example stops the application GUI and returns to the shell prompt.

shell> *gui_stop*

See Also

- gui_start
- start_gui
- stop_gui

Feedback

gui_update_attrgroup

Updates a group of attributes for an object type.

Syntax

```
status gui_update_attrgroup
-class design_object
-name name
[-attr_list {{attr_1}...{attr_n}}]
[-add]
[-delete]
[-move up | down | top | bottom | after | before]
[-attr attribute]
[-anchor attribute]
```

Data Types

```
design_object      string
name               string
attr_1             string
attr_n             string
attribute          string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the non-editable name of the attribute group to update for the specified object type.

`-attr_list {{attr_1}...{attr_n}}`

Lists and orders the attributes to be included in the group.

`-add`

Adds the attribute specified by the *-attr* option to the end of attributes list, by default, or after the attribute specified by the *-anchor* option.

`-delete`

Removes the attributes specified by the *-attr* option from the attribute list. Note that the attribute still exists.

`-move up | down | top | bottom | after | before`

Moves the attribute specified by the *-attr* option in the specified direction. If you specify *before* or *after* to move the attribute relative to the position of a reference attribute, use the *-anchor* option to specify the reference attribute.

Feedback

`-attr attribute`

Specifies the attribute to be added, removed, or moved with the *-add*, *-delete*, or *-move* option.

`-anchor attribute`

Specifies the reference attribute to be used with the *-add* or *-move* option.

Description

The *gui_update_attrgroup* command updates an attribute group for the specified object type. You can reset the entire attribute list by using the *-attr_list* option, or you can change the list by adding, removing, or moving with a single attribute.

The order of the attributes in an attribute group is important and is set by the *-attr_list* option when you create or update the group.

Examples

```
prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -attr_list { "TestAttr1" "TestAttr2" "TestAttr3" }

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -add -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -add -attr "TestAttr5" -anchor "TestAttr2"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -delete -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -move down -attr "TestAttr2"
```

---

gui_update_pref_file

Save current application preferences to the user preference file.

Syntax

string *gui_update_pref_file* [-file *FilePathName*]

`FilePathName` *String*

Feedback

Arguments

`-file FilePathName`

FilePathName specifies the full pathname of the user preference file to write the current preferences to. If this option is missing, the file to write to is controlled by the gui variables : pref_file_name and pref_file_path. These two variables are set with the gui_set_var command and their values retrieved with the gui_get_var command.

Description

This command updates the user preference file. Normally, application will automatically save user preferences to a default system preference file on exit, and retrieve the preferences from the default user preference file on application start. So, this command is rarely used, except internally.

---

gui_update_vm

Update Visual Mode

Syntax

string *gui_update_vm* -name *identifier*

`string identifier`

Feedback

Arguments

`-name identifier`

Specifies the visual mode name whose associated tcl update command will be executed. The tcl update command is associated with the visual mode using the -update_cmd option to the gui_create_vm or gui_set_vm commands.

Description

Execute a visual mode's associated tcl update command.

Examples

To force the visual mode "vm1" to execute its associated update command, use the following:

shell> *gui_update_vm -name vm1*

See Also

- gui_create_vm
- gui_create_vmbucket

- gui_remove_vm
- gui_remove_vmbucket
- gui_set_vmbucket
- gui_set_vm

---

gui_update_vm_annotations

Updates visual mode annotations.

Syntax

string *gui_update_vm_annotations*

-clear -center -add *points* -draw_net *style* [-type *shape*] [-text *message*] [-color *color*] [-pattern *pattern*] [-line_style *line_style*] [-width *width*] [-info_tip *info_tip*] [-query_text *query_text*] [-query_command *query_command*] *object*

Feedback

Data Types

points	list
style	string
shape	string
message	string
color	string
pattern	string
line_style	string
width	integer
info_tip	string
query_text	string
query_command	string
object	string

Arguments

`-clear`

Removes all annotations from the specified object.

`-center`

Interprets all object locations as the centers of the objects rather than their origins.

`-add` *points*

Adds points for the annotation shape that you specify with the *-type* option. The points are specified by a tool command language (Tcl) list in which each element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.

- bbox_ul : the annotation is placed at the upper left of the

  bounding box of the object. • bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

`-draw_net` *`style`*

Specifies how the nets are displayed in the layout view for this annotation if the specified objects are nets or physical buses.

This annotation overrides the current net display setting on the View Settings panel. The valid *style* values are

flyline
routing
routing_flyline

`-type` *`shape`*

Specifies the type of annotation. The valid *shape* values are

rect
line
arrow
polygon
polyline
text

`-text` *`message`*

Specifies a text string that you want to display.

`-color` *`color`*

Specifies the color. The default is the bucket color.

`-pattern` *`pattern`*

Specifies the fill pattern. The default is none.

Feedback

`-line_style` *line_style>*

Specifies the line style. The default is none.

`-width` *width*

Specifies the line width. The default is 1.

`-info_tip` *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_text` *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_command` *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
```

Feedback

```
%object  a collection containing the annotation
%x       the x position clicked in design coordinates
%y       the y position clicked in design coordinates
```

object

Specifies the object with which to associate the annotation.

Description

This command adds annotations to objects returned by the *gui_create_vm_objects* command.

Layout view visual modes are used to color objects in the layout view based on certain criteria. You can use the *gui_update_vm_annotations* command to display not only object coloring but some additional annotations for the objects in a visual mode bucket.

Examples

To create a bucket that displays cells and a line connecting those cells to the location (0,0), enter code like the following example:

```
prompt> set objs [gui_create_vm_objects $cells]
   foreach_in_collection o $objs {
      set c [get_attribute $o core_obj]
      gui_update_vm_annotations $o -type line -add [list {0 0} $c]
   }
prompt> gui_create_vmbucket -vmname $vm -name $bucket -color red
 -collection $objs
```

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_create_vm_objects

---

gui_view_port_history

Does the gui_view_port_history operations.

Syntax

gui_view_port_history

```
[-window window_name]
    [-next]
    [-previous]
    [-add name]
    [-to  name]
```

Feedback

```
[-list_names]
[-rect bounding box]
[-delete_name]
[-isprevious]
[-isnext]
[-dialog]
[-tcl_list]
[-help_cmd]
```

Arguments

`-window fwindow_name`

Give the name of a window. this is required option except if you use *-dialog* option.

`-next`

Specify if you want to go to previous stored view port history. If you use *-next* option you can not use any other option except *-window* option: they are mutually exclusive.

`-previous`

Specify if you want to go to previous stored view port history. If you use *-previous* option you can not use any other option except *-window* option: they are mutually exclusive.

`-add name`

Current view port will be stored by this name. *-add* option can be combined with *-rect* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name.

If you use *-add* option you can not use any other option except *-window* and *-rect* option : they are mutually exclusive.

`-to name`

Give the name of a view port history already stored. If you use *-to* option you can not use any other option except *-window* option: they are mutually exclusive.

`-list_names`

Specify if you want to see list of names of all the named view port history. If you use *-list_names* option you can not use any other option except *-window* option: they are mutually exclusive.

`-delete_name name`

The already stored view port history with this name will be deleted. If you use *-delete_name* option you can not use any other option except *-window* option: they are mutually exclusive.

Feedback

`-rect` *`boundingbox`*

Adds give the bounding box (in design units) to unnamed view port history. The values should be given in following format. format: {{x1 y1} {x2 y2}} *-rect* option can be combined with *-add* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name. If you use *-add* option you can not use any other option except *-window* and *-add* option : they are mutually exclusive.

`-isnext`

return true returns true if there previous zoom history. If you use *-isnext* option you can not use any other option except *-window* option: they are mutually exclusive.

`-isprevious`

returns true if there next zoom history. If you use *-isprevious* option you can not use any other option except *-window* option: they are mutually exclusive.

`-dialog`

specify to invoke dialog for named view port history. If you use *-dialog* option you can not use any other option except *-help_cmd* option: they are mutually exclusive.

`-tcl_list`

return a tcl_list of named view port history If you use *-tcl_list* option you can not use any other option except *-window* option: they are mutually exclusive.

`help_cmd` *`help_command`*

Give a command which will be executed when help buttonis clicked in the dialog.

Description

This command store view port for the application. At least one option needs to be specified.

last 100 View ports will be stored in view port history, which can be accessed by specifying *-previous* and *-next* options.

When you use *-add* then the current view port will be stored by the given name in the to view port history.

when you use *-to* then the view port stored by this name will be shown and added to the view port history.

Examples

The following example zooms in to the given rectangle.

Feedback

```
fpc_shell> gui_view_port_history -rect {{-2232.321 -536.887} {141.286
 2175.807}}
```

The following example zooms to next .

```
fpc_shell> gui_view_port_history -next
```

The following example zooms to previous.

```
fpc_shell> gui_view_port_history -previous
```

The following example gives list of all the named zooms.

```
fpc_shell> gui_view_port_history -list_names
```

The following example puts the current zoom in to zoom history by given name.

```
fpc_shell> gui_view_port_history -add xyz
```

The following example zooms to already stored to zoom .

```
fpc_shell> gui_view_port_history -to xyz
```

The following example deletes an already stored to zoom.

```
fpc_shell> gui_view_port_history -delete xyz
```

---

gui_write_annotations

Saves annotations to a Tcl file.

Syntax

```
status gui_write_annotations
-file filename
[-append]
[-force]
[-compress method]
[annotations]
```

Data Types

```
filename      string
method        string
annotations   collection
```

Arguments

`-file filename`

Specifies the name of the file in which the tool saves the annotation script.

Feedback

`-append`

Append the annotation script to an existing file instead of creating a new one. The specified file must exist. This option cannot work with *-force*.

`-force`

Overwrite the specified file, if it exists, with the new one. This option cannot work with *-append*.

`-compress` *method*

Specifies the compression type to use when writing the file. By default, no compression is performed.

`annotations`

Specifies a collection of annotations to write. Get a collection of annotations with the gui_get_annotations command. If this option is not specified, then all the annotations with *global* window handle and *global* group type would be written by, annotations with specific window handle or group type are excluded.

Description

This command writes a collection of annotations to a Tcl script. The attribute -visible will only be exported if it is set as invisible.

Examples

```
Write out all global annotations.

prompt> gui_write_annotations -file my_annotations.tcl

Write out all annotations in Layout.1.

prompt> gui_write_annotations -file my_annotations.tcl \\
    [gui_get_annotations -window Layout.1]
```

See Also

- gui_add_annotation
- gui_get_annotations
- gui_remove_all_annotations
- gui_remove_annotations

---

gui_write_charts_data

Write charts data

Feedback

Syntax

```
status gui_write_charts_data
-view view_name
[ -file file_name ]
```

Data Types

```
view_name  string
file_name  string
```

Arguments

`-view view_name`

View to output data for.

`-file file_name`

Filename to output data to. If not specified then the the output is sent to the terminal.

Description

Write charts data as a tcl script to terminal or a file.

This command allows the user to save the state of the plots in the current view to a tcl command which can be source'd to reproduce the plot.

Details of the models loaded for the view's plots, the views annotations, the plots and the plots annotations are saved.

Only the view and plot properties that have changed from their default values are saved.

Note: Only the filename, tcl variable or collection name of the model data can be saved so these external dependencies, file data, contents of the tcl variable, or contents of the collection will need to be recreated before the script can be used.

Examples

The following example writes view data to the file "view_data.tcl".

```
shell> gui_write_charts_data -view Charts.1 -file "view_data.tcl"
```

See Also

- gui_create_charts_model

---

gui_write_charts_image

Save charts plot or view to image file

Feedback

Syntax

```
status gui_write_charts_image
-view view_name
-plot plot_name
-file string
```

Data Types

```
view_name  string
plot_name  string
```

Arguments

`-view view_name`

Charts view to save (all charts).

`-plot plot_name`

Single charts plot in view to save.

`-file string`

Output filename.

The file suffix is used to determine type i.e. .png for PNG file or .svg for SVG file.

If the file suffix (converted to lower case) is not .png or .svg then PNG is used.

Description

Save charts plot or view to PNG or SVG image file.

Examples

The following example saves all charts in a view to a PNG file charts.png.

```
shell> gui_write_charts_image -view $view -file charts.png
```

---

gui_write_timing_paths

Writes a persistent path data file containing a timing path collection.

Syntax

```
status gui_write_timing_paths
-file name
[-overwrite]
[-design name]
[-lib name]
[-view name]
[-label name]
[-scenario name]
```

Feedback

```
[-mode name]
[-corner name]
[-tag name]
[-comment name]
clct_name
```

Data Types

```
name       string
clct_name  collection
```

Arguments

`-file name`

Specifies the name of the persistent path data file to be written. By default, if the file already exists, the command fails.

`-overwrite`

Specifies the file that already exists will be overwritten.

`-design name`

Set (overwrite) the design name for the given collection.

`-lib name`

Set library name for the given collection.

`-view name`

Set view name [default name = 'design']

`-label name`

Set label name.

`-scenario name`

Set scenario name [default name = 'default']

`-mode name`

Set mode name [default name = 'default']

`-corner name`

Set corner name [default name = 'default']

`-tag name`

User can tag timing path file with some arbitrary string.

`-comment name`

User comment for timing path file.

clct_name

Specifies the collection of timing paths to be written.

Description

The *gui_write_timing_paths* command writes a persistent path data file containing the given path collection. The persistent path data file contains all the information needed to recreate those timing paths using the *gui_read_timing_paths* command in ICC2.

For correct import to ICC2, you must provide a legal 'library', 'view', 'scenario', 'mode' and 'corner'.

The user also has the option of adding a custom tag and comment to the file that can be quickly read by ICC2 without having to load all the timing paths.

Examples

The following examples shows how a timing path collection can be written to a persistent path data file. Here we allow the write to use the current design name, and use 'default' for the scenario, mode and corner name.

```
> gui_write_timing_paths $paths -file "my.paths" -lib name -view name
```

---

gui_write_user_map

write snapshot of current map mode data to file.

Syntax

string *gui_write_user_map*

```
-name mapName
-file outputFile
[-metadata]       (Export header only)
```

Data Types

mapName string

outputFile string

Arguments

-map *mapName*

Specifies the current Visual/Map Mode name in layout

-file outputFile

Specifies the name of output file. It can be a single file name(generated in previous working directory) or have a absolute path.

`-metadata`

This option indicates that a meta data section should be included in the output. The meta data contains basic information of the map.

For displaying the output data as a user-map, including the meta data is recommanded.

For processing the data without displaying as user-map or other purposes, this option should not be turned on.

Description

Write snapshot of current map mode data into csv file. The map data is easier to read and adapt to other app. User map is a general feature and will not have all of the features of the map that was written only the basic data presentation and bucket settings.

Here's an example of the output file of cell density map:

```
#META_DATA
#type,name,property,value
#table,,tag,gui_write_user_map
#table,,app_name,icc2
#table,,version,"V1.0"
#table,,report_date,"2029-Jul-29 02:55:51"
#table,,title,"Cell Density"
#table,,bins,10
#table,,min_threshold,0.100000
#table,,max_threshold,1.100000
#table,,color_scale,TemperatureScale
#column,Coordinates,type,poly_rect
#column,value,type,double
#column,Comment,type,string
#END_META_DATA

Coordinates,Value,Comment
"{12.600 12.600} {25.200 0.000}",0.161270,0.16127
"{25.200 12.600} {37.800 0.000}",0.551746,0.55175
"{37.800 12.600} {50.400 0.000}",0.643175,0.64317
"{50.400 12.600} {63.000 0.000}",0.613333,0.61333
"{63.000 12.600} {75.600 0.000}",0.579048,0.57905
```

Exanmple of Global Route Congestion map:

```
#META_DATA
#type,name,property,value
#table,,tag,gui_write_user_map
#table,,app_name,icc2
#table,,version,"V1.0"
#table,,report_date,"1989-Jun-04 02:30:28"
#table,,title,"Global Route Congestion"
#table,,bins,9
#table,,min_threshold,0.000000
```

```
#table,,max_threshold,7.000000
#table,,color_scale,TemperatureScale
#column,Coordinates,type,poly_rect
#column,value,type,int
#column,Comment,type,string
#column,Special,type,string
#END_META_DATA

Coordinates,Value,Comment,Special
"{0.000 0.000} {2.520 0.000}",-23,-23/23
"{0.000 2.520} {0.000 0.000}",-26,-26/26
"{2.520 0.000} {5.040 0.000}",-26,-26/26
"{2.520 2.520} {2.520 0.000}",-26,-26/26
"{5.040 0.000} {7.560 0.000}",-24,-24/25
"{5.040 2.520} {5.040 0.000}",-25,-25/26
"{7.560 0.000} {10.080 0.000}",-26,-26/26
```

Examples

While the map is generated and presented in layout:

```
prompt>gui_wirte_user_map -map cellDensityMap -file cellden.csv
```

See Also

- gui_read_user_map
- gui_remove_user_map

---

gui_write_utable

Write the UserTable to file in native UserTable format.

Syntax

string *gui_write_utable*

```
-name         Table_Name
[-file        File_Name]
[-filter      Filter]
[-read_only]
[-overwrite]

Table_Name    String
File_Name     String
```

Arguments

`-name` *Table_Name*

The name of the user table to write out to a file.

Feedback

`-file File_Name`

The name of the file to write the table to, by default the name of the table is used with the '.utable' extension.

`-filter Filter`

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

`-read_only`

This flag closes the table that has been written out and then re-opens it in read-only (streaming) mode which can save a lot of system memory if the table is huge.

`-overwrite`

This flag will force the destination file to be overwritten.

Description

```
This command writes the given table name to a file in the native user
 table format,
preserving all meta data (filter, sort order and column information). The
 UserTable
file can then be later re-opened to copy the information back into memory
 or opened
in a read-only (streaming) mode using the command gui_open_utable.
```

Examples

```
The following example writes out the given table to a file name equal to
 the table name
plus the extension '.utable'.

shell> gui_write_utable -name my_table

The following example writes out the given table (overwrites the file if
 necessary) and
then closes the table in memory and re-opens it in read-only (streaming)
 mode.

shell> gui_write_utable -name my_table -read_only -overwrite
```

- gui_open_utable
- gui_show_utable

---

gui_write_window_image

Saves an image of a view or toplevel window in the specified file

Syntax

```
status gui_write_window_image
[ -file filename ]
[ -format image_format ]
[ -window window_name ]
[ -palette palette_type ]
[ -size window_size ]
[ -clip ]
```

Data Types

```
filename       string
image_format   string
window_name    string
palette_type   string
window_size    {width height}
```

Arguments

`-file filename`

Specifies the name of the file in which the tool saves the window image.

If you include a file name extension, it determines the image format unless you also specify the *-format* option.

If no file is specified it defaults to 'gui_image.png'.

`-format png | xpm | jpg | bmp`

Specifies the image format to be used in the file. The default value is png.

Note that if the format that you specify with the *-format* option is different from the format specified by the file name extension, the *-format* value takes precedence and the tool appends an additional extension to the file name.

Feedback

`-window` *`window_name`*

Specifies the name of the window for which you want to save an image in the specified image file.

You can view a list of the window names for all the open toplevel and view windows by using the *gui_get_window_ids* command.

By default, the tool saves an image of the most recently active view window.

`-palette` *`palette_type`*

Specifies the type or side of the palette for which you want to save an image in the specified image file. When a type is specified just the palette of that type is saved, if a side is specified all palettes on that side are saved.

If *-window* option is specified the palettes from that window are used otherwise palettes from the most current window are used.

Note: The palette type must exist and be visible. You can use the command *gui_show_palette* to display the palette.

You can view a list of the palette types by using the *gui_get_palette_types* command. The side can be 'left, right, top or bottom'.

`-size` *`window_size`*

The size of the image to be generated. If not specified then the full window size is used.

`-clip`

Clip the image to the contents skipping horizontal or vertical empty areas due to diffences in the aspect ratio of the view and data being displayed.

Only currently supported for Layout and Charts view windows.

Description

The *gui_write_window_image* command takes a snapshot of a specified toplevel window or child view window in a specified image format and writes the result to a specified file.

Examples

The following example writes a snapshot of the TopLevel.1 window to a image file "snapshot.png".

```
shell> gui_write_window_image -window TopLevel.1 -file snapshot.png
```

The following example writes a snapshot of the Layout.1 view to a image file "layout.png" of size 800 pixels by 600 pixels.

Feedback

```
shell> gui_write_window_image -window Layout.1 -file layout.png -size
 {800 600}
```

The following example writes a snapshot of the all palettes on the right side of the current active window to an image file "palettes.png".

```
shell> gui_write_window_image -palette right -file palettes.png
```

The following example writes a clipped snapshot of the current layout view to an image file "layout.png".

```
shell> set window [gui_get_current_window -mru -type Layout]
shell> gui_write_window_image -window $window -clip -file layout.png
```

See Also

- gui_get_window_ids
- gui_get_current_window
- gui_show_palette

---

gui_zoom

Change the viewport of a view

Syntax

gui_zoom

-window *window* [-fit | -exact] [-full] [-selection] [-rect *{{lx ly} {ux uy}}*] [-factor *factor*] [-at_point *{x y}*] [-clct *clct*] [-zoom_in_mode] [-zoom_out_mode] [-select_mode]

```
window          String
rect            String
factor          Float
```

Arguments

`-window` *window*

window specifies the window of which this command should change the viewport.

`-full`

Zoom such that all objects are visible.

`-factor` *`factor`*

Keep the center of the viewport and zoom by factor *factor*. A *factor*" > 1 causes a zoom-in, a *factor*" < 1 causes a zoom-out. The argument must be greater than zero.

`-at_point` *`{x y}`*

Can only be specified with -factor argument. If supplied, zoom is performed at specified point instead of viewport center. The option is not supported by all window types.

`-fit`

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to not over zoom. Will zoom a reasonable distance away from the rectangle or objects being zoomed. The definition of "reasonable" is window dependent. This argument is mutually exclusive with -exact.

`-exact`

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to zoom exactly to the arguments. This argument is mutually exclusive with -fit.

`-selection`

Zoom such that all selected objects that are represented in the window are visible and if possible are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

`-rect` *`{{lx ly} {ux uy}}`*

Zoom such that the window shows the rectangle *rect* in its viewport. What coordinates are assumed for *rect* are dependent on the window. If neither -fit or -exact is supplied, -exact is assumed.

`-clct` *`clct`*

Zoom such that all objects in *clct* that are represented in the window are visible and if possible, are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

`-zoom_in_mode`

Put the window in zoom-in mode.

`-zoom_out_mode`

Put the window in zoom-out mode.

`-select_mode`

Put the window in selection mode.

Feedback

Description

The *gui_zoom* controls the viewport of a view that supports zooming. Not all views need to support all of the functionality provided by the interface of this command.

Examples

The following example has the layout view show the entire design and then zooms in by a factor of 2, i.e. only a quarter of the area of the design is still visible:

```
gui_zoom -window Layout.1 -full
gui_zoom -window Layout.1 -factor 2
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}}
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}} -fit
gui_zoom -window Layout.1 -selection -exact
```

---

gui_zoom_all_layouts_to_current_view

Rescales all layout views to the current view.

Syntax

gui_zoom_all_layouts_to_current_view

Arguments

None.

Description

The command sets the zoom factor of all layout views to the zoom factor of current layout view.

Examples

```
prompt> gui_zoom_all_layouts_to_current_view
```

See Also

- gui_zoom

---

gui_zoom_to_selected_errors

Layout window zoom to errors selected in the error browser.

Syntax

string *gui_zoom_to_selected_errors*

Feedback

Description

If you have selected the errors in the error browser, you can execute this command to have layout zoom to the selected errors.

Examples

If you select errors, then perform layout zooming operations, the following command will force layout to zoom to selected errors: gui_zoom_to_selected_errors

- gui_get_errors
- gui_set_current_errors
- gui_set_selected_errors
- gui_set_error_browser_option

h

help

Displays quick help for one or more commands.

Syntax

```
string help
[-verbose]
[-groups]
[pattern]
```

Data Types

pattern	string

Arguments

`-verbose`

Displays the command options; for example *command_name -help*.

`-groups`

Displays a list of command groups only.

pattern

Displays commands matching the specified pattern.

Description

The *help* command is used to get quick help for one or more commands or procedures. This is not the same as the *man* command that displays reference manual pages for a command. There are many levels of help.

By typing the *help* command, a brief informational message is printed followed by the available command groups.

List all of the commands in a group by typing the group name as the argument to *help*. Each command is followed by a one-line description of the command.

To get a one-line help description for a single command, type *help* followed by the command name. You can specify a wildcard pattern for the name; for example, all commands containing the string "alias". Use the *-verbose* option to get syntax help for one or more commands. Use the *-groups* option to show only the command groups in the application. This option cannot be combined with any other option.

Examples

The following example lists the commands by command group:

```
prompt> help
Specify a command name or wild card pattern to get help on individual
commands. Use the '-verbose' option to get detailed option help for a
command. Commands also provide help when the '-help' option is passed to
the command.'

You can also specify a command group to get the commands available in
that group. Available groups are:

  Procedures:                Miscellaneous procedures
  Help:                      Help commands
  Builtins:                  Generic Tcl commands
 ...
```

The following example displays the list of procedures in the Procedures group:

```
prompt> help procedures
 ls                 # List files
 sh                 # Execute a shell command
```

The following example uses a wildcard character to display a one-line description of all commands beginning with *a*:

```
prompt> help a*
 alias                # Create a command which expands to words.
```

Feedback

```
 append                # Builtin
 array                 # Builtin
```

This example displays option information for the *source* command:

```
prompt> help -verbose source
 source                # Read a file and execute it as a script
   [-echo]                 (Echo all commands)
   [-verbose]              (Display intermediate results)
   file_name               (Script file to read)
```

See Also

---

help_attributes

Display help for attributes and object types

Syntax

string *help_attributes* [-verbose]

[-application] [-user] [*class_name*] [*attr_pattern*]

```
string  class_name
string  attr_pattern
```

Arguments

`-verbose`

Display attribute properties.

`-application`

Only display application defined attributes.

`-user`

Only display user defined attributes.

`class_name`

Object class to retrieve help for.

`attr_pattern`

Show attributes matching pattern.

Feedback

Description

The *help_attributes* command is used to get quick help for the set of available attributes. When this command is run with no arguments a brief informational message is printed followed by the available object classes.

Examples

```
prompt> help
cci_test> help_attributes
Specify an object type and an optional wild card pattern to get
 information
on the available attributes defined for the specified object type. Use
 the
-verbose option to get detailed information on the attributes

The available object types are:

  cell        net       pin
  ...
```

See Also

---

history

Displays or modifies the commands recorded in the history list.

Syntax

string *history*

```
[-h]
[-r]
[argument_list]
```

Data Types

argument_list	list

Arguments

`-h`

Displays the history list without the leading numbers. You can use this for creating scripts from existing history. You can then source the script with the

source command. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

`-r`

Reverses the order of output so that most recent history entries display first rather than the oldest entries first. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

`argument_list`

Additional arguments to *history* (see DESCRIPTION).

Description

The *history* command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." The most commonly used forms of the command are described below. You can combine each with either the *-h* or *-r* option, but not both.

- With no arguments, the *history* command returns a formatted string (intended for you to read) giving the event number and contents for each of the events in the history list.
- If a single, integer argument *count* is specified, only the most recent *count* events are returned. Note that this option is a nonstandard extension to Tcl.
- Initially, 20 events are retained in the history list. You can change the length of the history list using the following:

  history keep count

Tcl supports many additional forms of the *history* command. See the "Advanced Tcl History" section below.

Examples

The following examples show the basic forms of the *history* command. The first is an example of how to limit the number of events shown using a single numeric argument:

```
prompt> history 3
     7  set base_name "my_file"
     8  set fname [format "%s.db" $base_name]
     9  history 3
```

Using the *-r* option creates the history listing in reverse order:

```
prompt> history -r 3
     9  history -r 3
     8  set fname [format "%s.db" $base_name]
     7  set base_name "my_file"
```

Using the *-h* option removes the leading numbers from each history line:

```
prompt> history -h 3
set base_name "my_file"
set fname [format "%s.db" $base_name]
history -h 3
```

Advanced Tcl History

The *history* command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." When specifying an event to the *history* command, the following forms may be used:

- A number, which if positive, refers to the event with that number (all events are numbered starting at 1). If the number is negative, it selects an event relative to the current event; for example, *-1* refers to the previous event, *-2* to the one before that, and so on. Event *0* refers to the current event.
- A string selects the most recent event that matches the string. An event is considered to match the string either if the string is the same as the first characters of the event, or if the string matches the event in the sense of the *string match* command.

The *history* command can take any of the following forms:

history

Same as *history info*, described below.

history add command [exec]

Adds the *command* argument to the history list as a new event. If *exec* is specified (or abbreviated), the command is also executed and its result is returned. If *exec* is not specified, an empty string is returned.

history change newValue [event_number]

Replaces the value recorded for an event with *newValue*. The *event_number* specifies the event to replace, and defaults to the *current* event (not event *-1*). This command is intended for use in commands that implement new forms of history substitution and want to replace the current event (that invokes the substitution) with the command created through substitution. The return value is an empty string.

history clear

Erases the history list. The current keep limit is retained. The history event numbers are reset.

history event [event_number]

Returns the value of the event given by *event_number*. The default value of *event_number* is *-1*.

history info [count]

Returns a formatted string, giving the event number and contents for each of the events in the history list except the current event. If *count* is specified, then only the most recent *count* events are returned.

history keep [count]

Changes the size of the history list to *count* events. Initially, 20 events are retained in the history list. If *count* is not specified, the current keep limit is returned.

history nextid

Returns the number of the next event to be recorded in the history list. Use this for printing the event number in command-line prompts.

history redo [event_number]

Reruns the command indicated by *event* and returns its result. The default value of *event_number* is *-1*. This command results in history revision. See the following section for details.

History Revision

Pre-8.0 Tcl had a complex history revision mechanism. The current mechanism is more limited, and the *substitute* and *words* history operations have been removed. The *clear* operation was added.

The *redo* history option results in much simpler "history revision." When this option is invoked, the most recent event is modified to eliminate the history command and replace it with the result of the history command. If you want to redo an event without modifying the history, use the *event* operation to retrieve an event, and use the *add* operation to add it to history and execute it.

i

identify_interface_logic

Sets the *is_interface_logic_pin* attribute on pins of the current design that are part of its interface logic.

Feedback

Syntax

status *identify_interface_logic*

```
[-ignore_ports port_list]
[-auto_ignore]
[-latch_level levels]
[-context_borrow]
[-keep_ignored_fanout]
[-include_pins pin_list]
[-critical_pins]
[-include_all_net_pins]
[-traverse_disabled_arcs]
```

Data Types

port_list	list
levels	integer
pin_list	list

Arguments

`-ignore_ports` *port_list*

Specifies a list of input or output ports whose fanout or fanin is to be ignored when placing the *is_interface_logic_pin* attribute. Substitute the list of ports you want for the *port_list* value. Clock ports are automatically ignored; you do not have to specify them in this list.

You can use this option to exclude the fanout of ports connected to chip-level nets (for example, scan enable and reset) from affecting the contents of interface logic. If these nets are not explicitly ignored, they cause unnecessary logic (for example, internal registers) to be part of the interface logic on the current design. You can also use this option to selectively generate the interface logic for a subset of the ports on a block; for example, an interface logic model (ILM) can model only the timing behavior on a subset of the ports on a block.

By default all nonclock input and all output ports are used in identifying the contents of interface logic. The *-ignore_ports* and *-auto_ignore* options are mutually exclusive.

`-auto_ignore`

Enables automatic determination of ports whose fanout should be ignored when placing the *is_interface_logic_pin* attribute. A port is ignored if the percentage of the total registers in the design in the transitive fanout of the port exceeds a specified threshold percentage contained in the *ilm_ignore_percentage* variable. The default is 25.

You can use this option to help you identify the test enable and reset ports of your design. Before using it, examine the current value of the

ilm_ignore_percentage variable and reset it if necessary. Note that the *-auto_ignore* option might potentially ignore ports you do not want to ignore, or fail to ignore ports you want to ignore. Carefully read the messages issued by this command when you use this option to see which ports have been ignored and what percentage of registers to which they fanned out.

The *-ignore_ports* and *-auto_ignore* options are mutually exclusive.

`-latch_level` *`levels`*

Specifies the number of logic levels over which time borrowing can occur for latch chains that are a part of the interface logic. Substitute the number of levels you want for *levels*. By default, all latches found in interface logic are assumed to be potential borrowers. Thus, all logic from I/O ports to flip-flops or output ports are identified as belonging to interface logic. Note that this is the opposite of the default behavior of the *extract_model* command.

When you use this option, note that the value of *level* must account for the borrowing behavior of latches only on interface timing paths. If *n* represents a latch level, then *n* + 1 represents the number of latches maintained in latch chains that originate at input ports. The *n* + *1*th latch functions as an edge-triggered register and decouples I/O paths from internal paths. Use this option only when there are latches in the interface logic for a block. Specifying this option might potentially result in less accurate models, because not all latches are allowed to borrow. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-context_borrow`

Specifies that latch borrowing at the interface should be established based on the current context defined for the design. Therefore, latches that borrow based on arrival times defined on input ports and clocks defined on the design are traced through, but path tracing stops at nonborrowing latches. The *-context_borrow* and *-latch_level* options are mutually exclusive.

`-keep_ignored_fanout`

Specifies that the fanout from ignored input ports to interface logic is to be maintained in the model. Thus, ignored ports are not used to identify interface logic, but connections between ignored ports and interface logic are preserved. Using this option results in larger models, particularly in conjunction with the *-include_all_net_pins* option of the *write_ilm_netlist* command. Timing slacks for ignored ports might differ from those reported on the original netlist because connections from ignored ports to internal registers are not preserved in the model.

`-include_pins` *`pin_list`*

Specifies a list of pins that must be included in the interface logic. Substitute the list of pins you want for *pin_list*. This option can be used to optionally add internal pins to the interface logic. After the interface logic is determined, this list of pins is added to the interface logic. You can use this option to define additional interface logic pins that will otherwise be removed in the model. There will not be any affect on pins that are already in the interface logic. Use this option in conjunction with the *all_fanin* and *all_fanout* commands to include a particular cone of logic in the model.

`-critical_pins`

Specifies that critical pins interface logic must be identified. This option allows you to extract a model that keeps only the pins in the critical paths of the design.

You can use this option to extract a critical pins interface logic. The model generated contains the interface logic pins in the critical paths of the design. The model is compact compared to normal interface logic models, but might not be as accurate outside of the current context. This model can be used only to do critical path analysis. It might take much longer to generate this model than the normal model.

`-include_all_net_pins`

Specifies that all pins on nonclock interface logic nets and propagated clock interface logic nets are to be included in the netlist. Use this option if the interface logic model (ILM) is used in a non-SDF flows and delay calculations are performed using the information contained in the ILM. Preserving all pins on a net maintains correct pin capacitance information for the net.

The *-include_all_net_pins* option does not affect nonpropagated clock nets; that is, nets in the clock network that have user-specified source latency. This option is similar to the same option of the *write_ilm_netlist* command except that here it adds the extra pins to the interface logic. Therefore, if you query the interface logic pins by using the *get_ilm_objects* command, you notice these extra pins have been added.

The *write_ilm_netlist* command writes these pins only to the Verilog netlist, but does not add them to the interface logic. It is recommended that you use this option while extracting a critical pins interface logic model.

`-traverse_disabled_arcs`

Specifies that the interface logic should not be affected by disabled arcs/pins on the design. If specified, this option forces the traversal of disabled arcs while determining interface logic.

Feedback

Description

Sets the *is_interface_logic_pin* attribute on pins of the current design that are part of its interface logic. This is the first step in the generation of an ILM.

The interface logic on a block contains all cells whose timing is affected by, or affects, the external environment of a block. The following list describes such parts of the interface logic:

- All cells in timing paths that lead from input ports to registers or output ports that terminate the paths.
- All cells in timing paths that lead to output ports from registers or input ports that originate the paths.
- Clock trees that drive interface registers; including any registers in the clock tree. Clock-gating circuitry is part of interface logic if it is driven by external ports, but not if it is driven by registered outputs on a block.

Notice that interface logic does not include internal register-to-register paths and logic on a block associated only with these paths.

This command implicitly performs an update_timing on the design if required.

You can review the objects you have identified as interface logic by using the *get_ilm_objects* command. When you are satisfied with the interface logic designations, you can nondestructively generate a flattened Verilog netlist for the interface logic model (ILM) by using the *write_ilm_netlist* command. To generate script and back-annotation files for the ILM, use the *write_ilm_script*, *write_ilm_parasitics*, and *write_ilm_sdf* commands.

You can reset the *is_interface_logic_pin* attribute by executing the *identify_interface_logic* command again. You can remove all user-defined attributes, including the *is_interface_logic* attribute by using the *reset_design* command.

Examples

The following example places the *is_interface_logic_pin* attribute on all nonclock pins in the current design, except for pins in the fanin/fanout of ports *port1*, *port2*, and *port3*.

```
pt_shell> identify_interface_logic \\
-ignore [get_ports {port1 port2 port3}]
```

The following example additionally includes three levels of logic from internal pin *ff/Q*.

```
pt_shell> set ilm_pins [all_fanout -levels 3 \\
-flat [get_pin ff/Q]]
pt_shell> identify_interface_logic \\
-include_pins $ilm_pins
```

The following example extracts a critical pins interface logic model.

Feedback

```
pt_shell> identify_interface_logic -critical_pins \\
-include_all_net_pins
```

The following example places the *is_interface_logic_pin* attribute on all nonclock pins in the current design, except for pins identified by the *-auto_ignore* option. Because the value of the *ilm_ignore_percentage* variable is currently 35, pins are ignored if the percentage of the total design registers in their transitive fanout is greater than 35. The *-latch_level* option with a value of *1* states that the first latch encountered in I/O paths might potentially borrow, but the second latch can be treated as an edge-triggered device. Thus, two levels of latches are maintained in the interface logic.

```
pt_shell> printvar ilm_ignore_percentage
ilm_ignore_percentage = "35"
pt_shell> identify_interface_logic -auto_ignore \\
-latch_level 1
```

---

implement_eco

Performs ECO change implementation, including placement legalization, ECO routing, parasitics extraction, and static timing analysis.

Syntax

```
status implement_eco
  [-max_displacement_in_site_rows distance_in_minimum_site_rows]
  [-force]
```

Data Types

```
distance_in_minimum_site_rows       float
```

Arguments

`-max_displacement_in_site_rows distance_in_minimum_site_rows`

Specifies the maximum allowed displacement of cells that are moved, expressed as a multiple of the height of minimum-height site rows.

`-force`

Performs each implementation step, even if there are no ECO changes.

Description

The *implement_eco* command performs ECO change implementation, including placement legalization, ECO routing, parasitics extraction, and signoff-accurate static timing analysis, all in one command. This eliminates the need to pause PrimeTime after ECO operations and run different tools like IC Compiler II, StarRC, and IC Validator.

This command combines the ECO functions of multiple tools into a single command, allowing it to perform timing and physical co-optimization not possible when those tools are run separately, resulting in better QoR with less physical disturbance.

This command enables multiple iterations of incremental ECO without moving and transferring data between different tools, which is useful for manual ECO operations. When incremental extraction is enabled, the command records the current status and manages timing and physical data to enable incremental extraction and timing analysis. The incremental ECO is especially useful when the design is big but ECO changes are relatively few.

Requirements

These are the minimum requirements to run the *implement_eco* command in your sign-off environment:

- PrimeTime STA live or saved sessions
- NDM library path that matches your current PrimeTime session
- IC Compiler II and StarRC executable paths
- StarRC command file used for signoff extraction

To enable placement legalization, ECO routing, and extraction, you must specify the IC Compiler II and StarRC executables using the *set_implement_options* command. After you do this, run the *check_eco* command to initialize the tools and detect any environment setting errors. After the *check_eco* command runs successfully, you can run the *implement_eco* command.

Specifying Extraction Corners

For signoff-accurate parasitic extraction, you must specify the StarRC executable and StarRC command file used for extraction signoff. PrimeECO extracts the necessary information and uses it to perform incremental or full extraction while the *implement_eco* command is running.

If the PrimeTime session reads parasitic data files in SPEF format, you need to specify parasitic corners for each scenario. If the PrimeTime session reads parasitics files in GPD format, you need to set parasitic corners before you read the GPD parasitics.

The following script specifies the StarRC executable, command file, and parasitic corners. In this example, two scenarios named cold and hot have parasitic corners named cold.corner and hot.corner, respectively.

```
prompt> set_implement_options \\
  -starrc_exec StarXtract \\
  -starrc_cmd_files my_starrc.cmd \\
  -parasitic_corners {{cold cold.corner} {hot hot.corner}}
```

Specifying the StarRC Command File

PrimeECO uses a StarRC command file as a reference to create a new StarRC command file for extraction. It updates input and output data such as the design block name and parasitics file locations as specified in the *set_implement_options* command, but keeps other information such as the accuracy setting.

Lines ignored in original StarRC command file:

```
STAR_DIRECTORY
GPD
ECO_MODE
NETLIST_INCREMENTAL
NDM_DATABASE
BLOCK
COUPLING_REPORT_FILE
SUMMARY_FILE
```

New StarRC lines used for RC extraction:

```
NDM_DATABASE
BLOCK
ECO_MODE: YES
NETLIST_INCREMENTAL: YES
GPD
NETLIST_FORMAT: GPD
```

Other lines in the original StarRC command file are left unchanged.

In addition, PrimeECO supports the specification of multiple StarRC command files. This is needed when different command files are required across the set of the parasitic corners needed for static timing analysis. For example, if there are three parasitics corners named cold.corner, hot.corner and typical.corner, two command files can be put together as follows:

- "starrc.typical.corner.cmd" file contains the line

  ```
  SELECTED_CORNERS: typical.corner
  ```

- "starrc.other_corners.cmd" file contains the line

  ```
  SELECTED_CORNERS: cold.corner hot.corner
  ```

Both StarRC command files can be specified for PrimeECO as follows:

```
prompt> set_implement_options \\
  -starrc_exec StarXtract \\
  -starrc_cmd_files "starrc.typical.corner.cmd starrc.other_corners.cmd"
```

StarRC Extraction Mode

PrimeECO performs full extraction by default to generate the most accurate results. If incremental extraction mode is enabled, PrimeECO performs incremental extraction for ECO changes followed by incremental static timing analysis, resulting in faster turnaround. Incremental extraction is especially useful for small manual ECO changes.

Timer and Placement Legalizer Co-Optimization

By accessing timing and physical data simultaneously, PrimeECO places and legalizes ECO cells, and minimizes possible displacement, while avoiding unexpected timing changes. If PrimeECO cannot find good places for ECO cells, it moves neighbor cells with positive slack to create more room. When non-ECO cells are moved, the legalizer and timer work together to avoid new timing violations. For example, cells with larger positive timing slack can move farther than those with less slack.

You can also specify the maximum allowed displacement to further control unexpected timing changes. For example, to limit cell movement to no more than 2.0 minimum site rows heights:

```
prompt> implement_eco -max_displacement_in_site_rows 2.0
```

This maximum displacement is a soft limit, in which the tool tries to honor but does not guarantee.

Setting a Custom Environment for Implementation

You can use special settings for physical implementation such as legalization and routing by specifying custom IC Compiler II scripts using the *set_implement_options* command. The PrimeECO tool runs the specified scripts before or after executing the specified steps.

For example, the following command specifies custom configuration scripts for IC Compiler II setup, legalizing, and routing:

```
prompt> set_implement_options \\
  -icc2_post_link_script ./my_icc2_config.tcl \\
  -icc2_pre_leglize_script ./my_legalize_config.tcl \\
  -icc2_pre_route_script ./my_router_config.tcl
```

When you run the *implement_eco* command, the tool sources the respective configuration scripts at the times indicated in the option names: after linking, before legalizing, and before routing.

Custom Placement Legalization and Routing Scripts

Instead of allowing PrimeECO to control placement legalization and routing, you can direct the tool to use your own custom scripts to perform these steps, as shown in the following example.

```
prompt> set_implement_options \\
  -icc2_eco_legalize_script ./my_legalize.tcl \\
  -icc2_eco_route_script ./my_route.tcl
```

Specifying the Working Directory

The working directory is where the PrimeTime, IC Compiler II, and StarRC tools exchange data and files. You specify this directory with the *-work_dir* option of the *set_implement_options* command.

The working directory has the following subdirectories:

- *eco* -- Contains PrimeTime saved sessions for the incremental flow, change lists for IC Compiler II, and so on.
- *icc2* -- Contains temporary files for IC Compiler II execution.
- *starrc* -- Contains subdirectories used by StarRC extraction, including StarRC logs and summary files
- *lef* -- Contains LEF physical data files; created only if the *set_eco_options* command did not specify a different directory with the *-physical_lib_path* option

Fault Tolerance

To save runtime, the tool has fault tolerance features that record executed steps so that they do not need to be executed again by the *check_eco* or *implement_eco* command after you fix an error.

For example, suppose that *implement_eco* runs legalization and ECO routing successfully, but parasitic extraction fails due to an incorrect command file specification. After the issue is fixed, when you run the *implement_eco* again, PrimeECO skips legalization and ECO routing, as they have been executed already, and resumes StarRC extraction right away.

Feedback

Filler Cells

PrimeECO handles filler cells at various steps of the physical signoff ECO flow:

- During physically aware optimization commands (*fix_eco_timing*, *fix_eco_drc*, and *fix_eco_power*)
- During placement legalization performed by *implement_eco*
- During automatic filler cell insertion performed by *implement_eco*, when enabled by the *set_implement_options -insert_fillers* option

By default, filler cells are automatically detected as described in *set_eco_options* man page "Filler Cells" section.

Using the *-filler_cell_names* option of the *set_eco_options* command, you can specify additional filler cell types to be considered by PrimeECO during the filler cell steps mentioned above.

Inserting Metal Fill

You can instruct PrimeECO to invoke the IC Validator In-Design feature of IC Compiler II to perform initial and incremental metal fill insertion.

Initial metal fill insertion takes place after the NDM block is opened during the execution of the *check_eco* command. The following command example shows how you can specify your own IC Compiler II script for metal fill insertion in PrimeECO.

```
prompt> set_implement_options \\
  -icc2_post_link_script ./my_icv_init_script.tcl
```

For details, see "Inserting Metal Fill With IC Validator In-Design" in the IC Compiler II User Guide.

Incremental metal fill insertion takes place during the execution of the *implement_eco* command after the ECO routing step. This allows the metal fill to be considered by parasitic extraction.

The following command example shows how you can specify your own IC Compiler II script for incremental metal fill insertion in PrimeECO.

```
prompt> set_implement_options \\
  -icc2_pre_extract_script ./my_icv_eco_script.tcl
```

For details, see "Incremental Metal Fill Insertion" in the IC Compiler II User Guide.

Saving the ECO Design

To check legalization and routing status of the modified design, use the *check_legality* and *check_routes* commands. After you are comfortable with the results, save the design

with the *save_block* command. For details, see the man pages for the *check_legality*, *check_routes*, and *save_block* commands.

Writing Out the Implementation Changes

To write out the logical and physical changes performed in the current PrimeECO session, use the *write_implement_changes* command. Output formats include standard interfaces like Verilog and Design Exchange Format (DEF) to describe ECO changes in incremental form.

Incremental ECO and QoR

The PrimeECO tool supports incremental ECO flows with the following steps:

- Save PrimeTime sessions before ECO
- Perform ECO
- Incremental placement legalization
- ECO routing
- Incremental or full extraction
- Restore pre-ECO sessions
- Import physical and parasitics changes
- Run timing analysis for the final timing check

When StarRC incremental extraction is enabled, extraction and timing updates are also incremental, resulting in further runtime reduction.

For signoff accuracy, use StarRC full extraction. For faster runtime, especially for manual ECO operations with relatively few changes, use StarRC incremental extraction.

Note that slight timing differences between incremental and full extraction are expected due to the nature of incremental extraction and incremental timing updates.

Examples

The following example is a typical basic flow script.

```
# Configure PrimeECO
set_eco_options \\
  -physical_icc2_lib my_NDM \\
  -physical_icc2_blocks CPU_after_route
set_implement_options \\
  -icc2_exec icc2_shell \\
  -starrc_exec StarXtract

# Initialize
check_eco
```

```
# Run ECO
fix_eco_timing
implement_eco
```

Upon completion, the *implement_eco* command issues a report on the runtime spent in each step:

```
> Elapsed Time:
> Implementation Steps                        Seconds
> ------------------------------------------------
> Preprocessing                                    15
> Legalization                                     92
> ECO routing                                      47
> Post route processing                            55
> Extraction                                       60
> Timing update                                   581
> ------------------------------------------------
> Total implementation elapsed time               850

# Check final timing and physical DRC
report_global_timing
check_legality
check_routes

# Save the block
save_block -as CPU_after_eco
```

The following is a typical manual incremental ECO session.

```
# Configure PrimeECO with incremental extraction
set_eco_options \\
  -physical_icc2_lib my_NDM \\
  -physical_icc2_blocks CPU_after_route
set_implement_options \\
  -icc2_exec icc2_shell \\
  -starrc_exec StarXtract \\
  -starrc_mode incremental

# Initialize
check_eco

# 1st manual ECO
report_global_timing
size_cell ...
insert_buffer ...
implement_eco

# 2nd manual ECO
report_global_timing
size_cell ...
insert_buffer ...
implement_eco
```

```
# 3rd manual ECO
report_global_timing
size_cell ...
insert_buffer ...
implement_eco

# Check final timing and physical DRC
report_global_timing
check_legality
check_routes

# Save the block
save_block -as CPU_after_manual_eco
```

The following script runs a custom legalization script and a custom ECO routing script.

```
# Configure PrimeECO
set_eco_options \\
    -physical_icc2_lib my_NDM \\
    -physical_icc2_blocks CPU_after_route
set_implement_options \\
    -icc2_exec icc2_shell \\
    -starrc_exec StarXtract
set_implement_options \\
    -icc2_eco_legalize_script ./my_legalize.tcl \\
    -icc2_eco_route_script ./my_route.tcl

# Initialize
check_eco

# Run ECO
fix_eco_timing
implement_eco

# Check final timing and physical DRC
report_global_timing
check_legality
check_routes

# Save the block
save_block -as CPU_after_custom_eco
```

The following example specifies supplemental filler cell types on top of automatically detected ones. All filler cells are treated as open sites by physically aware optimization and placement legalization. In addition, *implement_eco* performs incremental filler cell insertion before ECO routing.

```
# Configure PrimeECO
set user_filler_cells "FILL4TLL"
set_eco_options \\
  -physical_icc2_lib my_NDM \\
  -physical_icc2_blocks CPU_after_route \\
```

```
  -filler_cell_names $user_filler_cells
set_implement_options \\
  -icc2_exec icc2_shell \\
  -starrc_exec StarXtract \\
  -insert_fillers

# Initialize
check_eco

# Run ECO
fix_eco_timing
implement_eco
```

The following example shows how IC Validator InDesign is configured for initial track-based metal fill insertion during *check_eco*.

The my_icv_init_script.tcl script file consists of the following:

```
#
# Setup or run ICV
#   This script is called right after ICC2  open_block is executed
#
set env(ICV_HOME_DIR) /global/apps/icv_2019.06-SP1-2
set target_arch "LINUX.64"
set env(PATH) "$env(ICV_HOME_DIR)/bin/$target_arch:$env(PATH)"
signoff_create_metal_fill -track_fill generic
```

You can specify this file in PrimeECO to perform initial metal fill with IC Validator as follows:

```
#
# Run ICV before ECO
#
set_implement_options -icc2_post_link_script ./my_icv_init_script.tcl
check_eco
```

Feedback

index_collection

Given a collection and an index into it, if the index is in range, create a new collection containing only the single object at the index in the base collection. The base collection remains unchanged.

Optionally, a second index can be passed which creates a new collection with the objects between the two indices in the base collection. Makes an implicit assumption that index<=index2

Syntax

collection *index_collection*

```
collection1
index
[index2]
[step]
```

Data Types

collection1	collection
index	index
index2	index
step	int

Arguments

collection1

Specifies the collection to be searched.

index

Specifies the index into the collection.

The index is either a simple integer to specify the offset from the start of the collection or the string "end" optionally followed by a negative integer to specify the offset from the end of the collection.

For the start offset case the value must range from 0 to *sizeof_collection* - 1. For the end offset case the negative integer (if specified) must range from 0 to -(*sizeof_collection* - 1).

index2

Specifies an optional second index into the collection.

Specifies a second index to create a collection of a range of objects from the base collection, defined by the two indices [index, index2] (boundaries inclusive)

Feedback

`step`

Specifies the step increment from index to index2. By default 1 is used.

Description

You can use the *index_collection* command to extract a single object from a collection. The result is a new collection containing only that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index.

The range of indices is from 0 to one less than the size of the collection. If the specified index is outside that range, an error message is generated.

Commands that create a collection of objects do not impose a specific order on the collection, but they do generate the objects in the same, predictable order each time. Applications that support the sorting of collections allow you to impose a specific order on a collection.

You can use the empty string for the *collection1* argument. However, by definition, any index into the empty collection is invalid. Therefore, using the *index_collection* command with the empty collection always generates the empty collection as a result and generates an error message.

Note that not all collections can be indexed.

Examples

The following examples from PrimeTime use the *index_collection* command to extract the first, second, last and penultimate object of a collection.

```
pt_shell> set c1 [get_cells {u1 u2 u3}]
{"u1", "u2", "u3"}
pt_shell> query_objects [index_collection $c1 0]
{"u1"}
pt_shell> query_objects [index_collection $c1 1]
{"u2"}
pt_shell> query_objects [index_collection $c1 0 1]
{"u1", "u2"}
pt_shell> query_objects [index_collection $c1 end]
{"u3"}
pt_shell> query_objects [index_collection $c1 end-1]
{"u2"}
pt_shell> query_objects [index_collection $c1 end-1 end]
{"u2", "u3"}
```

infer_switching_activity

Infers the switching activity on the drivers of the preset and clear pins of the current design.

Syntax

string *infer_switching_activity*

```
[-apply]
[-output file_name]
[-nosplit]
[-verbose]
```

Data Types

file_name string

Arguments

`-apply`

Applies the proposed switching activity annotation on the drivers of the preset and clear pins.

`-output file_name`

Writes the script to the specified file in ASCII format.

`-nosplit`

Prevents line splitting when the information exceeds the specified column width. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column's width, the next field begins on a new line starting with the correct column.

`-verbose`

Displays detailed information about the specified preset or clear pins. The current and the proposed switching activity annotation reported is applicable only to the drivers of the corresponding preset and clear pins.

Feedback

Description

Use the *infer_switching_activity* command to infer the switching activity on the drivers of the preset and clear pins. These pins can be asynchronous preset and clear, or synchronous preset and clear. The switching activity include simple toggle rate and static probability on the drivers of these pins.

Use the *-apply* option to apply the inferred switching activity values on the drivers of the pins. When you run the *update_power* command, the PrimePower tool uses the inferred values to calculate and report power consumption.

For statistics on the switching activity annotation on the current design, use the *report_switching_activity* command.

Examples

In the following example, the *infer_switching_activity* command is specified after reading in the design. This command displays the current and proposed switching activity annotation for the rst pin.

```

insert_buffer

Inserts a buffer at one or more pins.

Syntax

string *insert_buffer*

```
[-libraries lib_spec]
[-inverter_pair]
[-new_net_names new_net_names]
[-new_cell_names new_cell_names]
[-all_mim_instances]
pin_or_port_list
lib_cell
```

Data Types

lib_spec	list
new_net_names	list
new_cell_names	list
pin_or_port_list	list
lib_cell	string

Feedback

Arguments

`-libraries` *`lib_spec`*

If this option is specified, PrimeTime resolves the *lib_cell* value from the libraries contained only in the *lib_spec*. Libraries are searched in the order in which they appear in the *lib_spec*. *lib_spec* can be a list of library names, or collections of libraries loaded into PrimeTime; the latter can be obtained using the *get_libs* command. You cannot specify this option if a full library cell name has been specified.

`-inverter_pair`

Indicates that a pair of inverting library cells is to be inserted instead of a single non-inverting library cell.

`-new_net_names` *`new_net_names`*

Specifies the net name to be given to the new net that PrimeTime inserts. This option can only be used if only one buffer or an inverter pair is being inserted. If one buffer is being inserted, you have to pass only one net name. If an inverter pair is being inserted, you have to pass two net names. These names can be any valid net names, but must be the leaf names, that is, not the hierarchical names. The new names must not contain embedded hierarchical separators. The new names must be unique in the current context (as specified by current_instance). If you use this option, you have to also use the *-new_cell_names* option.

`-new_cell_names` *`new_cell_names`*

Specifies the cell name to be given to the new cell that PrimeTime inserts. This option can only be used if only one buffer or an inverter pair is being inserted. If one buffer is being inserted, you have to pass only one cell name. If an inverter pair is being inserted, you have to pass two cell names. These names can be any valid cell names, but must be the leaf names, that is, not the hierarchical names. The new names must not contain embedded hierarchical separators. The new names must be unique in the current context (as specified by current_instance). If you use this option, you have to also use the *-new_net_names* option.

`-all_mim_instances`

Insertion of a buffer at one or more pins in one MIM instance is replicated in all instances of a MIM set.

`pin_or_port_list`

Specifies a list of pins or ports to buffer.

lib_cell

Specifies the name of the library cell to use as a buffer (or inverter if the *-inverter_pair* option is specified). The *lib_cell* option can be library cell object or the name of a library cell. The former can be obtained using the *get_lib_cells* command. The latter can either be the full library cell name, such as *lib_name/lcell_name* or the just the base name of the library cell, such as *lcell_name*. You cannot specify the *-libraries* option and explicitly specify the full library cell name. If you invoke PrimeTime with the *-multi_scenario* option, you must use only the library cell-base name. For more information, see the "RESOLVING LIBRARY CELLS" section.

Description

The *insert_buffer* command adds a buffer at one or more specified pins or ports. Like all other netlist editing commands, for the *insert_buffer* command to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. The result of the *insert_buffer* command is a collection of the newly inserted cells on success, or the empty collection (empty string) on failure.

A library cell is a buffer if it has a single input and any number of outputs, as long as for each output, the logic function is either input or !input.

Newly created cells are given a unique name beginning with "U" and ending with a number; newly created nets are given a unique name beginning with "net" and ending with a number.

If you do not want PrimeTime to generate automatic names, you can use *-new_net_names* and *new_cell_names* options to override.

The *insert_buffer* command with *-all_mim_instances"* option applies changes to all the instances of the MIM set.

Suppose a CPU module is instantiated four times in the TOP module as CPU1, CPU2, CPU3 and CPU4.

The following example shows *insert_buffer* command being used in one instance of a MIM set i.e CPU1 with *-all_mim_instances"* option. The changes are replicated to all the other MIM instances of the set i.e CPU2, CPU3, CPU4.

```
pt_shell> insert_buffer CPU1/do1/D BUF1D9 -all_mim_instances"
Inserted 'U1' at 'CPU1/do1/D' with 'unit_delay_cells/BUF1D9'
Inserted 'U1' at 'CPU2/do1/D' with 'unit_delay_cells/BUF1D9'
Inserted 'U1' at 'CPU3/do1/D' with 'unit_delay_cells/BUF1D9'
Inserted 'U1' at 'CPU4/do1/D' with 'unit_delay_cells/BUF1D9'
1
```

The *insert_buffer* command uses the following basic rules to check its arguments:

- Each pin/port must be in scope (at or below the current instance). For a description of some special scoping rules, see the "BUFFERING INSIDE BOUNDARY PINS" section.
- Each pin/port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The *lib_cell* cannot be sequential.
- The *lib_cell* must be a buffer, as previously defined.
- Without the *-inverter_pair* option, the library cell must have a noninverting output. The first noninverting output is used.
- When the *-inverter_pair* option is specified, the library cell must have an inverting output. The first inverting output is used. In this case, two cells are inserted, preserving the logic of the path.
- This command is a rare case where the objects argument (in this case, *pin_or_port_list*) does not necessarily stand alone. Pins on the same net can be grouped.

For more information about grouping pins on the same net and for additional connection rules, see the "CONNECTING THE NEW BUFFER" section.

Although you can mimic buffer insertion using other commands, such as the *create_cell*, *create_net*, *disconnect_net*, and *connect_net* commands, it is much more efficient to use the *insert_buffer* command.

Connecting the New Buffer

The new buffer is connected according to the following rules:

- The output of the new cell is always the new net, and the input of the new cell is always the old net. For example, buffering e1/Z or e3/A as follows:

```
e1/Z --- old_net --- e3/A

creates the following:

e1/Z --- old_net --- U1 --- net1 --- e3/A
```

- If the pin is a load, it is disconnected from its net, and connected to the new net.
- If the pin is a driver, all loads on that net are disconnected from the old net and connected to the new net.

- When pins on the same net are specified, they are grouped, and one buffer is inserted. Loads and drivers are grouped separately.
- If the net is multidriven, all driving pins must be specified for the command to succeed. In the following example, you cannot specify only e1/Z; you must specify both e1/Z and e2/Z. However, for the loads in Circuit 1, any combination can be buffered.

```
e1/Z ---+                +--- e3/A
        |                |
        +----- net ------+--- e4/A
        |                |
e2/Z ---+                +--- e5/A

            Circuit 1
            ---------
```

- Certain parallel buffer cases are also examined more closely. In Circuit 2, you cannot subdivide the inputs of the parallel drivers. You must buffer the inputs of both cell1 and cell2.

```
+--- cell1 ---+
net1 ---+             +-- net2 ---
        +--- cell2 ---+

             Circuit 2
             ---------
```

BUFFERING INSIDE BOUNDARY PINS

When you specify insertion of a buffer at a pin on the boundary of a hierarchical block, the *insert_buffer* command inserts the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To insert the buffer inside the hierarchical block, set the scope to that block using the *current_instance* command and then execute the *insert_buffer* command.

The buffer is inserted within the block to which the *current_instance* command is set. For an example of buffering inside boundary pins, see the EXAMPLES section.

Buffering and its Effects on Parasitics

When parasitics are present and buffer insertion is performed the parasitics will only be preserved under the following conditions. (Note: What applies for a single buffer also applies for an inverter pair)

Buffering load pins in the presence of parasitics.

When a single load pin connected to a net with parasitics is buffered, the parasitics are preserved on the net connected to the input of the inserted buffer. There are no parasitics on the net connected to the output of the inserted buffer.

Feedback

Buffer load pin e3/A as follows:

```
+-- e4/A
                    |
e1/Z --- old_net ---|-- e3/A
             ^      |
             |      +-- e5/A
             |
      parasitics here
```

```
results in the parasitics being kept on the old net
```

```
                    +-- e4/A
                    |
e1/Z --- old_net ---|-- U1 --- net1 --- e3/A
             ^      |           ^
             |      +-- e5/A    |
             |                  |
      parasitics here     no parasitics
```

Buffering more than a single load pin results in the parasitics on the net connected to the input of the inserted buffer being removed and a warning being issued. (See PARA-060)

```
Buffer load pins e3/A, e4/A and e5/A
```

```
                    +-- e4/A
                    |
e1/Z --- old_net ---|-- e3/A
             ^      |
             |      +-- e5/A
             |
      parasitics here
```

```
results in the parasitics being removed
```

```
                                    +-- e4/A
                                    |
e1/Z --- old_net --- U1 --- net1 ---|-- e3/A
             ^                ^     |
             |                |     +-- e5/A
             |                |
     no parasitics     no parasitics
```

Buffering driver pins in the presence of parasitics.

When a single driver pin is buffered, on a net with only one driver, the parasitics are moved to the net connected to the output of the inserted buffer. There are no parasitics on the net connected to the input of the inserted buffer.

```
Buffer driver pin e1/Z as follows
```

```
                    +-- e4/A
                    |
```

```
e1/Z --- old_net ---|-- e3/A
            ^       |
            |       +-- e5/A
            |
      parasitics here

results in the parasitics being moved to net1

                                    +-- e4/A
                                    |
e1/Z --- old_net --- U1 --- net1 ---|-- e3/A
            ^                ^      |
            |                |      +-- e5/A
            |                |
     no parasitics     parasitics move here
```

Buffering more than a single driver pin on a multiply driven net results in the parasitics being removed from the net connected to the output of the inserted buffer. (See PARA-060)

Buffer driver pin e1/Z, e2/Z and e6/Z as follows:

```
e2/Z --+               +-- e4/A
       |               |
e1/Z --|--- old_net ---|-- e3/A
       |       ^       |
e6/Z --+       |       +-- e5/A
               |
       parasitics here

results in the parasitics being removed

e2/Z --+                              +-- e4/A
       |                              |
e1/Z --|--- old_net --- U1--- net1 ---|-- e3/A
       |       ^                ^     |
e6/Z --+       |                |     +-- e5/A
               |                |
        no parasitics    no parasitics
```

Resolving Library Cells

If the *lib_cell* option has been specified in base name only format, such as without a library from which to resolve it from, PrimeTime resolves the library cell according to the following methodology:

- If the *-libraries* option is specified, PrimeTime searches for library cells in the libraries contained within the *lib_spec* only.
- Alternatively, if the *-libraries* option is not specified, PrimeTime searches for the library cell in the libraries contained within the *link_path* variable.

The first library cell that is found is used.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Feedback

Examples

Refer to Circuit 1 for the following example; e1/Z and e2/Z both drive *net*. The first command specifies a *lib_cell* value that is not a buffer; the command fails, and an error message is generated. The second command specifies a buffer for a *lib_cell*, but does not specify all driver pins on a multi-driven net. Again the command fails with an error message. The third command specifies a buffer for *lib_cell* and specifies all pins for the multi-driven net. This time the command succeeds, and creates the new cell U1 and the new net net1.

```
pt_shell> insert_buffer e1/Z class/AN2P
Error: Could not insert 'class/AN2P' -
    lib_cell is not a buffer. (NED-010)
Error: No changes made. (NED-040)

pt_shell> insert_buffer e1/Z class/B1I
Error: Could not insert a buffer on object 'e1/Z':
    Multi-driver net and not all driver pins specified. (NED-012)
Error: No changes made. (NED-040)

pt_shell> insert_buffer {e1/Z e2/Z} class/B1I
Information: Inserted 'U1' at 'e1/Z', 'e2/Z' with 'class/B1I'. (NED-046)
{"U1"}
```

Refer to Circuit 1 for the following example. In the first command, an inverting buffer is inserted on two of the loads of "net". Two new cells are created, U2 and U3, as well as two new nets, net2 and net3. The second and third commands show the use of the *report_cell* and *report_net* commands to display the connections. Excerpts from the reports are shown.

```
pt_shell> insert_buffer {e3/A e4/A} class/IV -inverter_pair
Information: Inserted 'U2' and 'U3' at 'e3/A', 'e4/A' with 'class/IV.
 (NED-046)
{"U2", "U3"}
pt_shell> report_cell -connections e4
****************************************
Report : cell
         -connections
****************************************

Connections for cell 'e4':
    Reference:          B1I
    Library:            class

    Input Pins          Net
    ----------------    ------------
    A                   net3

    Output Pins         Net
    ----------------    ------------
    Z                   out2
```

```
1

pt_shell> report_net -connections net3
****************************************
Report : net
         -connections
****************************************

Connections for net 'net3':

    Driver Pins              Type
    ------------             ----------------
    U3/Z                     Output Pin (IV)

    Load Pins                Type
    ------------             ----------------
    e4/A                     Input Pin (B1I)
    e3/A                     Input Pin (B1I)

1
```

The following example demonstrates buffer insertion inside the boundary of a hierarchical block. To buffer a boundary pin on the inside of the hierarchical block, you must set the current instance to that block, as shown. Otherwise, the *insert_buffer* command would insert the buffer at the top level, outside instance e1.

Note the method used to get the boundary pin from within the block.

```
pt_shell> current_instance e1
u1
pt_shell> insert_buffer [get_pins ./z1] class/B1I
Uniquifying 'e1' (UBLOCK) as 'UBLOCK_0'.
Information: Inserted 'U1' at 'e1/z1' with 'class/B1I'. (NED-046)
{"e1/U1"}
```

---

is_false

Tests the value of a specified variable, and returns 1 if the value is 0 or the case-insensitive string *false*; returns 0 if the value is 1 or the case-insensitive string *true*.

Syntax

```
status is_false
value
```

Data Types

```
value       string
```

Arguments

value

Specifies the name of the variable whose value is to be tested.

Description

This command tests the value of a specified variable, and returns 1 if the value is either 0 or the case-insensitive string *false*. The command returns 0 if the value is either 1 or the case-insensitive string *true*. Any value other than 1, 0, *true*, or *false* generates a Tcl error message.

The *is_false* command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings *true* or *false*. When such variables are set to *true* or *false*, they cannot be tested in the negative in an *if* statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x FALSE
if { !$x } {
  set y TRUE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, *is_false* allows you to test both conditions safely.

Feedback

Examples

The following example shows the use of the *is_false* command:

```
prompt> set x TRUE
TRUE

prompt> if { ![is_false $x] } {
?         set y TRUE
?       }
TRUE

prompt>
```

See Also

---

is_true

Tests the value of a specified variable, and returns 1 if the value is 1 or the case-insensitive string *true*; returns 0 if the value is 0 or the case-insensitive string *false*.

Syntax

```
status is_true
value
```

Data Types

```
value      string
```

Arguments

value

Specifies the name of the variable whose value is to be tested.

Description

This command tests the value of a specified variable, and returns 1 if the value is either 1 or the case-insensitive string *true*. The command returns 0 if the value is either 0 or the case-insensitive string *false*. Any value other than 1, 0, *true*, or *false* generates a Tcl error message.

The *is_true* command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings *true* or *false*. When such variables are set to *true* or *false*, they cannot be tested in the negative in an *if* statement by simple variable

substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x TRUE
if { !$x } {
  set y FALSE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, *is_true* allows you to test both conditions safely.

Examples

The following example shows the use of the *is_true* command:

```
prompt> set x FALSE
FALSE

prompt> if { ![is_true $x] } {
?         set y FALSE
?       }

FALSE

prompt>
```

I

license_users

Lists the current users of the Synopsys licensed features.

Syntax

string *license_users*

```
[feature_list]
```

Data Types

```
feature_list     list
```

Feedback

Arguments

feature_list

Specifies a list of licensed features for which to obtain the information. If you do not use this option, all features are shown.

Description

This command displays information about all licenses, related users, and host names currently in use. This command works only when Network Licensing is enabled.

Examples

In this example, all users of the PrimeTime feature are displayed.

```
pt_shell> license_users PrimeTime

john@node2      PrimeTime
paul@node1      PrimeTime
george@node3    PrimeTime, PrimeTime
rstarr@node3    PrimeTime

4 users listed.
```

---

link

The *link* command, a synonym for the *link_design* command, exists in PrimeTime for compatibility with Design Compiler.

See Also

- link_design

---

link_design

Resolves references in a design.

Syntax

string *link_design*

```
[-verbose]
[-force]
[design_name]
```

Data Types

```
design_name     string
```

Arguments

`-verbose`

Displays verbose messages during link.

`-force`

Forces relinking of the design. If you omit this option, the tool does not relink a fully linked design.

design_name

Specifies the design to be linked; the default is the current design.

Description

The *link_design* locates all designs and library components that are referenced by the current design and links them to the current design. During linking, the tool loads all files specified by the *link_path* variable if they are not already in memory. Successful linking results in a fully instantiated design on which you can perform analysis.

By default, the case sensitivity of the link is determined by the source of the objects being linked. Although it is not recommended, you can change the default behavior by setting the *link_force_case* variable.

Automatic Loading of Designs and Libraries

If you set the *link_path* and *search_path* variables, you need to read only your top-level design and then link. The tool automatically finds and loads all other required designs and libraries.

In the following example, the newcpu.db top-level design uses the cmos.db library. Since the *link_path* variable specifies cmos.db, the *link_design* command loads cmos.db. As linking proceeds, the tools loads any required design that is not already in memory by searching the paths specified by the *search_path* variable. For example, the referenced BOX1 design is not in memory, so the tool searches for BOX1.db in the *search_path* variable and loads it.

```
pt_shell> set search_path "/designs/newcpu/v1.6/dbs /libs/cmos"
/designs/newcpu/v1.6/dbs /libs/cmos

pt_shell> set link_path "* cmos.db"
* cmos.db
```

```
pt_shell> read_db newcpu.db
Loading db file '/designs/newcpu/v1.6/dbs/newcpu.db'
1

pt_shell> link_design newcpu
Loading db file '/libs/cmos/cmos.db'
Linking design newcpu...
Loading db file '/designs/newcpu/v1.6/dbs/BOX1.db'
Loading db file '/designs/newcpu/v1.6/dbs/BOX2.db'
Loading db file '/designs/newcpu/v1.6/dbs/padring.db'
Design 'newcpu' was successfully linked.
1
```

Automatic Linking

Many PrimeTime commands attempt to link the current design for you. For example, the *report_timing* command performs linking if the current design is not linked. Automatic linking occurs only if the design is completely unlinked, and not if the current design is partially linked and has unresolved references. If the current design is fully linked, there is no need for automatic linking, so it is not attempted.

You can disable automatic linking by setting the *auto_link_disable* variable to *true*. Because determining the need for linking takes little runtime, setting this variable is normally unnecessary. The variable provides compatibility with Design Compiler.

Unresolved References

If the *link_design* command fails to resolve one or more references, you need to correct the source of the problem and relink the design. Failures are typically caused by

- Missing libraries or designs
- Incorrectly specified *link_path* or *search_path* variable
- A file that is located in the path but not accessible by you

After making the necessary corrections, you can decide whether to do an incremental relink or an initial link, or whether to allow the too to create black boxes for the unresolved references.

If you can resolve the references by changing the *link_path* or *search_path* variable, you must relink the design.

The creation of black boxes is controlled by the *link_create_black_boxes* variable, which is set to *true* by default. Unless you set this variable to *false*, the tool automatically converts each unresolved reference to a black box (an empty cell with no timing arcs). The result is a completely linked design on which analysis can be performed (assuming there are no other unrecoverable link errors). To prevent unresolved references, set the *link_create_black_boxes* variable to *true*.

Feedback

Black box creation can fail when there are multiple conflicting references, usually with generic logic. For example, if SELECT_OP has two references, one with five pins and the other with 20 pins, the second black box might not be created, and the design might not link. PrimeTime does not support generic logic, except for GTECH; if a design contains such generic logic, remove the design or replace it with an empty design.

Sometimes, black box creation fails. This occurs when there are multiple conflicting references. This happens most often with generic logic. For example, if there are two references to SELECT_OP, one with five pins, and the other with 20 pins, it is likely that the second black box is not created and the design does not link. Other than GTECH, PrimeTime does not support generic logic. Designs containing such generic logic should be removed or replaced by empty designs.

Linking With Mismatches

By default, if there are pin mismatches between instance and reference, the *link_design* command issues errors and fails. If you set the *link_allow_design_mismatch* variable to *true*, the *link_design* command issues warnings and continues. This allows you to gather useful information even when part of a design is missing.

To report mismatches, use the *report_design_mismatch* command.

Performance Considerations

The tool starts linking with the top design along with any other loaded designs and libraries. During the link process, other necessary designs and libraries are loaded. When the link process completes successfully, it produces a design that can be analyzed.

All subdesigns used to build the linked design are removed from memory.

Examples

The following examples show how a design links with many of the different linker options. First, the link fails when a library cannot be found in the link path because of a typo in the search path.

```
pt_shell> set search_path "/designs/newcpu/v1.6/dbs /libs/cmoss"
/designs/newcpu/v1.6/dbs /libs/cmoss
pt_shell> set link_path "* cmos.db"
* cmos.db
pt_shell> read_db newcpu.db
Loading db file '/design/newcpu/v1.6/dbs/newcpu.db'
1
pt_shell> link_design newcpu
Error: Can't read link_path file 'cmos.db' (LNK-001)
Linking design newcpu...
Loading db file '/designs/newcpu/v1.6/dbs/BOX1.db'
Loading db file '/designs/newcpu/v1.6/dbs/BOX2.db'
Loading db file '/designs/newcpu/v1.6/dbs/padring.db'
Warning: Unable to resolve reference to 'NR4' in 'newcpu'. (LNK-005)
```

```
Warning: Unable to resolve reference to 'ND2' in 'newcpu'. (LNK-005)
Warning: Unable to resolve reference to 'FD2' in 'newcpu'. (LNK-005)
Information: Design 'newcpu' was not successfully linked:
             16 unresolved references. (LNK-003)
```

Correcting the value of the *search_path* variable and doing an initial link completely links the design without black boxes.

```
pt_shell> set search_path "/designs/newcpu/v1.6/dbs /libs/cmos"
/designs/newcpu/v1.6/dbs /libs/cmos
pt_shell> link_design newcpu
Loading db file '/libs/cmos/cmos.db'
Linking design newcpu...
Loading db file '/designs/newcpu/v1.6/dbs/BOX1.db'
Loading db file '/designs/newcpu/v1.6/dbs/BOX2.db'
Loading db file '/designs/newcpu/v1.6/dbs/padring.db'
Design 'newcpu' was successfully linked.

---

list_attributes

Lists currently defined attributes.

Feedback

Syntax

string *list_attributes*

```
[-application]
[-class class_name]
[-nosplit]
```

Data Types

```
class_name       string
```

Arguments

`-application`

Lists application attributes as well as user-defined attributes.

`-class class_name`

Limit the listing to attributes of a single class. Valid classes are design, port, cell, net, and so on.

`-nosplit`

Prevents line-splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

Description

The *list_attributes* command displays an alphabetically sorted list of currently defined attributes. PrimeTime attributes divide into two categories: application-defined and user-defined. By default, the *list_attributes* command lists all user-defined attributes.

Using the *-application* option adds all application attributes to the listing. Note that there are many application attributes. It is often useful to limit the listing to a specific object class using the *class_name*.

Examples

This is an example listing of some attributes defined with *define_user_attribute*.

```
pt_shell> list_attributes

****************************************
Report : List of Attribute Definitions
Design :
****************************************

Properties:
    A - Application-defined
    U - User-defined
```

```
    I - Importable from db (for user-defined)

Attribute Name   Object  Type      Properties  Constraints
-------------------------------------------------------------
attr_b           cell    boolean   U
attr_d           cell    double    U
attr_f           cell    float     U
attr_i           cell    int       U,I
attr_ir1         cell    int       U           0 to 100
attr_ir2         cell    int       U           >= 0
attr_ir3         cell    int       U           <= 100
attr_oo          cell    string    U           A, B, C, D
attr_s           cell    string    U
attr_s           net     string    U
```

This example limits the listing to net attributes only.

```
pt_shell> list_attributes -application -class net

---

list_designs

Lists designs that have been read into PrimeTime.

Syntax

string *list_designs*

```
[-all]
[-only_used]
```

Arguments

`-all`

In addition to listing the designs in memory, the *-all* option lists the designs that are instantiated in the current design but are removed from memory.

`-only_used`

Lists only designs in use, including the current design, any design that is linked or partially linked, and any designs instantiated in a linked design.

Description

The *list_designs* command lists the designs that have been read into PrimeTime. When used without options, the commands lists only designs that are currently in memory.

The command output shows the status of each design with the following notation:

* - Design is the current design

L - Design is linked

N - Design is not in memory

l - Design is partially linked

Examples

The following example lists the designs in memory.

```
pt_shell> list_designs

Design Registry:
 *L AD4FULA         /abc/designs/top.db:AD4FULA
  N AD4PG           /abc/designs/add1.db:AD4PG
    ADD5A           /abc/designs/add2.db:ADD5A
    MULT1           /abc/designs/top.db:MULT1
```

The following example lists only the designs that are in use and in memory.

```
pt_shell> list_designs -only_used
Design Registry:
 *L AD4FULA         /abc/designs/top.db:AD4FULA
    ADD5A           /abc/designs/add2.db:ADD5A
    MULT1           /abc/designs/top.db:MULT1
```

If you remove the MULT1 design, you can display it using the *-all* option only.

```
pt_shell> remove_design MULT1
Removing design 'MULT1'...
1
pt_shell> list_designs -all -only_used
Design Registry:
 *L AD4FULA         /abc/designs/top.db:AD4FULA
    ADD5A           /abc/designs/add2.db:ADD5A
  N MULT1           /abc/designs/top.db:MULT1
```

---

list_key_bindings

Displays all the key bindings and edit mode of current shell session.

Syntax

status *list_key_bindings*

```
[-nosplit]
```

Arguments

`-nosplit`

Indicates that lines are not to be split when column fields overflow.

Feedback

Description

The *list_key_bindings* command displays current key bindings and the edit mode. To change the edit mode, set the *line_editing_mode* variable in either the .synopsys_pt.setup file or directly in the shell.

The text CTRL+K is read as `Control+K' and describes the character produced when the k key is pressed while the Control key is depressed.

The text META+K is read as `Meta+K' and describes the character produced when the Meta key is depressed, and the k key is pressed. The Meta key is labeled ALT on many keyboards. On keyboards with two keys labeled ALT (usually to either side of the space bar), the ALT on the left side is generally set to work as a Meta key. The ALT key on the right can also be configured to work as a Meta key or can be configured as some other modifier, such as a Compose key for typing accented characters.

If you do not have a Meta key, ALT key, or another key working as a Meta key, the identical keystroke can be generated by typing ESC first and then typing k. Either process is known as metafying the k key.

Alternative key bindings work only in vi alternate (command) mode.

---

list_libs

Lists libraries that are read into PrimeTime.

Syntax

string *list_libs*

```
[-only_used]
```

Arguments

`-only_used`

Lists only the libraries in use. A library is in use if a linked design links to library cells from the library.

Description

The *list_libs* command lists the libraries that are read into PrimeTime. You can filter unused libraries out of the display by using the *-only_used* option. A library is in use if a linked design links to library cells from the library.

The command output shows the status of each library with the following notation:

* - Main library for the current design. The main library is the first library in the link path which has a time unit.

M - Maximum library of a maximum/minimum library relationship created by the *set_min_library* command.

m - Minimum library of a maximum/minimum library relationship created by the *set_min_library* command.

Examples

The following example lists all libraries.

```
pt_shell> list_libs

Library Registry:
    bus1_lib      /u/lib/bus1_lib.db:bus1_lib
    tech1         /u/lib/tech1.db:tech1
```

After linking a design, the main library can be identified. Further, using the *-only_used* option limits the display to the libraries that were used to link the current design.

```
pt_shell> link_design top_flat
Linking design top_flat...

Designs used to link top_flat:
  <None>

Libraries used to link top_flat:
  tech1

Design 'top_flat' was successfully linked.
1
pt_shell> list_libs -only_used

Library Registry:
 *  tech1         /u/lib/tech1.db:tech1
```

- set_min_library

Feedback

list_licenses

Shows the licenses that are currently checked out.

Syntax

status *list_licenses*

Arguments

None.

Description

The *list_licenses* command lists the name and number of licenses that you currently have checked out.

In distributed multi-scenario analysis (DMSA), the command issued at the manager process returns the total count of licenses checked out for the analysis. If you run the command at a worker process, the command shows the licenses in use by the current scenario running at the worker process.

If scenarios are running sequentially because of a limited number of worker processes or licenses, running *list_licenses* at a worker process shows the instantaneous license count at the moment of command execution.

Examples

This example shows the output from the *list_licenses* command.

```
pt_shell> list_licenses

Licenses in use:
        PrimeTime (1)
        PrimeTime-SI (1)
```

See Also

- get_license
- license_users
- remove_license

lminus

Removes one or more named elements from a list and returns a new list.

Feedback

Syntax

list *lminus*

```
[-exact]
original_list
elements
```

Data Types

```
original_list     list
elements          list
```

Arguments

`[-exact]`

Specifies that the exact pattern is to be matched. By default, *lminus* uses the default match mode of *lsearch*, the *-glob* mode.

original_list

Specifies the list to copy and modify.

elements

Specifies a list of elements to remove from *original_list*.

Description

The *lminus* command removes elements from a list by using the element itself, rather than the index of the element in the list (as in *lreplace*). The *lminus* command uses the *lsearch* and *lreplace* commands to find the elements and replace them with nothing.

If none of the elements are found, a copy of *original_list* is returned.

The *lminus* command is often used in the translation of Design Compiler scripts that use the subtraction operator (-) to remove elements from a list.

Examples

The following example shows the use of the *lminus* command. Notice that no error message is issued if a specified element is not in the list.

```
prompt> set l1 {a b c}
a b c

prompt> set l2 [lminus $l1 {a b d}]
c

prompt> set l3 [lminus $l1 d]
a b c
```

The following example illustrates the use of *lminus* with the *-exact* option:

```
prompt> set l1 {a a[1] a* b[1] b c}
a a[1] a* b[1] b c

prompt> set l2 [lminus $l1 a*]
{b[1]} b c

prompt> set l3 [lminus -exact $l1 a*]
a {a[1]} {b[1]} b c

prompt> set l4 [lminus -exact $l1 {a[1] b[1]} ]
a a* b c
```

---

load_constraints

Reads in a script containing design constraints. In golden constraint reader, the mapped objects are used for defining constraint

Syntax

status *load_constraint*

```
[-scope instance_name]
file_name
```

Data Types

```
instance_name     string
file_name         string
```

Arguments

`-scope instance_name`

Specifies the scope where the constraints contained in the *file_name* file are to be executed. If you do not specify the *-scope* option, the tool uses the current scope.

file_name

Specifies the name of the file that contains the constraints to be read.

Description

The *load_constraints* command sets the scope to the specified instance and executes the set of UPF commands in the *file_name* file. Upon return, the current scope is restored to what it was before invocation. The commands are executed the same way as the *source* Tcl command.

Feedback

Examples

The following example loads the top.sdc script.

```
prompt> load_constraint top.sdc
1
```

- sdc_name_map
- source

---

load_distributed_design

Load design netlist and associated data from a scenario into the DMSA manager shell.

Syntax

status *load_distributed_design*

Description

The *load_distributed_design* command will load the appropriate image (decided internally) from live DMSA scenarios at workers. If no images are available then the appropriate commands needed to generate a scenario will be issued.

The following data is loaded by the load_distributed_design - Netlist - Timing arc traversal data - Physical location data (if available & needed) - Selected application variables

The data loaded does not include the timing state of the design, constraints, parasitics and other data restored by restore_session outside of DMSA.

Internally, the command checks if netlist signatures of all scenarios in the DMSA session are identical. If signatures are not identical, the command errors out and does not load design data. The command initiates a save_session on one of the scenarios and then loads he saved session into the DMSA manager process.

See Also

- cache_distributed_attribute_data

---

load_of

Gets the capacitance of a library cell pin. It is a DC Emulation command provided for compatibility with Design Compiler.

Feedback

Syntax

float *load_of*

```
        lib_pin
```

Data Types

```
lib_pin       string
```

Arguments

lib_pin

Specifies the name of the library cell pin, or a collection that contains the library cell pin, for which to get the capacitance.

Description

The *load_of* command returns the capacitance of the given library cell pin. The command exists in PrimeTime for compatibility with Design Compiler. Complete information about the *load_of* command can be found in the Design Compiler documentation. The supported method for getting the capacitance of a library cell pin is by using the *get_attribute* command with the *pin_capacitance* attribute.

See Also

- get_attribute

---

load_upf

Reads in a script in the Unified Power Format (UPF) format.

Syntax

status *load_upf*

```
[-scope instance_name]
[-version upf_version]
[-supplemental supp_file_name]
[-echo]
file_name
```

Data Types

```
instance_name     string
upf_version       string
supp_file_name    string
file_name         string
```

Feedback

Arguments

`-scope` *`instance_name`*

Specifies the scope where the UPF commands contained in the *file_name* file are to be executed. If you do not specify the *-scope* option, the tool uses the current scope.

`-version` *`upf_version`*

Specifies the version of UPF to which the file conforms. Allowed version is 1.1 (the default).

`-supplemental` *`supp_file_name`*

Specifies the supplemental UPF file name to be read. This option is only supported in Golden UPF mode.

`-echo`

Displays the UPF commands as they are executed. By default, the UPF commands are not echoed on the screen as they are executed.

`file_name`

Specifies the name of the file that contains the UPF script to be read. If you are not using the golden UPF mode, this argument is required. In golden UPF mode, this argument is optional and specifies the name of the golden UPF file.

Description

The *load_upf* command sets the scope to the specified instance and executes the set of UPF commands in the *file_name* file. Upon return, the current scope is restored to what it was before invocation. The commands are executed the same way as the *source* Tcl command.

Examples

The following example loads the top.upf script.

```
prompt> load_upf top.upf
1
```

- source

---

log_trace

Control creation of a replay log of traced commands.

Feedback

Syntax

string *log_trace* [-start file_name|-stop|-pause|-resume] [-log log_string] [-quiet]

string *file_name* string *log_string*

Arguments

`-start` *`file-Name`*

This option is mutually exclusive with -stop, -pause, and -resume. The argument is the pathname of the file to which the replay trace log is output. The option opens a file for output and begins logging command execution strings and application variable changes. Note that if the file already exists, the command overwrites the existing file. There can only be a single replay trace log output at any time.

`-stop`

This option is mutually exclusive with -start, -pause, and -resume. This option stops replay trace log output and closes the log file. Once stopped, the replay log cannot be repopened for appending.

`-pause`

This option is mutually exclusive with -start, -stop, and -resume. This option pauses replay trace log output. Execution of all commands and application variable settings are ignored and omitted from the log until output is resumed with -resume.

Note that pausing replay log output may render the resulting log unable to replay or incapable of replicating tool results.

`-resume`

This option is mutually exclusive with -start, -stop, and -pause. This option resumes replay trace log output.

`-log` *`log_string`*

This option outputs the given log_string, verbatim, to the replay trace log. The option may be used to explicitly log a command invocation or a comment. If the string is a comment, it must start with the Tcl comment character '#'.

`-quiet`

If given, this option causes the command to ignore error conditions such as an attempt to pause the trace log output before it is started. The command will exit quietly when it encounters an error condition.

Feedback

Description

The *log_trace* command performs operations related to creating a flat replay log of traced command execution and application variable changes. All options are optional. Upon successful completion, the command returns the pathname of the trace log file, if any, or an error message if the command fails.

Trace log output contains a comment header with the tool name and version, and the date and time when trace log output was started.

The resulting replay log is not 100% guaranteed to be able to replay or to reproduce tool results. One reason is that the tool execution environment may be different. If any operations are performed during log creation that would further compromise the ability to replay the resulting log or to replicate tool results, a warning message is appended to the log. Such operations including pausing log output.

Invoking the *log_trace* with no options will report the current status of logging: on, paused, or off, followed by the currently open log file name, if any.

Examples

The following example shows reporting of the log status before starting trace logging.

```
prompt> log_trace
off
```

The following example starts trace log creation.

```
prompt> log_trace -start ./tracelog.tcl
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

The following example pauses, then resumes log creation.

```
prompt> log_trace -pause
/an/absolute/path/.tracelog.tcl
prompt> log_trace
paused: /an/absolute/path/.tracelog.tcl
prompt> log_trace -resume
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

Feedback

ls

Lists the contents of a directory.

Syntax

string *ls* [*filename ...*]

```
string filename
```

Arguments

filename

Provides the name of a directory or filename, or a pattern which matches files or directories.

Description

If no argument is specified, the contents of the current directory are listed. For each *filename* matching a directory, *ls* lists the contents of that directory. If *filename* matches a file name, the file name is listed.

Examples

```
shell> ls *.db *.pt
test1.pt          c1.db          c3.db          c5.db
test2.pt          c2.db          c4.db          c6.db
```

m

man

Displays reference manual pages.

Syntax

```
string man
topic
```

Data Types

topic string

Arguments

topic

Specifies the subject to display. Available topics include commands, variables, and error messages

Feedback

Description

The *man* command displays the online manual page for a command, variable, or error message. You can write man pages for your own Tcl procedures and access them with the *man* command by setting the *sh_user_man_path* variable to an appropriate value. See the man page for the *sh_user_man_path* variable for details.

Examples

The following command displays the man page for the *echo* command:

```
prompt> man echo
```

The following command displays the man page for the error message CMD-025:

```
prompt> man CMD-025
```

---

map_design_mode

Maps specified design modes to cell modes, paths, or both.

Syntax

status *map_design_mode*

```
[-from from_pin_list]
[-to   to_pin_list]
[-through through_pin_list]
design_mode
[cell_mode_list]
[instance_list]
```

Data Types

```
from_pin_list          list
to_pin_list            list
through_pin_list       list
design_mode            list
cell_mode_list         list
instance_list          list
```

Feedback

Arguments

`-from` *from_pin_list*

Specifies a timing path from a given pin of the design that is active only for the specified design mode. The given paths are inactive for other design modes which are in the same design mode group.

`-to` *to_pin_list*

Specifies a timing path to a given pin of the design that is active only for the specified design mode. The given paths are inactive for other design modes which are in the same design mode group.

`-through` *through_pin_list*

Specifies a timing path through a given pin of the design that is active only for the specified design mode. The given paths are inactive for other design modes which are in the same design mode group.

design_mode

Specifies a design mode that is mapped to cell modes or paths. The design modes on the list must have been previously created using the *define_design_mode_group* command.

instance_list

Specifies a list of cells in which the specified modes are mapped to the design mode. This list must be accompanied by the *cell_mode_list* option.

cell_mode_list

Specifies a list of cell modes which are mapped to the design mode.

Description

The *map_design_mode* command maps design modes to cells or paths. The design modes must have been previously created by the *define_design_mode_group* command.

To map a design mode to a cell mode, use this command:

```
map_design_mode cell_mode_list instance_list design_mode
```

If the design mode changes from inactive to active, then all cell modes mapped to the design mode also become active.

To map a design mode to a path, use this command:

```
map_design_mode -from from_pin_list -to to_pin_list
  -through through_pin_list design_mode
```

Feedback

When a path is mapped to a design mode and the design mode is set inactive, the path becomes a false path. If the design mode is subsequently set active, then the path is reset and no longer considered false.

To see a report of the design modes specified for the current design, use the *report_mode -type design* command. The report also shows the cell modes and paths mapped to each design mode.

Examples

The following example defines two design modes, DM1 and DM2, maps the cell mode READ to design mode DM1 (for instance Uram1), then removes the design mode DM1. Removing DM1 also removes the mapping to the active cell mode READ.

```
pt_shell> define_design_mode_group {DM1 DM2}
pt_shell> map_design_mode READ Uram1 DM1
pt_shell> remove_design_mode DM1
```

See Also

---

mem

Shows the total memory used by PrimeTime.

Syntax

integer *mem*

Arguments

None.

Description

The *mem* command shows the maximum memory usage in kilobytes (KB) of this instance of PrimeTime.

The memory usage of a multiprocess application, such as PrimeTime, reflects aggregate memory used across all its processes. Conceptually, this is the total amount of memory

pages used for the entire application instance, without double counting shared pages (such as shared libraries and executables) across the application instance.

The memory usage of distributed processes is not included. For remote PrimeTime process memory usage, use the *report_host_usage* command.

Examples

The following example shows the memory usage information.

```
pt_shell> mem
8092
```

See Also

- cputime
- report_host_usage

---

merge_models

Merges multiple timing models (in LIB format) together to be one.

Syntax

string *merge_models*

```
[-lib_files lib_file_names]
[-mode_names mode_names]
[-group_names mode_group_names]
-output file_name
[-formats format_list]
[-tolerance merge_tolerance]
[-pin_cap_tolerance merge_tol_of_pin_cap]
[-single_mode]
[-keep_all_arcs]
[-merge_pg_pin {rail_name, [vol_opt]}]
```

Data Types

```
lib_file_names          list
mode_names              list
mode_group_names         list
file_name               string
format_list             list
merge_tolerance         float
merge_tol_of_pin_cap    float
rail_opt_list           list
```

Arguments

`-lib_files` *`lib_file_names`*

Specifies a list of Synopsys internal library (.lib) files to read, compile, and merge. The files must have been extracted using the *extract_model* command. Substitute the list you want for *lib_file_names*.

`-mode_names` *`mode_names`*

Specifies a list of mode names for the list of models in one mode group. All mode names specified by all mode_names option must match the list of library files specified. Substitute the list you want for *mode_names*. This option can be used multiple times. This option cannot be used with *merge_pg_pin* option.

`-group_names` *`mode_group_names`*

Specifies the names of the mode groups to which the models belong. If you do not specify this option, then default assign serial name *etm_modes_1*, *etm_modes_2*,... This option cannot be used with *merge_pg_pin* option.

`-output` *`file_name`*

Specifies the name of the output file that is used to save the merged model. Substitute the name you want for *file_name*.

`-formats` *`format_list`*

Specifies the formats the merge model is written in, either db, lib, or both. Substitute the formats that you want for *format_list*.

`-tolerance` *`merge_tolerance`*

Specifies the float tolerance used to compare delay or transition values of arcs in the timing models. It defines the tolerance for floating point number comparison when the timing arcs in the models are matched and compared against each other to determine they are equal. Float numbers are considered equal if the difference between them is within the tolerance.

The default is 0.04. The values from the first .lib file listed in the *-lib_file* option is used in the merged model. Substitute the tolerance you want for *merge_tolerance*; however, the value must be greater than or equal to zero.

This option cannot be used with the *keep_all_arcs* option.

`-pin_cap_tolerance` *`merge_tol_of_pin_cap`*

Specifies the float tolerance used to compare the capacitance attribute values for the matching pins across the models. Float numbers are considered equal if the absolute difference between them is within the specified tolerance.

The default is 0.002. The values from the first .lib file listed in the *-lib_file* option is used in the merged model if equal within tolerance.

`-single_mode`

Forces one timing arc to have only one defined mode or forces there to be only one single mode per timing arc in the merged model. This is necessary for downstream tools that cannot handle more than one mode on a timing arc. This normally results in larger, less compact timing models.

This option cannot be used with the *keep_all_arcs* option.

`-keep_all_arcs`

This makes the *merge_models* option ignore the *merge_tolerance* and suppresses all arc merging, and it implies *single_mode*. Use this option when performing two independent merges and the resulting merged models must have the same number of arcs. Resulting models are very large. This option cannot be used with either the *single_model* or *merge_tolerance* option.

`-merge_pg_pin` *`rail_opt_list`*

Specifies a list of voltage corners and their *high/low* options. If *high/low* not specified, merge with *default*: merge with all voltage corners from first lib file. All non-specified voltage must be the same. This option can be used multiple times. This option cannot be used with either the *mode_names* or *group_names* option. When this option is used, it is considered option *single_model* also applies.

Description

Merges multiple timing models together to be one. The timing models must be in Synopsys internal library (.lib) format. This command reads in all the specified files to generate a list of timing models. These timing models are processed, matched, compared, and merged to create a single timing model. This model has moded timing arcs such that, in any given mode, the static timing behavior of the merge model is equivalent to one of the models merged. The final merged model is saved on disk in the specified files and requested formats. PrimeTime and Design Compiler recognize the merged model with moded timing arcs for performing timing analysis.

The *keep_all_arcs* argument should only be used when a timing model has been extracted under several different conditions and the results are to be merged into two or more models in situations where the number of arcs must match. For example, say that a model TEST is extracted with two modes A and B, operating conditions min and max. There are four extractions, min A, min B, max A and max B. Now you want to merge all min values for modes A and B to get a minimum model, and all max values to get a maximum model. If you were going to use the merged models as the minimum and maximum libraries of the *set_min_library* command, their arcs must match. Therefore, you should merge the models using the *keep_all_arcs* option.

Feedback

Examples

The following command reads in the LIB models specified by the sram_write.lib and sram_read.lib files and generates a merged model containing an "SRAM_MODE" mode group with two "READ" and "WRITE" component modes. Timing arcs existing only in the sram_write.lib file are put into the merged model and marked with "WRITE" mode. Timing arcs existing only in the sram_read.lib file are marked with "READ" mode. Timing arcs existing in both models are compared to each other by their delay/transition values. If they are within 0.1 time units of each other, they are considered equal, and only one is kept in the merged model with no mode marked on the arc (valid for both modes); otherwise both arcs are kept in the merged model with each arc marked with a proper mode depending on which model it came from. Because the command requests all formats, the merged model is saved as sram_model_lib.db in Synopsys database format (.db), and sram_model.lib in Synopsys internal library format (.lib).

```
pt_shell> merge_models -lib_files \\
  {sram_write.lib sram_read.lib} \\
  -mode_names {WRITE READ} -mode_group SRAM_MODE \\
  -output sram_model -format {db lib} \\
  -tolerance 0.1
```

The following command reads in the LIB models specified by the sram_write.lib and sram_read.lib files and generates a merged model containing an "SRAM_MODE" mode group with two "READ" and "WRITE" component modes. Timing arcs existing only in the sram_write.lib file are put into the merged model and marked with "WRITE" mode. Timing arcs existing only in the sram_read.lib file are marked with "READ" mode. Timing arcs existing in both models are compared to each other by their delay/transition values. If they are within 0.1 time units of each other, they are considered equal, and only one is kept in the merged model with no mode marked on the arc (valid for both modes); otherwise both arcs are kept in the merged model with each arc marked with a proper mode depending on which model it came from. Because the command requests all formats, the merged model is saved as sram_model_lib.db in Synopsys database format (.db), and sram_model.lib in Synopsys internal library format (.lib).

```
pt_shell> merge_models -lib_files \\
  {etm_1.lib .lib} \\
  -mode_names {WRITE READ} -mode_group SRAM_MODE \\
  -output sram_model -format {db lib} \\
  -tolerance 0.1
```

The following command reads in the LIB models specified by the sram_write.lib and sram_read.lib files and generates a merged model containing the higher voltage of VDD1 ,the lower voltage of VDD2 from sram_write.lib and sram_read.lb and the VDD3 from sram_write.lib.

```
pt_shell> merge_models -lib_files \\
  {sram_write.lib sram_read.lib} \\
  -merge_pg_pin {VDD1 high} \\
```

Feedback

```
-merge_pg_pin {VDD2 low} \\
-merge_pg_pin VDD3 \\
-output sram_model -format {db lib} \\
-tolerance 0.1
```

merge_saif

Reads a list of SAIF files with their corresponding weights, annotates switching activity attributes with merged toggle_rate, glitch_rate, and merged static_probability for nets, pins, ports, and power arcs in the current instance, and generates a merged output SAIF file.

Syntax

```
status merge_saif
   -input_list saif_file_and_weight_list
   -strip_path inst_name
   [-path prefix]
   [-ignore ignore_name]
   [-exclude exclude_file_name]
   [-derate_glitch value]
   [-quiet]
   [-output merged_saif_name]
   [-simple_merge]
```

Data Types

saif_file_and_weight_list	list
inst_name	string
prefix	string
ignore_name	string
exclude_file_name	string
value	float
merged_saif_name	string

Arguments

`-input_list` *saif_file_and_weight_list*

Specifies the name and the corresponding weight of the SAIF file list. *saif_file_and_weight_list* contains a list of { -input name.saif -weight number }, where "-input" and "-weight" are keywords. In addition, 0 < number < 100, and the sum of all weights is equal to 100. For example, { -input gate_back_1.saif -weight 20 -input gate_back_2.saif -weight 80 } means that

the files gate_back_1.saif and gate_back_2.saif are weighted by 20% and 80%, respectively.

`-strip_path` *`inst_name`*

Specifies the name as it appears in each SAIF file of the current design instance you want to annotate. The *merge_saif* command annotates all subinstances in the hierarchy of the specified instance, as well as annotating the instance itself.

`-path` *`prefix`*

Specifies a relative path from the current design to the hierarchical low-level design for which the SAIF file has been created. By default, absolute path names are used. Use this option if the SAIF file refers to an object in a hierarchy. Also if you want to read the switching information for a portion of the design, this option can be used. For example, if the SAIF was generated for the whole design, and you want to put switching information only on the nets/ports on the boundary and hierarchically under instance add14, then *-path* add14 option can be used.

`-ignore` *`ignore_name`*

Specifies the name of an instance in the SAIF file for which switching activity is to be ignored. The *merge_saif* command ignores switching activity within the hierarchy of that instance in the SAIF file.

`-exclude` *`exclude_file_name`*

Specifies the name of a file that contains a list of names to be ignored. *exclude_file_name* is used when you want to ignore switching activity for several instances. The file must contain each *ignore_name* on a separate line, without the *-exclude* option. As with the *-ignore* option, the ignore names are recognized after the *-strip_path* argument.

`-derate_glitch` *`value`*

Specifies a default derating factor value to be used for inertial glitches in the SAIF file. If the *-derate_glitch* option is not specified, a default derating factor of 0.5 is used.

`-quiet`

Specifies quiet mode and for instance suppresses warnings on design objects in the SAIF file that could not be annotated on the design.

`-output` *`merged_saif_name`*

Specifies the name of the output merged SAIF file.

`-simple_merge`

Indicates that all SAIF files are to annotate 100% of the nets, ports and pins of the current instance, and the *merge_saif* command is to perform a simple merge

of SAIF file data (without propagating the switching activity of non-annotated objects). Use the *report_switching_activity* command to verify that each SAIF file annotates 100% of the current instance.

Description

The *merge_saif* command reads a list of SAIF files with weight, computes the merged toggle_rate, glitch_rate, and static_probability, and annotates the switching activity attributes toggle_rate, glitch_rate, and static_probability for nets, ports, pins, and power arcs of the current instance. In addition, the *merge_saif* command optionally generates a merged output SAIF file. To identify the instance (and corresponding subinstances) you want to annotate, use the *-strip_path* argument. To specify a default derating factor other than 0.5, use the *-derate_glitch* option.

Examples

The following example reads and merges weighted SAIF files, annotates switching activity for the current design, and generates an output SAIF file.

```
pt_shell> set SAIF_DIR /home/user/ptpx/saif
pt_shell> set SAIF1 ${SAIF_DIR}/gate_back1.saif
pt_shell> set SAIF2 ${SAIF_DIR}/gate_back2.saif
pt_shell> set SAIF3 ${SAIF_DIR}/gate_back3.saif
pt_shell> set SAIF4 ${SAIF_DIR}/gate_back4.saif
pt_shell> merge_saif -input_list \\
             " -input $SAIF1 -weight 10 \\
               -input $SAIF2 -weight 20 \\
               -input $SAIF3 -weight 30 \\
               -input $SAIF4 -weight 40 " \\
               -strip_path E/UUT -output merged_saif.saif
```

---

move_objects

Moves and rotates the specified objects.

Feedback

Syntax

status *move_objects*

```
[-delta delta]
[-from point]
[-to point]
[-x x]
[-y y]
[-rotate_by angle]
[-group]
[-force]
[-simple]
[object_list]
```

Data Types

```
object_list  collection or selection
delta        list of two floats: x and y
point        list of two floats: x and y
x            float
y            float
angle        float
```

Arguments

object_list

Specifies a collection or selection set containing objects to move. If this option is not specified, the global selection set is used.

-delta *point*

Specifies the distance in the x- and y-directions to move the objects from the object's current location. This option is mutually exclusive with the *-to*, *-from*, *-x* and *-y* options.

-from *point*

Specifies the reference point on the object, or the collection of objects to be moved, for the *-to* option. By default, the command uses the lower-left corner of the bounding box of the given object, or collection of objects, as the reference point. This option must be used together with the *-to* option.

-to *point*

Specifies the new location of the reference point for the object or objects. This option is mutually exclusive with the *-delta*, *-x* and *-y* options.

-x *float*

Specifies the x-coordinate for the given object or collection of objects. All objects are moved so that their left edge is placed at the specified x-coordinate. This option is mutually exclusive with the *-delta*, *-from* and *-to* options.

Feedback

`-y` *float*

Specifies the y-coordinate for the given object or collection of objects. All objects are moved so that their bottom edge is placed at specified y-coordinate. This option is mutually exclusive with the *-delta*, *-from* and *-to* options.

`-rotate_by` *angle*

Specifies the rotation angle of the objects.

The valid values are:

```
0, 90, 180, 270,
CW90, CW180, CW270, CCW90, CCW180, CCW270
FLIPX, FLIPY
R0, R90, R180, R270, MX, MXR90, MY, MYR90
```

The rotation value definitions are:

```
CW90    is 90 degrees clockwise
CW180   and CCW180 are 180 degrees
CW270   is 270 degrees clockwise
CCW90   is 90 degrees counterclockwise
CCW270  is 270 degrees counterclockwise
FLIPX   is the reflection about the x-axis
FLIPY   is the reflection about the y-axis
```

The following values are synonymous:

```
0,   R0
90,  CCW90,  R90
180, CCW180, R180
270, CCW270, R270,
FLIPX, MY
FLIPY, MX
```

`-group`

Specifies if rotation should be made around common pivot point. If omitted, the rotation is performed around the object centers.

`-force`

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using *get_edit_setting*.

`-simple`

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using *get_snap_setting*.

Feedback

Description

This command moves one or more specified objects to a given location skipping all fixed or locked objects. The command keeps pin/terminal on edge of parent block and updates its layer if corresponding edit setting is set. See the *set_edit_setting* command for details.

Snapping is done automatically using the global snap settings.

Examples

The following example moves all selected objects by delta (-100 100).

```
prompt> move_objects -to {-100 100} -from {0 0}
```

The alternative syntax uses collection to specify objects.

```
prompt> move_objects [get_selection] -to {-100 100} -from {0 0}
```

See Also

- snap_objects

O

---

open_drc_error_data

Opens an error data file so that you can query or modify the error data.

Syntax

```
collection open_drc_error_data
[-file_name file_name]
[-readwrite]
[-readonly]
[-checkonly]
```

Data Types

```
file_name string
```

Feedback

Arguments

`-file_name` *`file_name`*

Specifies the file path of an external error data file to open.

`-readwrite`

Opens the specified external error data file in read/write mode.

When you enable this mode, the tool can modify the contents of the error data file. If you open a file in read/write mode, it stays in that mode even if you later open it in read-only mode.

This is the default open mode for external error data files, which are opened with the *-file_name* option.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

`-readonly`

Opens the specified external error data file in read-only mode. However, if you previously opened the file in read/write mode, the file remains in read/write mode.

When you enable this mode, the tool cannot modify the contents of the error data file.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

`-checkonly`

Checks if the specified error data file is already open and returns a collection that contains the error data object if the file is open. If the file is not open, it returns an empty string.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

Description

The *open_drc_error_data* command opens an error data file so that you can query or modify the error data.

- External error data files are stored on disk.

  To open an external error data file, specify its file path with the *-file_name* option.

  When you open an external error data file, by default, the tool opens the file in read/write mode. To explicitly specify the open mode, use the *-readwrite* or *-readonly* option. When you use these options, the *-readwrite* option has the highest precedence. If you

Feedback

open the error data the *-readwrite* option and then open it again with the *-readonly* option, the open mode remains read/write.If you first open the error data with the *-readonly* option, and then open it again with the *-readwrite* option, the open mode changes to read/write.

The *open_drc_error_data* command increments the open count for the error data, except when you use the *-checkonly* option. The *open_drc_error_data* commands must be balanced by an equal number of *close_drc_error_data* commands to close the error data object.

The command returns a collection that contains the opened error data file. If no file is opened, the command returns an empty string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example opens the external error data file named "./my_design_dppinassgn.err" in read/write mode and returns a collection that contains the error data file.

```
prompt> open_drc_error_data -file_name ./my_design_dppinassgn.err
{my_design_dppinassgn.err}
```

p

parallel_execute

Specifies a list of commands to be executed in parallel and their output files.

Syntax

status *parallel_execute*

Feedback

```
[-commands_only]
[-compress]
concurrent_cmds
```

Data Types

```
concurrent_cmds     list
```

Arguments

`-commands_only`

Prints output of commands after all commands complete execution.

`-compress`

Compresses when writing to file. If redirecting to a file, this option specifies that the output should be compressed as it is written. The output file is in a format recognizable by "gzip -d". You cannot specify this option with the *-commands_only* option.

concurrent_cmds

The list of commands, if the option *-commands_only* is specified. Otherwise, it is a list of interleaved strings that are commands and their output files. When there are sufficient computing resources available, these commands are to be executed in parallel with their results written into the specified output files separately.

Description

This command is a parallel directive that instructs PrimeTime to execute the list of commands in parallel. The output of commands is either printed out (if the option *-commands_only* is specified) or written out to the specified log files. It enables you to exploit parallelism across unrelated PrimeTime Tcl commands.

The following syntax shows how to use the *parallel_execute* command:

```
update_timing -full
parallel_execute {
  report_cmd1  rpt_file1
  report_cmd2  rpt_file2
  ...          ...
  report_cmdN  rpt_fileN
}
```

Any post-update reporting and analysis commands are applicable.

The *parallel_execute* command honors the resource constraint specified by the *set_host_options* command with the *-local_process* and *-max_core* options.

When there are sufficient resources, executing multiple PrimeTime post update reporting and analysis commands in parallel can reduce the overall runtime of the

script, comparing to when those reporting commands are executed sequentially. The commands recommended for the *parallel_execute* command include many common post-update commands, such as the *report_clock_timing*, *check_timing*, *report_bottleneck*, *report_exceptions*, *report_min_pulse_width*, *save_session*, path-based analysis, *create_ilm*, and *extract_model* commands or even user-defined Tcl procedures that are custom reports based on these native PrimeTime reporting commands.

To get the best results, it is important to understand that the *parallel_execute* command should contain post update reporting and analysis commands. Any commands that cause changes to the computed timing data and trigger incremental update result in severe errors and script and command execution immediately stops.

The *parallel_execute* command honors the resource constraint specified by the *set_host_options* command with the *-local_process* and *-max_core* options.

Note that the number of commands allowed inside the *parallel_execute* command has no practical limit, and PrimeTime automatically and dynamically schedules these commands if there are more commands then number of computing resources (CPUs or cores) available.

Also note that the *parallel_execute* command is itself a blocking command, which means PrimeTime does not execute the next command following the *parallel_execute* command after finishing all the commands specified in the list. To get closest to optimal speed-up, it is recommended that the longer runtime commands be specified first.

Examples

In the following example, four cores are allocated on the local host to perform parallel execution. Next, after the *update_timing* command, the *report_timing*, *report_constraints*, *save_session* PrimeTime commands and user Tcl procedure *report_qor* are executed in parallel.

```
pt_shell> set_host_options -local -max_cores 4
  ...

pt_shell> update_timing
pt_shell> parallel_execute {
            {report_timing -max 10000 -nworst 10} rpt_tim.log
            {report_constraints -all_violators} rpt_cstr.log
            {report_qor} rpt_qor.log
            {save_session  design_dir/my_session} /dev/null
          }
```

In the second example, parallel_execute is used to evaluate and print out the output of commands *check_timing* and *report_analysis_coverage*.

```
pt_shell> parallel_execute -commands_only {
            {check_timing}
            {report_analysis_coverage}
```

```
          }
Output of command 'check_timing':
Information: Checking 'no_input_delay'.
Information: Checking 'no_driving_cell'.
Information: Checking 'unconstrained_endpoints'.
Information: Checking 'unexpandable_clocks'.
Information: Checking 'latch_fanout'.
Information: Checking 'no_clock'.
Information: Checking 'partial_input_delay'.
Information: Checking 'generic'.

---

parallel_foreach_in_collection

Iterates over the elements of a collection in parallel.

Feedback

Syntax

status *parallel_foreach_in_collection*

```
[-checks]
itr_var
collections
body
```

Data Types

itr_var	string
collections	list
body	string

Arguments

`-checks`

Enables the variable checks.

itr_var

Specifies the iterator variable. During each iteration, *itr_var* is set to a collection of exactly one object.

collections

Specifies a list of collections over which to iterate.

body

Specifies a script to execute one time per iteration at a worker process.

Description

Similarly to the *foreach_in_collection* command, the *parallel_foreach_in_collection* command iterates over elements of a collection, but with the added constraints and benefits of parallelism. It improves core utilization during the execution of custom Tcl scripts by executing multiple independent iterations simultaneously at worker processes. The required arguments for the *parallel_foreach_in_collection* command are the same as the arguments for the *foreach_in_collection* command: an iterator variable, the collections over which to iterate, and a script to apply at each iteration.

The *parallel_foreach_in_collection* command

- Automatically gathers any stdout/stderr output produced in parallel at workers during the execution of the *body* script. It prints the output, sorted by iteration order at the manager. For best performance, keep printing statements to a minimum as printing is done as a serial process.
- Requires a linked design; it attempts to perform an automatic link if a design is loaded but not linked.

- Supports the built-in *break*, *continue*, *return*, and *exit* commands, with the same syntax as other standard loop iteration constructs.
- Honors the resource constraints specified by using the *set_host_options* command with the *-local_process* and *-max_core* options.
- Falls back to running sequentially if used in the manager in distributed multi-scenario analysis (DMSA) mode.
- Falls back to running sequentially if nested within another parallel command such as *redirect -bg*, *parallel_execute*, or *parallel_foreach_in_collection* itself.
- Falls back to running sequentially if used while parasitics are being read in the background.

Constraints

The *body* script argument is subject to the following constraints, some of which can be lifted by using the sibling command *post_eval*:

- Modifications cannot be performed on any collections specified by the *collections* argument (for example, modifications through the use of the *append_to_collection* command).
- Modifications cannot be performed on the iterator variable *itr_var* during the loop.
- The *body* script can read and modify variables and call procedures defined in the local or global scope. However, it is forbidden to do so in a way that would lead to dependencies between iterations. In particular, an iteration of *body* is not allowed to write to a variable from local or global scope if another iteration reads the same variable.

  Note: The *body* script is run in parallel, and dependencies between iterations can potentially cause incorrect or unpredictable results due to race conditions.
- The *body* script is subject to the same restrictions imposed on the script argument of the *parallel_execute* command; that is, no change to the design state is allowed. This includes editing the design, changing constraints, performing updates, and setting user-defined attributes. If you attempt to execute such commands, the tool issues error messages.

  Additionally, do not expect modifications to local and global variables from within the *body* script to persist after the loop is completed because the *body* script is executed at worker processes (likewise parallel_execute).

Sibling Command: post_eval

You can issue the *post_eval* command from within *parallel_foreach_in_collection body* to perform persistent changes to variables and the design state. The *post_eval* command

has a single script argument that is submitted for execution at the manager process. This script is executed sequentially, and in guaranteed iteration order.

For more information, see the man page of the *post_eval* command.

Recommended Usage

The *parallel_foreach_in_collection* command speeds up custom complex Tcl scripts by applying parallelism to collection iteration, both pre- and post-update.

Although most commands in PrimeTime are capable of utilizing multiple cores (such as *get_pins* and *get_timing_paths*), many commonly-used built-in Tcl commands in custom Tcl scripts are inherently sequential. Therefore, their execution utilizes only one CPU core even if there are multiple cores allocated to PrimeTime. The *parallel_foreach_in_collection* command improves performance and scalability by utilizing the available CPU cores.

To convert your scripts to use the *parallel_foreach_in_collection* command, identify existing *foreach_in_collection* loops for conversion with the following guidelines:

- The loop should have a large overall runtime and iterate over many objects. If the collection is too small, then an ideal work balance cannot be achieved, resulting in under-utilization of available CPU cores.
- The loop should not contain any heavyweight commands that completely change the design such as timing, noise, or power updates, or link_design. These commands are generally too compute-intensive to be in a loop, and they are forbidden in *parallel_foreach_in_collection*.
- Each iteration of the loop should have a relatively compute-intensive filtering, reporting, analysis, or decision-making component, followed by one or more simple components, such as setting an attribute or modifying a variable to aggregate the results. In general, these components map to the *body* and *post_eval* arguments, respectively.
- Lastly, each iteration of the loop should have reasonable memory requirements, because parallel execution of multiple iterations can increase total memory consumption proportionally to this increment.

After you identify a loop for conversion to *parallel_foreach_in_collection*, review and restructure the loop so that you can add the relevant *post_eval* statements at the right places. Use the following guidelines for conversion:

- Global and local variables that are only read can be left unchanged, but variables that are modified need to be identified and classified according to their purpose. Temporary variables can be modified in the scope of the *body*, but any variable that is expected to persist after *parallel_foreach_in_collection* is completed needs to be moved into a *post_eval* statement.
- If there is any dependency between variables used in different iterations, it must be eliminated by rewriting the relevant part of the script. If a dependency

cannot be removed, then the loop is no longer a candidate for conversion to *parallel_foreach_in_collection*.

- Any changes to the design state, setting of constraints or user-defined attributes must be moved into a *post_eval* statement. During this process, it is important to ensure that there are no dependencies on design changes across loop iterations.
- The resulting *post_eval* statements should be reviewed to make sure that they are kept as small and fast as possible. *post_eval* statements are executed serially and ultimately determine the scalability and performance of the whole loop.

Variable Checks

When variable checks are enabled with the *-checks* option, PrimeTime monitors access to all Tcl variables and detects a broad variety of problems related to the misuse of variables or violations of the recommended usage of *parallel_foreach_in_collection*.

The variable checks are designed to aid in migrating from *foreach_in_collection*; you still need to carefully review the Tcl script being converted.

There are four main categories of errors that can be issued by the variable checks. For more information about these errors, see the man pages for MC-201, MC-202, MC-203, and MC-204.

Examples

The following example computes the endpoint with most violators and the number of violators for this endpoint.

```
set endpoints [add_to_collection [all_registers -data_pins -async_pins]
                                 [all_outputs] ]
set most_violators 0
set ep_with_most_violators ""
parallel_foreach_in_collection -checks endpoint $endpoints {
  set paths [get_timing_paths -to $endpoint -nw 1000
                              -slack_lesser_than 0]
  set num_violators [size_of_collection $paths]
  post_eval {
    if { $num_violators > $most_violators } {
      set most_violators $num_violators
      set ep_with_most_violators $endpoint
    }
  }
}
```

---

parse_proc_arguments

Parses the arguments passed into a Tcl procedure.

Syntax

string *parse_proc_arguments* -args *arg_list result_array*

```
list arg_list
string result_array
```

Arguments

`-args arg_list`

Specified the list of arguments passed in to the Tcl procedure.

`result_array`

Specifies the name of the array into which the parsed arguments should be stored.

Description

The *parse_proc_arguments* command is used within a Tcl procedure to enable use of the -help option, and to support argument validation. It should typically be the first command called within a procedure. Procedures that use *parse_proc_arguments* will validate the semantics of the procedure arguments and generate the same syntax and semantic error messages as any application command (see the examples that follow).

When a procedure that uses *parse_proc_arguments* is invoked with the -help option, *parse_proc_arguments* will print help information (in the same style as using *help -verbose*) and will then cause the calling procedure to return. Similarly, if there was any type of error with the arguments (missing required arguments, invalid value, and so on), *parse_proc_arguments* will return a Tcl error and the calling procedure will terminate and return.

If you didn't specify -help, and the specified arguments were valid, the array variable *result_array* will contain each of the argument values, subscripted with the argument name. Note that the argument name here is NOT the names of the arguments in the procedure definition, but rather the names of the arguments as defined using the *define_proc_attributes* command.

The *parse_proc_arguments* command cannot be used outside of a procedure.

Feedback

Examples

The following procedure shows how *parse_proc_arguments* is typically used. The argHandler procedure parses the arguments it receives. If the parse is successful, argHandler prints the options or values actually received.

```
proc argHandler args {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo "  $argname = $results($argname)"
  }
}
define_proc_attributes argHandler -info "argument processor" \\
  -define_args \\
  {{-Oos "oos help" AnOos one_of_string {required value_help {values {a
 b}}}}
   {-Int "int help" AnInt int optional}
   {-Float "float help" AFloat float optional}
   {-Bool "bool help" "" boolean optional}
   {-String "string help" AString string optional}
   {-List "list help" AList list optional}}
  {-IDup int dup AIDup int {optional merge_duplicates}}}
```

Invoking argHandler with the -help option generates the following:

```
prompt> argHandler -help
Usage: argHandler    # argument processor
        -Oos AnOos              (oos help:
                                 Values: a, b)
        [-Int AnInt]            (int help)
        [-Float AFloat]         (float help)
        [-Bool]                 (bool help)
        [-String AString]       (string help)
        [-List AList]           (list help)
```

Invoking argHandler with an invalid option causes the following output (and a Tcl error):

```
prompt> argHandler -Int z
Error: value 'z' for option '-Int' not of type 'integer' (CMD-009)
Error: Required argument '-Oos' was not found (CMD-007)
```

Invoking argHandler with valid arguments generates the following:

```
prompt> argHandler -Int 6 -Oos a
  -Oos = a
  -Int = 6
```

Feedback

pop_sms_scenario

Ends the scope of the closest/most recent previous *push_sms_scenario* command.

Syntax

string *pop_sms_scenario*

Description

The *pop_sms_scenario* command ends the scope of the closest/most recent previous *push_sms_scenario* command. It has no effect if no previous *push_sms_scenario* commands were executed. This command is only available with SMVA/SMC analysis.

Examples

The following example specifies 3 voltage reference names {high,low,typ} for each one of the supply groups SN1 and SN2. PrimeTime automatically considers all the relevant combinations of voltage levels, in this case up to nine prior to the use of the *push_sms_scenario* command. The example shows a sequence of a *push_sms_scenario* command followed by a *pop_sms_scenario* command and their expected effect on subsequent commands. For more examples, please look at the *push_sms_scenario* command manual.

```
pt_shell> set_voltage_levels SN1 -reference_names { high low typ }
pt_shell> set_voltage -o SN1 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN1 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN1 -reference_name typ 0.9 -min 1.0
pt_shell> set_voltage_levels SN2 -reference_names { high low typ }
pt_shell> set_voltage -o SN2 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN2 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN2 -reference_name typ 0.9 -min 1.0
```

The following command considers all SMS scenarios.

```
pt_shell> report_timing
```

The following command pushes the SN1:low SMS scenario collection.

```
pt_shell> push_sms_scenario -sms_scenarios [get_sms_scenario
 -supply_group SN1 -reference_name low]
```

The following command considers the SN1:low SMS scenario collection specified with the previous most recent *push_sms_scenario* command.

```
pt_shell> report_timing
```

The following command pops the SN1:low SMS scenario collection, ending its corresponding scope. There are no outstanding pushed SMS scenario collections after

Feedback

this command, as shown using the *get_current_sms_scenario* command. The subsequent command considers all SMS scenarios.

```
pt_shell> pop_sms_scenario
pt_shell> report_timing
pt_shell> get_current_sms_scenario
0
```

---

post_eval

Submits a script for sequential execution in the context of a parallel iterator.

Syntax

status *post_eval*

```
        script
```

Data Types

script string

Arguments

script

Specifies a script that to be executed sequentially at the manager process.

Description

The *post_eval* command can be used in the context of a parallel iterator such as the *parallel_foreach_in_collection* command to submit a script for execution at the manager process.

You can use multiple *post_eval* statements per loop iteration, and they can be put inside other constructs (such as *if* statements). *post_eval* statements are executed sequentially, and in guaranteed loop iteration order.

post_eval also supports built-in *break*, *continue*, *return*, and *exit* commands, with the same syntax as other standard loop iteration constructs.

Feedback

post_eval lifts from some of the restrictions normally imposed on the *body* of parallel iterators, and therefore can be used to perform actions such as changing constraints, setting user-defined attributes, and modifying persistent variables to aggregate results.

However, *post_eval* is still forbidden from executing any heavyweight commands that completely change the design such as timing, noise, or power updates, and link_design. These commands are generally considered to be too compute-intensive to be in a loop in the first place. If you use these commands, the tool issues error messages.

It is an error to issue a *post_eval* command outside of the context of a parallel iterator.

Variable Transfer and Identification

The *post_eval* argument is parsed at the beginning of the loop to identify references to variables from the worker process. Only variable references beginning with a '$' can be identified, and comments are ignored.

Because of this parsing requirement, *post_eval* statements can only be issued directly from within *parallel_foreach_in_collection body* (not from called Tcl procedures). Similarly, while the script argument to *post_eval* can call Tcl procedures, the parsing mechanism for variable identification does not follow called Tcl procedures.

The value of each of these variables at the worker at the point of the call to *post_eval* is sampled and transfered to the manager so that, when the *post_eval* script is executed at the manager, references to these variables can be successfully evaluated.

All basic Tcl types are supported for variable transfer, including string, boolean, integer, long, float, double, list, array, and dict. Collections of some types can also be transfered.

Supported collection object classes are pin, net, cell, port, lib, lib_cell, lib_pin, design, clock, and path_group.

For best performance, keep *post_eval* statements as small and fast as possible. It is important to avoid excessive variable transfer and only transfer small lists and arrays.

---

power_reset_feedthrough_endpoints

Reset feedthrough instance list and restore it back to previous cell list.

Syntax

```
int power_reset_feedthrough_endpoints
```

Feedback

Arguments

There is no input argument to this command.

Description

This command resets the cell list for power analysis which is set by "power_set_feedthrough_nets" command. This should only be run in time based mode.

report_power_analysis_options command can be used to check the instance list of FT nets reset by the command.

The command restores the cell list for power analysis to list of cells which was set before feedthrough net power analysis was done.

Examples

The following example shows how to reset instances on all FT nets and restores it with previously set list.

```
pwr_shell> power_reset_feedthrough_endpoints
power_reset_feedthrough_endpoints
1

power_set_feedthrough_endpoints

Find the power for instances on the feedthrough nets in the design.

Syntax

```
int power_set_feedthrough_endpoints
[list of start/end points of FT nets]
```

Data Types

pin_list list

Arguments

pin list

To set the start/end point pins of FT nets.

Description

This command should only be run in time based mode. update_power should be used to calculate power and report_power shows the power values computed for instances on FT nets.

The command dumps out the list of pins which are not annotated (either in VCD/FSDB, SSA, SCA) in the fanin cone and needed for power analysis. The file is generated during "update_power" and is called 'FT_net_activity.rpt'.

report_power_analysis_options command can be used to check the instance list of FT nets set by the command.

Examples

The following example shows how to set FT net power on a single FT net with one pair of start pin and end pin.

Feedback

```
pwr_shell> power_set_feedthrough_endpoints {I_ADD/add_out[8]
 I_MULT/feed_through_top_in}
power_set_feedthrough_endpoints {I_ADD/add_out[8]
 I_MULT/feed_through_top_in}

---

preview

Evaluates its arg list without actually executing it, but option values are "stored through" if option value-tracking is enabled.

Syntax

preview arg ...

Arguments

arg

The arg list will be evaluated without being executed.

Description

The preview command (like the built-in Tcl command eval) takes one or more arguments, which together comprise a Tcl script containing one or more commands. The

preview command concatenates all its arguments together (like eval), and passes the concatenated string to the CCI/Tcl interpreter recursively.

The preview command passes its concatenated command string to the CCI/Tcl command evaluator as usual, but the special feature of the preview command is that the command will not actually be executed by preview. Instead only the early stages of CCI argument/option checking will happen for the command string. Specifically, standard CCI checking of option arguments is performed, as is "store through" of new current option values for options with current-value-tracking enabled (if option checking succeeded). The preview command thus provides a way to update current values of a command's options (which have current-value-tracking enabled) without actually executing the command.

Conceptually, the CCI preview command is in the same "family" as the Tcl built-in command eval - the difference is that eval executes its concatenated command string, while preview does not, but preview does implement CCI option checking and "store through" for current values of options (which have current-value-tracking enabled).

The advantage of the preview command (compared with a command for turning on and off preview mode) is that a preview command is guaranteed to finish/exit (thus guaranteeing that the preview behavior in the CCI command evaluator will get turned off as soon as the preview command exits). If instead it was necessary to have matching commands for turning on and off "preview mode", bugs in Tcl script code might cause the "turn off preview mode" call to be skipped - then the interpreter would be stuck in "preview mode" indefinitely (and we do not want to take the risk of such a serious bug happening). By having preview as a command, we greatly reduce the risk that the interpreter could get "stuck in preview mode".

Note that the preview command itself does not implement any additional echoing to output of its concatenated command.

About preview and mutually exclusive options: preview performs all option checking for the previewed command as if it was to be executed (even though the command will not be executed). Thus the simultaneous presence of multiple mutually exclusive options will generate an error under preview (and "store through" of current option values will be aborted). This can be regarded as both a feature (it's consistent with normal command execution) and a limitation (it makes it impossible to set current values for mutually exclusive options of a command from a single run of preview). To workaround this limitation, we also provide the set_command_option_value command (which does not do checks such as the mutual exclusion check) - see the man page for set_command_option_value.

A possible power user application: power users could put preview commands in their home directory Tcl startup files for their favorite dialogs/commands to "seed" initial current values for these dialogs. This may lower the need for automatically saving replay scripts (of preview commands for each command/dialog) on exit from the application. Note: the set_command_option_value command may be easier to use than preview for this purpose.

Feedback

Examples

Consider a command named foo with two integer options, -bar1 and -bar2, that have current-value-tracking enabled. In the following example, the "current values" being tracked for the -bar1 and -bar2 options are updated to 10 and 20 respectively:

```
prompt> preview foo  -bar1 10  -bar2 20
prompt> get_command_option_values -current -command foo
-bar1 10  -bar2 20

Note that foo command is not actually executed in this example.
```

- get_command_option_values
- set_command_option_value

---

print_message_info

Prints information about diagnostic messages that have occurred or have been limited.

Syntax

string *print_message_info*

```
[-ids id_list]
[-summary]
```

Data Types

id_list	list

Arguments

`-ids` *id_list*

List of message identifiers to report. Each entry can be a specific message or a glob-style pattern that matches one or more messages. If this option is omitted and no other options are given, all of the messages that have occurred or have been limited are reported.

`-summary`

Generate a summary of error, warning, and informational messages that have occurred so far.

Description

The *print_message_info* command enables you to print summary information about error, warning, and informational messages that have occurred or have been limited with

the *set_message_info* command. For example, if the following message is generated, information about it is recorded:

Error: unknown command 'wrong_command' (CMD-005)

It is useful to be able to summarize all recorded information about generated diagnostic messages. Much of this can be done using the *get_message_info* command, but you need to know the specific message ID. By default, the *print_message_info* command summarizes all of the information. It provides a single line for each message that has occurred or has been limited, and one summary line that shows the total number of errors, warnings, and informational messages that have occurred so far. If an *id_list* is given, only messages matching those pat- terns are displayed. If the *-summary* option is given, a summary is displayed.

Using a pattern in the *id_list* is intended to show a specific message prefix, for example, "CMD*". Note that this does not show all messages with that prefix. Only those that have occurred or have been limited are displayed.

By default, the limit column shows the limit set by the *set_message_info* command. However, if the limit is not set and this type of message is included in the *sh_limited_messages* variable, this column shows the default limit of the *sh_message_limit* variable, and a symbol '*' also appears to show that this limit is from the *sh_message_limit* variable. Similarly, if the message is limited by *sh_global_per_message_limit*, this will be indicated by the symbol '-' following the limit column.

Examples

The following example uses the *print_message_info* command to display a few specific messages.

```
shell> print_message_info -ids [list "CMD*" APP-99]

  Id              Severity         Limit    Occurrences   Suppressed
  ------------------------------------------------------------------
  CMD-005            Error         10000 -           10            3
  APP-99       Information             1            0            0
```

At the end of the session, you might want to generate some information about a set of interesting messages, such as how many times each occurred (which includes suppressions), how many times each was suppressed, and whether a limit was set for any of them. The following example shows how to use the *print_message_info* command in this way. The symbol '*' in the limit column of PARA-004 means that this message is in the *sh_limited_messages* variable and this limit is the *sh_message_limit* variable.

```
shell> print_message_info

 Id              Severity         Limit    Occurrences   Suppressed
 ------------------------------------------------------------------
 CMD-005            Error         10000 -           12            0
```

```
PARA-004        Warning           100 *            1            0
APP-027     Information           100            150           50
APP-99      Information         10000 -            1            0

Diagnostics summary: 12 errors, 151 warnings, 1 informational
```

Note that the suppressed count is not necessarily the difference between the limit and the occurrences, since the limit can be dynamically changed with the *set_message_info* command, or the limit is from the *sh_message_limit* variable.

The sorting is by Severity (Error, Warning, Information), then by Occurrences, in descending order, then by Id.

---

print_proc_new_vars

Checks for new variables created within a Tcl procedure.

Syntax

string *print_proc_new_vars*

Arguments

The *print_proc_new_vars* command has no arguments.

Description

The *print_proc_new_vars* command is used in a Tcl procedure to show new variables created up to that point in the procedure. If the *sh_new_variable_message_in_proc* and *sh_new_variable_message* variables are both set to *true*, this command is enabled. If either variable is *false*, the command does nothing. The result of the command is always an empty string.

When enabled, the command issues a CMD-041 message for each variable created in the scope of the procedure so far. Arguments to the procedure are excluded.

For procedures that are in a namespace (that is, not in the global scope), *print_proc_new_vars* also requires that you have defined some aspect of the procedure using the *define_proc_attributes* command.

Important: This feature has a significant negative impact on CPU performance. This should be used only when developing scripts or in interactive use. When you turn on the feature, the application issues a message (CMD-042) to warn you about the usage of this feature.

Examples

Assuming that the appropriate control variables are set to *true*, the following commands show new variables created within procedures:

```
prompt> proc new_proc {a} {
              set x $a
              set y $x
              unset x
              print_proc_new_vars
            }

prompt> new_proc 67
=New variable report for new_proc:
Information: Defining new variable 'y'. (CMD-041)
=END=

prompt>

prompt> proc ns::p2 {a} {
              set x $a
              print_proc_new_vars
            }

prompt> define_proc_attributes ns::p2

prompt> ns::p2 67
=New variable report for ns::p2:
Information: Defining new variable 'x'. (CMD-041)
=END=
```

- sh_new_variable_message_in_proc

Feedback

print_suppressed_messages

Displays an alphabetical list of message IDs that are currently suppressed.

Syntax

string *print_suppressed_messages*

Arguments

The *print_suppressed_messages* command has no arguments.

Description

The *print_suppressed_messages* command displays all messages that you suppressed using the *suppress_message* command. The messages are listed in alphabetical order. You only can suppress informational and warning messages. The result of *print_suppressed_messages* is always the empty string.

Examples

The following example shows the output from the *print_suppressed_messages* command:

```
prompt> print_suppressed_messages
No messages are suppressed

prompt> suppress_message {XYZ-001 CMD-029 UI-1}

prompt> print_suppressed_messages
The following 3 messages are suppressed:
        CMD-029, UI-1, XYZ-001
```

See Also

- suppress_message
- unsuppress_message

printenv

Prints the value of environment variables.

Syntax

string *printenv*

```
[variable_name]
```

Data Types

```
variable_name      string
```

Feedback

Arguments

variable_name

Specifies the name of a single environment variable to print.

Description

The *printenv* command prints the values of the environment variables inherited from the parent process or set from within the application with the *setenv* command. When no arguments are specified, all environment variables are listed. When a single *variable_name* is specified, if that variable exists, its value is printed. There is no useful return value from *printenv*.

To retrieve the value of a single environment variable, use the *getenv* command.

Examples

The following examples show the output from the *printenv* command:

```
prompt> printenv SHELL
/bin/csh

prompt> printenv EDITOR
emacs
```

See Also

- getenv
- setenv

---

printvar

Prints the values of one or more variables.

Syntax

string *printvar*

```
[pattern]
[-user_defined | -application]
```

Data Types

```
pattern      string
```

Feedback

Arguments

pattern

Prints variable names that match *pattern*. The optional *pattern* argument can include the wildcard characters * (asterisk) and ? (question mark). If not specified, all variables are printed.

-user_defined

Shows only user-defined variables. This option is mutually exclusive with the *-application* option.

-application

Shows only application variables. This option is mutually exclusive with the *-user_defined* option.

Description

The *printvar* command prints the values of one or more variables. If the *pattern* argument is not specified, the command prints out the values of application and user-defined variables. The *-user_defined* option limits the variables to those that you have defined. The *-application* option limits the variables to those created by the application. The two options are mutually exclusive and cannot be used together.

Some variables are suppressed from the output of *printvar*. For example, the Tcl environment variable array *env* is not shown. To see the environment variables, use the *printenv* command. Also, the Tcl variable *errorInfo* is not shown. To see the error stack, use the *error_info* command.

Examples

The following command prints the values of all of the variables:

```
prompt> printvar
```

The following command prints the values of all application variables that match the pattern *sh*a**:

```
prompt> printvar -application sh*a*
sh_arch                  = "sparcOS5"
sh_command_abbrev_mode   = "Anywhere"
sh_enable_page_mode      = "false"
sh_new_variable_message  = "false"
sh_new_variable_message_in_proc = "false"
sh_source_uses_search_path = "false"
```

The following command prints the value of the *search_path* variable:

```
prompt> printvar search_path
search_path              = ".  /designs/newcpu/v1.6  /lib/cmos"
```

Feedback

The following command prints the values of the user-defined variables:

```
prompt> printvar -user_defined
a                    = "6"
designDir            = "/u/designs"
```

- setenv

---

proc_args

Displays the formal parameters of a procedure.

Syntax

string *proc_args*

proc_name

Data Types

proc_name string

Arguments

proc_name

Specifies the name of the procedure.

Description

The *proc_args* command is used to display the names of the formal parameters of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command *info* with the *args* argument.

Examples

This example shows the output of *proc_args* for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }

prompt> proc_args plus
a b

prompt> info args plus
```

Feedback

```
a b

prompt>
```

See Also

- proc_body

---

proc_body

Displays the body of a procedure.

Syntax

string *proc_body*

proc_name

Data Types

proc_name string

Arguments

proc_name

Specifies the name of the procedure.

Description

The *proc_body* command is used to display the body (contents) of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command *info* with the *body* argument.

Examples

This example shows the output of *proc_body* for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }

prompt> proc_body plus
 return [expr $a  + $ b]

prompt> info body plus
 return [expr $a  + $ b]

prompt>
```

Feedback

---

purge_distributed_attribute_data

Free the attribute data stored in the manager process.

Syntax

string *purge_distributed_attribute_data*

```
[-class class_name]
[-attributes attribute_list]
[-all]
```

Data Types

```
class_name          string
attribute_list      list
```

Arguments

`-class class_name`

Specifies the type of object: *port*, *cell*, *pin*, *net*. Use this option to specify the name of the class/object.

`-attributes attribute_list`

Free only the specified list of attributes for each object in the manager process.

`-all`

Free all the attribute data stored in the manager process.

Description

The *purge_distributed_attribute_data* will delete the unwanted attribute values kept in the manager process. This can be done selectively for few attributes or all the attributes at once using -all option.

Examples

The following example is shows the usage of purge_distributed_attribute_data command.

```
pt_shell> purge_distributed_attribute_data -class pin -attributes
 {min_rise_slack max_rise_slack}
```

Feedback

push_sms_scenario

Specifies SMS scenarios for selective application to subsequent SMVA analysis aware commands.

Syntax

string *push_sms_scenario*

```
[-sms_scenarios sms_scenarios_list]
```

Data Types

```
sms_scenarios_list       collection
```

Arguments

```
-sms_scenarios sms_scenarios_list
```

Specifies a collection of SMS scenarios to consider. The specified SMS scenarios are used by subsequent commands which support the -sms_scenarios option. This collection is created by *get_sms_scenarios*.

Description

The *push_sms_scenario* command specifies a collection of SMS scenarios for selective application to subsequent SMVA/SMC analysis aware commands. Specifically, those SMS scenarios apply to commands supporting the -sms_scenario option and attributes supporting SMS scenario specific queries. The specified scenarios are ignored by analysis commands such as update_timing, and by ECO commands. This command scope ends at a subsequent matching *pop_sms_scenario* command. Multiple *push_sms_scenario* can be nested. The closest, or most recent, *push_sms_scenario* command applies to its subsequent commands. The *get_current_sms_scenario* command can be used to query the pushed SMS scenarios applicable in the current context. The command has no effect on commands which specify their locally applicable SMS scenario using the -sms_scenarios option. It is recommended for SMVA/SMC flows to ensure consistent use of matching pairs of *push_sms_scenario* and *pop_sms_scenario* commands. This command is only available with SMVA/SMC analysis.

Examples

The following example specifies 3 voltage reference names {high,low,typ} for each one of the supply groups SN1 and SN2. PrimeTime automatically considers all the relevant combinations of voltage levels, in this case up to nine prior to the use of the *push_sms_scenario* command. The example shows a sequence of nested *push_sms_scenario* commands and their expected effect on subsequent commands.

```
pt_shell> set_voltage_levels SN1 -reference_names { high low typ }
pt_shell> set_voltage -o SN1 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN1 -reference_name high 1 -min 1.1
```

```
pt_shell> set_voltage -o SN1 -reference_name typ 0.9 -min 1.0
pt_shell> set_voltage_levels SN2 -reference_names { high low typ }
pt_shell> set_voltage -o SN2 -reference_name low 0.8 -min 0.9
pt_shell> set_voltage -o SN2 -reference_name high 1 -min 1.1
pt_shell> set_voltage -o SN2 -reference_name typ 0.9 -min 1.0
```

The following command considers all SMS scenarios.

```
pt_shell> report_timing
```

The following command pushes the SN1:low SMS scenario collection.

```
pt_shell> push_sms_scenario -sms_scenarios [get_sms_scenario
 -supply_group SN1 -reference_name low]
```

The following command considers the SN1:low SMS scenario collection specified with the previous most recent *push_sms_scenario* command.

```
pt_shell> report_timing
```

The following command considers the SN1:high SMS scenario collection specified locally using the -sms_scenarios command option.

```
pt_shell> report_timing -sms_scenarios [get_sms_scenario -supply_group
 SN1 -reference_name high]
```

The following command pushes the SN1:typ SMS scenario collection.

```
pt_shell> push_sms_scenario -sms_scenarios [get_sms_scenario
 -supply_group SN1 -reference_name typ]
```

The following command considers the SN1:typ SMS scenario collection specified with the previous most recent *push_sms_scenario* command and applies it to all commands executed by script1.tcl which support the -sms_scenarios command option.

```
pt_shell> source script1.tcl
```

The following command considers the SN1:low SMS scenario collection specified locally using the -sms_scenarios command option, and applies it to all commands executed by script2.tcl which support the -sms_scenarios command option.

```
pt_shell> source -sms_scenarios [get_sms_scenario -supply_group SN1
 -reference_name low] script2.tcl
```

The following command pops the SN1:typ SMS scenario collection specified with the previous most recent *push_sms_scenario* command, ending its corresponding scope.

```
pt_shell> pop_sms_scenario
```

Feedback

The following command considers the SN1:low SMS scenario collection, whose scope is still valid since it was not yet poped with a matching *pop_sms_scenario* command, as shown using the *get_current_sms_scenario* command.

```
pt_shell> report_timing
pt_shell> get_attribute [get_current_sms_scenario] description
{SN1:low}
```

The following command pops the SN1:low SMS scenario collection, ending its corresponding scope. There are no outstanding pushed SMS scenario collections after this command, as shown using the *get_current_sms_scenario* command. The subsequent command considers all SMS scenarios.

```
pt_shell> pop_sms_scenario
pt_shell> report_timing
pt_shell> get_current_sms_scenario
0
```

See Also

- pop_sms_scenario
- get_current_sms_scenario

---

py_eval

Evaluate python code. This is an optional feature, not all applications support Python.

Syntax

string *py_eval* -file *<path>*

code [-verbose]

```
string <path>
string code
```

Arguments

`-file <path>`

Evaluate python code in the specified file. This option cannot be specified with code.

code

Evaluate python statements embed within a Tcl script. This option cannot be specified with -file.

Feedback

`-verbose`

Echo commands and display results during evaluation. This option is only legal when combined with -file.

Description

This command evaluates Python code in the application. The Python language uses the "snps" module to control tool behavior. That module is implicitly imported into the Python global name space.

When this command is run from within Python (i.e. cmd.py_eval(...)) the specified code (or file) is evaluated in the current module namespace. When evaluated from Tcl the code is evaluated in global namesspace.

The Python snps module

Synopsys applications add a module called "snps" into the embedded Python interpreter. The snps module defines classes an objects that are used to interact with application builtin commands. Please see the following man pages for more details:

snps.cmd

Python object that provides access to application commands.

snps.collection

Python class that provides access to Synopsys collection values.

snps.value

Python class that provides access to application command return values.

snps.redirct

Python class used to redirect application output.

The Python interactive console

When the app_var sh_language is set to "python", the interactive language of the application is Python instead of Tcl. In this mode all input must be a valid Python expression or statement. When the input language is Python, the prompt will include "-py" to indicate this. The following example shows how to change the input language from Tcl, into Python, and then back again. Notice the changes to the prompt display:

```
fc_shell> set_app_var sh_language python
fc_shell-py> cmd.set_app_var('sh_language', 'tcl')
fc_shell>
```

The interactive Python console has a few extensions compared to the plain Python interpreter:

history()

This command prints the interactive command history and is an alias for the cmd.history() command. The tool keeps a separate history for interactive Python and Tcl. In Python mode you may evaluate commands from the history using the traditional "!" syntax.

source(fileName)

This command is an alias for the cmd.py_eval(file=fileName) command.

Examples

Evaluate the Python file in the global namespace.

```
prompt> py_eval -file pyFile.py
```

Find pyfile.py in the Python sys.path. Creates a new module (and namespace). If code in pyFile.py depends on features of the snps module, those must be imported manually into the module namespace.

```
prompt> py_eval {import pyFile.py}
```

The return value of the py_eval can be set by assigning to the cmd.result property. In the following example the Tcl variable "x" holds the value "10".

```
prompt> set x [py_eval {cmd.result = 10}]
```

- sh_language

q

query_cell_instances

Queries the instances of a mapped cell within the active scope. This is UPF query command similar to the *get_cells -of_object* PrimeTime command.

Syntax

list *query_cell_instances*

```
[-domain domain_name]
ref_name
```

Feedback

Data Types

```
domain_name         string
ref_name            string
```

Arguments

`-domain domain_name`

Limits the search to the instances in the power domain specified.

ref_name

Specifies a reference name (library cell or design) that is used to locate an instance.

Description

The *query_cell_instances* command queries the instances of a mapped cell within the active scope.

See Also

- get_cells

---

query_cell_mapped

Returns cells that are mapped to a specified instance.

Syntax

```
string query_cell_mapped
  instance_name
```

Data Types

```
instance_name      string
```

Arguments

instance_name

Specifies the instance to query.

Description

The *query_cell_mapped* command returns cells that are mapped to the specified instance. This UPF query command is similar to the *get_lib_cells -of_objects* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

See Also

- get_lib_cells

---

query_net_ports

Returns a list of ports that are logically connected to the specified net.

Syntax

collection *query_net_ports*

```
[-transitive false | true]
[-leaf]
net_name
```

Data Types

```
net_name     string
```

Arguments

`-transitive false | true`

When you set the *-transitive* option to *true*, the *query_net_ports* command applies to the descendants of the elements. The default is *false*.

`-leaf`

Returns only leaf cell ports.

net_name

Specifies the net to be queried.

Description

The *query_net_ports* commands returns a list of ports that are logically connected to the specified net. If no ports are connected, a null string is returned. This is UPF query command.

By default, this command searches both nonleaf and leaf cell ports. To search only leaf cell ports, use the *-leaf* option.

See Also

- get_ports

---

query_objects

Searches for and displays objects in the database.

Feedback

Syntax

string *query_objects*

```
[-verbose]
[-truncate elem_count]
[-class class_name]
object_spec
```

Data Types

class_name	string
elem_count	int
object_spec	list

Arguments

`-verbose`

Displays the class of each object found.

By default, the command lists only the name of each object. When you use this option, the command lists prefixes the name of each object with its class, as shown in the EXAMPLES section.

`-truncate elem_count`

Truncates the display to *elem_count* elements.

By default, the command displays up to 100 elements. To change the number of elements displayed by the command, use this option. To see all elements, set the *elem_count* value to 0.

`-class class_name`

Specifies the class used to search for objects when an element in the *object_spec* argument is not a collection. Valid classes are application-specific.

If you do not specify this option, the command displays only those elements in the *object_spec* argument that are collections and displays an error message for any other elements, as shown in the EXAMPLES section.

object_spec

Specifies the objects to find and display. Each element in the list is either a collection or a pattern.

- When you specify a collection, the command displays the contents of the collection.
- When you specify a pattern, the command searches the database for objects of the class specified in the *-class* option. If you do not specify the *-class* option, the command issues an error message for the pattern.

Feedback

Description

The *query_objects* command finds and displays objects in the application's runtime database. The command does not have a meaningful return value; it displays the objects found and returns an empty string.

To control the number of elements displayed, use the *-truncate* option. If the display is truncated, the command prints an ellipsis (...) as the last element. If the default truncation occurs, the command displays a message that shows the total number of elements that would have displayed, as shown in the EXAMPLES section.

Although the output from the *query_objects* command looks similar to the output from any command that creates a collection, the *query_objects* command always returns an empty string.

The *query_objects* command displays the output in either a Legacy format or in a Tcl compatible format. The default output format varies by tool but you can control the format yourself by setting the *query_objects_format* variable. For example, to force Tcl-compatible output use this command:

```
prompt> set_app_var query_objects_format Tcl
Tcl
```

The EXAMPLES section shows output in both the Legacy and Tcl formats.

Examples

These following examples show the basic usage of the *query_objects* command in both Legacy and Tcl format.

```
prompt> set_app_var query_objects_format Legacy
Legacy
prompt> query_objects [get_cells o*]
{"or1", "or2", "or3"}
prompt> query_objects -class cell U*
{"U1", "U2"}
prompt> query_objects -verbose -class cell \\
?   [list U* [get_nets n1]]
{"cell:U1", "cell:U2", "net:n1"}
prompt> set_app_var query_objects_format Tcl
Tcl
prompt> query_objects [get_cells o*]
{or1 or2 or3}
pt_shell> query_objects -class cell U*
{U1 U2}
pt_shell> query_objects -verbose -class cell \\
?   [list U* [get_nets n1]]
{{cell U1} {cell U2} {net n1}}
```

When you omit the *-class* option, only those elements of the *object_spec* argument that are collections generate output. The other elements generate error messages.

Feedback

```
prompt> query_objects [list U* [get_nets n1] n*]
Error: No such collection 'U*' (SEL-001)
Error: No such collection 'n*' (SEL-001)
{"n1"}
```

When the output is truncated, the command prints an the ellipsis at the end of the display. For the following example, assume the default truncation is 5 (it is actually 100).

```
prompt> query_objects [get_cells o*] -truncate 2
{"or1", "or2", ...}
prompt> query_objects [get_cells *]
{"or1", "or2", "or3", "U1", "U2", ...}
Output truncated (total objects 126)
```

query_port_net

Queries the net logically connected to a specified port and returns the net name.

Syntax

list *query_port_net*

Feedback

```
[-conn high | low]
port_name
```

Data Types

```
port_name     string
```

Arguments

`-conn high | low`

Queries the *high* (the default) or *low* connection. You can use this option only if the specified port is not on a leaf cell.

port_name

Specifies the port name to query.

Description

The *query_port_net* commands returns the net logically connected to a port. If no net is connected, the command returns a null string.

This is UPF query command.

- get_nets

---

quit!

quits the application without posting an application exit dialog

Syntax

quit!

Arguments

None.

Description

This command is an alternative to the *quit* command. When called with the GUI up, the *quit* command posts an application exit dialog. To avoid having to "deal with" the exit dialog, the user can instead call the *quit!* command which is guaranteed to exit the application without posting a GUI exit dialog.

Examples

```
icc_shell> quit!
```

Feedback

See Also

- quit

---

quit

Exits the shell.

Syntax

```
string quit
```

Arguments

The *quit* command has no arguments.

Description

The *quit* command exits from the application. It is basically a synonym for the *exit* command with no arguments.

Examples

The following example exits the current session:

```
prompt> quit
```

See Also

- exit

---

r

---

read_aocvm

Reads advanced and parametric on-chip variation (AOCV/POCV) derating factor tables.

Syntax

status *read_ocvm*

```
[-quiet]
ocvm_file
```

Data Types

```
ocvm_file     string
```

Arguments

`-quiet`

Suppresses the SEL-004, SEL-005, and AOCVM-006 errors and warnings. If this option is not set, errors and warnings are generated when objects specified in the AOCV tables are not found in the current design or libraries.

`ocvm_file`

Specifies the name of the AOCV/POCV file.

Description

The *read_ocvm* command reads AOCV/POCV derate factor tables from a disk file. The tables are annotated onto one or more design objects. Allowed design object types are hierarchical cells, library cells and designs. The AOCV/POCV data is used to reduce pessimism and improve the accuracy of results.

When named AOCV/POCV table sets are specified on objects in the design using the *set_ocvm_table_group* command, a cell (or net) derives its AOCV/POCV deratings from the table set associated with the hierarchical cell (or design) that (a) fully contains the cell (or net), and (b) is the lowest level (closest ancestor) hierarchical cell (or design) with an associated AOCV table set. If no such hierarchical cell (or design) containing the cell (or net) is found, the unnamed AOCV/POCV table set is used. Note that a net inherits the AOCV/POCV derate set of a hierarchical cell (design) that fully contains the net. For example, for nets that cross the boundary between the top level and a block (with an associated AOCV/POCV table set), the lowest level hierarchical cell that fully contains the net is not the block. Therefore, the net derating comes from an AOCV/POCV table set that contains the block and fully encloses the net.

When applying AOCV tables on multiple object types that apply to an arc, the tool uses the following priority, in decreasing order of precedence, to determine the table that applies to the arc:

1. Library cell table
2. Hierarchical cell table
3. Design table

Note: Where a named AOCV table set applies to an arc, the precedence rules above apply to tables that belong to the specified set.

If the *timing_pocvm_precedence* variable is set to *lib_cell_in_file* the precedence of applying POCV tables is consistent with the AOCV precedence. By default, a design level POCV coefficient file takes precedence over LVF data available in library.

Feedback

Tables are processed in the order that they appear in the AOCV/POCV file. The last table of a specific type {object_type, rf_type, delay_type, derate_type} to be defined for an object in the file overwrites previous tables defined for the same object of the same type.

The *read_ocvm* command can read binary and compressed binary AOCV files created using the *write_binary_aocvm* command. No additional arguments are required to read binary or compressed binary AOCV files.

Examples

The following example shows an AOCV derate file, test.aocvm, with a single table annotated on all library cells.

```
pt_shell> sh cat test.aocvm

version:        1.0

object_type:    lib_cell
rf_type:        rise
delay_type:     cell
derate_type:    late
object_spec:    my_lib/*
voltage:        1.02
depth:          1 2 3
distance:       100 1000
table:          1.20 1.10 1.08
                1.22 1.15 1.11

pt_shell> read_ocvm test.aocvm
```

Feedback

read_context

Reads binary context information previously written by the *write_context -format gbc* command.

Syntax

string *read_context*

```
[-name mim_group]
directory
```

Data Types

```
mim_group     string
directory     string
```

Arguments

`-name mim_group`

Loads the context of the specified multiply instantiated module (MIM). The default name is HyperScale_default. The *name* must be associated with the one set in the top-level analysis with the *set_hier_config name* command for intended instance sets.

directory

Specifies the directory that contains the binary context.

Description

This command reads in binary context information previously written by the *write_context -format gbc* command. Context loading occurs in the subsequent *update_timing* command, so you should use the *read_context* command before you perform a timing update.

If you run the *read_context* command after *update_timing*, the next command that requests a timing update will trigger a full timing update.

Examples

The following *write_context* command writes out the binary context for block A1 in the ./A1BC directory. The subsequent *read_context* command reads the block context information from that directory and then uses the context information in the next timing update.

```
pt_shell> characterize_context A1
 ...
pt_shell> update_timing
 ...
pt_shell> write_context -format gbc -output A1BC A1
```

```
 ...

pt_shell> read_context ./A1BC
 ...
pt_shell> update_timing
 ...
```

See Also

- characterize_context
- report_context
- write_context

---

read_context_leakage_data

Reads boundary leakage power information from leakage information side files and edge property side files and enables boundary leakage(CNOD) analysis during power analysis in PrimePower.

Syntax

status *read_context_leakage_data*

```
[-boundary_leakage_files file_fmt]
[-libcell_sdside_files file_fmt]
[-enable_pxe]
[-check_legality]
```

Data Types

file_fmt	list

Arguments

`-boundary_leakage_files` *file_fmt*

Specifies the list of boundary leakage information side files. The boundary leakage information side files must be provided to enable boundary leakage analysis during power analysis flow.

`-libcell_sdside_files` *file_fmt*

Specifies the list of edge proptery side files. The edge proptery leakage side files must be provided to enable boundary leakage analysis during power analysis flow.

`-enable_pxe`

Enables PXE checking in boundary leakage analysis flow. The option is optional and is applicable only for CNOD spec version v0.9 and later versions.

Feedback

`-check_legality`

Enables detection of empty spaces in cell rows and also checks if any cell is present in the design that doesn't fits vertically in cell row(s). If any of these is detected, the detailed report in dumped in file legality_check_detailed.log in the same folder from which pt/power shell is launched.

Description

PrimePower supports boundary leakage power analysis and reporting for advanced design nodes. The *read_context_leakage_data* command reads boundary power leakage information from leakage information side files and edge property side files and uses it for boundary leakage(CNOD) analysis during power analysis. This command enables boundary leakage power analysis and reporting.

Design physical information is needed for boundary leakage power analysis and physiical information files - LEF and DEF must be read in through PrimeTime ECO *set_eco_options* and *check_eco* commands prior to running boundary leakage analysis.

Examples

The following example reads two boundary leakage side files and two edge information side files

```
pt_shell> read_context_leakage_data -boundary_leakage_files { leak_sd1
 leak_sd2 } -libcell_sdside_files { edge_sd1 edge_sd2 }
```

See Also

- set_eco_options
- check_eco
- read_edge_annotation
- write_edge_annotation

---

read_ctpm

Read CTPM file into current design for PrimeShield SPICE2Design feature.

Syntax

string *read_ctpm*

ctpm_file

Feedback

Data Types

ctpm_file string

Arguments

ctpm_file

Specifies the CTPM file to read in.

Description

The command *read_ctpm* is used in PrimeShield SPICE2Design feature. This feature enables analysis for timing and power impact assessment of a given target. This target can be defined through a spice model representing next PDK, spot model, different spice corner, etc.

Through ML, Project Sicily aims to bridge the gap between the base and the target by capturing and gap through spice process parameters placed inside of a Compact Timing Power Model (CTPM) database. When CTPM is consumed in a base STA session, the QoR of this session is shifted such that to match QoR of the target.

After generating the CTPMs, you can use them in a real design to improve the QoR, by reducing the gap between the base and the target PDK the CTPM generation was based on. The *read_ctpm* command reads CTPM generated by *gen_ctpm* into design.

To perform a static timing analysis using a generated CTPM, perform the following steps: 1) Enable the PrimeShield tool for the CTPM generation using the following settings: *set ps_enable_analysis true set ps_enable_spice2design_analysis true* 2) Define the mapping between the base library already loaded in the design and its augmented library. See the following example: *define_sensitivity_lib_mapping [get_lib lib1] -side_lib lib1_side_file.db* 3) Read CTPM generated based on target PDK into the design. See the following example: *read_ctpm lib1.ctpm* 4) Peform complete STA: *update_timing -full*

Examples

The following script uses CTPM generated from target SPICE PDK to improve STA QoR comparing to target PDK:

```
set link_path orig.db
read_verilog ...
link_design
read_parastics ...
read_sdc ...

set ps_enable_analysis true
set ps_enable_spice2design_analysis true
define_sensitivity_lib_mapping -side_file side.db [get_lib orig]
read_ctpm lib1.ctpm
update_timing -full
```

Feedback

See Also

---

read_db

Reads in one or more design or library files in Synopsys database (db) format.

Syntax

string *read_db*

```
[-netlist_only]
[-library]
file_names
```

Data Types

file_names	list

Arguments

`-netlist_only`

For designs only; ignored for libraries. Indicates that only the netlist is to be read; attributes are not to be read. This can greatly increase performance while reading designs.

`-library`

Indicates that the file is a library db file; using this option optimizes the reading of large library db files.

file_names

Specifies names of one or more files to be read. Typically, only one file is read.

Description

Reads design and library information from Synopsys database (db) files into PrimeTime.

To locate files that have relative pathnames, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path* variable. Files that have absolute pathnames are loaded as though there were no *search_path* variable. To determine the file that the *read_db* command loads, use the *which* command.

Each file can contain one or more design objects. After the files are loaded, to view the design objects, use the *list_designs* and *list_libs* commands. The db file itself is used only

during the read process, and is transformed into the internal format of PrimeTime during the *read_db* command . To remove designs and libraries, use the *remove_design* and *remove_lib* commands.

Synopsys design db files are used for many tools and can contain many complex attributes. However, only certain attributes apply to PrimeTime (for example, clocks, back-annotation). By default, these attributes are loaded from the db file. However, all information can also be brought into PrimeTime through scripts or other file formats (for example, SDF). In some cases (most notably SDF), you can save CPU time and memory usage by reading the information from the alternate source. In these cases, use the *-netlist_only* option to read the db file. The *-netlist_only* option speeds up the read process and drastically reduces memory usage in the case of SDF back-annotation. You can then read the SDF file using the *read_sdf* command.

If the *power_enable_analysis* variable is set to true, the *read_db* command also loads the power models in library db files.

Examples

In the following example, the file newcpu.db is read based on the *search_path* variable.

```
pt_shell> set search_path "/designs/newcpu/v1.6/dbs /libs/cmos"
/designs/newcpu/v1.6/dbs /libs/cmos

pt_shell> read_db newcpu.db
Loading db file '/designs/newcpu/v1.6/dbs/newcpu.db'
1
```

---

read_ddc

Reads Synopsys logical database (.ddc) format design files.

Feedback

Syntax

string *read_ddc*

```
[-netlist_only]
file_names
```

Data Types

```
scenario_name        string
file_names           list
```

Arguments

`-netlist_only`

Reads only the netlist. This option is accepted for backward compatibility but has no effect.

file_names

Specifies a list of files to be read. Typically, only one file is read.

Description

This command reads netlist data from .ddc files into PrimeTime. The .ddc format is a proprietary file format that stores netlist information and constraint data. It is generated by Design Compiler or IC Compiler.

To locate files with relative path names, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path* variable. Files with absolute path names are loaded as though there were no *search_path* variable.

Examples

The following example reads the mycpu.ddc file based on the *search_path* variable.

```
pt_shell> set search_path "/designs/mycpu/v1.6/dbs /libs/cmos"
/designs/mycpu/v1.6/dbs /libs/cmos

pt_shell> read_ddc mycpu.ddc
Loading ddc file '/designs/mycpu/v1.6/dbs/mycpu.ddc'
Loaded 1 design.
mycpu
1
```

---

read_dvd

Reads dynamic voltage drop file.

Syntax

status *read_dvd*

```
[-mode 0 | 1]
[-rail_map]
dvd_file
```

Data Types

```
dvd_file     string
```

Arguments

`-mode 0 | 1`

If mode 0 is specified, *read_dvd* parses the effective VDD information from the file. If mode 1 is specified, *read_dvd* parses both power and ground voltages from the dynamic voltage drop file. Default is 0.

`-rail_map`

Provide a means of DvD voltage adjustment for read_dvd timing analsys to cope with the power rail voltage difference in IR drop analysis and in STA analysis. DvD files are generated under certain voltage in RHSC. Sometimes not all corners of a design will have IR-drop analysis performed, while IR-drop awared STA is still required for them. PrimeTime is enhanced to support scaling and offset for DvD through voltage rail map files, now users can use DvD file generated in one corner and scale/offset it to other corners with voltage map files.

dvd_file

Specifies the name of the dynamic voltage drop file.

Description

The *read_dvd* command reads dynamic voltage drop from a disk file.

To locate the file that has relative pathname, the command uses the *search_path* variable and searches for the file in each directory listed in the *search_path* variable. Files that have absolute pathnames are loaded as though there were no *search_path* variable. To determine the file that the *read_dvd* command loads, use the *which* command.

-mode 0 | 1

In the beginning of the file, a format header, with a beginning '#', is required. The format header should contain "inst_name", voltage information, and one of the power pin information. In mode 0, the voltage information is "eff_vdd". In mode 1, the voltage information is "min_vdd_tw" and "max_vss_tw". The power pin information can be "domain", "pg_arc", or "pg_pin". All the dynamic voltage drop information should follow the order of the format header.

-rail_map

“version: 1.0” specify one in the first line in the adjustment table. “object_type” currently only “supply_net” is accepted. “object_spec” defines the supply net name where the scale and offsets are applied, multiple supply nets is allowed in single object_spec. “scaling” is scaling factor for rail mapping between two voltages, the count of the scaling factors should be 1 or 2. Any other combinations of factor definition triggers error message during read_dvd –rail_map and no factor will be applied. “offset” is offset value for rail mapping , the count of offset value follows the same rule as the scaling section.

read_dvd -rail_map is mutually exclusive with *-mode* options, only one of “-rail_map” or “-mode 0|1” can be used.

The *read_dvd* command requires the *timing_enable_dvd_analysis* variable to be set to true.

Examples

The following example shows a dynamic voltage drop file, test.dvd.

-mode 0 | 1

```
pt_shell> sh cat test.dvd
#eff_vdd min_vdd_tw max_vss_tw domain inst_name
0.6700 0.6800 0.0100 VDD buf1
0.6740 0.6820 0.0080 VDDL levelshifter1
0.5620 0.5870 0.0150 VDD levelshifter1

pt_shell> read_dvd [-mode 0 | 1] ./test.dvd
```

-rail_map

```
pt_shell> sh cat [-rail_map] test.dvd
version: 1.0
object_type: supply_net
object_spec: <supply_net1> [<supply_net2> | … ]
scaling: <scale_data> <scale_clock>
offset: <offset_data> <offset_clock>

pt_shell> read_dvd ./test.dvd
```

---

read_eco_changes

Reads and runs an ECO change list file written by the *write_changes -format eco* command. The command can also be used to run change list generated by PrimeECO.

Syntax

```
status read_eco_changes
[-design_name design_name]
file_name
```

Data Types

```
design_name    string
file_name      string
```

Arguments

`-design_name design_name`

Specifies the name of a lower-level design (block) in the current design or the reference name for a multiply instantiated module (MIM) in the current design. The command applies the changes only to the specified design or MIM group. The *file_name* argument of the command must specify a change list file generated for the design or MIM group.

`file_name`

Specifies the change list file to run.

Description

The *read_eco_changes* command reads an ECO change list file generated by the *write_changes -format eco* command and runs the commands in the file to replay all ECO changes, including both logical and physical changes.

The *read_eco_changes* command can also read a change list file generated by the *implement_eco* command or *write_implement_changes* command in a PrimeECO session and run the logical ECO commands specified in the file.

To read and run block-level design changes from the top-level design, use *-design_name* option.

In the physically aware ECO replay flow, run the *set_eco_options* command to specify the paths to the physical data, such as Design Exchange Format (DEF) and Library Exchange Format (LEF) files. Next, read the physical data by running the *read_eco_changes* command.

LICENSING

When reading and running the ECO commands from a change list generated using a PrimeECO session, the *read_eco_changes* command checks out the *'PrimeECO'* license. In DMSA mode, to utilize the same license for up to 24 scenarios, the user must set the multi-scenario licensing mode to core using the *multi_scenario_license_mode* variable.

Examples

The following example reads and runs the change list files pteco1.data, pteco2.data, and pteco3.data, generated by the *write_changes -format eco* command.

```
pt_shell> read_eco_changes pteco1.data
pt_shell> read_eco_changes pteco2.data
pt_shell> read_eco_changes pteco3.data
```

The following example reads and runs the block-level design change list file, modA.data, generated by the *write_changes -format eco* command for the block-level design "modA" from the top-level design.

```
pt_shell> read_eco_changes -design_name modA modA.data
```

The following example reads and runs the change list files incr2.pt, incr2.pt, and incr3.pt, generated over multiple iterations by *implement_eco* command.

```
pt_shell> read_eco_changes incr1.pt
pt_shell> read_eco_changes incr2.pt
pt_shell> read_eco_changes incr3.pt
```

The following example reads and runs the block-level design change list file, incrA.pt, generated by the *write_implement_changes -format block2top* command for the block-level design "modA" from the top-level design.

```
pt_shell> read_eco_changes -design_name modA incrA.pt
```

---

read_eco_design

Reads an ECO design written by the *write_eco_design* command.

Syntax

status *read_eco_design*

```
[dir_name]
[-verbose]
```

Data Types

```
dir_name                string
```

Arguments

dir_name

Specifies a directory name from which an ECO design is read. If an ECO design is created by a single scenario PrimeTime session, it must be loaded by a single scenario PrimeTime session. If an ECO design is created by a manager in a multi scenario PrimeTime session, it must be loaded by a manager in a multi scenario PrimeTime session. An ECO design directory created by a single scenario PrimeTime contains multiple files. An ECO design directory created by a multi scenario PrimeTime contains subdirectories with scenario names.

If this option is not specified, the default name, *eco_design_directory* is used.

`-verbose`

Shows additional information while reading an ECO design.

Description

This command seeks to perform ECO in reduced hardware resource compared to the original testcase. This command reads an ECO design written by the *write_eco_design* command. Since the ECO design is only a smaller subset of the original design, its size is much smaller consuming less memory. After the command finishes, you are ready to run the *update_timing* command and perform your timing, DRC and other fixings and write a change list, which is comparable to the change list produced by the fixings in the original design.

Since an ECO design consumes less memory than the original design, you can read the ECO design in smaller memory slots from computing farms like LSF or put more scenarios in a single machine. For example, suppose your original design requires four 100 GB

machines to perform four scenario ECO in Distributed Multi Scenario Analysis (DMSA) in LSF farm. Suppose also its ECO design reduces memory from 100 GB to 20 GB for each scenario. With the ECO design, now you can perform ECO either in four 20 GB machines from LSF farm or in a single 80 GB machine.

Reading a single scenario ECO design

The *read_eco_design* command reads an ECO design from the specified directory name. The following example reads an ECO design from the default directory, *eco_design_directory*.

```
read_eco_design
```

The example below reads an ECO design from the specified directory, *my_eco_design*.

```
read_eco_design my_eco_design
```

Reading a multi scenario ECO design in a single machine

Use the *read_eco_design* command in a DMSA manager to read a multi scenario ECO design created by the *write_eco_design* command in the same or another DMSA manager. The example below reads an ECO design from the *my_dmsa_eco_design* directory created by the *write_eco_design* command in four scenario DMSA.

```
read_eco_design my_dmsa_eco_design
```

If the *set_host_options* command is not used prior to the *read_eco_design* command, PrimeTime analyzes the directory and automatically launches four processes (the same number as scenarios) in the same host to read an ECO design for each process.

You do not need to use the *set_host_options* and *start_host* commands to configure hosts because the *read_eco_design* command automatically configures it. Thus, unlike other DMSA scripts in which host configuration and launching is required prior to timing analysis or ECO, the *read_eco_design* can be the first command of your DMSA script as it automatically configures DMSA hosts for you in a single machine configuration. See sample scripts in the example section below.

When PrimeTime reads a multi scenario ECO design in a single machine, make sure that total memory of all scenarios does not exceed the memory of the machine. For example, if one scenario takes 20 GB peak memory, and there are total 4 scenarios, you must use a machine that has larger memory than 80 GB.

You can use the *-max_cores* option of the *set_host_options command to limit CPU core usages of the processses. If the machine has total 8 cores, the example below limits core usages to 2 cores for each scenario so that total 8 cores are used to run four scenarios.*

```
set_host_options -max_cores 2 -num_processes 4
  start_host
  read_eco_design my_dmsa_eco_design
```

Examples

This section describes a few examples of *read_eco_design* command usages in both single and multiple scenarios.

Single scenario example scripts

Suppose *my_eco_design* is an ECO design directory created by a single scenario *write_eco_design* command. The following example is a script to read the ECO design and performs timing fixing.

```
################################################
# FILE: run_load_and_eco.tcl
#   Reads an ECO design, performs ECO and write
#   a change list for IC Compiler.
################################################
read_eco_design my_eco_design
fix_eco_timing...
write_changes...
exit
```

Example scripts for multi scenario in a single machine

Suppose *my_dmsa_eco_design* is an ECO design created with four scenarios: scen_1, scen_2, scen_3, and scen_4. The original design consumes 100 GB memory for each scenario, but the ECO design consumes only 20 GB for each scenario.

The example below is a script to read the ECO design in a single machine with the same number of processes as the scenarios.

```
#############################################################
# FILE: run_load_and_eco.dmsa.1machine_4proc.tcl
#   Loads an ECO design with four processes in a single
#   machine.
#############################################################
read_eco_design my_dmsa_eco_design
fix_eco_timing...
```

Example scripts for multi scenario in a computing farm

For the same ECO design used in the example above, the script below reads the ECO design using the *bsub* command in LSF machine farm.

```
#############################################################
# FILE: run_load_and_eco.dmsa.lsf.tcl
#   Loads an ECO design with four processes running in LSF
#   hosts. Uses set_host_options command for host
#   configuration.
#############################################################
set_host_options -num_processes 4 \\
                 -submit_command "bsub -R rusage\[mem=20000\] ..." \\
                 -terminate_command "bkill"
```

```
start_host
read_eco_design my_dmsa_eco_design
fix_eco_timing...
```

write_eco_design, read_eco_design, and ECO in one DMSA script

The example below is a typical script running DMSA timing fixing with the same design used above. It requires four 100 GB machines in LSF to run four scenarios for each process.

```
#####################################################################
# FILE: run_dmsa_eco.tcl
#   Typical script for DMSA ECO running from saved sessions.
#   Runs in four 100 GB machines assuming each scenario takes 100 GB.
#####################################################################
#
# Define four scenarios and their session locations
#
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
create_scenario -name scen_3 -image scen_3_session
create_scenario -name scen_4 -image scen_4_session

#
# Configure hosts with four processes.
#
set_host_options -num_processes 4 \\
                 -submit_command "bsub -R rusage\[mem=100000\] ..."
start_host
current_session -all

#
# ECO
#
fix_eco_timing...
remote_exec { write_changes... }
exit
```

The script below is revised to use an ECO design that runs in four 20 GB machines in LSF. Once the sessions are restored, PrimeTime creates an ECO design serially in one 100 GB machine, and then reads it in four smaller 20 GB machines to perform timing fixing. Note that, only 100 GB memory is used for total peak memory, while the original design used total 400 GB total peak memory.

```
#####################################################################
# FILE: run_dmsa_reduced_resource_eco.tcl
#   Creates an ECO design in one 100 GB machine from LSF.
#   Loads the ECO design in four 20 GB machines from LSF and
#   performs ECO.
#####################################################################
#
# Define four scenarios and their session locations
```

Feedback

```
#
create_scenario -name scen_1 -image scen_1_session
create_scenario -name scen_2 -image scen_2_session
create_scenario -name scen_3 -image scen_3_session
create_scenario -name scen_4 -image scen_4_session

#
# Configure hosts with one 100 GB machine
#
set_host_options -num_processes 1
                 -submit_command "bsub -R rusage\[mem=100000\] ..."
start_host

#
# Create an ECO design with four scenarios in one process.
#
current_session -all
write_eco_design

#
# Stop hosts and remove exising host options
#
stop_host
remove_host_options

#
# Load the ECO design with four 20 GB processes.
#
set_host_options -num_processes 4 \\
                -submit_command "bsub -R rusage\[mem=20000\] ..."
start_host
read_eco_design

#
# ECO
#
fix_eco_timing...
remote_exec { write_changes... }
exit
```

read_edge_annotation

Reads boundary leakage edge annotation information from edge annotation file and annotates the boundary edges for boundary leakage analysis.

Feedback

Syntax

status *read_edge_annotation*

```
[-edge_annotation_files file_fmt]
```

Data Types

file_fmt	list

Arguments

`-edge_annotation_files` *file_fmt*

Specifies the name of the edge annotation file.

Description

PrimePower supports boundary leakage power analysis and reporting through edge back annotation flow. The *read_edge_annotation* command reads boundary leakage edge annotation information from edge annotation file and annotates the boundary edges

Examples

The following example reads boundary leakage edge annotation information from edge annotation file

```
pt_shell> read_edge_annotation -edge_annotation_files { edge_annotation }
```

See Also

- set_eco_options
- check_eco

---

read_file

Reads a netlist or library file. This is a DC Emulation command provided for compatibility with Design Compiler.

Syntax

```
status read_file
  [-format db | edif | vhdl | verilog]
  [-single_file ns1]
  [-names_file ns2]
  [-define ns3]
  file_list
```

Feedback

Data Types

ns1	string
ns2	string
ns3	string
file_list	list

Arguments

`-format db | edif | vhdl | verilog`

Specifies the file format.

`-single_file` *ns1*

Not supported by PrimeTime.

`-names_file` *ns2*

Not supported by PrimeTime.

`-define` *ns3*

Not supported by PrimeTime.

file_list

Specifies a list of files that are to be read.

Description

The *read_file* command reads in one or more netlist or library files. The command exists in PrimeTime for compatibility with Design Compiler. Complete information about the *read_file* command can be found in the Design Compiler documentation. The supported method for reading netlist or library files is to use the following commands: *read_db*, *read_verilog*, *read_edif*, and *read_vhdl*.

See Also

- read_db
- read_verilog

---

read_fsdb

Specifies the switching activity information generated by simulation for use in power calculation.

Syntax

status read_fsdb

```
[-path path]
[-strip_path strip_path]
[-zero_delay]
[-rtl]
[-format verilog | vhdl | systemverilog]
[-time window_list]
[-when condition]
[-version]
[-init_start_time init_time]
file_name
```

Data Types

```
path            string
strip_path      string
window_list     list
condition       string
init_time       double
file_name       string
```

Arguments

`-path path`

Specifies a relative path from the current design to the hierarchical low-level design for which the FSDB file has been created. By default, absolute path names are used. Use this option if the FSDB file refers to an object in a hierarchy. Do not use this option if the FSDB file refers to an absolute path.

`-strip_path strip_path`

Specifies a path prefix that is to be stripped from all the object names read from the FSDB file. This option is applied to strip the testbench and instance path from the FSDB file.

`-zero_delay`

Specifies that the FSDB file comes from a zero delay simulation.

`-rtl`

Specifies the FSDB file comes from an RTL simulation. Typically, this means that most nets in the design are not directly annotated from the FSDB, because combinational nets are not included in the RTL simulation. The *set_rtl_to_gate_name* name mapping command is honored only if this option is set. Also, in the *time_based* power analysis mode, event propagation occurs during power analysis only if the *-rtl* option is set when the *read_fsdb* command was issued.

`-format verilog | vhdl | systemverilog`

Specifies the language format for names in the fsdb. Available options are *verilog* (the default), *vhdl*, and *systemverilog*.

`-time` *`window_list`*

Specifies time windows in which the activities are counted for power calculation. The option accepts an even number list of float values in increasing order. For example, *-time {10 20 50 70}* specifies the time window [10ns, 20ns] and [50ns, 70ns]. If you do not know the end of simulation time, use a negative number in the *-time* option to indicate the end of the simulation. For example, *-time {10 -1}* specifies the activity time window from 10 ns to the end of simulation time in the FSDB file. The default activity time window is the whole simulation time in FSDB file. This option applies to averaged, time-based power analysis and statistical leakage power variation analysis. The time is automatically adjusted by the tool according to the timescale in the FSDB file or the *-waveform_interval* value in the *set_power_analysis_option* command. For example, if the *-waveform_interval* is 10, *-time {13 33}* becomes *-time {10 30}*.

`-when` *`condition`*

Specifies a Boolean condition to determine which simulation times from the FSDB should be considered for power analysis. The Boolean condition is a string using names of individual signals in FSDB (either annotated to design objects or not annotated), and also operators. Similar to the *-time* option, the *-when* option selects portions of a FSDB for analysis. However, with the *-when* option, the times selected are chosen automatically based on logical values in the FSDB. During simulation times when the Boolean condition is *true*, the events and power are included in power analysis up to and including the timestamp when the condition becomes false. For simulation times when the Boolean condition is false, the events and power are excluded from analysis up to and including the timestamp when the condition becomes true. The feature can be used in both *averaged* and *time_based* power analysis modes.

`version`

Reports FSDB file version and latest FSDB file version that is currently supported.

`-init_start_time` *`init_time`*

Puts all nets to soft initialization state using short fsdb which later can be overriden by propagation.Option used along with *-time*. Option accepts number of cycles to propagate wave from fsdb. Works only in time_based power analysis mode.

`file_name`

Specifies the switching activity file name to be read.

Description

The *read_fsdb* command specifies the switching activity file generated by simulation to be used for time-based power calculation.

When a FSDB file comes from a zero delay gate level simulation; most of events happen at clock edges. This leads to a very large unrealistic peak power. With the *-zero_delay* option, power is averaged over each clock cycle. This requires you to specify the Synopsys Design Constraint (SDC) file, at least clocks and transition time at primary inputs have to be defined.

If a FSDB file comes from RTL simulation, the *-rtl* option should be used. In this case, the *read_fsdb* attempts to find the name mapping between the objects in the FSDB file and in the gate level netlist automatically. The name mapping rules can be set by the *set_rtl_to_gate_name* command. During the average power calculation, the *update_power* command also automatically propagates the switching activity for those unannotated nets.

Behavior For Different Power Modes

Because of the way analysis is performed in different power analysis modes, the *read_fsdb* command has different behavior depending on the power analysis mode. To specify the power analysis mode, set the *power_analysis_mode* variable to *averaged*, *time_based*, or *leakage_variation*.

In the *averaged* and *leakage_variation* modes, power analysis is performed using toggle rates. In these modes the input activity file is converted to toggle rates and static probabilities, which are annotated onto the design.

In the *time_based* mode, power analysis is performed for individual events in the activity file. The *read_fsdb* command is a required part of this flow. In this flow, the header of the activity file is read when the *read_fsdb* command is issued, to determine what portion of the design is annotated. The remainder of the activity file is not read until power analysis is performed.

In the *time_based* mode, if you use the *-rtl* option, the tool uses name mapping (see the *set_rtl_to_gate_name* command), and power analysis uses zero delay simulation to create events on unannotated nets. Without the *-rtl* option, name mapping is not used and no events is simulated. It is intended that RTL FSDB be in the input if the option is used. In this case, sequential cells, primary inputs, and black box outputs are typically annotated, while combinational nets are not annotated. Events on these unannotated nets must be produced via simulation.

Examples

The following example reads the FSDB file dump.fsdb from the disk and uses the first 100 ns of the events in the file.

```
pt_shell> read_fsdb dump.fsdb -time {0 100}
```

The following example reads a FSDB file and excludes time periods when the specified condition is false.

```
pt_shell> read_fsdb dump.fsdb -when {net125 && net126}
```

```
pt_shell> read_fsdb dump.fsdb -init_start_time 10 -time {50 100}
```

---

read_hier_data

Reads binary model information previously written by the *write_hier_data -include model_reload_data* command.

Syntax

string *read_hier_data*

```
        directory
```

Data Types

```
directory     string
```

Arguments

directory

Specifies the directory that contains the binary model.

Description

This command reads in binary model information previously written by the *write_hier_data -include model_reload_data* command. The typical usage of this command is to debug the block model by simulating a top-level run of the block model without really providing a top-level circuit and constraints to instantiate the model. Use this command to directly load the block model into a separate PrimeTime run where the interface circuit of the original block is loaded and timed based on binary data captured in the MODEL directory. Only block models written with reload data are supported by this command.

Feedback

Examples

The following example writes out the binary model info for the current design in the ./ABC directory. The subsequent *read_hier_data* command reads the model information from that directory.

```
pt_shell> write_hier_data ./ABC -include model_reload_data
  ...

pt_shell> ### in a separate PrimeTime session
  ...
pt_shell> read_hier_data ./ABC
  ...
```

See Also

- write_hier_data

---

read_ivm

Reads user-defined via variation tables from a file.

Syntax

status *read_ivm*

```
        interconnect_file
```

Data Types

```
interconnect_file     string
```

Arguments

interconnect_file

Specifies the name of the via interconnect variation file.

Description

The *read_ivm* command reads via interconnect variation tables from a specified text file. Using this data in POCV timing analysis produces more accurate results by taking into account the effects of interconnect via variation.

The following example shows the syntax of the via interconnect variation file.

```
version : 1.0

object_type: design
delay_type: via
```

```
layer_name: *
area            : 0.1
table_min_sigma: 0.25
table_max_sigma: 0.4
table_meanshift: 0
table_stdev     : 0

object_type: design
delay_type: via
layer_name: V1
area            : 0.000400 0.000800  0.001600
table_min_sigma: 0.185     0.143     0.124
table_max_sigma: 0.223     0.204     0.184
table_meanshift: 0         0         0
table_stdev     : 0         0         0

object_type: design
delay_type: via
layer_name: V2
area            : 0.000400 0.000800  0.001600
table_min_sigma: 0.190     0.159     0.128
table_max_sigma: 0.224     0.208     0.192
table_meanshift: 0         0         0
table_stdev     : 0         0         0
```

Currently, only the sigma variation parameters are supported. The meanshift and stdev parameters must be set to zero.

To report the interconnect variation information that has been read in by the *read_ivm* command, use the *report_ivm* command.

Examples

The following command reads in the interconnect variation file named var1.ivm from the current working directory.

```
pt_shell> read_ivm var1.ivm
```

- remove_ivm
- report_ivm
- timing_enable_via_variation

---

read_lib

Reads in a Synopsys library (.lib) file.

Feedback

Syntax

status *read_lib*

file_name

Data Types

file_name	list

Arguments

file_name

Specifies the name of a library file to read.

Description

The *read_lib* command reads a Synopsys library (.lib) file into the PrimeTime tool. To locate files that have relative path names, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path* variable. Files that have absolute path names are loaded as though there is no *search_path*. To determine the file that the *read_lib* command loads, use the *which* command. After the library file is loaded, to list the library objects, use the *list_libs* command. To remove libraries, use the *remove_lib* command.

If the *power_enable_analysis* variable is set to *true*, the *read_lib* command also loads power models. If the variable is *false*, neither the *read_lib* nor *link_design* command nor the first power related command loads power models. The incremental power model loading only works on .db files by using either the *link_library* or *read_db* command or both of these commands. In other words, if you use .lib files and you want to do power analysis, you must set the *power_enable_analysis* variable to *true* and use the *read_lib* command to read in your .lib files.

For more information, see the Library Compiler documentation.

Examples

In the following example, the file bus1.lib is read based on the *search_path*.

```
pt_shell> set search_path "/designs/newcpu/v1.6 /libs/cmos"
/designs/newcpu/v1.6 /libs/cmos

pt_shell> read_lib bus1.lib
Beginning read_lib...
Reading '/libs/cmos/bus1.lib' ...
Technology library 'bus1' read successfully
1
pt_shell> list_libs
```

Feedback

```
Library Registry:
    bus1            bus1.lib:bus1

1
```

read_memory_config

Reads the memory states condition from memory configuration file.

Syntax

status *read_memory_config*

`[config_file]`

Data Types

`string config_file`

Arguments

config_file

Specifies the name of the file that contains the when states for memory cell.

Description

The command reads the specified energy when-condition rules for a spacific lib cell in analysis session.

Examples

The following examples shows read memory configuration file.

```
Sample configuration file

CURRENT_CHARACTERIZATION_METHOD PWL

CELL TZLRSREICYMNU3296X59B512M8SW0A

MODE_NAME PWL_READ
```

```
CONDITIONAL_INPUT = CS & !WE & !PD & SLEEPB
CONDITIONAL_PIN = CK { FALL }
END_MODE

MODE_NAME PWL_WRITE
CONDITIONAL_INPUT = CS & WE & !PD & SLEEPB
CONDITIONAL_PIN = CK { RISE }
END_MODE

END

pt_shell> read_memory_config config_file
```

---

read_memory_configuration

Reads the memory states condition from memory configuration file.

Syntax

status *read_memory_configuration*

`[config_file]`

Data Types

`string config_file`

Arguments

config_file

Specifies the name of the file that contains the when states for memory cell.

Description

The command reads the specified energy when-condition rules for a spacific lib cell in analysis session.

Examples

The following examples shows read memory configuration file.

```
Sample configuration file

CURRENT_CHARACTERIZATION_METHOD PWL

CELL TZLRSREICYMNU3296X59B512M8SW0A
```

```
MODE_NAME PWL_READ
CONDITIONAL_INPUT = CS & !WE & !PD & SLEEPB
CONDITIONAL_PIN = CK { FALL }
END_MODE

MODE_NAME PWL_WRITE
CONDITIONAL_INPUT = CS & WE & !PD & SLEEPB
CONDITIONAL_PIN = CK { RISE }
END_MODE

END

pt_shell> read_memory_configuration config_file
```

---

read_milkyway

Reads in a linked design from a Milkyway database.

Syntax

status *read_milkyway*

```
[-version version]
[-netlist_only]
[-library path]
[-scenario scenario_name]
CEL_name
```

Data Types

version	int
path	string
scenario_name	string
CEL_name	string

Arguments

`-version version`

Specifies the version of the design to be read. For example, there are design files under the CEL view in the Milkyway design library design_lib:

```
\\'design_lib/CEL/design1_pre_route1:1\\'
\\'design_lib/CEL/design1_post_route:2\\'
```

The 1 or 2 after the ':' is the version number of the design. The default is to read the most current version.

`-netlist_only`

Reads only the netlist is to be read; does not read constraints. By default, the command reads both netlist and constraints.

`-library` *`path`*

Specifies the absolute or relative path to the Milkyway design library. You can omit this option if the *mw_design_library* variable specifies the path to the Milkyway design library.

`-scenario` *`scenario_name`*

The Milkyway database can store multiple constraints that can correspond to various scenarios of running the design. This option specifies the name of the scenario for reading in constraints from Milkyway database. The default is to not use a scenario.

`CEL_name`

Specifies the design file name to be read. For example, there are design files under the CEL view in the Milkyway design library design_lib:

```
\\'design_lib/CEL/design1_pre_route1:1\\'
\\'design_lib/CEL/design1_post_route:2\\'
```

The design1_pre_route or design1_post_route are the CEL_name argument. Do not include version number in this argument.

Description

This command reads a linked design from Milkyway database into PrimeTime. The command can also optionally load the timing constraints from the Milkyway database.

The *read_milkyway* command always reads in a linked design. Before you run this command, you need to set the *link_path* and *search_path* variables. If a linked design already exists when you run the *read_milkyway* command, the command unlinks the existing design before reading the Milkyway design.

Do not run the *link_design* command after the *read_milkyway* command. If you do so, the tool could invalidate certain types of cell hierarchy. This method of reading Milkyway designs is consistent with other tools, but it is different from reading Verilog or VHDL designs, which require an explicit *link_design* command.

Feedback

The following variables affect the *read_milkyway* command:

- *link_path* - This variable controls the implicit design linking during the *read_milkyway* command.
- *link_path_per_instance* - If this variable is set so that certain instances have special link paths, the variable setting is honored even in the *read_milkyway* flow.
- *search_path* - This variable is used for automatic loading of the logic libraries.
- *mw_design_library* - If you run the *read_milkyway* command without the *-library* option, the tool gets the library path from this variable. If you specify the *-library* option, this variable is set to the value of the *-library* option.
- *mw_logic0_net* - Use this variable for logic 0 constant nets. The default is "VSS".
- *mw_logic1_net* - Use this variable for logic 1 constant nets. The default is "VDD".

The *link_create_black_boxes* variable does not affect the *read_milkyway* command because the command reads a linked design. If an expected library cell is not present in the libraries specified by the *link_path* or *link_path_per_instance* variable, a black box is created regardless of the *link_create_black_boxes* variable setting.

Examples

In the following example, the latest version of the mw_des design is read into PrimeTime from the mw_db Milkyway database. Any nets set to a constant 0 are created as "VSS", and any set to a constant 1 are created as "VDD".

```
pt_shell> read_milkyway -netlist_only -library ./mw_db mw_des
1
```

After you read a Milkyway database, you can read the parasitics in the database by using the *read_parasitics* command. If a *read_parasitics* command follows the *read_milkyway* command, you do not need to specify a file name for the *read_parasitics* command; it uses the same library and CEL_name as the *read_milkyway* command. For example:

```
pt_shell> read_milkyway -library mw_db mw_des
pt_shell> read_parasitics -format PARA
```

read_ndm

Reads in a netlist from an IC Compiler II design library.

Syntax

status *read_ndm*

```
[-exclude exclude_list]
[-include include_list]
icc2_block_list
```

Data Types

```
exclude_list     list
include_list     list
icc2_block_list  list
```

Arguments

`-exclude exclude_list`

Specifies netlist data to be excluded from reading (which is otherwise included by default):

- *pg_port* - Excludes PG ports

`-include include_list`

Specifies netlist data to be included during reading (which is otherwise excluded by default):

- *physical_only* - Includes physical-only cells as well as functional cells
- *user_pg* - Includes user-defined PG pins

icc2_block_list

Specifies the name of an IC Compiler II block design, or a list of such blocks. The command reads in the netlists for the listed blocks. If a block is hierarchical, the command reads in the netlists of the lower-level blocks as well as the top-level block itself.

Feedback

Specify at least the library name and optionally the path to the library, block name, label name, and view name, using the following form:

```
[path/]library[:block[/label]][.view]
```

For example,

```
my_lib                          reads netlists from all blocks in
 my_lib
my_lib:blockA                   reads netlist from blockA in
 my_lib
my_lib:blockA/postroute         reads netlist from postroute
 blockA
my_lib:blockA/postroute.design  reads netlist from postroute
 blockA design view
```

You can specify a relative or absolute path to the directory containing the library directory, as in the following examples.

```
my_dir/mylib:blockA             path relative to the current
 working directory
/home/data/icc2/mylib:blockA    absolute path
```

If you do not specify a path to the library, the command looks in the paths specified by the *search_path* variable in the order listed in the variable, and uses the first library found.

Description

The *read_ndm* command reads one or more IC Compiler II block netlists into the PrimeTime tool for static timing analysis.

By default, when reading the netlist data, the command includes PG ports, excludes physical-only cells, and excludes user-defined PG pins. You can change the default behavior by using the *-exclude* and *-include* options.

This command reads only netlist data. To read physical design data for the physically aware ECO flow, use the *set_eco_options* command with the *-physical_icc2_lib* and *-physical_icc2_blocks* options

Examples

The following command reads in the netlist from the IC Compiler II block named Top in the MyDesigns library:

```
pt_shell> read_ndm MyDesigns:Top
Loading NDM design 'Top'
1
```

The MyDesigns library must be in the current working directory or in a directory specified by the *search_path* variable.

Feedback

The following command reads in the netlist from the IC Compiler II block named Top, post_route label, in the MyDesigns library in a specific absolute path:

```
pt_shell> read_ndm /remote/icc2data/MyDesigns:Top/post_route
Loading NDM design 'Top'
1
```

The following commands set the *search_path* variable and read in the netlists from two blocks in the MyDesigns library. The command looks for the MyDesigns library directory in the current working directory first and then in the /remote/icc2data directory.

```
pt_shell> set_app_var search_path ". /remote/icc2data"
 . /remote/icc2data
pt_shell> read_ndm {MyDesigns:Top MyDesigns:Blk1}
Loading NDM design 'Top'
Loading NDM design 'Blk1'
1
```

---

read_ndm_lib

Reads in a CLIB library file in the Fusion Compiler flow.

Syntax

status *read_ndm_lib*

```
        clib_file_list
```

Data Types

clib_file_list list

Arguments

clib_file_list

Specifies the name of a CLIB file or a list of CLIB files to read.

If you do not specify a path to the CLIB file, the command looks in the paths specified by the *search_path* variable in the order listed in the variable, and uses the first CLIB library found.

Description

The *read_ndm_lib* command reads one or more CLIB files into the PrimeTime tool for static timing analysis. In the Fusion Compiler ECO flow, CLIB data replaces .db library data.

The command returns 1 for success and 0 for failure. It returns 0 if the list contains any CLIB file that contains only physical data and no timing data.

Examples

The following command reads in the CLIB file named MyLib.nlib, specified as an absolute path:

```
pt_shell> read_ndm_lib /home/data/icc2/MyLib.nlib
1
```

The following command reads in the CLIB file named MyLib.nlib, specified as a path relative to the current working directory:

```
pt_shell> read_ndm_lib my_dir/MyLib.nlib
1
```

---

read_ocvm

Reads advanced and parametric on-chip variation (AOCV/POCV) derating factor tables.

Syntax

status *read_ocvm*

```
[-quiet]
ocvm_file
```

Data Types

```
ocvm_file     string
```

Arguments

`-quiet`

Suppresses the SEL-004, SEL-005, and AOCVM-006 errors and warnings. If this option is not set, errors and warnings are generated when objects specified in the AOCV tables are not found in the current design or libraries.

`ocvm_file`

Specifies the name of the AOCV/POCV file.

Description

The *read_ocvm* command reads AOCV/POCV derate factor tables from a disk file. The tables are annotated onto one or more design objects. Allowed design object types are hierarchical cells, library cells and designs. The AOCV/POCV data is used to reduce pessimism and improve the accuracy of results.

When named AOCV/POCV table sets are specified on objects in the design using the *set_ocvm_table_group* command, a cell (or net) derives its AOCV/POCV deratings from the table set associated with the hierarchical cell (or design) that (a) fully contains the cell (or net), and (b) is the lowest level (closest ancestor) hierarchical cell (or design) with an associated AOCV table set. If no such hierarchical cell (or design) containing the cell (or net) is found, the unnamed AOCV/POCV table set is used. Note that a net inherits the AOCV/POCV derate set of a hierarchical cell (design) that fully contains the net. For example, for nets that cross the boundary between the top level and a block (with an associated AOCV/POCV table set), the lowest level hierarchical cell that fully contains the net is not the block. Therefore, the net derating comes from an AOCV/POCV table set that contains the block and fully encloses the net.

When applying AOCV tables on multiple object types that apply to an arc, the tool uses the following priority, in decreasing order of precedence, to determine the table that applies to the arc:

1. Library cell table
2. Hierarchical cell table
3. Design table

Note: Where a named AOCV table set applies to an arc, the precedence rules above apply to tables that belong to the specified set.

If the *timing_pocvm_precedence* variable is set to *lib_cell_in_file* the precedence of applying POCV tables is consistent with the AOCV precedence. By default, a design level POCV coefficient file takes precedence over LVF data available in library.

Tables are processed in the order that they appear in the AOCV/POCV file. The last table of a specific type {object_type, rf_type, delay_type, derate_type} to be defined for an object in the file overwrites previous tables defined for the same object of the same type.

The *read_ocvm* command can read binary and compressed binary AOCV files created using the *write_binary_aocvm* command. No additional arguments are required to read binary or compressed binary AOCV files.

Examples

The following example shows an AOCV derate file, test.aocvm, with a single table annotated on all library cells.

```
pt_shell> sh cat test.aocvm

version:        1.0

object_type:    lib_cell
rf_type:        rise
delay_type:     cell
derate_type:    late
object_spec:    my_lib/*
voltage:        1.02
depth:          1 2 3
distance:       100 1000
table:          1.20 1.10 1.08
                1.22 1.15 1.11

pt_shell> read_ocvm test.aocvm
```

Feedback

read_parasitics

Reads net parasitics information from an SPEF, DSPF, RSPF, PARA, or Galaxy Parasitics Database (GPD) and uses it to annotate the currently linked design.

Syntax

status *read_parasitics*

```
[-format file_fmt]
[-complete_with completion_type]
[-lumped_cap_only]
[-pin_cap_included]
[-path prefix]
[-coupling_reduction_factor factor]
[-triplet_type ttype]
[-verbose]
[-syntax_only]
[-eco file_name]
[-original_file_name file_name]
[-keep_capacitive_coupling]
[-x_offset xlist]
[-y_offset ylist]
[-axis_flip flip_list]
[-rotation rot_list]
[-parent]
file_names
```

Data Types

completion_type	string
factor	float
file_fmt	string
file_name	string
file_names	string
flip_list	string
prefix	string
rot_list	string
ttype	string
xlist	string
ylist	string

Arguments

`-format file_fmt`

Specifies the format of the parasitics file. The allowed values are SPEF, DSPF, RSPF, PARA (Milkyway), and GPD. If the *-format* option is not specified, the application can determine whether the file is GPD, SPEF, DSPF, RSPF, or a compressed version of those three ASCII formats. However, to read a file in PARA you must specify the *-format PARA* option.

`-complete_with` *completion_type*

This option does not apply to the RSPF format.

This option indicates that a net with partially annotated parasitics is to be completed by inserting capacitances and resistances according to the *completion_type* argument. The allowed values are *zero*, which completes the net by inserting zero capacitances and resistances, and *wlm*, which completes the net by inserting capacitances and resistances derived from wire load models.

This option is equivalent to reading the parasitics file and then using the *complete_net_parasitics -complete_with* command.

In a hierarchical flow where you read in multiple parasitics files, do not use this option until all parasitics files are read in, or you will create incorrect data for temporarily incomplete networks at block boundaries. Either use *-complete_with* on the final *read_parasitics* command only, or issue an explicit *complete_net_parasitics* command after issuing all *read_parasitics* commands.

Note: The *complete_net_parasitics* and *read_parasitics -complete_with* commands complete a net only if all missing segments are between two pins and the nets are partially annotated (nets are not affected if they are fully annotated or have no annotation at all). The net must also be hierarchical, so that if the parasitics for the block-level parts of a net are missing, those parasitics could exist in the top-level net. If any of these conditions are not met, you must manually correct the SPEF or DSPF file.

`-lumped_cap_only`

This option does not apply to the GPD format.

This option indicates that only the total capacitance of nets is to be annotated as a lumped capacitance on the annotated nets. The RC networks specified in the parasitics file are discarded. The annotated lumped capacitance is the capacitance specified when the net is declared in the parasitics file.

`-pin_cap_included`

Indicates that the RC networks are to include the pin capacitances. By default, the RC network does not include pin capacitances. This option does not apply to the RSPF format. The RC pi model in RSPF format has to always include effect of pin capacitances.

`-path` *prefix*

Specifies a list of relative paths from the current design to the hierarchical instance names for which the parasitics file has been created. By default, absolute path names are used. Use this option if the parasitics file refers to an object (for example, *net*) in a hierarchy (for example, *hier*). Do not use this

option if the parasitics file refers to an absolute path (for example, hier/net). If more than one prefix is supplied, all of the instances of the design can be annotated simultaneously.

`-coupling_reduction_factor` *`factor`*

This option applies only to the SPEF format format. A positive floating point number that specifies the factor to apply when reducing coupling capacitances to grounded capacitances. The default is 1.0. This option is disabled if the *-keep_capacitive_coupling* option is specified. The command fails if both options are specified.

`-triplet_type` *`ttype`*

This option applies only to the SPEF and PARA formats. Capacitor and resistor values in the SPEF and PARA files can be specified as triplets with minimum, typical, and maximum values. Be default, PrimeTime uses the maximum values. Use this option to specify which values are used by PrimeTime: *min*, *typ*, or *max*. The default is *max*.

`-verbose`

Indicates that the *report_annotated_parasitics* report is to be generated when the parasitic file has been read. By default, after reading the parasitics file, the *report_annotated_parasitics* command is not executed.

`-syntax_only`

Indicates that the *read_parasitics* command is to parse the file for syntax errors without performing any parasitic annotation. Use this option to troubleshoot your parasitics file and avoid generating error messages during the actual annotation. No design is required to use the *-syntax_only* option.

`-eco` *`file_name`*

This option specifies the ECO (incremental) parasitic file to be read along with the original parasitic file. The ECO parasitic annotation will update the original annotations. Parasitic errors and warnings for the original parasitic file will be suppressed, and only errors and warnings related to the ECO file will be issued. User should refer to the initial *read_parasitics* command to check for all warnings and errors. Note that in HyperScale top, this command cannot be used to update the parasitic annotations of a block.

This option is presently also supporting the old behavior which indicates that the file being currently annotated is an ECO parasitics from StarRC. PrimeTime SI can read ECO parasitics that are written out only by StarRC. The ECO parasitics can be annotated only when there are some existing parasitics that are already annotated. ECO parasitic files contain re-extracted parasitics for only the ECO nets and their immediate coupling neighbors and do not contain all the nets of

the design. Incremental analysis can be performed after reading ECO parasitics. The Galaxy Incremental Flow supports both the SPEF and GPD formats.

`-original_file_name` *`file_name`*

This option can only be used when the *-eco* option is being used. If the original annotation is performed through multiple parasitic files into PrimeTime SI, the ECO parasitic file corresponds to one of the original files (because it corresponds to one extracted database in StarRC). PrimeTime SI attempts to determine the corresponding original file, but it is not always possible. You can use this option to specify which original parasitic file the ECO file correspond to.

`-keep_capacitive_coupling`

Indicates that the cross capacitors are to be kept in the RC networks data structure. This facilitates the capacitive crosstalk analysis, but does not turn it on. This option disables the *-coupling_reduction_factor* option. The command fails if both options are specified. All coupling capacitors are split to ground with a factor of 1.0 if crosstalk analysis is not activated. This option applies to both the SPEF and the GPD format and requires a PrimeTime SI license.

`-x_offset` *`xlist`*

Indicates a list of x-offsets for all instances specified in the *-path* option. The order in which each x-offsets appears in the *-x_offset* option must correspond to the order of each instance in the *-path* option. Specify the x-offsets in nanometers.

`-y_offset` *`ylist`*

Indicates a list of y-offsets for all instances specified in the *-path* option. The order in which each y-offset appears in the *-y_offset* option must correspond to the order of each instance in the *-path* option. Specify the y-offsets in nanometers.

`-axis_flip` *`flip_list`*

Indicates a list of axis flips for all instances specified in the *-path* option. The order in which each axis flip appears in the *-axis_flip* option must correspond to the order of each instance in the *-path* option. The allowed values are *flip_x*, which indicates a flip across the x-axis, *flip_y*, which indicates a flip across the y-axis, *flip_both*, which indicates a flip along both axis and *flip_none*, which indicates no flip.

`-rotation` *`rot_list`*

Indicates a list of rotations for all instances specified in the *-path* option. The order in which each rotation appears in the *-rotation* option must correspond to the order of each instance in the *-path* option. The allowed values are *rotate_none*, *rotate_90*, *rotate_180*, and *rotate_270*, which indicate a counter-

clockwise rotation of 0, 90, 180, and 270 degrees, respectively. The default is *rotate_none*.

`-parent`

Indicates that the locations values provided by *-x_offset*, *-y_offset*, *-rotation*, or *-axis_flip* are in the coordinate system of the immediate parent hierarchy. By default, they are in the coordinate system of the top level.

`file_names`

When the format is SPEF, DSPF, RSPF, or GPD, this option specifies a list of files from which parasitics information is to be read.

Description

The *read_parasitics* command reads parasitic data from a file and annotates that data on the nets of the current design. For best performance, run this command as soon as possible after the *link_design* command.

The command can read data in SPEF, DSPF, RSPF, and Galaxy Parasitics Database (GPD) format. For SPEF, RSPF, and DSPF, the file can be a simple ASCII file, or it can be compressed with gzip. The *read_parasitics* command automatically detects this format information from the file, but you can specify the base format using the *-format* option.

GPD is an efficient format for sharing parasitics among Synopsys applications. You can use the PrimeTime *write_parasitics* command to write a parasitics file in GPD format.

You can specify parasitics in either reduced or detailed form. Reduced parasitics consist of an RC pi model specified for each driver pin of a net. An RC pi model contains two capacitances and one resistance. The first capacitance connects to the net driver pin; the resistance connects to the net driver pin and to a subnode to which the second capacitance connects. Both capacitances connect to the ground. The parasitics file, using the reduced form, also specifies the pin-to-pin net delays. The RC pi model is used to compute the effective capacitance of the nets at each driver of the net. The effective capacitance determines the cell delays and output slews. You can specify reduced parasitics with the SPEF, DSPF, or RSPF format.

Detailed parasitics consist of a network of resistances and capacitances for each net specified in the parasitics file. The capacitances must be with respect to the ground. Coupling capacitances are not supported unless the *-keep_capacitive_coupling* option is specified and you are using the SPEF or GPD format. Resistances connected to the ground are not connected. The detailed RC network must be complete; incomplete RC networks are discarded but the delays are computed using the incomplete subset of resistances and capacitances. You can specify detailed parasitics with the SPEF, GPD, DSPF, or RSPF formats.

The *read_parasitics* command does not overwrite lumped parasitics (set using the *set_load* or *set_resistance* command) if they already exist on the design. Instead,

a warning is issued. If the lumped parasitics are subsequently removed (using the *remove_capacitance* and *remove_resistance* commands) PrimeTime reverts to the reduced or detailed parasitics.

Incremental annotations are supported; if a small number of nets are affected, a full timing update is not required if the design is already timed. The maximum number of affected nets that avoid a full timing update depends on the total design size.

Multiple resistances and capacitances between the same nodes are also accepted. The values of multiple capacitances between a node are added together and multiple resistances between the same two nodes are kept separately and are considered during the delay calculation.

It is most efficient to read the top level last to minimize the amount of stitching that must be performed.

Net and instance pin names in the design must match instance names in the parasitics file. For example, if you create the parasitics file from a design using VHDL naming conventions, the design name must use VHDL naming conventions.

Parasitics of HyperScale instances are automatically read by PrimeTime when these instances are instantiated at top level, and user-specified parasitics reading of these instances is automatically skipped. Note that if the *-path* option in *read_parasitics* includes multiple instances among which some are HyperScale instances and the others are not, the parasitics reading for those non-HyperScale instances are not skipped.

To remove parasitics that were read and annotated with the *read_parasitics* command, use the *remove_annotated_parasitics* command. The *reset_design* command removes all attributes from the current design, including annotated parasitics.

In PrimeTime, the delay calculation algorithms impose no limit on the number of resistances and capacitances that can be annotated onto a single network; however, there are two shell variables you can manipulate to track and filter annotations that might cause unexpectedly large runtime. Use the *parasitics_warning_net_size* variable to specify the threshold number of nodes for which the PARA-003 message is to be issued, indicating that a large amount of annotation has been encountered for a given network. Similarly, use the *parasitics_rejection_net_size* variable to specify when such detailed annotation is to be rejected in favor of lumped annotation, issuing the PARA-004 warning message.

PrimeTime can also load locations information from parasitic files. This capability is controlled by the *read_parasitics_load_locations* variable. By default, this variable is *false*, and no locations are read into PrimeTime. You can set this variable to *true* to load locations.

Hierarchical parasitics with locations require geometric transformations to be associated with the sub-blocks (i.e.; -path option). PrimeTime computes these transformations based on: user defined transformation; StarRC location guidance for SPEF/GPD; Automatic determination of location transformation.

When reading PARA format the parasitics might not be the same as what is specified by the *-triplet_type* option. This happens when the specified type does not exist. In that case, the *read_parasitics* command chooses something according to the following table:

```
Parasitics stored as
  triplet_type      |   typ   min-max    min-max-typ
--------------------+---------------------------------
    min             |   typ     min          min
    typ             |   typ     max          typ
    max             |   typ     max          max
```

PrimeTime can read a multicorner parasitic file and select one corner of interest. You must specify the corner name by using the *parasitic_corner_name* variable, before using the *read_parasitics* command. After the parasitic corner is set, it cannot be changed between subsequent *read_parasitics* commands. With this feature, the parasitics for only one specific corner from the set of corners is read and annotated. All other parasitic commands would operate on this given corner. The feature is supported for both SPEF and GPD.

For GPD format, the log of *read_parasitics* command will show the list of annotated corners, with the first one being the selected corner for PrimeTime commands. The order of the other corners, if any, is not relevant.

If you read multicorner parasitics without setting the *parasitic_corner_name* variable, the first corner is used for the GPD format, and an error is issued for other formats.

The *parasitic_explorer_enable_analysis* mode allows you to read and annotate all corners in a GPD. However, non-explorer commands still operate on the default corner or the corner specified by *parasitic_corner_name*.

Examples

The following example reads the adder.spef parasitics file from the disk and uses it to annotate the RC parasitics on the current design. The parasitics file contains a description of the RC network for nets of a design.

```
pt_shell> read_parasitics adder.spef
```

The following example shows annotating hierarchical parasitics files. The second command reads parasitics information, for instance u1 of design mult16 from the disk file mult16_u1.spef. The parasitics are annotated on the design, MY_DESIGN. The *-verbose* option enables the automatic call to the *report_annotated_parasitics* command, which would report RC networks of the boundary nets of instance u1 that are not complete.

Pin capacitances are included in the annotated parasitics, as specified by the *-pin_cap_included* option. The second command reads another parasitics file in incremental mode, so that parasitics annotated on the boundary nets of instance u1 are not discarded.

Feedback

```
pt_shell> current_design MY_DESIGN
pt_shell> read_parasitics -pin_cap_included -path u1 mult16_u1.spef
pt_shell> read_parasitics -pin_cap_included -verbose mydesign.spef
```

The following example applies hierarchical parasitics files. The top-level design contains two instances each of block-level designs blkA and blkB.

```
pt_shell> read_parasitics blkA.spf -path {blkA_0 blkA_1}
pt_shell> read_parasitics blkB.spf -path {blkB_0 blkB_1}
pt_shell> read_parasitics top_level.spf
```

The following example completes any partially annotated parasitics after reading in hierarchical parasitics.

```
pt_shell> read_parasitics blkA.spf -path blkA
pt_shell> read_parasitics blkB.spf -path blkB
pt_shell> read_parasitics top_level.spf -complete_with zero
```

The following example removes annotated parasitics information from the current design.

```
pt_shell> remove_annotated_parasitics
```

The following example loads locations into PrimeTime memory.

```
pt_shell> set read_parasitics_load_locations true
pt_shell> read_parasitics adder.spef
```

The following example reads the C_2 corner from a multicorner parasitic file.

```
pt_shell> set parasitic_corner_name "C_2"
pt_shell> read_parasitics multi_corner.spef
```

---

read_saif

Reads a Switching Activity Interchange Format (SAIF) file and annotates switching activity information on nets, pins, ports, and cells in the current design.

Syntax

status *read_saif*

```
file_name
[-strip_path prefix]
[-report_inconsistent_annotation report_file]
[-path prefix]
[-ignore ignore_name]
[-exclude exclude_file_name]
[-derate_glitch value]
[-conflict]
[-quiet]
[-parallel strip strip_path inst_name file_name ... ]
[-exclude_hier_pins]
```

Data Types

```
file_name              string
prefix                 string
report_file            string
ignore_name            string
exclude_file_name      string
value                  float
```

Arguments

file_name

Specifies the name of the SAIF file to read. If the file name ends with .gz, .Z, or .bz2, it is read as a gzipped file, a compressed file, or a bzip2ed file, respectively. Otherwise, it is assumed that the file is uncompressed.

-strip_path *prefix*

The *read_saif* command assumes that the current design is instantiated as an instance in the testbench used to generate the SAIF file. The current design, therefore, appears as an instance in the SAIF file. The *-strip_path* argument specifies the name of the instance of the current design as it appears in the SAIF file.

The *read_saif* command annotates all subinstances in the hierarchy of the specified instance and annotates the instance itself. Enter each instance name completely, without any trailing hierarchy separator (/). For example, if the current design is instantiated in the simulation environment as TOP/DUT/U1, use -strip_path TOP/DUT/U1 and not -strip_path TOP/DUT/U.

`-report_inconsistent_annotation` *report_file*

This option specifies the report file name containing objects whose activity is overwritten with different values. When specified, read_saif checks the consistency of the annotated values on objects whose activity values are overwritten, and outputs any inconconsistencies in the report_file. If none occur, the report file is empty.

`-path` *prefix*

Specifies a relative path from the current design to the hierarchical low-level design for which the SAIF file has been created. By default, absolute path names are used. Use this option if the SAIF file refers to an object in a hierarchy. If you want to read the switching information for a portion of the design, you can also use this option. For example, if the SAIF was generated for the whole design and you want to put only switching information on the nets/ports on the boundary and hierarchically under instance add14, then use the *-path add14* option.

`-ignore` *ignore_name*

Specifies the name of an instance in the SAIF file for which switching activity is to be ignored. The *read_saif* command ignores switching activity within the hierarchy of that instance in the SAIF file. *ignore_name* can be a hierarchical name separated by a slash (/). The *-strip_path* option is applied first. The *read_saif* command then strips off the prefix of a net name that matches *prefix* before deciding whether this net name is under the hierarchy specified by the *-ignore* option.

`-exclude` *exclude_file_name*

Specifies the name of a file that contains a list of names to be ignored. The *exclude_file_name* option is used when you want to ignore switching activity for several instances. The file must contain each *ignore_name* on a separate line, without the *-exclude* option. As with the *-ignore* option, the ignore names are recognized after the *-strip_path* argument.

`-derate_glitch` *value*

Specifies a default derating factor value to be used for inertial glitches in the SAIF file. If the *-derate_glitch* option is not specified, a default derating factor of 0.5 is used.

`-conflict`

Indicates that the SAIF file contains conflict activities. These activities will be annotated to conflict cell instances which are specified by *set_power_analysis_options -conflict_activity_cells* and *power_enable_merged_fsdb* variable set to *true* before reading the SAIF file.

`-quiet`

Specifies quiet mode and for instance suppresses warnings on design objects in the SAIF file that could not be annotated on the design.

`parallel`

Specifies parallel saif file reading this option takes multiple of 3 arguments they represents strip_path instance_name and saif file. So, if 2 saif file need to be read parallelly then 6 arguments are passed. The variable power_enable_mt_namemapping need to be set true for parallel name mapping reading. otherwise -parallel option fails.

`-exclude_hier_pins`

This change enables skipping of writing activity information of hierarchical pins when *-exclude_hier_pins* switch is used along with *-rtl* option. This option should only be used with *-rtl* option.

Description

The *read_saif* command reads a SAIF file and annotates the switching activity attributes *toggle_rate* and *static_probability* for nets, ports, and pins of the current design. The *update_power* command uses this information to calculate dynamic power values. If a particular object in the SAIF file cannot be found in the current design, the object is ignored and a warning message is provided. The *read_saif* command returns 1 if at least one of the objects in the file is successfully annotated. Otherwise, it returns 0.

To identify the instance (and corresponding subinstances) you want to annotate, use the *-strip_path* option. To annotate switching information about a particular instance, use the *-path* option. To specify a default derating factor other than 0.5, use the *-derate_glitch* option.

If a SAIF file comes from RTL simulation, the *read_saif* command tries to automatically locate the name mapping between the objects in the SAIF file and in the gate level netlist. The name mapping rules can be set by the *set_rtl_to_gate_name* command. During the average power calculation, the *update_power* command also automatically propagates the switching activity for those unannotated nets.

Examples

The following example annotates switching activity for the current design in the pt_shell, for a design instantiated as Test/U1 in the simulation testbench.

Feedback

```
pt_shell> read_saif file -strip_path Test/U1
```

The following examples annotate the instance U10 under current design.

```
pt_shell> read_saif -file -strip_path Test/U1 -path U10
```

The following examples demonstrate annotation of multiple designs; the design "name1" is instantiated as Test1/U1, and design "name2" is instantiated as Test1/U2.

```
pt_shell> current_design name1

pt_shell> read_saif file_1 -strip_path Test1/U1

pt_shell> current_design name2

pt_shell> read_saif file_2 -strip_path Test1/U2
```

The following examples demonstrate conflict annotation of design. The cell instance "U1" is conflict activity cell and conflict.saif has activities of U1 which conflict with top level switching activities which are from toplevel.saif.

```
pt_shell> set_app_var power_enable_merged_fsdb true

pt_shell> set_power_analysis_options -conflict_activity_cells {U1}

pt_shell> read_saif -conflict -strip_path root conflict.saif

pt_shell> read_saif -strip_path root toplevel.saif
```

Feedback

read_sdc

Reads in a script in Synopsys Design Constraints (SDC) format.

Syntax

int *read_sdc*

```
[-echo]
[-syntax_only]
[-version sdc_version]
[-sms_scenarios sms_scenarios_list]
file_name
```

Data Types

sdc_version	string
file_name	string
sms_scenarios_list	collection

Arguments

`-echo`

Indicates that each constraint is to be echoed as it is executed.

`-syntax_only`

Indicates that SDC script is processed only to check the syntax and semantics of the script.

`-version sdc_version`

Specifies the version of SDC to which the file conforms. Allowed values are *1.0*, *1.1*, *1.2*, *1.3*, *1.4*, *1.5*, *1.6*, *1.7*, *1.8*, *1.9*, *2.0*, *2.1* and *latest* (the default).

`-sms_scenarios sms_scenarios_list`

Specifies a collection of SMS scenarios to be used for the commands included in the file. Each command applies the specified SMS scenarios collection according to thier specification. The option is ignored by commands which do not support the -sms_scenarios option. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

file_name

Specifies the name of the file that contains the SDC script to be read.

Description

The *read_sdc* command reads in a script file in Synopsys Design Constraints (SDC) format that contains commands for use by PrimeTime or by Design Compiler in its Tcl mode. SDC is also licensed by external vendors through the Tap-in program. SDC

formatted script files are Tcl scripts that use a subset of the commands supported by PrimeTime and Design Compiler.

By default, the *read_sdc* command executes the constraints as they are read. If there are errors part way through the script, it is possible that some constraints are applied, and some are not. You can use the *-syntax_only* option to simply check the script without applying any constraints. This option also verifies conformance to the specified SDC version. If there are any errors during the checking phase, the result of the *read_sdc* command is 0.

Like the *source* command, the *read_sdc* command is sensitive to variables that control script execution (for example, the *sh_continue_on_error* and *sh_script_stop_severity* variables). The *read_sdc* command uses the *sh_source_uses_search_path* variable to determine if the *search_path* command is used to find the script.

The *read_sdc* command supports several file formats. The file can be a simple ASCII script file, an ASCII script file compressed with gzip, or a Tcl byte code script, created by TclPro Compiler.

Note that SDC does not allow command abbreviation. Also note that the *exit* and *quit* commands do not cause the application to exit, but they do cause the reading of the SDC file to stop.

The latest SDC version supports the commands listed below. Those added for versions 1.3 and later are noted. Some constraints that PrimeTime ignores are not listed.

General Purpose Commands

```
list
expr
set
```

Object Access Functions

```
all_clocks

```

For a complete guide to using SDC with Synopsys applications, see the *Using the Synopsys Design Constraints Format Application Note* in Documentation on the Web, which is available through SolvNetPlus at the following address:

https://solvnetplus.synopsys.com/

Feedback

Using some of these commands is restricted when reading SDC. In some cases, some command options are not allowed. In some applications, some of the commands are not supported. For example, PrimeTime does not support the *set_logic** commands. These commands are ignored when loaded in with the *read_sdc* command and a message appears (for an example, see the EXAMPLES section). If an unsupported command is located by the *read_sdc* command, it appears as an unknown command along with a message. The same condition exists for command options. If an option is not supported by SDC, a message is issued indicating that condition. However, if the option is unknown, a different message is issued.

Note that although the *create_generated_clock* command is supported (beginning with version 1.3), there is no provision for the *get_generated_clocks* shortcut, which is available in PrimeTime and Design Compiler. Generated clocks are simply clocks with some additional attributes and in SDC, they are retrieved through the *get_clocks* command.

The following features are added for SDC Version 1.5 or later:

- The *set_clock_latency* command with the *-clock* option
- The *set_timing_derate* command with all of the options
- The *set_max_transition* command with the *-clock_path -data_path -rise*, and *-fall* options
- The *set_clock_uncertainty* command with the *-rise*, *fall*, *from*, and *to* options
- The *set_operating_conditions* command with the *-object_list* option
- Synonyms for all *get_object* commands
- The *get_objects -nocase* command support independently with the *-regexp* option
- Support for the *get_objects -regexp* command
- The *get_objects -of_objects* support for the *get_cells get_nets*, and *get_pins* commands.

The following features are added for SDC Version 2.0 or later:

- The *-reference_pin* option for the commands *set_input_delay* and *set_output_delay*. • The *set_min_pulse_width* command with the *-high* and *-low* options.

The following features are added for SDC Version 2.1 or later:

- The *set_sense* command with the *-type*, *-non_unate*, *-positive*, *-negative*, *-stop_propagation*, *-clock_leaf*, *-pulse*, *-clocks* options. • The *-dynamic* option for the command *set_clock_latency*. • The *-dynamic*, *-static*, and *-increment* options for the command *set_timing_derate*. • The *-ignore_clock_latency* option for the command *set_max_delay*. • The *-ignore_clock_latency* option for the command *set_min_delay*.

The following features are removed for SDC Version 2.1 or later, and are not recognized:

- The *set_clock_sense* command. • The *-multiply_by* option for the command *set_driving_cell*.

Examples

The following example reads the SDC script top.sdc.

```
pt_shell> read_sdc top.sdc -version 1.2
Reading SDC version 1.2...
1
```

The following example reads the SDC script top2.sdc, The script contains commands not supported by SDC, and CMD-005 messages are generated for those commands.

```
pt_shell> read_sdc -syntax_only top2.pt -version 1.2
Checking syntax/semantics using SDC version 1.2...
Error: Unknown command 'link_design' (CMD-005)
** Completed syntax/semantic check with 1 error(s) **
0
```

The following example shows the result when an unsupported command is in an SDC file. One SDC message is generated per instance of an unsupported command. At the end of the read, a summary of all unsupported commands in the file is generated. This SDC file was read into PrimeTime.

```
pt_shell> read_sdc t2.sdc -version 1.2
Reading SDC version 1.2...
Warning: Constraint 'set_logic_zero' is not supported by pt_shell.
 (SDC-3)
Warning: Constraint 'set_logic_zero' is not supported by pt_shell.
 (SDC-3)
Warning: Constraint 'set_logic_one' is not supported by pt_shell. (SDC-3)

Summary of unsupported constraints:
Information: Ignored 1 unsupported 'set_logic_one' constraint. (SDC-4)
Information: Ignored 2 unsupported 'set_logic_zero' constraints. (SDC-4)
1
```

The following example is a script that is not SDC-compliant, because it contains unsupported commands or command options.

```
current_design TOP
set_resistance -value 12.2 [get_nets i1t2]
```

The following example shows the output generated by the *read_sdc* command when reading the previous script. In SDC, the *current_design* command can be used only to get the current design; no arguments are allowed. Also, there is no *-value* option for the *set_resistance* command, so an appropriate message is generated.

```
pt_shell> read_sdc t3.tcl -echo -version 1.2
Reading SDC version 1.2...
current_design TOP
Error: extra positional option 'TOP' (CMD-012)
set_resistance -value 12.2 [get_nets i1t2]
Error: unknown option '-value' (CMD-010)
0
```

The following example shows the message generated when an option is supported by the command but not by SDC.

```
Information: The '-value' option for set_resistance is unsupported.
 (CMD-038)
```

---

read_sdf

Reads leaf cell and net timing information from a file in Standard Delay Format (SDF) and uses that information to annotate the current design.

Syntax

string *read_sdf*

```
[-path path_name]
[-load_delay cell | net]
[-analysis_type single | bc_wc | on_chip_variation]
[-min_file min_fname]
[-max_file max_fname]
[-type sdf_min | sdf_typ | sdf_max]
[-min_type sdf_min | sdf_typ | sdf_max]
[-max_type sdf_min | sdf_typ | sdf_max]
[-cond_use min | max | min_max]
[-syntax_only]
[-strip_path prefix_path]
[-verbose]
[-worst]
file_name
```

Feedback

Data Types

```
path_name       string
min_fname       string
max_fname       string
prefix_path     string
file_name       string
```

Arguments

`-path path_name`

Specifies the path from the current design to the subdesign for which the timing file has been created.

`-load_delay cell | net`

Specifies whether to read cell (the default) or net load delays in the timing file. The load delay is the portion of cell delay arising from the capacitive load of the net driven by the cell.

`-analysis_type single | bc_wc | on_chip_variation`

Use this option only if you have not already set an analysis type with the *set_operating_conditions -analysis_type* command. The available values are *single bc_wc*, and *on_chip_variation*. If you are in min_max mode, the default is the *bc_wc* value. The *single* value indicates that only one operating condition is to be used.

Specifying either the *bc_wc* or *on_chip_variation* values switches to min_max mode and causes both minimum and maximum delays to be read from the SDF file. Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max). By default, the *-analysis_type bc_wc | on_chip_variation* option reads the *sdf_min* and *sdf_max* delays, respectively. To change this, use the *-min_type* and *-max_type* options.

`-min_file min_fname`

Specifies the file from which minimum delay timing information is read. The timing file must be in SDF format version v1.0, v2.0, v2.1 or v3.0. Use this option only if the minimum and maximum delays are in two separate SDF files.

`-max_file max_fname`

Specifies the file from which maximum delay timing information is read. The timing file must be in SDF format version v1.0, v2.0, v2.1 or v3.0. Use this option only if the minimum and maximum delays are in two separate SDF files.

`-type sdf_min | sdf_typ | sdf_max`

Specifies the SDF triplet delay value that is read from the SDF file: *sdf_min*, *sdf_typ*, or *sdf_max* (the default). Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max).

Note: If you use the *-type* option while in min/max mode (for example, if you use the *-operating_conditions bc_bw | on_chip_variation* option), a single value is annotated onto both minimum and maximum values of an arc.

`-min_type sdf_min | sdf_typ | sdf_max`

Specifies the SDF triplet delay value that is read from the SDF file for minimum delay: *sdf_min* (the default), *sdf_typ*, or *sdf_max*. Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max). Use this option only with the *-analysis_type bc_wc | on_chip_variation* option.

`-max_type sdf_min | sdf_typ | sdf_max`

Specifies the SDF triplet delay value that is read from the SDF file for maximum delay: *sdf_min*, *sdf_typ*, or *sdf_max* (the default). Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max). Use this option only with the *-analysis_type bc_wc | on_chip_variation* option.

`-cond_use min | max | min_max`

Use this option only if the SDF file includes some conditional delays using the SDF construct COND, and if the Synopsys library in use does not specify conditional delays. The available values are *min*, *max*, *min_max*. The *min* value indicates that the minimum of all conditional delays is used to annotate the corresponding timing arc. The *max* value indicates to use the maximum; The *min_max* value indicates min_max operating conditions. The minimum of all conditional delays is used for the minimum operating condition, and the maximum of all conditional delays is used for the maximum operating condition. You cannot use the *min_max* value with a single operating condition; you must be in the min_max mode.

`-syntax_only`

Verifies the SDF syntax. No timing annotation is performed; only syntax is processed. Use this option to verify that your SDF syntax is correct.

`-strip_path` *`prefix_path`*

Specifies a prefix path that is stripped from all SDF objects. Such a prefix path is usually a result of generating an SDF file for a subdesign and using this subdesign as the current design.

`-verbose`

Use this option to enable execution of the *report_annotated_delay* and *report_annotated_check* commands after reading SDF.

`-worst`

Indicates that the *read_sdf* command annotates the current design only with delays worse than the current annotated delays; applies to annotated net and cell delays and annotated timing checks. The worst delay is defined as the most pessimistic delay. This means PrimeTime annotates the minimum of minima and maximum of maxima values.

`file_name`

Specifies the file from which timing information is read. The timing file must be in SDF format version v1.0, v2.0, v2.1 or v3.0.

Description

The *read_sdf* command reads from a disk file leaf cell and net timing information and uses it to annotate the current design. The timing file must be in SDF format v1.0, v2.0, v2.1 or v3.0. The file can be a simple ASCII file, or it can be compressed with gzip. Instance-specific pin-to-pin cell and net delays are read from the SDF file and annotated on the current design. When you specify the *-path* option, the *read_sdf* command annotates the current design with information from a timing file created for an instance of a subdesign of the current design. When you specify a subdesign, you cannot use the net delays to the ports of the subdesign to annotate the current design.

The load delay, also known as extra source gate delay, is that portion of the cell delay caused by the capacitive load of the driven net. Some delay calculators consider the load delay part of the net delay. Others consider the load delay part of the cell delay. By default, the *read_sdf* command assumes the load delay is included in the cell delay in the timing file being read. The *-load_delay* option allows you to inform the *read_sdf* command if your timing file includes the load delay in the net delay rather than in the cell delay.

Setup, hold, recovery, removal, period, width, nochange, and skew timing checks, when present in the timing file, are used to annotate the current design. Prior to SDF version 3.0, the SDF construct for removal is HOLD.

Instance names in the design must match instance names in the timing file. For example, if the timing file is created from a design using VHDL naming conventions, the design must use VHDL naming conventions.

To remove delays read and annotated with the *read_sdf* command, use the *reset_design* or *remove_annotated_delay* command. To remove timing checks annotated with the *read_sdf* command, use the *remove_annotated_check* command.

Only partial support for SDF version 3.0 is available. Supported v 3.0 constructs are: REMOVAL, RECREM, RETAIN, and CONDELSE.

Note that the *read_sdf* command does not support hierarchical SDF annotation. All pins must be specified at the leaf cell level. It is not possible to specify hierarchical pins.

When multiple annotations against the same arc are present in the annotation file, the last annotation will take precedence. If the *-worst* option is specified, each annotation is applied only if it is worse than the existing timing value for that arc.

Also note that if the *timing_use_zero_slew_for_annotated_arcs* variable is set to its default *auto* value and at least 95% of delay arcs are annotated, the pure SDF flow is switched on automatically. This results in faster performance of the *update_timing* command, at the expense of no longer calculating the slews on the load pins of annotated arcs. For more information, see the *timing_use_zero_slew_for_annotated_arcs* man page.

Examples

The following example reads the adder.sdf timing file from the disk and uses it to annotate the timing on the current design. The timing file contains load delays included in the cell delays.

```
pt_shell> read_sdf -load_delay cell  adder.sdf
```

The following example reads timing information for instance u1 of design MULT16 from the mult16_u1.sdf disk file that contains the timing for the instance u1 of design MULT16. The timing is annotated on the design MY_DESIGN. In this case, load delay is included in the net delays.

```
pt_shell> current_design MY_DESIGN
pt_shell> read_sdf -load_delay net -path u1 mult16_u1.sdf
```

The following example reads timing information and annotates the current design with the maximum timing when the timing file has different timing conditions for the same pin pair. The load delay is assumed to be included in the cell delay in this example.

```
pt_shell> remove_annotated_delay
pt_shell> read_sdf -cond_use max fname1.sdf
```

The following example reads minimum and maximum timing information and annotates the current design with delays corresponding to minimum and maximum operating conditions, respectively. When reporting minimum delay, PrimeTime uses delays annotated for the minimum condition. When reporting maximum delay, PrimeTime uses delays annotated for the maximum condition.

```
pt_shell> read_sdf -analysis_type bc_wc fname2.sdf
```

The following example reads minimum and maximum timing information from two separate SDF files and annotates the current design with delays corresponding to minimum and maximum operating conditions, respectively. When reporting minimum delay, PrimeTime uses delays annotated for the minimum condition. When reporting maximum delay, PrimeTime uses delays annotated for the maximum condition.

```
pt_shell> read_sdf -analysis_type bc_wc -min_file foo_min.sdf -max_file
 fname3_max.sdf
```

---

read_signal_em_rules

Reads electromigration (EM) rules from a file in a supported format.

Syntax

status *read_signal_em_rules*

```
-format rule_format
[rule_file]
[-design2itf_map map_file]
[-clear]
```

Data Types

```
string rule_format
string rule_file
string map_file
```

Arguments

`-format rule_format`

Specifies the format of the electromigration rules. The valid values are itf, ircx, and tcl (ratcl format). The default value is itf.

rule_file

Specifies the name of the file that contains the electromigration rules.

`-design2itf_map` *`map_file`*

Specifies the name of the mapping file that defines the name mapping between the layer names used in design database and those in the rule file.

`-clear`

clear loaded electromigration rules from current PrimePower session to release memory.

Description

The command reads the specified electromigration (EM) rules into the analysis session. When successful, the new rules replace the existing ones. These electromigration rules are used to perform electromigration analysis on the signal network. See the *check_signal_em* man page for further details.

In *design2itf_map* mapping file, the conducting_layers section defines the layer name mapping for metal layers. The via_layers section defines the layer name mapping for via layers. In each section, the layer names used in the design database are listed in the first column, where the layer names used in the TLUPlus file are in the second column. Lines starting with "*" are considered as comments.

When electromigration rules are specified in a itf file, this command parsed in the electromigration rule related information specified at header comment section of the itf file. This electromigration rule portion starts with string "#EM_INFORMATION", ends with string "#END_OF_EM_INFORMATION". The itf file might have multiple electromigration rules specified, for example, average, rms and peak. During static electromigration analysis, only average rule is used. During dynamic electromigration analysis, only average, rms and peak rules are used, and you can specify one or all of the three to be reported. See more details in the *check_signal_em* man page.

Regardless of the electromigration rule input format, the electromigration rules establish the current density limits for the geometries from *read_parasitics* command which reads StarRC SPEF file (with tail comment) or GPD database.

Examples

This example replaces the current electromigration rules with the rules read from *MyFile.itfem*:

```
pr_shell> read_signal_em_rules -format itf MyFile.itfem -design2itf_map
 layer_mapping_file
1
```

- check_signal_em

Feedback

read_tsv_timing

Consume TSV feedthrough path timing data at the stack(top) level.

Syntax

```
int read_tsv_timing
  [-path instance_name]
  tsv_file_name_list
```

Data Types

```
instance_name           string
tsv_file_name_list      list
```

Arguments

`-path instance_name`

Specifies the instance name of the intermediate die.

`tsv_file_name_list`

Specify a list of tsv path timing data files for that intermediate die.

Description

The *write_tsv_timing* command reads in a list of tsv feedthrough path timing data files in binary format at the stack level. Then it loads and annotates the tsv timing data before update_timing for all corners. The recovered skew for source synchronous stack level timing path is shown in *report_timing*.

Note: report_timing will only show the sssr after you use this command.

Examples

The following example reads a list of tsv feedthrough path timing data files at the stack level for corner 1, 2, and 3.

```
prompt> read_tsv_timing -path MD {tsv_1.dat tsv_2.dat tsv_3.dat}
```

See Also

- write_tsv_timing

read_vcd

Specifies the switching activity information generated by simulation for use in power calculation. Internally, non-VCD format switching activity is converted to VCD.

Feedback

Syntax

status read_vcd

```
[-pipe_exec pipe]
[-path path]
[-strip_path strip_path]
[-zero_delay]
[-rtl]
[-format verilog | vhdl | systemverilog]
[-time window_list]
[-when condition]
[-converter_options option_list]
file_name
```

Data Types

```
pipe            string
path            string
strip_path      string
window_list     list
condition       string
option_list     list
file_name       string
```

Arguments

`-pipe_exec pipe`

Specifies a shell command that is used to generate the VCD file *file_name*. This option invokes the command and directly pipe the output VCD file to PrimePower. In other words, the simulation and power analysis are in parallel run. No VCD disk file is generated at all.

`-path path`

Specifies a relative path from the current design to the hierarchical low-level design for which the VCD file has been created. By default, absolute path names are used. Use this option if the VCD file refers to an object in a hierarchy. Do not use this option if the VCD file refers to an absolute path.

`-strip_path strip_path`

Specifies a path prefix that is to be stripped from all the object names read from the VCD file. This option is applied to strip the testbench and instance path from the VCD file.

`-zero_delay`

Specifies that he VCD file comes from a zero delay simulation.

`-rtl`

Specifies the VCD file comes from an RTL simulation. Typically, this means that most nets in the design are not directly annotated from the VCD, because combinational nets are not included in the RTL simulation. The *set_rtl_to_gate_name* name mapping command is honored only if this option is set. Also, in the *time_based* power analysis mode, event propagation occurs during power analysis only if the *-rtl* option is set when the *read_vcd* command was issued.

`-format verilog | vhdl | systemverilog`

Specifies the language format for names in the VCD. Available options are *verilog* (the default), *vhdl*, and *systemverilog*.

`-time` *`window_list`*

Specifies time windows in which the activities are counted for power calculation. The option accepts an even number list of float values in increasing order. The time unit assume to be nanosecond. For example, *-time {10 20 50 70}* specifies the time window [10ns, 20ns] and [50ns, 70ns]. If you do not know the end of simulation time, use a negative number in the *-time* option to indicate the end of the simulation. For example, *-time {10 -1}* specifies the activity time window from 10 ns to the end of simulation time in the VCD file. The default activity time window is the whole simulation time in VCD file. This option applies to averaged, time-based power analysis and statistical leakage power variation analysis. The time is automatically adjusted by the tool according to the timescale in the VCD file or the *-waveform_interval* value in the *set_power_analysis_option* command. For example, if the *-waveform_interval* is 10, *-time {13 33}* becomes *-time {10 30}*.

`-when` *`condition`*

Specifies a Boolean condition to determine which simulation times from the VCD should be considered for power analysis. The Boolean condition is a string using names of individual signals in VCD (either annotated to design objects or not annotated), and also operators. Similar to the *-time* option, the *-when* option selects portions of a VCD for analysis. However, with the *-when* option, the times selected are chosen automatically based on logical values in the VCD. During simulation times when the Boolean condition is *true*, the events and power are included in power analysis up to and including the timestamp when the condition becomes false. For simulation times when the Boolean condition is false, the events and power are excluded from analysis up to and including the timestamp when the condition becomes true. The feature can be used in both *averaged* and *time_based* power analysis modes.

`-converter_options` *`option_list`*

Specifies options for external VCD converters. If the *-converter_options* is specified with list of options, the specified options will be used in conjunction with the external VCD converters, vpd2vcd or fsdb2vcd.

`file_name`

Specifies the switching activity file name to be read. If the *file_name* ends with the .gz, .Z, .bz or .bz2, .vpd, or .fsdb extension, it is read as a gzipped, compressed, bzip2ed, VPD (VCD Plus), or FSDB file, respectively; otherwise, it is assumed to be in the VCD format.

Description

The *read_vcd* command specifies the switching activity file generated by simulation to be used for time-based power calculation.

To read in a gzipped VCD file, a compressed VCD file, a BZIP2 file, a VPD file, and an FSDB file, your PATH should include gunzip, uncompress, bunzip, vcs, and fsdb2vcd (a utility from FSDB inventor Novas http://www.novas.com). The VPD file is generated by VCS. So you should define the environment variable VCS_HOME to tell the tool where to find the VCS utility. If you need to invoke 64-bit VCS utility, you need to set the environment variable VCS_MODE_FLAG to 64. You can also define the environment variable NOVAS_HOME to tell the tool where to find the fsdb2vcd executable.

The *-pipe_exec* option allows PrimePower to read in a VCD file directly from simulator, thus avoiding the need to generate a large VCD file. The VCD file name in this scenario serves as a pipe name. After simulation, the VCD file does not exist. There is no need to modify the existing testbench. The file name is treated like a normal VCD output.(inserting $dumpfile, $dumpvars, etc.) Nor is there any need to invoke the simulator. PrimePower automatically runs the simulation and directly read in the VCD output from the simulator.

When a VCD file comes from a zero delay gate level simulation; most of events happen at clock edges. This leads to a very large unrealistic peak power. With the *-zero_delay* option, power is averaged over each clock cycle. This requires you to specify the Synopsys Design Constraint (SDC) file, at least clocks and transition time at primary inputs have to be defined.

If a VCD file comes from RTL simulation, the *-rtl* option should be used. In this case, the *read_vcd* attempts to find the name mapping between the objects in the VCD file and in the gate level netlist automatically. The name mapping rules can be set by the *set_rtl_to_gate_name* command. During the average power calculation, the *update_power* command also automatically propagates the switching activity for those unannotated nets.

Behavior For Different Power Modes

Because of the way analysis is performed in different power analysis modes, the *read_vcd* command has different behavior depending on the power analysis mode. To specify the

power analysis mode, set the *power_analysis_mode* variable to *averaged*, *time_based*, or *leakage_variation*.

In the *averaged* and *leakage_variation* modes, power analysis is performed using toggle rates. In these modes the input activity file is converted to toggle rates and static probabilities, which are annotated onto the design.

In the *time_based* mode, power analysis is performed for individual events in the activity file. The *read_vcd* command is a required part of this flow. In this flow, the header of the activity file is read when the *read_vcd* command is issued, to determine what portion of the design is annotated. The remainder of the activity file is not read until power analysis is performed.

In the *time_based* mode, if you use the *-rtl* option, the tool uses name mapping (see the *set_rtl_to_gate_name* command), and power analysis uses zero delay simulation to create events on unannotated nets. Without the *-rtl* option, name mapping is not used and no events is simulated. It is intended that RTLVCD be in the input if the option is used. In this case, sequential cells, primary inputs, and black box outputs are typically annotated, while combinational nets are not annotated. Events on these unannotated nets must be produced via simulation.

Examples

The following example reads the VCD file dump.vcd from the disk and uses the first 100 ns of the events in the file.

```
pt_shell> read_vcd dump.vcd -time {0 100}
```

The following example runs VCS and pipes the VCD file dump.vcd directly to PrimePower:

```
pt_shell> read_vcd -pipe_exec "vcs -R tb.v design.v" dump.vcd
```

The following example reads a VCD file and excludes time periods when the specified condition is false.

```
pt_shell> read_vcd dump.vcd -when {net125 && net126}
```

Feedback

read_verilog

Reads in one or more Verilog files.

Syntax

status *read_verilog*

```
[-hdl_compiler]
file_names
```

Data Types

file_names	list

Arguments

`-hdl_compiler`

Reads the Verilog files with HDL Compiler through the PrimeTime external reader (ptxr).

file_names

Specifies the names the files to be read.

Description

This command reads one or more structural, gate-level Verilog netlists into PrimeTime. To a locate file with a relative path name, the command searches for the file in each directory specified by the *search_path* variable. The command locates a file with an absolute path name without considering the *search_path* variable. To determine the file that the *read_verilog* command loads, use the *which* command.

After the Verilog files are loaded, view the design objects by using the *list_designs* command. To remove designs, use the *remove_design* command.

The Verilog netlist must contain fully-mapped, structural designs. PrimeTime cannot link or perform timing analysis with netlists that are not fully mapped at the gate level. There must be no Verilog high-level constructs in the netlist.

Reading Verilog Files With the Native Verilog Reader

By default, the *read_verilog* command invokes the native Verilog reader. For large netlists, this reader is much faster and more memory-efficient than HDL Compiler, but it can only read structural Verilog constructs. The native Verilog reader automatically reads ASCII files or compressed gzip files. The reader uncompresses gzip files to a temporary file in the directory specified by the *pt_tmp_dir* variable.

Generally, the native Verilog reader does not create unconnected nets. If you need to have these nets in your design, set the *svr_keep_unconnected_nets* variable to *true*.

Feedback

Structural Constructs Supported by the Native Verilog Reader

The native Verilog reader supports the following subset of the Verilog language:

- module, endmodule
- input, output, inout
- wire
- tri, wand, wor - These constructs are supported, but they are considered to be the same as the wire construct -- that is, there is no special significance to these constructs.
- supply0, supply1 - These constructs create wires that are logic 0 and 1, respectively.
- assign
- tran - An exception from the gate instantiation subset, tran is supported to the extent that it relates one wire to another, as with assign. Beyond that, tran has no special significance.

If you enable the Verilog preprocessor by setting the *svr_enable_vpp* variable to *true*, the native Verilog reader supports the following directives:

- `define
- `else
- `endif
- `ifdef
- `include
- `undef

The PrimeTime Verilog reader reads and ignores the following constructs

- All simulation directives such as `timescale and `expand_vectornets
- parameter
- defparam
- specify, endspecify

Like HDL Compiler, the native Verilog reader accepts the *translate_off* and *translate_on* comment directives to bypass unsupported Verilog features.

Feedback

- To turn translation off, use one of these directives:

```
// synopsys translate_off
/* synopsys translate_off */
```

- To turn translation back on, use one of these directives:

```
// synopsys translate_on
/* synopsys translate_on */
```

The following example shows how to bypass an unsupported feature:

```
// synopsys translate_off
nand (n2, a1, s2);
// synopsys translate_on
```

Assign Statements and Synonyms

The native Verilog reader creates synonyms for discarded names in an assign statement. One net name is chosen, and the others assigned to it are synonyms. During back-annotation, an explicitly named net can be found through one of its synonyms. Although the *get_nets* command finds nets using their synonyms, it cannot find them when mixed with any wildcards. For example, given the assign statement of assign n1 = n2; where n1 wins, using the get_nets command finds the real net, as in:

```
pt_shell> get_nets n1
{"n1"}
```

You can find the net using the synonym. Notice that the result is the real net, n1, and not the synonym, n2 (which is not a real net):

```
pt_shell> get_nets n2
{"n1"}
```

You cannot use wildcards with synonyms:

```
pt_shell> get_nets n2*
Warning: No nets matched 'n2*' (SEL-004)
Error: Nothing matched for nets (SEL-005)
```

Limitations of the Native Verilog Reader

The native Verilog reader in PrimeTime does not support the following:

- Nonstructural constructs - For more information, see the "Structural Constructs Supported by the Native Verilog Reader" section.
- Parameters - The parameter and defparam statements are read and ignored.
- Gate instantiations

There is very limited support for global naming, that is, referencing a wire from a different module. For example, global.gnd means wire gnd in the global module. Global references are allowed only in instance connections; they cannot be in any other context. In addition, you must ensure the following:

- Reference is a logic constant.
- Global reference is not bussed.
- Referenced module is defined in the same file as the module that is referencing it.
- Referenced module is defined first.
- The global name is used over the default name, but a local name is used over the global name. For example, if global.gnd and 1'b0 are used, gnd is the wire name; however, if ZERO is assigned to 1'b0, and global.gnd is also used, ZERO is used.

Reading Verilog Files With HDL Compiler

Instead of using the native Verilog reader, you can optionally use the HDL Compiler reader, which supports the complete Verilog language. However, compared to the native Verilog reader, the HDL Compiler reader uses more CPU and memory.

To read Verilog files with HDL Compiler, use the *read_verilog* command with the *-hdl_compiler* option. This option requires an HDL Compiler license.

When invoking the HDL Compiler Verilog reader, the PrimeTime external reader (ptxr) reads the .synopsys_dc.setup files (not .synopsys_pt.setup). These include the system, home, and local setup files. The system setup file is always read. However, you can skip the home and local setup files by defining the *ptxr_setup_file* variable in PrimeTime to reference a user-defined ptxr-specific setup file. This user-defined variable does not exist until you define it.

You can use the *bus_naming_style* variable to control bus naming, but setting this variable in PrimeTime does not affect the reading of Verilog files with HDL Compiler.

When using the *-hdl_compiler* option, you can terminate the *read_verilog* command by pressing Ctrl+C three times. This terminates the read process but it does not terminate PrimeTime. This is especially useful if you need to terminate the reading of a very long netlist file.

Limitations of Using HDL Compiler

Reading with the *-hdl_compiler* option has these limitations:

- Any variables that affect Verilog reading are read from .synopsys_dc.setup files, not from .synopsys_pt.setup. These variables cannot be set from within PrimeTime. You can set the *ptxr_setup_file* variable in PrimeTime to restrict ptxr so that it reads only the system setup file and ignores your home and local setup files.

Feedback

- Some of the error messages that appear from the *read_verilog* process cannot be found using the *man* command from PrimeTime. You can access these message man pages from other Synopsys shells or from the UNIX man command.
- Pragmas are ignored.
- No warnings are issued if unmapped logic or HDL constructs exist in the Verilog netlist.

Examples

In the following example, the file newcpu.v is read based on the *search_path*.

```
pt_shell> set search_path "/designs/newcpu/v1.6 /libs/cmos"
/designs/newcpu/v1.6 /libs/cmos

pt_shell> read_verilog newcpu.v
Loading verilog file '/designs/newcpu/v1.6/newcpu.v'
1
pt_shell> remove_design -all
Removing design newcpu...

pt_shell> read_verilog newcpu.v -hdl_compiler
Beginning read_verilog...
Loading db file '/release/libraries/syn/standard.sldb'
Loading db file '/release/libraries/syn/gtech.db'
Loading verilog file '/designs/newcpu/v1.6/newcpu.v'
Reading in the Synopsys verilog primitives.
/designs/newcpu/v1.6/newcpu.v:
1
```

Feedback

read_xdomain_design

Reads an cross-domain design written by the *write_xdomain_design* command.

Syntax

status *read_xdomain_design*

[*dir_name*]

Data Types

dir_name	string

Arguments

dir_name

Specifies a directory name from which a cross-domain design is read. An cross-domain design directory created by PrimeTime contains multiple files.

If this option is not specified, the default name, *xdomain_design_directory* is used.

Description

This command seeks to perform SMVA in reduced hardware resource compared to the original testcase. This command reads an cross-domain design written by the *write_xdomain_design* command. Since the cross-domain design is only a smaller subset of the original design, its size is much smaller consuming less memory. After the command finishes, you are ready to run the *update_timing* command and perform your timing, which is comparable to the original design.

Since a cross-domain design consumes less memory than the original design, you can read the cross-domain design in smaller memory slots from computing farms like LSF. For example, suppose your original design requires four 100 GB machines to perform SMVA in LSF farm. Suppose also its cross-domain design reduces memory from 100 GB to 20 GB. With the cross-domain design, now you can perform SMVA in a 20 GB machine from LSF farm.

Examples

This section describes a few examples of *read_eco_design* command usages in both single and multiple scenarios.

Example scripts

Suppose *my_xdomain_design* is a cross-domain design directory created by *write_xdomain_design* command. The following example is a script to read the cross-domain design and performs timing analysis.

```
################################################
# FILE: run_load_and_xdomain.tcl
#   Reads a cross-domain design, performs SMVA
################################################
set timing_cross_voltage_domain_analysis_mode full
read_xdomain_design my_xdomain_design
update_timing...
report_timing...
exit
```

- read_xdomain_design

---

record_training_data

Enables recording of user-scripted ECO cell sizing operations for power recovery, allowing faster power recovery in future sessions using similar design data.

Syntax

```
status record_training_data
```

Arguments

This command has no arguments

Description

The *record_training_data* command enables the PrimeTime tool to learn user-scripted ECO cell sizing operations performed by *size_cell* commands for power recovery. After you run the *record_training_data* command, the tool learns the design context surrounding each cell sized by the *size_cell* command. After performing cell sizing operations, use the *write_training_data* command to save the training data.

In future PrimeTime sessions, you can invoke the same cell sizing operations during ECO power recovery for cells in the same or similar design context. When you use the *fix_eco_power* command, use the *-training_data* option to specify the names of the files previously generated by the *write_training_data* command, or use the *training_data_directory* variable to specify the directory where the training data files can be found.

In this flow, the PrimeTime tool does not check or evaluate the quality or benefit of the *size_cell* commands. It simply records the cell sizing changes and saves the timing and topological conditions surrounding those changes for future use during ECO power recovery.

A PrimeTime-ADV-PLUS license is required to use the *record_training_data* command.

Feedback

Examples

The following example starts power optimization training, performs cell sizing for power recovery, and writes the session training data into a file in a specified absolute path.

```
pt_shell> record_training_data
pt_shell> size_cell U100 ...
  ...
pt_shell> source my_eco_changes.tcl  # Cell sizing for power recovery
  ...
pt_shell> size_cell U200 ...
  ...
pt_shell> write_training_data -output /home/train_dir/my_training.td
```

In a future PrimeTime session using the same design or a similar design, the following command invokes the same cell sizing operations for power optimization using the previously saved training data.

```
pt_shell> fix_eco_power -training_data /home/train_dir/my_training.td ...
```

Alternatively, use the *training_data_directory* variable to specify the directory where the training data files can be found:

```
pt_shell> set_app_var training_data_directory /home/train_dir
/home/train_dir
pt_shell> fix_eco_power ...
```

See Also

- write_training_data

---

redirect

Redirects the output of a command to a file.

Syntax

string *redirect*

```
[-append]
[-tee]
[-file | -variable | -channel]
[-compress]
[-bg]
target
command_string
```

Feedback

Data Types

target	string
command_string	string

Arguments

`-append`

Appends the output to the *target* argument.

`-tee`

Like the UNIX command of the same name, sends output to the current output channel as well as to the *target* argument.

`-file`

Indicates that the *target* argument is a file name, and redirection is to that file. This is the default. It is exclusive of the *-variable* and *-channel* options.

`-variable`

Indicates that the *target* argument is a variable name, and redirection is to that Tcl variable. It is exclusive of the *-file* and *-channel* options.

`-channel`

Indicates that the *target* argument is a Tcl channel, and redirection is to that channel. It is exclusive of the *-variable* and *-file* options.

`-compress`

Compresses when writing to file. If redirecting to a file, this option specifies that the output should be compressed as it is written. The output file is in a format recognizable by "gzip -d". You cannot specify this option with the *-append* option.

`-bg`

Indicates that the redirected command executes in the background and in parallel with other foreground commands downstream. PrimeTime returns immediately to execute the next command after this redirect command, unless the next command is *exit* or *quit*, which blocks the run until all background commands with the *-bg* option are finished. Note the *-bg* option must be used together with the *-file* option and no other options are allowed. Redirect command returns the PID of the background process when this option is specified. If the process cannot be successfully started, an empty string is returned.

target

Indicates the target of the output redirection. This is either a filename, Tcl variable, or Tcl channel depending on the command arguments.

command_string

The command to execute. Intermediate output from this command, as well as the result of the command, is redirected to the *target* argument. The *command_string* option should be rigidly quoted with curly braces.

Description

The *redirect* command performs the same function as the traditional UNIX-style redirection operators > and >>. The *command_string* option must be rigidly quoted (that is, enclosed in curly braces) in order for the operation to succeed.

Output is redirected to a file by default. Output can be redirected to a Tcl variable by using the *-variable* option, or to a Tcl channel by using the *-channel* option.

Output can be sent to the current output device, as well as the redirect target by using the *-tee* option. See the Examples section for an example.

The result of a *redirect* command which does not generate a Tcl error, is the empty string. Screen output occurs only if errors occurred during execution of the *command_string* option (other than opening the redirect file). When errors occur, a summary message is printed. See the Examples section for an example.

Although the result of a successful *redirect* command is the empty string, it is still possible to get and use the result of the command that you redirected. Construct a *set* command in which you set a variable to the result of your command. Then, redirect the *set* command. The variable holds the result of your command. See the Examples section for an example.

The *redirect* command is much more flexible than traditional Unix redirection operators. With the *redirect* command, you can redirect multiple commands or an entire script. See the Examples section for an example of how to construct such a command.

Note that the built-in *puts* Tcl command does not respond to output redirection of any kind. Use the built-in *echo* command instead.

The *-bg* option is introduced to enable parallel processing on multicore hardware for performance reasons. PrimeTime returns immediately to execute the next command after this redirect command, unless the next command is *exit* or *quit*, which blocks the process until all background commands launched with the *-bg* option previously are finished. Note the *-bg* option must be used together with the *-file* option and no other options are allowed.

It is also very important to understand that the *-bg* option for the *redirect* command is targeted for post-update reporting and analysis commands. Any command executed in the background causes changes to timing data and triggers incremental update, which result in severe error and stop of execution. In addition, it is advisable to intentionally block

the foreground process if the command to be executed invalidates the existing timing analysis, such as the *update_timing*, *update_noise*, *remove_design* commands. Refer to the *parallel_execute* man page for more details. Use of the *parallel_execute* command is recommended whenever applicable to perform parallel execution of commands.

Examples

In the following example, the output of the plus procedure is redirected. The echoed string and the result of the plus operation is in the output file. Notice that the result was not echoed to the screen.

```
prompt> proc plus {a b} {echo "In plus" ; return [expr $a + $b]}
prompt> redirect p.out {plus 12 13}
prompt> exec cat p.out
In plus
25
```

In this example, a typo in the command created an error condition. The error message indicates that you can use the *error_info* command to trace the error, but you should first check the output file.

```
prompt> redirect p.out {plus2 12 13}
Error: Errors detected during redirect
        Use error_info for more info. (CMD-013)
prompt> exec cat p.out
Error: unknown command 'plus2' (CMD-005)
```

In this example, we explore the usage of results from redirected commands. Since the result of the *redirect* command for a command which does not generate a Tcl error is the empty string, use the *set* command to trap the result of the command. For example, assume that there is a command to read a file which has a result of "1" if it succeeds, and "0" if it fails. If you redirect only the command, there is no way to know if it succeeded.

```
        redirect p.out { read_a_file "a.txt" }
# Now what?  How can I redirect and use the result?
```

But if you set a variable to the result, then it is possible to use that result in a conditional expression and so forth.

```
        redirect p.out { set rres [read_a_file "a.txt"] }
if { $rres == 1 } {
  echo "Read ok!"
}
```

Feedback

The *redirect* command is not limited to redirection of a single command. You can redirect entire blocks of a script with a single *redirect* command. This example with the *echo* command demonstrates this feature:

```
prompt> redirect p.out {
?         echo -n "Hello "
?         echo "world"
?       }
prompt> exec cat p.out
Hello world
prompt>
```

The *redirect* command allows you to tee output to the previous output device and also to redirect output to a variable. This example with the *echo* command demonstrates these features:

```
prompt> set y "This is "
This is
prompt> redirect -tee x.out {
          echo XXX
          redirect -variable y -append {
            echo YYY
            redirect -tee -variable z {
              echo ZZZ
            }
          }
        }
XXX
prompt> exec cat x.out
XXX
prompt> echo $y
This is YYY
ZZZ

prompt> echo $z
ZZZ
```

---

redo

Reverses the effects of a previous *undo* command.

Feedback

Syntax

```
status redo
[-levels num_levels
[-check_only]
[-silent]
```

Data Types

```
num_levels      integer
```

Arguments

`-levels num_levels`

Redoes the effects of the specified number of undo command levels. The default is 1.

`-check_only`

Causes the command to return the same status and messages it would otherwise return without actually changing anything.

`-silent`

Suppresses messages and Tcl errors.

Description

This command redoes the effects of one or more previous *undo* commands.

The redone commands can be undone using the *undo* command again.

Examples

The following example undoes the result of *size_cell* and then redoes it.

```
pt_shell> size_cell InstSimple/InterNand ND2X4
 ...
pt_shell> undo
 ...
pt_shell> redo
 ...
```

See Also

- undo
- undo_config

Feedback

remote_execute

Builds a buffer of commands and triggers execution of these commands on remote workers.

Syntax

status *remote_execute*

```
[-pre_commands pre_command_string]
[-post_commands post_command_string]
[-verbose]
command_string
```

Data Types

pre_command_string	string
post_command_string	string
command_string	string

Arguments

`-pre_commands` *pre_command_string*

Specifies a string of commands to be executed in the worker context before the execution of the default command string. Commands are grouped using the semicolon ";" character.

`-post_commands` *post_command_string*

Specifies a string of commands to be executed in the worker context after the execution of the default command string. Commands are grouped using the ";" character.

`-verbose`

Specifies that the worker output should be piped back to the manager console.

command_string

Specifies a string of commands to be executed in the worker context. To group commands, use the semicolon ";" character.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

The *remote_execute* command builds up a buffer of commands and triggers execution of these commands on remote workers. All commands in the buffer are executed in the order in which they enter the buffer. This command can only be executed when you have set the current session. Use curly braces { } to force variables and expressions to be evaluated

in a worker context. Use quotation marks (" ") to force variables and expressions to be evaluated in a manager context.

Multi-Scenario Analysis Mode

In the multi-scenario analysis mode, the very first invocation of the *remote_execute* command for a particular session triggers baseline image generation.

Use the *-pre_commands* and *-post_commands* options to specify commands to be executed before and after the commands being remotely executed.

Examples

In the following examples, the s1 scenario is in focus. In the following example, the *remote_execute* command is used to execute a nonmerged report_timing. The output of the *report_timing* command is found in the $multi_scenario_working_directory/s1/out.log file.

```
pt_shell> remote_execute  {report_timing}

Start of Manager/Worker Task Processing
-----------------------------------
Started  : Command execution in scenario 's1'
Command execution in scenario 's1' : Succeeded
Finished : Command execution in scenario 's1'
-----------------------------------
End of Manager/Worker Task Processing
1
```

In the next example, the situation is as in the first example except that the *-pre_commands* option is used to set a variable before the report.

```
pt_shell> remote_execute  -pre_commands {set
rc_slew_lower_threshold_pct_fall 30.0} {report_timing}

Start of Manager/Worker Task Processing
-----------------------------------
Started  : Command execution in scenario 's1'
Command execution in scenario 's1' : Succeeded
Finished : Command execution in scenario 's1'
-----------------------------------
End of Manager/Worker Task Processing
1
```

Feedback

remove_annotated_check

Removes annotated timing checks from the design, either on specific cells, between specific pins, or on all cells in the current design.

Syntax

status *remove_annotated_check*

```
[-all]
[-from from_pins]
[-to to_pins]
[-rise]
[-fall]
[-clock clock_check]
[-setup | -recovery]
[-hold | -removal]
[-nochange_low]
[-nochange_high]
[-width]
[object_spec]
```

Data Types

from_pins	list
to_pins	list
clock_check	string
object_spec	list

Arguments

`-all`

Removes all annotated timing checks in the design. This option is exclusive of the *-from*, *-to*, and *object_spec* options. Options that specify the type of the timing check, such as *-setup* and *-hold* are ignored when you use the *-all* option.

`-from` *from_pins*

Specifies a list of leaf cell pins that are the startpoints of the timing arcs for which annotated checks are to be removed. You must use the *-from* option with the *-to* option, and you cannot combine these options with the *object_spec* option.

`-to` *to_pins*

Specifies a list of leaf cell pins that are the endpoints of the timing arcs for which annotated checks are to be removed. You must use the *-from* option with the *-to* option, and you cannot combine these options with the *object_spec* option.

`-rise`

Specifies that the timing check is for the rise transition on the constrained (the data *-to* pin). The *-rise* and *-fall* options are mutually exclusive. If you do not specify either the *-rise* or *-fall* option, both values are removed.

`-fall`

Specifies that the timing check is for the fall transition on the constrained (the data *-to* pin). The *-rise* and *-fall* options are mutually exclusive. If you do not specify either the *-rise* or *-fall* option, both values are removed.

`-clock` *clock_check*

Specifies whether the check is for clock rising or falling. By default, checks for both clock rise and fall are removed. The valid values for the *clock_check* options are *rise* or *fall*.

`-setup`

Removes only setup timing check information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed; however, you cannot specify the *-setup* option with the *-recover* option.

`-recovery`

Removes only recovery timing check information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed; however, you cannot specify the *-setup* option with the *-recover* option.

`-hold`

Removes only hold timing check information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed; however, you cannot specify the *-hold* option with the *-removal* option.

`-removal`

Removes only removal timing check information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed; however, you cannot specify the *-hold* option with the *-removal* option.

`-nochange_low`

Removes only nochange timing check information against data low information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed;

however, you cannot specify the *-nochange_low* option with the *-nochange_high* option.

`-nochange_high`

Removes only nochange timing check information against data high information. If no timing check option is specified for removal, all annotated timing checks are removed. You can specify more than one type of timing check to be removed; however, you cannot specify the *-nochange_low* option with the *-nochange_high* option.

`-width`

Removes only minimum pulse width check annotation.

`object_spec`

Removes annotated timing checks from the specified list of leaf cells. You cannot combine this option with the *-from* and *-to* options.

Description

This command removes annotated timing checks from the design, either on specific cells, between specific pins, or on all cells in the current design. Timing checks are annotated either from a Standard Delay Format (SDF) file by using the *read_sdf* or *set_annotated_check* command. Timing check types include setup, hold, recovery, removal, and nochange.

You can use the *remove_annotated_check* command in the following ways:

- You can remove all annotated checks from the entire design by using the *-all* option; in this case, you cannot remove a specific check. The command ignores options that specify the type of the timing check such as, the *-setup* and *-hold* options when you use the *-all* option.
- You can remove annotated checks from a list of cells by using the *object_spec* option. Without specifying any timing check type options, the command removes all annotated checks from each cell in the list. By using options that specify the type of the timing check, such as the *-setup* and *-hold* option you can remove only specific checks. You can use this method to remove all checks of a certain type from the entire design. For an example, see the EXAMPLES section.
- You can remove annotated checks between specific pins by using the *-from* and *-to* options. Each from/to pair must be on the same cell. Without specifying any timing check type options, the command removes all annotated checks from each from/to pair. By using options that specify the type of the timing check,, such as the *-setup* and *-hold* options, you can remove only specific checks.

Examples

The following example removes all annotated cell timing checks from the current design.

Feedback

```
pt_shell> remove_annotated_check -all
1
```

The following example removes only setup checks from all cells in the current design.

```
pt_shell> remove_annotated_check -setup [get_cells *]
1
```

The following example removes checks between pins. It also shows the error condition when the pins are not on the same cell and the warning when there are no annotated checks.

```
pt_shell> remove_annotated_check -from ffb/CP -to ffa/D

Error: Cannot remove annotated check from 'ffb/CP' to 'ffa/D':
       pins are on different cells (PTE-032)
0
pt_shell> remove_annotated_check -from ffa/CP -to ffa/D -setup -hold
1
pt_shell> remove_annotated_check -from ffa/CP -to ffa/D
Warning: No annotated timing checks were removed. (PTE-031)
0
```

---

remove_annotated_clock_network_power

Removes the annotated power on clock networks.

Syntax

status *remove_annotated_clock_network_power*

```
[-clock domain_clock]
```

Data Types

```
domain_clock     string
```

Feedback

Arguments

`-clock` *domain_clock*

Specifies the clock of the related clock network on which the annotated power values are removed.

Description

The *remove_annotated_clock_network_power* command removes the annotated power information specified by the *set_annotated_clock_network_power* command on the current design. If the *-clock* option is used, only the annotated clock network power for the specific clock domain is removed; otherwise, the annotated power values for all clock domains are removed. If the power is not annotated for the specified clock domain, a PWR-294 error message is issued and the command fails.

Examples

In the following example, the *remove_annotated_clock_network_power* command is used before the *report_power* command and after the *set_annotated_clock_network_power* command. The output from the *report_power* command is not affected.

```
pt_shell> set_annotated_clock_network_power -internal 1.0e-03 -switching
 2.0e-03
pt_shell> remove_annotated_clock_network_power
pt_shell> report_power
```

See Also

- report_power
- set_annotated_clock_network_power

---

remove_annotated_delay

Removes annotated delays from the design, either on specific cells or nets, between specific pins, or all annotated delays in the design.

Syntax

status *remove_annotated_delay*

```
[-all]
[-from from_list]
[-to to_list]
[object_spec]
```

Feedback

Data Types

from_list	list
to_list	list
object_spec	list

Arguments

`-all`

Removes all annotated delays in the design. This option is exclusive of the *-from*, *-to*, and *object_spec* options.

`-from` *from_list*

Specifies a list of pins or ports that are the startpoints of the timing arcs for which annotated delays are removed. You cannot combine this option with the *object_spec* option.

`-to` *to_list*

Specifies a list of pins or ports that are the endpoints of the timing arcs for which annotated delays are removed. You cannot combine this option with the *object_spec* option.

object_spec

Removes all annotated delays from the specified list of leaf cells or nets. You cannot combine this option with the *-from* and *-to* options.

Description

The *remove_annotated_delay* command removes annotated cell and net delays from the current design. Delays are annotated either from an SDF file (using the *read_sdf* command) or by using the *set_annotated_delay* command.

There are several ways to use the *remove_annotated_delay* command.

- You can remove all annotated delays from the entire design using the *-all* option.
- You can remove all annotated delays from a list of cells or nets using the *object_spec* option.
- You can remove annotated delays between specific pins using the *-from* and *-to* options.

Examples

The following example removes all annotated net and cell delays from the current design.

```
pt_shell> remove_annotated_delay -all
1
```

The following example removes annotated delays from specific cells.

```
pt_shell> remove_annotated_delay [get_cells u1*]
1
```

The following example removes annotated delays between pins. Also shown is the warning when there are no annotated delays between the specified pins.

```
pt_shell> remove_annotated_delay -from ffb/Q
1
pt_shell> remove_annotated_delay -from ffb/Q -to u1/A
Warning: No annotated delays from 'ffb/Q' to 'u1/A'. (PTE-030)
0
```

---

remove_annotated_parasitics

Removes all annotated parasitics from nets of the current design.

Syntax

status *remove_annotated_parasitics*

```
[-all]
[net_list ]
```

Data Types

net_list	list

Arguments

`-all`

Indicates that all annotated nets in the design are to be removed, which is the default. The *-all* and *net_list* options are mutually exclusive.

net_list

Specifies a list of nets from which annotated parasitics are to be removed. By default, all annotated parasitics are removed from the design. The *-all* and *net_list* options are mutually exclusive.

Description

This command removes all net parasitics annotated on nets of the current design. The annotated parasitics are usually added using the *read_parasitics* command to read a SPEF or standard parasitic format (SPF) file and annotate the parasitics on nets of the current design. The *remove_annotated_parasitics* command also removes the annotated parasitics completed by the *complete_net_parasitics* command.

There are two ways to use the *remove_annotated_parasitics* command.

- You can remove all annotated parasitics from the entire design by using the *-all* option or by executing the command without options.
- You can remove all annotated parasitics from a list of nets using the *net_list* option.

Examples

The following example removes all annotated net parasitics from the current design.

```
pt_shell> remove_annotated_parasitics -all
1
```

The following example removes annotated parasitics from the net "CLK".

```
pt_shell> remove_annotated_parasitics [get_nets CLK]
1
```

See Also

---

remove_annotated_power

Removes previously annotated power from unresolved black box cells or leaf cells.

Syntax

status *remove_annotated_power*

```
-all
cell_list
```

Feedback

Data Types

cell_list list

Arguments

-all

Specifies that all annotated powers in the design are to be removed. The *-all* and *cell_list* options are mutually exclusive.

cell_list

Specifies a list of cells from which annotated powers are to be removed. The *-all* and *cell_list* options are mutually exclusive.

Description

The *remove_annotated_power* command removes internal power and leakage power that were previously annotated on cells by using the *set_annotated_power* command. There is no way to remove only internal power or leakage power.

Examples

The following example shows how power is annotated, removed, and reported.

```
pt_shell> set_annotated_power -internal_power 1 -leakage_power 0.01 u0/*
1
pt_shell> report_annotated_power -list_annotated
****************************************

---

remove_annotated_transition

Removes previously-annotated transition times from pins or ports in the current design.

Syntax

status *remove_annotated_transition*

```
-all
pin_or_port_list
```

Data Types

```
pin_or_port_list     list
```

Arguments

`-all`

Removes all annotated transition times in the design. You cannot use this option together with the *pin_list* option.

`pin_or_port_list`

Removes annotated transition times from the specified list of pins or ports. You cannot use this option together with the *-all* option.

Description

The *remove_annotated_transition* command removes transition times previously annotated on pins or ports from the current design using the *set_annotated_transition* command.

To view current settings, use the *report_timing* command.

Feedback

Examples

The following example removes all annotated pin and port transition times from the current design.

```
pt_shell> remove_annotated_transition -all
1
```

The following example removes annotated transition time from the input pin *A* of cell "U1/U2/U3".

```
pt_shell> remove_annotated_transition [get_pins U1/U2/U3/A]
1
```

---

remove_aocvm

Removes advanced and parametric on-chip variation (AOCV / POCV) information.

Syntax

status *remove_ocvm*

```
[-coefficient]
[-derate]
[object_list]
```

Data Types

object_list list

Arguments

-coefficient

Removes only the AOCV coefficients. The *-coefficient* and *-derate* options are mutually exclusive.

Feedback

`-derate`

Removes only the AOCV/POCV derating factors. The *-coefficient* and *-derate* options are mutually exclusive.

`object_list`

Specifies the objects from which AOCV/POCV information is removed.

Description

Removes user-specified AOCV coefficients and AOCV/POCV derating factors that were previously set with the *set_aocvm_coefficient* and *read_ocvm* commands, respectively. If the command is specified with no options, all AOCV/POCV data is removed.

To display AOCV/POCV deratings and coefficients, use the *report_ocvm* command.

Examples

The following example removes the AOCV coefficients from the library cell named lib/bufA:

```
pt_shell> remove_ocvm -coefficient lib/bufA
```

The following example removes all AOCV/POCV derating factors that were set using the *read_ocvm* command:

```
pt_shell> remove_ocvm -derate
```

The following example removes all AOCV/POCV derating factors from the current design:

```
pt_shell> remove_ocvm -derate [current_design]
```

See Also

- read_ocvm
- report_ocvm
- set_aocvm_coefficient

---

remove_buffer

Removes specified buffers from the current design.

Syntax

int *remove_buffer*

```
[-all_mim_instances]
cell_list
```

Feedback

Data Types

cell_list list

Arguments

cell_list

Specifies a list of buffer cells to be removed.

-all_mim_instances

Removal of buffer cells in one MIM instance is replicated in all instances of a MIM set.

Description

The *remove_buffer* command is used to remove buffer cells from the netlist. A buffer is one or more cells that conforms to the rules the *insert_buffer* command uses to create buffers. Like all other netlist editing commands, for the *remove_buffer* command to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. The *remove_buffer* command returns a 1 if successful and a 0 if unsuccessful.

If the input and output net of the buffer has parasitics, they are stitched into the resulting net, by default.

The *remove_buffer* command with *-all_mim_instances"* option applies changes to all the instances of the MIM set.

Suppose a CPU module is instantiated four times in the TOP module as CPU1, CPU2, CPU3 and CPU4.

The following example shows *remove_buffer* command being used in one instance of a MIM set i.e CPU1 with *-all_mim_instances"* option. The changes are replicated to all the other MIM instances of the set i.e CPU2, CPU3, CPU4.

```
pt_shell> remove_buffer CPU1/U3 -all_mim_instances"
Removed buffer 'CPU1/U3'.
Removed buffer 'CPU2/U3'.
Removed buffer 'CPU3/U3'.
Removed buffer 'CPU4/U3'.
1
```

Similar to the *insert_buffer* command, the arguments for the *remove_buffer* command can be grouped. The basic interpretation of the *cell_list* is

```
(one non-inverting buffer | two cascaded inverting buffers)+
```

To determine whether a removable buffer configuration exists, the *remove_buffer* command applies the following rules to the cells in the *cell_list*:

- Each cell must be a buffer as defined by the *insert_buffer* command
- The input pin of each cell must be connected to a net
- For multioutput cells, only one output pin can be connected
- There can be no standalone inverting cells
- The output net cannot be multidriven
- Inverter pairs must be connected together and the intermediate net can be connected only to the two inverters

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
```

Feedback

```
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

The following diagram contains inverters U1 and U2:

```
e1/Z -- old_net -- U1 -- net1 --- U2 -- net2 --- e3/A
```

The following example removes U1 and U2.

```
pt_shell> remove_buffer {U1 U2}
Removed buffer 'U1', 'U2'

1
```

After removing the buffer, the configuration is as follows:

```
e1/Z -- old_net --- e3/A
```

See Also

- write_changes

---

remove_capacitance

Removes capacitance on nets or ports.

Syntax

```
status remove_capacitance
  net_or_port_list
```

Data Types

```
net_or_port_list      list
```

Feedback

Arguments

net_or_port_list

Specifies a list of ports and nets in the current design, whose capacitances are removed.

Description

Specifies that the lumped capacitance annotated on the list of nets or ports must be removed. PrimeTime reverts to using the capacitance from detailed parasitics (set using the *read_parasitics* command), if they exist. If not, the internally estimated net capacitance is used.

Annotated capacitances are also removed on the full design by doing a *reset_design*.

Examples

The following example removes the annotated capacitance on net w23.

```
pt_shell> remove_capacitance [get_nets "w23"]
```

The following example removes the annotated capacitance on all ports that name match "P2*".

```
pt_shell> remove_capacitance [get_ports "P2*"]
```

---

remove_case_analysis

Removes the case analysis value on input.

Syntax

```
status remove_case_analysis
  [-all]
  port_or_pin_list
```

Feedback

Data Types

port_or_pin_list list

Arguments

-all

Removes all logic constant values from the current design. Using this option overrides any port or pin specifications.

port_or_pin_list

Removes case analysis from the specified ports or pins.

Description

This command removes previously specified entries of case analysis on ports or pins. You must specify either the *port_or_pin_list* or *-all* option.

To specify case analysis, run the *set_case_analysis* command.

Examples

The following example specifies that ports in0 and in2 are set to the constant logic value 0:

```
pt_shell> set_case_analysis 0 {in0 in2}
pt_shell> report_case_analysis

****************************************
Report : case_analysis
 ...
****************************************

Pin name                 Case analysis value
---------------------------------------------
in2                      0
in0                      0
```

The following example removes the case analysis entry on port in2:

```
pt_shell> remove_case_analysis {in2}
pt_shell> report_case_analysis

****************************************
Report : case_analysis
 ...
****************************************

Pin name                 Case analysis value
---------------------------------------------
in0                      0
```

Feedback

See Also

- report_case_analysis
- set_case_analysis

---

remove_case_sequential_propagation

Disables case propagation for sequential cell instances or library cells.

Syntax

```
status remove_case_sequential_propagation
  [-all]
  cellinstance_or_libcell_list
```

Data Types

```
cellinstance_or_libcell_list     list
```

Arguments

`-all`

Disables case propagation on all sequential cell instances or library cells.

cellinstance_or_libcell_list

Disables case propagation on the specified sequential cell instances or library cells.

Description

This command disables previously enabled cell instances or library cells for selective sequential propagation. Selective sequential propagation can be enabled for a supported sequential cell using the *set_case_sequential_propagation* command.

To disable sequential propagation on a set of a set of previously enabled cell instances or library cells for sequential propagation, set the *case_analysis_sequential_propagation* variable to *never*.

Examples

The following example enables sequential propagation on cell FF1, FF2, and FF3 and subsequently disables FF1.

```
pt_shell> set_case_sequential_propagation FF1
pt_shell> set_case_sequential_propagation {FF2 FF3}
pt_shell> report_case_analysis -sequential_propagation
****************************************
Report : case_analysis
        -sequential_propagation
```

```
 ...
****************************************

--------------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 3
--------------------------------------------------------------------
Cell Instance : 'FF1'
Cell Instance : 'FF2'
Cell Instance : 'FF3'
--------------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 0
--------------------------------------------------------------------

pt_shell> remove_case_sequential_propagation FF1
pt_shell> report_case_analysis -sequential_propagation
****************************************
Report : case_analysis
        -sequential_propagation
 ...
****************************************

--------------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 2
--------------------------------------------------------------------
Cell Instance : 'FF2'
Cell Instance : 'FF3'
--------------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 0
--------------------------------------------------------------------
```

The following example enables sequential propagation on all cell instances with the same library cell 'snps_test/D_FF' and 'snps_test/D_FF_R'. Additionally, cell instances FF1 and FF2 are enabled in the same list.

```
pt_shell> set_case_sequential_propagation { snps_test/D_FF
 snps_test/D_FF_R FF1 FF2 }
pt_shell> report_case_analysis -sequential_propagation
****************************************
Report : case_analysis
        -sequential_propagation
 ...
****************************************

--------------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 2
--------------------------------------------------------------------
Cell Instance : 'FF1'
Cell Instance : 'FF2'
--------------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 2
--------------------------------------------------------------------
```

```
Library Cell : 'snps_test/D_FF_R'
Library Cell : 'snps_test/D_FF'
```

The following example disables sequential propagation on all enabled cell instances and library cells.

```
pt_shell> remove_case_sequential_propagation -all
pt_shell> report_case_analysis -sequential_propagation
****************************************
Report : case_analysis
        -sequential_propagation
 ...
****************************************

--------------------------------------------------------------------
Selective Sequential Propagation Cells : Total = 0
--------------------------------------------------------------------
Selective Sequential Propagation Lib Cells : Total = 0
--------------------------------------------------------------------
```

See Also

- report_case_analysis
- set_case_analysis
- set_case_sequential_propagation
- case_analysis_sequential_propagation

---

remove_cell

Removes cells from the current design.

Syntax

int *remove_cell*

```
-all
cell_list
```

Data Types

```
cell_list      list
```

Arguments

`-all`

Indicates that all cells are to be removed from the current design. The *-all* and *cell_list* options are mutually exclusive; you can specify only one.

Note: Using the *-all* option at the top of the design effectively removes the entire design.

cell_list

Specifies a list of cells to be removed from the current design. The *-all* and *cell_list* options are mutually exclusive; you can specify only one.

Description

The *remove_cell* command removes cells from the current design. Like all other netlist editing commands, for the *remove_cell* command to succeed, all of its arguments must succeed. If any arguments fail, the netlist remains unchanged. The *remove_cell* command returns a 1 if successful and a 0 if unsuccessful.

Each cell specified must be in scope; that is, at or below the current instance. The *remove_cell* command can be used on leaf cells or hierarchical cells. Duplicate arguments of the *remove_cell* command are ignored with a warning. As the *remove_cell* command progresses, it echoes the cells passed to it. However, only the cells that were actually deleted are logged to the change list. For more information, see the EXAMPLES section.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following example, the first command shows the cells within u1 and u2. The second command removes what appears to be four cells; in fact, more than four cells are deleted. Because u1 and u2 each contain three cells, a total of eight cells are actually deleted. Note also that the change list has only three entries. Because u1/u2 is contained within u1 and is removed after u1, u1/u2 is dropped from the change list.

```
pt_shell> get_cells {u1/* u2/*}
{"u1/u1", "u1/u2", "u1/u3", "u2/u1", "u2/u2", "u2/u3"}
pt_shell> remove_cell {u1 u1/u2 u2/u3 u2}
Information: Removed cell 'u1'. (NED-015)
Information: Removed cell 'u1/u2'. (NED-015)
Information: Removed cell 'u2/u3'. (NED-015)
Information: Removed cell 'u2'. (NED-015)
1
pt_shell> write_changes
########################################
# Change list, formatted for PrimeTime
########################################
current_instance
remove_cell {u1}
current_instance
current_instance u2
remove_cell {u3}
current_instance
remove_cell {u2}
1
```

Feedback

- write_changes

---

remove_clock

Removes one or more clocks from the current design.

Syntax

string *remove_clock*

```
-all
clock_list
```

Data Types

```
clock_list      list
```

Arguments

`-all`

Specifies to remove all clocks in the current design.

clock_list

Specifies a list of collections containing clocks or patterns matching the clock names.

Description

Removes the specified clock objects from the current design. You must specify either the *clock_list* or *-all* options.

If a removed clock is the only member of a path group, the path group is also removed. For information about path groups, refer to the *group_path* command man page. To list all clock sources in the design, use the *report_clock* command.

All arrival and required times specified by the *set_input_delay* and *set_output_delay* commands relative to the clock that is being removed are also removed.

Examples

The following example removes clock CLK1.

```
pt_shell> remove_clock CLK1
```

The following example removes all clocks from the current design.

Feedback

```
pt_shell> remove_clock -all
```

See Also

---

remove_clock_exclusivity

Removes the clock exclusivity setting on cell previously set by the *set_clock_exclusivity* command.

Syntax

status *remove_clock_exclusivity*

```
[-output output_pins]
[-all]
```

Data Types

output_pins	list

Arguments

`-output` *output_pins*

Specifies the output pin of a cell that has been previously set as exclusive by the *set_clock_exclusivity* command.

`-all`

Removes all clock exclusivity settings in the current design previously set by the *set_clock_exclusivity* command.

Feedback

Description

This command removes the exclusivity previously set on an output pin of a cell by the *set_clock_exclusivity* command. In that case, the tool will no longer infer exclusivity of clocks that pass through the cell and reach that output pin.

Examples

The following example removes two points of exclusivity previously set by the *set_clock_exclusivity* command:

```
pt_shell> remove_clock_exclusivity -output {AND37/A AND37/B}
```

The following example removes all the exclusivities from the current design.

```
pt_shell> remove_clock_exclusivity -all
```

See Also

- set_clock_exclusivity
- report_clock
- set_disable_auto_mux_clock_exclusivity
- timing_enable_auto_mux_clock_exclusivity

---

remove_clock_gating_check

Removes clock-gating checks.

Syntax

```
status remove_clock_gating_check
   [-setup]
   [-hold]
   [-rise]
   [-fall]
   [-high]
   [-low]
   [-sms_scenarios sms_scenarios_list]
   [object_list]
```

Data Types

```
object_list       list
```

Feedback

Arguments

`-setup`

Removes the clock-gating constraint on the setup time only. If you do not specify either the *-setup* or *-hold* option, both setup and hold constraints are removed.

`-hold`

Removes the clock-gating constraint on the hold time only. If you do not specify either the *-setup* or *-hold* option, both setup and hold constraints are removed.

`-rise`

Removes the clock-gating constraint on the rising delays only. If you do not specify either the *-rise* or *-fall* option, constraints on both rising and falling delays are removed.

`-fall`

Removes the clock-gating constraint on the falling delays only. If you do not specify either the *-rise* nor *-fall* option, constraints on both rising and falling delays are removed.

`-high`

Removes the high specification from the object list, previously set up by the *set_clock_gating_check* command. This option has to be either high or low.

`-low`

Removes the low specification from the object list, previously set up by the *set_clock_gating_check* command. This option has to be either high or low.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios for which the removal applies. When this option is not given, the removal applies to all SMS scenarios. This collection is created by the *get_sms_scenarios* command.

`object_list`

Specifies a list of objects in the current design from which to remove the clock gating check. The objects can be clocks, pins, or cells. If you specify a cell, all input pins of that cell are affected. If you do not specify any objects, the clock-gating check is removed from the current design.

Description

The *remove_clock_gating_check* command removes clock gating checks for design objects set by the *set_clock_gating_check* command.

An alternative way to remove information set by the *set_clock_gating_check* command is to use the *reset_design* command.

Feedback

Examples

The following example removes the setup requirement (for rising and falling delays) on all gates in the clock network involved with clock CK1 path.

```
pt_shell> remove_clock_gating_check -setup [get_clocks CK1]
```

The following example removes the hold requirement on the rising delay of gate and1.

```
pt_shell> remove_clock_gating_check -hold -rise [get_cells and1]
```

See Also

- remove_disable_clock_gating_check
- report_constraint
- reset_design
- set_clock_gating_check
- set_disable_clock_gating_check

---

remove_clock_groups

Removes specific exclusive or asynchronous clock groups from the current design.

Syntax

```
status remove_clock_groups
   [-logically_exclusive]
   [-physically_exclusive]
   [-exclusive]
   [-asynchronous]
   [-name name_list]
   [-all]
```

Data Types

name_list list

Arguments

-logically_exclusive

Specifies that the groups set for logically exclusive clocks are to be removed. The *-physically_exclusive*, *-logically_exclusive*, and *-asynchronous* options are mutually exclusive; you must choose only one.

Feedback

`-physically_exclusive`

Specifies that the groups set for physically exclusive clocks are to be removed. The *-physically_exclusive*, *-logically_exclusive*, and *-asynchronous* options are mutually exclusive; you must choose only one.

`-exclusive`

Specifies that the groups set for logically exclusive clocks are to be removed.

`-asynchronous`

Specifies that groups set for asynchronous clocks are to be removed. The *-physically_exclusive*, *-logically_exclusive*, and *-asynchronous* options are mutually exclusive; you must choose only one.

`-name` *`name_list`*

Specifies a list of clock groups to be removed, which matches the groups in the given names. These clock groups are predefined by the *set_clock_groups* command. The *-name* and *-all* options are mutually exclusive.

`-all`

Specifies to remove all groups set for exclusive or asynchronous clocks in the current design. The *-name* and *-all* options are mutually exclusive.

Description

This command removes specific exclusive or asynchronous clock groups from the current design. You must specify either the *-exclusive* or *-asynchronous* option. You must specify either the *name_list* or *-all* option.

To list the existing clock groups, run the *report_clock* command with the *-groups* option.

Examples

The following example removes exclusive clock groups named mux.

```
pt_shell> remove_clock_group -exclusive -name mux
```

The following example removes all asynchronous clock groups from the current design.

```
pt_shell> remove_clock_group -asynchronous -all
```

See Also

- get_clock_relationship
- report_clock
- set_clock_groups

Feedback

remove_clock_jitter

Removes clock jitter information previously set by the *set_clock_jitter* command.

Syntax

```
status remove_clock_jitter
   -clock clock_list
```

Data Types

```
clock_list     list
```

Arguments

`-clock clock_list`

Specifies a list of clocks from which to remove the clock jitter.

Description

This command removes the cycle-to-cycle jitter or the duty-cycle jitter of the clock that was previously set by the *set_clock_jitter* command.

Examples

The following example removes the cycle-to-cycle jitter of 0.5 and duty-cycle jitter of 0.7 specified on the clock mclk

```
pt_shell> set_clock_jitter -clock [get_clocks mclk] -cycle 0.5
 -duty_cycle 0.7
pt_shell> remove_clock_jitter -clock [get_clocks mclk]
```

See Also

- report_clock_jitter
- set_clock_jitter

remove_clock_latency

Removes clock latency information from specified objects.

Syntax

string *remove_clock_latency*

```
[-source]
[-clock clock_list]
[-sms_scenarios sms_scenarios_list]
object_list
```

Feedback

Data Types

clock_list	list
object_list	list
sms_scenarios_list	collection

Arguments

`-source`

Specifies that clock source latency should be removed.

`-clock` *clock_list*

Removes any network latency defined on the pin/port objects in the *object_list* that refers the clocks in the *clock_list* option from the design. If the *-clock* option is supplied when the *object_list* refers to clock objects, a warning is issued that the option is not relevant in this case and the command proceeds as if the *-clock* was not provided. This option does not remove a more general latency setting without any specific clock.

object_list

Provides a list of clocks, ports, or pins.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the clock latency compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes clock latency information from specified objects. It removes the user-specified clock network or source latency information from specified objects. If a dynamic component of clock source latency has been specified this is also removed.

Clock Network latency is the time it takes for a clock signal on the design to propagate from the clock definition point to a register clock pin. Clock Source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design.

Clock network and source latency information is set on objects using the *set_clock_latency* command. For more information, see the *set_clock_latency* man page.

To report clock network and source latency information, use the *report_clock* command with the *-skew* option.

Examples

The following example removes clock latency information from the *CLK1* clock.

Feedback

```
pt_shell> remove_clock_latency [get_clocks CLK1]
```

The following example removes clock source latency information from the *CLK1* clock.

```
pt_shell> remove_clock_latency -source [get_clocks CLK1]
```

See Also

- create_clock
- remove_clock
- remove_clock_uncertainty
- report_clock
- set_clock_latency
- set_clock_uncertainty

---

remove_clock_map

Removes the user-specified mapping of clocks across hierarchical design levels.

Syntax

status *remove_clock_map*

```
[-instances inst_cells]
[-all]
clock
```

Data Types

```
inst_cells      list
clock           list
```

Arguments

`-instances` *inst_cells*

Removes the user-specified clock mapping from the specified list of cells. Clock mapping can be instance-specific even when the instances refer to same physical block. This option can only be used at top level with to specify removing mapping for subblock instances. It can be only used to remove the user-specified clock mapping that was previously set with the *set_clock_map -instances* command.

`-all`

Removes all user-specified clock mappings.

clock

Removes the user-specified clock mapping for the specified clock.

Description

This command removes user-specified clock mapping for the specified objects that was previously set by the *set_clock_map* command. Note that this command does not remove the automatic clock mapping. The removal of the mapping is corresponding to the set of the clock map. If the clock mapping is set with the *-instance* options, it should be removed with the *-instance* option.

Examples

The following example sets and removes mapping

```
pt_shell> set_clock_map SYSCLK -block_clock BCLK1
pt_shell> set_clock_map SYSCLK -block_clock BCLK2
pt_shell> remove_clock_map SYSCLK
```

The following example sets the mapping and removes all the mappings for blk_inst1, but fails to remove the clock map on SYSCLK for blk_inst2.

```
pt_shell> set_clock_map SYSCLK -block_clock BCLK_1 -instance blk_inst1
pt_shell> set_clock_map SYSCLK -block_clock BCLK_x -instance blk_inst2
pt_shell> remove_clock_map -instance blk_inst1
pt_shell> remove_clock_map SYSCLK
```

---

remove_clock_sense

The *remove_clock_sense* command is deprecated. Use the *remove_sense* command instead.

Feedback

See Also

- remove_sense
- set_sense

---

remove_clock_transition

Removes clock transition time information.

Syntax

string *remove_clock_transition*

clock_list

Data Types

clock_list list

Arguments

clock_list

Specifies a list of clocks for which to remove clock transition time.

Description

Removes clock transition information specified by the *set_clock_transition* command. To list all the set clock transition values, use the *report_clock* command with the *-skew* option.

Examples

The following example removes clock transition information from all clocks in the current design.

```
pt_shell> remove_clock_transition [all_clocks]
```

See Also

- all_clocks
- report_clock
- set_clock_transition
- create_clock
- set_clock_latency
- set_clock_uncertainty

Feedback

remove_clock_uncertainty

Removes clock uncertainty information previously set by the *set_clock_uncertainty* command.

Syntax

string *remove_clock_uncertainty*

```
[object_list
[-from from_clock
   | -rise_from rise_from_clock
   | -fall_from fall_from_clock]
[-to to_clock
   | -rise_to rise_to_clock
   | -fall_to fall_to_clock]]
[-rise]
[-fall]
[-setup]
[-hold]
[-sms_scenarios sms_scenarios_list]
```

Data Types

```
object_list           list
from_clock            list
rise_from_clock       list
fall_from_clock       list
to_clock              list
rise_to_clock         list
fall_to_clock         list
sms_scenarios_list    collection
```

Arguments

object_list

Specifies a list of clocks, ports, or pins from which uncertainty information is removed. You can use either the pair of the *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to* options or the *object_list* option, but you cannot specify both; they are mutually exclusive.

`-from` *from_clock*

This option specifies the source clock for interclock uncertainty. You must specify either the pair of the *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to*, or *object_list* options; you cannot specify both.

`-rise_from` *rise_from_clock*

Same as the *-from* option, but indicates that *uncertainty* applies only to rising edge of the source clock. You can use only one of the *-from*, *-rise_from*, or

-fall_from options. Use the *-rise_from* option instead of the obsolete *-from_edge rise* option.

`-fall_from` *`fall_from_clock`*

Same as the *-from* option, but indicates that *uncertainty* applies only to falling edge of the source clock. You can use only one of the *-from*, *-rise_from*, or *-fall_from* options. Use the *-fall_from* instead of the obsolete *-from_edge fall* option.

`-to` *`to_clock`*

This option specifies the destination clocks for interclock uncertainty. You must specify either the pair of the *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to*, or *object_list* options; you cannot specify both.

`-rise_to` *`rise_to_clock`*

Same as the *-to* option, but indicates that *uncertainty* applies only to rising edge of the destination clock. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options. Use the *-rise_to* option instead of the obsolete *-to_edge rise* option.

`-fall_to` *`fall_to_clock`*

Same as the *-to* option, but indicates that *uncertainty* applies only to falling edge of the destination clock. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options. Use the *-fall_to* option instead of the obsolete *-to_edge fall* option.

`-rise`

Specifies that uncertainty is removed for only the rising clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty and is now obsolete. Unless you need this option for backward-compatibility, use the *-rise_to* option instead.

`-fall`

Specifies that uncertainty is removed for only the falling clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty and is now obsolete. Unless you need this option for backward-compatibility, use the *-fall_to* option instead.

`-setup`

Specifies that only setup check uncertainty is removed. By default, both setup and hold check uncertainties are removed.

`-hold`

Specifies that only hold check uncertainty is removed. By default, both setup and hold check uncertainties are removed.

Feedback

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the clock uncertainty compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes clock uncertainty information previously set by the *set_clock_uncertainty* command from clocks, ports, pins, or between specified clocks. To display clock uncertainty information, use the *report_clock* command with the *-skew* option.

Examples

The following example removes uncertainty information from a clock named *CLK* and a pin named *clk_buf/Z*.

```
pt_shell> remove_clock_uncertainty [get_clocks CLK]
pt_shell> remove_clock_uncertainty [get_pins clk_buf/Z]
```

The following example removes interclock uncertainties between the *PHI1* and *PHI2* clock domains.

```
pt_shell> remove_clock_uncertainty -from PHI1 -to PHI1
pt_shell> remove_clock_uncertainty -from PHI2 -to PHI2
pt_shell> remove_clock_uncertainty -from PHI1 -to PHI2
pt_shell> remove_clock_uncertainty -from PHI2 -to PHI1
```

- set_clock_transition
- set_clock_uncertainty

---

remove_command_hook

Remove hook from command execution

Syntax

string *remove_command_hook* -before *name*

Feedback

-after *name* -replace *name commandName*

```
string name
string commandName
```

Arguments

`-before name`

Remove the before hook named *name*

`-after name`

Remove the after hook named *name*

`-replace name`

Remove the replace hook named *name*

commandName

Command to update

Description

The *remove_command_hook* removes a hook previously added to a command. When a hook is created via the *add_command_hook* the name of the hook is returned. Use that name to remove the hook. The get_command_hooks command can also be used to determine the name of each registered hook.

Examples

```
prompt> remove_command_hook place_opt -before before0
```

See Also

- add_command_hook
- get_current_hook_command
- get_command_hooks

---

remove_connection_class

Removes connection class value from ports.

Syntax

integer *remove_connection_class*

object_list

Feedback

Data Types

```
object_list      list
```

Arguments

object_list

Specifies ports whose connection classes are to be removed.

Description

Removes any values for previously set on port with the *set_connection_class* command.

Examples

The following example removes any existing connection class values for an xyz port name.

```
pt_shell> remove_connection_class xyz
```

See Also

- set_connection_class
- report_constraint

---

remove_context

Deletes timing context information previously created by the *characterize_context* command.

Syntax

string *remove_context*

```
-block block_name
[-top]
[-instances cell_list]
```

Data Types

```
block_name    string
cell_list     list
```

Arguments

-block *block_name*

Specifies the name of the design subblock for which its context to be removed. This argument is required.

Feedback

`-top`

Specifies the previously captured top only context information to be removed.

`-instances` *`cell_list`*

Specifies a list of one or more instance names in the current design, all of which must all be instances of the reference block specified by the *-block block_name* argument. If you do not use the *-instances* option, the command affects all instances of the block named by the *-block* argument.

Description

This command deletes the context information previously captured by the *characterize_context* command for the specified list of instances. When you need to recharacterize the context for some instances, first use the *remove_context* command to remove the previously generated context for those instances.

Examples

The following command deletes the context information for instances I1 and I2.

```
pt_shell> remove_context -instances {I1 I2} -block B
```

See Also

- characterize_context
- write_context
- report_context

---

remove_context_margin

Removes context margin information previously set by the *set_context_margin* command.

Syntax

status *remove_context_margin*

```
[-all]
[-global]
[-type clock | data]
[objects]
```

Data Types

type	string
objects	list

Feedback

Arguments

`-all`

Removes all included context margins inside *object*. If no object is specified, it removes all context margins in the current design.

`-global`

Removes the global context margin in this design.

`-type clock | data`

Removes context margins only for the specified type, either *clock* or *data*. By default, both types are removed.

`objests`

Specifies a list of instances or pins/ports for which the context margin is removed

Description

The *remove_context_margin* command removes context margins previously set by the *set_context_margin* command. You can choose to delete only clock or data margin by specifying the *-type* option.

By default, *remove_context_margin* removes only context margin on the specified *objects*. To delete context margins on all objects, use the *-all* option.

Examples

The following example removes only the data context margin on BLK.

```
pt_shell> remove_context_margin -type data BLK
```

The following example removes all context margins in the current design.

```
pt_shell> remove_context_margin -all
```

The following example removes the clock context margins on BLK and all context margins on boundary pins inside BLK.

```
pt_shell> remove_context_margin -all -type clock BLK
```

See Also

- set_context_margin
- report_context

Feedback

remove_coupling_separation

Removes the constraints set by the *set_coupling_separation* command.

Syntax

```
status remove_coupling_separation
   [-pairwise pnets]
   -all
   nets
```

Data Types

```
pnets            list
nets             list
```

Arguments

`-pairwise` *pnets*

Specifies that all coupling capacitances between only *pnets* and *nets* are excluded. The *-pairwise* option can only be used to remove separation constraints applied on the nets using the *set_coupling_separation* command with the *-pairwise* option. Any coupling separation applied on the nets globally without the *-pairwise* option cannot be reset by this option.

`-all`

Resets coupling separation constraints on all nets.

nets

Specifies a list of nets from which separation constraints are to be removed.

Description

This command removes the constraints set by the *set_coupling_separation* command.

This command restores any prior settings on *pnets* or *nets* from the *set_si_delay_analysis* or *set_si_noise_analysis* command.

Instances of this command are recorded for output by the *write_changes* command. This feature allows you to communicate the separation constraint to other implementation tools along with netlist changes.

To verify the result of this command, run the *report_si_delay_analysis* or *report_si_noise_analysis* command with the *-coupling_separated* option.

Examples

In the following example, all the nets named CLK_NET_* are returned to their original state in crosstalk analysis.

Feedback

```
pt_shell> set_coupling_separation [get_nets CLK_NET*]
1
pt_shell> remove_coupling_separation [get_nets CLK_NET*]
1
```

In the following example, the separation is applied pairwise on the nets and is removed by using the *-pairwise* option.

```
pt_shell> set_coupling_separation -pairwise [get_nets {n1 n2}] [get_nets
 n3]
1
pt_shell> remove_coupling_separation -pairwise [get_nets {n1 n2}]
 [get_nets n3]
1
```

However if the separation is applied globally on the net for all its coupled nets, it cannot be removed by using the *-pairwise* option.

```
pt_shell> set_coupling_separation [get_nets {n4}]
1
pt_shell> remove_coupling_separation [get_nets {n4}] -pairwise [get_nets
 n3]
Warning: Cannot remove an effect that was not set on net(s) n4 n3.
 (XTALK-107)
1
```

The coupling separation can be applied on the net pairwise with all its coupled nets in the following way so that pairwise exclusions can be applied on the net with any of its coupled nets.

```
pt_shell> set_coupling_separation [get_nets VIC_NET] -pairwise
[get_attribute -class net [get_nets VIC_NET] aggressors]
1

pt_shell> remove_coupling_separation [get_nets VIC_NET] -pairwise
[get_nets AGG_NET*]
1

pt_shell> remove_coupling_separation -all
1
```

See Also

- report_si_delay_analysis
- report_si_noise_analysis
- set_coupling_separation
- write_changes

Feedback

remove_current_session

Removes the previously set session.

Syntax

status *remove_current_session*

Arguments

None.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

In the multi-scenario analysis, a list of scenarios is brought into session and command focus (selected for analysis) by using the *current_session* command. These scenarios are then defocused using the *remove_current_session* command. However, the scenarios are not removed from memory and could be set in focus for another subsequent session.

Examples

In the following example, two scenarios are in the current session. These scenarios are then removed from focus.

```
pt_shell> current_session {scen2 scen3}
1
pt_shell> remove_current_session
1
```

See Also

- report_multi_scenario_design
- remove_scenario

remove_data_check

Removes specified data-to-data checks previously set by the *set_data_check* command.

Syntax

string *remove_data_check*

```
[-from from_object
   | -rise_from from_object
   | -fall_from from_object]
[-to to_object
   | -rise_to to_object
   | -fall_to to_object]
```

```
[-setup | -hold]
[-clock clock_object]
[-sms_scenarios sms_scenarios_list]
```

Data Types

```
from_object          collection
to_object            collection
clock_object         collection
sms_scenarios_list   collection
```

Arguments

`-from from_object`

Specifies a pin or port in the current design as the related pin of the data-to-data check is removed. Both rising and falling checks are removed. You must specify one of the *-from*, *-rise_from*, or *-fall_from* options.

`-rise_from from_object`

Similar to the *-from* option, but applies only to rising delays at the related pin. You must specify one of the *-from*, *-rise_from*, or *-fall_from* options.

`-fall_from from_object`

Similar to the *-from* option, but applies only to falling delays at the related pin. You must specify one of the *-from*, *-rise_from*, or *-fall_from* options.

`-to to_object`

Specifies a pin or port in the current design as the constrained pin of the data-to-data check is created. Both rising and falling checks are removed. You must specify one of the *-to*, *-rise_to*, or *-fall_to* options.

`-rise_to to_object`

Similar to the *-to* option, but applies only to rising delays at the constrained pin. You must specify one of the *-to*, *-rise_to*, or *-fall_to* options.

`-fall_to to_object`

Similar to the *-to* option, but applies only to falling delays at the constrained pin. You must specify one of the *-to*, *-rise_to*, or *-fall_to* options.

`-setup`

Indicates that only the setup data check is removed. If neither the *-setup* or *-hold* option is specified, both setup and hold checks are removed.

`-hold`

Indicates that only the hold data check is removed. If neither the *-setup* or *-hold* is specified, both setup and hold checks are removed.

`-clock` *clock_object*

Indicates that the data check for the specified clock at the related pin is removed. This option applies only if a previous *set_data_check* command used the *-clock* option to specify the same clock; otherwise, this option is ignored.

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only data checks compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

The *remove_data_check* command specifies that data-to-data checks be removed between a "from" (related) object and a "to" (constrained) object. These checks were previously set using the *set_data_check* command.

Examples

The following example removes a data-to-data check from and1/B to and1/A with respect to the rising edge of signals at and1/B. Both setup and hold checks are removed.

```
pt_shell> remove_data_check -rise_from and1/B -to and1/A
```

The following example removes setup data-to-data check between and1/B to and1/A with respect to the rising edge of signals at and1/B, coming from startpoints triggered with clock CK1, falling edge of signals at and1/A.

```
pt_shell> remove_data_check -rise_from and1/B -fall_to and1/A -setup
 -clock [get_clock CK1]
```

See Also

- report_timing
- set_data_check
- update_timing

---

remove_design

Removes one or more designs from memory.

Syntax

string *remove_design*

```
-all
-hierarchy
designs
```

Data Types

designs	list

Arguments

`-all`

Indicates that all designs are to be removed. The *-all*, *-hierarchy*, and *designs* options are mutually exclusive; you can specify only one.

`-hierarchy`

Indicates that all designs in the hierarchy of the current design are to be removed, including the current design. The *-all*, *-hierarchy*, and *designs* options are mutually exclusive; you can specify only one.

designs

Specifies a list of designs to remove. The *-all*, *-hierarchy*, and *designs* options are mutually exclusive; you can specify only one.

Description

The *remove_design* command removes designs from pt_shell. You must specify either the *-all*, *-hierarchy* or *designs* option, but not more than one of them. The *remove_design* command does not remove libraries; use the *remove_lib* command for that purpose.

Note that you cannot combine the *-hierarchy* option with a list of designs. The *-hierarchy* option is restricted to the current design. If the current design is not linked, it is automatically linked. Then, all designs in the hierarchy of the current design are removed, including the current design itself.

Examples

The following example removes the 'd1' and 'd2' designs:

```
pt_shell> remove_design {d1 d2}
Removing design 'd1'...
Removing design 'd2'...
1
```

The following example removes all designs in memory:

```
pt_shell> remove_design -all
Removing design 'd3'...
1
```

The following example removes all designs in the hierarchy of the current design. In this example, the design was already linked.

```
pt_shell> remove_design -hierarchy
Removing design 'TOP'...
Removing design 'eBlock'...
Removing design 'iBlock'...
Removing design 'mBlock'...
1
```

See Also

- current_design
- list_designs
- remove_lib

---

remove_design_mode

Removes specified design modes and/or cell mode and path mappings to design modes.

Syntax

status *remove_design_mode*

```
[-from from_pin_list]
[-to to_pin_list]
[-through through_pin_list]
mode_list
[cell_mode_list]
[instance_list]
```

Data Types

from_pin_list	list
to_pin_list	list
through_pin_list	list
mode_list	list
cell_mode_list	list
instance_list	list

Arguments

`-from` *from_pin_list*

Specifies a timing path, from a given pin of the design, that is active only for the specified design mode. The given paths are inactive for other design modes. These paths are unmapped from the specified design mode and any previous settings on the path due to the design mode are removed.

`-to` *`to_pin_list`*

Specifies a timing path to a given pin of the design, that is active only for the specified design mode. The given paths are inactive for other design modes. These paths are unmapped from the specified design mode and any previous settings on the path due to the design mode are removed.

`-through` *`through_pin_list`*

Lists the pins, ports, or nets through which the paths pass. The paths become active for the specified mode. You can specify the *-through* option more than one time in one command invocation. Nets are interpreted to imply the leaf-level driver pins. These paths are unmapped from the *design_mode and* command and any previous settings on the path due to the design mode are reset.

`mode_list`

Specifies a list of design modes to be removed. Design modes on the list must have been previously created using the *define_design_mode_group* command.

`cell_mode_list`

Specifies a list of cell modes to be unmapped from the specified design mode. Any previous settings on any cell mode due to the design mode are reset.

`instance_list`

Specifies a list of cells in which the specified modes are unmapped from the design mode. This list must be accompanied by the *cell_mode_list* option.

Description

The *remove_design_mode* command removes specified design modes previously created by the *define_design_mode_group* command or removes mappings for specified design modes created by the *map_design_mode* command.

A design mode can be removed from a design mode group using the *remove_design_mode* command. When a design mode is removed from a design mode group, all previous settings on cell modes and paths are reset. Also, if this design mode was the active design mode, then all other design modes in the design mode group are reset to default.

A path can be unmapped from a design mode using the *remove_design_mode -from [from_pin_list] -to [to_pin_list] -through [through_pin_list]* command. The pin specification must exactly match the pin specification set using a previous *map_design_mode* command. When a path is unmapped from a design mode, all paths are reset if they have been previously set false by that design mode. When a cell mode is unmapped from a design mode, all cell modes are reset if they have been previously set by that design mode.

To see a report of the design modes specified for the current design, use the *report_mode* command. The report also shows the cell modes and paths mapped to each design mode.

Examples

The following example defines two design modes, DM1 and DM2, maps the cell mode READ to design mode DM1 for instance Uram1, then removes the design mode DM1. Removing DM1 also removes the mapping to the active cell mode READ.

```
pt_shell> define_design_mode_group {DM1 DM2}
pt_shell> map_design_mode READ Uram1 DM1
pt_shell> remove_design_mode DM1
```

See Also

- define_design_mode_group
- map_design_mode
- report_mode
- reset_mode
- set_mode

---

remove_disable_clock_gating_check

Restores clock gating checks, previously disabled by the *set_disable_clock_gating_check* command, for specified cells and pins.

Syntax

string *remove_disable_clock_gating_check*

```
        object_list
```

Data Types

object_list list

Arguments

object_list

Specifies a list of cells, pins, lib-pins or lib-cells for which previously-disabled clock gating checks are to be restored.

Feedback

Description

Restores timing clock gating checks previously disabled with the *set_disable_clock_gating_check* command.

Examples

The following example restores disabled clock gating checks for the object an1.

```
pt_shell> remove_disable_clock_gating_check an1/A
```

The following example restores all disabled gating checks on the cell U1/or2.

```
pt_shell> remove_disable_clock_gating_check U1/or2
```

The following example restores all disabled gating checks on the lib-cell class/AND1.

```
pt_shell> remove_disable_clock_gating_check [get_lib_cells
 {"class/AND1"}]
```

The following example restores all disabled gating checks on the lib-pin class/AND1/A.

```
pt_shell> remove_disable_clock_gating_check [get_lib_pins
 {"class/AND1/A"}]
```

See Also

- set_disable_clock_gating_check

---

remove_disable_timing

Enables the previously disabled timing arcs.

Syntax

status *remove_disable_timing*

```
[-from from_pin_name]
[-to to_pin_name]
object_list
```

Data Types

from_pin_name	string
to_pin_name	string
object_list	list

Feedback

Arguments

`-from` *from_pin_name*

Specifies that only the arcs from this pin on the specified cell or library cell are to be disabled. When used, the *-from* and *-to* options must be specified together.

`-to` *to_pin_name*

Specifies that only the arcs to this pin on the specified cell or library cell are to be disabled. When used, the *-from* and *-to* options must be specified together.

object_list

Specifies a list of cells, pins, ports, library cells, library cell pins, cell timing arcs, or library timing arcs. If the *-from* and *-to* options are specified, the *object_list* argument must contain only cells or library cells.

Description

Restore timing arcs previously disabled with the *set_disable_timing* command. When the *-from* and *-to* option pins are specified, all arcs between these two pins on the cell or library cell are restored.

To list the timing arcs for a library cell, use the *report_lib -timing_arcs* command.

Examples

The following example restores disabled setup and hold arcs between pins CLK and TE on library cell SFF1.

```
pt_shell> remove_disable_timing -from CLK -to TE tech_lib/SFF1
```

The following example restores all disabled cell arcs from or to pin A on cell U1/U2.

```
pt_shell> remove_disable_timing U1/U2/A
```

See Also

- report_disable_timing
- report_lib
- set_disable_timing

---

remove_distributed_design

Removes design netlist and associated data from the DMSA manager shell.

Syntax

status *remove_distributed_design*

Feedback

Description

The *remove_distributed_design* command will remove the design data previously loaded by the *load_distributed_design* command.

See Also

- cache_distributed_attribute_data

---

remove_dont_override

Removes user-specified *set_dont_override* commands from specified objects.

Syntax

string *remove_dont_override*

```
        object_list
```

Data Types

object_list list

Arguments

object_list

Removes user-specified *set_dont_override* commands from the specified objects.

Description

This command removes user-specified *set_dont_override* commands at the HyperScale block-level flow.

Examples

Assuming a design with two levels of hierarchy, where TOP instantiates a subblock BOT, and the named scenario of interest is fast_func. To perform hierarchical timing analysis for BOT and automatically generate a reduced and accurate timing representation for its parent level analysis, use the following commands:

```
pt_shell> set hier_enable_analysis true
pt_shell> set_hier_config -parent -name "fast_func" -path /design/TOP
pt_shell> set_hier_config -name "fast_func" -path /design/blocks/BOT
```

Feedback

In addition, for the block BOT, it is necessary to freeze the timing budget defined for the bused port DATAIN so that PrimeTime does not automatically use the actual context pushed from TOP to override your settings, use the following command:

```
pt_shell> set_dont_override [get_port DATAIN*]
```

The following example removes the previous user-specified set_dont_override:

```
pt_shell> remove_dont_override [get_port DATAIN*]
```

See Also

- link_design
- report_constraint
- save_session
- set_dont_override
- set_hier_config
- update_timing
- hier_enable_analysis

---

remove_drc_error_data

Removes DRC error data objects.

Syntax

```
status remove_drc_error_data
drc_error_data
[-force]
```

Data Types

```
drc_error_data   collection
```

Arguments

drc_error_data

Specifies the collection of DRC error data objects to remove.

-force

Removes the specified DRC error data object, regardless of pending multiple opens that have not been matched with a close.

Feedback

Description

The *remove_drc_error_data* command removes the specified DRC error data objects. The command first closes the error data objects, which decrements the open count for the error data objects. If the open count decrements to zero, the command removes the error data object from memory. If the error data object was created as an external error data file, the error data file is removed from disk.

The open count for a DRC error data object is incremented each time you run the *create_drc_error_data* or *open_drc_error_data* command on it. The open count is decremented each time you run the *close_drc_error_data* command. The error data object is removed from memory when the open count reaches zero.

Use the *-force* option to remove the error data object from memory and remove the external error data file from disk, regardless of the open count value.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes the DRC error data object named "dppinassgn.err".

```
prompt> remove_drc_error_data dppinassgn.err
1
```

The following example first opens an error data object named "dppinassgn.err", and then deletes it.

```
prompt> set data [open_drc_error_data -all dppinassgn.err]
{"dppinassgn.err"}
prompt> remove_drc_error_data $data
1
```

See Also

- close_drc_error_data
- create_drc_error_data
- get_drc_error_data
- open_drc_error_data
- save_drc_error_data

---

remove_drc_error_types

Removes physical DRC error type objects.

Feedback

Syntax

```
status remove_drc_error_types
-error_data drc_error_data
drc_error_types
```

Data Types

```
drc_error_data     collection
drc_error_types    collection
```

Arguments

`-error_data drc_error_data`

Specifies the error data from which to remove physical DRC error types.

drc_error_types

A collection of physical DRC error type objects to remove.

Description

The *remove_drc_error_types* command removes physical DRC error type objects from the given error data. When an error type is removed, all errors of the type are also deleted from the error data.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all error_types that have the error_class value of *short*.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_error_types -error_data $data \\
   [get_drc_error_types -error_data $data -filter {error_class==short}]
```

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes the error type named "pin short".

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_error_types -error_data $data \\
   [get_drc_error_types -error_data $data {"pin short"}]
```

See Also

- create_drc_error_type
- get_drc_error_types

Feedback

remove_drc_errors

Removes phyiscal DRC error data objects

Syntax

```
status remove_drc_errors
-error_data drc_error_data
drc_errors
```

Data Types

```
drc_error_data      collection
drc_errors          collection
```

Arguments

`-error_data drc_error_data`

Specifies the error data from which to remove errors.

drc_errors

A collection of physical DRC error data objects to remove.

Description

The *remove_drc_errors* command removes physical DRC error objects from the given error data.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all errors that have the status value of *fixed*.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_errors -error_data $data \\
        [get_drc_errors -error_data $data -filter {status==fixed}]
```

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all errors that are of type "pin short".

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
```

```
prompt> set pinShortType [get_drc_error_types -error_data $data {"pin
 short"}]
{"pin short"}
prompt> remove_drc_errors -error_data $data \\
        [get_drc_errors -error_data $data -of_objects $pinShortType]
```

---

remove_drive_resistance

Removes drive resistance for input or inout ports.

Syntax

string *remove_drive_resistance*

```
        port_list
```

Data Types

port_list list

Arguments

port_list

Specifies a list of input or inout port names of the current design from which the drive values are to be removed.

Description

The *remove_drive_resistance* command removes the drive resistance value from one or more input or inout ports. This is equivalent to using the *set_drive_resistance 0* command. In fact, that is how this command works. So, if output ports are passed into the *remove_drive_resistance* command, a DES-003 message is issued, indicating that the *set_drive_resistance* command could not be performed on those ports.

Feedback

Examples

The following command shows the difference in the output report after using the *remove_drive_resistance* command:

```
pt_shell> set_drive_resistance 5 [get_ports {A B C}]
1
pt_shell> report_port -drive {A B C}

****************************************
Report : port
         -drive
Design : counter
****************************************

                  Resistance          Transition
Input Port     Rise      Fall      Rise      Fall
------------------------------------------------------------
A              5.00      5.00      --        --
B              5.00      5.00      --        --
C              5.00      5.00      --        --

1
pt_shell> remove_drive_resistance A
1
pt_shell> report_port -drive {A B C}

Feedback

remove_driving_cell

Removes port driving cell information.

Syntax

string *remove_driving_cell*

```
[-rise]
[-fall]
[-min]
[-max]
[-clock clock_name]
[-clock_fall]
port_list
```

Data Types

clock_name	string
port_list	list

Arguments

`-rise`

Removes rise driving cell information.

`-fall`

Removes fall driving cell information.

`-min`

Removes min driving cell information.

`-max`

Removes max driving cell information.

`-clock clock_name`

Removes the driving cell set relative to the specified clock.

`-clock_fall`

Removes the driving cell relative to the falling edge of the clock. The default is the rising edge.

port_list

Provides a list of input or output ports.

Feedback

Description

Removes driving cell information from the specified ports. The driving cell information is specified with the *set_driving_cell* command. The default is to remove all the *-rise* and *-fall* option information.

To see port drive information, use the *report_port -drive* command.

Examples

The following example removes all driving cell information for port IN2.

```
pt_shell> remove_driving_cell IN2
```

See Also

- report_port
- set_driving_cell

---

remove_dvd

Removes dynamic voltage drop information from the current design.

Syntax

status *remove_dvd*

```
[-rail_map_only]
```

Arguments

`-rail_map_only`

Removes rail map scaling/offset values applied by *read_dvd -rail_map*, while still leaving the voltage drop values themselves in place.

This option can be used to efficiently move the analysis from one scaled corner to another.

Description

Removes user-specified dynamic voltage drop information that was previously applied with the *read_dvd* command.

Examples

The following example removes all dynamic voltage drop information from the design:

```
pt_shell> remove_dvd
```

Feedback

The following example removes only the rail-map scaling/offset information:

```
pt_shell> remove_dvd -rail_map_only
```

- read_dvd
- report_timing
- report_voltage_robustness
- timing_enable_dvd_analysis

---

remove_fanout_load

Removes fanout load information from output ports in the current design.

Syntax

status *remove_fanout_load*

```
[-sms_scenarios sms_scenarios_list]
port_list
```

Data Types

```
port_list            list
sms_scenarios_list   collection
```

Arguments

port_list

Specifies a list of output ports.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the fanout load compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes fanout load information specified by the *set_fanout_load* command. Fanout load for a net is the sum of the *fanout_load* attributes for all input pins and output ports connected to the net. Output pins can have maximum fanout limits, specified in the library or with the *set_max_fanout* command. The *fanout_load* is used when checking max_fanout design values.

Feedback

Use the *report_constraint* command with the *-max_fanout* option to show maximum fanout constraint evaluations. Use the *report_port* command with the *-design_rule* option to show port fanout load values.

Examples

The following example removes the fanout load on ports matching "OUT*".

```
pt_shell> remove_fanout_load OUT*
```

See Also

- report_constraint
- report_port
- set_fanout_load
- set_max_fanout

---

remove_from_collection

Removes objects from a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *remove_from_collection*

```
[-intersect]
collection1
object_spec
```

Data Types

collection1	collection
object_spec	list

Arguments

`-intersect`

Removes objects from collection1 not found in object_spec. Without this option, removes objects from collection1 that are found in object_spec.

collection1

Specifies the base collection to be copied to the result collection. Objects matching *object_spec* are removed from the result collection.

object_spec

Specifies a list of named objects or collections to remove. The object class of each element in this list must be the same as in the base collection. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

Description

The *remove_from_collection* command removes elements from a collection, creating a new collection.

If the base collection is homogeneous, any element of the *object_spec* that is not a collection is searched for in the database using the object class of the base collection. If the base collection is heterogeneous, any element of the *object_spec* that is not a collection is ignored.

If the *-intersect* option is not specified, which is the default mode, and if nothing matches the *object_spec*, the resulting collection is a copy of the base collection. If everything in the *collection1* option matches the *object_spec*, the result is the empty collection. With the *-intersect* option the results are reversed.

For background on collections and querying of objects, see the *collections* man page.

Examples

The following example from PrimeTime gets all input ports except "CLOCK".

```
pt_shell> set cPorts [remove_from_collection [all_inputs] CLOCK]
{"in1", "in2"}
```

See Also

- add_to_collection

---

remove_generated_clock

Removes generated clock objects from the current design.

Syntax

status *remove_generated_clock*

```
-all
clock_list
```

Data Types

```
clock_list        list
```

Feedback

Arguments

`-all`

Indicates that all generated clocks are to be removed.

`clock_list`

Specifies a list of names of generated clocks to be removed.

Description

This command removes from the current design generated clocks previously created using the *create_generated_clock* command. All attributes set on generated clocks such as, *false_paths* and *multicycle_paths*, are also removed.

To display information about clocks and generated clocks in the design, use the *report_clock* command.

Examples

The following example removes the generated clock GEN1 from the design.

```
pt_shell> remove_generated_clock GEN1
```

The following example removes all generated clocks from the design.

```
pt_shell> remove_generated_clock -all
```

See Also

- create_generated_clock
- report_clock

---

remove_host_options

Removes hosts options set using the *set_host_options* command.

Syntax

int *remove_host_options*

`[`*`host_option_names`*`]`

Data Types

`host_option_names`	`list`

Feedback

Arguments

host_option_names

This option specifies a list of named host options to remove.

Description

Given a list of host option names, removes those host options. The host option names specifed must have been previously set using the *set_host_options* command. If no host option names are specified, all host options are removed. All processes belonging to the host options being removed are shutdown.

In a DMSA manager process, if a host option is removed then it will also be removed from the affinity specification of all scenarios. If all host options are removed then all scenario affinities will be removed. Where scenarios specify an affinity the removal of host opitons will reduce the set of workers upon which the scenario can run.

Examples

In the following example, the manager process is running on the host named ptnlm15 using a 64-bit binary and specifies several different sets of host options.

The first host options, named "my_opts1", specifies

```
- to use one process on the same host as the manager process
- no upper limit on the number of cores to use so the default applies.
```

The second host options, named "my_opts2", specifies

```
- to use one process on the same host as the manager, explicitly
  mentioning the manager host by name
- to use a maximum of two cores.
```

The third host options, named "my_opts3", specifies

```
- to use one process on the host named ptnlm11, since no submit
  command is specified, "rsh" will be used to connect to ptnlm11
- to use a maximum of three cores.
```

The fourth host options named "my_opts4", specifies

```
- to use one process on the host named ptnlm12 connecting to
  ptnlm12 using the submit command "/usr/bin/rsh"
- no upper limit on the numebr of cores to use so the default applies.
```

The fifth host options named "my_opts5", specifies

```
- to use one process on an LSF farm, using the "bsub" command found
  from the environment path to submit the job, requiring 1GB of
  memory and two slots per compute server. Notice that the farm job
  must be specified with the number of slots needed to support the
  number of cores to use with the -n 2 -R span\\[ptile=2\\]
```

Feedback

```
  options.
- to use the terminate command "bkill" found from the environment
  path for the termination of jobs that do not come online.
- to use a maximum of two cores.
```

The sixth host options named "my_opts6", specifies

```
- to use one process on a Grid farm, using the "qsub" command found
  from the environment path to submit the job, using the project
  named "bnormal", requiring 1GB of memory and four slots per compute
  server. Notice that the farm job must be specified with the number
  of slots needed to support the number of cores to use by targeting
  the parallel environment "mt" requesting 4 slots with the "-pe mt 4"
  options.
- to use the terminate command "qdel" found from the environment
  path for the termination of jobs that do not come online.
- to use a maximum of four cores.
```

Note: After the *remove_host_options* command has been called all processes are shutdown and all the host options are removed.

Call the *set_host_options* command to specify the host options.

```
pt_shell> set_host_options -name my_opts1 -num_processes 1
1
pt_shell> set_host_options -name my_opts2 -num_processes 1 \\
          ptnlm15 -max_cores 2
1
pt_shell> set_host_options -name my_opts3 -num_processes 1 \\
          ptnlm11 -max_cores 3
Warning: no submit command specified to access remote host
 'ptnlm10'. The 'rsh' command will be used. (CMCR-004)
1
pt_shell> set_host_options -name my_opts4 -num_processes 1 \\
          -submit_command "/usr/bin/rsh" ptnlm12
1
pt_shell> set_host_options -name my_opts5 -num_processes 1 \\

Feedback

remove_ideal_aggressor

Removes ideal aggressor marking on the specified ideal aggressor nets. Removes the *si_ideal_aggressor* attribute on these nets.

Syntax

int *remove_ideal_aggressor*

```
-all
net_list
```

Data Types

```
net_list    list
```

Arguments

`-all`

Indicates that ideal aggressor marking on all nets of the current design is to be removed. The *-all* and *net_list* options are mutually exclusive; you can specify only one.

net_list

Specifies a list of ideal aggressor nets.

Description

This command removes ideal aggressor merking on the specified nets of the current design. The *si_ideal_aggressor* attribute on these nets is removed.

See the *set_ideal_aggressor* command for more details on ideal aggressor handling.

You can query the *si_ideal_aggressor* attribute by using the *get_attribute* command to confirm that the attribute is successfully removed.

Examples

The following command removes ideal aggressor marking on ideal aggressor nets "n_ideal_aggr1" and "n_ideal_aggr2".

```
pt_shell> remove_ideal_aggressor [get_nets {n_ideal_aggr1 n_ideal_aggr2}]
1
```

In the following example, the *si_ideal_aggressor* attribute is set using *set_ideal_aggressor* command and then queried using *get_attribute* command. The *get_attribute* command returns *true* for the *si_ideal_aggressor* attribute. The command *remove_ideal_aggressor -all* is used to remove ideal aggressor marking on all nets of the design. The *get_attribute* command then returns *false* for the *si_ideal_aggressor* attribute.

Feedback

```
pt_shell> get_attribute [get_net n_ideal_aggr] ref_name
n_ideal_aggr

pt_shell> get_attribute [get_net n_ideal_aggr] si_ideal_aggressor
false

pt_shell> set_ideal_aggressor [get_net n_ideal_aggr]
1

pt_shell> get_attribute [get_net n_ideal_aggr] si_ideal_aggressor
true

pt_shell> remove_ideal_aggressor -all
1

pt_shell> get_attribute [get_net n_ideal_aggr] si_ideal_aggressor
false
```

See Also

- set_ideal_aggressor
- get_attribute

---

remove_ideal_latency

Removes ideal latency values from the specified objects.

Syntax

int *remove_ideal_latency*

```
[-rise]
[-fall]
[-min]
[-max]
object_list
```

Data Types

object_list	list

Arguments

`-rise`

Specifies that only rise ideal latency should be removed. By default, both rise and fall ideal latency are removed.

Feedback

`-fall`

Specifies that only fall ideal latency should be removed. By default, both rise and fall ideal latency are removed.

`-min`

Specifies that only minimum ideal latency should be removed. By default, both minimum and maximum ideal latency are removed.

`-max`

Specifies that only maximum ideal latency should be removed. By default, both minimum and maximum ideal latency are removed.

`object_list`

Specifies a list of ports or pins from where to remove ideal latency.

Description

Removes the user-specified ideal latency that was previously set by the *set_ideal_latency* command from specified objects in the *object_list* argument.

You can remove selected portions of ideal latency by specifying applicable *-rise*, *-fall*, *-min*, and *-max* options.

To list ideal latency values, use the *report_ideal_network* command.

Examples

The following example removes ideal latency from the output pin named *Z* of cell instance *U1/U2/U3*.

```
pt_shell> remove_ideal_latency {U1/U2/U3/Z}
```

The following example removes only rise ideal latency information from a port named *A*.

```
pt_shell> remove_ideal_latency -rise {A}
```

See Also

- remove_ideal_network
- remove_ideal_transition
- report_ideal_network
- report_timing
- set_ideal_network
- set_ideal_latency

Feedback

remove_ideal_network

Removes sources of ideal networks in the current design. Cells and nets in the transitive fanout of the specified objects are no longer treated as ideal.

Syntax

int *remove_ideal_network*

```
        object_list
```

Data Types

object_list	list

Arguments

object_list

Specifies a list of ideal sources. The source objects can be ports or pins of leaf cells at any hierarchical level of the design. If nets are specified in the *object_list* option, all of the nets' global driver ideal source pins that were set with the *-no_propagate* option are removed.

Description

This command removes the ideal network property from a set of ports or pins in the design that were previously marked as ideal sources using the *set_ideal_network* command. You specify only the source of the network. The ideal network is automatically updated by PrimeTime. The criteria for propagating the ideal property are detailed in the *set_ideal_network* man page.

All ideal networks are removed using the *reset_design* command.

Examples

The following example sets up an ideal network on objects in the design CLOCK_GEN and then removes part of the network:

```
pt_shell> current_design CLOCK_GEN
pt_shell> set_ideal_network {port1 port2}
pt_shell> remove_ideal_network port2
```

The following example creates an ideal network and then removes part of the ideal network.

```
pt_shell> current_design {TOP}
pt_shell> set_ideal_network {IN1 IN2}
pt_shell> remove_ideal_network {IN1}
```

Feedback

The following example removes an ideal network that was set on a net.

```
pt_shell> set_ideal_network -no_propagate {netB}
Warning: Transferring ideal net attribute onto driver pin 'AN2/Z' of net
 'netB'. (UITE-450)
pt_shell> remove_ideal_network {netB}
```

See Also

- remove_ideal_latency
- remove_ideal_transition
- report_ideal_network

- set_ideal_network

---

remove_ideal_transition

Removes ideal transition values from the specified objects.

Syntax

int *remove_ideal_transition*

```
[-rise]
[-fall]
[-min]
[-max]
object_list
```

Data Types

object_list	list

Arguments

`-rise`

Specifies that only rise ideal transition should be removed. By default, both rise and fall ideal transitions are removed.

`-fall`

Specifies that only fall ideal transition should be removed. By default, both rise and fall ideal transitions are removed.

`-min`

Specifies that only minimum ideal transition should be removed. By default, both minimum and maximum ideal transitions are removed.

Feedback

`-max`

Specifies that only maximum ideal transition should be removed. By default, both minimum and maximum ideal transitions are removed.

`object_list`

Specifies a list of ports or pins from which to remove ideal transition.

Description

Removes the user-specified ideal transition that was previously set by the *set_ideal_transition* command from specified objects in the *object_list* option.

You can remove selected portions of ideal transition by specifying applicable *-rise*, *-fall*, *-min*, and *-max* options.

To list ideal transition values, use the *report_ideal_network* command.

Examples

The following example removes ideal transition from the output pin named *Z* of cell instance *U1/U2/U3*.

```
pt_shell> remove_ideal_transition {U1/U2/U3/Z}
```

The following example removes only rise ideal transition information from a port named *A*.

```
pt_shell> remove_ideal_transition -rise {A}
```

See Also

- remove_ideal_network
- report_ideal_network
- report_timing
- set_ideal_network
- set_ideal_transition

---

remove_input_delay

Removes input delay information from ports or pins.

Syntax

string *remove_input_delay*

```
[-clock clock_name]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-sms_scenarios sms_scenarios_list]
port_pin_list
```

Data Types

```
clock_name           list
port_pin_list        list
sms_scenarios_list   collection
```

Arguments

`-clock clock_name`

Relative clock; '' for no clock. Use this option to remove only input delay relative to one clock.

`-clock_fall`

Delay is relative to falling edge of clock.

`-level_sensitive`

Delay is from level-sensitive latch.

`-rise`

Removes rising input delay.

`-fall`

Removes falling input delay.

`-max`

Removes maximum input delay.

`-min`

Removes minimum input delay.

`port_pin_list`

Specifies a list of ports and pins.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the input delay compatible with the specified

Feedback

SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes input delay information from ports or pins in the current design. Input delay is specified with the *set_input_delay* command. To show input delays on ports, use the *report_port -input_delay* command. The default is to remove all input delay information in the *port_pin_list* option.

Examples

The following example removes all input delay from ports IN*.

```
pt_shell> remove_input_delay [get_ports IN*]
```

The following example removes input delay relative to CLK rise edge from port DATA[5].

```
pt_shell> remove_input_delay -clock CLK {DATA[5]}
```

See Also

- report_port
- set_input_delay
- set_output_delay
- remove_output_delay

---

remove_input_noise

Removes input noise for a library pin or port.

Syntax

int *remove_input_noise*

```
[-above]
[-below]
[-low]
[-high]
object_list
```

Data Types

list *object_list*

Feedback

Arguments

`-above`

Removes the input noise for above ground or power rail noise analysis region.

`-below`

Removes the input noise for below ground or power rail noise analysis region.

`-low`

Removes the input noise for ground rail noise.

`-high`

Removes the input noise for power rail noise. 1.0.

`object_list`

Specifies a list of lib-pins or ports.

Description

This command removes the input noise information set by the *set_input_noise* command.

Examples

This example removes input noise information for the above the ground rail noise for pin A of library cell IV in the lsi_10k library:

```
pt_shell> remove_input_noise -above lsi_10k/IV/A
```

See Also

- set_input_noise

---

remove_ivm

Removes the user-defined via variation tables.

Syntax

```
status remove_ivm
   [-layer_name string]
```

Data Types

```
string     string
```

Feedback

Arguments

`-layer_name` *string*

Specifies the name of the layer. By default, the command removes via variation tables for all layers.

Description

This command removes the via variation tables previously read in with the *read_ivm* command. To remove via variation for only a specific layer, specify the layer name. To remove all via variation data, use the *read_ivm* command by itself, without arguments.

Examples

The following command removes the via variation data for only the V2 layer.

```
pt_shell> remove_ivm -layer_name V2
```

See Also

- read_ivm
- report_ivm
- timing_enable_via_variation

---

remove_lib

Removes one or more libraries from memory.

Syntax

string *remove_lib*

```
-all
libraries
```

Data Types

libraries	list

Arguments

`-all`

Removes all libraries.

libraries

Provides a list of libraries to remove.

Feedback

Description

This command removes a list of libraries. You must specify either the *libraries* or *-all* option. For a library to be removed, none of its library cells can be instantiated in any design, nor can any environment information (such as operating conditions or wire load models) be in use from the library. If this is the case, a message is issued and you must remove the design by first using the *remove_design* command and then using the *remove_lib* command.

Examples

The following command removes all the libraries read in.

```
pt_shell> remove_lib -all
Removing library '/u/libraries/cmos1.db:cmos1'...
1
```

The following command removes a library that was part of a max/min pair created by the *set_min_library* command.

```
pt_shell> remove_lib lib_ff
Removed max/min library relationship:
  Max: /u/libraries/lib_ss.db:lib_ss
  Min: /u/libraries/lib_ff.db:lib_ff
Removing library '/u/libraries/lib_ff.db:lib_ff'...
1
```

See Also

- list_libs
- list_designs
- remove_design
- set_min_library

---

remove_license

Checks in a licensed feature.

Syntax

```
status remove_license
   [-keep num_licenses]
   feature_list
```

Data Types

```
num_licenses     integer
feature_list     list
```

Feedback

Arguments

`-keep` *num_licenses*

Specifies the number of licenses to retain for each feature after the command has completed. If you do not use this option, the command checks in all of the features licenses. Incremental licensing must be enabled if you want to reduce number of licenses to a number larger than zero.

feature_list

Removes the licenses of the specified list of features. To specify more than one feature, enclose the list in curly braces ({ }). For a list of all features that are available at your site, see the key file.

Description

This command removes (checks in) the specified licensed features from the features you are currently using.

For multicore runs, where multiple licenses might be required for certain features, you can use the *-keep* option to restrict the number of licenses that are checked in. This is analogous to the *get_license -quantity* command.

Reducing the number of licenses to a number larger than zero requires incremental licensing to be enabled. Incremental licensing is enabled by default. To disable it, set the *SNPSLMD_ENABLE_INCREMENTAL_LICENSE_HANDLING* UNIX enviroment variable to *FALSE*.

To list the features that you currently have checked out, run the *list_licenses* command.

Examples

This example checks in the PrimePower and PrimeTime SI licenses.

```
pt_shell> remove_license {PrimePower PrimeTime-SI}
Checked in license 'PrimePower' (PT-020)
Checked in license 'PrimeTime-SI' (PT-020)
1
```

See Also

- get_license
- license_users
- list_licenses

---

remove_license_limit

Removes the limit on the number of licenses of given features that can be checked out.

Feedback

Syntax

```
status remove_license_limit
  feature_list
```

Data Types

feature_list	list

Arguments

feature_list

Specifies a list of features for which limits should be removed.

Description

The *remove_license_limit* command removes the upper limit on the number of licenses of given features that can be checked out previously set by the *set_license_limit* command.

By default, the command removes all limits set for any feature. If the optional *feature_list* is given, it removes the limits only for the features given in the list.

Examples

In the following example, the license limit for PrimeTime feature is removed.

```
pt_shell> remove_license_limit PrimeTime
Information: Removing license limit for feature PrimeTime. (PT-024)
1
```

---

remove_max_area

Removes the *max_area* attribute from the current design.

Syntax

int *remove_max_area*

Feedback

Arguments

None.

Description

The *remove_max_area* command removes the *max_area* attribute from the current design. This attribute represents the target area of the design.

Use the *set_max_area* command to set the *max_area* attribute on the current design.

Use the *report_constraint* command to show area cost of the design.

Examples

The following example removes the target area from the current design.

```
pt_shell> remove_max_area
1
pt_shell> get_attribute [get_design [current_design]] max_area
Warning: Attribute 'max_area' does not exist on design 'TOP' (ATTR-3)
```

See Also

- current_design
- get_attribute
- set_max_area
- report_constraint
- reset_design

---

remove_max_capacitance

Removes maximum capacitance limits from pins, library pins, ports, clocks, or designs.

Syntax

string *remove_max_capacitance*

```
[-sms_scenarios sms_scenarios_list]
object_list
```

Data Types

object_list	list
sms_scenarios_list	collection

Feedback

Arguments

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the maximum capacitance limits compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

`object_list`

Provides a list of pins, library pins, ports, clocks, or designs from which to remove maximum capacitance limits.

Description

This command removes maximum capacitance limits from pins, library pins, ports, clocks, or designs. A maximum capacitance limit is specified with the *set_max_capacitance* command.

The *report_constraint -max_capacitance* command shows maximum capacitance constraint evaluations. The *report_port -design_rule* command shows port maximum capacitance limits. The *report_design* command shows the default maximum capacitance limit for the current design.

Examples

The following example removes the maximum capacitance limit from ports "OUT*".

```
pt_shell> remove_max_capacitance [get_ports "OUT*"]
```

The following example removes the maximum capacitance limit from the current design.

```
pt_shell> remove_max_capacitance [current_design]
```

See Also

Feedback

remove_max_fanout

Removes maximum fanout limits from ports or designs.

Syntax

string *remove_max_fanout*

```
[-sms_scenarios sms_scenarios_list]
object_list
```

Data Types

```
object_list          list
sms_scenarios_list   collection
```

Arguments

object_list

Lists the ports or designs from which to remove maximum fanout limits.

-sms_scenarios *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the maximum fanout limits compatible with the specified SMS scenarios. This option is only available with SMVA/SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes maximum fanout limits from ports or designs. A maximum fanout limit is specified with the *set_max_fanout* command.

The *report_constraint -max_fanout* command shows maximum fanout constraint evaluations. The *report_port -design_rule* command shows port maximum fanout limits. The *report_design* command shows the default maximum fanout setting for the current design.

Examples

The following example removes the maximum fanout limit on ports "OUT*".

```
pt_shell> remove_max_fanout [get_ports "OUT*"]
```

The following example removes the maximum fanout limit on the current design.

```
pt_shell> remove_max_fanout [current_design]
```

Feedback

See Also

---

remove_max_time_borrow

Removes time borrow limit for latches.

Syntax

string *remove_max_time_borrow*

```
        object_list
```

Data Types

```
object_list        list
```

Arguments

object_list

Lists clocks, cells, data pins, or clock (enable) pins. If you specify a cell, all enable pins on that cell are affected.

Description

Removes maximum time borrow limit on objects. Time borrowing limits are specified with the *set_max_time_borrow* command. When the limit is removed, full time borrowing is allowed on level-sensitive latches.

To show time borrow limits, use the *report_exceptions* command.

Feedback

Examples

The following example removes the maximum time borrow limit on clock PHI1.

```
pt_shell> remove_max_time_borrow [get_clocks PHI1]
```

The following example removes the maximum time borrow limit on all the pins of cells matching U1/latch*.

```
pt_shell> remove_max_time_borrow [get_cells U1/latch*]
```

See Also

- report_exceptions
- set_max_time_borrow

---

remove_max_transition

Removes maximum transition limits from pins, ports, clocks, or designs.

Syntax

string *remove_max_transition*

```
[-sms_scenarios sms_scenarios_list]
object_list
```

Data Types

object_list	list
sms_scenarios_list	collection

Arguments

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the maximum transition limits compatible with the specified SMS scenarios. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

object_list

Provides a list of pins, ports, clocks, or designs from which to remove maximum transition limits.

Description

This command removes maximum transition limits from pins, ports, clocks or designs. A maximum transition limit is specified with the *set_max_transition* command.

The *report_constraint -max_transition* command shows maximum transition constraint evaluations. The *report_port -design_rule* command shows port maximum transition limits. The *report_design* command shows the default maximum transition limit for the current design.

Examples

The following example removes the maximum transition limit from ports "OUT*".

```
pt_shell> remove_max_transition [get_ports "OUT*"]
```

The following example removes the maximum transition limit from the current design.

```
pt_shell> remove_max_transition [current_design]
```

remove_min_capacitance

Removes minimum capacitance limits from ports or designs.

Syntax

string *remove_min_capacitance*

```
[-sms_scenarios sms_scenarios_list]
object_list
```

Data Types

object_list	list
sms_scenarios_list	collection

Feedback

Arguments

`-sms_scenarios` *sms_scenarios_list*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only the minimum capacitance limits compatible with the specified SMS scenarios. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

object_list

Provides a list of ports or designs from which to remove minimum capacitance limits.

Description

This command removes minimum capacitance limits from ports or designs. A minimum capacitance limit is specified with the *set_min_capacitance* command.

The *report_constraint -min_capacitance* command shows minimum capacitance constraint evaluations. The *report_port -design_rule* command shows port minimum capacitance limits. The *report_design* command shows the default minimum capacitance limit for the current design.

Examples

The following example removes the minimum capacitance limit from ports "OUT*".

```
pt_shell> remove_min_capacitance [get_ports "OUT*"]
```

The following example removes the minimum capacitance limit from the current design.

```
pt_shell> remove_min_capacitance [current_design]
```

---

remove_min_pulse_width

Removes a previously-specified minimum pulse width constraint from specified design objects.

Syntax

string *remove_min_pulse_width*

```
[-low]
[-high]
[object_list]
```

Data Types

object_list list

Arguments

`-low`

Indicates that the minimum pulse width constraint is to be removed only for low clock signal levels. If you do not specify the *-low* or *-high* option, the constraint is removed for both low and high pulses of clock signals.

`-high`

Indicates that the minimum pulse width constraint is to be removed only for high clock signal levels. If you do not specify the *-low* or *-high* option, the constraint is removed for both low and high pulses of clock signals.

object_list

Specifies a list of clocks, cells, pins, or ports in the current design for which the minimum pulse width constraint is to be removed. If you specify a cell, all pins on that cell are affected. If you do not specify any objects, the minimum pulse width check is removed from all objects in the current design.

Description

The *remove_min_pulse_width* command removes the pulse width check previously specified by the *set_min_pulse_width* command for clock signals in clock trees or at sequential devices.

To generate a report of pulse width constraints, use the *report_constraint -min_pulse_width* or *report_min_pulse_width* command.

The *reset_design* command removes all user-specified attributes from a design, including those set by the *set_min_pulse_width* command.

Examples

The following example removes a minimum pulse width requirement previously set for clock CK1.

```
pt_shell> remove_min_pulse_width [get_clocks CK1]
```

The following example removes a minimum pulse width requirement previously set for pin U1/Z.

pt_shell> *remove_min_pulse_width U1/Z*

See Also

- current_design
- report_constraint
- report_min_pulse_width
- reset_design
- set_min_pulse_width

---

remove_multi_scenario_design

Removes all multi-scenario objects from memory and removes from disk all images generated by multi-scenario analysis.

Syntax

status *remove_multi_scenario_design*

Arguments

None.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

The *remove_multi_scenario_design* command removes all multi-scenario objects from pt_shell. The current session and all scenarios are removed from memory. All netlist, baseline and current images generated during the multi-scenario analysis are removed from disk.

Feedback

Examples

The following example removes all multi-scenario objects and removes all images from the disk.

```
pt_shell> remove_multi_scenario_design
1
```

See Also

- report_multi_scenario_design

---

remove_net

Removes nets from the current design.

Syntax

int *remove_net*

```
-all
net_list
```

Data Types

```
net_list      list
```

Arguments

`-all`

Indicates that all nets are to be removed from the current design. The *-all* and *net_list* options are mutually exclusive; you can specify only one.

net_list

Specifies a list of nets to be removed from the current design. The *-all* and *net_list* options are mutually exclusive; you can specify only one.

Description

The *remove_net* command removes specified nets or all nets from the current design. Like all other netlist editing commands, for the *remove_net* command to succeed, all of its arguments must succeed. If any argument fails, the netlist remains unchanged. The *remove_net* command returns a 1 if successful and 0 if unsuccessful.

Each net specified must be in scope; that is, at or below the current instance.

Managing Changes

The changes caused by netlist editing commands are recorded in a *change list*, which is annotated on the design. The contents of the change list can be displayed or exported

using the *write_changes* command. The script output formats for PrimeTime and Design Compiler are the most useful. For details, see the *write_changes* man page.

Edits to lower levels of the hierarchy can be undone by swapping in the original version of the design with *swap_cell*. However, edits to the top level of a design cannot be undone without removing the design, rereading the original design, and re linking it.

Uniquification

Uniquification is the process of making each hierarchical block unique in a set of multiple instances of a design. For example, if the block is an instance of BLOCK, PrimeTime searches for a design name (BLOCK_0, BLOCK_1, and so on), until an unused name is found. That becomes the name of the unique design. Uniquification in PrimeTime is somewhat different from uniquification in other Synopsys applications, in that new designs are not created at the time that uniquification occurs. A placeholder for the design is created, similar to the placeholder that exists when a design is removed from memory by *link_design -remove_sub_designs*. Uniquified designs can be listed using *list_designs -all*. They become real designs only when that becomes necessary; for example, when the design is relinked.

The tool automatically uniquifies the necessary blocks -- the edited block and its parent blocks up to the top of the hierarchy. A block that is an instance of a design with multiple instances becomes unique when you edit it. The tool informs you when uniquification occurs.

The following example shows the *size_cell* command being used on a cell and causing uniquification, which is reported by the messages.

```
pt_shell> size_cell n1 class/NR4P
Uniquifying 'i1/low' (low) as 'low_0'.
Uniquifying 'i1' (inter) as 'inter_0'.
Sized 'i1/low/n1' with 'class/NR4P'
1
```

In addition to performing automatic uniquification, the tool marks an edited block and its parent blocks with the *is_edited* Boolean attribute, available on a design and hierarchical cells. The following example shows that the value of the *is_edited* attribute on i1/low is *true* after the *size_cell* command was used in the previous example.

```
pt_shell> get_attribute [get_cells i1/low] is_edited
true
```

Examples

In the following example, nets are removed if their names begin with "new":

```
pt_shell> remove_net [get_nets new*]
Information: Removed net 'new_net1'. (NED-017)
Information: Removed net 'new_net2'. (NED-017)
1
```

Feedback

- size_cell
- swap_cell
- write_changes

---

remove_noise_immunity_curve

Removes noise immunity curve for a library pin or port.

Syntax

int *remove_noise_immunity_curve*

```
[-above]
[-below]
[-low]
[-high]
object_list
```

Data Types

```
object_list      list
```

Arguments

`-above`

Removes the noise immunity curve for above ground or power rail noise analysis region.

`-below`

Removes the noise immunity curve for below ground or power rail noise analysis region.

`-low`

Removes the noise immunity curve for ground rail noise.

`-high`

Removes the noise immunity curve for power rail noise. 1.0.

object_list

Specifies a list of lib-pins or ports.

Description

This command removes the noise immunity curve information set by the *set_noise_immunity_curve* command.

Feedback

Examples

This example removes noise immunity curve information for the above the ground rail noise for pin A of library cell IV in the lsi_10k library:

```
pt_shell> remove_noise_immunity_curve -above lsi_10k/IV/A
```

See Also

- set_noise_immunity_curve

---

remove_noise_lib_pin

Removes an equivalent noise library pin for a driver or load.

Syntax

int *remove_noise_lib_pin*

pins

Data Types

pins list

Arguments

pins

Specifies the collection of pins for which the equivalent noise library pin is set by the *set_noise_lib_pin* command that needs to be removed.

Description

Given a collection of pins, this command allows you to remove a noise library pin previously set as an equivalent in terms of library noise information.

Examples

The following example removes any equivalent noise information on two input pins of the design, which is the same as an input library pin:

```
pt_shell> remove_noise_lib_pin [get_pins {cell/pin1 cell/pin2}] \\
```

See Also

- set_noise_lib_pin
- update_noise

Feedback

- report_noise
- report_noise_calculation

---

remove_noise_margin

Removes noise margin for a library pin or port.

Syntax

int *remove_noise_margin*

```
[-above]
[-below]
[-low]
[-high]
object_list
```

Data Types

object_list	list

Arguments

`-above`

Removes the noise margin for above ground or power rail noise analysis region.

`-below`

Removes the noise margin for below ground or power rail noise analysis region.

`-low`

Removes the noise margin for ground rail noise.

`-high`

Removes the noise margin for power rail noise. 1.0.

object_list

Specifies a list of lib-pins or ports.

Description

This command removes the noise margin information set by the *set_noise_margin* command.

Feedback

Examples

This example removes noise margin information for above the ground rail noise for pin A of library cell IV in the lsi_10k library:

```
pt_shell> remove_noise_margin -above lsi_10k/IV/A
```

See Also

- set_noise_margin

---

remove_ocvm

Removes advanced and parametric on-chip variation (AOCV / POCV) information.

Syntax

status *remove_ocvm*

```
[-coefficient]
[-derate]
[object_list]
```

Data Types

object_list list

Arguments

`-coefficient`

Removes only the AOCV coefficients. The *-coefficient* and *-derate* options are mutually exclusive.

`-derate`

Removes only the AOCV/POCV derating factors. The *-coefficient* and *-derate* options are mutually exclusive.

object_list

Specifies the objects from which AOCV/POCV information is removed.

Description

Removes user-specified AOCV coefficients and AOCV/POCV derating factors that were previously set with the *set_aocvm_coefficient* and *read_ocvm* commands, respectively. If the command is specified with no options, all AOCV/POCV data is removed.

To display AOCV/POCV deratings and coefficients, use the *report_ocvm* command.

Feedback

Examples

The following example removes the AOCV coefficients from the library cell named lib/bufA:

```
pt_shell> remove_ocvm -coefficient lib/bufA
```

The following example removes all AOCV/POCV derating factors that were set using the *read_ocvm* command:

```
pt_shell> remove_ocvm -derate
```

The following example removes all AOCV/POCV derating factors from the current design:

```
pt_shell> remove_ocvm -derate [current_design]
```

See Also

- read_ocvm
- report_ocvm
- set_aocvm_coefficient

---

remove_operating_conditions

Removes operating conditions from current design, cells, or ports.

Syntax

string *remove_operating_conditions*

```
[-object_list objects]
```

Data Types

objects list

Arguments

-object_list objects

Specifies the cells or ports to remove operating conditions from. The command undoes operating conditions set by the *set_operating_conditions* command. Without the *-object_list* option, all the operating conditions are removed from the design. Both leaf cells and hierarchical blocks are accepted with the *-object-list* option.

Description

Removes operating conditions settings from the current design, individual blocks, leaf cells, or ports.

Feedback

Examples

This example removes all operating conditions from the current design. Both design-specific and cell-specific operating conditions are removed.

```
pt_shell> remove_operating_conditions
```

See Also

- set_operating_conditions

---

remove_output_delay

Removes output delay from output ports or pins.

Syntax

string *remove_output_delay*

```
[-clock clock_name]
[-clock_fall]
[-level_sensitive]
[-rise]
[-fall]
[-max]
[-min]
[-sms_scenarios sms_scenarios_list]
port_pin_list
```

Data Types

clock_name	string
port_pin_list	list
sms_scenarios_list	collection

Arguments

`-clock` *clock_name*

Relative clock; {""} for input delay relative to no clock.

`-clock_fall`

Removes the delay relative to falling edge of clock. If you specify the *clock_name* variable without the *-clock_fall* command, the delay relative to rising edge of the clock is removed.

`-level_sensitive`

Removes level-sensitive output delay.

`-rise`

Removes rising output delay.

`-fall`

Removes falling output delay.

`-max`

Removes maximum output delay.

`-min`

Removes minimum output delay.

`port_pin_list`

Specifies a list of ports and pins. Each element in the list is either a collection of ports or pins, or a pattern which matches ports or pins on the current design.

`-sms_scenarios` *`sms_scenarios_list`*

Specifies a collection of SMS scenarios. The command uses this option to restrict its scope, removing only output delays compatible with the specified SMS scenarios. This option is only available with SMVA or SMC analysis. This collection is created by *get_sms_scenarios*.

Description

Removes output delay values for objects in the current design. Set output delay with the *set_output_delay* command. By default, all output delays on each object in the *port_pin_list* command are removed. To restrict the removed output delay values, use the *-clock*, *-clock_fall*, *-min*, *-max*, *-rise*, or *-fall* options. To show output delays associated with ports, use the *report_port -output_delay* command.

Examples

The following example removes all output delay values from all output ports in the current design.

```
pt_shell> remove_output_delay [all_outputs]
```

The following example removes output maximum rise delay values from OUT1, OUT3, and BIDIR12.

```
pt_shell> remove_output_delay -max -rise {OUT1 OUT3 BIDIR12}
```

The following example removes all output delays for port OUT1 relative to the falling edge of CLK2.

```
pt_shell> remove_output_delay -clock CLK2 -clock_fall OUT1
```

The following example removes all output delays not relative to any clock for port OUT2.

```
pt_shell> remove_output_delay -clock {""} OUT2
```

See Also

- all_outputs
- collections
- report_port
- set_output_delay
- set_input_delay

---

remove_parasitic_corner

Removes a previously set parasitic corner in the presence of variation-aware parasitics.

Syntax

status *remove_parasitic_corner*

Arguments

None.

Description

The *remove_parasitic_corner* command removes the parasitic corner information previously set via the *set_parasitic_corner* command. The command succeeds only if variation-aware parasitics were annotated and the *set_parasitic_corner* command is used to set the parasitic corner.

After using this command, all the parasitic attributes and analysis use nominal values instead of corner values.

Examples

The following example removes the parasitics corner information set previously.

```
pt_shell> remove_parasitic_corner
```

See Also

- set_parasitic_corner
- read_parasitics
- report_annotated_parasitics

Feedback

remove_path_group

Removes path group objects.

Syntax

string *remove_path_group*

```
-all
path_group_list
```

Data Types

```
path_group_list        list
```

Arguments

`-all`

Removes all path groups in the current design.

`path_group_list`

Specifies path group names to remove. Each element in the list is either a collection of path groups or a pattern matching path group names.

Description

Removes path groups in the current design. The *group_path* and *create_clock* commands create path groups. Path groups affect the cost function for optimization and influence the timing reports. If you remove a path group, any paths in that group are implicitly assigned to the default path group. To show path group information, use the *report_path_group* command.

Examples

The following example removes all path groups in the design.

```
pt_shell> remove_path_group -all
```

The following example removes path group "BUS1".

```
pt_shell> remove_path_group BUS1
```

See Also

- collections
- create_clock
- group_path

Feedback

- report_path_group
- report_timing

---

remove_path_tag_set

Removes path tag sets or removes paths from path tag sets.

Syntax

status *remove_path_tag_set*

```
[path_collection]
[-name tag_names]
```

Data Types

```
path_collection     collection
tag_names           list
```

Arguments

path_collection

Specifies a collection of paths. The command removes these paths from the named path tag sets or all path tag sets, reducing the number of paths in those path tag sets. Without this option, the command removes whole path tag sets.

-name *tag_names*

Specifies a single path tag or a list of path tag sets to remove, or to reduce by removing the paths specified by the *path_collection* option. Without the *-name* option, the command applies to all path tag sets.

Description

This command removes a named path tag set or list of named path tag sets, or all path tag sets if the *-name* option is not used.

If you specify a path collection, the command removes those paths from the named path tag sets or all path tag sets.

Examples

The following example removes all path tag sets.

```
pt_shell> remove_path_tag_set
```

The following example removes the path tag sets named tag1 and tag3.

```
pt_shell> remove_path_tag_set -name {tag1 tag3}
```

The following example removes a collection of paths from the tag1 path set.

```
pt_shell> remove_path_tag_set -name tag1 [get_timing_paths -max_paths 20]
```

See Also

- create_path_tag_set
- report_path_tag_set
- enable_path_tagging

---

remove_placement_blockage

Removes a placement blockage.

Syntax

status *remove_placement_blockage*

```
[-name blockage_name]
[-all]
```

Data Types

```
blockage_name     string
```

Arguments

`-name blockage_name`

Specifies the optional name of the blockage.

Description

This command removes a placement blockage that controls the placement of ECO cells when you use the *fix_eco_drc* or *fix_eco_timing* command with the *-physical_mode* option.

You can remove a placement blockage to remove the placement blockages created by *create_placement_blockage* command. You can also specify the -all option to remove all placement blockages.

Examples

The following example removes a placement blockage named placeblockage_10.

```
pt_shell> remove_placement_blockage -name placeblockage_10
```

Feedback

See Also

- create_placement_blockage
- write_changes

---

remove_port_fanout_number

Removes fanout number information on ports.

Syntax

string *remove_port_fanout_number*

```
        port_list
```

Data Types

port_list	list

Arguments

port_list

Specifies a list of ports. Each element in the list is either a collection of ports or a pattern that matches ports on the current design.

Description

Removes the *fanout_number* settings on ports. The *set_port_fanout_number* command sets the number of external fanout pins on ports, which is used along with wire load models to calculate capacitance and resistance of nets. To show port fanout number information, use the *report_port -wire_load* command.

Examples

This example removes the port fanout_number settings from ports OUT1*.

```
pt_shell> remove_port_fanout_number [get_ports OUT1*]
```

See Also

- collections
- get_ports
- report_port

Feedback

- set_port_fanout_number
- set_wire_load_model

---

remove_power_groups

Remove the existing power groups.

Syntax

string *remove_power_groups*

```
-all
group_names
```

Data Types

```
group_names          list
```

Arguments

`-all`

Removes all the user-defined power groups. Note that predefined power groups are note deleted using this option.

group_names

Specifies the groups to be removed.

Description

The *remove_power_groups* command removes some or all power groups that are previously created but no longer interested. The predefined power groups can be removed, but not with the *-all* option. The predefined power group names need to be explicitly specified.

Examples

In the following example, all the user defined power groups are removed.

```
pt_shell> remove_power_groups -all
1
```

In the following example, the predefined clock_network power group is removed.

```
pt_shell> remove_power_groups clock_network
1
```

Feedback

See Also

- create_power_group
- report_power_groups
- get_power_group_objects

---

remove_propagated_clock

Removes a propagated clock specification.

Syntax

string *remove_propagated_clock*

object_list

Data Types

object_list list

Arguments

object_list

Lists clocks, ports, or pins.

Description

Removes propagated clock specification from clocks, ports, or pins in the current design. The *set_propagated_clock* command specifies that delays be propagated through the clock network to determine latency at register clock pins. If this is not specified, ideal clocking is assumed. Ideal clocking means clock networks have a user specified latency (set by the *set_clock_latency* command) or zero latency, by default. Propagated clock latency is normally used for post layout, after final clock tree generation.

Ideal clock latency provides an estimate of the clock tree for prelayout. You can also use the *set_clock_latency* command to specify an ideal latency, which overrides the propagated clock specification for an object.

For information about propagated clock attributes on clocks, see the *report_clock* man page.

Examples

The following example removes propagated clock specifications from all clocks in the design.

```
pt_shell> remove_propagated_clock [all_clocks]
```

Feedback

See Also

- report_clock
- set_clock_latency
- set_propagated_clock

---

remove_pulse_clock_max_transition

Removes maximum transition limits from pulse clock network and input of pulse generator.

Syntax

string *remove_pulse_clock_max_transition*

```
[-rise]
[-fall]
[-transitive_fanout]
object_list
```

Data Types

```
object_list       list
```

Arguments

`-rise`

Removes the rise transition constraint.

`-fall`

Removes falling transition constraint.

`-transitive_fanout`

Removes the constraint from the transitive fanout of the pulse generator. If this option is not specified, the constraint is removed from the input of pulse generator.

`object_list`

Lists the pulse generator cell, pulse generator lib cell, clock, and design from which to remove maximum pulse clock transition limits.

Description

Removes maximum pulse clock transition limits from the specified objects. A maximum transition limit is specified with the *set_pulse_clock_max_transition* command. This command can change the constraint on the object, which has conflicting constraints due to overlap. You can use the *-rise* and *-fall* options to remove only the rising or the falling transition respectively. If neither the *-rise* nor the *-fall* option is specified, both rise and fall

transition limits are removed. You must specify the *-transitive_fanout* option to remove pulse clock maximum transition constraint from the transitive fanout of pulse generators.

Examples

The following example removes the pulse clock maximum transition limit from the input of all the cells corresponding to the library cell pulse_rise_high in the library celllib.

```
pt_shell> remove_pulse_clock_max_transition {"celllib/pulse_rise_high"}
```

The following example removes maximum transition limit from all the pulse clock networks in the clock network clk

```
pt_shell> remove_pulse_clock_max_transition -transitive_fanout
 [get_clocks clk]
```

See Also

- current_design
- set_pulse_clock_max_transition
- report_pulse_clock_max_transition
- report_constraint

---

remove_pulse_clock_max_width

Removes maximum pulse width limits from pulse clock network.

Syntax

string *remove_pulse_clock_max_width*

```
[-transitive_fanout]
object_list
```

Data Types

object_list	list

Arguments

`-transitive_fanout`

Remove the constraints from the transitive fanout of pulse generators. In this release, specifying or not specifying this option has the same behavior.

object_list

Lists the pulse generator cell, pulse generator lib cell, clock and design from which to remove maximum pulse clock width limits.

Feedback

Description

Removes maximum pulse clock width limits from the specified objects. A maximum width limit is specified with the *set_pulse_clock_max_width* command. This command can change the constraint on the object, which has conflicting constraints due to overlap.

Examples

The following example removes maximum width limit from all the pulse clock networks in the design.

```
pt_shell> remove_pulse_clock_max_width [current_design]
```

See Also

- current_design
- set_pulse_clock_max_width
- report_pulse_clock_max_width
- report_constraint

---

remove_pulse_clock_min_transition

Removes minimum transition limits from input of pulse generator.

Syntax

string *remove_pulse_clock_min_transition*

```
[-rise]
[-fall]
object_list
```

Data Types

object_list	list

Arguments

`-rise`

Removes the rise transition constraint.

`-fall`

Removes the falling transition constraint.

object_list

Lists the pulse generator cell, pulse generator lib cell, clock and design from which to remove minimum pulse clock transition limits.

Feedback

Description

Removes minimum pulse clock transition limits from the input of specified objects. If clock or design is specified, the minimum transition limit is removed from the input of all the pulse generators in the clock network or design, respectively. A minimum transition limit is specified with the *set_pulse_clock_min_transition* command. This command can change the constraint on the object, which has conflicting constraints due to overlap. You can use the *-rise* and *-fall* options to remove only the rising or the falling transition, respectively. If neither the *-rise* or *-fall* option is specified, both rise and fall transition limits are removed.

Examples

The following example removes a minimum transition limit from input of all the cells corresponding to the *pulse_rise_high* library cell in the *celllib* library.

```
pt_shell> remove_pulse_clock_min_transition {"celllib/pulse_rise_high"}
```

See Also

- current_design
- set_pulse_clock_min_transition
- report_pulse_clock_min_transition
- report_constraint

---

remove_pulse_clock_min_width

Removes minimum pulse width limits from pulse clock network.

Syntax

string *remove_pulse_clock_min_width*

```
[-transitive_fanout]
object_list
```

Data Types

object_list	list

Arguments

`-transitive_fanout`

Removes the constraints from the transitive fanout of pulse generators. In this release, specifying or not specifying this option has the same behavior.

object_list

Lists the pulse generator cell, pulse generator lib cell, clock and design from which to remove minimum pulse clock width limits.

Description

Removes minimum pulse clock width limits from the specified objects. A minimum width limit is specified with the *set_pulse_clock_min_width* command. This command can change the constraint on the object, which has conflicting constraints due to overlap.

Examples

The following example removes minimum width limit from all the pulse clock networks in the clock network clk.

```
pt_shell> remove_pulse_clock_min_width [get_clocks clk]
```

See Also

- current_design
- set_pulse_clock_min_width
- report_pulse_clock_min_width
- report_constraint

---

remove_qtm_attribute

Removes an attribute setting from the QTM object.

Syntax

string *remove_qtm_attribute*

```
-class lib | lib_cell | lib_pin
attribute_name
object_names
```

Data Types

```
attribute_name      string
object_names        list
```

Arguments

```
-class lib | lib_cell | lib_pin
```

Specifies the class of the QTM objects to remove attribute from.

attribute_name

Specifies the name of the attribute.

object_names

Specifies the names of the objects from which to remove the named attribute. Each element in the list must be a name to identify an object in the specified class. The object names should not be specified when the object class is either *lib* or *lib_cell*. It must be specified when the class is *lib_pin*, in which case the object names should be the names of ports already defined for the QTM.

Description

The *remove_qtm_attribute* command removes attributes you set with the *set_qtm_attribute* command.

You can remove either application attributes or user attributes you defined for QTM object with the *define_qtm_attribute* command.

Examples

The following example defines the is_XYZ Boolean attribute for QTM cell, then sets the value on the QTM cell under construction. Finally, it removes the attribute from the cell.

```
pt_shell> define_qtm_attribute -type boolean -class lib_cell "is_XYZ"
pt_shell> set_qtm_attribute -class lib_cell "is_XYZ" "true"
pt_shell> remove_qtm_attribute -class lib_cell "is_XYZ"
```

The following example defines the my_float_attr user attribute for all QTM port objects, sets the value for two QTM ports, and removes the attribute from one of the ports.

```
pt_shell> define_qtm_attribute -type float -class lib_pin
 "my_float_attr"
pt_shell> set_qtm_attribute -class lib_pin "my_float_attr" 100.0 {IN,
 OUT}
pt_shell> remove_qtm_attribute -class lib_pin "my_float_attr" {OUT}
```

See Also

- define_qtm_attribute
- define_user_attribute
- set_qtm_attribute

---

remove_qtm_constraint_arc

Removes a constraint arc for a quick timing model.

Feedback

Syntax

string *remove_qtm_constraint_arc*

```
[-name arc_names]
[-setup]
[-hold]
[-recovery]
[-removal]
[-from port_spec]
[-to port_spec]
[-edge rise | fall]
[-signal_edge rise | fall]
[-quiet]
```

Data Types

arc_names	list
port_spec	list

Arguments

`-name arc_names`

Specifies the names of constraint arcs to be removed.

`-setup`

Removes setup arcs.

`-hold`

Removes hold arcs.

`-recovery`

Removes recovery arcs.

`-removal`

Removes removal arcs.

`-from port_spec`

Remove arcs with given starting constraining clock port.

`-to port_spec`

Remove arcs with given ending constrained input/inout port.

`-edge rise | fall`

Remove arcs with given triggering edge.

`-signal_edge rise | fall`

Remove arcs with given direction of the signal at the constrained port.

Feedback

`-quiet`

Suppress the warning message and silently return true if no arc is removed.

Description

This command allows you to remove previously defined constraint arcs by *create_qtm_constraint_arc* in a quick timing model. The options are filters to select matching QTM arcs. More options make the removal more specific. The *-from* port denotes the constraining port, and the *-to* port denotes the constrained port. The *-from* port must be defined as a clock port and the *-to* port must be an input or inout port. You can use *-signal_edge* option to specify the the direction of the signal at the constrained port specified by the -to option.

Use the *-setup*, *-hold*, *-recovery* and *-removal* options to remove setup, hold, recovery or removal arcs. You must use at leaset one of the switches. Use the *-edge* option and specify rise or fall for the triggering clock of the arcs to be removed.

If no predefined QTM arcs satisfy the condition in the command, no arcs will be removed. A warning will be issued unless you use the *-quiet* option.

Examples

The following commands create and remove setup arcs from the positive edge of constraining port CLK to IN1, and then create a new arc with updated constraint value.

```
pt_shell> create_qtm_constraint_arc -setup -edge rise -from CLK -to IN1
 -value 3.0
pt_shell> remove_qtm_constraint_arc -setup -edge rise -from CLK -to IN1
pt_shell> create_qtm_constraint_arc -setup -edge rise -from CLK -to IN1
 -value 5.0
```

The following command removes all setup and hold arcs from the positive edge of constraining port CLK.

```
pt_shell> create_qtm_constraint_arc -setup -hold -edge rise -from CLK
```

See Also

- create_qtm_constraint_arc
- create_qtm_delay_arc
- create_qtm_model
- create_qtm_path_type
- get_qtm_ports
- report_qtm_model
- save_qtm_model

Feedback

remove_qtm_delay_arc

Removes a delay arc for a quick timing model (QTM).

Syntax

string *remove_qtm_delay_arc*

```
[-name arc_names]
[-from port_spec
[-to port_spec]
[-edge rise | fall]
[-from_edge rise | fall]
[-to_edge rise | fall]
[-quiet]
```

Data Types

arc_names	list
port_spec	list

Arguments

`-name arc_names`

Specifies the names of delay arcs to be removed.

`-from port_spec`

Specifies the startpoint of the delay arc to be removed. This must be QTM port name or a collection of QTM ports.

`-to port_spec`

Specifies the endpoint of the delay arc to be removed. This must be QTM port name or a collection of QTM ports with output or inout type.

`-edge rise | fall`

Remove arcs with given triggering edge.

`-from_edge rise | fall`

Remove arcs with given triggering edge (clock startpoints) or the signal direction (data startpoints).

`-to_edge rise | fall`

Remove arcs with given the signal direction at the data endpoints.

`-path_type path_type`

Specifies the path type you want to use to set the delay.

`-quiet`

Suppress the warning message and silently return true if no arc is removed.

Description

This command allows you to remove previously defined delay arcs by *create_qtm_delay_arc* in a quick timing model.

The options are filters to select matching QTM arcs. More options make the removal more specific. By default, if you specify a list of ports for the -from and *-to* ports, all delay arcs between these ports will be removed.

One of *-from* and *-to* option is required for the command. To remove only edge triggered arcs, use the -edge option.You can use *-from_edge* and *-to_edge* to remove arcs with specify the triggered edge for clock start points or the signal direction for data startpoints and endpoints.

If no predefined QTM arcs satisfy the condition in the command, no arcs will be removed. A warning will be issued unless you use the *-quiet* option.

Examples

The following commands create and removes a delay arc from input ports IN* to output port OUT with a delay value of 2.0 time units, and then creates a new arc with updated delay values.

```
pt_shell> create_qtm_delay_arc -from [get_qtm_ports IN*] -to OUT -edge
 rise -value 2.0
pt_shell> remove_qtm_delay_arc -from [get_qtm_ports IN*] -to OUT -edge
 rise
pt_shell> create_qtm_delay_arc -from [get_qtm_ports IN*] -to OUT -edge
 rise -value 5.0
```

The following commands first create and remove a delay arc from clock CLK to output ports OUT* with a delay value of 2.0 time units. And then it create a new generated clock and creates a new delay arc starting from it.

```
pt_shell> create_qtm_delay_arc -from CLK -to [get_qtm_ports OUT*] -edge
 rise -value 2.0
pt_shell> remove_qtm_delay_arc -from CLK -to [get_qtm_ports OUT*] -edge
 rise
pt_shell> create_qtm_generated_clock GCLK -source CLK -divide_by 2
pt_shell> create_qtm_delay_arc -from GCLK -to [get_qtm_ports OUT*] -edge
 rise -value 5.0
```

See Also

- create_qtm_path_type
- get_qtm_ports
- report_qtm_model
- save_qtm_model

---

remove_qtm_generated_clock

Removes a QTM generated clock.

Syntax

string *remove_qtm_generated_clock*

```
[clock_list]
[-all]
[-quiet]
```

Data Types

```
clock_list        list
all            boolean
quiet          boolean
```

Arguments

clock_list

Specifies a list of names of the generated clocks to be removed.

-all

Remove all generated clocks in the qtm model. *clock_list* and *-all* are mutually exclusive. At least one of these options must be given.

-quiet

Suppress the warning message and silently return true if no clock is removed.

Description

This command removes QTM generated clocks created by *create_qtm_generated_clock*. When removing a QTM generated clock, the command will automatically remove all arcs triggered by the clock. All generated clocks whose master clock is this clock will also be removed.

If the generated clock to be removed is defined on an internal port in the QTM, that internal port will also be removed.

Feedback

If no predefined QTM generated clocks satisfy the condition in the command, no clocks will be removed. A warning will be issued unless you use the *-quiet* option.

Examples

The following example creates and removes a divide by 2 generated clock on an internal port, assume there is no port defined with name "GCLK_int", with master clock CLK. It then creates a new divide by 3 generated clock to replace it.

```
pt_shell> create_qtm_generated_clock GCLK_int -source CLK -divide_by 2
pt_shell> remove_qtm_generated_clock GCLK_int
pt_shell> create_qtm_generated_clock GCLK_int -source CLK -divide_by 3
```

The following example removes all generated clocks in the QTM.

```
pt_shell> remove_qtm_generated_clock -all
```

See Also

- report_qtm_model
- save_qtm_model

---

remove_qtm_port

Removes a quick timing model (QTM) port.

Syntax

string *remove_qtm_port*

```
port_list
[-quiet]
```

Data Types

```
port_list     list
```

Arguments

port_list

Specifies the list of QTM ports you want removed.

Feedback

`-quiet`

Suppress the warning message and silently return true if no port is removed.

Description

This command removes QTM ports created by *create_qtm_port*. You can remove a single port or a list of ports with this command. When removing a QTM port, the command will automatically remove all arcs connected to the ports. If the port is a clock port, all generated clocks whose master clock is this will also be removed.

Bus ports must be removed together by giving the start and end index (A[0:5]). A single bus port can not be removed.

If no predefined QTM ports satisfy the condition in the command, no ports will be removed. A warning will be issued unless you use the *-quiet* option.

Examples

The following example removes a bused QTM port A[0:5].

```
pt_shell> remove_qtm_port A[0:5]
```

The following example removes QTM ports A, B, C, and D.

```
pt_shell> remove_qtm_port {A B C D}
```

See Also

- set_qtm_port_load

---

remove_rail_voltage

Removes power rail voltage that was set by the *set_rail_voltage* command on cells.

Syntax

int *remove_rail_voltage*

```
        cell_list
```

Data Types

```
cell_list          list
```

Arguments

cell_list

Specifies a list of cells from which to remove rail voltages.

Description

Removes power rail voltage that was set by the *set_rail_voltage* command on cells. If dynamic components of rail voltage have been specified they are also removed along with the total rail voltage. This command "undoes" the voltages specified by the *set_rail_voltage* command. It can be applied to both leaf cells and hierarchical blocks.

Examples

The following example removes rail voltages from a cell named *h1/u3*.

```
pt_shell> remove_rail_voltage [get_cells {h1/u3}]
1
```

See Also

- set_operating_conditions
- set_rail_voltage

---

remove_resistance

Removes resistance on nets.

Syntax

status *remove_resistance*

```
        net_list
```

Data Types

```
net_list     list
```

Feedback

Arguments

net_list

Specifies a list of nets in the current design, whose resistances are removed.

Description

Specifies that the lumped resistance annotated on the list of nets must be removed. PrimeTime will revert to using the resistance from detailed parasitics (set using the *read_parasitics* command), if they exist. If not, the internally estimated net resistance is used.

Annotated resistances can also be removed on the full design by using the *reset_design* command.

Examples

The following example removes the annotated resistance on net w23.

```
pt_shell> remove_resistance [get_nets "w23"]
```

See Also

- all_outputs
- current_design
- set_resistance
- report_net
- report_port
- reset_design
- set_drive

---

remove_ruleset

Removes specified rulesets.

Syntax

Boolean *remove_ruleset*

ruleset_list

```
list ruleset_list
```

Feedback

Arguments

ruleset_list

The list of rulesets to remove.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Removes specified rulesets. Note that removing a ruleset does not remove the rules in that ruleset, as one rule may be in multiple rulesets. To remove all rules in a ruleset, use the *remove_rule* command instead.

Examples

The following example removes the ruleset named "my_set1".

```
pt_shell> remove_ruleset my_set1
```

See Also

- create_rule
- create_ruleset
- get_rules

---

remove_scenario

Removes a scenario in the multi-scenario analysis mode.

Syntax

status *remove_scenario*

```
        scenario_list
```

Data Types

scenario_list list

Arguments

scenario_list

Specifies unique strings used to identify each scenario.

Description

This command is available only if you invoke the pt_shell with the *-multi_scenario* option.

The *remove_scenario* command removes the specified scenario from memory. To determine the current scenarios that exist, execute the following:

```
report_multi_scenario_design -scenarios
1
```

Examples

In the following example, two scenarios named scen1 and scen2 are removed.

```
pt_shell> remove_scenario {scen1 scen2}
1
```

See Also

- create_scenario
- report_multi_scenario_design

---

remove_scenario_case_analysis

Removes the scenario case analysis value on a port or pin.

Syntax

```
status remove_scenario_case_analysis
  port_or_pin_list
  [-sms_scenarios sms_scenarios_list]
  [-all]
```

Data Types

```
port_or_pin_list     list
sms_scenarios_list           collection
```

Arguments

port_or_pin_list

Removes case analysis from the specified ports or pins.

-sms_scenarios

Describes the scenarios on which the scenario case analysis is to be removed. If this option is ommitted, all scenario case analysis is removed from the ports or pins.

all

Removes all scenario case analysis throughout the design.

Feedback

Description

This command removes previously specified entries of scenario case analysis on ports or pins. You must specify either the *port_or_pin_list* option, or *-all*.

Regular case analysis set using *set_case_analysis* is not removed by *remove_scenario_case_analysis*.

See Also

- report_case_analysis
- set_scenario_case_analysis

---

remove_sense

Removes sense information defined on pins or cell timing arcs.

Syntax

```
status remove_sense
   [-type clock | data]
   [-clocks clock_list]
   [-all]
   object_list
```

Data Types

```
clock_list      list
object_list     list
```

Arguments

`-type clock | data`

Specifies the removal of sense from *clock* (the default) or *data* networks.

`-clocks clock_list`

Specifies a list of clock objects to be associated with the given pin objects in the *object_list*. This option removes the unateness only for the specified clock domain. This option can only remove clock sense predefined by the *set_sense -type clock* command. It does not remove the default clock sense setting for this given pin.

`-all`

Removes all unateness information in current design. Please note that when no type is specified, it removes all the sense information from *clock* (the default) network.In order to remove all the sense information from the *data* network, please explicitly specify *-type data*.

object_list

Specifies a list of pins or cell timing arcs from which to remove predefined unateness.

Description

This command removes the unateness information that was previously defined by the *set_sense* command.

Examples

This example removes positive unateness defined on the XOR/Z pin with respect to the CLK1 clock but does not remove the negative unateness.

```
pt_shell> set_sense -positive -clocks [get_clocks CLK1] XOR/Z
pt_shell> set_sense -negative XOR/Z
pt_shell> remove_sense -clocks [get_clocks CLK1] XOR/Z
```

This example removes all unateness information in the current design.

```
pt_shell> remove_sense -all
```

See Also

- set_sense

---

remove_si_aggressor_exclusion

Removes the exclusive groups set by the *set_si_aggressor_exclusion* command.

Syntax

status *remove_si_aggressor_exclusion*

```
[-rise]
[-fall]
[-all]
[nets]
```

Data Types

nets list

Arguments

-rise

Removes the exclusive group set for the aggressor nets *anets* in the *rise* direction. If neither the *-rise* nor the *-fall* option is specified, the exclusive groups of the aggressor nets *anets* in both *-rise* and *-fall* directions are removed.

`-fall`

Removes the exclusive group set for the aggressor nets *anets* in the *fall* direction. If neither the *-rise* nor the *-fall* option is specified, the exclusive groups of the aggressor nets *anets* in both *-rise* and *-fall* directions are removed.

`-all`

Removes all the exclusive groups set on the design.

nets

Specifies the list of nets belonging to one exclusive group that are to be removed.

Description

The *remove_si_aggressor_exclusion* command removes the effect of the *set_si_aggressor_exclusion* command that was set on the aggressor nets. Only those groups that have been set can be removed. A warning message is issued if you are trying to remove a group that has not been set.

These exclusive commands are independent of parasitics, so they can be applied even before reading in parasitics.

Note that application of exclusive aggressors are not done incrementally. The next *update_timing* and *update_noise* commands would produce a full update.

You can use the *report_si_aggressor_exclusion* command to check whether the *remove_si_aggressor_exclusion* command was applied to the exclusive groups.

Examples

The following example shows how to remove the exclusion on nets *SCAN_LOGIC** for rise direction.

```
pt_shell> set_si_aggressor_exclusion [get_nets SCAN_LOGIC*] -rise
1
pt_shell> remove_si_aggressor_exclusion [get_nets SCAN_LOGIC*]
1
```

The following example shows how to remove all exclusive groups set on the design.

```
pt_shell> remove_si_aggressor_exclusion -all
1
```

See Also

- report_delay_calculation
- report_noise_calculation
- report_si_aggressor_exclusion

Feedback

- set_si_aggressor_exclusion
- set_si_delay_analysis
- set_si_noise_analysis
- si_analysis_logical_correlation_mode

---

remove_si_delay_analysis

Removes the effect of the *set_si_delay_analysis* command.

Syntax

int *remove_si_delay_analysis*

```
[-ignore_arrival inets]
[-victims vnets]
[-aggressors anets]
[-rise]
[-fall]
[-min]
[-max]
[-all]
```

Data Types

```
inets        list
vnets        list
anets        list
```

Arguments

`-ignore_arrival inets`

Removes the effect of using the *set_si_delay_analysis* command with its *-ignore_arrival* option. You cannot use this option with the *-victims* and *-aggressors* options.

`-victims vnets`

Removes the effect of using the *set_si_delay_analysis* command with its *-victims* option. When you use the *-victims* option with the *-aggressors* option, the command restores the pair-wise relationship. However, when the *-victims* option is used to remove the effect set by the *set_si_delay_analysis* command with the *-aggressors* option, it does not remove any exclusion on the nets. You cannot use the *-victims* option with the *-ignore_arrival* option.

`-aggressors anets`

Removes the effect of the *set_si_delay_analysis* command with its *-aggressors* option. When you use the *-aggressors* option with the *-victims* option, the

command restores the pair-wise relationship. However, when the *-aggressors* option is used to remove the effect set by the *set_si_delay_analysis* command with the o-*victims* option, it does not remove any exclusion on the nets. You cannot use the *-aggressors* option with the *-ignore_arrival* option.

`-rise`

Removes the effect of the *set_si_delay_analysis -exclude -rise* command.

`-fall`

Removes the effect of the *set_si_delay_analysis -exclude -fall* command.

`-min`

Removes the effect of the *set_si_delay_analysis -exclude -min* command.

`-max`

Removes the effect of the *set_si_delay_analysis -exclude -max* command.

`-all`

Removes all the effects of the *set_si_delay_analysis* command on all the nets.

Description

Removes the effect of the *set_si_delay_analysis* command.

The *set_si_delay_analysis* command allows you to exclude nets from crosstalk analysis or setting some net as infinite window as infinite window as both aggressor and victim . The *remove_si_delay_analysis* command removes such overrides.

The *remove_si_delay_analysis* command returns a *1* if successful and a *0* if unsuccessful. If the remove command is used to remove a effect that has not been set, the warning message *XTALK-107* is issued.

To view the result of this command, use the *report_si_delay_analysis* command.

Examples

In the following example, all the nets named *CLK_NET_** are returned to their original state in crosstalk analysis.

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets CLK_NET_*]
1

pt_shell> remove_si_delay_analysis -victims [get_nets CLK_NET_*]
1
```

However in the following examples, none of the nets named *REG_NET_** are returned to their original state in crosstalk analysis.

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets REG_NET_*]
1

pt_shell> remove_si_delay_analysis -aggressors [get_nets REG_NET_*]
Warning: Cannot remove an effect that was not set on net(s) REG_NET_1.
 (XTALK-107)
Warning: Cannot remove an effect that was not set on net(s) REG_NET_2.
 (XTALK-107)
1

pt_shell> remove_si_delay_analysis -aggressors [get_nets REG_NET_*]
-victims [get_nets CLK_NET]
1
```

If there is a VIC_NET with aggressors AGG_NET_* and you had set pairwise exclusion on the nets with the list of its aggressors, the AGG_NET_* nets cannot be returned to their original state by using only *-aggressors* option. For example,

```
pt_shell> set_si_delay_analysis -exclude -victims [get_nets VIC_NET]
-aggressors [get_nets AGG_NET*]
1

pt_shell> remove_si_delay_analysis -aggressors [get_nets AGG_NET*]
1
```

In order to reset the pairwise exclusion on the nets VIC_NET and AGG_NET_*, the pairwise reset should be used as shown below

```
pt_shell> remove_si_delay_analysis -victims [get_nets VIC_NET]
-aggressors [get_nets AGG_NET*]
1
```

To verify if the exclusion was removed on the nets, use the *report_si_delay_analysis* command with the *-excluded* option.

- report_si_delay_analysis
- si_enable_analysis

---

remove_si_delay_disable_statistical

Removes the effect of the *set_si_delay_disable_statistical* command.

Feedback

Syntax

int *remove_si_delay_disable_statistical*

```
        dnets
```

Data Types

dnets	list

Arguments

dnets

A list of nets for which the effect of the *set_si_delay_disable_statistical* command is removed.

Description

Removes the effect of the *set_si_delay_disable_statistical* command.

The *set_si_delay_disable_statistical* command allows you to disable the statistical analysis for the *dnets* option if selected in composite aggressor group for crosstalk analysis.

The *remove_si_delay_disable_statistical* command removes such effect.

Examples

The following example shows how to put net back into statistical analysis when considered as a composite aggressor.

```
pt_shell> remove_si_delay_disable_statistical [get_nets LOGIC1]
1
```

See Also

- set_si_delay_disable_statistical
- report_si_delay_analysis

---

remove_si_noise_analysis

Removes the effect of the *set_si_noise_analysis* command.

Syntax

int *remove_si_noise_analysis*

```
[-ignore_arrival inets]
[-victims vnets]
```

Feedback

```
[-aggressors anets]
[-above]
[-below]
[-low]
[-high]
[-all]
```

Data Types

inets list *vnets* list *anets* list

Arguments

`-ignore_arrival inets`

Removes the effect of using the *set_si_noise_analysis* command with its *-ignore_arrival* option. You cannot use this option with the *-victims* or *-aggressors* option.

`-victims vnets`

Removes the effect of using the *set_si_noise_analysis* command with its *-victims* option. When the *-victims* option is used to remove the effect set by the *set_si_noise_analysis* command with the *-aggressors* option, it does not remove any exclusion on the nets. However, when you use the *-victims* option with *-aggressors* option, the command restores the pair-wise relationship. You cannot use the *-victims* option with the *I-ignore_arrival* option.

`-aggressors anets`

Removes the effect of the *set_si_noise_analysis* command with its *-aggressors* option. When the *-aggressors* option is used to remove the effect set by the *set_si_noise_analysis* command with the *-victims* option, it does not remove any exclusion on the nets. However, when you use the *-aggressors* option with the *-victims* options, the command restores the pair-wise relationship. You cannot use the *-aggressors* option with the *-ignore_arrival* option.

`-above`

Removes the effect of the *set_si_noise_analysis -exclude -above* command.

`-below`

Removes the effect of the *set_si_noise_analysis -exclude -below* command.

`-low`

Removes the effect of the *set_si_noise_analysis -exclude -low* command.

`-high`

Removes the effect of the *set_si_noise_analysis -exclude -high* command.

`-all`

Removes all the effects of the *set_si_noise_analysis* command on all the nets.

Description

Removes the effect of the *set_si_noise_analysis* command.

The *set_si_noise_analysis* command allows you to exclude nets from noise analysis, or set some net as infinite window as aggressor. The *remove_si_noise_analysis* command removes such overrides.

The *remove_si_noise_analysis* command returns a *1* if successful and a *0* if unsuccessful. If remove command is used to remove a effect that has not been set, the warning message XTALK-107 is issued.

Examples

In the following example, all the nets named *CLK_NET_** are returned to their original state in noise analysis.

```
pt_shell> set_si_noise_analysis -exclude -victims [get_nets CLK_NET]
1

pt_shell> remove_si_noise_analysis -victims [get_nets CLK_NET*]
1
```

However in the following example, none of the nets named *REG_NET_** are returned to their original state in noise analysis.

```
pt_shell> set_si_noise_analysis -exclude -victims [get_nets REG_NET_*]
1

pt_shell> remove_si_noise_analysis -aggressors [get_nets REG_NET_*]
Warning: Cannot remove an effect that was not set on net(s) REG_NET_1.
 (XTALK-107)
Warning: Cannot remove an effect that was not set on net(s) REG_NET_2.
 (XTALK-107)
1

pt_shell> remove_si_noise_analysis -aggressors [get_nets REG_NET_*]
-victims [get_nets CLK_NET]
Warning: Cannot remove an effect that was not set on net(s) REG_NET_1
CLK_NET. (XTALK-107)
Warning: Cannot remove an effect that was not set on net(s) REG_NET_2
CLK_NET. (XTALK-107)
1
```

Feedback

If there is a VIC_NET with aggressors AGG_NET_* and you had set pairwise exclusion on the nets with the list of its aggressors, the AGG_NET_* nets cannot be returned to their original state in noise analysis. For example,

```
pt_shell> set_si_noise_analysis -exclude -victims [get_nets VIC_NET]
-aggressors [get_attribute -class net [get_nets VIC_NET] aggressors]
1

pt_shell> remove_si_noise_analysis -aggressors [get_nets AGG_NET*]
Warning: Cannot remove an effect that was not set on net(s)
AGG_NET_1. (XTALK-107)
Warning: Cannot remove an effect that was not set on net(s)
AGG_NET_2. (XTALK-107)
1
```

In order to reset the pairwise exclusion on the nets VIC_NET and AGG_NET_*, the pairwise reset should be used as shown below

```
pt_shell> remove_si_noise_analysis -victims [get_nets VIC_NET]
-aggressors [get_nets AGG_NET*]
1
```

To verify if the exclusion was removed on the nets, use the *report_si_noise_analysis* command with the *-excluded* option.

- si_enable_analysis

---

remove_si_noise_disable_statistical

Removes the effect of the *set_si_noise_disable_statistical* command.

Syntax

int *remove_si_noise_disable_statistical*

dnets

Data Types

dnets list

Feedback

Arguments

dnets

A list of nets for which the effect of the *set_si_noise_disable_statistical* command is removed.

Description

Removes the effect of the *set_si_noise_disable_statistical* command.

The *set_si_noise_disable_statistical* command allows you to disable the statistical analysis for the *dnets* option if selected in composite aggressor group for noise analysis.

The *remove_si_noise_disable_statistical* command removes such effect.

Examples

The following example shows how to put net back into statistical analysis when considered as a composite aggressor.

```
pt_shell> remove_si_noise_disable_statistical [get_nets LOGIC1]
1
```

See Also

- set_si_noise_disable_statistical
- report_si_noise_analysis

---

remove_steady_state_resistance

Removes steady state resistance for a library pin or port.

Syntax

int *remove_steady_state_resistance*

```
[-above]
[-below]
[-low]
[-high]
object_list
```

Data Types

object_list	list

Feedback

Arguments

`-above`

Removes the steady state resistance for above ground or power rail noise analysis region.

`-below`

Removes the steady state resistance for below ground or power rail noise analysis region.

`-low`

Removes the steady state resistance for ground rail noise.

`-high`

Removes the steady state resistance for power rail noise. 1.0.

`object_list`

Specifies a list of lib-pins or ports.

Description

This command removes the steady state resistance information set by the *set_steady_state_resistance* command.

Examples

This example removes steady state resistance information for the above the ground rail noise for pin A of library cell IV in the lsi_10k library:

```
pt_shell> remove_steady_state_resistance -above lsi_10k/IV/A
```

See Also

- set_steady_state_resistance

---

remove_target_library_subset

Removes target library subset specifications from the top-level design or hierarchical cells.

Syntax

status *remove_target_library_subset*

```
[-objects objects]
[-top]
```

Data Types

objects	list or collection

Feedback

Arguments

`-objects` *objects*

Removes the subset specifications from the specified hierarchical cells.

If you do not specify this option or the *-top* option, the tool uses the *-top* option by default.

`-top`

Removes the subset specification from the top-level design.

If you do not specify this option or the *-objects* option, the tool uses the *-top* option by default.

Description

This command removes the target library subset specifications from the specified design objects.

This command removes only subsets that were explicitly set on objects with the *set_target_library_subset* command. It does not remove subsets that are implicitly inherited from a parent hierarchical cell.

Examples

The following example removes the target library subset from the top-level hierarchy.

```
prompt> remove_target_library_subset -top
```

The following example removes the target library subset from a hierarchical cell.

```
prompt> remove_target_library_subset -objects [get_cells top/mid]
```

See Also

- set_target_library_subset
- report_target_library_subset

---

remove_upf

Removes the UPF constraints from the design.

Syntax

status *remove_upf*

Description

The *remove_upf* command is used to clean up UPF data for the design.

Feedback

Examples

The following example shows a typical use of the remove_upf command:

```
pt_shell> link
pt_shell> load_upf upf_file_1
pt_shell> remove_upf
pt_shell> load_upf upf_file_2
pt_shell> create_clock -period 1  CLK
```

See Also

- load_upf
- remove_design

---

remove_user_attribute

Removes a user attribute from an object.

Syntax

string *remove_user_attribute*

```
[-quiet]
[-class class_name]
object_spec
attr_name
```

Data Types

class_name	string
object_spec	list
attr_name	string

Arguments

`-quiet`

Does not report any messages.

`-class class_name`

If the *object_spec* option is a name, this is its class. Allowable values are *design*, *port*, *cell*, *pin*, *net*, *lib*, *lib_cell*, or *lib_pin*.

object_spec

Shows objects from which to remove the attribute. Each element in the list is either a collection or a pattern that combines with the *class_name* option to find the objects.

Feedback

attr_name

Provides the name of the attribute.

Description

The *remove_user_attribute* command removes attributes that you set with the *set_user_attribute* command.

You cannot remove application attributes with this command. Each application attribute that can be removed has a command dedicated to it. For example, the *fanout_load* attribute is removed with the *remove_fanout_load* command.

Examples

This example defines an attribute 'X' for cells then sets the value on all cells in this level of the hierarchy. Finally, the example removes the attribute from one cell.

```
pt_shell> define_user_attribute -type int -class cell X
pt_shell> set_user_attribute [get_cells *] X 30
Set attribute 'X' on 'i1'
Set attribute 'X' on 'i2'
pt_shell> remove_user_attribute [get_cells i1] X
Removed attribute 'X' from 'i1'
```

See Also

- collections
- define_user_attribute
- get_attribute
- list_attributes
- set_user_attribute
- report_attribute

---

remove_waiver

Remove violation waivers satisfying the given requirements.

Syntax

Boolean *remove_waiver*

```
[-names waiver_name_list]
[-rules rule_name_list]
[-design design]
[-scenarios scenario_name_list]
```

Feedback

Data Types

waiver_name_list	list
rule_name_list	list
design	string
scenario_name_list	list

Arguments

`-names` *waiver_name_list*

Remove waivers with names in the given list.

`-rules` *rule_name_list*

Remove waivers of the givens rules.

`-design` *design*

Remove the waivers for the given design only.

`-scenarios` *scenario_name_list*

Remove waivers active in the given scenarios (waivers for scenario-dependent rules only). This option should be used in conjuction of the "-design" option.

Description

This command is available only if you invoke the pt_shell with the *-constraints* option.

Remove waivers with the given names, for the given rules, and active in the given scenarios of the given design. If no *-names* option given, all waiver names are included; if no *-rules* option is given, waivers for all rules are included; if no *-scenarios* option given, waivers active in any scenario, including waivers for scenario-independent rules, are included. If none of the *-names*, *-rules*, *-design*, or *-scenarios* options are given, all existing waivers will be removed.

Note that multiple waivers can be applied that affect same instances. For example, using the *create_waiver -cells* option, instance based waivers can be set on a hierarchical cell and also on a particular instance inside the hierarchical cell. In such cases, all the waivers affecting the instance should be removed before the waiver is completely gone.

Examples

The following example removes a waiver named my_waiver1:

```
pt_shell> remove_waiver -names my_waiver1
```

Feedback

remove_waveform_integrity_analysis

Removes static or dynamic constraints for waveform integrity analysis.

Syntax

string *remove_waveform_integrity_analysis*

```
[-static]
[-dynamic]
[-sms_scenarios sms_scenarios_list]
[object_list]
```

Data Types

object_list	list
sms_scenarios_list	collection

Arguments

`-static`

Removes the constraint for static waveform integrity analysis.

`-dynamic`

Removes the constraint for dynamic waveform integrity analysis.

object_list

Specifies a list of cell input pins.

`-sms_scenarios` *sms_scenarios_list*
